Message from the General Chair

Welcome to the 2024 meeting of the North American Association for Computational Linguistics! This year, the conference is in Mexico City. NAACL was actually already planned for Mexico City in 2021, but due to the pandemic the entire conference was moved online. This year, finally, we get to go! So it is my sincere pleasure to welcome you to Mexico City, whether in person or virtually. Having the conference in Mexico City is a good opportunity to emphasize that NAACL is our flagship conference for ACL members not only in North America but also in Central and South America, even though NAACL has been bearing "North" in its name. At this year's conference, we have a theme to match, with a theme track on the *Languages of Latin America* to showcase the linguistic diversity of the region.

This year, we decided, along with EACL and ACL, to rely fully on ACL Rolling Review (ARR) for conference submissions. It has been exciting and impressive to see, up close, the amount of work that went into making the process run smoothly. Many thanks to the ARR editors in chief, in particular Thamar Solorio and Mausam, for developing innovations for the reviewing process to keep pace with our growing community. Many thanks to the program chairs of all three conferences, for dealing with all the detail troubles as they arose. A big thank you also to the OpenReview team, in particular Andrew McCallum, Melissa Bok and Harold Rubio, for adding improvements to the platform specifically for ACL and for working tirelessly with us to handle whatever came up. And an extra big thank you to Ryan Cotterell, who has been building the software that we use to publish from ARR and who worked with the OpenReview team to design the platform improvements, and to the ACL board, in particular Iryna Gurevych, for putting money into making OpenReview/ARR publishing better.

The opportunity to present at NAACL should not depend on a researcher's travel budget, or their family status. This is why it is so important to make virtual participation at NAACL as good an experience as possible – but we want to also provide a good experience for in-person participants. As a community, we are still working out the best way to do that. This year at NAACL, we are trying out a big virtual poster session ahead of the conference, with the hope that this will make make for a lively and interactive experience. At the same time, we are reducing virtual oral presentations, which seem to be particularly tricky to make to work well. A big thanks to the NAACL program chairs and to Luciana Benotti for all their ideas and work to improve the virtual experience. And participants, virtual as well as in-person: Please let us know what worked for you and what didn't, so we can continue to improve hybrid conferences.

I have been lucky to work with many amazing people. Without their insight, dedication and patience, and without the many hours of work they put in, NAACL would not have been possible. A huge thank you to the program chairs Helena Gomez, Kevin Duh, and Steven Bethard – you are the best!

And special thanks to Jenn Rachford, the ACL business manager, who has dealt with room assignments, local arrangements in Mexico City, and so many details of conference planning. We couldn't have done it without your support and guidance.

And many thanks also to...

- The workshop chairs Niranjan Balasubramanian, Malihe Alikhani, and Alexis Palmer
- The tutorial chairs Rui Zhang, Nathan Schneider and Snigdha Chaturvedi
- The demo chairs Nazneen Rajani, Kai-Wei Chang and Annie Lee
- The industry track chairs Avi Sil, Yi Yang, Anoop Kumar, and Aida Davani
- The student workshop chairs Trista Cao, Isabel Papadimitriou and Anaelia Ovalle, and their faculty advisors Marcos Zampieri, Frank Ferraro and Swabha Swayamdipta
- The publication chairs Ryan Cotterell, Maarten Sap and Lifu Huang

- The website chairs Vered Shwartz and Xinya Du
- The publicity and social media chairs Ximena Gutierrez-Vasques, Samuel González-López and Najoung Kim
- The diversity and inclusion chairs Ziyu Yao, Gemma Bel Enguix and Maria Pacheco
- The sponsorship chairs Ivan Meza and Mohit Iyyer
- The student volunteers chairs Lucy Lu Wang and Liang Huang
- The ethics chairs Cissi Alm, Diana Galvan Sosa, Anjalie Field, Ameeta Agrawal, Daniel Fried, Mark Yatskar, Maria Antoniak, and Alane Suhr
- The handbook chair Luke Gessler
- The reproducibility chairs Ghazaleh Kazeminejad, Koustuv Sinha, Peter Jansen, Pastor Lopez, and Ian Magnusson
- The best paper committee chairs Isabelle Augenstein and Manuel Montes-y-Gómez
- The local chair Hiram Calvo

Many thanks also to the chairs of the previous year's conferences, who were always ready to help and share their experience, and to the members of the ACL and NAACL Executive Committees for their support, feedback and advice, especially Iryna Gurevych, Emily Bender, and Graham Neubig.

Finally, I would like to thank all authors, invited speakers and panelists, area chairs and reviewers, the volunteers organizing and chairing sessions, and all attendees, in-person and virtual. Thank you for helping us make NAACL 2024 come to life.

Welcome and hope you all enjoy the conference!

Katrin Erk
The University of Texas at Austin
NAACL 2024 General Chair

Message from the Program Chairs

Hi, Welcome to the 2024 Annual Conference of the North American Association for Computational Linguistics! NAACL 2024 is a hybrid conference, and we are excited to have attendees and presenters join us both in person in Mexico City and online from all over the world. We are especially thrilled to hold the conference in Mexico City, which was originally planned for NAACL 2021 before COVID-19 required the transition to a virtual meeting. This will be the first NAACL conference in Latin America, and we hope this will contribute to a tradition of broadening access and participation in the greater region.

Special Theme: Languages of Latin America Languages are the heart and soul of cultural identity and communication, and nowhere is this more evident than in the vibrant tapestry of Latin America and the Caribbean. With a rich linguistic diversity that spans Spanish, Portuguese, and numerous indigenous languages, the region offers a unique challenge and opportunity for natural language processing researchers. For NAACL 2024, we invited submissions to the special theme track on "Languages of Latin America". This track was dedicated to taking stock of past research and developments in the field of natural language processing for languages of Latin America and the Caribbean while charting the course for future investigations. We received 19 submissions to the special theme, of which 10 have been accepted to appear at the conference.

Review Process NAACL 2024 implemented a two stage review process, where submissions were first sent to ACL Rolling Review (ARR) for reviews by reviewers and for meta-reviews by area chairs, and then sent to a separate NAACL 2024 commitment site for recommendations by senior area chairs and final acceptance decisions by program chairs.

For the ARR submission part of the process, NAACL program chairs coordinated with EACL 2024 and ACL 2024 program chairs to ensure a smooth revise-and-resubmit cycle across the three conferences. We also coordinated across conferences to recruit thousands of new reviewers and hundreds of new area chairs to ARR, resulting in 7344 reviewers and 870 ACs in the 2023 December ARR cycle to which most NAACL 2024 papers were submitted. Overall, the ARR process went mostly smoothly, successfully delivering three reviews and a meta-review for all 2604 papers submitted. Several of the suggestions that NAACL 2024 program chairs collected for improving the process (e.g., better OpenReview integration of the responsible NLP checklist) have already been adopted by ARR for future cycles.

For the NAACL commitment part of the process, NAACL program chairs recruited 73 senior area chairs for the 25 research areas defined by ARR. Senior area chairs made acceptance recommendations for 1140 committed papers based on the papers, reviews, and meta-reviews, and program chairs finalized the recommendations into acceptance decisions.

Acceptance Rate The acceptance rate calculation follows precedent set by previous conferences that also go through ARR, e.g. NAACL 2022, EACL 2024. The calculation takes into account the multi-stage process of ARR where a paper may get revised in ARR and then later committed to the conference. The denominator includes:

- Papers in the ARR December 2023 cycle that selected NAACL as a preferred venue.
- Papers in the ARR December 2023 cycle that did not select any conference as a preferred venue.
- Papers in the ARR December 2023 cycle that selected another conference, but then committed to NAACL 2024.
- Papers in the ARR cycles before December 2023 that committed to NAACL 2024.

In total, we had 2604 submissions in the ARR December 2023 cycle. Among these, 29 were withdrawn before reviews were released and 115 were desk-rejected. Of the remaining, 2328 had either an unspecified venue or included NAACL as the desired venue. Further, 17 out of the 132 submissions that selected other venues were committed to NAACL. Finally, an additional 89 papers from other cycles were committed. So in total, the denominator for acceptance rate calculation is 2328 + 17 + 89 = 2434. Among these, 1140 papers were officially committed to NAACL, and 565 were accepted. The acceptance rate for Main Conference papers is therefore: 565 / 2434 = 23.2

Findings papers are those which are not accepted at the Main Conference, but nevertheless have been judged worthy of publication as solid work with sufficient substance, quality and novelty. The next 304 / 2434 = 12.5

Presentation Format At NAACL 2024, we aimed to set all main conference papers on equal ground. All presenters were allowed the same 13 minute video recording on the virtual site, regardless of whether a paper was long or short, whether the presenter decided to attend in-person or virtually, and whether the paper was assigned an oral presentation or a poster presentation.

To ensure there was no prestige associated with getting to present in oral vs. poster format, we tried a new approach to presentation decisions: we assigned them randomly. Specifically, we calculated the counts of papers across research areas, took the square roots of the counts to slightly upweight smaller areas, converted the counts to a distribution, and then randomly sampled 130 orals from the research areas according to the distribution (sampling in blocks of 5 to match the duration of oral sessions at the conference).

Program Format At NAACL 2024, we aimed to improve both the in-person and virtual experiences. For this, we are implemented the following two actions:

- A pre-conference virtual poster session was scheduled for Thursday, June 13, 2024, avoiding conflicts with the conference's in-person sessions, and including different sessions to accommodate various time zones. The goal of this move was to encourage all attendees, both virtual and in-person, to join the virtual poster session.
- Oral presentations were given only to in-person attendees. (Oral presentations were still set to be live-streamed for all virtual attendees). The goal of this move was to avoid Zoom fatigue and encourage more in-person engagement with oral presenters.

The program includes live (and live-streamed) keynotes, plenaries, and panels, more than 100 live (and live-streamed) oral presentations, more than 400 live poster presentations, and more than 200 virtual poster presentations at the pre-conference event. The keynotes cover exciting topics including large language models and indigenous languages (Claudio Pinhanez, IBM Research Brazil) and large language models and neuroscience (Seana Coulson, UCSD), while the panel addresses the important issue of large language models and their impact on education (Victoria Yaneva, National Board of Medical Examiners; Swapna Somasundaran, Educational Testing Service; Karen Matías, Universidad Nacional Autónoma de México; and Ekaterina Kochmar, Mohamed Bin Zayed University of Artificial Intelligence). Other plenaries include the NAACL business meeting and the best paper awards session. The program is rounded out with dedicated sessions during the main conference for industry track, demonstrations track, student research workshop, NAACL Findings papers, and TACL/CL accepted papers.

Gratitude Conference organization is a team effort. We are very grateful for the support and contributions of many people, including:

- The General Chair, Katrin Erk

- The ARR Editors-in-Chief of the Dec 2023 cycle (Mausam, Vincent Ng) and the entire team (Viviane Moreira, Thamar Solorio, Lilja Øvrelid, Jun Suzuki, Jonathan Kummerfield)
- The OpenReview team, especially Harold Rubio
- The 73 Senior Area Chairs
- The 870 Area Chairs and 7344 Reviewers
- The best paper committee chairs, Isabelle Augenstein and Manuel Montes y Gómez
- The ethics chairs (Cecilia Alm, Diana Galvan Sosa, Anjalie Field, Ameeta Agrawal, Daniel Fried, Mark Yatskar, Maria Antoniak, Alane Suhr) and their team of reviewers
- The website chairs, Vered Shwartz and Xinya Du
- The publication chairs, Ryan Cotterell, Maarten Sap, and Lifu Huang, and their team of student helpers
- The publicity chairs, Ximena Gutierrez-Vasques, Samuel Gonzalez-Lopez, and Najoung Kim
- The local chair, Hiram Calvo
- The volunteers chairs, Lucy Lu Wang and Liang Huang
- The ACL Anthology Director, Matt Post, and his team
- The Program Chairs of EACL 2024 (Yvette Graham, Matthew Purver) and ACL 2024 (Lun-Wei Ku, Andre Martins, Vivek Srikumar)
- Damira Mršić and Underline Team
- Jenn Rachhford and entire conference support staff

Kevin Duh, Helena Gomez, and Steven Bethard
NAACL 2024 Program Committee Co-Chairs

Organizing Committee

General Chair

Katrin Erk, The University of Texas at Austin

Program Chairs

Kevin Duh, Johns Hopkins University
Helena Gomez, Universidad Nacional Autónoma de México
Steven Bethard, University of Arizona

Local Arrangements

Priscilla Rasmussen, ACL
Jennifer Rachford, ACL
Hiram Calvo, CIC-IPN

Industry Track Chairs

Avi Sil, IBM
Yi Yang, ASAPP
Anoop Kumar, Amazon
Aida Davani, Google

Tutorial Chairs

Rui Zhang, Penn State University
Nathan Schneider, Georgetown University
Snigdha Chaturvedi, UNC-Chapel Hill

Demo Chairs

Nazneen Rajani, Hugging Face
Kai-Wei Chang, UCLA
Annie Lee, University of Toronto

Workshops Chairs

Niranjan Balasubramanian, Stony Brook University
Malihe Alikhani, Northeastern University
Alexis Palmer, University of Colorado Boulder

Student Research Workshop Chairs

Yang (Trista) Cao, University of Maryland
Isabel Papadimitriou, Stanford University
Anaelia Ovalle, UCLA

Advisors for the Student Research Workshop

Marcos Zampieri, George Mason University
Frank Ferraro, University of Maryland Baltimore County
Swabha Swayamdipta, University of Southern California

Publication Chairs

Ryan Cotterell, ETH Zürich
Maarten Sap, Carnegie Mellon University
Lifu Huang, Virginia Tech

Ethics Chairs

Cecilia Alm, Rochester Institute of Technology
Diana Galvan Sosa, ALTA Institute, University of Cambridge
Anjalie Field, Johns Hopkins University
Ameeta Agrawal, Portland State University
Daniel Fried, Carnegie Mellon University
Mark Yatskar, University of Pennsylvania
Maria Antoniak, Allen Institute for AI
Alane Suhr, UC Berkeley

Handbook Chair

Luke Gessler, University of Colorado Boulder

Reproducibility Chairs

Ghazaleh Kazeminejad, IBM
Koustuv Sinha, Meta AI
Peter Jansen, University of Arizona
Pastor Lopez, CIMAT
Ian Magnusson, Allen Institute for AI

Sponsorship Chairs

Ivan Meza, IIMAS /UNAM
Mohit Iyyer, UMass Amherst

Diversity & Inclusion Chairs

Ziyu Yao, George Mason University
Gemma Bel Enguix, Universidad Nacional Autónoma de México
Maria Pacheco, University of Colorado Boulder

Volunteers Chairs

Lucy Lu Wang, University of Washington
Liang Huang, Oregon State University

Publicity Chairs

Ximena Gutierrez-Vasques, University of Zürich
Samuel Gonzalez-Lopez, Technological University of Nogales, Sonora
Najoung Kim, Boston University

Website Chairs

Vered Shwartz, University of British Columbia
Xinya Du, University of Texas at Dallas

Best Paper Committee Chairs

Isabelle Augenstein, University of Copenhagen
Manuel Montes y Gómez, National Institute of Astrophysics, Optics and Electronics

Keynote Talk

Harnessing the Power of LLMs to Vitalize Indigenous Languages

Claudio Pinhanez
IBM Research Brazil

Monday, June 17 – Time: **9:30 – 10:30** –

Abstract: How can Large Language Models (LLMs) and modern NLP be used to increase the use and the documentation of Indigenous languages which are in danger of disappearing? First, I report on the development of high-quality translators for Indigenous languages by fine-tuning SOTA machine translators with tiny amounts of data, and discuss how to avoid some common pitfalls. Next, I present prototypes built with Indigenous communities aiming to stimulate and facilitate writing, using LLM models to create spell-checkers, next-word predictors, and similar tools. Finally, I discuss a future for documentation where dying languages are preserved as interactive language models.

Bio: Claudio Pinhanez is a scientist, innovator, and professor. He is currently a Principal Scientist in the laboratory of IBM Research in Brazil where he leads research on artificial intelligence, human-machine interaction, and natural language processing. He is also the Deputy Director of the Center for Artificial Intelligence of the University of São Paulo, where he is a Visiting Professor at the Institute of Advanced Studies. Claudio got his Ph.D. from the MIT Media Laboratory in 1999, joined the IBM Research T.J. Watson laboratory in New York and in 2010 co-founded the IBM Research laboratory in Brazil. Since 2022 he leads a joint project of IBM Research and the University of São Paulo focused on the use of AI technology to document and vitalize Brazilian Indigenous languages.

Keynote Talk

Distributional Semantics: What do large language models have to say?

Seana Coulson
University of California San Diego

Wednesday, June 19 – Time: **14:00 – 15:00** –

Abstract: Large language models motivate an approach to meaning known as distributional semantics, that words mean what they do because of how they're distributed in language. In this talk I will describe some evidence from my lab that suggests metrics from large language models do a good job of predicting behavioral and neural responses to some aspects of human language. I go on to describe some research that highlights important differences in meaning processing in humans and the 'understanding' displayed by language models. Discrepancies are particularly noteworthy in studies of joke comprehension.

Bio: Seana Coulson received her Ph.D. in Cognitive Science from the University of California San Diego in 1997. The recipient of fellowships from the McDonnell Pew foundation and the NIH NRSA, she worked as a post-doctoral fellow in the Psychology Department at the University of Arizona from 1997-1999. In 1999, she returned as faculty to UC San Diego's Cognitive Science Department. She is currently a full Professor, holds the Jeffrey Elman Chancellor's Endowed Chair of Cognitive Science, and co-directs the UCSD/SDSU Joint Doctoral Program in Language and Communicative Disorders. She directs the Brain and Cognition Lab at UC San Diego where her research concerns how people understand language and other meaningful stimuli.

Yinghao Li, Haorui Wang and Chao Zhang 59

TelME: Teacher-leading Multimodal Fusion Network for Emotion Recognition in Conversation
Taeyang Yun, Hyunkuk Lim, Jeonghwan Lee and Min Song 82

Effective and Efficient Conversation Retrieval for Dialogue State Tracking with Implicit Text Summaries
Seanie Lee, Jianpeng Cheng, Joris Driesen, Alexandru Coca and Anders Johannsen 96

Promptly Predicting Structures: The Return of Inference
Maitrey Mehta, Valentina Pyatkin and Vivek Srikumar 112

On Linearizing Structured Data in Encoder-Decoder Language Models: Insights from Text-to-SQL
Yutong Shao and Ndapa Nakashole 131

Extractive Summarization with Text Generator
Thang Le and Anh Tuan Luu 157

Self-generated Replay Memories for Continual Neural Machine Translation
Michele Resta and Davide Bacciu 175

Measuring and Improving Chain-of-Thought Reasoning in Vision-Language Models
Yangyi Chen, Karan Sikka, Michael Cogswell, Heng Ji and Ajay Divakaran 192

Building Knowledge-Guided Lexica to Model Cultural Variation
Shreya Havaldar, Salvatore Giorgi, Sunny Rai, Thomas Talhelm, Sharath Chandra Guntuku and Lyle Ungar 211

Adaptive Rank Selections for Low-Rank Approximation of Language Models
Shangqian Gao, Ting Hua, Yen-Chang Hsu, Yilin Shen and Hongxia Jin 227

An Empirical Study of Consistency Regularization for End-to-End Speech-to-Text Translation
Pengzhi Gao, Ruiqing Zhang, Zhongjun He, Hua Wu and Haifeng Wang 242

Unleashing the Emergent Cognitive Synergy in Large Language Models: A Task-Solving Agent through Multi-Persona Self-Collaboration
Zhenhailong Wang, Shaoguang Mao, Wenshan Wu, Tao Ge, Furu Wei and Heng Ji 257

FPT: Feature Prompt Tuning for Few-shot Readability Assessment
Ziyang Wang, Sanwoo Lee, Hsiu-Yuan Huang and Yunfang Wu 280

Self-Prompting Large Language Models for Zero-Shot Open-Domain QA
Junlong Li, Jinyuan Wang, Zhuosheng Zhang and hai zhao 296

Head-to-Tail: How Knowledgeable are Large Language Models (LLMs)? A.K.A. Will LLMs Replace Knowledge Graphs?
Kai Sun, Yifan Ethan Xu, Hanwen Zha, Yue Liu and Xin Luna Dong 311

kNN-ICL: Compositional Task-Oriented Parsing Generalization with Nearest Neighbor In-Context Learning
Wenting Zhao, Ye Liu, Yao Wan, Yibo Wang, Qingyang Wu, Zhongfen Deng, Jiangshu Du, Shuaiqi Liu, Yunlong Xu and Philip S. Yu 326

ARES: An Automated Evaluation Framework for Retrieval-Augmented Generation Systems
Jon Saad-Falcon, Omar Khattab, Christopher Potts and Matei Zaharia 338

DEMO: A Statistical Perspective for Efficient Image-Text Matching
Fan Zhang, Xian-Sheng Hua, Chong Chen and Xiao Luo 355

SeaEval for Multilingual Foundation Models: From Cross-Lingual Alignment to Cultural Reasoning
Bin Wang, Zhengyuan Liu, Xin Huang, Fangkai Jiao, Yang Ding, AiTi Aw and Nancy F. Chen 370

Volcano: Mitigating Multimodal Hallucination through Self-Feedback Guided Revision
Seongyun Lee, Sue Hyun Park, Yongrae Jo and Minjoon Seo 391

LLMs Are Few-Shot In-Context Low-Resource Language Learners
Samuel Cahyawijaya, Holy Lovenia and Pascale Fung 405

Simple and effective data augmentation for compositional generalization
Yuekun Yao and Alexander Koller 434

Rethinking Tabular Data Understanding with Large Language Models
Tianyang Liu, Fei Wang and Muhao Chen 450

From Shortcuts to Triggers: Backdoor Defense with Denoised PoE
Qin Liu, Fei Wang, Chaowei Xiao and Muhao Chen 483

BookSQL: A Large Scale Text-to-SQL Dataset for Accounting Domain
Rahul Kumar, Amar Raja Dibbu, Shrutendra Harsola, Vignesh Subrahmaniam and Ashutosh Modi 497

FLAP: Flow-Adhering Planning with Constrained Decoding in LLMs
Shamik Roy, Sailik Sengupta, Daniele Bonadiman, Saab Mansour and Arshit Gupta 517

DuRE: Dual Contrastive Self Training for Semi-Supervised Relation Extraction
Yuxi Feng and Laks V. S. Lakshmanan 540

Query-Efficient Textual Adversarial Example Generation for Black-Box Attacks
Zhen Yu, Zhenhua Chen and Kun He 556

Embrace Divergence for Richer Insights: A Multi-document Summarization Benchmark and a Case Study on Summarizing Diverse Information from News Articles
Kung-Hsiang Huang, Philippe Laban, Alexander Fabbri, Prafulla Kumar Choubey, Shafiq Joty, Caiming Xiong and Chien-Sheng Wu 570

AMRFact: Enhancing Summarization Factuality Evaluation with AMR-Driven Negative Samples Generation
Haoyi Qiu, Kung-Hsiang Huang, Jingnong Qu and Nanyun Peng 594

PILOT: Legal Case Outcome Prediction with Case Law
Lang Cao, Zifeng Wang, Cao Xiao and Jimeng Sun 609

ALoRA: Allocating Low-Rank Adaptation for Fine-tuning Large Language Models
Zequan Liu, Jiawen Lyn, Wei Zhu and Xing Tian 622

R-Spin: Efficient Speaker and Noise-invariant Representation Learning with Acoustic Pieces
Heng-Jui Chang and James R. Glass 642

InsCL: A Data-efficient Continual Learning Paradigm for Fine-tuning Large Language Models with Instructions
Yifan Wang, Yafei Liu, Chufan Shi, Haoling Li, Chen Chen, Haonan Lu and Yujiu Yang 663

Language Agnostic Code Embeddings
Saiteja Utpala, Alex Gu and Pin-Yu Chen 678

An Examination of the Compositionality of Large Generative Vision-Language Models
Teli Ma, Rong Li and Junwei Liang 692

Two Heads are Better than One: Nested PoE for Robust Defense Against Multi-Backdoors
Victoria Graf, Qin Liu and Muhao Chen 706

VertAttack: Taking Advantage of Text Classifiers' Horizontal Vision
Jonathan Rusert 719

KDMCSE: Knowledge Distillation Multimodal Sentence Embeddings with Adaptive Angular margin Contrastive Learning
Cong-Duy T Nguyen, Thong Thanh Nguyen, Xiaobao Wu and Anh Tuan Luu 733

The taste of IPA: Towards open-vocabulary keyword spotting and forced alignment in any language
Jian Zhu, Changbing Yang, Farhan Samir and Jahurul Islam 750

Think Before You Act: A Two-Stage Framework for Mitigating Gender Bias Towards Vision-Language Tasks
Yunqi Zhang, Songda Li, Chunyuan Deng, Luyi Wang and Hui Zhao 773

BeLLM: Backward Dependency Enhanced Large Language Model for Sentence Embeddings
Xianming LI and Jing Li 792

Assessing Factual Reliability of Large Language Model Knowledge
Weixuan Wang, Barry Haddow, Alexandra Birch and Wei Peng 805

Dial-MAE: ConTextual Masked Auto-Encoder for Retrieval-based Dialogue Systems
Zhenpeng Su, Xing W, Wei Zhou, Guangyuan Ma and Songlin Hu 820

Toolink: Linking Toolkit Creation and Using through Chain-of-Solving on Open-Source Model
Cheng Qian, Chenyan Xiong, Zhenghao Liu and Zhiyuan Liu 831

Create! Don't Repeat: A Paradigm Shift in Multi-Label Augmentation through Label Creative Generation
Letian Wang, Xianggen Liu and Jiancheng Lv 855

Neurocache: Efficient Vector Retrieval for Long-range Language Modeling
Ali Safaya and Deniz Yuret 870

Unveiling the Generalization Power of Fine-Tuned Large Language Models
Haoran Yang, Yumeng Zhang, Jiaqi Xu, Hongyuan Lu, Pheng-Ann Heng and Wai Lam 884

A Closer Look at the Self-Verification Abilities of Large Language Models in Logical Reasoning
Ruixin Hong, Hongming Zhang, Xinyu Pang, Dong Yu and Changshui Zhang 900

Exploring Self-supervised Logic-enhanced Training for Large Language Models
Fangkai Jiao, Zhiyang Teng, Bosheng Ding, Zhengyuan Liu, Nancy F. Chen and Shafiq Joty . 926

MATHSENSEI: A Tool-Augmented Large Language Model for Mathematical Reasoning
Debrup Das, Debopriyo Banerjee, Somak Aditya and Ashish Kulkarni 942

CoUDA: Coherence Evaluation via Unified Data Augmentation
Dawei Zhu, Wenhao Wu, Yifan Song, Fangwei Zhu, Ziqiang Cao and Sujian Li 967

mEdIT: Multilingual Text Editing via Instruction Tuning
Vipul Raheja, Dimitris Alikaniotis, Vivek Kulkarni, Bashar Alhafni and Dhruv Kumar 979

Navigation as Attackers Wish? Towards Building Robust Embodied Agents under Federated Learning
Yunchao Zhang, Zonglin Di, Kaiwen Zhou, Cihang Xie and Xin Eric Wang 1002

In-context Learning and Gradient Descent Revisited
Gilad Deutch, Nadav Magar, Tomer Bar Natan and Guy Dar 1017

Corpus Considerations for Annotator Modeling and Scaling
Sarumi Olufunke Oluyemi, Béla Neuendorf, Joan Plepi, Lucie Flek, Jörg Schlötterer and Charles Welch 1029

On Large Language Models' Hallucination with Regard to Known Facts
Che Jiang, Biqing Qi, Xiangyu Hong, Dayuan Fu, Yang Cheng, Fandong Meng, Mo Yu, Bowen Zhou and Jie Zhou 1041

One-Size-Fits-All"? Examining Expectations around What Constitute Fairor GoodNLG System Behaviors
Li Lucy, Su Lin Blodgett, Milad Shokouhi, Hanna Wallach and Alexandra Olteanu 1054

Language Models Hallucinate, but May Excel at Fact Verification
Jian Guan, Jesse Dodge, David Wadden, Minlie Huang and Hao Peng 1090

A Rationale-centric Counterfactual Data Augmentation Method for Cross-Document Event Coreference Resolution
Bowen Ding, Qingkai Min, Shengkun Ma, Yingjie Li, Linyi Yang and Yue Zhang 1112

TrojFSP: Trojan Insertion in Few-shot Prompt Tuning
Mengxin Zheng, Jiaqi Xue, Xun Chen, Yanshan Wang, Qian Lou and Lei Jiang 1141

Ensuring Safe and High-Quality Outputs: A Guideline Library Approach for Language Models
Yi Luo, Zhenghao Lin, YuHao Zhang, Jiashuo Sun, Chen Lin, Chengjin Xu, Xiangdong Su, yelong shen, Jian Guo and Yeyun Gong 1152

X-PARADE: Cross-Lingual Textual Entailment and Information Divergence across Paragraphs
Juan Diego Rodriguez, Katrin Erk and Greg Durrett 1198

Topics, Authors, and Institutions in Large Language Model Research: Trends from 17K arXiv Papers
Rajiv Movva, Sidhika Balachandar, Kenny Peng, Gabriel Agostini, Nikhil Garg and Emma Pierson 1223

E^5: Zero-shot Hierarchical Table Analysis using Augmented LLMs via Explain, Extract, Execute, Exhibit and Extrapolate
Zhehao Zhang, Yan Gao and Jian-Guang Lou 1244

S3Eval: A Synthetic, Scalable, Systematic Evaluation Suite for Large Language Model
Fangyu Lei, Qian Liu, Yiming Huang, Shizhu He, Jun Zhao and Kang Liu 1259

MMC: Advancing Multimodal Chart Understanding with Large-scale Instruction Tuning
Fuxiao Liu, Xiaoyang Wang, Wenlin Yao, Jianshu Chen, Kaiqiang Song, Sangwoo Cho, Yaser Yacoob and Dong Yu 1287

Visual Grounding Helps Learn Word Meanings in Low-Data Regimes
Chengxu Zhuang, Evelina Fedorenko and Jacob Andreas 1311

Accurate Knowledge Distillation via n-best Reranking
Hendra Setiawan 1330

AutoPRM: Automating Procedural Supervision for Multi-Step Reasoning via Controllable Question Decomposition
Zhaorun Chen, Zhuokai Zhao, Zhihong Zhu, Ruiqi Zhang, Xiang Li, Bhiksha Raj and Huaxiu Yao 1346

SEMQA: Semi-Extractive Multi-Source Question Answering
Tal Schuster, Adam D Lelkes, Haitian Sun, Jai Gupta, Jonathan Berant, William W. Cohen and Donald Metzler 1363

Fine-Tuning Language Models with Reward Learning on Policy
Hao Lang, Fei Huang and Yongbin Li 1382

A Universal Dependencies Treebank for Highland Puebla Nahuatl
Robert Pugh and Francis M. Tyers 1393

COPAL-ID: Indonesian Language Reasoning with Local Culture and Nuances
Haryo Akbarianto Wibowo, Erland Hilman Fuadi, Made Nindyatama Nityasya, Radityo Eko Prasojo and Alham Fikri Aji 1404

IterAlign: Iterative Constitutional Alignment of Large Language Models
Xiusi Chen, Hongzhi Wen, Sreyashi Nag, Chen Luo, Qingyu Yin, Ruirui Li, Zheng Li and Wei Wang 1423

OrchestraLLM: Efficient Orchestration of Language Models for Dialogue State Tracking
Chia-Hsuan Lee, Hao Cheng and Mari Ostendorf 1434

Multi-Operational Mathematical Derivations in Latent Space
Marco Valentino, Jordan Meadows, Lan Zhang and Andre Freitas 1446

Large Language Models Help Humans Verify Truthfulness – Except When They Are Convincingly Wrong
Chenglei Si, Navita Goyal, Tongshuang Wu, Chen Zhao, Shi Feng, Hal Daumé Iii and Jordan Lee Boyd-Graber 1459

XferBench: a Data-Driven Benchmark for Emergent Language
Brendon Boldt and David R Mortensen 1475

Evaluating Large Language Models as Generative User Simulators for Conversational Recommendation
Se-eun Yoon, Zhankui He, Jessica Maria Echterhoff and Julian McAuley 1490

A Symbolic Framework for Evaluating Mathematical Reasoning and Generalisation with Transformers
Jordan Meadows, Marco Valentino, Damien Teney and Andre Freitas 1505

Identifying Linear Relational Concepts in Large Language Models
David Chanin, Anthony Hunter and Oana-Maria Camburu 1524

Benchmark Transparency: Measuring the Impact of Data on Evaluation
Venelin Kovatchev and Matthew Lease 1536

JAMDEC: Unsupervised Authorship Obfuscation using Constrained Decoding over Small Language Models
Jillian Fisher, Ximing Lu, Jaehun Jung, Liwei Jiang, Zaid Harchaoui and Yejin Choi 1552

REST: Retrieval-Based Speculative Decoding
Zhenyu He, Zexuan Zhong, Tianle Cai, Jason D. Lee and Di He 1582

Sub-Sentence Encoder: Contrastive Learning of Propositional Semantic Representations
Sihao Chen, Hongming Zhang, Tong Chen, Ben Zhou, Wenhao Yu, Dian Yu, Baolin Peng, Hongwei Wang, Dan Roth and Dong Yu 1596

MSciNLI: A Diverse Benchmark for Scientific Natural Language Inference
Mobashir Sadat and Cornelia Caragea 1610

Causal Inference for Human-Language Model Collaboration
Bohan Zhang, Yixin Wang and Paramveer Dhillon 1630

SELF-GUARD: Empower the LLM to Safeguard Itself
Zezhong Wang, Fangkai Yang, Lu Wang, Pu Zhao, Hongru Wang, Liang Chen, Qingwei Lin and Kam-Fai Wong 1648

COSIGN: Contextual Facts Guided Generation for Knowledge Graph Completion
Jinpeng Li, Hang Yu, Xiangfeng Luo and Qian Liu 1669

Toward Informal Language Processing: Knowledge of Slang in Large Language Models
Zhewei Sun, Qian Hu, Rahul Gupta, Richard Zemel and Yang Xu 1683

Ghostbuster: Detecting Text Ghostwritten by Large Language Models
Vivek Verma, Eve Fleisig, Nicholas Tomlin and Dan Klein 1702

End-to-End Beam Retrieval for Multi-Hop Question Answering
Jiahao Zhang, Haiyang Zhang, Dongmei Zhang, Liu Yong and Shen Huang 1718

Leveraging Generative Large Language Models with Visual Instruction and Demonstration Retrieval for Multimodal Sarcasm Detection
Binghao Tang, Boda Lin, Haolong Yan and Si Li 1732

Multi-Scale Prompt Memory-Augmented Model for Black-Box Scenarios
Xiaojun Kuang, C. L. Philip Chen, Shuzhen Li and Tong Zhang 1743

Ungrammatical-syntax-based In-context Example Selection for Grammatical Error Correction
Chenming Tang, Fanyi Qu and Yunfang Wu 1758

BUFFET: Benchmarking Large Language Models for Few-shot Cross-lingual Transfer
Akari Asai, Sneha Kudugunta, Xinyan Velocity Yu, Terra Blevins, Hila Gonen, Machel Reid, Yulia Tsvetkov, Sebastian Ruder and Hannaneh Hajishirzi 1771

TISE: A Tripartite In-context Selection Method for Event Argument Extraction
Yanhe Fu, Yanan Cao, Qingyue Wang and Yi Liu 1801

Reasoning or Reciting? Exploring the Capabilities and Limitations of Language Models Through Counterfactual Tasks
Zhaofeng Wu, Linlu Qiu, Alexis Ross, Ekin Akyürek, Boyuan Chen, Bailin Wang, Najoung Kim, Jacob Andreas and Yoon Kim 1819

TRUE-UIE: Two Universal Relations Unify Information Extraction Tasks
Yucheng Wang, Bowen Yu, Yilin Liu and Shudong Lu 1863

zrLLM: Zero-Shot Relational Learning on Temporal Knowledge Graphs with Large Language Models
Zifeng Ding, Heling Cai, Jingpei Wu, Yunpu Ma, Ruotong Liao, Bo Xiong and Volker Tresp1877

Embodied Executable Policy Learning with Language-based Scene Summarization
Jielin Qiu, Mengdi Xu, William Han, Seungwhan Moon and Ding Zhao 1896

Metacognitive Prompting Improves Understanding in Large Language Models
Yuqing Wang and Yun Zhao 1914

MART: Improving LLM Safety with Multi-round Automatic Red-Teaming
Suyu Ge, Chunting Zhou, Rui Hou, Madian Khabsa, Yi-Chia Wang, Qifan Wang, Jiawei Han and Yuning Mao 1927

DialogCC: An Automated Pipeline for Creating High-Quality Multi-Modal Dialogue Dataset
Young-Jun Lee, Byungsoo Ko, Han-Gyu Kim, Jonghwan Hyeon and Ho-Jin Choi 1938

Routing to the Expert: Efficient Reward-guided Ensemble of Large Language Models
Keming Lu, Hongyi Yuan, Runji Lin, Junyang Lin, Zheng Yuan, Chang Zhou and Jingren Zhou 1964

Automatic Generation of Model and Data Cards: A Step Towards Responsible AI
Jiarui Liu, Wenkai Li, Zhijing Jin and Mona T. Diab 1975

FUN with Fisher: Improving Generalization of Adapter-Based Cross-lingual Transfer with Scheduled Unfreezing
Chen Cecilia Liu, Jonas Pfeiffer, Ivan Vulić and Iryna Gurevych 1998

Are Multilingual LLMs Culturally-Diverse Reasoners? An Investigation into Multicultural Proverbs and Sayings
Chen Cecilia Liu, Fajri Koto, Timothy Baldwin and Iryna Gurevych 2016

The Colorful Future of LLMs: Evaluating and Improving LLMs as Emotional Supporters for Queer Youth
Shir Lissak, Nitay Calderon, Geva Shenkman, Yaakov Ophir, Eyal Fruchter, Anat Brunstein Klomek and Roi Reichart 2040

IPED: An Implicit Perspective for Relational Triple Extraction based on Diffusion Model
Jianli Zhao, Changhao Xu and Bin. Jiang 2080

QualEval: Qualitative Evaluation for Model Improvement
Vishvak Murahari, Ameet Deshpande, Peter Clark, Tanmay Rajpurohit, Ashish Sabharwal, Karthik R Narasimhan and Ashwin Kalyan 2093

Quantum-inspired Language Model with Lindblad Master Equation and Interference Measurement for Sentiment Analysis
Kehuan Yan, Peichao Lai and yilei wang 2112

VisLingInstruct: Elevating Zero-Shot Learning in Multi-Modal Language Models with Autonomous Instruction Optimization
Dongsheng Zhu, Daniel Tang, Weidong Han, Jinghui Lu, Yukun Zhao, Guoliang Xing, Junfeng Wang and Dawei Yin 2122

A Wolf in Sheep's Clothing: Generalized Nested Jailbreak Prompts can Fool Large Language Models Easily
Peng Ding, Jun Kuang, Dan Ma, Xuezhi Cao, Yunsen Xian, Jiajun Chen and Shujian Huang2136

P^{3}Sum: Preserving Author's Perspective in News Summarization with Diffusion Language Models
Yuhan Liu, Shangbin Feng, Xiaochuang Han, Vidhisha Balachandran, Chan Young Park, Sachin Kumar and Yulia Tsvetkov 2154

Bridging the Novice-Expert Gap via Models of Decision-Making: A Case Study on Remediating Math Mistakes
Rose E Wang, Qingyang Zhang, Carly D Robinson, Susanna Loeb and Dorottya Demszky . 2174

RST-LoRA: A Discourse-Aware Low-Rank Adaptation for Long Document Abstractive Summarization
Dongqi Pu and Vera Demberg 2200

Strings from the Library of Babel: Random Sampling as a Strong Baseline for Prompt Optimisation
Yao Lu, Jiayi Wang, Raphael Tang, Sebastian Riedel and Pontus Stenetorp 2221

ReTA: Recursively Thinking Ahead to Improve the Strategic Reasoning of Large Language Models
Jinhao Duan, Shiqi Wang, James Diffenderfer, Lichao Sun, Tianlong Chen, Bhavya Kailkhura and Kaidi Xu 2232

Fact Checking Beyond Training Set
Payam Karisani and Heng Ji 2247

Program-Aided Reasoners (Better) Know What They Know
Anubha Kabra, Sanketh Rangreji, Yash Mathur, Aman Madaan, Emmy Liu and Graham Neubig 2262

The Perspectivist Paradigm Shift: Assumptions and Challenges of Capturing Human Labels
Eve Fleisig, Su Lin Blodgett, Dan Klein and Zeerak Talat 2279

Principles from Clinical Research for NLP Model Generalization
Aparna Elangovan, Jiayuan He, Yuan Li and Karin Verspoor 2293

First Tragedy, then Parse: History Repeats Itself in the New Era of Large Language Models
Naomi Saphra, Eve Fleisig, Kyunghyun Cho and Adam Lopez 2310

Found in the Middle: Permutation Self-Consistency Improves Listwise Ranking in Large Language Models
Raphael Tang, Crystina Zhang, Xueguang Ma, Jimmy Lin and Ferhan Ture 2327

From Language Modeling to Instruction Following: Understanding the Behavior Shift in LLMs after Instruction Tuning
Xuansheng Wu, Wenlin Yao, Jianshu Chen, Xiaoman Pan, Xiaoyang Wang, Ninghao Liu and Dong Yu 2341

POLYIE: A Dataset of Information Extraction from Polymer Material Scientific Literature
Jerry Junyang Cheung, Yuchen Zhuang, Yinghao Li, Pranav Shetty, Wantian Zhao, Sanjeev Grampurohit, Rampi Ramprasad and Chao Zhang 2370

LLM-based Medical Assistant Personalization with Short- and Long-Term Memory Coordination
Kai Zhang, Yangyang Kang, Fubang Zhao and Xiaozhong Liu 2386

SumTra: A Differentiable Pipeline for Few-Shot Cross-Lingual Summarization
Jacob Parnell, Inigo Jauregi Unanue and Massimo Piccardi 2399

KTRL+F: Knowledge-Augmented In-Document Search
Hanseok Oh, Haebin Shin, Miyoung Ko, Hyunji Lee and Minjoon Seo 2416

How Well Do Large Language Models Truly Ground?
Hyunji Lee, Se June Joo, Chaeeun Kim, Joel Jang, Doyoung Kim, Kyoung-Woon On and Minjoon Seo 2437

ALBA: Adaptive Language-Based Assessments for Mental Health
Vasudha Varadarajan, Sverker Sikström, Oscar Kjell and H. Schwartz 2466

FREB-TQA: A Fine-Grained Robustness Evaluation Benchmark for Table Question Answering
Wei Zhou, Mohsen Mesgar, Heike Adel and Annemarie Friedrich 2479

MILL: Mutual Verification with Large Language Models for Zero-Shot Query Expansion
Pengyue Jia, Yiding Liu, Xiangyu Zhao, Xiaopeng LI, Changying Hao, Shuaiqiang Wang and Dawei Yin 2498

Efficient Benchmarking (of Language Models)
Yotam Perlitz, Elron Bandel, Ariel Gera, Ofir Arviv, Liat Ein-Dor, Eyal Shnarch, Noam Slonim, Michal Shmueli-Scheuer and Leshem Choshen 2519

ReFACT: Updating Text-to-Image Models by Editing the Text Encoder
Dana Arad, Hadas Orgad and Yonatan Belinkov 2537

A Likelihood Ratio Test of Genetic Relationship among Languages
V.S.D.S.Mahesh Akavarapu and Arnab Bhattacharya 2559

PaD: Program-aided Distillation Can Teach Small Models Reasoning Better than Chain-of-thought Fine-tuning
Xuekai Zhu, Biqing Qi, Kaiyan Zhang, Xinwei Long, Zhouhan Lin and Bowen Zhou 2571

MEGAVERSE: Benchmarking Large Language Models Across Languages, Modalities, Models and Tasks
Sanchit Ahuja, Divyanshu Aggarwal, Varun Gumma, Ishaan Watts, Ashutosh Sathe, Millicent Ochieng, Rishav Hada, Prachi Jain, Mohamed Ahmed, Kalika Bali and Sunayana Sitaram 2598

Unlocking Emergent Modularity in Large Language Models
Zihan Qiu, Zeyu Huang and Jie Fu 2638

A School Student Essay Corpus for Analyzing Interactions of Argumentative Structure and Quality
Maja Stahl, Nadine Michel, Sebastian Kilsbach, Julian Schmidtke, Sara Rezat and Henning Wachsmuth 2661

Adjusting Interpretable Dimensions in Embedding Space with Human Judgments
Katrin Erk and Marianna Apidianaki 2675

PatentEval: Understanding Errors in Patent Generation
You Zuo, Kim Gerdes, Éric Villemonte de la Clergerie and Benoît Sagot 2687

Contextual Refinement of Translations: Large Language Models for Sentence and Document-Level Post-Editing
Sai Koneru, Miriam Exel, Matthias Huck and Jan Niehues 2711

Metaphor Detection with Context Enhancement and Curriculum Learning
Kaidi Jia and Rongsheng Li 2726

What Causes the Failure of Explicit to Implicit Discourse Relation Recognition?
Wei Liu, Stephen Wan and Michael Strube 2738

UniverSLU: Universal Spoken Language Understanding for Diverse Tasks with Natural Language Instructions
Siddhant Arora, Hayato Futami, Jee-weon Jung, Yifan Peng, Roshan Sharma, Yosuke Kashiwagi, Emiru Tsunoo, Karen Livescu and Shinji Watanabe 2754

How Trustworthy are Open-Source LLMs? An Assessment under Malicious Demonstrations Shows their Vulnerabilities
Lingbo Mo, Boshi Wang, Muhao Chen and Huan Sun 2775

Paraphrase and Solve: Exploring and Exploiting the Impact of Surface Form on Mathematical Reasoning in Large Language Models
Yue Zhou, Yada Zhu, Diego Antognini, Yoon Kim and Yang Zhang 2793

TriSum: Learning Summarization Ability from Large Language Models with Structured Rationale
Pengcheng Jiang, Cao Xiao, Zifeng Wang, Parminder Bhatia, Jimeng Sun and Jiawei Han . . 2805

GenRES: Rethinking Evaluation for Generative Relation Extraction in the Era of Large Language Models
Pengcheng Jiang, Jiacheng Lin, Zifeng Wang, Jimeng Sun and Jiawei Han 2820

Curated Datasets and Neural Models for Machine Translation of Informal Registers between Mayan and Spanish Vernaculars
Andrés Lou, Juan Antonio Pérez-Ortiz, Felipe Sánchez-Martínez and Víctor M. Sánchez-Cartagena 2838

The Effect of Data Partitioning Strategy on Model Generalizability: A Case Study of Morphological Segmentation
Zoey Liu and Bonnie J Dorr 2851

Measuring Entrainment in Spontaneous Code-switched Speech
Debasmita Bhattacharya, Siying Ding, Alayna Nguyen and Julia Hirschberg 2865

A Survey of Meaning Representations – From Theory to Practical Utility
Zacchary Sadeddine, Juri Opitz and Fabian M. Suchanek 2877

Mitigating Language-Level Performance Disparity in mPLMs via Teacher Language Selection and Cross-lingual Self-Distillation
Haozhe Zhao, Zefan Cai, Shuzheng Si, Liang Chen, Yufeng He, Kaikai An and Baobao Chang 2893

Evaluating In-Context Learning of Libraries for Code Generation
Arkil Patel, Siva Reddy, Dzmitry Bahdanau and Pradeep Dasigi 2908

Visually-Aware Context Modeling for News Image Captioning
Tingyu Qu, Tinne Tuytelaars and Marie-Francine Moens 2927

Regularized Conventions: Equilibrium Computation as a Model of Pragmatic Reasoning
Athul Paul Jacob, Gabriele Farina and Jacob Andreas 2944

TopicGPT: A Prompt-based Topic Modeling Framework
Chau Minh Pham, Alexander Hoyle, Simeng Sun, Philip Resnik and Mohit Iyyer 2956

ChatGPT as an Attack Tool: Stealthy Textual Backdoor Attack via Blackbox Generative Model Trigger
Jiazhao Li, Yijin Yang, Zhuofeng Wu, V.G.Vinod Vydiswaran and Chaowei Xiao 2985

Social Meme-ing: Measuring Linguistic Variation in Memes
Naitian Zhou, David Jurgens and David Bamman 3005

ExpertQA: Expert-Curated Questions and Attributed Answers
Chaitanya Malaviya, Subin Lee, Sihao Chen, Elizabeth Sieber, Mark Yatskar and Dan Roth 3025

What if you said that differently?: How Explanation Formats Affect Human Feedback Efficacy and User Perception
Chaitanya Malaviya, Subin Lee, Dan Roth and Mark Yatskar 3046

When Life Gives You Lemons, Make Cherryade: Converting Feedback from Bad Responses into Good Labels
Weiyan Shi, Emily Dinan, Kurt Shuster, Jason E Weston and Jing Xu 3066

Kreyòl-MT: Building MT for Latin American, Caribbean and Colonial African Creole Languages
Nathaniel Romney Robinson, Raj Dabre, Ammon C Shurtz, Rasul Dent, Onenamiyi Onesi, Claire Bizon Monroc, Loïc Grobol, Hasan Muhammad, Ashi Garg, Naome A Etori, Vijay Murari Tiyyala, Olanrewaju Samuel, Matthew Dean Stutzman, Bismarck Bamfo Odoom, Sanjeev Khudanpur, Stephen D. Richardson and Kenton Murray 3083

Instructions as Backdoors: Backdoor Vulnerabilities of Instruction Tuning for Large Language Models
Jiashu Xu, Mingyu Derek Ma, Fei Wang, Chaowei Xiao and Muhao Chen 3111

Modeling Empathetic Alignment in Conversation
Jiamin Yang and David Jurgens 3127

Native Language Identification in Texts: A Survey
Dhiman Goswami, Sharanya Thilagan, Kai North, Shervin Malmasi and Marcos Zampieri . 3149

LoRETTA: Low-Rank Economic Tensor-Train Adaptation for Ultra-Low-Parameter Fine-Tuning of Large Language Models
Yifan Yang, Jiajun Zhou, Ngai Wong and Zheng Zhang 3161

Which One? Leveraging Context Between Objects and Multiple Views for Language Grounding
Chancharik Mitra, Abrar Anwar, Rodolfo Corona, Dan Klein, Trevor Darrell and Jesse Thomason 3177

Do Localization Methods Actually Localize Memorized Data in LLMs? A Tale of Two Benchmarks
Ting-Yun Chang, Jesse Thomason and Robin Jia 3190

PromptFix: Few-shot Backdoor Removal via Adversarial Prompt Tuning
Tianrong Zhang, Zhaohan Xi, Ting Wang, Prasenjit Mitra and Jinghui Chen 3212

Comparing Explanation Faithfulness between Multilingual and Monolingual Fine-tuned Language Models
Zhixue Zhao and Nikolaos Aletras 3226

A Pretrainer's Guide to Training Data: Measuring the Effects of Data Age, Domain Coverage, Quality, & Toxicity
Shayne Longpre, Gregory Yauney, Emily Reif, Katherine Lee, Adam Roberts, Barret Zoph, Denny Zhou, Jason Wei, Kevin Robinson, David Mimno and Daphne Ippolito 3245

Instructional Fingerprinting of Large Language Models
Jiashu Xu, Fei Wang, Mingyu Derek Ma, Pang Wei Koh, Chaowei Xiao and Muhao Chen . . 3277

Reinforced Multiple Instance Selection for Speaker Attribute Prediction
Alireza Salkhordeh Ziabari, Ali Omrani, Parsa Hejabi, Preni Golazizian, Brendan Kennedy, Payam Piray and Morteza Dehghani 3307

DynaMo: Accelerating Language Model Inference with Dynamic Multi-Token Sampling
Shikhar Tuli, Chi-Heng Lin, Yen-Chang Hsu, Niraj Jha, Yilin Shen and Hongxia Jin 3322

Few-shot Knowledge Graph Relational Reasoning via Subgraph Adaptation
Haochen Liu, Song Wang, Chen Chen and Jundong Li 3346

Uncertainty Quantification for In-Context Learning of Large Language Models
Chen Ling, Xujiang Zhao, Xuchao Zhang, Wei Cheng, Yanchi Liu, Yiyou Sun, Mika Oishi, Takao Osaki, Katsushi Matsuda, Jie Ji, Guangji Bai, Liang Zhao and Haifeng Chen 3357

HelpSteer: Multi-attribute Helpfulness Dataset for SteerLM
Zhilin Wang, Yi Dong, Jiaqi Zeng, Virginia Adams, Makesh Narsimhan Sreedhar, Daniel Egert, Olivier Delalleau, Jane Polak Scowcroft, Neel Kant, Aidan M Swope and Oleksii Kuchaiev 3371

A Preference-driven Paradigm for Enhanced Translation with Large Language Models
Dawei Zhu, Sony Trenous, Xiaoyu Shen, Dietrich Klakow, Bill Byrne and Eva Hasler 3385

Fair Abstractive Summarization of Diverse Perspectives
Yusen Zhang, Nan Zhang, Yixin Liu, Alexander Fabbri, Junru Liu, Ryo Kamoi, Xiaoxin Lu, Caiming Xiong, Jieyu Zhao, Dragomir Radev, Kathleen McKeown and Rui Zhang 3404

What Are We Measuring When We Evaluate Large Vision-Language Models? An Analysis of Latent Factors and Biases
Anthony Tiong, Junqi Zhao, Boyang Li, Junnan Li, Steven Hoi and Caiming Xiong 3427

Show Your Work with Confidence: Confidence Bands for Tuning Curves
Nicholas Lourie, Kyunghyun Cho and He He 3455

GRASP: A Disagreement Analysis Framework to Assess Group Associations in Perspectives
Vinodkumar Prabhakaran, Christopher M Homan, Lora Aroyo, Aida Mostafazadeh Davani, Alicia Parrish, Alex Taylor, Mark Diaz, Ding Wang and Gregory Serapio-García 3473

Event Causality Is Key to Computational Story Understanding
Yidan Sun, Qin Chao and Boyang Li 3493

Subspace Representations for Soft Set Operations and Sentence Similarities
Yoichi Ishibashi, Sho Yokoi, Katsuhito Sudoh and Satoshi Nakamura 3512

My Heart Skipped a Beat! Recognizing Expressions of Embodied Emotion in Natural Language
Yuan Zhuang, Tianyu Jiang and Ellen Riloff 3525

Low-Cost Generation and Evaluation of Dictionary Example Sentences
Bill Cai, Ng Boon Liang Clarence, Daniel Tan Wee Liang and Shelvia Hotama 3538

Making Language Models Better Tool Learners with Execution Feedback
Shuofei Qiao, Honghao Gui, chengfei lv, Qianghuai Jia, Huajun Chen and Ningyu Zhang . . 3550

Complex Claim Verification with Evidence Retrieved in the Wild
Jifan Chen, Grace Kim, Aniruddh Sriram, Greg Durrett and Eunsol Choi 3569

Multimodal Multi-loss Fusion Network for Sentiment Analysis
zehui wu, Ziwei Gong, Jaywon Koo and Julia Hirschberg 3588

Confronting LLMs with Traditional ML: Rethinking the Fairness of Large Language Models in Tabular Classifications
Yanchen Liu, Srishti Gautam, Jiaqi Ma and Himabindu Lakkaraju 3603

Analyzing the Use of Metaphors in News Editorials for Political Framing
Meghdut Sengupta, Roxanne El Baff, Milad Alshomary and Henning Wachsmuth 3621

SharpSeq: Empowering Continual Event Detection through Sharpness-Aware Sequential-task Learning
Thanh-Thien Le, Viet Dao, Linh Van Nguyen, Thi-Nhung Nguyen, Linh Van Ngo and Thien Huu Nguyen 3632

Dissecting Paraphrases: The Impact of Prompt Syntax and supplementary Information on Knowledge Retrieval from Pretrained Language Models
Stephan Linzbach, Dimitar Dimitrov, Laura Kallmeyer, Kilian Evang, Hajira Jabeen and Stefan Dietze 3645

Know When To Stop: A Study of Semantic Drift in Text Generation
Ava Spataru 3656

Curriculum Masking in Vision-Language Pretraining to Maximize Cross Modal Interaction
Kraig Yuheng Tou and Zijun Sun 3672

Elote, Choclo and Mazorca: on the Varieties of Spanish
Cristina España-Bonet and Alberto Barrón-Cedeño 3689

Ada-LEval: Evaluating long-context LLMs with length-adaptable benchmarks
Chonghua Wang, Haodong Duan, Songyang Zhang, Dahua Lin and Kai Chen 3712

A Zero-Shot Monolingual Dual Stage Information Retrieval System for Spanish Biomedical Systematic Literature Reviews
Regina Ofori-Boateng, Magaly Aceves-Martins, Nirmalie Wiratunga and Carlos Francisco Moreno-Garcia 3725

LayoutPointer: A Spatial-Context Adaptive Pointer Network for Visual Information Extraction
Huang Siyuan, yongping xiong and Wu Guibin 3737

Long-form evaluation of model editing
Domenic Rosati, Robie Gonzales, Jinkun Chen, Xuemin Yu, Yahya Kayani, Frank Rudzicz and Hassan Sajjad 3749

Analyzing the Role of Semantic Representations in the Era of Large Language Models
Zhijing Jin, Yuen Chen, Fernando Gonzalez Adauto, Jiarui Liu, Jiayi Zhang, Julian Michael, Bernhard Schölkopf and Mona T. Diab 3781

TRAQ: Trustworthy Retrieval Augmented Question Answering via Conformal Prediction
Shuo Li, Sangdon Park, Insup Lee and Osbert Bastani 3799

MapGuide: A Simple yet Effective Method to Reconstruct Continuous Language from Brain Activities
Xinpei Zhao, Jingyuan Sun, Shaonan Wang, Jing Ye, Xhz Xhz and Chengqing Zong 3822

On-the-fly Definition Augmentation of LLMs for Biomedical NER
Monica Munnangi, Sergey Feldman, Byron C Wallace, Silvio Amir, Tom Hope and Aakanksha Naik 3833

This Land is Your, My Land: Evaluating Geopolitical Bias in Language Models through Territorial Disputes
Bryan Li, Samar Haider and Chris Callison-Burch 3855

Set-Aligning Framework for Auto-Regressive Event Temporal Graph Generation
Xingwei Tan, Yuxiang Zhou, Gabriele Pergola and Yulan He 3872

LanguageFlow: Advancing Diffusion Language Generation with Probabilistic Flows
Shujian Zhang, Lemeng Wu, Chengyue Gong and Xingchao Liu 3893

Towards Improved Multi-Source Attribution for Long-Form Answer Generation
Nilay Patel, Shivashankar Subramanian, Siddhant Garg, Pratyay Banerjee and Amita Misra 3906

Synthetic Query Generation for Privacy-Preserving Deep Retrieval Systems using Differentially Private Language Models
Aldo Gael Carranza, Rezsa Farahani, Natalia Ponomareva, Alexey Kurakin, Matthew Jagielski and Milad Nasr 3920

Okay, Let's Do This! Modeling Event Coreference with Generated Rationales and Knowledge Distillation
Abhijnan Nath, Shadi Manafi Avari, Avyakta Chelle and Nikhil Krishnaswamy 3931

Can Knowledge Graphs Reduce Hallucinations in LLMs? : A Survey
Garima Agrawal, Tharindu Sandaruwan Kumarage, Zeyad Alghamdi and huan liu 3947

Pedagogically Aligned Objectives Create Reliable Automatic Cloze Tests
Brian David Ondov, Kush Attal and Dina Demner-Fushman 3961

Take One Step at a Time to Know Incremental Utility of Demonstration: An Analysis on Reranking for Few-Shot In-Context Learning
Kazuma Hashimoto, Karthik Raman and Michael Bendersky 3973

LM-Infinite: Zero-Shot Extreme Length Generalization for Large Language Models
Chi Han, Qifan Wang, Hao Peng, Wenhan Xiong, Yu Chen, Heng Ji and Sinong Wang 3991

CONSCENDI: A Contrastive and Scenario-Guided Distillation Approach to Guardrail Models for Virtual Assistants
Albert Sun, Varun Nair, Elliot Schumacher and Anitha Kannan 4009

Advancing Beyond Identification: Multi-bit Watermark for Large Language Models
KiYoon Yoo, Wonhyuk Ahn and Nojun Kwak 4031

HTCCN: Temporal Causal Convolutional Networks with Hawkes Process for Extrapolation Reasoning in Temporal Knowledge Graphs
Tingxuan Chen, Jun Long, Liu Yang, Zidong Wang, Yongheng Wang and Xiongnan Jin 4056

SemStamp: A Semantic Watermark with Paraphrastic Robustness for Text Generation
Abe Bohan Hou, Jingyu Zhang, Tianxing He, Yichen Wang, Yung-Sung Chuang, Hongwei Wang, Lingfeng Shen, Benjamin Van Durme, Daniel Khashabi and Yulia Tsvetkov 4067

Media Bias Detection Across Families of Language Models
Iffat Maab, Edison Marrese-Taylor, Sebastian Padó and Yutaka Matsuo 4083

Better Zero-Shot Reasoning with Role-Play Prompting
Aobo Kong, Shiwan Zhao, Hao Chen, Qicheng Li, Yong Qin, Ruiqi Sun, Xin Zhou, Enzhi Wang and Xiaohang Dong 4099

Event-Content-Oriented Dialogue Generation in Short Video
Fenghua Cheng, Xue Li, Zi Huang, Jinxiang Wang and Sen Wang 4114

DoG-Instruct: Towards Premium Instruction-Tuning Data via Text-Grounded Instruction Wrapping
Yongrui Chen, Haiyun Jiang, Xinting Huang, Shuming Shi and Guilin Qi 4125

Beyond Borders: Investigating Cross-Jurisdiction Transfer in Legal Case Summarization
Santosh T.y.s.s, Vatsal Venkatkrishna, Saptarshi Ghosh and Matthias Grabmair 4136

EDC: Effective and Efficient Dialog Comprehension For Dialog State Tracking
Qifan Lu, Bhaskar Ramasubramanian and Radha Poovendran 4151

Automatic Restoration of Diacritics for Speech Data Sets
Sara Shatnawi, Sawsan Alqahtani and Hanan Aldarmaki 4166

XNLIeu: a dataset for cross-lingual NLI in Basque
Maite Heredia, Julen Etxaniz, Muitze Zulaika, Xabier Saralegi, Jeremy Barnes and Aitor Soroa 4177

MDR: Model-Specific Demonstration Retrieval at Inference Time for In-Context Learning
Huazheng Wang, Jinming Wu, Haifeng Sun, Zixuan Xia, Daixuan Cheng, Jingyu Wang, Qi Qi and Jianxin Liao 4189

Exploring Cross-Cultural Differences in English Hate Speech Annotations: From Dataset Construction to Analysis
Nayeon Lee, Chani Jung, Junho Myung, Jiho Jin, Jose Camacho-Collados, Juho Kim and Alice Oh 4205

Enhancing Contextual Understanding in Large Language Models through Contrastive Decoding
Zheng Zhao, Emilio Monti, Jens Lehmann and Haytham Assem 4225

Generalizable Sarcasm Detection is Just Around the Corner, of Course!
Hyewon Jang and Diego Frassinelli 4238

Encoding of lexical tone in self-supervised models of spoken language
Gaofei Shen, Michaela Watkins, Afra Alishahi, Arianna Bisazza and Grzegorz Chrupała . . . 4250

A Systematic Comparison of Contextualized Word Embeddings for Lexical Semantic Change
Francesco Periti and Nina Tahmasebi 4262

iACOS: Advancing Implicit Sentiment Extraction with Informative and Adaptive Negative Examples
Xiancai XU, Jia-Dong Zhang, Lei Xiong and Zhishang Liu 4283

Rectifying Demonstration Shortcut in In-Context Learning
Joonwon Jang, Sanghwan Jang, Wonbin Kweon, Minjin Jeon and Hwanjo Yu 4294

Universal NER: A Gold-Standard Multilingual Named Entity Recognition Benchmark
Stephen Mayhew, Terra Blevins, Shuheng Liu, Marek Suppa, Hila Gonen, Joseph Marvin Imperial, Börje F. Karlsson, Peiqin Lin, Nikola Ljubešić, Lester James Validad Miranda, Barbara Plank, Arij Riabi and Yuval Pinter 4322

ODD: A Benchmark Dataset for the Natural Language Processing Based Opioid Related Aberrant Behavior Detection
Sunjae Kwon, Xun Wang, Weisong Liu, Emily Druhl, Minhee L. Sung, Joel I. Reisman, Wenjun Li, Robert D Kerns, William C. Becker and hong yu 4338

A Comprehensive Study of Gender Bias in Chemical Named Entity Recognition Models
Xingmeng Zhao, Ali Shahzad Niazi and Anthony Rios 4360

The Promises and Pitfalls of Using Language Models to Measure Instruction Quality in Education
Paiheng Xu, Jing Liu, Nathan D Jones, Julie Cohen and Wei Ai 4375

Differentially Private Next-Token Prediction of Large Language Models
James Flemings, Meisam Razaviyayn and Murali Annavaram 4390

Improving Adversarial Data Collection by Supporting Annotators: Lessons from GAHD, a German Hate Speech Dataset
Janis Goldzycher, Paul Röttger and Gerold Schneider 4405

Memory Augmented Language Models through Mixture of Word Experts
Cicero Nogueira dos Santos, James Lee-Thorp, Isaac Noble, Chung-Ching Chang and David Uthus 4425

Impossible Distillation for Paraphrasing and Summarization: How to Make High-quality Lemonade out of Small, Low-quality Model
Jaehun Jung, Peter West, Liwei Jiang, Faeze Brahman, Ximing Lu, Jillian Fisher, Taylor Sorensen and Yejin Choi 4439

TofuEval: Evaluating Hallucinations of LLMs on Topic-Focused Dialogue Summarization
Liyan Tang, Igor Shalyminov, Amy Wing-mei Wong, Jon Burnsky, Jake W. Vincent, Yu'an Yang, Siffi Singh, Song Feng, Hwanjun Song, Hang Su, Lijia Sun, Yi Zhang, Saab Mansour and Kathleen McKeown 4455

MOKA: Moral Knowledge Augmentation for Moral Event Extraction
Xinliang Frederick Zhang, Winston Wu, Nicholas Beauchamp and Lu Wang 4481

Fixing Rogue Memorization in Many-to-One Multilingual Translators of Extremely-Low-Resource Languages by Rephrasing Training Samples
Paulo Cavalin, Pedro Henrique Leite da Silva Pires Domingues, Claudio Pinhanez and Julio Nogima 4503

Backdoor Attacks on Multilingual Machine Translation
Jun Wang, Qiongkai Xu, Xuanli He, Benjamin I. P. Rubinstein and Trevor Cohn 4515

Personalized Jargon Identification for Enhanced Interdisciplinary Communication
Yue Guo, Joseph Chee Chang, Maria Antoniak, Erin Bransom, Trevor Cohen, Lucy Lu Wang and Tal August 4535

Flames: Benchmarking Value Alignment of LLMs in Chinese
Kexin Huang, Xiangyang Liu, Qianyu Guo, Tianxiang Sun, Jiawei Sun, Yaru Wang, Zeyang Zhou, Yixu Wang, Yan Teng, Xipeng Qiu, Yingchun Wang and Dahua Lin 4551

Mitigating Bias for Question Answering Models by Tracking Bias Influence
Mingyu Derek Ma, Jiun-Yu Kao, Arpit Gupta, Yu-Hsiang Lin, Wenbo Zhao, Tagyoung Chung, Wei Wang, Kai-Wei Chang and Nanyun Peng 4592

Extending CLIP's Image-Text Alignment to Referring Image Segmentation
Seoyeon Kim, Minguk Kang, Dongwon Kim, Jaesik Park and Suha Kwak 4611

Generating Attractive and Authentic Copywriting from Customer Reviews
Yu-Xiang Lin and Wei-Yun Ma 4629

Effective Long-Context Scaling of Foundation Models
Wenhan Xiong, Jingyu Liu, Igor Molybog, Hejia Zhang, Prajjwal Bhargava, Rui Hou, Louis Martin, Rashi Rungta, Karthik Abinav Sankararaman, Barlas Oguz, Madian Khabsa, Han Fang, Yashar Mehdad, Sharan Narang, Kshitiz Malik, Angela Fan, Shruti Bhosale, Sergey Edunov, Mike Lewis, Sinong Wang and Hao Ma 4643

Empowering Diffusion Models on the Embedding Space for Text Generation
Zhujin Gao, Junliang Guo, Xu Tan, Yongxin Zhu, Fang Zhang, Jiang Bian and Linli Xu 4664

Aligning as Debiasing: Causality-Aware Alignment via Reinforcement Learning with Interventional Feedback
Yu Xia, Tong Yu, Zhankui He, Handong Zhao, Julian McAuley and Shuai Li 4684

Fake Alignment: Are LLMs Really Aligned Well?
Yixu Wang, Yan Teng, Kexin Huang, Chengqi Lyu, Songyang Zhang, Wenwei Zhang, Xingjun Ma, Yu-Gang Jiang, Yu Qiao and Yingchun Wang 4696

Visually Guided Generative Text-Layout Pre-training for Document Intelligence
Zhiming Mao, Haoli Bai, Lu Hou, Lifeng Shang, Xin Jiang, Qun Liu and Kam-Fai Wong . . 4713

HILL: Hierarchy-aware Information Lossless Contrastive Learning for Hierarchical Text Classification
He Zhu, Junran Wu, Ruomei Liu, Yue Hou, Ze Yuan, Shangzhe Li, Yicheng Pan and Ke Xu 4731

Investigating the Emergent Audio Classification Ability of ASR Foundation Models
Rao Ma, Adian Liusie, Mark Gales and Kate Knill 4746

In-context Learning Generalizes, But Not Always Robustly: The Case of Syntax
Aaron Mueller, Albert Webson, Jackson Petty and Tal Linzen 4761

Prompt-Singer: Controllable Singing-Voice-Synthesis with Natural Language Prompt
Yongqi Wang, Ruofan Hu, Rongjie Huang, Zhiqing Hong, Ruiqi Li, Wenrui Liu, Fuming You, Tao Jin and Zhou Zhao 4780

Lost in Transcription: Identifying and Quantifying the Accuracy Biases of Automatic Speech Recognition Systems Against Disfluent Speech
Dena Mujtaba, Nihar R. Mahapatra, Megan Arney, J Scott Yaruss, Hope Gerlach-Houck, Caryn Herring and Jia Bin 4795

MAFALDA: A Benchmark and Comprehensive Study of Fallacy Detection and Classification
Chadi Helwe, Tom Calamai, Pierre-Henri Paris, Chloé Clavel and Fabian M. Suchanek 4810

Diffusion Glancing Transformer for Parallel Sequence-to-Sequence Learning
Lihua Qian, Mingxuan Wang, Yang Liu and Hao Zhou 4846

No Context Needed: Contextual Quandary In Idiomatic Reasoning With Pre-Trained Language Models
Kellen Tan Cheng and Suma Bhat 4863

Multi-stage Retrieve and Re-rank Model for Automatic Medical Coding Recommendation
Xindi Wang, Robert Mercer and Frank Rudzicz 4881

Anisotropy is Not Inherent to Transformers
Anemily Machina and Robert Mercer 4892

Finding Replicable Human Evaluations via Stable Ranking Probability
Parker Riley, Daniel Deutsch, George Foster, Viresh Ratnakar, Ali Dabirmoghaddam and Markus Freitag 4908

Stealthy and Persistent Unalignment on Large Language Models via Backdoor Injections
Yuanpu Cao, Bochuan Cao and Jinghui Chen 4920

Generalizable and Stable Finetuning of Pretrained Language Models on Low-Resource Texts
Sai Ashish Somayajula, Youwei Liang, Li Zhang, Abhishek Singh and Pengtao Xie 4936

Detecting Bipolar Disorder from Misdiagnosed Major Depressive Disorder with Mood-Aware Multi-Task Learning
Daeun Lee, Hyolim Jeon, Sejung Son, Chaewon Park, Ji hyun An, Seungbae Kim and Jinyoung Han 4954

Leveraging Code to Improve In-Context Learning for Semantic Parsing
Ben Bogin, Shivanshu Gupta, Peter Clark and Ashish Sabharwal 4971

Improving Pre-trained Language Model Sensitivity via Mask Specific losses: A case study on Biomedical NER
Micheal Abaho, Danushka Bollegala, Gary Leeming, Dan W Joyce and Iain Edward Buchan5013

Language Models Implement Simple Word2Vec-style Vector Arithmetic
Jack Merullo, Carsten Eickhoff and Ellie Pavlick 5030

AutoLoRA: Automatically Tuning Matrix Ranks in Low-Rank Adaptation Based on Meta Learning
Ruiyi Zhang, Rushi Qiang, Sai Ashish Somayajula and Pengtao Xie 5048

SportQA: A Benchmark for Sports Understanding in Large Language Models
Haotian Xia, Zhengbang Yang, Yuqing Wang, Rhys Tracy, Yun Zhao, Dongdong Huang, Zezhi Chen, Yan Zhu, Yuan-fang Wang and Weining Shen 5061

Revisiting subword tokenization: A case study on affixal negation in large language models
Thinh Hung Truong, Yulia Otmakhova, Karin Verspoor, Trevor Cohn and Timothy Baldwin 5082

Generating Mental Health Transcripts with SAPE (Spanish Adaptive Prompt Engineering)
Daniel Cabrera Lozoya, Alejandro Casar Berazaluce, Juan Alberto Barajas Perches, Eloy Hernández Lúa, Mike Conway and Simon D'Alfonso 5096

Where are you from? Geolocating Speech and Applications to Language Identification
Patrick Foley, Matthew Wiesner, Bismarck Bamfo Odoom, Leibny Paola Garcia Perera, Kenton Murray and Philipp Koehn 5114

Teaching Language Models to Self-Improve through Interactive Demonstrations
Xiao Yu, Baolin Peng, Michel Galley, Jianfeng Gao and Zhou Yu 5127

MAGID: An Automated Pipeline for Generating Synthetic Multi-modal Datasets
Hossein Aboutalebi, Hwanjun Song, Yusheng Xie, Arshit Gupta, Lijia Sun, Hang Su, Igor Shalyminov, Nikolaos Pappas, Siffi Singh and Saab Mansour 5150

Zero-shot Generative Linguistic Steganography
Ke Lin, Yiyang Luo, Zijian Zhang and Luo ping 5168

Does GPT-4 pass the Turing test?
Cameron Robert Jones and Ben Bergen 5183

Polarity Calibration for Opinion Summarization
Yuanyuan Lei, Kaiqiang Song, Sangwoo Cho, Xiaoyang Wang, Ruihong Huang and Dong Yu 5211

Sentence-level Media Bias Analysis with Event Relation Graph
Yuanyuan Lei and Ruihong Huang 5225

EMONA: Event-level Moral Opinions in News Articles
Yuanyuan Lei, Md Messal Monem Miah, Ayesha Qamar, Sai Ramana Reddy, Jonathan Tong, Haotian Xu and Ruihong Huang 5239

DLM: A Decoupled Learning Model for Long-tailed Polyphone Disambiguation in Mandarin
Beibei Gao, Yangsen Zhang, Ga Xiang and Yushan Jiang 5252

You don't need a personality test to know these models are unreliable: Assessing the Reliability of Large Language Models on Psychometric Instruments
Bangzhao Shu, Lechen Zhang, Minje Choi, Lavinia Dunagan, Lajanugen Logeswaran, Moontae Lee, Dallas Card and David Jurgens 5263

CASA: Causality-driven Argument Sufficiency Assessment
Xiao Liu, Yansong Feng and Kai-Wei Chang 5282

MacGyver: Are Large Language Models Creative Problem Solvers?
Yufei Tian, Abhilasha Ravichander, Lianhui Qin, Ronan Le Bras, Raja Marjieh, Nanyun Peng, Yejin Choi, Thomas L. Griffiths and Faeze Brahman 5303

To Translate or Not to Translate: A Systematic Investigation of Translation-Based Cross-Lingual Transfer to Low-Resource Languages
Benedikt Ebing and Goran Glavaš 5325

Enhancing Large Language Models Against Inductive Instructions with Dual-critique Prompting
Rui Wang, Hongru Wang, Fei Mi, Boyang Xue, Yi Chen, Kam-Fai Wong and Ruifeng Xu . . 5345

GLiNER: Generalist Model for Named Entity Recognition using Bidirectional Transformer
Urchade Zaratiana, Nadi Tomeh, Pierre Holat and Thierry Charnois 5364

XSTest: A Test Suite for Identifying Exaggerated Safety Behaviours in Large Language Models
Paul Röttger, Hannah Rose Kirk, Bertie Vidgen, Giuseppe Attanasio, Federico Bianchi and Dirk Hovy 5377

Carpe diem: On the Evaluation of World Knowledge in Lifelong Language Models
Yujin Kim, Jaehong Yoon, Seonghyeon Ye, Sangmin Bae, Namgyu Ho, Sung Ju Hwang and Se-Young Yun 5401

Fine-grained Gender Control in Machine Translation with Large Language Models
Minwoo Lee, Hyukhun Koh, Minsung Kim and Kyomin Jung 5416

DialogVCS: Robust Natural Language Understanding in Dialogue System Upgrade
Zefan Cai, Xin Zheng, Tianyu Liu, Haoran Meng, Jiaqi Han, Gang Yuan, Binghuai Lin, Baobao Chang and Yunbo Cao 5431

LLatrieval: LLM-Verified Retrieval for Verifiable Generation
Xiaonan Li, Changtai Zhu, Linyang Li, Zhangyue Yin, Tianxiang Sun and Xipeng Qiu 5453

Mapping Long-term Causalities in Psychiatric Symptomatology and Life Events from Social Media
Siyuan Chen, Meilin Wang, Minghao Lv, Zhiling Zhang, Juqianqian Juqianqian, Dejiyangla Dejiyangla, Yujia Peng, Kenny Q. Zhu and Mengyue Wu 5472

Multimodal Chart Retrieval: A Comparison of Text, Table and Image Based Approaches
Averi Nowak, Francesco Piccinno and Yasemin Altun 5488

Retrieval Helps or Hurts? A Deeper Dive into the Efficacy of Retrieval Augmentation to Language Models
Seiji Maekawa, Hayate Iso, Sairam Gurajada and Nikita Bhutani 5506

AudioChatLlama: Towards General-Purpose Speech Abilities for LLMs
Yassir Fathullah, Chunyang Wu, Egor Lakomkin, Ke Li, Junteng Jia, Yuan Shangguan, Jay Mahadeokar, Ozlem Kalinli, Christian Fuegen and Mike Seltzer 5522

Whispers of Doubt Amidst Echoes of Triumph in NLP Robustness
Ashim Gupta, Rishanth Rajendhran, Nathan Stringham, Vivek Srikumar and Ana Marasovic 5533

Sequential Compositional Generalization in Multimodal Models
Semih Yagcioglu, Osman Batur İnce, Aykut Erdem, Erkut Erdem, Desmond Elliott and Deniz Yuret 5591

Generating Uncontextualized and Contextualized Questions for Document-Level Event Argument Extraction
Md Nayem Uddin, Enfa Rose George, Eduardo Blanco and Steven Corman 5612

Evidence-Driven Retrieval Augmented Response Generation for Online Misinformation
Zhenrui Yue, Huimin Zeng, Yimeng Lu, Lanyu Shang, Yang Zhang and Dong Wang 5628

Open-Vocabulary Federated Learning with Multimodal Prototyping
Huimin Zeng, Zhenrui Yue and Dong Wang 5644

Exploring Key Point Analysis with Pairwise Generation and Graph Partitioning
Xiao Li, Yong Jiang, Shen Huang, Pengjun Xie, Gong Cheng and Fei Huang 5657

Understanding the Capabilities and Limitations of Large Language Models for Cultural Commonsense
Siqi Shen, Lajanugen Logeswaran, Moontae Lee, Honglak Lee, Soujanya Poria and Rada Mihalcea 5668

Code Models are Zero-shot Precondition Reasoners
Lajanugen Logeswaran, Sungryull Sohn, Yiwei Lyu, Anthony Zhe Liu, Dong-Ki Kim, Dongsub Shim, Moontae Lee and Honglak Lee 5681

Contrastive and Consistency Learning for Neural Noisy-Channel Model in Spoken Language Understanding
Suyoung Kim, Jiyeon Hwang and Ho-Young Jung 5698

Do Large Language Models Rank Fairly? An Empirical Study on the Fairness of LLMs as Rankers
Yuan Wang, Xuyang Wu, Hsin-Tai Wu, Zhiqiang Tao and Yi Fang 5712

TabSQLify: Enhancing Reasoning Capabilities of LLMs Through Table Decomposition
Md Mahadi Hasan Nahid and Davood Rafiei 5725

Contextual Label Projection for Cross-Lingual Structured Prediction
Tanmay Parekh, I-Hung Hsu, Kuan-Hao Huang, Kai-Wei Chang and Nanyun Peng 5738

Event Detection from Social Media for Epidemic Prediction
Tanmay Parekh, Anh Mac, Jiarui Yu, Yuxuan Dong, Syed Shahriar, Bonnie Liu, Eric J Yang, Kuan-Hao Huang, Wei Wang, Nanyun Peng and Kai-Wei Chang 5758

RESPROMPT: Residual Connection Prompting Advances Multi-Step Reasoning in Large Language Models
Song Jiang, Zahra Shakeri, Aaron Chan, Maziar Sanjabi, Hamed Firooz, Yinglong Xia, Bugra Akyildiz, Yizhou Sun, Jinchao Li, Qifan Wang and Asli Celikyilmaz 5784

BPE-knockout: Pruning Pre-existing BPE Tokenisers with Backwards-compatible Morphological Semi-supervision
Thomas Bauwens and Pieter Delobelle 5810

How are Prompts Different in Terms of Sensitivity?
Sheng Lu, Hendrik Schuff and Iryna Gurevych 5833

LSTDial: Enhancing Dialogue Generation via Long- and Short-Term Measurement Feedback
Guanghui Ye, Huan Zhao, Zixing Zhang, Xupeng Zha and Zhihua Jiang 5857

The ART of LLM Refinement: Ask, Refine, and Trust
Kumar Shridhar, Koustuv Sinha, Andrew Cohen, Tianlu Wang, Ping Yu, Ramakanth Pasunuru, Mrinmaya Sachan, Jason E Weston and Asli Celikyilmaz 5872

Modularized Multilingual NMT with Fine-grained Interlingua
Sungjun Lim, Yoonjung Choi and Sangha Kim 5884

ParallelPARC: A Scalable Pipeline for Generating Natural-Language Analogies
Oren Sultan, Yonatan Bitton, Ron Yosef and Dafna Shahaf 5900

AWESOME: GPU Memory-constrained Long Document Summarization using Memory Mechanism and Global Salient Content
Shuyang Cao and Lu Wang 5925

NLP Systems That Can't Tell Use from Mention Censor Counterspeech, but Teaching the Distinction Helps
Kristina Gligoric, Myra Cheng, Lucia Zheng, Esin Durmus and Dan Jurafsky 5942

Debiasing with Sufficient Projection: A General Theoretical Framework for Vector Representations
Enze Shi, Lei Ding, Linglong Kong and Bei Jiang 5960

Semi-Supervised Dialogue Abstractive Summarization via High-Quality Pseudolabel Selection
Jianfeng He, Hang Su, Jason Cai, Igor Shalyminov, Hwanjun Song and Saab Mansour 5976

AfriMTE and AfriCOMET: Enhancing COMET to Embrace Under-resourced African Languages
Jiayi Wang, David Ifeoluwa Adelani, Sweta Agrawal, Marek Masiak, Ricardo Rei, Eleftheria Briakou, Marine Carpuat, Xuanli He, Sofia Bourhim, Andiswa Bukula, Muhidin A. Mohamed, Temitayo Olatoye, Tosin Adewumi, Hamam Mokayed, Christine Mwase, Wangui Kimotho, Foutse Yuehgoh, Anuoluwapo Aremu, Jessica Ojo, Shamsuddeen Hassan Muhammad, Salomey Osei, Abdul-Hakeem Omotayo, Chiamaka Ijeoma Chukwuneke, Perez Ogayo, Oumaima Hourrane, Salma El Anigri, Lolwethu Ndolela, Thabiso Mangwana, Shafie Abdi Mohamed, Hassan Ayinde, Oluwabusayo Olufunke Awoyomi, Lama Alkhaled, sana Sabah al-azzawi, Naome A Etori, Millicent Ochieng, Clemencia Siro, Njoroge Kiragu, Eric Muchiri, Wangari Kimotho, Toadoum Sari Sakayo, Lyse Naomi Momo Wamba, Daud Abolade, Simbiat Ajao, Iyanuoluwa Shode, Ricky Sambo Macharm, Ruqayya Nasir Iro, Saheed Salahudeen Abdullahi, Stephen Edward Moore, Bernard Opoku, Zainab Akinjobi, Abeeb Afolabi, Nnaemeka Casmir Obiefuna, Onyekachi Ogbu, Sam Brian Ochieng', Verrah Akinyi Otiende, Chinedu Emmanuel Mbonu, Yao Lu and Pontus Stenetorp 5997

TableLlama: Towards Open Large Generalist Models for Tables
Tianshu Zhang, Xiang Yue, Yifei Li and Huan Sun 6024

PEMA: An Offsite-Tunable Plug-in External Memory Adaptation for Language Models
HyunJin Kim, Young Jin Kim and JinYeong Bak 6045

Backdooring Instruction-Tuned Large Language Models with Virtual Prompt Injection
Jun Yan, Vikas Yadav, Shiyang Li, Lichang Chen, Zheng Tang, Hai Wang, Vijay Srinivasan, Xiang Ren and Hongxia Jin 6065

Exploring the Factual Consistency in Dialogue Comprehension of Large Language Models
Shuaijie She, Shujian Huang, Xingyun Wang, Yanke Zhou and Jiajun Chen 6087

Multilingual Pretraining and Instruction Tuning Improve Cross-Lingual Knowledge Alignment, But Only Shallowly
Changjiang Gao, Hongda Hu, Peng Hu, Jiajun Chen, Jixing Li and Shujian Huang 6101

A Study on the Calibration of In-context Learning
Hanlin Zhang, YiFan Zhang, Yaodong Yu, Dhruv Madeka, Dean Foster, Eric P. Xing, Himabindu Lakkaraju and Sham M. Kakade 6118

DialogBench: Evaluating LLMs as Human-like Dialogue Systems
Jiao Ou, Junda Lu, Che Liu, Yihong Tang, Fuzheng Zhang, Di Zhang and Kun Gai 6137

GINopic: Topic Modeling with Graph Isomorphism Network
Suman Adhya and Debarshi Kumar Sanyal 6171

CMB: A Comprehensive Medical Benchmark in Chinese
Xidong Wang, Guiming Hardy Chen, Song Dingjie, Zhang Zhiyi, Zhihong Chen, Qingying Xiao, Junying Chen, Feng Jiang, Jianquan Li, Xiang Wan, Benyou Wang and Haizhou Li 6184

Massive End-to-end Speech Recognition Models with Time Reduction
Weiran Wang, Rohit Prabhavalkar, Haozhe Shan, Zhong Meng, Dongseong Hwang, Qiujia Li, Khe Chai Sim, Bo Li, James Qin, Xingyu Cai, Adam Stooke, Chengjian Zheng, Yanzhang He, Tara N Sainath and Pedro J Moreno Mengibar 6206

SlimFit: Memory-Efficient Fine-Tuning of Transformer-based Models Using Training Dynamics
Arash Ardakani, Altan Haan, Shangyin Tan, Doru Thom Popovici, Alvin Cheung, Costin Iancu and Koushik Sen 6218

Effective Large Language Model Adaptation for Improved Grounding and Citation Generation
Xi Ye, Ruoxi Sun, Sercan O Arik and Tomas Pfister 6237

Assisting in Writing Wikipedia-like Articles From Scratch with Large Language Models
Yijia Shao, Yucheng Jiang, Theodore A Kanell, Peter Xu, Omar Khattab and Monica Lam . 6252

Grounding Gaps in Language Model Generations
Omar Shaikh, Kristina Gligoric, Ashna Khetan, Matthias Gerstgrasser, Diyi Yang and Dan Jurafsky 6279

When Does Monolingual Data Help Multilingual Translation: The Role of Domain and Model Scale
Christos Baziotis, Biao Zhang, Alexandra Birch and Barry Haddow 6297

ContraSim – Analyzing Neural Representations Based on Contrastive Learning
Adir Rahamim and Yonatan Belinkov 6325

Universal Prompt Optimizer for Safe Text-to-Image Generation
Zongyu Wu, Hongcheng Gao, Yueze Wang, Xiang Zhang and Suhang Wang 6340

Language Model Based Unsupervised Dependency Parsing with Conditional Mutual Information and Grammatical Constraints
Junjie Chen, Xiangheng He and Yusuke Miyao 6355

The Bias Amplification Paradox in Text-to-Image Generation
Preethi Seshadri, Sameer Singh and Yanai Elazar 6367

Grammar-based Data Augmentation for Low-Resource Languages: The Case of Guarani-Spanish Neural Machine Translation
Agustín Lucas, Alexis Baladón, Victoria Pardiñas, Marvin M. Agüero-Torales, Santiago Góngora and Luis Chiruzzo 6385

Global Gallery: The Fine Art of Painting Culture Portraits through Multilingual Instruction Tuning
Anjishnu Mukherjee, Aylin Caliskan, Ziwei Zhu and Antonios Anastasopoulos 6398

Toward Interactive Regional Understanding in Vision-Large Language Models
Jungbeom Lee, Sanghyuk Chun and Sangdoo Yun 6416

ScriptMix: Mixing Scripts for Low-resource Language Parsing
Jaeseong Lee, Dohyeon Lee and seung-won hwang 6430

MT-PATCHER: Selective and Extendable Knowledge Distillation from Large Language Models for Machine Translation
Jiahuan Li, Shanbo Cheng, Shujian Huang and Jiajun Chen 6445

Abstract

Named entity recognition is a key component of Information Extraction (IE), particularly in scientific domains such as biomedicine and chemistry, where large language models (LLMs), e.g., ChatGPT, fall short. We investigate the applicability of transfer learning for enhancing a named entity recognition model trained in the biomedical domain (the source domain) to be used in the chemical domain (the target domain). A common practice for training such a model in a few-shot learning setting is to pretrain the model on the labeled source data, and then, to finetune it on a hand-full of labeled target examples. In our experiments, we observed that such a model is prone to mislabeling the source entities, which can often appear in the text, as the target entities. To alleviate this problem, we propose a model to transfer the knowledge from the source domain to the target domain, but, at the same time, to project the source entities and target entities into separate regions of the feature space. This diminishes the risk of mislabeling the source entities as the target entities. Our model consists of two stages: 1) entity grouping in the source domain, which incorporates knowledge from annotated events to establish relations between entities, and 2) entity discrimination in the target domain, which relies on pseudo labeling and contrastive learning to enhance discrimination between the entities in the two domains. We conduct our extensive experiments across three source and three target datasets, demonstrating that our method outperforms the baselines by up to 5% absolute value[1].

1 Introduction

Named entity recognition is a crucial step in IE tasks. Existing models have achieved remarkable performance in the general domain (Lin et al., 2020; Wang et al., 2021b; Zhang et al., 2023; Shen et al., 2023b). However, in the scientific domains, e.g., medical or chemical domains, these models usually struggle due to the extremely large quantity of concepts, the wide presence of multi-token entities, and the ambiguity in detecting entity boundaries.

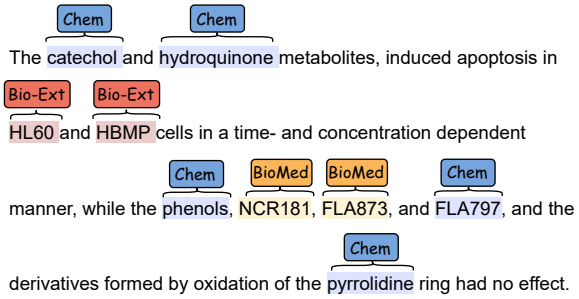

Figure 1: A test example in the chemical domain. The words marked with blue indicators are chemical entities, and the words marked with red and orange indicators are biomedical entities. The entities in red are mislabeled by a few-shot model as chemical entities.

Large language models (LLMs) show an impressive performance on various NLP tasks such as question answering or text summarization (OpenAI, 2022). Models such as ChatGPT (OpenAI, 2022) can achieve outstanding results given just a few training examples (Wang et al., 2022). However, Kandpal et al. (2023) recently report that the performance of these models is proportional to the number of relevant documents present in their pretraining corpus. Thus, one can expect that their performance fluctuates across domains. This is particularly expected to occur across certain scientific subjects, where the data may be scarce. Given the already existing challenges of the named entity recognition task in the scientific domain—mentioned earlier—this factor can further exacerbate the problem. For instance, in our early few-shot learning experiments, we observed that the results of ChatGPT in the chemical domain named entity recognition task are significantly worse than

[1]Code, data, and resources are publicly available for research purposes: https://github.com/Lhtie/Bio-Domain-Transfer.

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 1–21
June 16-21, 2024 ©2024 Association for Computational Linguistics

those in the general domain.[2]

In the present work, we employ transfer learning (Pan and Yang, 2010) to alleviate this problem. Transfer learning methods exploit the label data from one domain (called the source domain) to minimize the prediction error in another domain (namely the target domain). We particularly focus on a realistic setting, where given a large set of labeled data from the source domain and a small set of labeled data from the target domain, the goal is to develop a model for the target domain[3]. There are more resources in the biomedical domain than in the chemical domain due to funding priorities and BioNLP workshops. Therefore, as a case study, we take the biomedical domain as the source and the chemical domain as the target.

Figure 1 shows the challenges a named entity recognition model can face in the chemical domain. The model is trained in a few-shot learning setting. Thus, it is trained on labeled biomedical data, and then, further finetuned on a few labeled examples from the chemical domain. The task is to recognize only the chemical entities—ignoring other types of entities. Blue indicators represent chemical entities, while red and orange indicators denote biomedical entities. The model categorizes the entities marked with blue and red as chemical entities. The first observation is that, to an inexpert human, it is difficult to perform the task because the entities are highly domain-specific. The second observation is that the model wrongfully labels some entities from the source domain as the target entities. Therefore, engineers developing such a model face a dilemma: while not using the source data dramatically deteriorates performance,[4] simply pretraining with the source data increases the false positive rate. The third, and perhaps the most important, observation is that the examples from the source and target domains can co-occur in the same document. This problem setting contradicts the regular transfer learning setting, where the examples from the source and the target domains are fully disjoint (Ben-David et al., 2010). The latter property poses difficulties in the applicability of the traditional transfer learning methods in this setting.

Our core idea is to train a named entity recognition model such that it is able to project the representations of the source and target entities into separate regions of the feature space. Such a model can potentially transfer knowledge from the source domain to the target domain by constructing a shared feature space between the two domains. Furthermore, it reduces the similarity between the representations of the entities in the two domains, and consequently, it can potentially minimize the number of source entities that are mislabeled as target entities. To achieve this, our model consists of a pretraining stage on the source data, and a finetuning stage on the target data.

In the pretraining stage, we propose two methods to enrich the feature space with auxiliary data. The auxiliary data is extracted from the event mentions that the entities participate in. Additionally, during this stage, we propose to employ the multi-similarity loss term (Wang et al., 2019), which enables us to partition (or group) the source entities. Our empirical analysis shows that constructing such a feature space during the pretraining stage facilitates our projection step during the finetuning stage. In the finetuning stage, we detect the potentially false positive entities by pseudo-labeling them. Then, we aim to construct a feature space that projects the pseudo-labeled entities and the target entities into separate regions. We achieve this by employing the multi-similarity loss again. We evaluate our method across twelve use cases and show it outperforms the baselines in most experiments, with improvements of up to 5% in absolute value. We also empirically analyze our method and show that each proposed technique is individually effective. Our contributions are threefold:

- We propose a new pretraining algorithm for the named entity recognition task in the transfer learning setting. Our algorithm involves two steps: first, extracting auxiliary information about the source entities through the event mentions they participate in; and second, proposing an entity grouping technique using the multi-similarity loss. Our methods have proven effective for the named entity recognition task in the target domain. Our study is carried out in the scientific domain, particularly from the biomedical data as the source domain to the chemical data as the target domain. This is a crucial and challenging real-world problem. All of our claims, here and later, are only about this task.
- We propose a finetuning algorithm, which aims to project the target entities and the

[2]We report this complementary experiment in Appendix A.

[3]In the literature, this setup is often called the semi-supervised transfer learning setting (Saito et al., 2019).

[4]We empirically support this in the analysis section.

entities that may be potentially mislabeled into separate regions of the feature space. It comprises two steps: first, detecting the potentially out-of-domain entities by pseudo-labeling them; and second, obtaining dissimilar representations for the two sets of entities using the multi-similarity loss.

- We conduct extensive experiments across twelve cases, showing that our method significantly outperforms the baselines and shedding light on various aspects of our model.

2 Background

2.1 Named Entity Recognition

We view the named entity recognition task as a sequence labeling problem. We denote the training data by $D = \{(\mathbf{X}_i, \mathbf{Y}_i)\}_{i=1}^{n}$, where n is the number of input passages (or texts). To train a classifier f with parameter θ, we minimize the loss as follows:

$$\mathcal{L}_{NER} = \mathbb{E}_{(\mathbf{X}_i, \mathbf{Y}_i) \sim D} \left[CE \left(f(\mathbf{Y}_i | \mathbf{X}_i; \theta), \mathbf{Y}_i \right) \right], \quad (1)$$

where CE is the cross-entropy loss.

2.2 Transfer Learning

We are given examples from the source domain $\mathbb{S}$ and the target domain $\mathbb{T}$, where the training set size in the target domain is much smaller than the source domain, i.e., $|\mathbf{X}^{\mathbb{T}}| << |\mathbf{X}^{\mathbb{S}}|$. Given this data, we aim to develop a model for the target domain and minimize its prediction error.

We focus on the named entity recognition task, and take the biomedical domain as the source and the chemical domain as the target. Note that the data distributions in the two domains are different. Therefore, a model solely trained on the source data is usually not as competitive as one trained on the target data. The baseline solution in this setting, *direct transfer*, is to pretrain the model on the labeled source data and finetune it on the labeled target data.

2.3 Multi-Similarity Loss

We enhance our named entity recognition model in the source domain by capturing the similarities between entity pairs. To achieve this, we employ an objective term called the multi-similarity (MS) contrastive loss proposed by Wang et al. (2019) for metric learning. MS can incorporate self-similarity, relative positive similarity, and relative negative similarity. Self-similarity depends on the properties of the data point itself, such as hardness, while negative and positive similarities are measured with respect to an anchor data point.

In the following sections, we use the final encoder hidden states of input tokens as entity representations. If an entity consists of multiple tokens, we take the average of their representations. Additionally, we denote the relative similarity between entity pairs as $S_{\cdot}$, using cosine similarity.

The multi-similarity loss is calculated in two stages. First, given the *i-th* entity denoted by x_i and its label denoted by y_i, we aim to extract the most difficult positive and negative entities. This is achieved by thresholding over the relative similarity scores as follows:

$$\begin{aligned} \mathcal{P}_i &= \{x_j | S_{ij}^{+} < \max_{y_k \neq y_i} S_{ik} + \epsilon\}, \\ \mathcal{N}_i &= \{x_j | S_{ij}^{-} > \min_{y_k = y_i} S_{ik} - \epsilon\}, \end{aligned} \quad (2)$$

where $\mathcal{P}_i$ is the set of positive, $\mathcal{N}_i$ is the set of negative, and ϵ is a margin penalty.

Second, we calculate a soft weight score for the extracted pairs to reflect their importance:

$$\begin{aligned} w_{ij}^{+} &= \frac{e^{-\alpha(S_{ij}-\gamma)}}{1 + \sum_{k \in \mathcal{P}_i} e^{-\alpha(S_{ik}-\gamma)}}, \\ w_{ij}^{-} &= \frac{e^{\beta(S_{ij}-\gamma)}}{1 + \sum_{k \in \mathcal{N}_i} e^{\beta(S_{ik}-\gamma)}}, \end{aligned} \quad (3)$$

where α, β, and γ are hyperparameters. We observe that in each set, the weights are the ratio of the self-similarity scores to the sum of all the relative scores in the set.

The final multi-similarity loss is:

$$\begin{aligned} \mathcal{L}_{MS} = \frac{1}{n_e} \sum_{i}^{n_e} \Bigg\{ & \frac{1}{\alpha} \log\Big[1 + \sum_{k \in \mathcal{P}_i} e^{-\alpha(S_{ik}-\gamma)}\Big] \\ & + \frac{1}{\beta} \log\Big[1 + \sum_{k \in \mathcal{N}_i} e^{\beta(S_{ik}-\gamma)}\Big] \Bigg\}, \end{aligned} \quad (4)$$

where n_e is the total number of the entities. Note that the values of $S_{\cdot}$ already contain the weights computed in Equation 3.

3 Proposed Method

Figure 2 illustrates our framework. It consists of two stages, pretraining on the source data, and then, finetuning on the target data. In the source domain, we employ external knowledge to construct

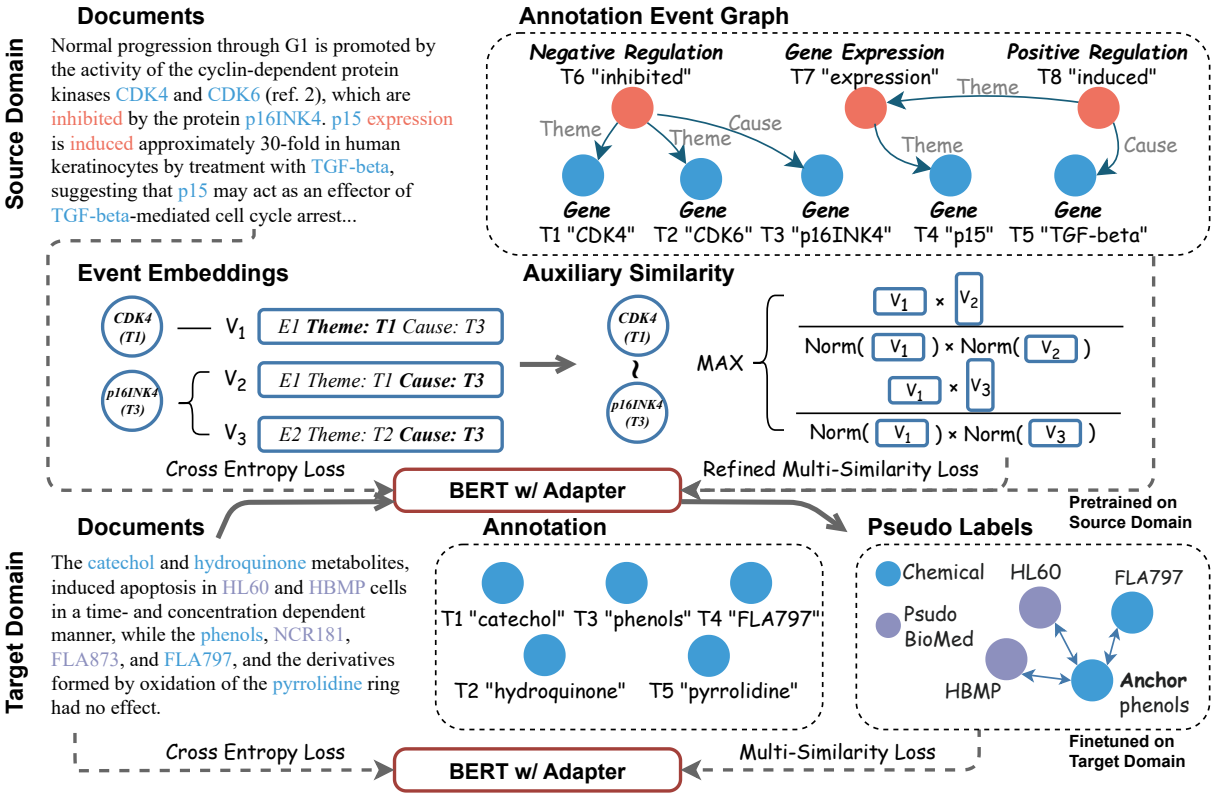

Figure 2: Overview of proposed entity grouping and entity discrimination frameworks. Entity grouping on the source domain is shown in the upper part. Based on event annotations, a set of event embeddings is constructed under two paradigms. Afterward, pairwise auxiliary similarity scores are calculated according to argument embeddings. Extended multi-similarity loss concerning four types of similarities, combined with cross-entropy loss, are jointly learned during pretraining. Entity discrimination on the target domain is shown in the lower part. Pseudo labels are formed by the named entity recognition model pretrained in the source domain, and in contrast to annotated labels, a multi-similarity loss is injected into finetuning.

an event feature space based on their arguments, and to calculate the auxiliary similarity scores between entities. Then, the similarity scores are used in the multi-similarity loss to shape the entity feature space. In the target domain, we aim to enhance the model's ability to distinguish the target entities from the entities that are likely to be mislabeled, such as the entities that potentially belong to the source domain. To achieve this, we propose an algorithm to extract pseudo-labels and employ the multi-similarity loss for the second time.

3.1 Source Domain Pretraining

Using external knowledge, we enrich entity representations for source domain pretraining. Since the source domain consists of a set of various subdomains (or sub-topics), discovering these subdomains in the source domain facilitates the subsequent process of domain transfer (Hoffman et al., 2012). Specifically, by detecting these sub-domains and grouping the data, we enable the contrastive loss in the next step to consider each one individually and transform them accordingly. This approach avoids the oversimplification of treating the entire source domain as a single cluster. Below, we propose two separate approaches to obtain the auxiliary embedding vectors, both exploiting event mentions that the entities appear in. Given the auxiliary vectors, we describe our method for calculating the auxiliary similarity scores. Finally, we provide an overview of the pretraining loss function, which incorporates the entity similarity scores and the auxiliary similarity scores.

Concatenation-based Event Embedding. Our first approach relies on an off-the-shelf token encoder pretrained on biomedical data, called SapBERT (Liu et al., 2021a). Given an event mention, we encode its arguments using SapBERT, and then concatenate the resulting vectors to obtain the event representation. Note that in some cases, an argument may be a nested event, or an event may have a varying number of arguments. In those cases, we

use vector averaging to compress the representations or padding to fill in the extra argument slots[5].

Sentence-Encoder based Event Embedding. In our second approach, we use templates generated by a LLM. We begin by extracting all event types from the source domain. We then submit each type and its arguments to the LLM, using prompts to construct a template. A few examples of such templates are reported in Table 1, and a larger set of templates along our prompt instruction can be found in Appendix C.2. Then, for the event mentions in the source data, we complete their corresponding templates by replacing the placeholders with the actual arguments. The resulting passages are sent through an off-the-shelf sentence encoder to obtain the final representation vectors. In our experiments, we use ChatGPT (OpenAI, 2022) as the LLM, and use the S-PubMed-BERT (Deka et al., 2022) as the sentence encoder. In § 4, we individually evaluate each one of the methods for extracting the auxiliary embedding vectors.

Auxiliary Similarity. Given $E(x_i)$ and $E(x_j)$ as the sets of auxiliary vectors for the entities x_i and x_j respectively, we define the similarity between the two entities as the maximum inter-similarity between all the vector pairs across the two sets. More specifically, we formulate it as follows:

$$\kappa_{ij} = \max_{\mu \in E(x_i), \nu \in E(x_j)} \frac{\mu^T \cdot \nu}{|\mu| \cdot |\nu|}. \tag{5}$$

The value of κ_{ij} captures the relatedness between the contexts that the two entities appear in. If $E(x_\bullet)$ is empty, then we set $\kappa_{i\bullet}$=0.

Contrastive Grouping. We adapt the multi-similarity loss (Wang et al., 2019) to consider the primary similarity scores between entities, which is the cosine similarity between the encoder outputs for the entities, as well as the auxiliary similarity scores described earlier in this section. Our core idea is to assign a higher weight to the more informative pairs. In the case of positive pairs, this translates into assigning a higher weight to the instances that have a smaller primary similarity and a higher auxiliary similarity. In the case of negative pairs, it is the reverse, i.e., assigning a higher weight to the pairs with higher primary similarity and a lower auxiliary similarity.

[5]The details can be found in Appendix C.1.

The intuition behind these design choices is as follows. In the case of positive pairs, a low primary similarity and a high auxiliary similarity potentially mean that the encoder is unable to properly project the entities, but there is a strong external signal that the pair must have similar representations. In the case of negative pairs, a high primary similarity and a low auxiliary similarity potentially mean that the model needs to revise the parameters to take into account the external signal.

To implement these ideas, we exploit the soft weights discussed in Equations 3 to derive the weights for the positive pairs as follows:

$$\begin{aligned} \hat{w}^+_{ij} &= \frac{1}{e^{-I^+_{ij}} + \sum_{k \in \mathcal{P}_i} e^{-J^+_{ik} + J^+_{ij}}}, \\ I^+_{ij} &= \alpha(\gamma - S_{ij}) + \rho\kappa_{ij}, \\ J^+_{ij} &= \alpha S_{ij} - \rho\kappa_{ij}. \end{aligned} \tag{6}$$

The value of $\hat{w}^+_{ij}$ is the second formulation of the soft weights introduced by Wang et al. (2019). We see that instead of only relying on the values of $S_\bullet$ to define $I^+_\bullet$, we incorporate the auxiliary similarity scores $\kappa_\bullet$ via the hyperparameter ρ.

Similarly, we re-define the soft weights for the negative pairs as follows:

$$\begin{aligned} \hat{w}^-_{ij} &= \frac{1}{e^{I^-_{ij}} + \sum_{k \in \mathcal{N}_i} e^{J^-_{ik} - J^-_{ij}}}, \\ I^-_{ij} &= \beta(\gamma - S_{ij}) + \tau\kappa_{ij}, \\ J^-_{ij} &= \beta S_{ij} - \tau\kappa_{ij}, \end{aligned} \tag{7}$$

where τ is a hyperparameter to balance the contributions of $S_\bullet$ and $\kappa_\bullet$.

Given the re-defined soft weights, the refined multi-similarity objective (RMS) can be re-written as follows:

$$\begin{aligned} \mathcal{L}_{RMS} = \frac{1}{n_e} \sum_{i}^{n_e} \Bigg\{ & \frac{1}{\alpha} \log\Big[1 + \sum_{k \in \mathcal{P}_i} e^{-\alpha(S_{ik} - \gamma) + \rho\kappa_{ik}}\Big] \\ & + \frac{1}{\beta} \log\Big[1 + \sum_{k \in \mathcal{N}_i} e^{\beta(S_{ik} - \gamma) - \tau\kappa_{ik}}\Big] \Bigg\}, \end{aligned} \tag{8}$$

where, as mentioned earlier, ρ and τ are to maintain a balance between the primary and the auxiliary representations. Note that we use the information extracted from events to construct the auxiliary representations. However, additional sources of information can be considered if it is present.

Type	Template
Phosphorylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is modified by the addition of a phosphate group at a particular site <Site>, facilitated by another molecule <Cause>.
Acetylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes the addition of an acetyl group at a particular site <Site>, catalyzed by another molecule <Cause>.
Pathway	Indicated by the given trigger <Trigger>, involving one or more molecules <Participant> that collaborate to accomplish a specific biological function or response.

Table 1: Examples of templates for sentence-encoder based embeddings. Angle brackets <·> in templates are placeholders to be replaced by actual entities as corresponding arguments.

The pretraining objective function consists of the supervised named entity recognition term and the unsupervised RMS term, as follows:

$$\mathcal{L} = \mathcal{L}_{NER} + \lambda_{\mathbb{S}} \mathcal{L}_{RMS}, \tag{9}$$

where $\lambda_{\mathbb{S}}$ is a penalty term.

3.2 Target Domain Finetuning

The source and target domains in our problem setting share the same context. In the same documents (or even sentences) that the entities from one domain appear, the entities from the other domain may be used, too. This makes the recognition task particularly challenging in the target domain for two reasons: the training data in this domain is scarce, and the presence of entities from the source domain can potentially lead to a high false positive rate. Our core idea is that, while finetuning the model on the target data, we train the encoder such that it projects the target entities and the entities that potentially belong to the source domain into separate regions of the feature space. To implement this idea, we employ pseudo labeling along the multi-similarity loss–introduced in §2.3.

Pseudo Labeling. Given a passage with annotated target entities in the target training data, we use the model introduced in §3.1 to automatically detect the entities that may belong to the source domain. These entities act as pseudo labels in our algorithm. Note that while there may be passages that do not contain such entities, in general, due to the nature of the two domains that we are studying (i.e., biomedical and chemical domains), this is an expected observation. In the results section, we will also empirically support our argument.

Contrastive Discrimination. In the next step, we enable the model to discriminate between the target and pseudo-labeled source entities. For this purpose, we use the multi-similarity loss. We use multi-similarity loss in Eq. 4 to calculate contrastive objective by defining the labels as follows:

$$y_i = \begin{cases} 0, & x_i \in \mathcal{Q} \\ 1, & x_i \notin \mathcal{Q} \end{cases} \tag{10}$$

where x_i represents the entity and $\mathcal{Q}$ is the set of entities with pseudo labels.

The final target domain fine-tuning objective is:

$$\mathcal{L} = \mathcal{L}_{NER} + \lambda_{\mathbb{T}} \mathcal{L}_{MS}, \tag{11}$$

where $\lambda_{\mathbb{T}}$ is a penalty terms.

4 Experiments

4.1 Experimental Setup

Dataset	# Train/ Valid/ Test	# Train/ Valid/ Test (All)
PC	-	260 / 89 / 175
ID	-	150 / 46 / 117
CG	-	300 / 100 / 200
CHEMDNER	81 / 72 / 2478	2916 / 2907 / 2478
BC5CDR	86 / 88 / 500	500 / 500 / 500
DrugProt	93 / 88 / 600	597 / 597 / 600

Table 2: Overview of the datasets. The top three are the biomedical source datasets, and the bottom three are the chemical target datasets. The target datasets were down-sampled randomly to be used in the few-shot setting.

Datasets. As the source datasets, we use three benchmarks: Pathway Curation (PC), Cancer Genetics (CG), and Infectious Diseases (ID). The first two datasets were released by BioNLP Shared Task 2013 (Nédellec et al., 2013), and the third one was released by BioNLP Shared Task 2011 (Pyysalo et al., 2011). All three datasets have the same format. We aggregate them to create a fourth dataset called the *biomedical multi-task* dataset. As the target datasets, we use three benchmarks: CHEMDNER (Krallinger et al., 2015), BC5CDR (Kim et al., 2015), and DrugPort (Miranda et al., 2021).

Target Tasks	*CHEMDNER*			*BC5CDR*			*DrugProt*		
Metrics	**Precision**	**Recall**	**F1**	**Precision**	**Recall**	**F1**	**Precision**	**Recall**	**F1**
Target Only	42.73	51.69	46.77	72.44	85.86	78.51	63.80	67.42	65.49

Table 3: Evaluation results precision, recall, and F1(%) scores on three target tasks with Biomedical Multi-task as source task. All the reported scores are averaged over 3 different random seeds. We include two baselines, along with our methods EG (Entity Grouping), ED (Entity Discrimination), and their combination.

Each dataset contains extra annotations unrelated to its domain. For instance, the CG dataset has annotations not relevant to biomedicine. We preprocess all the datasets by removing such annotations. For few-shot experiments, we down-sample the training and validation sets of target datasets to sizes randomly chosen between 70 and 100. Table 2 summarizes the dataset statistics.

Baselines. We compare our method with two baselines. *Target Only*: a model finetuned on the labeled target data. *Direct Transfer*: a model pretrained on the labeled source data and then finetuned on the labeled target data.

Implementation Details. We use BERT (bert-base-uncased) (Devlin et al., 2019) as the backbone for all the models. To train the model, we update the parameters of the adapter layers (Houlsby et al., 2019) and freeze the rest, due to limited computational resources. We iteratively select each source and target dataset pair as the training and evaluation benchmarks. All the experiments are repeated three times. Following Nakayama (2018), we report average macro Precision, Recall, and F1 scores[6].

4.2 Main Results

Table 3 reports the performance of our model compared to the *target Only* and the *Direct Transfer* models, when the dataset *biomedical multi-task* is used as the source data. All the other use cases are reported in Appendix E. Our final model EG(•)+ED outperforms the baselines in the majority of the cases. We also report the performance of each component of our method in the table—i.e., our entity grouping (EG) and entity discrimination (ED) techniques. We observe that, on average, the method further improves when they are both used in the pipeline. One exception is the DrugProt dataset, which we discuss in the next section.

[6]Training and tuning details can be found in Appendix D.

Target Tasks	*CHEMD*	*BC5CDR*	*DrugProt*
Direct Transfer	46.18	78.55	68.17
Pse-Augment	47.13±0.8	76.43±0.2	68.20±0.8
Pse-Classifier	46.93±1.4	78.80±0.3	69.42±0.1
Ours	**47.78**±1.3	**80.88**±0.9	**70.96**±0.1

Table 4: F1(%) scores of our method compared to two alternative methods for using pseudo-labels. All the reported scores are averaged over 3 different random seeds. Additional experiment details are in Appendix E.3.

4.3 Empirical Analysis

Pseudo Label Usage. Table 4 reports a comparison between our model and two alternative methods. *Pse-Augment*, where the detected pseudo-labels are marked and augmented with the target entities and a classifier trained to label unseen target entities. *Pse-Classifier*, where a classifier is trained to detect pseudo-labels and to filter them out, before being potentially mislabeled. This experiment aims to reveal the efficacy of the multi-similarity (MS) loss for discriminating between the source and the pseudo-labeled entities. The results indicate that our ED method that leverages MS loss is an effective way to use pseudo labels. For *Pse-Augment*, adding source domain entity labels to the target task leads to the negative transfer (NT) problem (Zhang et al., 2020). For *Pse-Classifier*, the pipeline suffers from error propagation, where errors caused by the classifier can severely affect the performance of target entity predictions.

How is the Representation Enhanced? To investigate the effect of our proposed methods, we project entity representations (i.e., averaged hidden states of entity tokens in input texts) into a two-

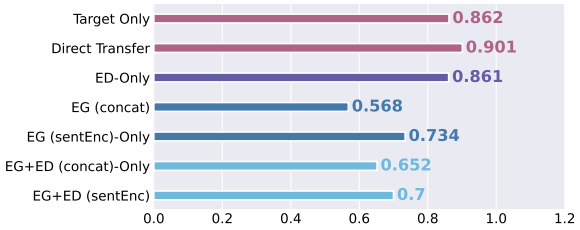

Figure 3: Davies-Bouldin index criterion of clusters. For baseline and ED-concerned settings, pseudo entities are included and viewed in the same cluster as *Disease*.

dimensional space using t-SNE (van der Maaten and Hinton, 2008)[7]. For better comparison, we adopt the Davies-Bouldin index (DB) (Davies and Bouldin, 1979) as the criterion. The lower the DB, the better the clustering of the data points.

With our ED method, the model effectively learns to disperse the representations of chemical entities and pseudo-labeled entities. Therefore, it becomes easier for our model to assign a negative label to a source domain entity by measuring similarities between its representations and the target domain entity representations. Furthermore, our EG method also plays a vital role in the formation of feature space of the target domain. The projection results in clearer clustering of chemical entities, while disease entities are dispersed from them, making it easier to extract chemical entities. For a more precise comparison, Figure 3 reports the DB index. Our methods achieve lower DB compared to the baselines, which indicates that the improved representations of the target domain are learned with our methods.

Method	Precision	Recall	F1
Target Only	41.32±1.9	45.52±2.0	43.31±1.9
Direct Transfer	42.16±1.3	48.51±1.4	45.08±0.6
EG(sentEnc)	45.49±1.0	49.03±1.9	47.16±0.8
ED	45.35±3.2	47.88±3.5	46.58±3.3
EG(sentEnc)+ED	44.94±0.4	49.37±2.0	47.03±0.8

Table 5: Averaged F1 scores (%) over 3 different random seeds for CHEMDNER trained on full BERT model.

Role of Adapters To clarify that the use of adapters does not interfere with the conclusion of our proposed methods, we additionally finetune the full BERT model on the CHEMDNER dataset, and the results are reported in Table 5. The performance of the full model is similar to the performance of adapters or even slightly worse than our adapter models (47.03 vs 48.26). Our methods remain effective when fine-tuned with the full model, demonstrating that the results in the paper are reliable and sufficient.

[7]We show the visualization of target task BC5CDR in Appendix F.

0.59	16.74	19.12	17.18

Table 7: Averaged F1 scores (%) over three different random seeds for the CrossNER dataset, transferring from the Science domain to the AI domain.

Compatibility Across Other Domain Pairs In the above experiments, we focus on transfer learning between the biomedical domain and the chemical domain. To show the generalization ability of our proposed framework on other domain pairs, we conduct the experiments on two additional domains based on CrossNER (Liu et al., 2021b), transferring from the Science domain to the AI domain. These two domains are highly related and share similar named entities. We downsample the train and validation data to roughly 10% of the full dataset for the target domain. Detailed statistics are shown in Table 6. The F1 scores averaged over three runs are reported in Table 7. It shows that our methods have strong generalization ability.

5 Related Work

Biomedical and Chemical Entity Extraction. Entity extraction is a primary step in facilitating scientific discovery (Wang et al., 2021a). Previous biomedical entity extraction methods can be categorized into several classes, including domain adaptive pretraining (Labrak et al., 2023), boundary denoising diffusion model (Shen et al., 2023a), question answering-based classification (Arora and Park, 2023), Cocke-Younger-Kasami (CYK) algorithm (Corro, 2023), in-context learning (Chen et al., 2023), synthetic data (Khandelwal et al., 2022; Chen et al., 2022; Hiebel et al., 2023), and prototype learning (Cao et al., 2023).

Although there's a shared corpus between the biomedical and chemical domains, entity extrac-

tion in the chemical domain remains underexplored. The chemical entity extraction task is usually viewed as an auxiliary task for biomedical named entity recognition (Phan et al., 2021; Kocaman and Talby, 2021; Luo et al., 2022; Lee et al., 2023). Similar to Nguyen et al. (2022) and Wang et al. (2024), our paper differs from previous papers by viewing the chemical domain as an independent subject. Previous methods try to address this task by distant-supervision (Wang et al., 2021c) or span-representation learning (Nguyen et al., 2023). On the contrary, given the shared corpus between the biomedical and chemical domains, we leverage the large labeled data in the biomedical domain through transfer learning.

Transfer Learning for Named Entity Recognition. Transfer learning is an effective method to address low-resource named entity recognition tasks (Lee et al., 2018; Cao et al., 2018) and has shown its effectiveness in the biomedical domain (Peng et al., 2019). Prior work has explored the role of continual pretraining on the target domain data (Gururangan et al., 2020; Liu et al., 2021b). However, Mahapatra et al. (2022) argues that continual pretraining is inefficient regarding computational resources. In contrast to domain-adaptive pretraining, we aim to improve the representation of entities by projecting the source and target entities into separate regions of feature space. Inspired by the success of incorporating external knowledge for biomedical information extraction (Zhang et al., 2021; Banerjee et al., 2021), we use biomedical events to augment the representations. To separate the potentially false positive examples in the target domain, we introduce pseudo-labels. Previous papers have adopted pseudo-labels in cross-lingual named entity recognition (Zhou et al., 2023; Ma et al., 2023). However, they aim to align the entities in the source and target language instead of separating source entities from target entities. Compared to our method, Zhou et al. (2023) has a different contrastive objective, which aims to separate different entity types, rather than the entities from the two domains.

6 Conclusions

We proposed a named entity recognition task for transferring knowledge from the biomedical domain to the chemical domain. Our core idea is to train a shared feature space between the two domains to facilitate the knowledge transfer, and, at the same time, to project the source and target entities into separate regions of the feature space to reduce the false negative rate. We achieve this in a few steps. We begin by enriching the source feature space with information about events, then train a named entity recognition model to cluster similar entities into groups. We then use the trained model to label the entities that may belong to the source domain, and use these entities in a multi similarity loss function to achieve our goal. Our experiments across three source and three target datasets signify the effectiveness of our method.

7 Limitations

Our method partly relies on external knowledge. Therefore, the quality of external knowledge significantly influences the effect of our method. Especially when human annotations are unavailable, the performance of automatic annotators, typically neural networks, is an important factor to consider.

In this paper, we propose a framework that incorporates external knowledge during training. For instance, the compression function in §3.1 and templates in Section C.2 can be altered. Besides, such designs require prior knowledge of the source domain.

Our method leverages a contrastive learning strategy. However, the training algorithm doesn't fully utilize GPU resources, leading to training inefficiencies.

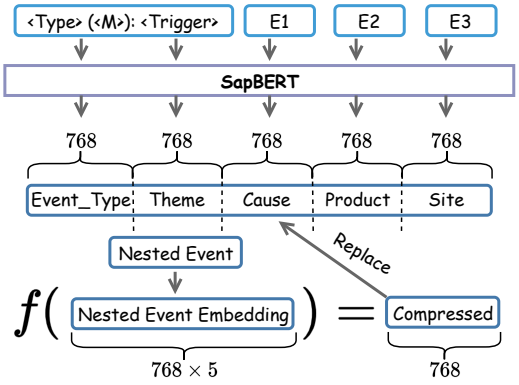

Figure 4: Components of concatenation based event embeddings. Arguments of events, along with event type, are encoded by an off-the-shelf model and concatenated afterwards. For nested events as arguments, we fill in compressed event embeddings recursively.

A Details of ChatGPT evaluation on CHEMDNER

To evaluate ChatGPT's few-shot ability of named entity recognition in the chemical domain, we elaborately select three named entity recognition examples in the CHEMDNER dataset that include all types of entities. An instructional description of the CHEMDNER task and examples constitute the prompt used to instruct the prediction. Configuration of prompts is shown in Table 8. The precision, recall, and macro-F1 scores on the CHEMDNER test set are 11.09%, 35.37%, and 16.88% respectively. Laskar et al. (2023) reports the ChatGPT's named entity recognition performance on general domain named entity recognition task-WNUT 17 dataset (Derczynski et al., 2017) with precision: 18.03%, recall: 56.16%, and F1: 27.03%. This highlights ChatGPT's weaker performance in solving chemical domain named entity recognition tasks.

B Notation Table

We present definitions for all notations we used in Table 9.

C Details of Event Embedding Construction.

C.1 Concatenation based Event Embedding

An overview of concatenation based event embedding strategy is shown in Figure 4. Each type of annotated event contains a trigger and various arguments, including theme, cause, product, and site. We prepare raw texts of each argument and encode

Role	Prompt
System	You are an expert of chemical named entity recognition tasks
User	Description: In this task, you are given a small paragraph of a PubMed article, and your task is to identify all the named entities (particular chemical related entity) from the given input and also provide type of the each entity according to structure-associated chemical entity mention classes (ABBREVIATION, IDENTIFIER, FORMULA, SYSTEMATIC, MULTIPLE, TRIVIAL, FAMILY). Specifically, the paragraph are given with seperate tokens and you need to list all the chemical named entities in order and also tag their types. Generate the output in this format: entity1 <type_of_entity1>, entity2 <type_of_entity2>. Examples: Input: In situ C-C bond cleavage of vicinal diol following by the lactolisation resulted from separated treatment of Arjunolic acid (1) , 24-hydroxytormentic acid (2) and 3-O-β-D-glucopyranosylsitosterol (3) with sodium periodate and silica gel in dried THF according to the strategic position of hydroxyl functions in the molecule . Output: C-C <FORMULA>, vicinal diol <FAMILY>, Arjunolic acid <TRIVIAL>, 24-hydroxytormentic acid <SYSTEMATIC>, 3-O-β-D-glucopyranosylsitosterol <SYSTEMATIC>, sodium periodate <SYSTEMATIC>, silica gel <TRIVIAL>, THF <ABBREVIATION>, hydroxyl <SYSTEMATIC> Input: Structural studies using LC/MS/MS analysis and (1) H NMR spectroscopy showed the formation of a glycosidic bond between the primary hydroxyl group of RVX-208 and glucuronic acid . Output: (1) H <FORMULA>, primary hydroxyl <FAMILY>, RVX-208 <IDENTIFIER>, glucuronic acid <TRIVIAL> Input: The lystabactins are composed of serine (Ser) , asparagine (Asn) , two formylated/hydroxylated ornithines (FOHOrn) , dihydroxy benzoic acid (Dhb) , and a very unusual nonproteinogenic amino acid , 4,8-diamino-3-hydroxyoctanoic acid (LySta) . Output: lystabactins <FAMILY>, serine <TRIVIAL>, Ser <FORMULA>, asparagine <TRIVIAL>, Asn <FORMULA>, formylated/hydroxylated ornithines <MULTIPLE>, FOHOrn <ABBREVIATION>, dihydroxy benzoic acid <SYSTEMATIC>, Dhb <ABBREVIATION>, 4,8-diamino-3-hydroxyoctanoic acid <SYSTEMATIC>, LySta <ABBREVIATION> Please continue: Input: %s Output:

Table 8: Prompts of ChatGPT evaluation. %s is to be replaced by test context.

Notation	Definition
$\mathbf{X}$	Set of input documents
$\mathbf{Y}$	Set of named entity tags
n_e	Total number of entities
x_i	The i-th entity
y_i	Label of the i-th entity
f	Classifier model
$\mathbb{S}$	Source domain
$\mathbb{T}$	Target domain
S_*	Relative similarity
$E(*)$	Set of embedding vectors
κ_*	Auxiliary similarity
$\mathcal{P}_i$	Set of selected positive entities
$\mathcal{N}_i$	Set of selected negative entities
$\mathcal{Q}$	Set of entities with pseudo labels
I^+, J^+	Auxiliary term for positive pairs
I^-, J^-	Auxiliary term for negative pairs
w^+	Soft weight of positive pairs
w^-	Soft weight of negative pairs
$\hat{w}^+_{ij}$	Adjusted soft weight of positive pairs
$\hat{w}^-_{ij}$	Adjusted soft weight of negative pairs
$\mathcal{L}_{NER}$	Classification loss for NER task
$\mathcal{L}_{MS}$	Multi-similarity loss
$\mathcal{L}_{RMS}$	Refined multi-similarity loss
θ	Classifier parameter
ϵ	Margin penalty
$\alpha, \beta, \gamma, \rho, \tau$	Hyperparameters
$\lambda_{\mathbb{S}}, \lambda_{\mathbb{T}}$	Balance term for losses

Table 9: Notation Table

them into argument embeddings. To illustrate the formation of raw texts, let's consider an example. Imagine a gene named "IL-1ra" which is associated with two event annotations, "M1, Negation, E9" and "E9, Binding:forms a complex, Theme:IL-1ra, Theme2:Type I IL-1R". Raw text for "event_type" comprises the event name, "M" label, and trigger. The example's raw text should be "Binding (Negation): forms a complex". Raw text typically is the corresponding entity itself for the rest of the arguments. However, for the focusing entity, "IL-1ra" for instance, raw text is specified as "self", deriving "IL-1ra (self)" in this case. There are several corner cases to tackle with:

Nested Event. As mentioned in §3.1, for the nested event, we first recursively compose the event embedding for it and compress it to the same length as partial embedding. To achieve this, let's consider the nested event embedding as e. We then implement the compression function by averaging several successive elements:

$$f(e) = \left[\frac{1}{5}\sum_{k=0}^{4} e_k, \frac{1}{5}\sum_{k=5}^{9} e_k, ..., \frac{1}{5}\sum_{k=5i}^{5i+4} e_k, ... \right]^T, \tag{12}$$

Full embedding has 768×5 dimensions, and we average every 5 element and concatenate the values into a 768-dimension embedding.

Padding It is necessary that some arguments do not apply to some events or miss in annotation. A padding scheme is necessary for missing arguments, and we choose to fill in random partial embedding with the same length sampled from Gaussian distribution with the same mean and covariance as all other encoded partial embeddings.

C.2 Sentence-Encoder based Event Embedding

The prompt we use to instruct ChatGPT to generate explanatory templates for events is: *give a one-sentence definition of biomedical event type XXX with arguments XXX, XXX...*. For instance, we generate a template for the Phosphorylation event with *give a one-sentence definition of biomedical event type Phosphorylation with arguments Trigger, Theme:Molecule, Cause:Molecule, Site:Simple chemical*. The full list of the used templates is shown in Table 14, 15, 16, 17, and 18.

D Experiment Details

We select *bert-base-uncased* version of BERT model as our backbone model, and we only train 0.817% of parameters (894,528) of the entire model using transformer-adapter utils (Pfeiffer et al., 2020). For source task pretraining, we use a batch size of 64; while for target task fine-tuning, we use a batch size of 16, considering the relatively small training set. We use AdamW optimizer and an initial learning rate of $1e-4$ for pretraining and finetuning. To fully train our model, we first train 80 epochs and then stop when f1 scores on the held-out validation set fail to update the best score for at least 20 epochs in a row. For hyperparameters, we tune balance factor $\lambda_{\mathbb{S}}$ from scale $\{0.10, 0.15, 0.20, 0.25, 0.30\}$ and tune $\lambda_{\mathbb{T}}$ from scale $\{0.6, 0.8, 1.0, 1.2, 1.4\}$. Due to the limitation of computational resources, we select ϵ and γ as 0.1 and 0.5 respectively, and α, β, ρ, τ as 4.0, 3.0, 8.0, 6.0 respectively considering the ratio of number of positive and negative pairs in contrastive learning.

Our models are trained on 4 Nvidia RTX 2080Ti GPUs in a data parallel fashion. Source task pretraining with contrastive learning takes around 5 hours, while target task finetuning with contrastive learning takes around 30 minutes.

E Full Experiment Results

Full evaluation results are reported in Table 13.

Target Tasks	*CHEMD*	*BC5CDR*	*DrugProt*
Direct Transfer	46.18	78.55	**68.17**
EG(MS)	46.08	78.87	68.00
EG(concat)	**47.03**	78.89	67.49
EG(sentEnc)	46.91	**79.76**	67.93

Table 10: F1(%) scores on three target tasks. Performance of our EG method using vanilla MS loss without external knowledge is reported as *EG(MS)*. All the reported scores are averaged over 3 different random seeds.

E.1 Generalization Ability

Event Annotator	Target Tasks	*CHEMD*	*BC5CDR*	*DrugProt*
Gold-std	Concat	47.03	78.89	67.49
	SentEnc	46.91	79.76	67.93
Auto-sys	Concat	46.06	79.49	68.31
	SentEnc	46.11	79.39	68.04

Table 11: F1(%) scores of our proposed EG methods based on human/machine annotated events. We highlight better scores between Gold-std and Auto-sys annotators under each setting with underlines. All the reported scores are averaged over 3 different random seeds.

To alleviate the reliance on gold-standard event annotations, which may be hard to obtain, we generate the event annotations using DeepEventMine (Trieu et al., 2020). Table 11 reports the performance of the EG methods. We see that the performance is comparable to that of the gold-standard annotations. We also observe that in the DrugProt dataset, the performance with automatic annotations is better than that of the gold-standard annotations, suggesting that the human annotations are low quality and noisy.

E.2 External Knowledge

Table 10 reports the performance of our EG method without external knowledge (i.e., event annotations), where simple MS loss replaces our RMS loss. The performance over three target tasks mirrors the *Direct Transfer* setting, suggesting that the vanilla MS objective has minimal impact and the main improvement stems from the auxiliary data extracted from the event mentions.

E.3 Pseudo Label Usage

Pse-Augment We augment annotations of target tasks with pseudo entities within the target corpus labeled as "Out of Distribution (OOD)" entities. Then, the model is trained with a single cross-entropy loss.

Pse-Classifer We first use a pretrained model as a classifier separating pseudo entities and gold-standard annotated entities. We then predict with the former directly finetuned model and filter out entities labeled "OOD" by the classifier.

Dataset	Precision	Recall	F1
Few-shot	42.73	51.69	46.77
Oracle	**73.56**	**80.03**	**76.66**

Table 12: Comparison of the target-only results for different training set sizes in CHEMDNER.

E.4 Size of Target Set

Since the training documents for the target domain are downsampled to roughly 10% of the original corpus, we compare our downsampled training results (few-shot) with those trained on the entire target set (Oracle). We finetune the BERT model with adapters on the full target dataset CHEMDNER in Table 12. The large gap indicates that the limited training data indeed severely hinders the model's learning of the task and justifies the need for transferring knowledge from a high-resource source domain.

F Visualization

The t-SNE projection visualization of BC5CDR test entity representations is shown in Figure 5.

G Scientific Artifacts

Type	Template
Conversion	A specific trigger <Trigger> causes the transformation of a molecule <Theme> into another molecule <Product>.
Phosphorylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is modified by the addition of a phosphate group at a particular site <Site>, facilitated by another molecule <Cause>.
Dephosphorylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has a phosphate group removed from a particular site <Site>, facilitated by another molecule <Cause>.
Acetylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes the addition of an acetyl group at a particular site <Site>, catalyzed by another molecule <Cause>.
Deacetylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has an acetyl group removed from a particular site <Site>, facilitated by another molecule <Cause>.
Ubiquitination	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is modified by the attachment of one or more ubiquitin molecules at a particular site, facilitated by another molecule <Cause>, often involving a simple chemical group <Site> as the site of attachment.
Deubiquitination	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has ubiquitin molecules removed from a particular site, facilitated by another molecule <Cause> involving a simple chemical group <Site> as the site of removal.
Hydroxylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes the addition of a hydroxyl group at a particular site, catalyzed by another molecule <Cause> involving a simple chemical group <Site> as the site of attachment.
Dehydroxylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has a hydroxyl group removed from a particular site, facilitated by another molecule <Cause> involving a simple chemical group <Site> as the site of removal.
Methylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes the addition of a methyl group at a particular site, facilitated by another molecule <Cause> involving a simple chemical group <Site> as the site of attachment.
Demethylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has a methyl group removed from a particular site, facilitated by another molecule <Cause> involving a simple chemical group <Site> as the site of removal.
Localization	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is directed to or away from a particular cellular component <AtLoc><FromLoc><ToLoc> or subcellular location within the cell.
Transport	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is moved or conveyed to or away from a particular cellular component <FromLoc><ToLoc> or subcellular location within the cell.
Gene Expression	Indicated by the given trigger <Trigger>, genetic information from a gene <Theme> is used to produce a functional gene product, such as RNA or protein.
Transcription	Indicated by the given trigger <Trigger>, genetic information from a gene <Theme> is transcribed into RNA, usually messenger RNA (mRNA), by RNA polymerase.
Translation	Indicated by the given trigger <Trigger>, the genetic information carried by mRNA <Theme> is used to synthesize a protein by ribosomes in the cell.
Degradation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes breakdown or degradation into smaller components.
Binding	Indicated by the given trigger <Trigger>, a specific molecule <Theme> interacts and forms a complex with another molecule(s) resulting in the product of a molecular complex <Product>.

Table 14: Templates for PathwayCuration Dataset.

Type	Template
Binding	Indicated by the given trigger <Trigger>, a specific molecule <Theme> interacts and forms a complex with another molecule(s) resulting in the product of a molecular complex <Product>.
Dissociation	Indicated by the given trigger <Trigger>, a specific complex <Theme> breaks apart, resulting in the release of individual molecules <Product> as products.
Regulation	Indicated by the given trigger <Trigger>, an entity <Theme> is controlled or influenced by another entity <Cause> to achieve a specific biological effect or outcome.
Positive Regulation	Indicated by the given trigger <Trigger>, an entity <Theme> is promoted or enhanced by another entity <Cause> to achieve a specific biological effect or outcome.
Activation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is stimulated or facilitated by another entity <Cause> to increase its activity, function, or biological effect.
Negative Regulation	Indicated by the given trigger <Trigger>, an entity <Theme> is inhibited or suppressed by another entity <Cause> to achieve a specific biological effect or outcome.
Inactivation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is deactivated or rendered inactive by another entity <Cause>, leading to a reduction or cessation of its biological function.
Pathway	Indicated by the given trigger <Trigger>, involving one or more molecules <Participant> that collaborate to accomplish a specific biological function or response.

Table 15: Continuation of templates for PathwayCuration Dataset.

Type	Template
Gene Expression	Indicated by the given trigger <Trigger>, a specific protein or a group of genes <Theme> are involved in the transcription and translation of genetic information to produce functional gene products, such as RNA or protein.
Transcription	Indicated by the given trigger <Trigger>, a specific protein or a group of genes <Theme> are involved in the synthesis of RNA from DNA template by RNA polymerase.
Protein Catabolism	Indicated by the given trigger <Trigger>, a specific protein <Theme> is broken down or degraded into smaller peptide fragments or amino acids.
Phosphorylation	Indicated by the given trigger <Trigger>, a specific protein <Theme> undergoes the addition of a phosphate group at a particular site <Site>, resulting in the modification of the protein's structure and function.
Localization	Indicated by the given trigger <Trigger>, a specific core entity <Theme> is directed to or away one location <AtLoc><ToLoc> within the cell or organism.
Binding	Indicated by the given trigger <Trigger>, a specific core entity <Theme> interacts and forms a connection with another entity <Site>, leading to the formation of a complex or association.
Regulation	Indicated by the given trigger <Trigger>, a specific core entity or event <Theme> is controlled or influenced by another core entity or event <Cause> through interactions at specific sites on molecules or entities <Site><CSite>, potentially resulting in modulation of biological processes.
Positive Regulation	Indicated by the given trigger <Trigger>, a specific core entity or event <Theme> is promoted or enhanced by another core entity or event <Cause> through interactions at specific sites on molecules or entities <Site><CSite>, potentially resulting in an increase in the intensity or rate of a biological process.
Negative Regulation	Indicated by the given trigger <Trigger>, a specific core entity or event <Theme> is inhibited or suppressed by another core entity or event <Cause> through interactions at specific sites on molecules or entities <Site><CSite>, potentially resulting in a decrease in the intensity or rate of a biological process.
Process	Indicated by the given trigger <Trigger>, involving a core entity that collaborates to accomplish a specific biological function or response.

Type	Template
Development	Indicated by the given trigger <Trigger>, a specific anatomical or pathological entity <Theme> undergoes progressive changes or growth, leading to the formation of a more complex and specialized structure or condition over time.
Blood Vessel Development	Indicated by the given trigger <Trigger>, blood vessels <Theme> undergo progressive changes or growth at a specific location <AtLoc>, leading to the formation and maturation of the vascular network.
Growth	Indicated by the given trigger <Trigger>, a specific anatomical or pathological entity <Theme> undergoes an increase in size, quantity, or complexity over time.
Death	Indicated by the given trigger <Trigger>, a specific anatomical or pathological entity <Theme> ceases to exhibit signs of life and undergoes irreversible loss of vital functions.
Cell Death	Indicated by the given trigger <Trigger>, a specific cell <Theme> undergoes a series of events leading to its own demise, often through programmed cell death or other mechanisms.
Breakdown	Indicated by the given trigger <Trigger>, a specific anatomical or pathological structure <Theme> disintegrates, decomposes, or undergoes degradation over time.
Cell Proliferation	Indicated by the given trigger <Trigger>, a specific cell <Theme> undergoes rapid and controlled replication or division, leading to an increase in the number of daughter cells.
Cell Division	Indicated by the given trigger <Trigger>, a specific cell <Theme> divides into two or more daughter cells through mitosis or meiosis.
Cell Differentiation	Indicated by the given trigger <Trigger>, a specific cell <Theme> undergoes changes in gene expression and morphology to become specialized and acquire distinct functions at a specific anatomical or pathological location <AtLoc>.
Remodeling	Indicated by the given trigger <Trigger>, a specific tissue <Theme> undergoes structural changes, reorganization, and modification in response to various stimuli or during growth and development.
Reproduction	Indicated by the given trigger <Trigger>, a specific organism <Theme> produces offspring through sexual or asexual means, leading to the continuation of the species.
Mutation	indicated by the given trigger <Trigger>, a specific gene, genome, or protein <Theme> undergoes a heritable change in its genetic sequence or structure at a particular site <Site>, potentially leading to alterations in its function or expression within a specific anatomical or pathological context <AtLoc>.
Carcinogenesis	Indicated by the given trigger <Trigger>, a specific anatomical or pathological entity <Theme> undergoes a series of genetic and cellular changes at a specific anatomical or pathological location <AtLoc>, leading to the development of cancer.
Cell Transformation	Indicated by the given trigger <Trigger>, a specific cell <Theme> undergoes changes in its phenotype, function, or behavior at a specific anatomical or pathological location <AtLoc>, often associated with the acquisition of abnormal or cancerous characteristics.
Metastasis	Indicated by the given trigger <Trigger>, a specific anatomical or pathological entity <Theme> spreads and establishes secondary growths or lesions at a different anatomical or pathological location <ToLoc> from the primary tumor site.
Infection	Indicated by the given trigger <Trigger>, an organism <Participant> invades and establishes itself in a specific anatomical or pathological site <Theme>, leading to a disease condition.
Metabolism	Indicated by the given trigger <Trigger>, collective chemical reactions occur within an organism <Theme> involving the processing, transformation, and utilization of specific molecules to maintain cellular functions and energy requirements.
Synthesis	Indicated by the given trigger <Trigger>, a specific simple chemical <Theme> is produced or created through chemical reactions or biological processes.
Catabolism	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes chemical reactions or metabolic pathways to break down into simpler compounds, releasing energy in the process.
Amino Acid Catabolism	Indicated by the given trigger <Trigger>, a specific amino acid <Theme> is broken down through metabolic pathways, leading to the release of energy and the generation of byproducts like ammonia and carbon compounds.
Glycolysis	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes a series of enzymatic reactions, ultimately converting glucose into pyruvate and producing ATP and NADH as energy carriers.

Table 17: Templates for Cancer Genetics Dataset.

Type	Template
Glycosylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes the addition of carbohydrate molecules (glycans) to specific sites, typically on proteins or lipids, leading to the formation of glycoproteins or glycolipids with diverse biological functions.
Acetylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes the addition of an acetyl group at a particular site <Site>, catalyzed by another molecule <Cause>.
Deacetylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has an acetyl group removed from a particular site <Site>, facilitated by another molecule <Cause>.
Ubiquitination	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is modified by the attachment of one or more ubiquitin molecules at a particular site, facilitated by another molecule <Cause>, often involving a simple chemical group <Site> as the site of attachment.
Deubiquitination	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has ubiquitin molecules removed from a particular site, facilitated by another molecule <Cause> involving a simple chemical group <Site> as the site of removal.
Gene Expression	Indicated by the given trigger <Trigger>, a specific gene, genome, or protein <Theme> is activated, leading to the production of RNA or protein and subsequent biological functions.
Transcription	Indicated by the given trigger <Trigger>, genetic information from a specific gene, genome, or RNA molecule <Theme> is used as a template to produce complementary RNA (usually messenger RNA) by RNA polymerase.
Translation	Indicated by the given trigger <Trigger>, the genetic information carried by messenger RNA <Theme> is used to synthesize a protein by ribosomes in the cell.
Protein Processing	Indicated by the given trigger <Trigger>, the series of post-translational modifications, folding, and transportation of a specific gene, genome, or protein <Theme> in the cell to achieve its mature and functional form.
Phosphorylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> undergoes the addition of a phosphate group at a particular site <Site> within a protein domain or region, often regulating the molecule's activity or function.
Dephosphorylation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> has a phosphate group removed from a particular site <Site> within a protein domain or region, often resulting in the modulation or termination of its activity or function.
DNA Methylation	Indicated by the given trigger <Trigger>, a specific gene or genome <Theme> has a methyl group added to a particular site <Site> within a protein domain or region, often resulting in the regulation of gene expression and epigenetic modifications.
DNA Demethylation	Indicated by the given trigger <Trigger>, a specific gene or genome <Theme> has a methyl group removed from a particular site <Site> within a protein domain or region, often resulting in the modulation of gene expression and epigenetic modifications.
Pathway	Indicated by the given trigger <Trigger>, involving a specific molecule <Participant> that collaborates to accomplish a specific biological function or response.
Binding	Indicated by the given trigger <Trigger>, a specific molecule <Theme> forms a physical association or interaction with another molecule or region <Site> on a protein or DNA, potentially leading to functional changes or regulatory effects.
Dissociation	Indicated by the given trigger <Trigger>, a specific molecule <Theme> separates or detaches from another molecule or region <Site> on a protein or DNA, leading to the termination or disruption of their interaction or complex formation.
Localization	Indicated by the given trigger <Trigger>, a specific molecule <Theme> is directed to or away from a particular cellular component <AtLoc><FromLoc><ToLoc> or subcellular location within the cell.
Regulation	Indicated by the given trigger <Trigger>, an entity <Theme> is controlled or influenced by another entity <Cause> to achieve a specific biological effect or outcome.
Positive Regulation	Indicated by the given trigger <Trigger>, an entity <Theme> is promoted or enhanced by another entity <Cause> to achieve a specific biological effect or outcome.
Negative Regulation	Indicated by the given trigger <Trigger>, an entity <Theme> is inhibited or suppressed by another entity <Cause> to achieve a specific biological effect or outcome.
Planned Process	Indicated by the given trigger <Trigger>, a specific entity <Theme> is involved or manipulated using an instrument <Instrument> for a predetermined outcome or purpose.

Abstract

The diffusion model, a new generative modeling paradigm, has achieved great success in image, audio, and video generation. However, considering the discrete categorical nature of the text, it is not trivial to extend continuous diffusion models to natural language. In this work, we propose SeqDiffuSeq, a text diffusion model, to approach sequence-to-sequence text generation with an encoder-decoder Transformer architecture. To improve the generation performance, SeqDiffuSeq is equipped with the self-conditioning technique and our newly proposed adaptive noise schedule technique. Self-conditioning enables SeqDiffuSeq to better use the predicted sequence information during the generation process. The adaptive noise schedule balances the difficulty of denoising across time steps at the token level. Experiment results illustrate the improved performance on five sequence-to-sequence generation tasks compared to other diffusion-based models regarding text quality and inference time.

1 Introduction

Generative modeling is drawing more attention in recent years of machine learning research due to the development of diffusion models (Ho et al., 2020). Diffusion models define the forward process and the reverse process where the former gradually diffuses data to random noise while the latter recovers data from random noise iteratively, which have shown superior performance on synthesizing images (Rombach et al., 2021), audios (Kong et al., 2020), and videos (Ho et al., 2022) over other generative methods, such as generative adversarial network (GAN) (Goodfellow et al., 2014) and normalizing flow (Kobyzev et al., 2021).

It is not trivial to extend diffusion models to the generation of natural languages. Most of the existing diffusion models are applied to continuous feature space (Ho et al., 2020; Nichol and Dhariwal, 2021) while texts are sequences of discrete categorical tokens. Recently, research has explored categorical diffusion models in discrete space for text generation (Hoogeboom et al., 2021; Austin et al., 2022). There also exists research such as DiffusionLM (Li et al., 2022) that applies continuous diffusion models to word embedding. However, these works only focus on unconditional and controlled text generation.

Sequence-to-sequence text generation is a fundamental natural language processing setting and covers various practical downstream tasks, such as dialogue (Ni et al., 2021) and machine translation (Liu et al., 2020). In recent practice, researchers resort to auto-regressive (AR) (Dai et al., 2019) or non-auto-regressive (NAR) (Gu et al., 2019) Transformers for the tasks, and achieve good generation performance. Using diffusion models, a recent work named DiffuSeq (Gong et al., 2022) applies the diffusion-based method for sequence-to-sequence text generation. They deploy encoder-only Transformers and partially define diffusion and denoising processes on output sequences.

In this work, we explore diffusion models with encoder-decoder Transformer architecture for sequence-to-sequence generation. We propose SeqDiffuSeq which extends the continuous diffusion framework proposed in DiffusionLM (Li et al., 2022) to sequence-to-sequence settings. We equip SeqDiffuSeq with the self-conditioning technique (Chen et al., 2022) and our newly proposed adaptive noise schedule. Self-conditioning helps the model better capture the information from former iterations during the generation. The proposed adaptive noise schedule learns a token-level noise schedule to better control the amount of noise injected and information recovered during the forward and reverse process (Nichol and Dhariwal, 2021).

We conduct experiments on five generation tasks. Results show that SeqDiffuSeq achieves compet-

[*] Work done at Alibaba DAMO Academy. Codes are released in https://github.com/Yuanhy1997/SeqDiffuSeq

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 22–39
June 16-21, 2024 ©2024 Association for Computational Linguistics

itive performance compared with AR and NAR baselines in terms of generation quality and diversity. SeqDiffuSeq also shows improved generation performance and inference speed compared to text diffison model DiffuSeq. Ablation studies demonstrate that our model can benefit from self-conditioning and adaptive noise schedule techniques, and both are complementary to each other in sequence-to-sequence settings.

To summarize, the main contributions of this work are as follows:

1. We propose SeqDiffuSeq that extends the continuous text diffusion model to sequence-to-sequence text generation with encoder-decoder Transformer architecture.

2. The self-conditioning and newly proposed adaptive noise schedule technique can effectively improve the generation quality of the text diffusion model.

3. Experiments show SeqDiffuSeq achieves promising performance with the previous diffusion-based method DiffuSeq as well as AR and NAR models on five generation tasks.

2 Related Work

Since the great success of diffusion models in vision (Ho et al., 2020; Rombach et al., 2021; Song et al., 2021b), researchers have explored extending diffusion models to text generation. Considering the discrete and categorical nature of texts, Multinomial Diffusion (Hoogeboom et al., 2021) and D3PM (Austin et al., 2021) are proposed for modeling categorical data. They define discrete diffusion models using discrete categorical transitions directly on texts. DiffusionBERT (He et al., 2022) follows D3PM and introduces pre-trained models for language modeling. Besides, recent research also explores converting texts into continuous features to adapt to diffusion models. Bit Diffusion (Chen et al., 2022) encodes discrete data as binary bits and treats these binary bits as real number features. Yu et al. (2022) is proposed to build text diffusion models in continuous latent space. DiffusionLM (Li et al., 2022) uses the word embedding space for continuous diffusion models and introduces auxiliary losses to enable joint learning of embedding and network parameters. Following DiffusionLM, recent research explores improving text generation quality (Strudel et al., 2022), and DiffuSeq (Gong et al., 2022) extends it to sequence-to-sequence settings. Compared to DiffuSeq, we propose a different model architecture and self-conditioning and adaptive noise schedule techniques to improve sequence-to-sequence generation performance.

Noise schedules in diffusion models control the level of noise injected and the level of information recovered in the forward and reverse process respectively. Previous research in vision and texts demonstrates that appropriate noise schedule design can improve the generation quality performance of diffusion models (Nichol and Dhariwal, 2021; Li et al., 2022). Concurrently, DiffusionBERT (He et al., 2022) proposes a spindle schedule for language modeling, and CDCD (Dieleman et al., 2022) designs a learned noise schedule for language modeling and machine translation. Different from both concurrent works, SeqDiffuSeq is proposed with a token-level noise schedule that balances the difficulty of denoising across time steps. Gao et al. (2023) proposes Differmer and is orthogonal to our work.

3 Preliminary

Diffusion model is generally formulated by a designed forward diffusion process and a learnt reverse denoising process. In the forward diffusion process, samples gradually mix with random noise, while in the reverse denoising process, the random noise is gradually denoised to generate synthetic samples. We adopt the forward and reverse processes proposed in DDPM (Ho et al., 2020).

For the forward process, given a sample z_0 from a real-world data distribution $q(z_0)$. At each time step $t \in \{1, 2, \cdots, T\}$, a noise sample z_t is sampled from $z_t \sim q(z_t|z_{t-1}) = \mathcal{N}(z_t; \sqrt{\alpha_t} z_{t-1}, (1-\alpha_t)I)$, where α_t control the noise added at time step t. In this regard, when T is large enough, a real-world sample will gradually and ultimately diffuse to a standard Gaussian noise distribution.

For the reverse process, the diffusion model uses a learnt parameterized denoising distribution $z_{t-1} \sim p_\theta(z_{t-1}|z_t)$ to gradually recover samples from noise. The denoising distribution is parameterized by θ and is to fit the posterior distribution $q(z_{t-1}|z_t, z_0)$ of the forward process.

$$q(z_{t-1}|z_t, z_0) = \mathcal{N}(z_{t-1}; \tilde{\mu}(z_0, z_t), \tilde{\beta}_t I). \quad (1)$$

In this equation,

$$\tilde{\mu}(z_0, z_t) = \frac{\sqrt{\bar{\alpha}_{t-1}}\beta_t}{1-\bar{\alpha}_t} z_0 + \frac{\sqrt{\alpha_t}(1-\bar{\alpha}_{t-1})}{1-\bar{\alpha}_t} z_t, \quad (2)$$

$$\bar{\alpha}_t = \prod_{s=1}^{t} \alpha_s, \quad \beta_t = 1-\alpha_t, \quad \tilde{\beta}_t = \frac{1-\bar{\alpha}_{t-1}}{1-\bar{\alpha}_t}\beta_t. \quad (3)$$

With learnt denoising distribution p_θ, a synthetic real-world sample z_0 can be generated from pure random noise z_T step-by-step.

4 Approach

In this section, we present the main design of our proposed SeqDiffuSeq for sequence-to-sequence language generation. The overview of SeqDiffuSeq is depicted in Figure 1. In the following sections, the input and output sequences are denoted as w_x and w_y respectively. For the i-th token in w_y, the token is denoted as w_y^i, where $0 < i \leq n$ and n represents the maximum output sequence word length. In order to avoid lengthy notations, we omit the indices referring to different data samples.

4.1 Diffusion Model

Forward Process To fit diffusion models to sequence-to-sequence settings, we extend the text diffusion model, DiffusionLM (Li et al., 2022).

In the sequence-to-sequence setting, the forward process gradually changes the target output sequence w_y to random noise. Diffusing w_y to pure random noise is independent of the input sequence w_x. For the sequence w_y, we use an embedding function g_ϕ to map the word tokens w_y^i to continuous word embedding $g_\phi(w_y^i) \in \mathbb{R}^d$, where d represents the dimension of embedding and ϕ represents the parameters of the word embedding function. The embedding for the sequence w_y is defined by stacking the tokens' embedding and is denoted as $g_\phi(w_y) \in \mathbb{R}^{n \times d}$. At the beginning of the forward process, a Markovian transition parameterized by $q_\phi(z_0|w_y) = \mathcal{N}(z_0; g_\phi(w_y), \beta_0 I)$ is added. Extended by $q_\phi(z_0|w_y)$, the forward process can continue to diffuse continuous features of z_0 iteratively. For each time step t, we apply the diffusion distribution $q(z_t|z_{t-1})$ to get noisier samples. Ultimately, the output sequence w_y becomes z_T which is nearly pure random noise following standard Gaussian distribution.

Reverse Process Diffusion models generate the synthetic samples by successively sampling the denoising distribution in the reverse process. For each time step t in the reverse process, a learnt denoising distribution p_θ parameterized by θ generates samples z_{t-1} conditioned on the former noisier samples z_t. In the sequence-to-sequence setting, the generated sequences correlate to input sequences. Therefore, the denoising distribution is additionally conditioned on the input sequence w_x, and $p_\theta = p_\theta(z_{t-1}|z_t, w_x)$. After the reverse denoising process reaches $T = 0$, we round each column of the generated $\hat{z}_0$ to its nearest word in the embedding space by the rounding distribution $\tilde{p}_\phi(w_y|\hat{z}_0)$ to generate the final word sequences.

Training Objective We optimize θ and embedding parameters by minimizing the variational bound of the data log-likelihood:

$$\begin{aligned}\mathcal{L}_{VB} = \mathbb{E}_{q_\phi(z_{0:T}, w_x, w_y)}[&\log \frac{q(z_T|z_0)}{p(z_T)} \\ &+ \sum_{t=2}^{T} \log \frac{q(z_{t-1}|z_0, z_t)}{p_\theta(z_{t-1}|z_t, w_x)} - \log p_\theta(z_0|z_1, w_x) \\ &+ \log q_\phi(z_0|w_y) - \log \tilde{p}_\phi(w_y|z_0)], \end{aligned} \quad (4)$$

The training objective is to narrow down the discrepancy between $p_\theta(z_{t-1}|z_t, w_x)$ and the posterior $q(z_{t-1}|z_t, z_0)$ in the forward process. Since $q(z_{t-1}|z_t, z_0)$ follows the form of Gaussian distribution, we parameterize the denoising distribution following Gaussian distribution family and $p_\theta(z_{t-1}|z_t, w_x) = \mathcal{N}(z_{t-1}; \tilde{\mu}_\theta(z_t, w_x, t), \tilde{\beta}_t I)$, where

$$\begin{aligned}&\tilde{\mu}_\theta(z_t, w_x, t) = \\ &\frac{\sqrt{\bar{\alpha}_{t-1}}\beta_t}{1-\bar{\alpha}_t} z_\theta^0(z_t, w_x, t) + \frac{\sqrt{\alpha_t}(1-\bar{\alpha}_{t-1})}{1-\bar{\alpha}_t} z_t. \end{aligned} \quad (5)$$

$z_\theta^0(z_t, w_x, t)$ is named the denoising function and predicts the estimated output embedding sequences at each reverse step t. Then according to density functions q and p_θ following Gaussian distribution, the objective can be further simplified as:

$$\begin{aligned}&\mathcal{L}_{simple} = \\ &\mathbb{E}_{q_\phi(z_0, w_x, w_y)}[\sum_{t=2}^{T} \mathbb{E}_{q(z_t|z_0)} \|z_\theta^0(z_t, w_x, t) - z_0\|^2 \\ &+ \|\tilde{\mu}(z_T, z_0)\|^2 + \|z_\theta^0(z_1, w_x, 1) - g_\phi(w_y)\|^2 \\ &- \log \tilde{p}_\phi(w_y|z_0)], \end{aligned} \quad (6)$$

where $q(z_t|z_0) = \mathcal{N}(z_t; \sqrt{\bar{\alpha}_t} z_0, (1-\bar{\alpha}_t) I)$ for efficient sampling of z_t during training, and $\mu_T(z_0) = \sqrt{\bar{\alpha}_T} z_0$. We leave the detailed derivation to Appendix B. The training objective becomes to fit

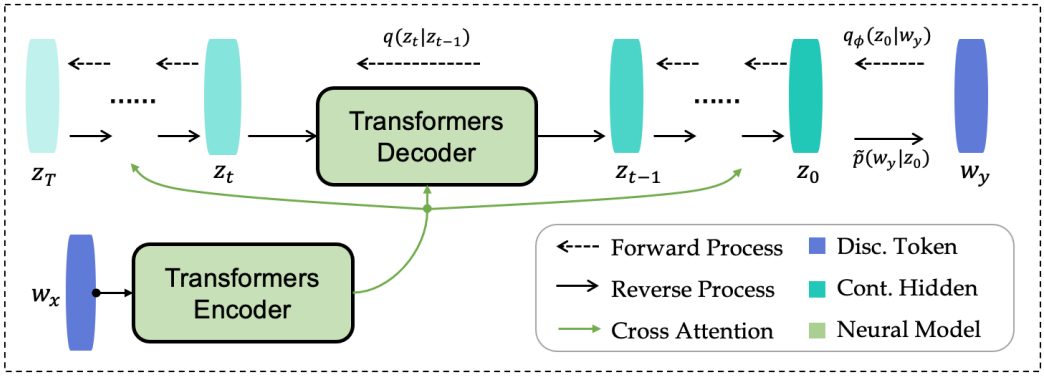

Figure 1: The overview of SeqDiffuSeq with an encoder-decoder Transformers architecture.

$g_\phi(w_y)$ and the denoising function $z_\theta^0(z_t, w_x, t)$, which we can model with encoder-decoder Transformers architectures. During training, the sampling distribution q_ϕ contains trainable parameters of word embedding. We can backpropagate through this with reparameterization trick (Kingma and Welling, 2013).

Denoising with Encoder-Decoder Framework Unlike DiffuSeq (Gong et al., 2022) using encoder-only Transformer architecture, we propose using an encoder-decoder Transformers architecture to model the input and output text sequences. For $z_\theta^0(z_t, w_x, t)$, we use the encoder to process the input sequences w_x and use the decoder to model the noisy output sequence z_t. Following the previous work (Li et al., 2022), we inject time step information t by adding time step embedding to z_t. Using the encoder-decoder architecture has computational convenience during generation because the input sequences w_x only require one forward computation through the encoder network during the whole reverse process. Considering the reverse process requires thousands of iterations to generate the output sequences of high quality, the saving of computational resources can be significant.

During training and generation, the function z_θ^0 generates denoised samples at the sequence level. Therefore making predictions from the denoising function z_θ^0 resembles the non-autoregressive natural language generation. In this regard, we use a decoder with full attention matrices instead of causal attention matrices to model z_t at the sequence level.

4.2 Self-Conditioning

At each time step t in the reverse process, the denoising function $z_\theta^0(z_t, w_x, t)$ makes output sequence predictions based on the noisier sample z_t. z_t is sampled from the former denoising distribution by mixing former sequence prediction $\hat{z}_0^t = z_\theta^0(z_{t+1}, w_x, t+1)$, z_{t+1} and random noise. In this regard, part of the information contained in the former prediction $\hat{z}_0^t$ is discarded. Bit-Diffusion (Chen et al., 2022) proposed the self-conditioning technique mitigating this waste of information by additionally taking former sequence predictions as inputs. The denoising function is formulated as $z_\theta^0(z_t, \hat{z}_0^t, w_x, t)$. Self-conditioning may enable the denoising function to refine the former sequence predictions rather than make new predictions from scratch. It is empirically verified that the self-conditioning technique can boost the performance of text diffusion models (Strudel et al., 2022).

To fit the technique into the Transformers modeling of z_θ^0 in our sequence-to-sequence setting, the sequence features $\hat{z}_0^t$ from the former predictions are concatenated with noisier sequence features z_t on the embedding dimension. Hence, the dimension of input features of Transformer decoder becomes $n \times 2d$. Since the former sequences at time step t are sampled successively from T to t which is computational-tedious during training, we take an efficient training scheme. With half probability, $z_\theta^0(z_t, \hat{z}_0^t, w_x, t)$ is trained by setting the input $\hat{z}_0^t$ to 0. Otherwise, $\hat{z}_0^t$ is first estimated by $z_\theta^0(z_t, 0, w_x, t)$ and then is used for self-conditioning training. Under the second circumstance, we do not backpropagate through the first forward propagate estimated $\hat{z}_0^t$.

4.3 Adaptive Noise Schedule

In the domain of vision and audio, the generated sample quality (Nichol and Dhariwal, 2021) and likelihood estimation (Kingma et al., 2021) may potentially benefit from different appropriate time schedules. Previous research uses different simple functions such as linear function (Ho et al., 2020)

or cosine function (Nichol and Dhariwal, 2021) of α against time step t to design noise schedules. Such designs may results in unbalanced denoising difficulties for each step and lead to unsatisfying generation quality. Some works proposed to alleviate this problem by importance sampling (Li et al., 2022) or loss reweighing (Gong et al., 2022).

We propose a novel adaptive noise schedule at the token-level. Firstly, we propose to adaptively adjust the time schedules during training to make the denoising difficulties of z_θ^0 predicting output sequence increase linearly with respect to the time step. Secondly, we separately set adaptive noise schedule for different token positions, unlike previous text diffusion research that only designs noise schedules on the whole sequence level. Since the intrinsic features for embedding sequences are different across token positions within, we assume that for different token positions the expected noise schedules are different.

Concretely, we measure the difficulties of denoising task at each time step t and token position i by the training losses $\mathcal{L}_t^i = \mathbb{E}_{q_\phi(w_x,w_y,z_t,z_0)}\|z_\theta^0(z_t,\hat{z}_0^t,w_x,t)^i - z_0^i\|^2$. We use the schedule of $\bar{\alpha}_t^i$ which ranges from 0 to 1 to access the noise schedule design. $\bar{\alpha}_t^i$ controls the noise level at each time step t. Our adaptive noise schedule for each token position i is to fit a mapping $\bar{\alpha}^i = M_i(\mathcal{L}^i)$ between $\mathcal{L}_t^i$ and $\bar{\alpha}_t^i$ by linear interpolation. For time step t, $\forall x \in [\mathcal{L}_{t-1}^i, \mathcal{L}_t^i)$,

$$M_i(x) = \frac{\bar{\alpha}_t^i - \bar{\alpha}_{t-1}^i}{\mathcal{L}_t^i - \mathcal{L}_{t-1}^i}(x - \mathcal{L}_{t-1}^i) + \bar{\alpha}_{t-1}^i, \quad (7)$$

After initializing a noise schedule, we record the loss $\mathcal{L}_t^i$[1]. The mapping M_i is fitted after each training period. Ideally, the training losses should be monotonic with respect to the time step t since for larger T the input features z_t to the denoising function are noisier. However, overall time step T is usually by thousands, hence this results in a fine-grained discretization of $\bar{\alpha}^i$. Due to the empirical loss estimation errors, training losses may not be monotonic between some successive time steps. To alleviate this issue and fit a smoother mapping M_i, we form a coarse-grained discretization s for $\bar{\alpha}^i$ and $\mathcal{L}^i$: $\mathcal{L}_s^i = \frac{1}{K}\sum_{t=s\times K}^{s\times(K+1)} \mathcal{L}_t^i$, $\bar{\alpha}_s^i = \frac{1}{K}\sum_{t=s\times K}^{s\times(M+1)} \bar{\alpha}_t^i$, $s = \lfloor \frac{t}{K} \rfloor$, where K is the stride to evenly downsample t and $\lfloor\cdot\rfloor$ rounds the number down to it nearest integer.

[1]We do not record the losses $\mathcal{L}_t^i$ for the padding tokens.

Algorithm 1 Adaptive Noise Schedule

Input: Current recorded losses $\mathcal{L}_t^i$ and noise schedules $\bar{\alpha}_t^i$ for each time step t and token position i

if Train Step % Update Step == 0 **then**
  for each token position i **do**
    Fit the mapping M_i by Equation 7,
    Take new $\mathcal{L}_t^{i,new}$ value with equal interval between $\min_t(\mathcal{L}_t^i)$ and $\max_t(\mathcal{L}_t^i)$,
    Get new schedule $\bar{\alpha}_t^{i,new} = M_i(\mathcal{L}_t^{i,new})$,
  end for
end if
return Noise schedule $\bar{\alpha}_t^{i,new}$ for each t and i

With the learnt linear interpolation mapping $\bar{\alpha}_s^i = M_i(\mathcal{L}_s^i)$, we can obtain the adjusted discretized noise schedule $\bar{\alpha}_t^{i,new}$ by $\bar{\alpha}_t^{i,new} = M_i(\mathcal{L}_t^{i,new})$ where $\mathcal{L}_t^{i,new}$'s are evenly taken between the minimum and maximum recorded values. As the training progresses, we adaptively calibrate the noise schedule $\bar{\alpha}^i$ by repeating the above-mentioned procedure once per training updates. The pseudo-code for setting adaptive noise schedules during training is shown in Algorithm 1.

5 Experiments

5.1 Datasets

We conduct experiments on six datasets across five different text generation tasks: Quora Question Pairs (QQP) (DataCanary et al., 2017) for Paraphrase Generation, Wiki-Auto (Jiang et al., 2020) for Text Simplification, Quasar-T (Dhingra et al., 2017) for Question Generation, Commonsense Conversation Dataset (CCD) (Zhou et al., 2018) for Dialogue Generation as well as the German(DE)-English(EN) pairs of IWSLT14 and WMT14 for Machine Translation. Detailed introductions and statistics of the datasets as shown in Appendix C.

5.2 Baselines

We consider three kinds of models as baselines. First, vanilla encoder-decoder Transformers and pre-trained GPT-2 are selected as strong AR baselines. Second, since SeqDiffuSeq denoises outputs at the sequence level, we compare it with an NAR baseline Levenshtein Transformer (LevT) (Gu et al., 2019). For machine translation, we also use CMLM (Ghazvininejad et al., 2019) which is an NAR translation method with iterative refinement as baselines. Besides, we compare it to other

Table 1: Main results on Paraphrase, Text Simplification, Question Generation, Dialogue, and Machine Translation. We use the results reported in the DiffuSeq paper for CCD results since reproducing CCD results requires more than 10 days of training on 8 NVIDIA A100 80GB GPUs.

diffusion-based methods. DiffuSeq (Gong et al., 2022) is a recently proposed text diffusion model using an encoder-only Transformer structure. We also compare with concurrently proposed CDCD (Dieleman et al., 2022) on machine translation.

5.3 Implementation Details

We use a 6 layers encoder-decoder Transformer (Vaswani et al., 2017) with GeLU activation (Hendrycks and Gimpel, 2016). For the diffusion process, we set the maximum diffusion step T to 2000, and use the *sqrt* schedule from DiffusionLM (Li et al., 2022) to initialize the adaptive time schedule. For translation tasks, we construct vocabulary using BPE (Sennrich et al., 2016). The vocabulary size is set to 10,000 for IWSLT14 and 32,768 for WMT14. For other tasks, we use the vocabulary of `bert-base-uncased` (Devlin et al., 2019).

For training of SeqDiffuSeq, we use a learning rate of 10^{-4} with 10,000 warm-up steps and a linearly-decreasing schedule. The proposed adaptive noise schedule is updated every 20,000 training steps and K is set to 20. We explore maximum Bayes risk (MBR) decoding (Koehn, 2004) following previous research (Li et al., 2022) for improving generation quality during inference. Details on experiment settings and MBR are in Appendix D.

5.4 Main Results

To assess the generation quality of each model, we use BLEU (Papineni et al., 2002) and BERTScore (Zhang et al., 2020) as metrics. We also use distinct uni-gram (dist.1) to measure the word diversity within generated sentences. A high dist.1 score indicates fewer repeated words. For machine translation tasks, we additionally consider SacreBLEU (Post, 2018). The results are listed in Table 1. To better present the generation performance, we provide human evaluation results in Appendix G.

Primarily, for text generation quality, our proposed SeqDiffuSeq achieves much better performance measured by BLEU than DiffuSeq and other baselines with single generation on QQP, Wiki-Auto, and Quasar-T. On Wiki-Auto and Quasar-T, SeqDiffuSeq even achieves better performance with single generation than recently proposed DiffuSeq with MBR of 10 candidates. When incorporating with MBR, SeqDiffuSeq enjoys a boost of performance and achieves superior results over all baselines on QQP, Wiki-Auto, and Quasar-T.

		IWSLT14 EN-DE S-BLEU	IWSLT14 DE-EN S-BLEU	Paraphrase QQP BLEU	Paraphrase QQP BERTSco.	Text Simplification Wiki-Auto BLEU	Text Simplification Wiki-Auto BERTSco.	Avg. ΔBLEU
SeqDiffuSeq	$\mathcal{A}$	21.96	30.16	23.28	83.91	37.09	82.11	-
$\mathcal{A}$ w/o Apt. Sche.	$\mathcal{B}$	19.89	28.60	21.82	81.78	33.04	79.74	-2.29
$\mathcal{A}$ w/o Self-Cond.	$\mathcal{C}$	20.76	28.28	21.64	81.45	36.46	81.62	-1.34
$\mathcal{C}$ w/o Apt. Sche.	$\mathcal{D}$	17.50	24.39	19.73	79.95	28.03	76.06	-5.71

Table 2: Ablation studies on IWSLT14, QQP and Wiki-Auto. S-BLEU represents Sacre-BLEU. BERTSco. represents BERTScore. Self-Cond. and Apt. Sche. are short for self-conditioning and adaptive noise schedule.

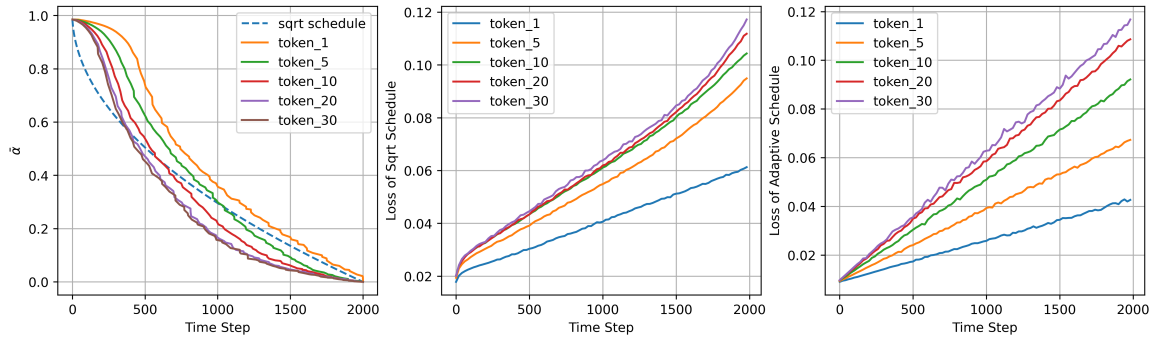

Figure 2: The left figure depicts the adaptive noise schedule at different token positions on IWSLT14 DE-EN dataset. The middle and right figures show the loss for each time step at different token positions with and without adaptive noise schedule, respectively. Best viewed in color.

The performance is better than the pre-trained then fine-tuned GPT-2 with more parameters on Wiki-Auto and QQP. This indicates that SeqDiffuSeq can generate texts with good quality for sequence-to-sequence tasks (except CCD that all models have inferior performance). On translation tasks, the performance lags behind the AR Transformers baseline consistently across different datasets, while compared with NAR methods, SeqDiffuSeq consistently surpasses CMLM with 1 refinement iteration by 6.32 and 6.75 averaged points across four datasets without and with MBR. CMLM with 4 iterations has better performance. When comparing with CDCD, the performance with and without MBR are competitive on WMT14 EN-DE while the performance is worse on DE-EN. For diversity within sequences, texts generated by SeqDiffuSeq have fewer repeated words averagely than Transformers and DiffuSeq.

6 Analysis and Discussion

6.1 Ablation Study

To verify the effectiveness of the proposed techniques in SeqDiffuSeq, we conduct ablation studies on QQP, Wiki-Auto, and IWSLT14. As shown in Table 2, after removing the adaptive noise schedule from SeqDiffuSeq and instead using the fixed *sqrt* schedule proposed in DiffusionLM ($\mathcal{B}$), the performance drops consistently and the BLEU scores decrease by 2.29 on average. Without self-conditioning ($\mathcal{C}$), the performance also degrades by 1.34 on average. By further removing adaptive noise schedule ($\mathcal{D}$), the performance drops sharply by 5.71 on average and the largest drop in terms of BLEU is 8.43 on Wiki-Auto. Comparing adaptive noise schedule and self-conditioning technique, it is illustrated that our proposed adaptive noise schedule brings larger improvement and two techniques are complementary to each other.

6.2 Time Schedule

It is verified in the ablation study that the proposed adaptive noise schedule can improve sequence-to-sequence text generation. On the IWSLT14 DE-EN dataset, we visualize the adaptive noise schedules as well as the loss at each time step with and without adaptive noise schedule. For the adaptive noise schedule, we plot $\bar{\alpha}_t^i$ at different token positions i against the diffusion time step t. And for losses, we plot averaged training losses $\mathcal{L}_t^i$ at each position i against time step t. Depicted in Figure 2, the dashed line in the first sub-figure shows the *sqrt* schedule, while the other lines represent the noise schedules at different token positions. The figure shows that the adaptive noise schedules deviate from the *sqrt* schedule. At both ends of time steps, the adaptive noise schedules are flatter compared

	Time	Acceleration
DiffuSeq	317 sec.	-
SeqDiffuSeq	89 sec.	×3.56

Table 3: Inference time on QQP on one NVIDIA V100 GPU. The inference batch size is set to 50 and the overall time step is set to 2000 for both models.

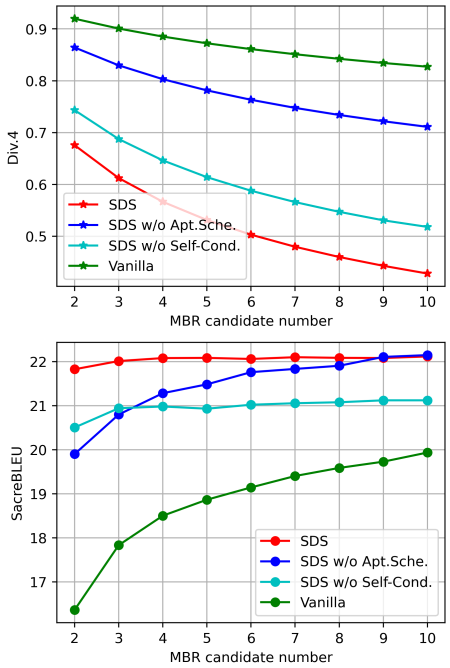

Figure 3: The top figure plots the sequence-level Div.4 score against different MBR candidate numbers on IWSLT14 EN-DE. The bottom figure plots SacreBLEU against different MBR candidate numbers. SDS represents SeqDiffuSeq. Best viewed in color.

to *sqrt* schedule, especially for tokens at larger position orders. Besides, adaptive noise schedules are diverse for different positions, although the trends along time steps are similar. For the token positions at larger orders, the noise schedule lines move toward the lower-left direction. Therefore, at each time step, the tokens at earlier positions have smaller noise than later positions. The information of tokens on the left is recovered earlier at each step. SeqDiffuSeq resembles the left-to-right generation of texts. Through a case study in Appendix H, the phenomenon is also verified.

Comparing the second and third sub-figures, the losses $\mathcal{L}^i$ with adaptive noise schedule increase linearly with respect to time steps as expected. At each time step, the losses at earlier token positions are smaller, indicating earlier tokens are easier to generate for SeqDiffuSeq . More visualizations on other datasets are listed in Appendix F.

6.3 Inference Speed

We compare SeqDiffuSeq with DiffuSeq in terms of inference time in Table 3. Our SeqDiffuSeq achieves 3.56 times acceleration generating one batch of text samples. The acceleration mainly originated from: (1) SeqDiffuSeq only requires forward computation of encoder once, while DiffuSeq needs to run forward computation for the input sequences for each diffusion step; (2) At each time step, SeqDiffuSeq only models the output sequence, while DiffuSeq has to model the concatenation of both input and output sequences.

6.4 MBR Inference

It is shown in Table 1 that MBR with 10 candidates improves DiffuSeq to more than 6 BLEU score, while improves SeqDiffuSeq by 1.06 BLEU score on QQP. In Figure 3, we plot SacreBLEU scores and Diverse 4-gram (Div.4) scores (Deshpande et al., 2018) against MBR candidate numbers. Div.4 measures the proportion of distinct 4-grams in a set of generated sequences. A higher Div.4 score means better sequence-level diversity by different generation runs. The figure shows that the self-conditioning technique and adaptive noise schedule make the text diffusion model generate less diverse sequences, and the single generated sequence will have higher quality with both techniques. Self-conditioning technique and adaptive noise schedule deliver a trade-off between generation quality and generation diversity. With both techniques, MBR inference is needless to generate high-quality samples for SeqDiffuSeq resulting in a more efficient generation procedure. We also propose a new sampling scheme to compensate the marginal MBR improvements for SeqDiffuSeq which is discussed in detail in Appendix E.

7 Conclusion

In this work, we explore to approach sequence-to-sequence text generation with continuous diffusion models. We propose SeqDiffuSeq which uses an encoder-decoder Transformers architecture to learn the denoising function. In order to improve text generation performance, the denoising function in SeqDiffuSeq is integrated with self-conditioning technique. SeqDiffuSeq also includes a newly proposed adaptive noise schedule which makes the denoising difficulty evenly distributed across all time steps and assigns exclusive noise schedules for tokens from different positional orders. Through

experiments, we illustrate the superior performance of SeqDiffuSeq in terms of generation quality and inference speed and provide insights into our proposed adaptive noise schedule technique.

Limitation

Diffusion models generate high-quality synthetic samples through thousands of iterations in the reverse process. Thousands of reverse process iterations require a huge amount of forward propagation computation of Transformers model which is computationally costly, although we save nearly four times of computational budget for one forward computation compared to the previous diffusion-based model DiffuSeq. In the domain of vision synthetic, there exists research to profoundly reduce the time step needed for generation (Song et al., 2021a). Reducing the reverse steps for text generation would be a promising direction for future research.

As shown in the discussion, equipping text diffusion models with self-conditioning and adaptive noise schedules can profoundly increase the generation quality. However, such quality improvement is at the cost of generation diversity under different random seeds. This leads to marginal MBR inference improvements. Although we propose a compensation discussed in Appendix E. The in-depth discussion on improving SeqDiffuSeq generation diversity is left to future research.

Ethic Statements and Boarder Impact

The datasets and baseline models used in our research are publicly available. Diffusion models, previously successful in vision, face challenges in NLP due to discrete token sequences. Promising results have been shown in DiffusionLM (Li et al., 2022) and DiffuSeq (Gong et al., 2022), but both works use encoder-only models and have limitations in scalability and efficiency. This research explores and improves the diffusion-based sequence-to-sequence text generation models. Our work alters to encoder-decoder Transformers which are widely applied in recent LLMs such as FLAN-T5 (Chung et al., 2022) for better scalability, potential, and sampling speed acceleration (Section 6.3). Our work also incorporates novel techniques like self-conditioning and adaptive noise schedules, outperforming several AR and NAR baselines. SeqDiffuSeq demonstrates the feasibility of encoder-decoder diffusion models for sequence-to-sequence tasks and may serve as a starting point for future exploration of text diffusion models' potential, serving as another method approaching sequence-to-sequence text generation besides widely implemented AR and NAR models. Considering the excellent performance of diffusion models in other domains such as vision, text diffusion models have great potential in generating text sequences with high quality and may be an emerging framework of text generation.

A Derivation of Posterior

Given $z_t \sim q(z_t|z_{t-1}) = \mathcal{N}(z_t; \sqrt{\alpha_t}z_{t-1}, (1-\alpha_t)I)$, we can reparameterize $z_t = \sqrt{\alpha_t}z_{t-1} + \sqrt{1-\alpha_t}\epsilon_t$. Then, recursively,

$$\begin{aligned} & z_t \\ &= \sqrt{\alpha_t}(\sqrt{\alpha_{t-1}}z_{t-2} + \sqrt{1-\alpha_{t-1}}\epsilon_{t-1}) + \sqrt{1-\alpha_t}\epsilon_t \\ &= \sqrt{\bar{\alpha}_t}z_0 + \sqrt{1-\bar{\alpha}_t}\epsilon_t \\ &\sim \mathcal{N}(z_t; \sqrt{\bar{\alpha}_t}z_0, (1-\bar{\alpha}_t)I). \end{aligned} \tag{8}$$

Therefore, $q(z_t|z_0) = \mathcal{N}(z_t; \sqrt{\bar{\alpha}_t}z_0, (1-\bar{\alpha}_t)I)$. According to Bayes rule, we have:

$$q(z_{t-1}|z_t, z_0) = \frac{q(z_t|z_{t-1})q(z_{t-1}|z_0)}{q(z_t|z_0)}, \tag{9}$$

since $q(z_t|z_{t-1})$ and $q(z_{t-1}|z_0)$ are all Gaussian distributed, we will have:

$$q(z_{t-1}|z_t, z_0) = \mathcal{N}(z_{t-1}; \tilde{\mu}(z_0, z_t), \tilde{\beta}_t I), \tag{10}$$

where

$$\tilde{\mu}(z_0, z_t) = \frac{\sqrt{\bar{\alpha}_{t-1}}\beta_t}{1-\bar{\alpha}_t}z_0 + \frac{\sqrt{\alpha_t}(1-\bar{\alpha}_{t-1})}{1-\bar{\alpha}_t}z_t, \tag{11}$$

$$\bar{\alpha}_t = \prod_{s=1}^{t}\alpha_s, \quad \beta_t = 1-\alpha_t, \quad \tilde{\beta}_t = \frac{1-\bar{\alpha}_{t-1}}{1-\bar{\alpha}_t}\beta_t. \tag{12}$$

B Derivation of Training Objective

We present the detailed derivation of training objective following Ho et al. (2020); Li et al. (2022). As mentioned in main texts, the forward process successively perturbs the real-world sample z_0 with random noise, where z_0 gradually changes to z_T for a T-time step diffusion process. z_T can be approximately regarded as pure random noise which follows standard Gaussian distribution in our case. We define the forward process as follows:

$$q(z_t|z_{t-1}) = \mathcal{N}(z_t; \sqrt{\alpha_t}z_{t-1}, (1-\alpha_t)I), \tag{13}$$

where α_t controls the noise level at each time step t.

For the reverse process, we learn a parameterized denoising distribution $p_\theta(z_{t-1}|z_t, w_x, t)$. By successively sampling from p_θ, a synthetic real-world sample z_0 can be recovered from pure random noise z_T.

The training objective of diffusion model is to minimize the negative likelihood of data distribtuion, which is:

$$\tilde{\mathcal{L}} = \mathbb{E}[-\log p_\theta(z_0)], \tag{14}$$

then with the forward and revser process defined as above, we can derive the variational bound for the objective $\tilde{\mathcal{L}}$:

$$\begin{aligned} \tilde{\mathcal{L}} =& \mathbb{E}_{q(z_0)}[-\log p_\theta(z_0)] \\ \leq& \mathbb{E}_{q(z_{0:T})}\left[-\log\frac{p_\theta(z_{0:T})}{q(z_{1:T}|z_0)}\right] \\ =& \mathbb{E}_{q(z_{0:T})}\left[-\log p(z_T) - \sum_{t\geq 1}\log\frac{p_\theta(z_{t-1}|z_t)}{q(z_t|z_{t-1})}\right] \\ =& \mathbb{E}_{q(z_{0:T})}\Bigg[-\log p(z_T) - \sum_{t>1}\log\frac{p_\theta(z_{t-1}|z_t)}{q(z_t|z_{t-1})} \\ & - \log\frac{p_\theta(z_0|z_1)}{q(z_1|z_0)}\Bigg]. \end{aligned} \tag{15}$$

In our sequence-to-sequence settings, following the notations in Section 4, we let the denoising distribution p_θ condition on the input sequence w_x, which is $p_\theta(z_{t-1}|z_t, w_x)$. Besides, with the Markov transition extensions of embedding mapping transition $q_\phi(z_0|w_y)$ in the forward process and rounding transition $\tilde{p}_\phi(w_y|z_0)$ in the reverse process, the objective in Equation 15 can be extended as:

$$\begin{aligned} \mathcal{L} =& \mathbb{E}_{q_\phi(z_{0:T}, w_x, w_y)}\Bigg[-\log p(z_T) \\ & - \sum_{t>1}\log\frac{p_\theta(z_{t-1}|z_t, w_x)}{q(z_t|z_{t-1})} \\ & - \log\frac{p_\theta(z_0|z_1, w_x)}{q(z_1|z_0)} \\ & - \log\tilde{p}_\phi(w_y|z_0) + \log q_\phi(z_0|w_y)\Bigg]. \end{aligned} \tag{16}$$

By Bayes rule, we can derive the posterior distribution of q with respect to z_{t-1}:

$$q(z_{t-1}|z_t, z_0) = \frac{q(z_t|z_{t-1}, z_0)q(z_{t-1}|z_0)}{q(z_t|z_0)}, \tag{17}$$

then, we have:

$$q(z_t|z_{t-1}) = \frac{q(z_{t-1}|z_t, z_0)q(z_t|z_0)}{q(z_{t-1}|z_0)}. \tag{18}$$

We substitute $q(z_t|z_{t-1}), \forall t > 1$ in Equation 16 with Equation 18:

$$\begin{aligned} \mathcal{L}_{VB} =& \mathbb{E}_{q_\phi}\Bigg[-\log\frac{p(z_T)}{q(z_T|z_0)} \\ & - \sum_{t>1}\log\frac{p_\theta(z_{t-1}|z_t, w_x)}{q(z_{t-1}|z_t, z_0)} \\ & - \log p_\theta(z_0|z_1, w_x) \\ & - \log\tilde{p}_\phi(w_y|z_0) + \log q_\phi(z_0|w_y)\Bigg] \end{aligned} \tag{19}$$

For the time step $t, t > 1$, the terms $-\mathbb{E}_{q_\phi}\left[\log \frac{p_\theta(z_{t-1}|z_t)}{q(z_{t-1}|z_t,z_0)}\right]$ between two Gaussian distributions has a closed form solution, following Li et al. (2022); Ho et al. (2020), we have:

$$\begin{aligned}
&-\mathbb{E}_{q_\phi}\left[\log \frac{p_\theta(z_{t-1}|z_t)}{q(z_{t-1}|z_t,z_0)}\right] \\
=&\mathbb{E}_{q_\phi}\left[\left\|\frac{1}{2\sigma_t^2}\left(\tilde{\mu}_\theta(z_t,w_x,t)-\tilde{\mu}(z_0,z_t)\right)\right\|^2\right]+C \\
\propto&\mathbb{E}_{q_\phi}\left[\left\|\tilde{\mu}_\theta(z_t,w_x,t)-\tilde{\mu}(z_0,z_t)\right\|^2\right], \qquad (20)
\end{aligned}$$

where C is a constant and $\sigma_t^2=\tilde{\beta}_t$, then substituting $\tilde{\mu}$ and $\tilde{\mu}_\theta$ by Equation 2 and 5, we have:

$$\begin{aligned}
&\left\|\tilde{\mu}_\theta(z_t,w_x,t)-\tilde{\mu}(z_0,z_t)\right\|^2 \\
=&\frac{\sqrt{\bar{\alpha}_{t-1}}\beta_t}{1-\bar{\alpha}_t}\left\|z_\theta^0(z_t,w_x,t)-z_0\right\|^2 \\
\propto&\left\|z_\theta^0(z_t,w_x,t)-z_0\right\|^2. \qquad (21)
\end{aligned}$$

After omitting $\frac{1}{2\sigma_t^2}$ and $\frac{\sqrt{\bar{\alpha}_{t-1}}\beta_t}{1-\bar{\alpha}_t}$ for any $t>2$, and substituting terms $-\mathbb{E}_{q_\phi}\left[\log \frac{p_\theta(z_{t-1}|z_t)}{q(z_{t-1}|z_t,z_0)}\right]$ in Equation 19 with Equation 20, 21, we have the simplified loss function:

$$\begin{aligned}
\tilde{\mathcal{L}}_{simple}=&\mathbb{E}_{q_\phi}\Bigg[-\log\frac{p(z_T)}{q(z_T|z_0)} \\
&+\sum_{t>1}\left\|z_\theta^0(z_t,w_x,t)-z_0\right\|^2 \\
&-\log\frac{p_\theta(z_0|z_1,w_x)}{q_\phi(z_0|w_y)} \\
&-\log\tilde{p}_\phi(w_y|z_0)\Bigg]. \qquad (22)
\end{aligned}$$

We can further substituting terms $-\mathbb{E}_{q_\phi}\left[\log \frac{p(z_T)}{q(z_T|z_0)}\right]$ and $-\mathbb{E}_{q_\phi}\left[\log \frac{p_\theta(z_0|z_1,w_x)}{q_\phi(z_0|w_y)}\right]$ similarly with:

$$-\mathbb{E}_{q_\phi}\left[\log\frac{p(z_T)}{q(z_T|z_0)}\right]\propto\mathbb{E}_{q_\phi}\left[\left\|\tilde{\mu}(z_T,z_0)\right\|^2\right], \qquad (23)$$

$$\begin{aligned}
&-\mathbb{E}_{q_\phi}\left[\log\frac{p_\theta(z_0|z_1,w_x)}{q_\phi(z_0|w_y)}\right] \\
\propto&\,\mathbb{E}_{q_\phi}\left[\left\|z_\theta^0(z_1,w_x,1)-g_\phi(w_y)\right\|\right]^2. \qquad (24)
\end{aligned}$$

Therefore we can derive $\mathcal{L}_{simple}$ in Equation 6 by subsitituting terms in $\tilde{\mathcal{L}}_{simple}$ with Equation 23 and 24:

$$\begin{aligned}
&\mathcal{L}_{simple} \\
&=\mathbb{E}_{q_\phi}\Bigg[\sum_{t>1}\left\|z_\theta^0(z_t,w_x,t)-z_0\right\|^2 \\
&\quad+\left\|\tilde{\mu}(z_T,z_0)\right\|^2+\left\|z_\theta^0(z_1,w_x,1)-g_\phi(w_y)\right\|^2 \\
&\quad-\log\tilde{p}_\phi(w_y|z_0)\Bigg] \qquad (25) \\
&=\mathbb{E}_{q_\phi(z_0,w_x,w_y)}\Bigg[\sum_{t=2}^{T}\mathbb{E}_{q(z_t|z_0)}\left\|z_\theta^0(z_t,w_x,t)-z_0\right\|^2 \\
&\quad+\left\|\tilde{\mu}(z_T,z_0)\right\|^2+\left\|z_\theta^0(z_1,w_x,1)-g_\phi(w_y)\right\|^2 \\
&\quad-\log\tilde{p}_\phi(w_y|z_0)\Bigg]. \qquad (26)
\end{aligned}$$

C Datasets

We conduct experiments on following datasets. The data statistics and licenses are shown in Table 4 and 5.

Quora Question Pairs (QQP) (DataCanary et al., 2017) is a paraphrase identification dataset. We use the positive pairs as the paraphrase generation task. The models need to generate a restatement expressing the same meaning to the given sentence.

Wiki-Auto (Jiang et al., 2020) is a text simplification dataset to revise a complex text with simplified grammar and word choices. The dataset aligns sentences between English Wikipedia and Simple English Wikipedia with automatic pre-processing and identifying procedure.

Quasar-T (Dhingra et al., 2017) is a question-answering dataset containing trivia questions paired with answers and contexts. We use the dataset for evaluating question generation which aims to generate related questions with given contexts. We use the pre-processed data from Lin et al. (2018) following Gong et al. (2022).

Commonsense Conversation Dataset (CCD) (Zhou et al., 2018) is extracted from single-round dialogues on Reddit and is used for evaluating open domain dialogue generation. The task requires generating feedback with commensense knowledge given the dialogue contexts.

IWSLT14 and **WMT14** are both widely used benchmarks for machine translation. We use the German(DE)-English(EN) pairs for both directions of translation. We follow fairseq (Ott et al., 2019) for data pre-processing using Moses script (Koehn et al., 2007) and tokenizing the sentences with byte-pair encoding (BPE) (Sennrich et al., 2016).

Dataset	Train size	Dev size	Test Size
QQP	144,715	2,048	2,500
Quasar-T	116,953	2,048	10,000
Wiki-Auto	677,751	2,048	5,000
CCD	3,382,137	2,048	10,000
IWSLT14	160,239	7,283	6,750
WMT14	4,475,414	45,206	3,003

D Implementation Details

D.1 Details on Experiment Setting

Here we give details for the implementation details of our experiments. For the Transformers structure and model training, we list detailed design in Table 6. For all the tasks, the set the maximum training step to 1000,000 and save checkpoints every 10,000 steps. We select the best checkpoint on the development set. For WMT14 task, we use batch size 1024 while for other tasks we use batch size 128. For training on each datasets, we train for one run on NVIDIA A100 GPUs with 80GB memory. For inference, we set the maximum time step to $T = 2000$, and we do not use the clamping trick as proposed in DiffusionLM (Li et al., 2022), since the clamping trick does not consistently improve the generation quality across datasets.

D.2 Details on MBR

Following DiffusionLM (Li et al., 2022), we apply Minimum Bayes Risk (MBR) decoding for one single generation output with improved quality. For each sample, MBR decoding uses a generated sequences candidate set $\mathcal{C}$ and finds the candidate sequence s^* that minimize a expected risk R:

$$s^* = \arg\min_{s\in\mathcal{C}} R(s) = \arg\min_{s\in\mathcal{C}} \frac{1}{|\mathcal{C}|}\sum_{s'\in\mathcal{C}} r(s,s'), \tag{27}$$

where $r(\cdot,\cdot)$ is a specific risk function and we use the negative BLEU score following DiffusionLM and sequence candidates in the candidate set $\mathcal{C}$ are generated from the diffusion models under different random seeds.

E Sampling by Prior

Since at each time step t, the Transformers denoising function z_θ^0 models the prediction $\hat{z}_0^t$ of target output sequences. In the reverse process, sampling z_{t-1} is according to the denoising distribution p_θ as:

$$p_\theta(z_{t-1}|z_t, w_x) = \mathcal{N}(z_{t-1}; \tilde{\mu}_\theta(z_t, w_x, t), \tilde{\beta}_t I). \tag{28}$$

However, we can also use the prior distribution q in the forward process to generate z_{t-1}, which is:

$$\begin{aligned} z_{t-1} \sim & q(z_{t-1}|\hat{z}_0^t) \\ = & \mathcal{N}(z_{t-1}; \sqrt{\bar{\alpha}_{t-1}}\hat{z}_0^t, (1-\bar{\alpha}_{t-1})I). \end{aligned} \tag{29}$$

Comparing to generation by Equation 28, using Equation 29 theoretically have larger variance.

$$1 - \bar{\alpha}_{t-1} \geq \tilde{\beta}_t = \frac{1-\bar{\alpha}_{t-1}}{1-\bar{\alpha}_t}\beta_t, \tag{30}$$

because $\frac{\beta_t}{1-\bar{\alpha}_t} = \frac{1-\alpha_t}{1-\bar{\alpha}_t} \leq 1$ where $\alpha_t < 1, \forall t$ and $\bar{\alpha}_t = \prod_{s=1}^{t} \alpha_s$.

To increase the sequence level diversity, we experiment with randomly replacing the denoising distribution p_θ by high variance distribution in Equation 29 in the reverse process during generation. We denote the replacing probability as p_1.

Besides, considering the variance difference between the two sampling distribution are larger at

Tasks	Translation	Non-Translation
Encoder Layer	6	6
Decoder Layer	6	6
Head Number	8	12
Hidden Dimension	512	768
FFN Dimension	2048	3072
Embedding Dimension	128	128
Max. Input Length	128	128
Max. Output Length	64	64
Dropout	0.3	0.1

Table 6: Translation represents the machine translation tasks on IWLST14 and WMT14. Non-Translation represents the Paraphase, Text Simplification, Queation Generation and Dialogue tasks on QQP, Wiki-Auto, Quasar-T and CCD respectively.

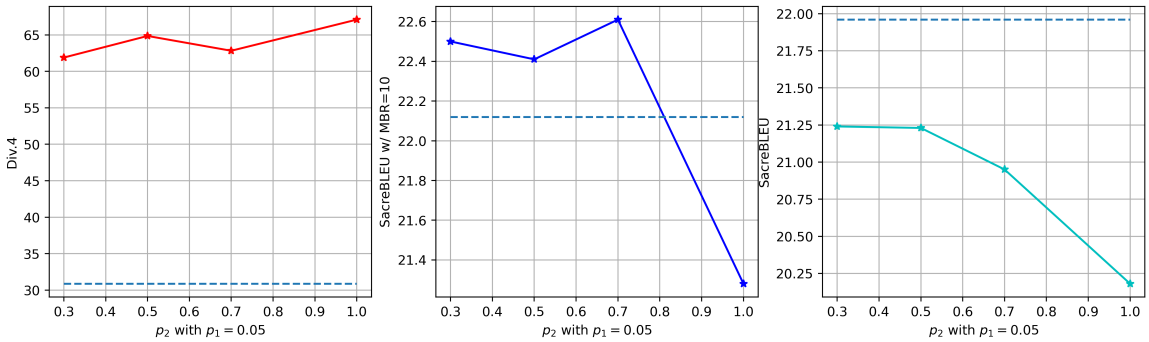

Figure 4: The figures from left to right plot the diversity, SacreBLUE with MBR=10 and SacreBLEU for single candidates against p_2 on IWSLT14 EN-DE dataset with $p_1 = 0.05$ fixed, repectively. The dashed lines in each figure represents the default generation results of SeqDiffuSeq.

earlier time step in the reverse process, we also explore to only replace the sampling distribution in the first p_2 percent of time steps. We generate 10 candidate output sentences for each sample under different random seeds to compute Div.4 and SacreBLEU scores.

As shown in the left subfigure of Figure 4, when fixing the replacing probability to 0.05, the generation diversity are consistently and profoundly improved. In the right subfigure, the generation quality consistently degrades when replacing the denoising distribution when generation, even though the replacing probability is low. In the middle subfigure, we can see that although the generation quality degrades for each candidate, the final output sequences by MBR may improve with proper p_2. In Figure 5, we can get similar results when fixing $p_2 = 0.5$. In the middle subfigure of Figure 5, the final output sequences are consistently better with different p_1.

To conclude, it is shown that replacing the sampling distribution from the denoising distribution p_θ to the prior distribution q can provide a trade-off between the generation diversity and generation quality. With a proper combination of p_1 and p_2, the generation quality of SeqDiffuSeq with the aid of MBR can be further improved. The benefits of sampling with the prior distribution q are always neglected in previous research.

F More Results on Adaptive Noise Schedule

We present more visualizations of the learned adaptive noise schedules and the losses for each time step on other datasets. Figure 6, 7 and 8 present the visualizations on IWSLT14 EN-DE, QQP, and Wiki-Auto respectively with the same arrangement as Figure 2. The results from the figures are consistent with those discussed in the main texts.

G Human Evaluation

To better demonstrate the performance of the proposed SeqDiffuSeq , we conduct human evaluations to compare the generated results of SeqDiffuSeq to those of DiffuSeq on the paraphrasing task QQP dataset. We randomly sample 100 data points in the test sets and let annotators decide for the same input sequence, which generated text sequence is better, worse, or of similar quality. We compare SeqDiffuSeq with the previous state-of-

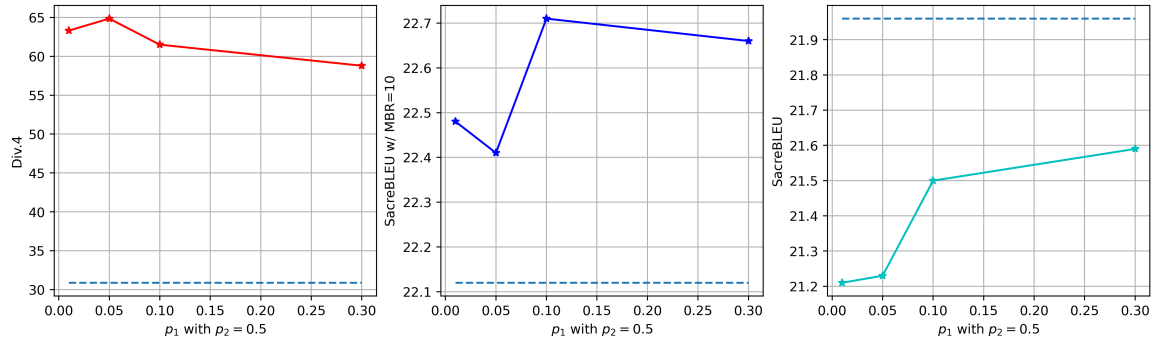

Figure 5: The figures from left to right plot the diversity, SacreBLUE with MBR=10 and SacreBLEU for single candidates against p_1 on IWSLT14 EN-DE dataset with $p_2 = 0.5$ fixed, repectively. The dashed lines in each figure represents the default generation results of SeqDiffuSeq.

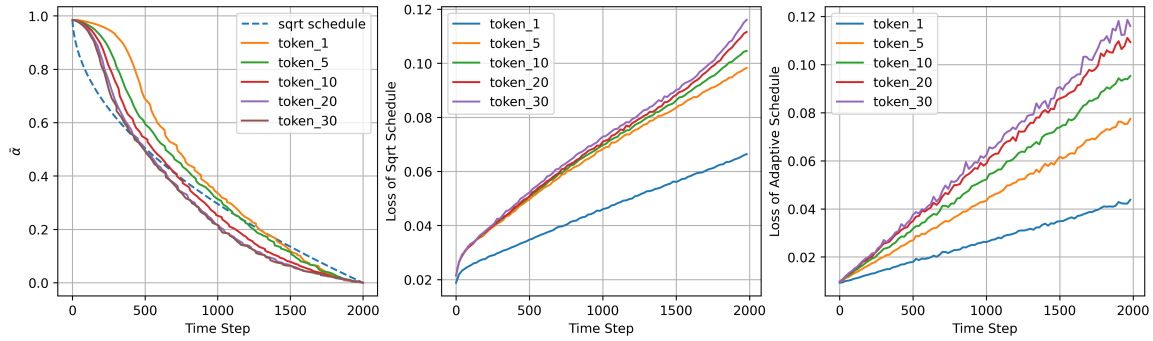

Figure 6: The left figure depicts the adaptive noise schedule at different token positions on IWSLT14 EN-DE dataset. The middle figure shows the loss for each time step at different token positions without the adaptive noise schedule. The right figure shows the loss for each time step at different token positions with the adaptive noise schedule. Best viewed in color.

the-art text diffusion model DiffuSeq. For fairness, the human evaluations are designed to be blind evaluations (i.e., the annotators are unaware of which model the output sequence is related to).

The human annotators are graduate university students who are proficient in English and are asked to compare the generated sequences based on the following instruction. *Decide which generated output sequence is better based on whether the one is more consistent with the input question, whether the one has higher grammatical and syntactic quality.* Figure 9 shows the human evaluation results.

The results show that both annotators prefer the generated output sequences by SeqDiffuSeq more. Generated output sequences on QQP from SeqDiffuSeq win by 36% and 44% from two annotators, while those from DiffuSeq only win by 24% and 30% respectively. Human evaluation results show that SeqDiffuSeq can generate text sequences of higher quality than DiffuSeq.

H Case Study

We select three illustrative cases and investigate the generation process of SeqDiffuSeq. From the cases, it shows that SeqDiffuSeq can generate reasonable text sequences. The generation process reveals that

1. SeqDiffuSeq decides the output sequence length by generating [SEP] tokens at the early stage of sampling;

2. The generation process seems to follow a left-to-right refining order;

3. The position of [SEP] token will not change during sampling, even though there exists token repetition in the generated sequences as shown in red.

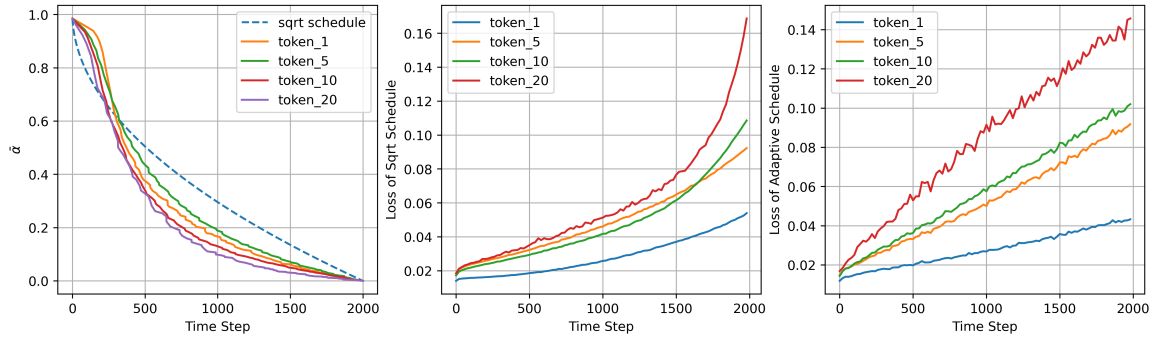

Figure 7: The left figure depicts the adaptive noise schedule at different token positions on QQP dataset. The middle figure shows the loss for each time step at different token positions without the adaptive noise schedule. The right figure shows the loss for each time step at different token positions with the adaptive noise schedule. Best viewed in color.

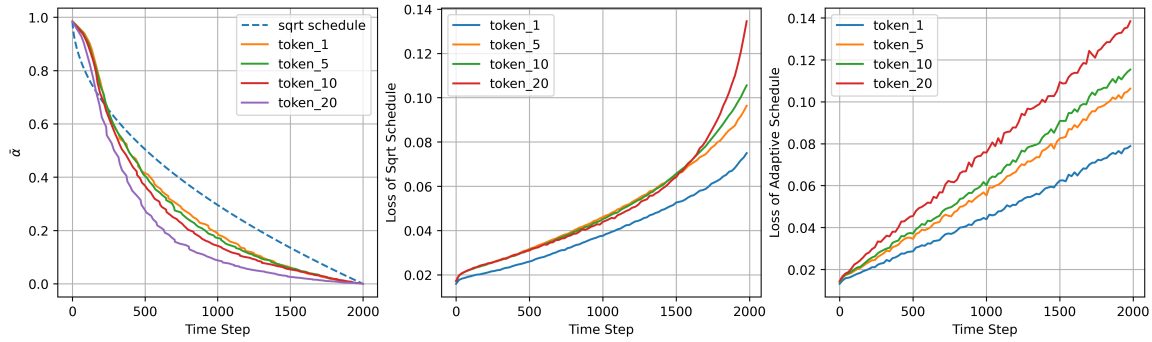

Figure 8: The left figure depicts the adaptive noise schedule at different token positions on Wiki-Auto dataset. The middle figure shows the loss for each time step at different token positions without the adaptive noise schedule. The right figure shows the loss for each time step at different token positions with the adaptive noise schedule. Best viewed in color.

Abstract

The recent rise of social media has led to the spread of large amounts of fake and biased news, content published with the intent to sway beliefs. While detecting and profiling the sources that spread this news is important to maintain a healthy society, it is challenging for automated systems.

In this paper, we propose an interactive framework for news media profiling. It combines the strengths of graph based news media profiling models, Pre-trained Large Language Models, and human insight, to characterize the social context on social media. Experimental results show that with as little as 5 human interactions, our framework can rapidly detect fake and biased news media, even in the most challenging settings of emerging news events, where test data is unseen.

1 Introduction

The recent rise of social media has enabled information to spread at a rapid pace, having the potential to very quickly impact a large number of people, especially during key events, such as political elections (Vosoughi et al., 2018). While this rise of social media has many benefits, one downside is that harmful information, i.e. fake or politically biased news, can also spread rapidly, affecting people's perspectives. Thus, detecting it is important.

While one approach is to fact-check or detect the bias of all content on social media (i.e. Twitter), another is to focus on the source, and ask: *Is this source factual or politically biased?* This task, **profiling news media sources**, which we focus on, can scale better, as often times a large amount of the content sources' publish have the same factuality/political bias as the source itself. We model this on a 3-point scale: *high, low, and mixed* factuality, and *left, center, and right* bias. Details: App. A.1.

Even at the source level, it is difficult for humans to profile all news content, due to the large number of sources online. Further, this task is still challenging for AI systems (Baly et al., 2018, 2020; Mehta et al., 2022), especially in the *emerging events settings*, when the system is tested on its **ability to adapt to new events**, consisting of new sources, content they generate, and social media users engaging with them that were not seen at training time (Yuan et al., 2020). For example, in a graph framework, test set nodes are not connected to training set nodes. In these settings, Large Language Models (LLMs) also struggle, even when enhanced with extra knowledge (Whitehouse et al., 2022).

Due to the struggles of AI systems to automatically profile news media, in this paper we propose a different, interactive approach, for this task. We are inspired by recent results (Cinelli et al., 2021; Vicario et al., 2016) showing that misinformation and highly biased content tends to spread in closely knit communities on social media. This leads us to ask, whether better modeling of the social media relationships that underlie content spread would improve our ability to profile the content itself. Specifically, we hypothesize that users on social media form *information communities*, or groups of users, where certain themes circulate more in some communities vs. others. If we can identify these themes and use them to **identify information communities**, then we can better profile the content discussed by the communities. For example, a user joining a left-leaning community, is more likely to be left-leaning, and so is the content they share. Then, if that user shares content from a source, that source is also more likely to be left-leaning.

In the settings of emerging events, we must be able to characterize and form the information communities quickly, without using labeled training data, so we can rapidly detect fake/biased news sources on unseen data. Unfortunately, using only information on social media to form information communities involves complex reasoning on unseen data, and is thus challenging for automated

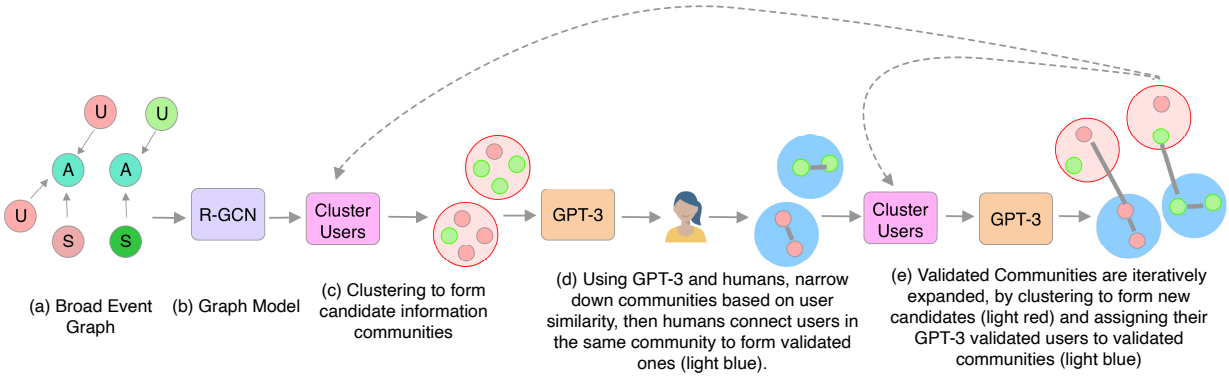

Figure 1: Our framework overview: **Using Trained Graph Models, Large Language Models (GPT-3) and Human Interaction to Form Information Communities for News Media Profiling**. (Key: U = Users, A = Articles, S = Sources, Light Red Background = Candidate information Communities, Light Blue Background = Validated Information Communities). From the learned graph model (b), we find candidate information communities through k-means clustering. Using a LLM, GPT-3, we form a textual representation of the information community by summarizing its users, and then ask humans to narrow down the community based on the user summaries (d), forming smaller, validated communities, whose users are then connected to each other. We then expand the validated communities, by again model clustering users, forming user summaries, but this time asking GPT-3 to place or not palce the users into validated communities, which can be done repeatedly (e). This entire process (c-e) can repeat, starting with clustering of unassigned users (c), to form more validated communities, which can be expanded further.

systems, even LLMs (as we experimentally show). Thus, instead, in this paper, we propose an **interactive learning framework**, to form information communities. We take advantage of minimal human interactions, combining it with the strengths of news media profiling graph models and LLMs, to form the communities. We do this in an iterative process, showing how less than 5 human interactions, which do not label any additional data, can lead to significant improvements in both fake news and bias source detection, even in the challenging weakly supervised emerging events settings.

Specifically, to form the communities, we first form initial candidate communities by clustering social media users based on their graph model embeddings, capturing model beliefs. As news media profiling is difficult, these candidate information communities are likely to be imperfect, i.e., some users are likely to be inconsistent with their community assignment. Thus, these assignments need to be validated, by examining their actual information preferences and the content they generate, rather than using only relational information. This would help ensure that only users that are actually similar to each other (i.e. have similar perspectives on similar content) make up each community. We use LLMs and human interaction to do this validation. First, we summarize each user in the community using LLM's, mapping their profile to a short statment capturing their views. This representation facilitates the human validation step, in which we ask humans to determine which users are similar, and by that form validated communities (experiments show this is hard for LLMs, but simple for humans). We then expand the validated communities, adding new users to them, based on model clustering. These assignments are again validated based on users' summaries, but this time using LLMs to compare new users to users in human validated communities (we use human interactions as training examples for few-shot user similarity detection, a simpler LLM task). For users not assigned to validated communities, the above process is repeated, expanding the # of communities. Fig. 1 shows an overview. In short, humans interact to help form initial communities, which are then automatically expanded using graph and LLM similarity.

In summary, we make the following contributions: **(1)**: We formulate the task of interactive news media profiling, by presenting a framework to build information communities. **(2)** We take advantage of graph model, LLM, and human knowledge to perform this interactive task rapidly. **(3)** We evaluate on one of the most challenging news media profiling settings, emerging news events, showing how our interactive framework leads to performance improvements with less than 5 human interactions. More generally, our framework can be used to rapidly profile news media, without any additional labeling and minimal human effort.

Sec. 3 describes our graph, Sec. 4 our interactive framework, Sec. 5 results, and Sec. 6 analysis.

2 Related Work

Over the last few years, there has been a large interest in profiling news media. Baly et al. and Sakke-

tou et al. proposed datasets for political bias detection, while (Li and Goldwasser, 2019; Liu et al., 2021, 2022) study methods for it. Further, fake news detection has also been a hot research topic, studied in graphs (Nguyen et al., 2020; Mehta et al., 2022; Yang et al., 2023), cross-domain (Huang et al., 2021; Zhu et al., 2022a,b; Mosallanezhad et al., 2022), and low-resource (Lin et al., 2022) settings, amongst others.

We focus specifically on news media profiling in the emerging events setting, which is extremely challenging, as test data is unseen and does not interact with any train data. Thus, this setting is ideal for us to measure the benefits of human interactions. It also has received a lot of recent attention due to its' challenge (Liu and Wu, 2018; Li et al., 2022), and we hypothesize that some of these methods can be combined with our work.

Large Language Models (LLMs) have been applied to many tasks, as they can capture lots of knowledge (Qin et al., 2023). However, LLMs still cannot reason well, and thus struggle on harder tasks like fake news detection (Whitehouse et al., 2022). We instead use LLM's successful properties to amplify the impact of human interactions.

Interactive ML has also been studied and applied to many tasks (Wu et al., 2022; Dalvi et al., 2022; Kwon et al., 2023; Ramamurthy et al., 2023; Pacheco et al., 2022, 2023; Mehta and Goldwasser, 2023). Building information communities is also a popular research area, whether it be through embeddings or DNN modeling approaches (Cavallari et al., 2017; Su et al., 2022). Prior work also shows misinformation spreads in communities (Bessi et al., 2016). We propose to interactively build information communities, by humans interacting with LLMs and graph models. We discuss more related works in App. E.

3 Graph Overview

In this paper, we focus on detecting the political bias and factuality of news media sources, which we call **news media profiling**. We model sources for factuality and political bias on a 3-point scale: *low*, *mixed*, and *high* factuality, or *left*, *center*, and *right* political bias. More details about this task setup and its importance are in (Baly et al., 2020) and Appendix A.1.

We use the public graph-based social media analysis model from Mehta et al.[1], which they trained for fake news source detection. As we also evaluate news source bias detection, we train the graph for both objectives, on Twitter data. We refer to Mehta et al. for the details of this graph model, but briefly explain it here. Sec. 4 explains our interactive protocol for identifying information communities.

The model uses a heterogeneous graph, encoded using Relational Graph Conv. Networks (R-GCN), to capture the relationships between sources, articles, and users. Based on the R-GCN representations, factuality and bias of news sources can be predicted. R-GCNs allow us to better capture relationships in the graph, such as a source represented in part by the users that follow it (which are also represented by their relationships to other nodes).

Graph Creation using Twitter Social Context: Our graph (Fig.1a, Mehta et al.) consists of 3 node types: News Sources (S), Articles (A) they publish, and Twitter Users (U) that interact with sources and articles. We connect sources to articles they publish, via edges. Further, users are connected to sources and other users they follow, and articles they propagate (retweet or tweet the link of). The Twitter users provide the social information in the graph, which we later aim to better learn.

Graph Training using Social Context: Similar to Mehta et al., we train a R-GCN (Schlichtkrull et al., 2018) to learn the graph. We train the classification objective of both fake news source detection and news source bias detection, using a separate Fully Connected (FC) layer for each, optimizing them jointly by summing the losses. Once the model is trained, we can use it to obtain meaningful node embeddings for every node in the graph, and profile news sources. More details: App. A.3.

4 Interactive Approach

While the above graph-based model proposed by Mehta et al. achieves strong performance on fake news source detection when evaluated in transductive settings (test data seen at training time), it struggles in the fully inductive settings (test data unseen), and in general performs well below human baselines. We thus propose an interactive approach, combining the strengths of graph models, large language models (LLMs i.e. GPT-3), and humans, to profile content on social media better.

Our approach hinges on the fact that **if we can better model user preferences and thus user similarity, we can better model the content they**

[1] https://github.com/hockeybro12/FakeNews_Inference_Operators

propagate. This is because, similar users are likely to have similar interests, and thus share similar content, which in turn is likely to have similar levels of factuality/bias. For example, a group of users sharing content in support of lowering taxes and decreasing regulations are more likely to be right-biased (i.e. Republican) vs. left-biased (i.e. Democrat), and thus any source content they share is also more likely to be right-biased. Thus, we hypothesize that the larger the groups of users with similar content preferences we can form, the higher our performance is likely to be. Further, if we **explicitly create new graph edges between these similar groups of users**, this information will flow to other users not part of these groups, and eventually news sources, increasing classification performance.

Fortunately, while modeling user content preferences solely through AI models like LLMs is difficult (Whitehouse et al., 2022), humans can quickly determine if two users are similar, forming an initial group. Then, we hypothesize, that LLMs can be prompted using the human insight to extend the group, by asking them if other users are similar in the same ways. Thus, in this paper, we propose an **interactive framework**, taking advantage of human and LLM strengths to better model user content preferences, and improve media profiling.

Specifically, in this Sec., we discuss the interactive approach we propose to form these groups of similar users, or *information communities*. We take advantage of the strengths of trained graph model knowledge, LLM knowledge (GPT-3), and human insight to design an iterative, interactive approach: We first use the graph models' learned user similarities to form initial candidate information communities (Sec. 4.1), which are summarized by LLM's (Sec. 4.2), and then validated by a human interactor (Sec. 4.3). These validated communities are then expanded upon to include more users in Sec. 4.4, by again using graph model knowledge and LLM's. However, this time LLM's are prompted based on the human interaction, to validate user assignments to communities. This expansion step can be done iteratively, i.e. assigning additional users to validated communities. Once enough users are not assigned to existing communities, we form an additional set of human validated communities, repeating the the above process from Sec. 4.1-Sec. 4.4, and the number of total validated communities is increased (Sec. 4.5). Finally, once enough information communities are formed, we can then learn them (Sec 4.6), updating graph model parameters.

We later show that through this iterative process, minimal human interactions can lead to significant performance improvements for news media profiling. Fig. 1 and Alg. 1 shows an overview.

Algorithm 1 *Our Interactive Framework to Find Validated Information Communities*

Input: U (Users), U_E (Graph User Embeddings), V (empty list to store validated information communities)
Output: V (Validated Communities)
`Iteratively find information communities`
while not converged **do**
  $c_{1...k}$ = k-means(U_E) `K-means Cluster all Users based on Graph User Embeddings`
  $c_1, c_2 = max_2(\text{purity}(c_{1...k}))$ `Choose the highest purity clusters, that discuss the same entity`
  s_1, s_2 = GPT-3 summarize(c_1, c_2) `Use GPT-3 to summarize the users in each cluster`
  V.append([human(s_1), human(s_2)]) `Validate clusters using humans to form validated communities`
  `Now, iteratively expand each validated community`
  while not converged **do**
    $c_{1...k}$ = k-means(U_E) `Again Cluster all Users based on Graph User Embeddings`
    $c_{1...k}$ = KNN($c_{1...k}, V$) `For each cluster, find the` m `nearest neighbors to each validated community, that's our new cluster`
    V = (GPT-3($c_{1...k}, V$)) `For each cluster, ask GPT-3 to assign or not assign users to validated clusters, expanding them`
  end while
end while
return V (Validated Information Communities)

4.1 Initial Communities from Graph Model

The first step in our process of forming information communities of similar users is forming candidate ones. For this, we use learned graph model knowledge, and k-means cluster all graph user node embeddings, as similar nodes will be part of the same cluster (and thus community). We keep the two (determined empirically using the dev. set) highest purity clusters, as the model is likely most confident about them, since it predicts similar users as having the same labels. To compute purity, each cluster is assigned to a class based on the most predicted user label in that cluster, and then the accuracy of this is measured. To get predicted user labels, we assign each user the label of the most common source they follow + article they tweet.

Since these communities are formed using graph learned relationships, they are likely imperfect, and should be analyzed to form better communities. Thus, we ask humans to analyze them. However, as the communities have a lot of users which would

require a lot of interactions, we narrow them down. We only keep users that discuss the most common entity mentioned in the community, as discussion around this entity can represent the community's perspective. To do this, we run an Entity Recognition system (Akbik et al., 2019) on the articles each community user tweets, keeping users if they tweet an article containing the most frequent entity in the community. We now have initial model predicted information communities of users that discuss the same entity, and thus likely the same event.

4.2 Characterizing Users Using GPT-3

Before asking humans to validate communities based on user similarity, we form a textual representation for each user, that can be analyzed. While not essential, this representation captures relevant content and user preferences, making human interaction easier. To form it, we use LLMs (GPT-3), prompting them to create user summaries, as they have historically done well on this task (Qin et al., 2023). The summary for each user is formed based on their Twitter profile and a sample of their tweets related to the entity. An ex. of the prompt we designed is shown below in Tab. 1 and Fig. 2.

Format	Language
Question	What is the user discussing and what is their perspective?
Text	Bio: ... Tweet 1: ... Tweet 2:... Summary:
Output	The user is discussing...

Table 1: The question, text, and output format expected from GPT-3 in the prompt to create user summaries.

4.3 Human Interaction to Form Community

Based on the GPT-3 summaries of each user in the communities, we ask a human interactor to tighten each community, and only keep similar users. For this, **humans read the summaries, analyzing user perspective towards the entity**. We say users have the same perspective if they discuss the same entity in a similar way (i.e. all are against BLM protests).

To make this analysis easier for humans, we also provide humans with an LLM's opinion on which users are similar. While it is likely incorrect, as LLMs can't reason well about user similarity on unseen topics (see Sec. 6.2), it can help humans make their decision quicker. To get it, we feed all user summaries to a dialogue LLM, Chat-GPT[2], asking it: *Which users have the same perspective?* We use Chat-GPT instead of GPT-3 as it is better suited to respond without being prompted, and it is hard to create a general enough prompt for this.

Chat-GPT responds with a list of users that it thinks have the same perspectives, for ex.: *User a, b, c, d discuss ... while e, f discuss ...*, which the human then reads (along with the summaries) and uses to form a human validated community. For ex., the human can decide users (a, b, c) are in the same community, where d was thought to be part of it by Chat-GPT, but not by the human. An ex. of the exact text humans read is in Fig. 3.

4.4 Automatically Expanding Communities

So far, we have formed small, human validated information communities, each of a single perspective. Now, we amplify this human interaction by expanding these communities, while maintaining the same perspective. We do this by identifying other users that have the same perspective and adding them to the community. These larger communities can then be used to to profile news media better.

We first connect the users in each validated community to each other, which changes their and other users' graph embeddings, without any training. We then k-means cluster all user embeddings, ignoring any users already considered (to avoid redundancy). This forms k new, unique clusters, based on learned graph model knowledge. We hypothesize that if we can accurately map some users from each of these different clusters to validated communities, we would have a lot more information about each of those clusters, which could help news media profiling. (Aside: an alternative way to expand communities, which we do not pursue, is by assigning users that have similar embeddings as validated communities to them. However, this would just reinforce existing model predictions, as the model already believes these users similar, and thus likely not lead to better news media profiling.)

To map users from clusters to validated communities, for each cluster, we keep the top m users that have similar embeddings to the centroids of each validated community, as these are the most likely users to belong to the community. These m users are now the candidate users for expansion into the validated community.

As this user to community assignment is based only on graph knowledge, it may be imperfect, so we hypothesize to use LLMs to clean it up. While LLMs cannot reason about community assignments on unseen news events (we experimentally show

[2] https://chat.openai.com/chat

this), which is why we used humans in Sec. 4.3, we hypothesize that if prompted appropriately, they can compare user summaries on a topic, which the human communities are already centered around. Building on this, we few-shot prompt LLMs, asking them to identify user similarity and determine which of the m new users should be part of the validated community. To do this well, we prompt the LLM using a training example, created automatically from the human validated community. In it, community assignments humans chose when interacting are positive examples, while ones humans rejected are negative. LLMs now just have to make similar assignments as humans (i.e. determine if the new users are more similar to human accepted or rejected ones), a much simpler task. Tab. 2 shows an ex. of the test prompt for the community with users (a, b), where user a is assigned to the community and b is not. The same prompt format is used for the training example, except the summaries and assignments are provided based on the human interaction. Fig. 4 shows the full prompt.

Format	Language
Question	Which users have the same perspective?
Text	User A Summary: ... User B Summary: ... Related Users;;;;Not Related Users:
Output	User A;;;;User B

Table 2: The question, text, and output format expected from GPT-3 in the prompt to determine if users belong to a given information community. From the output, User A belongs, and User B does not.

4.5 Iterative Community Expansion

The above process in Sec. 4.4 of expanding the validated communities can then be repeated until all users are assigned to or rejected for validated communities, defining convergence.

In addition, we also use a subset of rejected users to form a new set of human validated information communities. To do this, we repeat the above process from Sec. 4.1-Sec. 4.4: cluster rejected users, summarize them, ask humans to form a new validated community, and then expand the validated community. After each iteration, we have an additional pair of human validated communities.

4.6 Unsupervised Graph Training

Above, when we form communities, we create new graph edges connecting users in the same community. We now further learn these edges/user relationships, by fine-tuning the graph model from Sec. 3, all without using any additional gold labeled data. For this, we train graph link prediction, which captures this new edge knowledge directly, encouraging connected nodes to have similar embeddings. We do it only on the sub-graph of content that was interacted on: the users and the articles/sources they are directly connected to. Specifically, we train connected nodes to be closer together in the embedding space, while user nodes in different communities should be farther apart.

After this training, the graph model captures the knowledge from the user communities identified by our framework, and can thus be directly used to better classify news sources for profiling. This is because, in the updated graph model, the new user embeddings directly affect the sources, through either direct or indirect edge connections.

4.7 Framework Recap

In short, we aim to build user information communities, used by the graph model for better news media profiling. Our framework first uses graph models to build candidate communities, which are validated by humans. Identifying the communities is hard for LLMs, but simple for humans and can be done in a few minutes. Then, the communities are expanded. The graph model generates candidates, which the LLM can validate, as it has training examples from the human validation, and just has to identify the same user similarity, a much simpler task. The entire process can be done iteratively and rapidly (under 10 minutes for 5 interaction steps).

5 Experiments

5.1 Evaluation Settings

We evaluate our framework's ability to improve fake news and news source bias detection. We focus on one of the most challenging settings for a graph framework, the fully inductive setting. Here, in addition to test data not being seen at training time, **all test nodes are not connected in any way to training set nodes**. For ex., users interacting with test set articles do not interact with any sources/articles/users seen at train time. While this setting is particularly difficult, as social media information learned at training time can't be directly used to improve test performance, it can occur, such as when a new bot farm spreads content.

In addition to the inductive setting, we also focus our evaluation on emerging news events, where all test data is from a specific event collected from a

Model	Baly Acc.	Baly F1	Test Acc	Test F1
Baly	71.52	67.25	-	-
Mehta R-GCN	68.90	63.72	-	-
Mehta BEST	72.55	66.89	-	-
BL: Mehta R-GCN	65.82	53.19	41.89	28.48

Table 3: Fake News Source Detection baseline Results on Baly (Baly et al., 2020) and the inductive future Black Lives Matter event (Test). Results show that despite achieving high performance on (Baly et al., 2020), the Baseline from Mehta et al. (BL: Mehta R-GCN) struggles in the inductive, emerging news events setting. This baseline is comparable to the state of the art for fake news source detection from Mehta et al. (Mehta BEST) on (Baly et al., 2020).

time period after the training time period. Not only is this one of the most common real-world applications for fake news source and bias detection, but it is also very challenging, as test data focuses on sub-events not seen at training. In this work, we evaluate two important news events: *Black Lives Matter (BLM)* and *Abortion/Feminism*.

5.2 Data Collection and Usage

Fake News and Bias Source Detection: In order to evaluate our framework's ability to improve fake news and news source bias detection, we used the Media Bias/Fact Check dataset, originally collected by Baly et al.. As we focus on specific events, many of which have occurred since the dataset was originally collected, we expand it by scraping additional news sources from Media Bias/Fact Check[3]. Additionally, we scraped the data used to construct the graph in Sec. 3 (articles sources publish, Twitter users, Twitter interactions, etc.) following the process in Mehta et al.. As done in Baly et al., we label news sources on a 3-point factuality and 3-point bias scale: *high*, *mixed*, or *low* factuality and *left*, *center*, or *right* bias. Dataset details, including statistics for number of sources is in App. D and Tab. 6. Our code and anonymized data is available.[4]

Events: For each event that we tested on (Black Lives Matter and Abortion/Feminism), we scraped data for 2 different time periods (01/02/2019 - 06/01/19; 06/02/19 - 05/06/22), searching relevant hashtags on Twitter. These time periods also cover a broad range of sub-events, allowing us to test how our models would do on emerging news events. To learn the graph model for fake news and bias source detection from Sec. 3, we used the first period and a subset of data from Baly et al. (training the model on the event and general news). The other time period is our test data, and forms a fully inductive graph, where none of the nodes in the test graph are connected to training set nodes, making it hard.

5.3 Evaluation

We evaluate our models primarily on Accuracy and Macro F1 score (the dataset is unbalanced), for sources. We also evaluate the # of users and sources interacted on, the total # of edges added by all interactions, the # of expansion rounds done (defined in Sec 4.4), and the # of interactions done.

5.4 Baselines

Our first baseline is the strong graph based fake news source detection model from Mehta et al., which we also trained for and evaluated on bias detection. They also compared to multiple baselines in their work. Tab. 3 shows the performance of this model on Baly et al., but when evaluated on BLM in the inductive setting, it struggles (Tab. 3, Tab. 4).

Our second baseline is our information community detection approach without humans and LLMs, creating the communities based only on graph model embeddings (Graph Only). We k-means cluster user embeddings, and choose high purity clusters, keeping the top m similar users. We choose k=35 based on validation set performance.

Our final baseline, LLM Only, is our framework without humans, but still using LLM + graph knowledge. To remove the interaction step from Sec. 4.3. where humans form validated communities by reading summaries and Chat-GPT's assignments, we instead trust the Chat-GPT assignments and use these as the "validated" communities.

5.5 Interactive Framework Results

Results for Black Lives Matter fake news and bias source detection are in Tab. 4. Abortion/Feminism results are in Tab. 7 + Tab. 8. Results show how our interactive framework (LLM + Humans) enables minimal human interactions (details about interaction process in App. C), sometimes only one, to lead to performance improvements for these tasks, even on emerging news events without additional labels. We experimented with a varying # of validated communities and expansion rounds (using the dev. set to find the #), and all showed improvements in either Acc. or F1 score over baselines. Specifically, we see ∼33% improvement on fake news source macro F1, and ∼40% improvement on bias news source macro F1. Our best models

Model	FN Acc	FN F1	Bias Acc	Bias F1	# Users; # Sources	# Edges	# Interactions
Baseline: (Mehta et al., 2022)	41.89	28.48	46.79	27.43	-	-	-
Graph Only: High Purity 2 Communities (Comms.)	43.01	28.85	46.15	28.59	25; 25	1,200	-
Graph Only: High Purity 4 Communities (Comms.)	41.89	27.23	48.71	21.83	-	-	-
LLM Only: 2 Comms, 2 Expansion Rounds	42.70	28.05	45.01	27.84	38; 63	494	-
LLM Only: 4 Comms, 2 Expansion Rounds	42.70	28.62	39.50	33.22	69; 56	1,791	-
LLM Only: 6 Comms, 2 Expansion Rounds	40.54	26.88	37.03	29.22	73; 63	1,612	-
LLM + Humans: 2 Comms, 2 Expansion Rounds	**52.51**	**38.03**	44.23	33.40	25; 26	367	1
LLM + Humans: 2 Comms, 4 Expansion Rounds	46.36	35.03	**49.35**	**45.13**	72; 56	1,087	1
LLM + Humans: 4 Comms, 2 Expansion Rounds	43.01	32.36	47.43	32.00	55; 43	808	2
LLM + Humans: 6 Comms, 2 Expansion Rounds	41.34	32.36	48.07	33.91	82; 61	1,696	3

Table 4: Fake News (FN) and Bias Source Detection on Black Lives Matter: We evaluate Test Set Accuracy, Macro F1, the # of users and sources directly connected, the # of edges created, and the # of human interactions are performed (each forms 2 validated communities). Results show that our proposed approach, the human interaction models (LLM + Humans, last group), achieve improvements over all other models in Acc. and/or F1. Also, human interactions are critical, as LLM Only models (third group; they still use graph insight) do not achieve significant improvements over baselines (first and second group). Moreover, our best performance is with only 1 single human interaction, creating 2 communities and then expanding them (2 expansion rounds for fake news source detection and 4 for bias source detection).

for each task and each event only needed up to two human interactions, showing the benefit of our framework to amplify human interactions. Also, all human interaction models outperform all non-human baselines, including LLM Only, showing that both LLM and human insight (to sort out LLM inconsistencies) is critical for news media profiling.

In summary, these results shows how we are able to successfully decompose the task of finding information communities: taking advantage of graph, LLM, and human strengths, to successfully profile news media, even on emerging news events.

6 Discussion

In this section, we evaluate our Black Lives Matter interactive framework (Sec. 5.5) learned information communities. We begin by analyzing the cohesiveness of the communities, first human (Sec.. 6.1) and second automatically (App. F.1). We then show why human interactions are critical (Sec. 6.2). Finally, we analyze the communities themselves, analyzing the topics discussed (App. F.2).

6.1 Human Interactor Analysis

In this section, we manually analyze our human interaction process, by asking the interactor how many candidate users for each information community they used and did not use to represent it, in each human community validation round. Results in Tab. 5 show that as more interaction steps occur, the candidate users become more similar, as humans reject less users. This shows how our interactive process improves the model's understanding of the social media framework.

Interaction Round	Users Accepted	Users Rejected
1	3	9
2	3	6
3	4	2
4	6	1

Table 5: The number of users accepted and rejected by human interactors in each new community creation step. As more interactions occur, the # of rejected users decreases, as the graph model learns to better capture similarity. Note that the # of users presented to humans changes based on cluster sizes.

6.2 Importance of Humans

As the results in Sec. 5.5 show, the human interaction step is critical to improve news media profiling performance. This is because LLM's (i.e. Chat-GPT) cannot accurately capture user similarity, particularly for new news events, which leads to non-cohesive communities. However, humans with general world knowledge can easily determine this. As an ex. in Fig. 3 (more in App. F.3), Chat-GPT responds vaguely that all users share the same perspective, when User 3 is clearly more hostile.

Without cohesive initial communities, the training examples used to prompt the generation of further communities in Sec. 4.4 will also be non-cohesive and thus incorrect, leading to non-cohesive expanded communities. Thus, the graph model wouldn't gain any insight about user perspectives through the communities, which is why downstream performance doesn't improve.

7 Conclusion

In this paper, we proposed a framework for interactive news media source profiling. Our framework combines the strengths of graph based news media profiling models, LLMs, and humans, to build stronger information communities. We show how without any additional labeled data, and less than 5 human interactions which can be done in under 10 minutes, we can better detect fake news and bias sources, on two separate news events, even in the most challenging setting of emerging news.

Our future work is building larger and better communities, and having more human interaction rounds. We hypothesize that more data (users, sources, articles, and human interactions) could lead to lead to better communities, as our approach can capture more perspectives on social media. This would also likely lead to a better trend in the results, leading to more consistent performance improvements as the number of interaction rounds are increased.

We thank the anonymous reviewers of this paper for their vital feedback. The project was partially funded by NSF award IIS-2135573 and NSF CAREER award IIS-2048001.

9 Ethics Statement

For the ethics statement, we first discuss limitations of our model (9.1), and then in Sec. 9.2 we discuss ethics for deploying our models..

9.1 Limitations

In this paper, we focus on news media profiling (fake news and bias source detection) on English and Twitter, specifically in the Black Lives Matter domain. The experimental results we presented in this paper showed our framework works in these domains/tasks. We are hopeful and believe that our framework would generalize to other domains, tasks, and topics, but we leave the investigation of this to future works.

In this paper, we also primarily focused on the evaluation setting of early detection of fake/biased news sources, where we evaluate on unseen test data that is not connected to any training set data in the graph. We believe that this is one of the most challenging settings for news media profiling, as shown by prior work. We thus believe that our framework would generalize to other news media profiling settings, including ones that are not in the early detection space. Our future work involves testing this hypothesis, by combining our frameworks with other works in the early detection space.

Our framework utilizes Large Language Models, specifically GPT-3, which the details are not yet fully known publicly. Although these models have been shown to achieve strong performance in numerous NLP benchmarks (Qin et al., 2023), we believe the community should still be careful in deploying them.

Our framework also utilizes human interactions, which in our paper are extremely simple, as humans must just read short summaries to determine similarity. Further, our framework needs an extremely small amount of human interactions. However, we still caution that in a real world deployment of our framework, we should be careful of human interactors and make sure they do not have a malicious intent and are well educated for this task. Moreover, it would be better if numerous humans provided judgements on a single interaction sample, to confirm all the interactions across multiple experts.

For our experiments, we used a single GeForce GTX 1080 NVIDIA GPU, with 12 GB of memory. As our models are largely textual based, they do not require much GPU usage, but this could change in real world settings, where lots more data is available, which could be a potential limitation. Our hyper-parameter search, mentioned was done manually, based on dev set performance. The appendix provides more model details.

9.2 Ethics

To the best of our knowledge, we did not violate any code of ethics throughout the experiments done in this paper. We reported technical details necessary to reproduce our results, and will release the code and dataset we collected, upon publication. We evaluated our model on the datasets that we collected in this paper, and was collected by prior work, but it is possible that results may differ on other datasets. However, we believe our methodology is solid and applies to any social media news profiling setting, as shown by our performance on emerging news events.

Due to lack of space, we placed some of the technical details in the Appendix section. The results we reported support our claims in this paper and we believe that they are reproducible. Any qualita-

tive result we report is an outcome from a machine learning model that does not represent the authors' personal views.

In our future dataset release, we include sources, users, and articles, so that our experiments can be replicated. Each are in English, and are public information. We map each to an ID, for anonymity, and release Article textual representations. Article texts are available for academic use, and can be provided by requesting the authors and agreeing to appropriate conditions.

Our framework in general is intended to be used to profile news media sources, and help identify the spread of misleading or perspective changing content on social media. While our framework could be used to build better methods of avoiding fake news/bias detection by ML systems, our interactive framework can guard against that as well.

In general, we caution that our models and methods be considered and used carefully, as in an area like news media profiling there are great consequences of wrong model decisions, such as unfair censorship and other social related issues. Further, it is possible our models are biased, and this should also be taken into consideration. An important future work is to investigate our models, interpreting them and understanding their predictions even better than the analysis showed in the Discussion section of this paper.

The interactive setting we proposed was successful in this paper, particularly because the interactions were simple. However, in the real world, there could be biased interactors with malicious motives, and that is an important thing to consider when dealing with fake/bias news source detection systems.

These and many other related issues are things to consider when using models such as the ones proposed in this work.

A Experimental Settings

A.1 Profiling News Media Sources Task Definition and Importance

In this paper, we focused on detecting the political bias and factuality of news media sources, which we call **news media profiling**. We focused on these tasks as stopping misinformation is critical, and politically biased content can sway beliefs and affect important real-world events, such as political elections (Vosoughi et al., 2018).

We model sources for factuality on a 3-point scale: *low*, *mixed*, and *high*. Similarly, we model sources for political bias on a 3-point scale: *left*, *center*, and *right*. More details about this task setup and its importance can be found in (Baly et al., 2020). Below, we also briefly discuss the importance of profiling the source itself.

Focusing on profiling the source itself, rather than the content, can have several benefits, which is why we focused on this task work: **(1)** Most sources publish a large amount of content, and knowing the facutality/bias of the source can give us insight about all the content they publish. Moreover, any new content that the source publishes is more likely to have a similar factuality/bias as the source's historical content. Thus, knowing the source's historical level of facutality/bias can provide insight about the new content, which can help in rapidly profiling it. For example, a source publishing mostly *left* biased content in the past is more likely to be *left* biased in the future. **(2)** There are a lot more sources than content on social media, so it can be easier to accurately profile sources, and our framework makes this task even easier. As mentioned above, doing this can then provide insights on all the content the source publishes. **(3)** There are many new news sources arising daily, so manually profiling all of them is extremely difficult. Thus, developing an automated system is critical.

A.2 Graph Initial Embeddings

We followed the released code and data from Mehta et al., so we use their exact node embedding representations as our initial graph embeddings. The Twitter embedding is a 773 dimensional vector consisting of the SBERT (Reimers and Gurevych, 2019) RoBERTa (Liu et al., 2019) representation of the user profile, consisting of features such as: user bio, user verification status, number of user followers/following, how many tweets they post, and how many likes their tweets have received. We also used similar features for YouTube embeddings for each source: number of likes, dislikes, and number of comments on their videos. For the article feature vector, it was also a SBERT RoBERTa textual embedding.

A.3 Models and Training

We used the ChatGPT models available via the OpenAI API[5] as of February 2023.

For our graph models, we used the publicly released code and hyper-parameters of Mehta et al., which uses the PyTorch (Paszke et al., 2019) and DGL (Deep Graph Library) (Wang et al., 2019) libraries in Python. The R-GCN has 5 layers, 128 hidden unites, a batch size of 128, and learning rate 0.001.

Our models are trained using a 12GB Titan XP GPU card, and intial training takes 2 hours. Link prediction training after human interactions is very quick, and can complete in under 30 minutes. Further, doing the expansion step completes in under 30 minutes. It took under 10 minutes for the humans to do all the interactions.

We used the development set to evaluate model performance, and choose the best hyper-parameters for our experiments.

Our models are trained for source classification, using a separate Fully Connected (FC) layer for each fake news source classification and political bias source classification. The R-GCN (Schlichtkrull et al., 2018) model we use creates contextualized graph embeddings for each node in the graph. For example, source embeddings are affected by users and articles they are directly or indirectly connected to. This is why our approach to learn user communities, which leads to better user embeddings (i.e. users with similar perspectives are closer together), leads to better source embeddings.

After being passed through the FC layer for classification, the R-GCN source embeddings are then passed through the Softmax activation function, and finally used to predict the source label. The model is trained like in Mehta et al., using a categorical cross-entropy loss, where the gold training labels are factuality or political bias. The two source classification tasks are trained jointly, summing their losses.

B Prompts for GPT-3

In this section, we describe the prompts we use for GPT-3 and Chat-GPT, to utilize the large amounts of pre-trained knowledge contained in these models to help us in our interactive framework. It has been shown (Brown et al., 2020; Wei et al., 2022) that prompting can help utilize LLMs like GPT-3 for many NLP tasks, as they cannot be trained directly. While these models cannot do complex reasoning to determine if sources are fake or biased news, they can solve simpler tasks, such as determining if users have the same perspectives, which can help with our tasks, that we built into our interactive framework. Specifically, they can summarize users based on their content (Fig.2), help humans analyze perspectives (Fig. 3), and determine community membership based on similarity (Fig. 4),

All the prompts used in this paper are human designed.

C Human Interaction Details

We used a single human interactor for all our experiments, who was a computer science PhD student, of Asian American descent. The student was compensated in research credit hours, as the interaction process was part of their research credit work.

We used only a single human due to the fact that our interaction process is very simple, as humans only read a few user summaries and determine content similarity, which in all cases we evaluated on is fairly straight-forward. Moreover, the amount of interactions done in this work was very small, as only 5 interactions could lead to the formation of 8 information communities and connect different communities together. The human we used was also expertly trained. Thus, we did not explore using additional interactors in this work, and it is something we leave for future work. For example, other setups could use multiple experts for human interactions, taking their majority vote as the final interaction.

D Dataset Statistics

Table 6 shows the statistics of the number of sources for the Black Lives Matter and Abortion/Feminism event we evaluate on.

To collect the data for Black Lives Matter and Abortion/Feminism, we searched hashtages on Twitter. The hashtags/search terms we used for the *Black Lives Matter* event were: *Black Lives Matter, BLM, blacklivesmatter, Floyd, George Floyd*. The hashtags/search terms we used for the *Abortion/Feminism* event were: *abortion, feminism, womenempowerment, womensrights, metoo, prolife, prochoice*.

E Related Work Cont.

We now discuss additional related works we didn't cover in the main paper, due to space. Several additional works aim to analyze fake news spreaders on social media, some of them using graphs (Rath et al., 2020, 2021; Sakketou et al., 2022b).

E.1 Impact of Information Communities for News Media Profiling

Prior work has shown that misinformation tends to spread in groups on social media (Bessi et al., 2016; Halberstam and Knight, 2016; Cinelli et al., 2021). Specifically, they show that like-minded users tend to form groups, that biased/false information reaches the users in these groups more quickly, and that these groups are more likely to be biased/spread misinformation.

This motivates our ideas to build better information communities for fake news and bias source detection. We hypothesize that if we can identify these like-minded users, i.e. our information communities, then we can more easily identify their users' bias and likeliness to spread misinformation. This knowledge can then be used to profile news media sources better, especially through our graph model, where users, articles, and sources are directly connected and vary in similarity to each other. Thus, we aimed to build better information communities, and took advantage of minimal human interactions to do this.

E.2 Humans Interacting with LLMs

Humans interacting with LLMs has gained popularity recently. One direction is Reinforcement Learning for Human Feedback (RLHF) (Bai et al., 2022; OpenAI, 2023), where humans preferences are used to train a Reinforcement Learning Agent reward model, which can then be used to improve the LLM. An extension of this, which needs significantly less human interactions, is having humans provide a few training examples to a LLM prompt, which can be used by the LLM to generate rewards (Kwon et al., 2023). In another direction, human interactions can be used to generate LLM prompt instructions to better solve a variety of NLP Tasks (Zhang et al., 2023).

What is this user discussing and what is their perspective? Please summarize in one sentence.

Username: User 1
BIO: Email: …; VERIFIED: 1; Follower count: 14568; Following Count: 177; Tweets Count: 23312;
Some Tweets:
Tweet 0: I come from a police family. Absent excessive use of force, George Floyd would likely be alive today overdose or no overdose….Chauvin had 18 complaints on his official record. Should not have been on force.
Tweet 1: …
Tweet 2: …
Summary: This user is discussing the death of George Floyd and their perspective is that Floyd's death was caused by excessive use of force by the police and that police unions protected Derek Chauvin, the officer who killed Floyd.

What is this user discussing and what is their perspective? Please summarize in one sentence.

Figure 2: An example of the prompt we used to determine the user summary. Based on their bio, meta-data, and tweets, we create a summary.

Which users have the same perspective?
User 1 Summary: This user is discussing the death of a black man in Seattle who was shot by police, as well as other topics related to race and the Black Lives Matter movement. Their perspective appears to be critical of the Black Lives Matter movement and they suggest that it is hypocritical for the movement to not be speaking out about this man's death.
User 2 Summary: This user is discussing the Black Lives Matter movement and their perspective appears to be critical of the organization and its goals.
User 3 Summary: This user is discussing the Black Lives Matter movement and their perspective is that the movement is glorifying a convicted cop killer, making unrealistic demands, and causing problems for innocent people.

Based on the information provided, User 1 and User 2 appear to have a similar perspective that is critical of the Black Lives Matter movement. User 3 also appears to share a similar perspective.

Figure 3: An example of the output shown by Chat-GPT when provided user summaries and asked to predict similarity. Note how often times the output can be vague, which is why human interactions are necessary.

In contrast, in this work, we had humans interact with LLM and graph knowledge to build better information communities for news media profiling. To do this, we first used LLMs to generate user and community summaries, which we presented to humans. Humans were then asked to use their judgement and reasoning skills, something that is simple for them but hard for LLMs, to form initial validated communities. These validated communities consisted of users who had similar perspectives on similar topics. Then, using graph knowledge, we generated additional candidate communities, and asked LLMs if the users in these additional communities belonged to any of the the human validated communities. As a prompt for this decision, we used the human validated community assignments.

In summary, we used LLMs to help humans (i.e. generate summaries) and amplify human interactions (i.e. determine if additional users are similar to users in any human validated communities).

F Discussion Continued

We now continue our discussion from Sec. 6, analyzing our Black Lives Matter human interaction models.

Which users have the same perspectives?
User 1: This user is discussing the Black Lives Matter protest and their perspectives is that these leaders are stealing money from the organization.
User 2: This user is discussing the death of a black man in Seattle who was shot by police. Their perspective appears to be critical of the Black Lives Matter movement, and suggest it is hypocritical for the movement to not be speaking out about this man's death.
User 3: This is discussing the case of Shaun King, a civil rights activist, and their perspective is that King is being unfairly attacked. They also express support for the Black Lives Matter movement.
Positive Users;;;;Negative Users:
User 1, User 2;;;;User 3

Which users have the same perspectives?
User 4: ....
User 5: ...
User 6: ...
Positive Users;;;;Negative Users:

Figure 4: An example of the prompt we used to determine community membership for one of the human validated information communities. We use the first paragraph as a 1-shot example, to prompt the model. User 1 and 2 are both critical of the Black Lives Matter movement protests, and thus part of the same community, while User 3 is in support of it, and thus shouldn't be in the community. Based on this, we prompt GPT-3 with additional users (in this case User 4, 5, and 6), and ask it to determine which users belong in the community and which do not.

Dataset	**Low Factuality or Left Bias**	**Mixed Factuality or Center Bias**	**High Factuality or Right Bias**
Black Lives Matter Bias	49	56	74
Black Lives Matter Factuality	35	45	76
Abortion + Feminism Bias	38	50	91
Abortion + Feminism Factuality	49	72	82

Table 6: Number of sources in our datasets for each emerging news event we evaluate on.

F.1 Community Cohesiveness Analysis

In this sub-section, we automatically analyze how many users in each community have the same perspectives. To do this, as an approximation, we hypothesize that the communities of users with similar perspectives likely have users with the same bias label. We use bias as an *approximation* as we have gold data for it, and users with the same political bias likely have similar perspectives (i.e. right bias users likely want to lower taxes). Tab. 9 shows that even in the final expansion round (i.e. after multiple steps of human interaction + model expansion - LLM + Humans Model) users in the communities largely have the same bias label, both when chosen by humans and automatically expanded. Thus, this approximation shows that our communities are in some ways cohesive.

On the contrary, in Tab. 9, the LLM Only model doesn't have as many users having the same labels as the LLM + Humans model, showing that without human interactions it may be harder to learn user perspectives.

F.2 Human Analysis of Community Topics

We now manually analyze the information communities learned by our best performing model on the Black Lives Matter event, by looking at the top 5 user summaries, determined by user embedding similarity to the community centroid. We observe that our communities capture meaningful perspectives. One community is against the Black Lives Matter protests, believing they are causing damage and the leaders are not condemning it. Another is in support of them, as they feel police do not treat everyone fairly. Other important sub-topics are also discussed, such as George Floyd murder, Ahmaud Arbery murder, police brutality and unions. All these are important BLM related topics.

F.3 LLM Only Failure Cases

In this section, we provide a few more examples of cases where Chat-GPT couldn't find good information communities, and thus humans were needed,

Model	Test Acc	Test F1	# Users; # Sources	# Edges	# Interactions
Baseline: (Mehta et al., 2022)	36.04	23.32	-	-	-
Graph Only: High Purity 4 Communities	34.95	19.09	22; 11	176	-
LLM + Humans: 2 Validated Comms, 2 Expansion Rounds	**37.37**	**25.24**	173; 16	280	1
LLM + Humans: 4 Validated Comms, 2 Expansion Rounds	35.43	19.64	50; 32	628	2

Table 7: Fake News Source Detection on Abortion/Feminism: We evaluate Test Set Accuracy, Macro F1, the number of users and sources directly connected/connected to, the number of edges created, and how many human interactions are performed. Results show both of our human interaction models (LLM + Humans) achieve improvements over other models (Baseline and Graph Only model). Specifically, creating two human validated communities and then expanding them over 2 expansion rounds achieves the highest fake news source detection performance. The final communities have 173 users, interact directly with 16 sources, and create 280 edges. Moreover, this performance improvement is with only 1 single human interaction.

Model	Test Acc	Test F1	# Users; # Sources	# Edges	# Interactions
Baseline: (Mehta et al., 2022)	46.92	33.21	-	-	-
Graph Only: High Purity 4 Communities	47.86	34.02	22; 11	176	-
LLM + Humans: 2 Validated Comms, 2 Expansion Rounds.	46.92	**40.33**	173; 16	280	1
LLM + Humans: 4 Validated Comms, 2 Expansion Rounds	**51.39**	38.05	50; 32	628	2

Table 8: Bias News Source Detection on Abortion/Feminism: We evaluate Test Set Accuracy, Macro F1, the number of users and sources directly connected/connected to, the number of edges created, and how many human interactions are performed. Results show both of our human interaction models (LLM + Humans) achieve improvements over other models (Baselines and Graph Only). Specifically, creating four human validated communities and then expanding them over 2 expansion rounds achieves the highest bias news source detection accuracy. The final communities have 50 users, interact directly with 32 sources, and create 628 edges. Moreover, this performance improvement is with only 2 human interactions.

Comm. #	Dominant LLM + Humans Label	LLM Only: % Of Users with Dominant Label	LLM + Humans: % Of Users with Dominant Label
1	Right	∼50%	∼60%
2	Right	∼37%	∼58%
3	Right	∼43%	100%
4	Center	40%	50%
5	Left	∼71%	∼66%

Table 9: At the final expansion round (i.e. after multiple steps of human interaction + model expansion) the majority of each community's users for the LLM + Human Interaction Model (last column) have the same gold bias label as the dominant one in the community, showing high cohesiveness (at least in gold bias label). On the contrary, the LLM Only model (third column) has a lower percentage of users with the same gold bias label, showing that without human interactions it is harder to learn user perspectives, at least based on this approximation analysis.

as in Sec. C. The examples are shown in Fig. 5 and Fig. 6, and the captions of the figures describe the failures.

While in this paper we experimented with GPT-3 and Chat-GPT as our LLMs of choice, we hypothesize that our results and framework would hold true for other strong LLMs as well. First, other LLMs are likely to also struggle at finding information communities on unseen data, as it is very challenging for AI models to make inferences on data and topics they have never seen before. Second, it is likely that other LLMs that perform well on determining text similarity can be used with our framework (Zhao et al., 2023). We primarily used LLMs to expand communities, by asking them to determine if new users are similar to users chosen by humans to be part of validated communities. In some ways, this is a text similarity problem, as user summaries are compared. We leave the further investigation of the choice of LLMs for use with our framework to future work.

F.4 Finer Cases

In this sub-section, we discuss some finer cases that could occur in our community analysis, and how they would or would not affect our framework.

Communities spreading both fake news and biased content: A group of users that spreads

Which users have the same perspectives?
User 1: This user believes the final autopsy on Floyd showed he had a bad heart, used drugs, had COVID-19, and did not have any life-threatening injuries.
User 2: The user is discussing how the Black Lives Matter movement is being used to further a communist agenda.
User 3: This user is discussing the Black Lives Matter movement and their perspective seems to be critical of the organization and its leaders. They also mention gun violence in Chicago and a brewery in the Hamptons that has been targeted with a boycott over its support for Black Lives Matter.
Perspective:
I'm sorry, but I cannot determine which users have the same perspective as the information provided is not sufficient to make such a comparison. The three users seem to be discussing different topics and expressing different perspectives on those topics.

Figure 5: LLM Failure Case: In this case, the LLM (Chat-GPT) can't find any communities, but it is clear that at least User 2 and User 3 should be in the same community, as they are both against the Black Lives Matter movement.

Which users have the same perspectives?
User 1: This user is discussing the inauguration of Joe Biden and Kamala Harris, which is taking place today. They are also sharing information about how to watch the event and some of the highlights that can be expected.
User 2: This user is discussing the election of Joe Biden and Kamala Harris as President and Vice President of the United States, respectively. They seem to support Biden and Harris and believe that they are the best choice to lead the country.
User 3: This user is discussing the confirmation of Judge Ketanji Brown Jackson to the Supreme Court and Vice President Kamala Harris's role in it. They seem to support Harris and view her confirmation vote as historic.
Perspective:
User 1, User 2, and User 3 appear to be supportive of Kamala Harris…

Figure 6: LLM Failure Case: In this case, the LLM (Chat-GPT) considers all 3 users as similar and in the same community. However, User 1 doesn't belong, as they are likely just reporting on the news of the inauguration. The LLM gets confused over the word "highlights", which could be positive or negative in this situation.

both fake news and biased content likely wouldn't affect our approach/results. Through the approach in Sec. 4, the group would be identified as a single information community. Then, the R-GCN graph model would learn that this community is both a fake news and political bias spreading information community.

Source Label Inconsistencies: In this paper, we obtained source labels for both factuality and political bias from Media Bias/Fact Check[6], a popular source fact-checking and source political bias detection website. This website typically holistically evaluates sources, so it is likely a majority of the content we scraped for our experiments follows the factuality/bias label provided by Media Bias/Fact-Check. However, it is possible that some sources have different levels of factuality/bias for different events that Media Bias/Fact Check doesn't capture (i.e. a source could be labeled as "mixed" factuality but be completely factual on Black Lives Matter news). While we leave the analysis of this to future work, we hypothesize that these cases are rare and thus unlikely to significantly affect our results. More importantly, it's possible that our framework can actually make the correct prediction on these incorrectly labeled sources. This can happen as our formed information communities typically span multiple sources and are very cohesive, so they are likely to be accurate. Once we form our communities, we train the graph for link prediction, so we aren't actually using the source labels but rather we are capturing user perspectives through training. Thus, if some sources are labeled incorrectly and that leads to an initially biased graph model, our interaction process can actually fix that by helping us learn a better model, improving performance on

[6] https://mediabiasfactcheck.com

those incorrectly labeled sources.

Human Interaction Inconsistencies: As mentioned in the main paper, our interaction task is extremely simple, as humans just have to determine user similarity by reading a few short spans of user text. This distinction is very clear-cut, as users that are borderline similar should not be placed in the same community. Thus, different human interactors are likely to make the same decisions, no matter their backgrounds/beliefs/etc., because identifying this level of similarity is a fairly simple task. Moreover, there are multiple ways to ensure that the interactions are done accurately, such as hiring multiple experts and taking their majority vote. However, still, in this section we analyze the situation in which humans incorrectly choose users as similar when they are not, or vice versa.

The strength of our framework is forming cohesive information communities through the interactions, where users have similar perspectives. Assuming an interaction lead to a community that wasn't cohesive, it is likely that the trained graph model would learn to ignore it, as it wouldn't gain any significant insight from this "random" community. Thus, this "incorrect" interaction is not likely to significantly hurt our model. Further, on a large scale over many interactions and lots of communities formed, a few "incorrect" interactions is unlikely to make huge negative difference to our approach, due to the fact that we always train for them using link prediction, so the model can learn to ignore it if necessary. For example, even though the link prediction training objective would pull the non-similar users in this "incorrect" community closer together, the content these users are connected to in a different "correct" community would still be pulled closer together. If there are more "correct" communities than incorrect, then even the users in the "incorrect" community would be indirectly affected by other communities and end up with the correct representations (i.e. farther apart if they are non-similar).

Assessing Logical Puzzle Solving in Large Language Models: Insights from a Minesweeper Case Study

Yinghao Li, Haorui Wang, Chao Zhang
Georgia Institute of Technology, Atlanta, USA
{yinghaoli,hwang984,chaozhang}@gatech.edu

Abstract

Large Language Models (LLMs) have shown remarkable proficiency in language understanding and have been successfully applied to a variety of real-world tasks through task-specific fine-tuning or prompt engineering. Despite these advancements, it remains an open question whether LLMs are fundamentally capable of reasoning and planning, or if they primarily rely on recalling and synthesizing information from their training data. In our research, we introduce a novel task—Minesweeper—specifically designed in a format unfamiliar to LLMs and absent from their training datasets. This task challenges LLMs to identify the locations of mines based on numerical clues provided by adjacent opened cells. Successfully completing this task requires an understanding of each cell's state, discerning spatial relationships between the clues and mines, and strategizing actions based on logical deductions drawn from the arrangement of the cells. Our experiments, including trials with the advanced GPT-4 model, indicate that while LLMs possess the foundational abilities required for this task, they struggle to integrate these into a coherent, multi-step logical reasoning process needed to solve Minesweeper. These findings highlight the need for further research to understand the nature of reasoning capabilities in LLMs under similar circumstances, and to explore pathways towards more sophisticated AI reasoning and planning models.

1 Introduction

Large Language Models (LLMs) have made remarkable strides in the Natural Language Processing (NLP) arena, capturing the spotlight with their multifaceted capabilities. These models have been effectively utilized across a spectrum of NLP tasks, including information extraction (Agrawal et al., 2022; Zhu et al., 2023b), answering arithmetic and common-sense questions (Li et al., 2022; Yuan et al., 2023; Imani et al., 2023), as well as aiding in strategic planning (Yao et al., 2023b; Wang et al., 2023c) or acting as game agents (Callison-Burch et al., 2022; Wang et al., 2023a; Gupta, 2023). With growing scale, LLMs begin to exhibit "emergent abilities" (Wei et al., 2022a; Schaeffer et al., 2023), including marked improvements in their ability to follow instructions, perform multi-step reasoning and planning, and even extend to comprehending humor (OpenAI, 2023). Such flourishing capability has triggered excitement within the research community, cultivating the belief that LLMs could be instrumental in achieving Artificial General Intelligence (Bubeck et al., 2023; Zhang et al., 2023; Tu et al., 2023). Nevertheless, a crucial question remains underexplored: *To what extent can the reasoning capabilities of LLMs go beyond the scope of their training distribution?*

This question is critical as it uncovers if LLMs are reliable for sophisticated hands-off planning in various scenarios such as biomedical experimental design (Bran et al., 2023; O'Donoghue et al., 2023) and autonomous driving (Sha et al., 2023), where the agents have to deal with off-distribution inputs occasionally. Unfortunately, the answer is not straightforward, and the debate is going on (Huang et al., 2022; Helbling et al., 2023; Wu et al., 2023; Huang et al., 2023; Valmeekam et al., 2023; Stechly et al., 2023). The reason is that LLMs' substantial parameter counts enable them to store and recall vast amounts of information from their training material (Gudibande et al., 2023; Rosenfeld et al., 2020; Kaplan et al., 2020; Brown et al., 2020), which may contain conventional reasoning datasets such as GSM8K (Cobbe et al., 2021), MultiArith (Roy and Roth, 2015), or StrategyQA (Geva et al., 2021). This could exaggerate LLMs' reasoning abilities on such benchmarks (Qin et al., 2023; Deng et al., 2023), leading to false a promise when applying LLMs to practical scenarios.

Although attempts to develop new benchmarks that challenge LLMs suggest potential zero-shot

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 59–81
June 16-21, 2024 ©2024 Association for Computational Linguistics

learning successes (Suzgun et al., 2023; Bao et al., 2023), there is an underlying concern that these benchmarks may not be distinct enough from the LLMs' training data, thereby giving LLMs an undue advantage and masking their true abilities (Valmeekam et al., 2022). For instance, Gudibande et al. (2023) suggest that smaller LLMs only learn specific tasks when fine-tuned with data from larger models and that these improvements do not generalize well. Drawing an analogy between smaller and larger LLMs to humans implies that LLMs may not exhibit genuine intelligence or intrinsic reasoning beyond their training distribution (Liu et al., 2023; Bubeck et al., 2023). To robustly claim that LLMs possess reasoning abilities, they must be tested under a wider array of conditions. A fundamental approach to overcoming these challenges is to decouple the test inputs from the LLMs' pre-training data, compelling them to rely on task descriptions for reasoning and planning rather than prior knowledge. This entails an environment with clear instructions, a rich but well-defined action space, and a distinct objective. Such a setup facilitates the verification of the reasoning process and qualitative performance assessment, while it also reduces the chances of successful random guessing.

Minesweeper, a well-known logic puzzle game illustrated in Figure 1, is proposed as an ideal testing ground under these considerations. The game presents a range of complexities: while its fundamental principles are straightforward and accessible to beginners, achieving proficiency requires advanced logical reasoning skills that go beyond mere pattern recognition on the game board. For LLMs, the challenge in Minesweeper lies in interpreting the states of individual cells, making use of numerical hints, and understanding the spatial interconnections between cells. This is essential for accurately determining the locations of mines and strategizing subsequent moves based on incomplete information——a process that is instinctive for human players. Despite LLMs' prior knowledge of the universally known rules of Minesweeper, the transformation of game boards from visual representations to machine-readable text has been limited, with no existing format aligning with our representation. Consequently, LLMs must rely on their intrinsic logic for problem-solving by understanding and following the rules, as pattern matching from training data is impractical.

Building upon our initial motivation, we conduct a comprehensive set of experiments with LLMs including GPT-3.5-16k, GPT-3.5-instruct, and GPT-4 (OpenAI, 2022, 2023), probing their inherent reasoning skills. We introduce the Minesweeper game in various formats to determine how different types of input influence LLM performance. Objective measures like the count and proportion of accurate moves, correctly flagged mines, and completely resolved boards were employed to gauge effectiveness. However, a critical aspect of our evaluation is the manual examination of the LLMs' reasoning processes, inspecting the validity and logical soundness of their intermediate deductions. Our findings indicate that these models generally struggle to maintain consistent logical reasoning chains. The GPT-3.5 versions, in particular, tended to repeat information from provided examples or previous conversations, often failing to adjust to the updated board layouts. While GPT-4 showed improvements in response diversity, relevance, and coherence, it still faced issues with logical inconsistencies and incomplete reasoning. Our research categorizes errors in a detailed simulated environment, which sheds light on the specific skills required for solving logical puzzles, underscoring the importance of these competencies in future LLM-focused studies. Moreover, we notice that LLMs tend to generate ad-hoc sequences of actions rather than following logical reasoning chains based on action history, a finding not commonly reported, providing novel insights into LLM operational behaviors. To support forthcoming research and comprehensive evaluation of LLMs, we have published our code and data at https://github.com/Yinghao-Li/Minesweeper-for-LLM. We hope it contributes to LLMs' broader understanding and future development.

2 Related Works

Recent studies have explored the reasoning capabilities of LLMs, with several investigations underway to understand (Qin et al., 2023; Bang et al., 2023; Liu et al., 2023; Xu et al., 2023; bench authors, 2023; Bao et al., 2023), enhance (Wei et al., 2022b; Imani et al., 2023), and leverage (Yao et al., 2023b; Sha et al., 2023) these abilities for various applications. Some critics argue that the datasets used for evaluation are overly simplistic and potentially compromised by inclusion in the training data of LLMs (OpenAI, 2023; Wei et al., 2023), casting doubt on the authenticity of these purported capabilities (Valmeekam et al., 2022; Bao et al., 2023). In response, new tasks and evaluation frameworks

Figure 1: An example of Minesweeper on a 9×9 board containing 10 mines, along with its interaction format. Subfigure 1a displays the game's GUI; Subfigure 1b shows a plain-text, table-formatted representation of the game board, enhanced with color for improved visualization; Subfigure 1c depicts the coordinate-based plain-text representation of the board; and Subfigure 1d provides a log of the player's (in this case, the first author's) actions, where "`L`", "`R`", and "`M`" denote left-click, right-click, and middle-click actions, respectively.

have been suggested (Valmeekam et al., 2022; Xu et al., 2023; Bao et al., 2023; Vervoort et al., 2023; Wang et al., 2023a). However, these tend to focus narrowly on specific aspects of arithmetic or commonsense reasoning, often presented in unstructured natural language that intersects with LLMs' pre-existing world knowledge. This overlap presents a challenge in fully assessing LLMs' inductive reasoning abilities. In contrast, the game of Minesweeper encompasses symbolic, arithmetic, and commonsense reasoning in a structured format lying outside the scope of LLMs' training data, and thus demands genuine reasoning skills for successful resolution.

Alone another track, the use of LLMs in gameplay has gained attention, with efforts to harness them for diverse games such as card games (Gupta, 2023; Guo et al., 2023), interactive narrative games (Callison-Burch et al., 2022; Tsai et al., 2023; Cui et al., 2023; Zhu et al., 2023a), chess (Noever et al., 2020; Stöckl, 2021; Suzgun et al., 2023; Feng et al., 2023), and video games like Minecraft (Wang et al., 2023a,b). Nonetheless, we contend that such games are intrinsically distinct from Minesweeper in both structure and the level of challenge they pose to LLMs. Card and interactive narrative games largely draw on common sense and narrative understanding, with a constrained range of actions. This limitation can obscure whether LLM decisions stem from deep reasoning or instinctual response. Chess, while offering a more extensive range of possibilities, presents an abstract playfield that typically requires tailored pre-training for LLMs to grasp its rules. Minecraft poses a further challenge with its complex syntax and the need for meticulous, often biased, prompt engineering, making it an impressive display but not an accurate indicator of LLMs' functional application. Minesweeper, by comparison, offers a straightforward yet strategically rich gameplay experience with clear objectives and direct evaluation criteria, making it an exemplary model for assessing the practical reasoning capabilities of LLMs.

3 Minesweeper

Minesweeper, a classic logic game, has been a part of the Windows operating system since around 1990s. Though the rule is simple, it features a rich and discrete action space, a clear goal, and direct feedbacks and evaluation metrics. The objective is straightforward: players must unveil all cells on a board peppered with hidden mines without detonating any. Each cell on the board can exist in one of four possible states (Figure 1b):

- **Unopened** ("?"): The state of these cells is unknown; they could transition into any of the other three states.
- **Numbered** ("1" to "8"): These cells reveal the count of adjacent mines, including diagonals, providing critical clues for safe navigation.
- **Blank** ("."): These cells have no adjacent mines, often opening up larger areas of the board.
- **Flagged** ("F"): Cells suspected to contain mines are marked accordingly for safety.

Notably, the choice of symbols is arbitrary and should not impact the model performance, as they serve as mere representations of concepts.

During gameplay, players may execute one of three actions per turn: left-click ("`L`") to reveal a cell's contents, right-click ("`R`") to flag a suspected mine, and middle-click ("`M`") to verify the correctness of flagged cells based on adjacent numbers. On a beginner's 9×9 board (Figure 1a), this results in 243 potential actions per round (Figure 1d), creating an extensive action landscape despite numerous actions being invalid (as listed in Table 3). The game provides immediate feedback for each action, with outcomes ranging from revealing or flagging cells to error messages, game endings or victories, allowing models to adjust their strategies in real-time. Victory is reached by correctly identifying and flagging all mines or revealing all non-mine cells, whereas failure occurs upon missteps such as erroneous left-click on mines or incorrect flag placements during middle-click verifications. With action space and game objective established, metrics such as the proportion of valid moves, the percentage of successfully solved games, and the average number of moves to resolve a board can be readily computed. In summary, Minesweeper serves as a less knowledge-intensive, more symbol-comprehension and basic math-reasoning benchmark, pivoting on spatial reasoning over pure information retrieval.

We employ two plain-text formats to present the game board when interacting with LLMs, aiming to understand LLMs' capabilities of comprehending each of them and to reduce the potential influence of input format on the reasoning process. The first format is **table representation**, depicted in Figure 1b. Here, the game board is portrayed as a table with the states of each cell enclosed in LaTeX-style quotation marks (grave accent "`` ` `` " and apostrophe "`'`") to differentiate them from the cell indices and separators. Rows and columns are delineated by line break "`\n`" and comma "`,`" respectively, with indices for the first row and column serving as the coordinates for the cells. This format is intuitive for human interpretation; LLMs equipped with capabilities to understand tables, as suggested by the literature (Chen, 2023; Singha et al., 2023), should process it similarly. For comparison, we also employ **coordinate representation** (Figure 1c). It explicitly associates each cell's coordinates with its state in the form of a look-up table, potentially offering a more direct description for LLMs to comprehend the board's configuration.

The following sections first explore two critical skills required for Minesweeper agents (§ 4). Then, they evaluate the proficiency of LLMs in playing Minesweeper, detailing objective scores and case studies that highlight their reasoning and planning capabilities (§ 5). Each section begins with a brief introduction of the experimental setup, with comprehensive details available in appendix A.

Task	Representation	3.5-16k	3.5-instr
Board Navigation	table	66.7	53.3
	− ids	63.7	40.7
	+ example	64.3	47.0
	+ verification	66.3	-
	coordinate	82.3	66.7
	+ example	**89.7**	61.0
Neighbor Counting	table	33.3	16.7
	coordinate	**37.3**	30.3

Table 1: Comparative analysis of GPT-3.5 variants in board understanding tasks. The performance are quantified using exact-matching accuracy percentages. The notation "− ids" indicates the omission of indices in the table representation, while "+ example" denotes the inclusion of additional examples in the prompts. The "+ verification" symbol refers to the application of the self-verification technique as described in (Weng et al., 2022). As GPT-3.5-instruct is not optimized for conversational contexts, the self-verification is not applicable.

4 Board Understanding

4.1 Experiment Setup

A fundamental skill for LLMs in Minesweeper is the ability to comprehend the game board. To assess this capability, we conducted two types of straightforward experiments: **board navigation** and **neighbor counting**. In board navigation, LLMs are presented with a game board and a specific coordinate, and they are tasked to identify the corresponding cell state. For neighbor counting, LLMs are given an additional arbitrary state from the set {`` `?' ``, `` `. ``, `` `1' ``, `` `2', ``} and are required to calculate the number of occurrences of this state (ranging from 0 to 8) surrounding the provided coordinate. We annotated 100 randomly generated 9×9 boards, each containing 10 mines, with complete action steps (refer to Figure 1d). The boards were randomized at different stages of the game, either fully or partially revealed, and 3 sets of coordinates were selected randomly for the experiments.

4.2 Results

The performance of GPT-3.5-16k and GPT-3.5-instruct was evaluated using both table and coordinate representations, as shown in Table 1. With the

table representation, GPT-3.5-16k demonstrated a notable deficiency in accurately identifying the cell state, failing approximately one-third of the time in board navigation tasks. GPT-3.5-instruct showed even lower performance. Attempts to enhance performance through various modifications to the boards and prompts, including removing indices, adding examples, and requesting models to revise their outputs, were unsuccessful. However, with the coordinate representation, both models exhibited improved results. This suggests that the challenge of interpreting tables might be a limiting factor for the models in subsequent gameplay tests. Nonetheless, GPT-3.5 displayed a failure rate of over 10%, which is suboptimal given that the task essentially involves copying and pasting values in coordinate-state mappings. In neighbor counting tasks, both models achieved a maximum accuracy of about one-third, significantly better than random guessing. This indicates that GPT-3.5 models possess basic arithmetic and geographical planning skills, which are essential for Minesweeper. These findings suggest that the models have a moderate level of board understanding, which is sufficient to not severely impede the gameplay tests that follow.

5 Minesweeper Gameplay

5.1 Experiment Setup

In our study, we utilize 5×5 Minesweeper boards containing 4 hidden mines, a setup less complex than the conventional beginner level. LLMs are instructed to start the game by left-clicking the center cell and then proceed with either left, right, or middle-click actions on cells they assess as beneficial for advancing gameplay. We craft and annotate 100 boards for GPT-3.5 models, ensuring the initial left-click would reveal at least 10 cells (40% of the board). This strategy aims to streamline the length of the prompts and minimize the number of interactive rounds required. For GPT-4, we randomly subsample 10 boards from the pool to reduce the experiment time and expense.

Prompting techniques such as chain-of-thought reasoning (Wei et al., 2022b) and few-shot in-context learning (appendix A.3) are employed to activate the LLMs' reasoning capabilities and provide sufficient information for decision-making. Each game session permits a maximum of 10 actions per board, concluding either when the model achieves victory, triggers a mine, or produces unrecognizable responses. Given that human annotators, on average, complete each board with an average of 6.14 actions, we deemed a 10-action limit adequate for the model to effectively resolve most boards, contingent on its reasoning ability.

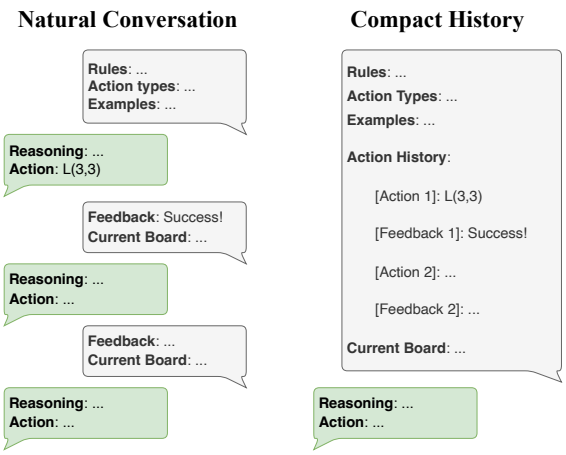

Figure 2: Interaction prompting modes. The "Natural Conversation" mode encompasses the full interaction history, whereas the "Compact History" mode condenses the actions generated by the LLM and the game's feedback into a succinct, unified prompt.

To balance the influence of prompt details and accommodate models with shorter prompt constraints, our study introduces two distinct prompting approaches: 1) **Natural Conversation** (NC) mode, and 2) **Compact History** (CH) mode, as illustrated in Figure 2. In the NC mode, each game commences with a detailed explanation of rules and examples. During each round, we prompt LLMs to execute actions along with their associated reasoning. The game system then provides feedback on these actions and updates the board in a new user message, while maintaining the complete history of the interaction. CH mode, on the other hand, condenses all relevant information and interaction history into a concise, singular prompt, eliminating the need for extensive conversational details. This approach significantly shortens the length of the conversation history. Given the turn-based nature of Minesweeper, the CH mode is effective in providing all vital information required for the model to make well-informed decisions.

5.2 Metrics

The evaluation of our model's performance is anchored in objective metrics, which encompass: the count of valid actions, the accurate identification of mines, the number of successfully completed games, and the logical coherence of reasoning

	Human	3.5-16k (NC)		3.5-16k (CH)		3.5-instr (CH)		4 (NC)	
	GUI	Table	Coord	Table	Coord	Table	Coord	Table	Coord
Game Outcome									
# Total Games		100						10	
• % Solved (↑)	89.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0	0.0
• % Failed (↓)	11.0	17.0	35.0	17.0	35.0	19.0	41.0	70.0	70.0
Mine Identification									
# Total Mines		400						40	
• % Flagged (↑)	93.0	2.8	11.7	8.0	9.5	11.7	23.3	30.0	45.0
Action Accuracy									
# Total Actions	514	825	679	700	687	813	642	41	52
• % Valid (↑)	99.6	7.2	22.4	15.7	22.6	24.1	64.6	82.9	82.7
• % Repeated (↓)	5.1	43.6	44.6	42.3	45.3	39.4	19.9	0.0	0.0
Reasoning Soundness									
# Selected Reasoning Chains	-	34	38	45	39	45	45	25	38
• % Valid Actions (↑)	-	61.8	81.1	46.7	59.0	80.0	95.6	88.0	84.2
• % Accurate and Coherent Logic (↑)	-	0.0	0.0	0.0	0.0	0.0	0.0	12.0	26.4

Table 2: The comparison of GPT model variants, prompting modes, and board representation formats on 5×5 boards with 4 mines. "#" indicates the number of instances; "%" represents the percentage ratio. The initial action, `L(3,3)`, is consistently excluded from the count. GPT-3.5-instruct is prompted using the compact history mode, as it is not optimized for chat-based interactions. The terms "Table" and "Coord" in the table refer to the table-format and coordinate-format representations of the Minesweeper board, respectively. The percentages of solved and failed cases do not sum to 100% due to instances where the game was not completed within 10 steps. The repetition is calculated independently for each board.

chains. A "valid" action is one that advances gameplay without activating a mine. Table 3 details a broad spectrum of negative examples. The metric for correctly flagged mines is based on the quantity of mines identified by the model that align with the actual mine locations at the game's conclusion. A game is deemed "solved" when all mines are accurately marked and no extraneous cells are flagged. To assess the reasoning chains, we initially select 5 game boards where each model executed the highest number of valid actions. We then perform a manual inspection to ensure these chains are logically sound and directly pertinent to the gameplay. Due to the variable action counts across different models and boards, the totals of actions and reasoning chains differ, as Table 2 illustrates.

5.3 Results and Discussion

Table 2 showcases the performance comparisons between various GPT family models and a human benchmark, focusing on valid actions, correctly identified mines, completed games, and logical reasoning chains. In line with the findings on board comprehension, models utilizing coordinate representation exhibit superior performance across all metrics compared to table representation. This supports our previous assertion that LLMs struggle with tables containing symbols not found in their training data, preferring familiar in-domain terminology as evidenced in the studies by Chen (2023) and Singha et al. (2023).

Objective Scores In assessing specific gameplay metrics, we first focus on three main areas: Game Outcomes, Mine Identification, and Action Accuracy. Among the GPT-3.5 variants, 3.5-instruct demonstrates better overall performance compared to 3.5-16k in these metrics, albeit with a marginally increased failure rate, which diverges from the board understanding results. A detailed analysis of GPT-3.5-instruct's *initial* move reveals a consistent anomaly: the model persistently selects the `R(2,2)` action, contrary to the given instruction of `L(3,3)` (refer to Table 3 for invalid actions and Listing 5, Line 83 for the specific prompt). After receiving feedback, it switches to the `L(1,1)` action. This action often uncovers fewer cells in our specially selected boards, usually just the chosen cell itself (as illustrated in Figure 3), which increases the probability of the next action being valid. This be-

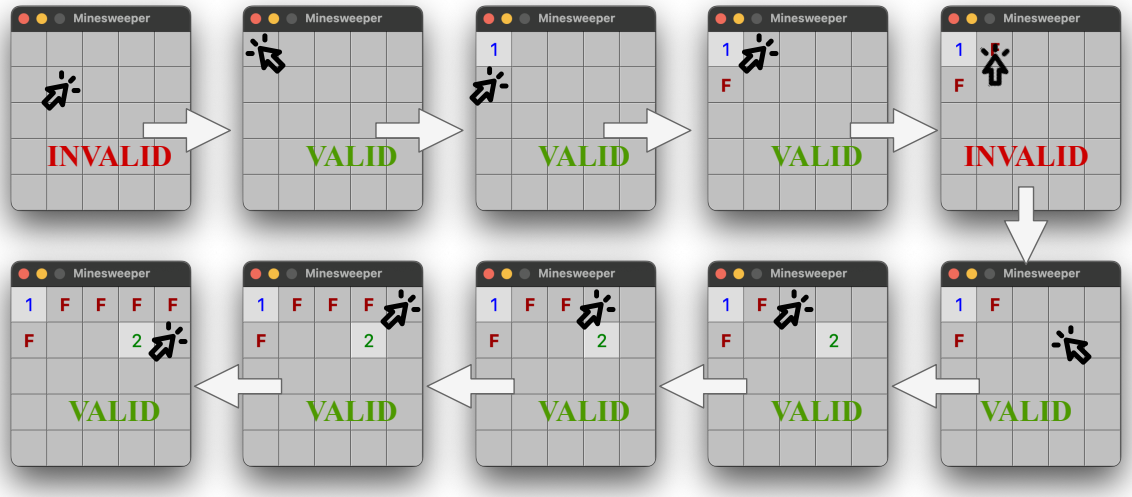

Figure 3: A detailed analysis of the example interactions performed by GPT-3.5-instruct. Arrows oriented to the left and right signify left and right mouse clicks, respectively. The arrow pointing upwards represents a middle-click. The majority actions are technically allowed but do not effectively advance the gameplay.

```
```
>> ASSISTANT (gpt-3.5-turbo-16k):
REASONING:
Looking at the current board, we can see that the cell at (2,4) has a number `4', indicating that there are four mines in its neighboring cells. Out of these neighboring cells, three are already opened, and one remains unopened at (1,4). Since there are four mines in total, it is logical to deduce that the unopened cell at (1,4) contains a mine. Therefore, our next move is to flag the cell at (1,4) with a right-click.

ACTION:
R(1,4)
```

havior could also explain the higher failure rate and lower repeatance rate observed in GPT-3.5-instruct compared to the 3.5-16k model. Furthermore, GPT-3.5-instruct tends to make conservative moves by flagging all cells on the board, which accounts for its inability to solve any board despite having a higher ratio of flagged mines. Overall, all GPT-3.5 models present a noticeable pattern of repetitive actions during board solving, persisting even with direct instructions to avoid repetition (see Listing 5, line 29). This repetitive behavior suggests a significant limitation in the models' capacity to fully understand and reason about the nuanced variations occurring on the board at each turn. As Transformer-based models designed primarily for next-token prediction (Vaswani et al., 2017), their focus likely remains on static aspects of cell states, overlooking subtle changes. This attentional bias, compounded by the lack of pre-training on tasks resembling this one, often leads to the repeated execution of identical actions.

In contrast, GPT-4 exhibits a marked improvement in following instructions, achieving a zero rate of repetition while maintaining a high frequency of valid actions. Notably, it flags the most mines, despite not solving any board and recording a high percentage of game failures, which is partly attributed to its tendency for divergent actions. When both operated in NC mode, GPT-4 is more prone to generating unrecognizable actions compared to GPT-3.5-16k, as illustrated in Figure 5, even when the conversation history is within the token limit. A plausible interpretation of this behavior is that GPT-4 demonstrates heightened sensitivity to recent changes in board states, allocating more attention to these immediate alterations. Conversely, it appears to pay less regard to the more distant historical context, where the constraints governing action formats are established.

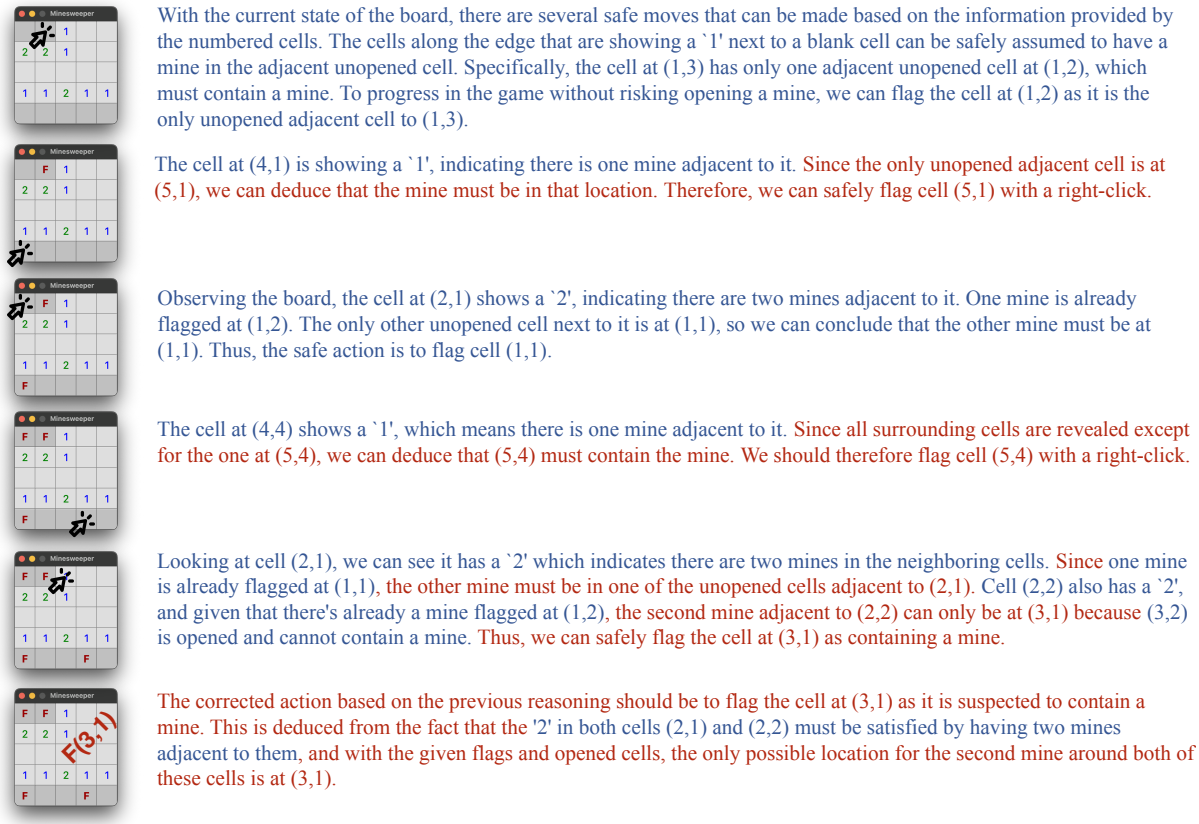

Figure 5: This figure presents a case study of the reasoning sequences formulated by GPT-4 with coordinate board representation during action planning. The GUI on the left shows the board states and actions taken by the agent during the game. Elements highlighted in blue represent accurate facts and logical inferences as assessed by human evaluation, while those marked in red indicate incorrect observations or illogical conclusions. Notably, the final generated action "`F(3,1)`" deviates from the permissible action formats, resulting in the termination of the game.

Reasoning Chains The foregoing discussion highlights that merely counting valid actions is not an adequate measure of the models' reasoning skills. Therefore, we shift our focus to the logical coherence of their reasoning chains. A review of the final section in Table 2 reveals that the GPT-3.5 variants struggle to generate coherent reasoning. For instance, in a typical case from GPT-3.5-16k, shown in Figure 4, the model correctly identifies cell `4'at (2,4) and understands that there are four mines around, but fails to grasp the concept of "neighboring cells" or to accurately count the surrounding cell states, as indicated by the statement marked in red. Furthermore, the statement in golden font is not well-grounded, making it challenging to discern any logical connection between its first and second halves. This sentence appears more like an unsuccessful attempt to replicate our in-context example "*Given that there's just one adjacent mine, it's logical to deduce that the unopened cell at (2,3) contains the mine*" (refer to Listing 5, Line 51) rather than a display of genuine reasoning. While this example is specifically for GPT-3.5-16k, similar errors are prevalent across all GPT-3.5 outputs. It appears that despite possessing a certain degree of individual capabilities in elementary symbolic understanding, geographical reasoning, and arithmetic calculation, as suggested by the board understanding results, the GPT-3.5 models fall short in integrating these skills cohesively for action planning, resulting in a fragmented reasoning chain.

GPT-4 exhibits more encouraging results compared to its predecessors. While its achievements are modest, GPT-4 demonstrates a certain level of logical understanding in this unfamiliar task, suggesting an ability to grasp the game's rules and dynamics beyond mere replication. To explore the extent and origin of this reasoning, we delve deeper into GPT-4's reasoning chains, analyzing a representative case in Figure 5. It shows that GPT-4 can logically reason if the number of neighboring un-

opened cells equals the remaining unflagged mines near a numbered cell, specifically in simple scenarios like `1'and `2', and particularly around the board's corners (*e.g.*, (1,2) or (5,4)). Yet, even in such basic situations, GPT-4 shows around 50% fails. The model struggles particularly with configurations where exactly three unopened cells surround a `3'cell and other complex setups, as seen in the lower rows of the example. To determine if GPT-4's ability stems from the rules or the examples, we conducted a control experiment by omitting Example 1 from the initial prompt (Listing 5, Line 43), which closely mirrors the successful scenarios and is the sole example of left-clicking. This led to a dramatic 90% reduction in coherent reasoning with the coordinate board representation, indicating the significant role of examples in GPT-4's reasoning process, likely by providing a familiar context for reference and imitation.

Another notable point from Figure 5 is GPT-4's non-linear action sequence. For a human player, following the initial action of R(1,2), the logical next step would be to mark the adjacent unopened cell as a mine, *i.e.*, R(1,1). However, GPT-4 instead opts for R(5,1), an irrational choice that strays from the focus of the previous action, before returning to (1,1). This behavior suggests that GPT-4 might not fully consider its historical actions and lacks the capability for long-term, multi-step planning, a crucial aspect in evaluating an agent's intrinsic reasoning abilities as opposed to mere summarization capabilities.

It is important to note that the results discussed were derived from experiments conducted on 5×5 boards, and it is reasonable to anticipate that performance may further deteriorate on larger boards with more flexible mine arrangements.

6 Conclusion

In this study, we assessed the capabilities of LLMs in solving logical puzzles by examining their performance in the game Minesweeper, a task for which they have received limited exposure during the pre-training phase. This approach aims to assess the intrinsic reasoning capabilities of LLMs. Our experiments reveal that GPT-3.5 models exhibit basic abilities in spatial navigation, symbol recognition, and counting. However, they struggle with multi-step planning and generating coherent reasoning chains. GPT-4 shows improvement in simpler scenarios with shorter logic chains but still encounters issues with hallucinations and inconsistent context awareness. We find that GPT-4 can learn from examples and apply this knowledge to similar situations but is less adept at deducing underlying rules and applying them to novel scenarios, unlike GPT-3.5 models which tend to replicate examples. Our conclusion seems to be in correlation with Yadlowsky et al. (2023): LLMs do not produce new knowledge (a situation where logical reasoning is necessary); they are just (good) handlers of existing experience.

We do not intend to diminish the significance of LLMs or their transformative impact on natural language processing. Rather, we believe it is premature to consider LLMs as an intelligent object and a threat to human society. They resemble a comprehensive dictionary, useful for reference but lacking in comprehension. We hope that our work can inspire future research on this topic, and we will continue exploring the capabilities of LLMs.

Limitations

In our study, we employed two board representation methods: table and coordinate representations. Our results indicate that coordinate representation is more effective for LLM comprehension and offers a wider range for evaluating the model's reasoning abilities. However, we did not explore other board representation methods, such as different table formats (*e.g.*, HTML, Markdown) or image-based approaches. According to Singha et al. (2023), alternative table formats may not significantly differ in effectiveness from our chosen method. Still, it's possible that other representations could be more suitable for our specific context. Moreover, our initial attempts to use an image-based Web interface with board GUI were not successful. Therefore, we focus on text-based representations in this study. While advanced prompting methods like Program of Thoughts (PoT, Chen et al., 2022) or Tree of Thoughts (ToT, Yao et al., 2023a) may boost performance, their use could divert from assessing the true reasoning abilities of LLMs and their applicability in simplifying complex issues without extensive external input. Hence, we deferred the application of these sophisticated techniques to future studies.

Another area for exploration is fine-tuning LLMs like Llame-2-70b (Touvron et al., 2023) with specific reasoning capabilities on our dataset labeled with human actions. The idea is that if a fine-tuned

model outperforms the original or GPT-4 when the fine-tuning and testing data match in terms of symbol usage, board size, and representation, and does not improve with variations in these factors, we can infer that the "reasoning capability" is tied to the training data and not broadly generalizable. However, due to constraints in computational resources, we haven't conducted these experiments, leaving them for future research.

At last, we would like to emphasize that we can easily extend the Minesweeper dataset to a scale of $\binom{n_{\text{row}} \times n_{\text{column}}}{n_{\text{mine}}}$ with zero effort. Nonetheless, we keep a relatively small scale of test cases as it is sufficient to support our conclusion. With the future development of LLMs, a larger evaluation set might be desired for a more robust and unbiased objective metric-based evaluation.

A Experiment Setup

A.1 GPT Versions

In this paper, we discuss three distinct versions of the GPT model: GPT-3.5-16k, GPT-3.5-instruct, and GPT-4. The term GPT-3.5-16k is used to denote the "gpt-3.5-turbo-16k" model as listed on the OpenAI API model webpage, specifically the checkpointed 0613.[1] The GPT-3.5-instruct model refers to the "gpt-3.5-turbo-instruct" variant, with the checkpoint version dated 2023-09-15. Lastly, GPT-4 represents the "gpt-4" model, utilizing also the 0613 checkpoint version. All mentioned checkpoints are hosted on Microsoft Azure,[2]. The model temperature is set to 0 in all cases.

A.2 Board Understanding

In our board understanding experiments, we initially generate 1,000 randomly arranged boards, each featuring a 9×9 grid with 10 hidden mines. Notably, the central cells, positioned at `(5,5)`, are always mine-free. From this pool, we select 100 boards, ensuring that the initial click at the center `L(5,5)` reveals at least 10 cells. Subsequently, we conduct gameplay using the graphical user interface depicted in Figure 1a. The actions of the annotators, who are average players in Minesweeper and unaware of the board's layout beyond the initial instruction to click the center, are recorded as shown in Figure 1d. Although not all trials are successful——with about 90% boards being solved and the remainder failing due to human errors or 50-50 guesses——the entire action history, including unsuccessful attempts, is preserved for analysis.

For each board, we randomly choose an action (excluding the first and last from the history) and associate board state as the focus. We then select 3 random coordinates per board, setting two challenges for LLMs: to determine the status of each selected cell (board navigation), and to count the number of specific symbols within {`` `?' ``, `` `. ``, `` `1' ``, `` `2' ``} in their neighbors, including diagonally adjacent ones (neighbor counting). This process yields 300 test cases for each task.

As outlined in § 4, we employ two distinct board representations: table and coordinate. Each required a slightly different approach in prompting. Specifically, the table representation uses LaTeX-style quotation marks, while the coordinate representation does not use quotations for board cell states and employs regular double quotes in the necessary positions in the game description. Examples illustrating these differences are provided below.

Listing 1: An example of board navigation prompting with table representation.

```
You will be presented with a 9 by 9 board for the Minesweeper game. The board is wrapped in a 10 by 10 table, where the first row and the first column with numbers in double quotation marks are the row and column indices. A coordinate (x,y) represents the cell at the x-th row and y-th column, where x and y, starting from 1, are the row and column indices, respectively. The state of each cell is represented by the following symbols:
- `.' represents a blank cell.
- `1' to `8' represents numbered cells with that number of mines in the adjacent cells.
- `F' represents a flagged cell.
- `?' represents an unopened cell.

--- EXAMPLES ---
--- PARTIAL BOARD ---

"7",`?',`?',`?',`?',`?',`?',`?',`?',`?'
"8",`?',`?',`?',`?',`?',`?',`?',`?',`?'
"9",`?',`?',`?',`?',`?',`?',`?',`?',`?'

QUESTION: What is the cell at coordinate (2,1)?
ANSWER:
```

Listing 2: An example of board navigation prompting with coordinate representation.

```
You will be presented with a 9 by 9 board for the Minesweeper game, which is devided into cells. The cells are presented as "coordinate: state" mappings. A coordinate (x,y) represents the element at the x-th row and y-th column, where x and y, starting from 1, are the row and column indices, respectively. The state of each cell is represented by the following symbols:
- "." represents a blank cell.
- "1" to "8" represents numbered cells with that number of mines in the adjacent cells.
- "F" represents a flagged cell.
- "?" represents an unopened cell.

QUESTION: What is the cell at coordinate (2,1)?
ANSWER:
```

Listing 3: An example of neighbor counting prompting with table representation.

```
You will be presented with a 9 by 9 board for the Minesweeper game. The board is wrapped in a 10 by 10 table, where the first row and the first column with numbers in double quotation marks are the row and column indices. A coordinate (x,y) represents the cell at the x-th row and y-th column, where x and y, starting from 1, are the row and column indices, respectively. The state of each cell is represented by the following symbols:
- `.' represents a blank cell.
- `1' to `8' represents numbered cells with that number of mines in the adjacent cells.
- `F' represents a flagged cell.
- `?' represents an unopened cell.

--- EXAMPLES ---
--- PARTIAL BOARD ---
"0","1","2","3","4","5"
"1",`?',`?',`?',`?',`?'
"2",`?',`?',`?',`?',`?'
"3",`?',`?',`?',`1',`1'
"4",`?',`?',`?',`1',`.'
"5",`?',`?',`?',`1',`.'

QUESTION: How many cells `F' are neighbors (including diagonal) of the cell with coordinate (2,1)?
ANSWER:

To find out how many cells with the value `1' are neighbors of the cell with coordinate (2,1), we need to look at the 8 neighboring cells of (2,1). These coordinates are:
(1,1), (1,2), (3,1), (3,2), (2,2).

Now, we will check the values of these cells on the given Minesweeper board:

(1,1) = `?'
(1,2) = `?'
(3,1) = `?'
(3,2) = `?'
(2,2) = `?'

All of these neighboring cells are `?'. So, the number of cells with `1' that are neighbors of the cell (2,1) is:

ANSWER: 0.

--- END OF EXAMPLES ---

--- CURRENT BOARD ---

QUESTION: How many cells "1" are neighbors (including diagonal) of the cell with coordinate (2,1)?
Let's think step by step.
ANSWER:
```

In our analysis of the prompts, we employ the Chain-of-Thought (COT) technique, as described by Wei et al. (2022b), for the neighbor counting task but not for board navigation. The rationale behind this is that neighbor counting necessitates multi-step action: initially identifying the neighboring cells of a given target cell and subsequently tallying a specific symbol within these neighbors.

In contrast, the board navigation task is straightforward, involving a direct query about a specified target cell. We have observed that incorporating COT into the neighbor counting process notably enhances its performance.

Furthermore, we have made the inclusion of in-context examples optional for the board navigation task, but mandatory for neighbor counting. The need for examples in neighbor counting arises from the models' propensity to generate unclear outputs in this task. By providing an example, we aim to guide the models towards producing more interpretable responses.

A.3 Minesweeper

The detailed setup of the Minesweeper experiment is presented in § 5. We hereby provide the actual initial prompts with table-formatted board representation used in our experiments. The coordinate representation closely mirrors the variations found in Listing 3 and Listing 4 and will not be omitted.

Listing 5: Initial prompt for Minesweeper gameplay.

```
>> SYSTEM:
You are a helpful assistant who is good at playing Minesweeper.

>> USER:
--- MINESWEEPER INTRODUCTION ---
In Minesweeper, 4 hidden mines are scattered throughout a 5 by 5 board, which is divided into cells. The rows are seperated by newlines, and columns by commas. The board is structured as a 6 by 6 table, with the first row and column labeled using numbers in double quotation marks to indicate row and column indices. Cells have multiple possible states:
- Unopened cells (represented by `?', which cover the board at the start of the game, can also be made by removing flags)
- Numbered cells (represented by `1' to `8', which indicate the number of mines in the eight neighboring cells, including those diagonally adjacent)
- Blank cells (represented by `.', which have no neighboring mines)
- Flagged cells (represented by `F', which are marked by the player to indicate a potential mine location)

A player selects a cell to open it. If a player opens a cell containing a mine, the game ends in a loss. Otherwise, the opened cell displays either a number, indicating the number of mines diagonally and/or adjacent to it, or a blank tile (sometimes shown as a 0), and all adjacent cells will automatically be opened. To win a game of Minesweeper, all non-mine cells must be opened without opening a mine.

--- ACTION OPTIONS ---
There are three permissible actions in Minesweeper:

- Left-click an unopened cell (`?') to reveal it.
- Right-click an unopened cell (`?') to place a flag or a flagged cell (`F') to remove the flag.
- Middle-click on a numbered cell (`1' to `8') to unveil its neighboring cells, but only if all adjacent mines have been correctly flagged. If any flags are misplaced, you'll lose the game.

--- ACTION FORMAT ---
Each of your actions should be formatted as "A(row, col)", where:
- "A" represents the action type: "L" denotes a left-click, "R" indicates a right-click, and "M" signifies a middle-click.
- "row" specifies the row number of the targeted cell.
- "col" details the column number of the targeted cell.
For instance, an action like "L(1,2)" translates to a left-click on the cell located at the first row and second column.

please ensure:
- You do not duplicate actions.
- You submit only one action at a time.

--- CURRENT BOARD ---
```
"0","1","2","3","4","5"
"1",`?',`?',`?',`?',`?'
"2",`?',`?',`?',`?',`?'
"3",`?',`?',`?',`?',`?'
"4",`?',`?',`?',`?',`?'
"5",`?',`?',`?',`?',`?'
```

--- EXAMPLES ---
Example 1:
--- PARTIAL BOARD ---
```
"0","1","2","3","4"
"1",`.',`1',`?',`?'
"2",`.',`1',`?',`?'
"3",`.',`1',`2',`4'
"4",`.',`.',`.',`2'
```

REASONING: The cell located at (3,2) displays the number `1', indicating there's a single mine in its neighboring cells. Among these neighbors, 7 are opened as empty or numbered, and only one remains unopened at (2,3). Given that there's just one adjacent mine, it's logical to deduce that the unopened cell at (2,3) contains the mine. Thus, our next move is to flag the cell at (2,3) with a right-click.

ACTION: R(2,3)

Example 2:
--- PARTIAL BOARD ---
```
"0","4","5","6","7"
"1",`.',`1',`?',`?'
"2",`.',`1',`F',`?'
"3",`.',`1',`2',`4'
"4",`.',`.',`.',`2'
```

REASONING: The cell at (1,5) displays the number `1', indicating a single adjacent mine. Upon examining its neighboring cells, only the cell at (2,6) is flagged with `F'. This suggests that all mines neighboring (1,5) have been identified. Consequently, we can safely unveil the other surrounding cells by middle-clicking on (1,5).

ACTION: M(1,5)

Example 3:
--- PARTIAL BOARD ---
```
"0","1","2","3","4"
"1",`1',`1',`2',`?'
"2",`?',`?',`?',`?'
"3",`?',`?',`?',`?'
```

REASONING: The cell at (1,1) indicates there's a single mine amongst its neighbors. Examining the cells adjacent to it, both (2,1) and (2,2) remain unopened, implying one of them contains a mine. Similarly, the cell at (1,2) displays a `1', suggesting that out of (2,1), (2,2), and (2,3), one holds a mine. Since one of (2,1) or (2,2) already contains a mine, it becomes evident that (2,3) is mine-free. We can then safely uncover (2,3) with a left-click.

ACTION: L(2,3)
```

Type of Invalid Actions	Example	Feedback
	Coordinate	
Coordinate Out of Bound	"`L(0,10)`" on a 9×9 board	Invalid Coordinates! Please make sure your coordinate are within [1, 9] for rows and [1, 9] for columns.
	Game Initialization	
Starting by Right-Clicking	"`R(5,5)`" on a new board	Please begin by left-clicking on the center cell.
Starting by Middle-Clicking	"`M(5,5)`" on a new board	Please begin by left-clicking on the center cell.
	Left-Clicking	
Left-Clicking on Blank Cell	"`L(5,5)`" where (5,5) is opened as `` `.' ``	Invalid action: Cannot left-click a blank cell. Left-click is only for unopened cells (`` `?' ``).
Left-Clicking on Flagged Cell	"`L(5,5)`" where (5,5) is flagged as `` `F' ``	Invalid action: Cannot left-click a flagged cell. Left-click is only for unopened cells (`` `?' ``).
Left-Clicking on Numbered Cell	"`L(5,5)`" where (5,5) is opened as `` `2' ``	Invalid action: Cannot left-click a numbered cell. Left-click is only for unopened cells (`` `?' ``).
	Middle-Clicking	
Middle-Clicking on Blank Cell	"`M(5,5)`" where (5,5) is opened as `` `.' ``	Invalid action: Cannot middle-click a blank cell. Middle-click is only for numbered cells (`` `1' `` to `` `8' ``).
Middle-Clicking on Flagged Cell	"`M(5,5)`" where (5,5) is flagged as `` `F' ``	Invalid action: Cannot middle-click a flagged cell. Middle-click is only for numbered cells (`` `1' `` to `` `8' ``).
Middle-Clicking on Unopened Cell	"`M(5,5)`" where (5,5) is unopened (`` `?' ``)	Invalid action: Cannot middle-click an unopened cell. Middle-click is only for numbered cells (`` `1' `` to `` `8' ``).
Middle-Clicking When Numbered Cell Has no Flagged Neighbor		Error: No flagged cells detected nearby. Flag adjacent mines before middle-clicking.
Middle-Clicking When # Flagged Neighbor Mismatchs Cell Number		Error: Flag count mismatch. Ensure all adjacent mines are flagged before middle-clicking.
	Right-Clicking	
Right-Clicking on Blank Cell	"`R(5,5)`" where (5,5) is opened as `` `.' ``	Invalid action: Cannot right-click a blank cell. Right-click is only for unopened cells (`` `?' ``) or flagged cells (`` `?' ``).
Right-Clicking on Numbered Cell	"`R(5,5)`" where (5,5) is opened as `` `1' ``	Invalid action: Cannot right-click a numbered cell. Right-click is only for unopened cells (`` `?' ``) or flagged cells (`` `?' ``).

Table 3: Types and feedbacks for invalid actions.

```
--- END OF EXAMPLES ---

--- RESPONSE GUIDE ---
Let's think step by step.

Begin by detailing your rationale in the "REASONING"
     section, followed by specifying your move
    using the previously mentioned format in the "
    ACTION" section. Ensure your reasoning doesn't
    exceed 200 words. To commence the game, left-
    click the center cell at (3, 3).

REASONING:
ACTION:
```

In subsequent iterations, the prompts are modified based on the model's responses. When the model generates a valid action, the updated game board is presented, followed by a request for the model to initiate the next move. In contrast, if the action is invalid, an error message is displayed, prompting the model to select an alternative action. Table 3 enumerates the various types of invalid actions and their corresponding feedback tailored for LLMs. Note that these actions do not directly violate the game rules. Rather, they are deemed invalid within the scope of our experiments because they are logically ungrounded and do not contribute to the progression of the game.

B Obfuscation and Numerical Expression

To study the impact of existing Minesweeper-related description within LLMs' training materials, we conduct additional experiments to assess the impact of varying the game descriptions and the representation of numerical values on the performance of the model. In the obfuscation experiment, we replaced all instances of "Minesweeper" with descriptions of a generic logical puzzle, substituting "mine" with "thorn" and standard mouse-click

	Original Representation		Game Obfuscation		Numerical Expression	
	Table	Coord	Table	Coord	Table	Coord
# Total Games	100					
% Solved	0	0	0	0	0	0
% Failed	17	35	13	47	15	41
# Total Mines	400					
% Flagged Mines	2.8	11.7	4.5	13.8	7.0	14.5
# Total Actions	825	679	833	653	790	672
% Valid	7.2	22.4	7.3	28.8	9.9	28.6
% Repeated	43.6	44.6	57.5	44.1	44.6	39.7

Table 4: Ablation study on game obfuscation and numerical expressions. The results are all achieved using GPT-3.5-16k with NC mode.

actions within game description and action feedbacks with abstract symbols (*e.g.*, "L/R/M"). In the other set of experiments, Arabic numerals that indicate the numbers of surrounding mines (*e.g.*, 1,2,. . . ,8) were converted to their Roman counterparts (*e.g.*, I, II, · · · , VIII), with other elements remaining unchanged. The outcomes are summarized in Table 4. They show that these variations have minimal effect on model performance, indicating that these factors do not significantly hinder the model's reasoning abilities. Our findings suggest that the general exposure to Minesweeper game rules across the internet does not provide a distinct advantage for GPT models in solving these puzzles, and our assumption of "Minesweeper being a new challenge for GPTs" holds.

C Interaction Examples

In this section, we provide more case studies on the reasoning chains generated by LLMs as support of our discussion in § 5. **For better readability, we convert all coordinate representations to table representations.** Please refer to our GitHub repository for a complete set of experiment results.

Listing 6: An example of LLM-system interaction with table representation in NC mode from GPT-3.5-16k.

```
// Initial Instructions are Omitted

>> ASSISTANT:
REASONING: Since the board is completely covered with unopened cells, there is no specific information available to make an informed decision about which cell to open first. Therefore, I will start by randomly selecting a cell to open.

ACTION: L(3,3)

>> USER:
--- CURRENT BOARD ---
```
"0","1","2","3","4","5"
"1",`?',`?',`?',`?',`?'
"2",`?',`2',`1',`2',`?'

--- RESPONSE GUIDE ---
Let's think step by step.

Begin by detailing your rationale in the "REASONING"
     section, followed by specifying your move
     using the previously mentioned format in the "
     ACTION" section. Ensure your reasoning doesn't
     exceed 200 words.

REASONING:
ACTION:

>> ASSISTANT:

REASONING: The cell at (4,5) is a numbered cell with
     a value of "3". This indicates that there are
     three mines in its neighboring cells. Out of
     the three neighboring cells, two are already
     flagged with "F". This means that the remaining
     unopened cell at (5,3) must contain the third
     mine. Therefore, we can safely flag the cell at
     (5,3) with a right-click.

ACTION: R(5,3)
```

"5",`?`,`?`,`?`,`?`,`?`
```

please ensure:
- You do not duplicate actions.
- You submit only one action at a time.

REASONING:
ACTION:

>> ASSISTANT:
REASONING:
The cell at (2,2) indicates there are 2 mines in its neighboring cells. Since (1,1), (2,1), and (3,1) are the only unopened cells around it, we can deduce that two of these cells contain mines. Similarly, the cell at (3,2) also indicates there are 2 mines in its neighboring cells. Considering that (3,1), (4,1), and (5,1) are the only unopened cells around it, and we know that two of (1,1), (2,1), and (3,1) contain mines, we can conclude that (4,1) and (5,1) are safe to open.

ACTION: L(4,1)

Abstract

Emotion Recognition in Conversation (ERC) plays a crucial role in enabling dialogue systems to effectively respond to user requests. The emotions in a conversation can be identified by the representations from various modalities, such as audio, visual, and text. However, due to the weak contribution of non-verbal modalities to recognize emotions, multimodal ERC has always been considered a challenging task. In this paper, we propose Teacher-leading Multimodal fusion network for ERC (TelME). TelME[1] incorporates cross-modal knowledge distillation to transfer information from a language model acting as the teacher to the non-verbal students, thereby optimizing the efficacy of the weak modalities. We then combine multimodal features using a shifting fusion approach in which student networks support the teacher. TelME achieves state-of-the-art performance in MELD, a multi-speaker conversation dataset for ERC. Finally, we demonstrate the effectiveness of our components through additional experiments.

1 Introduction

Emotion recognition holds paramount importance, enhancing the engagement of conversations by providing appropriate responses to the emotions of users in dialogue systems (Ma et al., 2020). The application of emotion recognition spans various domains, including chatbots, healthcare systems, and recommendation systems, demonstrating its versatility and potential to enhance a wide range of applications (Poria et al., 2019). Emotion Recognition in Conversation (ERC) aims to identify emotions expressed by participants at each turn within a conversation. The dynamic emotions in a conversation can be detected through multiple modalities such as textual utterances, facial expressions, and acoustic signals (Baltrušaitis et al., 2018; Liang et al., 2022; Majumder et al., 2019; Hu et al., 2022b; Chudasama et al., 2022). Figure 1 illustrates an example of a multimodal ERC.

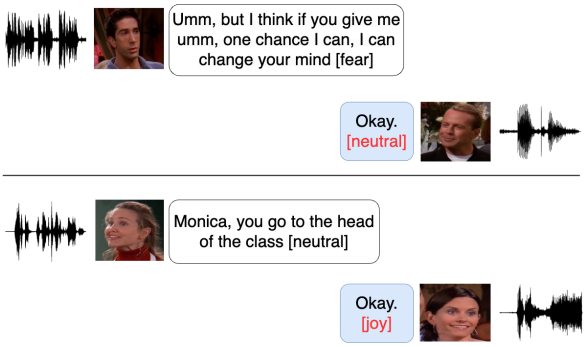

Figure 1: Examples of multimodal ERC. Even the same "Okay" answer varies depending on the conversation situation and captures emotions in various modalities.

Much research on ERC has mainly focused on context modeling from text modality, disregarding the rich representations that can be obtained from audio and visual modalities. Text-based ERC methods have demonstrated that contextual information derived from text data is a powerful resource for emotion recognition (Kim and Vossen, 2021; Lee and Lee, 2021; Song et al., 2022a,b). However, non-verbal cues such as facial expressions and tone of voice, which are not covered by text-based methods, provide important information that needs to be explored in the field of ERC. Multimodal approaches demonstrate the possibility of integrating features from three modalities to improve the robustness of ERC systems (Mao et al., 2021; Chudasama et al., 2022; Hu et al., 2022b). Nevertheless, these frameworks frequently ignore the varying degrees of impact the individual modalities have on emotion recognition and instead treat them as homogeneous components. This implies a promising opportunity to improve the ERC system by differentiating the level of contribution made by each modality.

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 82–95
June 16-21, 2024 ©2024 Association for Computational Linguistics

In this paper, we propose Teacher-leading Multimodal fusion network for the ERC task (TelME) that strengthens and fuses multimodal information by accentuating the powerful modality while bolstering the weak modalities. Knowledge Distillation (KD) can be extended to transfer knowledge across modalities, where a powerful modality can play the role of a teacher to share knowledge with a weak modality (Hinton et al., 2015; Xue et al., 2022). While Figure 2 shows the robustness of text in ERC tasks compared to the other two modalities, the other modalities present valuable information nonetheless. Thus, TelME enhances the representations of the two weak modalities through KD utilizing the text encoder as the teacher. Our approach aims to mitigate heterogeneity between modalities while allowing students to learn the preferences of the teacher. TelME then incorporates Attention-based modality Shifting Fusion, where the student networks strengthened by the teacher at the distillation stage assist the robust teacher encoder in reverse, providing details that may not be present in the text. Specifically, our fusion method creates displacement vectors from non-verbal modalities, which are used to shift the emotion embeddings of the teacher.

We conduct experiments on two widely used benchmark datasets and compare our proposed method with existing ERC methods. Our results show that TelME performs well on both datasets and particularly excels in multi-party conversations, achieving state-of-the-art performance. The ablation study also demonstrates the effectiveness of our knowledge distillation strategy and its interaction with our fusion method.

Our contributions can be summarized as follows:

- We propose Teacher-leading Multimodal fusion network for Emotion Recognition in Conversation (TelME). The proposed method considers different contributions of text and non-verbal modalities to emotion recognition for better prediction.
- To the best of our knowledge, we are the first to enhance the effectiveness of weak non-verbal modalities for the ERC task through cross-modal distillation.
- TelME shows comparable performance in two widely used benchmark datasets and especially achieves state-of-the-art in multi-party conversational scenarios.

2 Related Work

2.1 Emotion Recognition in Conversation

Recently, ERC has gained considerable attention in the field of emotion analysis. ERC can be categorized into text-based and multimodal methods, depending on the input format. Text-based methods primarily focus on context modeling and speaker relationships (Jiao et al., 2019; Li et al., 2020; Hu et al., 2021a). In recent studies (Lee and Lee, 2021; Song et al., 2022a), context modeling has been carried out to enhance the understanding of contextual information by pre-trained language models using dialogue-level input compositions. Additionally, there are graph-based approaches (Zhang et al., 2019; Ishiwatari et al., 2020; Shen et al., 2021; Ghosal et al., 2019) and approaches that utilize external knowledge (Zhong et al., 2019; Ghosal et al., 2020; Zhu et al., 2021).

On the contrary, multimodal methods (Poria et al., 2017; Hazarika et al., 2018a,b; Majumder et al., 2019) reflect dialogue-level multimodal features through recurrent neural network-based models. Other multimodal approaches (Mao et al., 2021; Chudasama et al., 2022) integrate and manipulate utterance-level features through hierarchical structures to extract dialogue-level features from each modality. EmoCaps (Li et al., 2022) considers both multimodal information and contextual emotional tendencies to predict emotions. UniMSE (Hu et al., 2022b) proposes a framework that leverages complementary information between Multimodal Sentiment Analysis and ERC. Unlike these methods, our proposed TelME is one in which the strong teacher leads emotion recognition while simultaneously bolstering attributes from weaker modalities

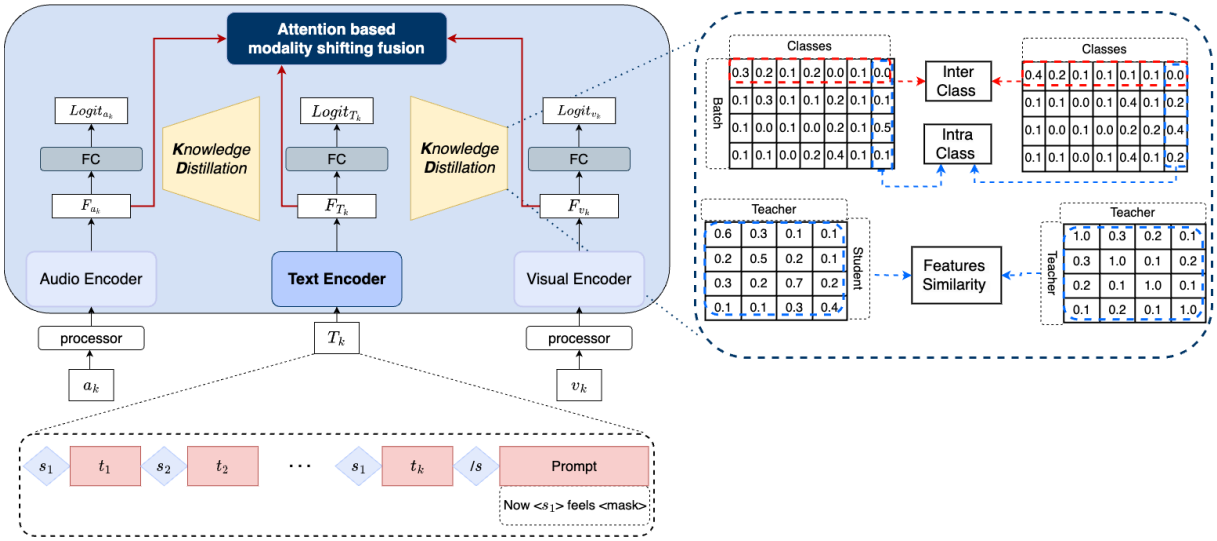

Figure 3: The overview of TelME

to complement and enhance the teacher.

2.2 Knowledge Distillation

The initial proposition of KD (Hinton et al., 2015) involves transferring knowledge by reducing the KL divergence between the prediction logits of teachers and students, demonstrating its effectiveness through improved performance of the student models. Subsequently, KD has been extended to distillation between intermediate features (Heo et al., 2019). Furthermore, KD approaches (Gupta et al., 2016; Jin et al., 2021; Tran et al., 2022) have also been shown to transfer knowledge between modalities effectively in multimodal studies. Li et al. (2023b) mitigate multimodal heterogeneity by constructing dynamic graphs in which each vertex exhibits modality and each edge exhibits dynamic KD. However, since this work is not a study of ERC and is based on graph distillation, there is an intrinsic difference from our KD strategy. Ma et al. (2023) proposes a transformer-based model utilizing self-distillation for ERC. Our proposed method, in contrast, uses response and feature-based distillation simultaneously to maximize the effectiveness of two other modalities by the teacher network based on text modality.

3 Method

3.1 Problem Statement

Given a set of conversation participants S, utterances U, and emotion labels Y, a conversation consisting of k utterances is represented as $[(s_i, u_1, y_1), (s_j, u_2, y_2, ..., (s_i, u_k, y_k)]$, where $s_i, s_j \in S$ are the conversation participants. If $i = j$, then s_i and s_j refer to the same speaker. $y_k \in Y$ is the emotion of the k-th utterance in a conversation, which belongs to one of the predefined emotion categories. Additionally, $u_k \in U$ is the k-th utterance. u_k is provided in the format of a video clip, speech segment, and text transcript. i.e., $u_k = \{t_k, a_k, v_k\}$, where $\{t, a, v\}$ denotes a text transcript, speech segment, and a video clip. The objective of ERC is to predict y_k, the emotion corresponding to the k-th utterance in a conversation.

3.2 TelME

3.2.1 Model Overview

We propose Teacher-leading Multimodal fusion network for ERC (TelME), as illustrated in Figure 3. This framework is devised based on the hypothesis that by exploiting the varying levels of modality-specific contributions to emotion recognition, there is a potential to enhance the overall performance of an ERC system. Therefore, we introduce a strategic approach that focuses on accentuating the powerful modality while bolstering the weak modalities. We first extract powerful emotional representations through context modeling from text modality while capturing auditory and visual features of the current speaker from non-verbal modalities. However, due to the limited emotional recognition capability of audio and visual features as well as the heterogeneity between the modalities, effective multimodal interactions cannot be guaranteed (Zheng et al., 2022). We thus mitigate the heterogeneity between modalities while maxi-

mizing the effectiveness of non-verbal modalities by distilling emotion-relevant knowledge of the teacher model into non-verbal students. We also use a fusion method in which strong emotional features from the teacher encoder are shifted by referring to representations of students strengthened in reverse. In the subsequent sections, we discuss the three components of TelME: Feature Extraction, Knowledge Distillation, and Attention-based modality Shifting Fusion.

3.2.2 Feature Extraction

Figure 3 visually illustrates how each modality encoder receives its corresponding input to extract emotional features. In this section, we explain the methodologies employed to generate emotional features corresponding to each modality's input signals.

Text: Following previous research (Lee and Lee, 2021; Song et al., 2022a), we conduct context modeling, considering all utterances from the inception of the conversation up to the k-th turn as the context. To handle speaker dependencies and differentiate between speakers, we represent speakers using the special token, $< s_i >$. Additionally, we construct the prompt, "Now $< s_i >$ feels $< mask >$" to emphasize the emotion of the most recent speaker. We report the effect of the prompt in Appendix A.1. The emotional features are derived from the embedding of the special token, $< mask >$. For our text encoder, we employ the modified Roberta (Liu et al., 2019), which has exhibited its efficacy across various natural language processing tasks. We can extract emotional features from the text encoder as follows.

$$C_k = [< s_i >, t_1, < s_j >, t_2, ..., < s_i >, t_k] \quad (1)$$

$$P_k = Now < s_i > feels < mask > \quad (2)$$

$$F_{T_k} = TextEncoder(C_k < /s > P_k) \quad (3)$$

where $< s_i >$ is the special token indicating the speaker and $< /s >$ is the separation token of Roberta. $F_{T_k} \in R^{1\times d}$ is the embeddings of the mask token, $< mask >$ and d is the dimension of the encoder.

Audio: Self-supervised learning using Transformer has witnessed remarkable achievement, not only within the field of natural language processing but also in the realms of audio and video (Bertasius et al., 2021; Baevski et al., 2022). In line with this trend, we set the initial state of our audio encoder with data2vec (Baevski et al., 2022). To focus solely on the voice of the current speaker, we only utilize a speech segment of the k-th utterance, denoted as a_k. This speech segment is processed according to the pre-trained processor. The audio encoder then extracts emotional features from the processed input as follows.

$$F_{a_k} = AudioEncoder(a_k) \quad (4)$$

where $F_{a_k} \in R^{1\times d}$ is the embeddings of a_k and d is the dimension of the encoder.

Visual: Following the same reasoning as the audio modality, we configure the initial state of our visual encoder using Timesformer (Bertasius et al., 2021). In order to concentrate exclusively on the facial expressions of the current speaker, we solely utilize a video clip of the k-th utterance, denoted as v_k. We extract the frames corresponding to the k-th utterance from the video and construct v_k through image processing. The visual encoder then extracts emotional features from the processed input as follows.

$$F_{v_k} = VisualEncoder(v_k) \quad (5)$$

where $F_{v_k} \in R^{1\times d}$ is the embedding of v_k and d is the dimension of the encoder.

3.2.3 Knowledge Distillation

Addressing the challenge of heterogeneity between modalities and low emotional recognition contributions of non-verbal modalities holds great potential in facilitating satisfactory multimodal interactions (Zheng et al., 2022). Thus, we distill strong emotion-related knowledge of a language model that understands linguistic contexts, thereby augmenting the emotional features extracted from the other two modalities with comparatively lower contributions. We employ two distinct types of knowledge distillation concurrently: response and feature-based distillation. The overall loss for the student can be composed of the classification loss, response-based distillation loss, and feature-based distillation loss, i.e.,

$$L_{student} = L_{cls} + \alpha L_{response} + \beta L_{feature} \quad (6)$$

where α and β are the factors for balancing the losses.

$L_{response}$ utilizes DIST (Huang et al., 2022), a technique originally used in image networks, as a cross-modal distillation for ERC. As shown in

Figure 2, effective knowledge distillation can be challenging due to the significant gap between the text modality and the other two modalities. Therefore, unlike conventional KD methods, we use a KD approach($L_{response}$) that utilizes Pearson correlation coefficients instead of KL divergence as follows.

$$d(\mu, \upsilon) = 1 - \rho(\mu, \upsilon) \tag{7}$$

where $\rho(\mu, \upsilon)$ is the Pearson correlation coefficient between two probability vectors μ and υ.

Specifically, $L_{response}$ aims to distill preferences (relative rankings of predictions) by teachers through the correlations between teacher and student predictions, which can usefully perform knowledge distillation even in the extreme differences between teacher and student. We gather the predicted probability distributions for all instances within a batch and calculate the Pearson correlation coefficient between the teacher and student for inter-class and intra-class relations (Figure 3). Subsequently, we transfer the inter-class and intra-class relation to the student. The specific formulation of the response-based distillation can be described as follows.

$$Y^t_{i,:} = softmax(Z^t_{i,:}/\tau) \tag{8}$$

$$Y^s_{i,:} = softmax(Z^s_{i,:}/\tau) \tag{9}$$

$$L_{inter} = \frac{\tau^2}{B}\sum_{i=1}^{B} d(Y^s_{i,:}, Y^t_{i,:}) \tag{10}$$

$$L_{intra} = \frac{\tau^2}{C}\sum_{j=1}^{C} d(Y^s_{:,j}, Y^t_{:,j}) \tag{11}$$

$$L_{response} = L_{inter} + L_{intra} \tag{12}$$

Given a training batch B and the emotion categories C, $Z^s \in R^{B\times C}$ is the prediction matrix of the student and $Z^t \in R^{B\times C}$ is the prediction matrix of the teacher. $\tau > 0$ is a temperature parameter to control the softness of logits.

However, rather than relying solely on $L_{response}$, we introduce $L_{feature}$ as an additional distillation loss to better leverage the embedded information in the teacher network. $L_{feature}$ aims to mitigate the heterogeneity between the representations of the teacher and student models, allowing us to distill richer knowledge from the teacher compared to using only $L_{response}$. Through this, the features of the students can faithfully support the teacher during the multimodal fusion stage. $L_{feature}$ leverages the similarity among normalized representation vectors of the teacher and the student within a batch (Figure 3). We construct the target similarity matrix by performing a dot product between the representation matrix of the teacher and its transposition matrix. By applying the softmax function to this matrix, we derive the target probability distribution as follows.

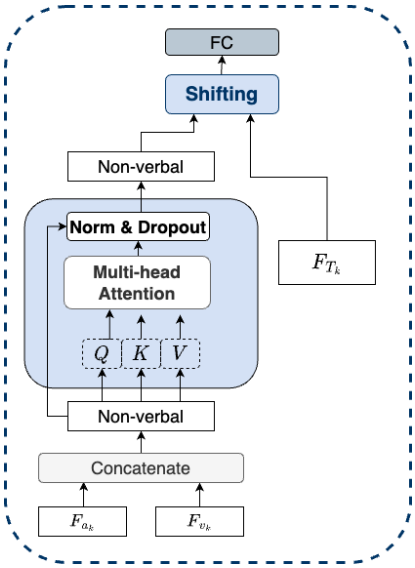

Figure 4: Attention-based modality Shifting Fusion

$$P_i = \frac{exp(M_{i,j}/\tau)}{\sum_{l=1}^{B} exp(M_{i,l}/\tau)}, \forall i, j \in B \tag{13}$$

where B is a training batch and $M \in R^{B\times B}$ is the target similarity matrix. $\tau > 0$ is a temperature parameter controlling the smoothness of the distribution. P_i is the target probability distribution.

Similarly, we can compute the similarity matrix between the teacher and the student by taking the dot product of their representations. Subsequently, we can calculate the similarity probability distribution as follows.

$$Q_i = \frac{exp(M'_{i,j}/\tau)}{\sum_{l=1}^{B} exp(M'_{i,l}/\tau)}, \forall i, j \in B \tag{14}$$

where $M' \in R^{B\times B}$ is the similarity matrix of student and teacher. Q_i is the similarity probability distribution of teacher and student.

With these two probability distributions, we compute the KL divergence as the loss for the feature-based distillation.

$$L_{feature} = \frac{1}{B}\sum_{i=1}^{B} KL(P_i \parallel Q_i) \quad (15)$$

where KL is the Kullback–Leibler divergence.

3.2.4 Attention-based modality Shifting Fusion

The emotional features from the enhanced student networks can impact the teacher model's emotion-relevant representations, providing information that may not be captured from the text. To fully utilize these features, we adopt a multimodal fusion approach where feature vectors from the student models manipulate the representation vectors from the teacher, effectively incorporating non-verbal information into the representation vector. To highlight non-verbal characteristics, we concatenate the vectors of the student models and perform multi-head self-attention. The vectors of non-verbal information generated through the multi-head self-attention process and emotional features of the teacher encoder enter the input of the shifting step (Figure 4). We are inspired by Rahman et al. (2020) to construct the shifting step. In the shifting step, a gating vector is generated by concatenating and transforming the vector of the teacher model and the vector of the non-verbal information.

$$g^k_{AV} = R(W_1 \cdot < F_{T_k}, F^k_{attention} > + b_1) \quad (16)$$

where <,> is the operation of vector concatenation, $R(x)$ is a non-linear activation function, W_1 is the weight matrix for linear transform, and b_1 is scalar bias. $F_{attention}$ is the emotional representation vectors of non-verbal information. g_{AV} is the gating vector. The gating vector highlights the relevant information in the non-verbal vector according to the representations of the teacher model. We define the displacement vector by applying the gating vector as follows.

$$H_k = g^k_{AV} \cdot (W_2 \cdot F^k_{attention} + b_2) \quad (17)$$

where W_2 is the weight matrix for linear transform and b_2 is scalar bias. H is the non-verbal information-based displacement vector.

We subsequently utilize the weighted sum between the representation vector of the teacher and the displacement vector to generate a multimodal vector. Finally, we predict emotions using the multimodal vector.

$$Z_k = F_{T_k} + \lambda \cdot H_k \quad (18)$$

Dataset	IEMOCAP			MELD		
	train	dev	test	train	dev	test
Dialogue	108	12	31	1038	114	280
Utterance	5163	647	1623	9989	1109	2610
Classes		6			7	

Table 1: Statistics of the two benchmark datasets.

$$\lambda = min(\frac{\|F_k\|_2}{\|H_k\|_2} \cdot \theta, 1) \quad (19)$$

where Z is the multimodal vector. We apply the scaling factor λ to control the magnitude of the displacement vector and θ as a threshold hyperparameter. $\|F_k\|_2, \|H_k\|_2$ denote the L2 norm of the F_k and H_k vectors respectively.

4 Experiments

4.1 Datasets

We evaluate our proposed network on MELD (Poria et al., 2018) and IEMOCAP (Busso et al., 2008) following other works on ERC listed in Appendix A.3. The statistics are shown in Table 1.

MELD is a multi-party dataset comprising over 1400 dialogues and over 13,000 utterances extracted from the TV series Friends. This dataset contains seven emotion categories for each utterance: neutral, surprise, fear, sadness, joy, disgust, and anger.

IEMOCAP consists of 7433 utterances and 151 dialogues in 5 sessions, each involving two speakers per session. Each utterance is labeled as one of six emotional categories: happy, sad, angry, excited, frustrated and neutral. The train and development datasets consist of the first four sessions randomly divided at a 9:1 ratio. The test dataset consists of the last session.

We purposely exclude CMU-MOSEI (Zadeh et al., 2018), a well-known multimodal sentiment analysis dataset, as it comprises single-speaker videos and is not suitable for ERC, where emotions dynamically change within each conversation turn.

4.2 Experiment Settings

We evaluate all experiments using the weighted average F1 score on two class-imbalanced datasets. We use the initial weight of the pre-trained models from Huggingface's Transformers (Wolf et al., 2019). The output dimension of all encoders is unified to 768. The optimizer is AdamW and the initial learning rate is 1e-5. We use a *linear schedule with*

warmup for the learning rate scheduler. All experiments are conducted on a single NVIDIA GeForce RTX 3090. More details are in Appendix A.2.

4.3 Main Results

We compare TelME with various multimodal-based ERC methods (explained in Appendix A.3) on both datasets in Table 2. TelME demonstrates robust results in both datasets and achieves state-of-the-art performance on MELD. Specifically, TelME outperforms the previous state-of-the-art method (M2FNet) in MELD by 0.66%, and exhibits a substantial 3.37% improvement in MELD compared to EmoCaps, which currently achieves state-of-the-art performance in IEMOCAP. Previous methods, such as EmoCaps and UniMSE, have also shown effectiveness in IEMOCAP but exhibit somewhat weaker performance on MELD.

As shown in Table 2, we report the performance of various methods for emotion labels in MELD. TelME outperforms other models in all emotions except Surprise and Anger. However, assuming that Surprise and Fear, as well as Disgust and Anger, are similar emotions, Emocaps shows a bias towards Surprise and Anger during inference, only achieving 3.03% and 7.69% in F1 score for Fear and Disgust, respectively. On the other hand, TelME distinguishes these similar emotions better, bringing the scores for Fear and Disgust up to 26.97% and 26.42%. We speculate that our framework predicts minority emotions more accurately as the non-verbal modality information (e.g., intensity and pitch of an utterance) enhanced through our KD strategy better assists the teacher in judging the confusing emotions.

Methods	Remarks	IEMOCAP	MELD
Audio	KD	48.11	46.60
Visual	KD	18.85	36.72
Text	-	66.60	66.57
Text + Visual	ASF	67.94	67.05
Text + Audio	ASF	69.26	67.19
TelME		**70.48**	**67.37**

Table 3: Performance comparison for single modality and multiple multimodal combinations

4.4 The Impact of Each Modality

Table 3 presents the results for single-modality and multimodal combinations. The single-modality performances for audio and visual are the results after applying our knowledge distillation method, and the same fusion approach as TelME is used for dual-modality results. The text modality performs the best among the single-modality, which supports our decision to use the text encoder as the teacher model. Additionally, the combination of non-verbal modalities and text modality achieves superior performance compared to using only text. Our findings indicate that the audio modality significantly contributes more to emotion recognition and holds greater importance compared to the visual modality. We speculate this can be attributed to its ability to capture the intensity of emotion through variations in the tone and pitch of the speaker. Overall, our method achieves 3.52% improvement in IEMOCAP and 0.8% in MELD over using only text.

4.5 Ablation Study

We conduct an ablation study to validate our knowledge distillation and fusion strategies in Table 4. The initial row for each dataset represents the out-

Dataset	ASF	L_response	L_feature	F1
IEMOCAP	✗	✗	✗	63.33
	✓	✗	✗	68.19
	✓	✓	✗	69.42
	✓	✓	✓	**70.48**
MELD	✗	✗	✗	67.04
	✓	✗	✗	66.75
	✓	✓	✗	67.23
	✓	✓	✓	**67.37**

Table 4: Results of ablation study. Here, $L_{response}$ is our response-based distillation, $L_{feature}$ is our feature-based distillation and ASF is our fusion method.

come of training each modality encoder using cross-entropy loss and concatenating the embeddings without incorporating distillation loss and our fusion method.

Using our fusion method alone, IEMOCAP showed performance improvement, but MELD showed poor performance. The effectiveness of our fusion method in achieving optimal modality interaction cannot be guaranteed without knowledge distillation. Because each encoder is trained independently, focusing solely on improving its performance without considering the multimodal interaction. On the other hand, as our knowledge distillation components are added, these bring about consistent improvements for both datasets.

When we examine the specific effects of the KD strategy, we observe performance improvements for both datasets, even when using only $L_{response}$, presenting its efficacy in closing the gap between the teacher and the students. Furthermore, adding $L_{feature}$ aimed to leverage the richer knowledge of the teacher is more effective in IEMOCAP and shows marginal performance enhancements in MELD. However, we speculate that the slight improvement in MELD may be attributed to class imbalance. While TelME significantly outperforms existing approaches in minority classes of MELD, the weighted F1 score is only slightly improved due to the low number of samples. We show an analysis of this class imbalance problem in Section 4.7 as well as an error analysis of the emotion classes in Appendix A.4.

Figure 5 shows the individual performance of the audio and visual modalities based on the distillation loss. We observe that applying both types of distillation loss is more effective compared to not applying them. The performance of visual modality on the IEMOCAP dataset has declined, possibly because facial expressions are not effectively captured in the limited image frames of a short utterance. However, even with lower individual performance, all modalities have been shown to contribute to the improvement of emotion recognition performance through our approach (Table 3).

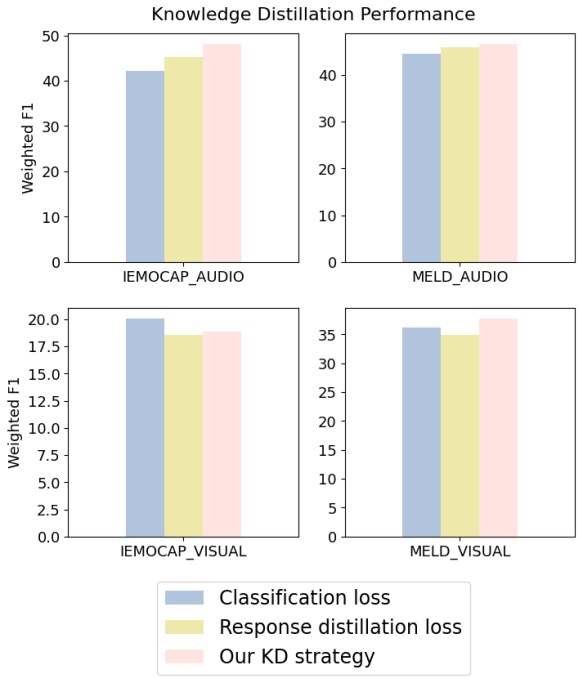

Figure 5: Individual performance of audio and visual modalities according to knowledge distillation type.

4.6 Study on Teacher Modality

	MELD	IEMOCAP
TelME (Audio Teacher)	56.28	49.36
TelME (Visual Teacher)	56.85	56.78
TelME (Text Teacher)	**67.37**	**70.48**

Table 5: TelME Performance by Teacher Modality

To assess the optimality of employing text modality as the teacher, we conduct comparative experiments by setting each modality as the teacher modality, which is shown in Table 5. Our study shows that the TelME framework performs best with the text encoder as the teacher, while treating the other modalities as the teacher significantly hinders model performance.

Additionally, Table 6 reports the individual performance of the student models based on the teacher modality. The diagonals (cases where the teacher and student modalities are the same) in Table 6 represent results without performing

		Audio Student	Visual Student	Text Student

	Text Teacher	**46.60**	**36.72**	**66.60**
IEMOCAP	Audio Teacher	42.24	20.45	57.42
	Visual Teacher	44.13	**22.06**	63.94
	Text Teacher	**48.11**	18.85	**66.57**

Table 6: Teacher Modality Study on MELD and IEMOCAP

Knowledge Distillation (KD). Our comparative experiment results show that a robust text encoder can most effectively serve as the teacher. Specifically, designating the text encoder as the teacher enhances the performance of all student models except for the visual student in IEMOCAP. On the other hand, it is evident that treating a weak non-verbal model as the teacher impairs student performance, thereby performing suboptimally compared to having a text-based teacher.

4.7 Class Imbalance

Figure 6: Count distribution of emotion classes for both MELD and IEMOCAP datasets

Figure 6 illustrates the label distribution within the MELD and IEMOCAP datasets. Notably, the MELD dataset exhibits a pronounced imbalance, with the "neutral" class comprising the majority at 47% of the data, followed by "joy" with 17% and "surprise" with 12%. This substantial class imbalance presents a challenge in the context of distillation, specifically for the teacher encoder to initially identify the minority classes and subsequently transfer this information to the non-verbal student encoders. We believe that this class imbalance is a contributing factor to the limited observed improvements associated with $L_{feature}$ in the MELD dataset compared to the IEMOCAP dataset.

5 Conclusion

This paper proposes Teacher-leading Multimodal fusion network for ERC (TelME), a novel multimodal ERC framework. TelME incorporates a cross-modal distillation that transfers the knowledge of text encoders trained in linguistic contexts to enhance the effectiveness of non-verbal modalities. Moreover, we employ the fusion method that shifts the features of the teacher model by referring to non-verbal information. We show through experiments on two benchmarks that our approach is practical in ERC. TelME delivers robust performance in both datasets and especially achieves state-of-the-art results in the MELD dataset, which consists of multi-party conversational scenarios. We believe that this research presents a new direction that can incorporate multimodal information for ERC.

Limitations

This study has a limitation wherein the visual modality shows a lower capability to recognize emotions compared to the audio modality. To address this limitation, future research should focus on developing techniques to accurately capture and interpret the facial expressions of the speaker during brief utterances. By improving the extraction of visual features, the effectiveness of knowledge distillation can be significantly enhanced, thus showcasing its potential to make a more substantial contribution to emotion recognition.

A Appendix

A.1 Effect of the prompt

	MELD	IEMOCAP
w/o prompt ([cls]+context)	65.25	66.48
context + prompt	**66.57**	**66.60**

Table 7: Comparison of the teacher performance based on the use of the prompt

Table 7 shows an ablation experiment on the prompt. We remove the prompt and use the CLS token to compare emotion prediction results with the results using the prompt. We observe from the results that the prompt helps to infer the emotion of a recent speaker from a set of textual utterances.

A.2 Hyperparameter Settings

Through our KD strategy, audio and visual encoders are trained using the loss functions mentioned in Equation 6. In $L_{student}$, the balancing factors are all set to 1, excluding α for IEMOCAP. The temperature parameter for the $L_{response}$ function is adjusted to 4 for MELD and 2 for IEMOCAP. The temperature parameter for $L_{feature}$ is set to 1 regardless of the dataset. We also use a fusion method that shifts vectors in the teacher model, where the threshold parameter is set to 0.01 for IEMOCAP and 0.1 for MELD. Furthermore, Dropout is adjusted to 0.2 for MELD and 0.1 for IEMOCAP. The number of heads used in the multi-head attention process is 4 for IEMOCAP and 3 for MELD.

Hyperparameter	IEMOCAP	MELD
Knowledge distillation		
Balance factors for $L_{student}$	α=0.1	1
Temperature for $L_{response}$	4	2
Temperature for $L_{feature}$	1	1
Attention modality Shifting Fusion		
Threshold parameter	0.01	0.1
Dropout	0.2	0.1
The number of heads for multi-head attention	4	3

Table 8: hyperparameter settings of TelME on two datasets

A.3 Compared Models

We compare TelME against the following models: DialogueRNN (Majumder et al., 2019) employs Recurrent Neural Networks (RNNs) to capture the speaker identity as well as the historical context and the emotions of past utterances to capture the nuances of conversation dynamics. ConGCN (Zhang et al., 2019) utilizes a Graph Convolutional Network (GCN) to represent relationships within a graph that incorporates both context and speaker information of multiple conversations. MMGCN (Hu et al., 2021b) also proposes a GCN-based approach, but captures representations of a conversation through a graph that contains long-distance flow of information as well as speaker information. DialogueTRM (Mao et al., 2021) focuses on modeling both local and global context of conversations to capture the temporal and spatial dependencies. DAG-ERC (Shen et al., 2021) studies how conversation background affects information of the surrounding context of a conversation. MMDFN (Hu et al., 2022a) proposes a framework that aims to enhance integration of multimodal features through dynamic fusion. EmoCaps (Li et al., 2022) introduces an emotion capsule that fuses information from multiple modalities with emotional tendencies to provide a more nuanced understanding of emotions within a conversation. UniMSE (Hu et al., 2022b) seeks to unify ERC with multimodal sentiment analysis through a T5-based framework. GA2MIF (Li et al., 2023a) introduces a two-stage multimodal fusion of information from a graph and

an attention network. FacialMMT (Zheng et al., 2023) focuses on extracting the real speaker's face sequence from multi-party conversation videos and then leverages auxiliary frame-level facial expression recognition tasks to generate emotional visual representations.

A.4 Error Analysis

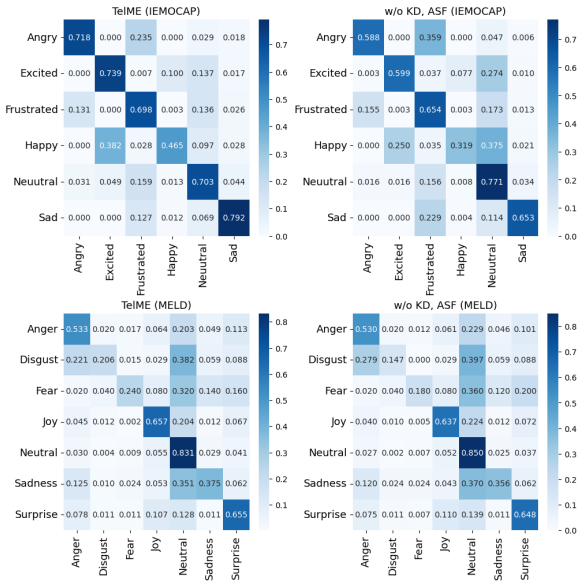

Figure 7: Confusion Matrices on IEMOCAP and MELD

Figure 7 shows the normalized confusion matrices of the TelME and the understated model for two datasets. We can evaluate the quality of the emotion prediction through the confusion matrix. TelME shows better True Positive results in almost all emotion classes. This suggests that TelME is extracting and fusing finer-grained features to infer emotions without bias. TelME better classifies similar emotions compared to the understated model(e.g., excited and happy, angry and frustrated). However, the result of misclassifying happy as exciting is a little high. This result is due to the lowest percentage of happy in IEMOCAP with unbalanced classes. Even in the case of MELD, the emotion in which most emotion classes are misclassified is neutral, with the highest count. We can observe a similar misclassification tendency in other research (Chudasama et al., 2022; Hu et al., 2023) as well. Hence, we suspect that the cause of misclassification is not a problem with the method we proposed but rather stems from a class imbalance issue.

SEED	MELD	IEMOCAP
0	67.27	70.50
1	67.41	70.69
1234	67.44	70.21
2023	67.24	69.95
42	67.37	70.48
mean	67.35	70.37
standard deviation	0.0781	0.2581

Table 9: Performance of the full framework for five random seeds

A.5 Results of Random Seed Numbers

We report all outcomes based on the seed number 42 following previous studies (Lee and Lee, 2021; Song et al., 2022a; Hu et al., 2022b). However, to validate TelME's robustness to randomness, we present experiment results with different seed numbers in Table 9. The results in Table 10 demonstrate that the performance of TelME is robust to seed variations.

A.6 Utility of TelME

TelME	Label	Text	Audio	Visual
anger	**anger**	disgust	**anger**	neutral
neutral	**neutral**	surprise	**neutral**	**neutral**
joy	**joy**	surprise	anger	neutral
anger	**anger**	surprise	neutral	neutral
joy	**joy**	disgust	**joy**	**joy**
sadness	**sadness**	fear	neutral	neutral
joy	**joy**	surprise	**joy**	anger
neutral	**neutral**	sadness	**neutral**	sadness

Table 10: inference results of each unimodal model and TelME on MELD

Table 10 presents a segment of the ground truth label from the MELD dataset, along with inference outcomes of each unimodal model (Text teacher, non-verbal students) and TelME. The results indicate that student models can make different judgments than the text teacher even after knowledge distillation. Moreover, the final decision of TelME, supported by complementary information from non-verbal modalities, might diverge from the prediction of the text teacher, rectifying any inaccuracies. This implies that TelME utilizes multimodal information instead of heavily depending on any of the three modalities.

Models	IEMOCAP: Emotion Categories						
	Happy	Sad	Neutral	Anger	Excited	Frustrated	F1

Abstract

Few-shot dialogue state tracking (DST) with Large Language Models (LLM) relies on an effective and efficient conversation retriever to find similar in-context examples for prompt learning. Previous works use raw dialogue context as search keys and queries, and a retriever is fine-tuned with annotated dialogues to achieve superior performance. However, the approach is less suited for scaling to new domains or new annotation languages, where fine-tuning data is unavailable. To address this problem, we handle the task of conversation retrieval based on text summaries of the conversations. A LLM-based conversation summarizer is adopted for query and key generation, which enables effective maximum inner product search. To avoid the extra inference cost brought by LLM-based conversation summarization, we further distill a light-weight conversation encoder which produces query embeddings without decoding summaries for test conversations. We validate our retrieval approach on MultiWOZ datasets with GPT-Neo-2.7B and LLaMA-7B/30B. The experimental results show a significant improvement over relevant baselines in few-shot DST settings.

1 Introduction

Dialogue state tracking (DST) is one of the most crucial components in task-oriented dialogue systems. The goal of DST is to track users' intents, slots and values at every turn of a dialogue based on a predefined schema (Budzianowski et al., 2018). The challenge of training a supervised DST model lies in the cost of dialogue state annotations, which is not scalable to new schemas, domains or annotation languages. To address these challenges, recent works (Hu et al., 2022; Chen et al., 2023) adopt in-context learning with pre-trained large language models (LLM) for few-shot DST. In the few-shot setting, similar dialogue exemplars are retrieved based on the test sample and then these exemplars are added to the LLM prompt for target generation. This approach is attractive since no domain-specific fine-tuning is required for the LLM but it can still generalize to unseen domains.

One challenge in few-shot DST is how to retrieve salient conversation exemplars (e.g., in a set of 3 to 5) from the support set, which serves as demonstrations for the LLM. Ideally, a retrieved exemplar should carry both the same dialogue history and state change as the test sample. However, in a practical few-shot setting (e.g., with at most 100 annotated support examples), it is likely that no exemplar in the support set satisfies the above requirement. Consider a test example with two user turns:

```
user: book a flight to London Heathrow
system: where are you departing from
user: Amsterdam
```

It is possible that the closest exemplar we can get from the support set is:

```
user: I'm leaving Manchester by air
system: where are you flying to
user: To Paris
```

which neither matches the test dialogue state nor the state change. Nevertheless, we hope that LLM can generalize by learning from such exemplars with an identical user intent. The retrieval task gets harder when the conversation becomes lengthy with only partial history related to the current user input. For example, in another test dialog:

```
user: what's the weather in London
system: sunny
user: book a flight to London Heathrow
system: where are you departuring from
user: Amsterdam
```

the user's current intent is identical to the earlier test sample, but it involves unrelated history. Still we want to match the test sample to a similar exemplar, which reflects the user's intent up to the current point of conversation. This retrieval cannot be easily accomplished with pre-trained dense

* Work done during an internship at Apple.

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 96–111
June 16-21, 2024 ©2024 Association for Computational Linguistics

retrieval models based on word or sentence similarity. To optimize retrieval performance, previous works (Hu et al., 2022; Chen et al., 2023) fine-tune a dense retriever with "structurally similar" dialogue examples identified from dialogue state annotations with heuristics. Hu et al. (2022) additionally report that including dialogue state information in the retrieval key is helpful. However, the approach is not scalable to a practical few-shot setting (with fewer than 100 annotated support examples), as fine-tuning easily leads to overfitting and catastrophic forgetting (McCloskey and Cohen, 1989; Lee et al., 2022). It is also impractical to expect every domain owner to create their own fine-tuning data with well-engineered rules.

In this work, we propose a new solution for conversation retrieval starting with the introduction of a LLM-based conversation summarizer. For each exemplar to be indexed and also each test dialog, the summarizer produces a text summarizing *what the user wants at this point of the conversation*. In Section 2, we provide a discussion of this specific summarization choice and how it compares to dialogue state. The summaries are then used as condensed search keys and queries applicable to pre-trained dense retrievers with standard nearest neighbor search. We empirically show that in the few-shot setting, using summaries as retrieval keys and queries is more effective than using raw dialogues.

Notably the conversation summarization task described above can be easily handled by state-of-the-art LLMs via prompt learning, as we will show in an ablation study. However, the deployment of such a retrieval system also introduces extra model parameters and inference cost. Unlike search keys, which can be pre-built offline, a search query needs to be auto-regressively decoded for each test dialogue right during inference. To improve the efficiency of this conversation retriever, our second contribution in this work focuses on distilling a light-weight conversation encoder which embeds a raw dialogue directly into a vector space similar to the embedding of its summary. The light-weight conversation encoder enables efficient conversation search over a vector database without explicit query generation. When evaluated on the MultiWOZ dataset with GPT-Neo-2.7B (Black et al., 2022), LLaMA-7B, and LLaMA-30B (Touvron et al., 2023) for few-shot DST, we find that the distilled conversation encoder is not only more efficient, but also more effective than a cascaded conversation retriever with explicit query generation. Our approach also significantly outperforms relevant baselines, which use annotated dialogues for retriever fine-tuning.

2 Conversation Retrieval with Summaries for LLM-based DST

In the context of task-oriented dialogues with multiple turns of interactions between a user and a system, the objective of DST is to predict the accumulated intents, slots and values at each user turn. In a LLM-based approach, the generation of a dialogue state is conditioned on a task-specific prompt. The prompt includes at least the test conversation and a set of k demonstration examples, from which we expect the LLM to learn to generalize. Considering the size limit of the prompt, k is expected to be small (3-5 examples). Each of the retrieved examples is an annotated conversation sharing similar features as the test conversation. We expect to retrieve these exemplars with a dense retriever from a "support set" (e.g., 100 annotations) that can be constructed with minimum effort for domain scaling.

There are two major challenges of conversation retrieval for LLM-based DST described above. First, a good representation of search keys and queries need to be found. As we analyze in Section 1, the similarity of two dialogues is not directly quantifiable by semantic distance, but rather requires more sophisticated structural matching mechanism or a higher-order similarity function. This requirement leads to the second challenge as to how to train an effective conversation retriever that can scale across domains. Previous works (Hu et al., 2022; Chen et al., 2023) mainly fine-tune pre-trained dense retrievers with annotated dialogues obtained from the support set. However, fine-tuning is not realistic in a few-shot setting and for every domain.

As shown in Figure 1-(a), our work introduces a query/key generation step in the LLM-based DST. The generation is performed with another LLM which transforms the raw dialogue context into a text summary whose similarity can be evaluated more easily with pretrained retrievers. Specifically, the text summary represents the user's intent up to the current point of the conversation. It grounds the latest user input onto the dialogue history, keeping only information related to the

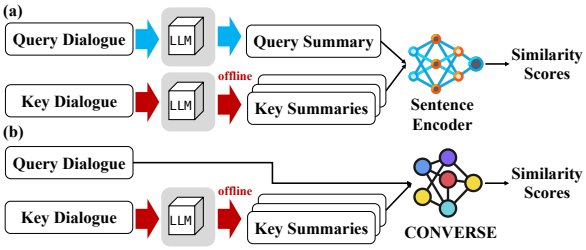

Figure 1: Comparison between **(a)** off-the-shelf retriever with query generation and **(b)** CONVERSE w/o query generation.

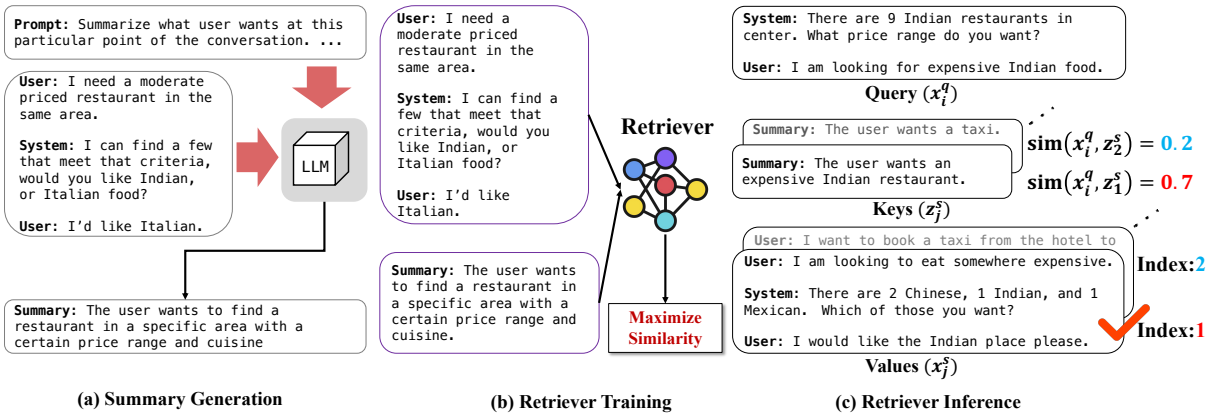
current user intent. Note that the summary is a contextual rewriting of the current user intent that is possibly expressed in multiple turns, with applied ellipsis recovery (Hardt, 1997) and co-reference resolution (Pradhan et al., 2012). Examples of the conversation summary are in Table 6. The summary can also be viewed as a text description of an updated dialogue state which is to be predicted by the LLM. Unlike the dialogue state, the summary does not maintain all conversation history but only includes information relevant to the current user input.

With the introduction of an explicit query/key generation step, we expect that the conversation retrieval becomes easier and the search index can be built more efficiently. To construct the search index, an offline process can be triggered to generate text summaries for every example in the support set. Note that search key generation does not add any inference cost. However, the query generation step comes at an extra cost since the generation needs to happen in an online process. In the next section, we describe how to make the conversation retrieval more efficient by stepping away from explicit query generation.

3 Conversation Encoder Distillation



Note that in the proposed conversation retriever, the LLM-based conversation summarizer needs to be invoked for every test sample to generate the search query as shown in Figure 1-(a). To eliminate the extra inference cost, we propose to distill a light-weight conversation encoder which directly embeds a dialogue into a vector space similar to its summary, by maximizing their embedding similarity. The encoder is trained with large-scale dialogue-summary pairs generated by the conversation summarizer in an offline process. After training the model, as shown in Figure 1-(b), we can directly encode each dialogue into a query embedding for maximum inner product search. We call our conversation encoder CONVERSE, standing for **CON**versation embeddings for **VE**rsatile **R**etrieval with implicit **S**ummari**E**s. Next we explain the structure and training objective of CONVERSE.

3.1 Model

Preliminaries In our problem setup, we are given a set of unlabeled conversations between a user and system, denoted as $\mathcal{D}^u = \{\mathbf{x}_i\}_{i=1}^n$ where each conversation $\mathbf{x}_i$ consists of l_i utterances $(\mathbf{u}_{i,j}, \ldots, \mathbf{u}_{i,l_i})$ and each utterance $\mathbf{u}_{i,j}$ is a sequence of $T_{i,j}$ tokens $(x_{i,j,1}, \ldots, x_{i,j,T_{i,j}})$. As shown in Figure 2-(b), the training data of CONVERSE is prepared by invoking the conversation summarizer to generate a summary for each conversation $\mathbf{x}_i$, denoted as $\mathbf{z}_i$, which consists of T_i' tokens with $T_i' \ll \sum_{j=1}^{l_i} T_{i,j}$. We denote the dataset augmented with summaries as $\mathcal{D}^a = \{(\mathbf{x}_i, \mathbf{z}_i)\}_{i=1}^n$. For brevity, we omit the first subscript i if there is no ambiguity. Given the set of conversation-summary pairs, the goal is to train an encoder $f_\theta : \mathcal{V}^T \rightarrow \mathbb{R}^{T \times d}$ such that the similarity between a conversation and its summary is maximized, where $\mathcal{V}$ denotes a set of predefined tokens.

Conversation and Summary Embedding To match a conversation against a summary, we leverage the commonly used architecture in dense retrieval known as the dual encoder (Yih et al., 2011; Lee et al., 2019; Karpukhin et al., 2020a), where a conversation and a summary are encoded jointly for similarity comparison. State-of-the-art dual encoders (Khattab and Zaharia, 2020) represent each encoding as multiple vectors, typically the contextualized token vectors, to represent the text. These models largely improve the model expressiveness, and exhibit much stronger performance and robustness compared to their single-vector counterparts (Thakur et al., 2021). Based on it, we represent both the conversation embedding $f_\theta(\mathbf{x})$ and the summary embedding $f_\theta(\mathbf{z})$ as a matrix. While the summary encoder in the dual architecture can be directly integrated into off-the-shelf sentence encoders, our conversation encoder (CONVERSE) is designed to reflect the inductive bias of the summarization task.

CONVERSE Remember that the task of the conversation summarizer is to summarize the current user intent by grounding it to the conversation history. Hence the latest user input (the state delta) is most important and any past utterances irrelevant to the latest input should be dropped out.

(a) Summary Generation (b) Retriever Training (c) Retriever Inference

Figure 2: **Concept. (a)** Generating a summary of a dialogue with language model (LM). **(b)** Training the retriever to maximize a similarity between the dialogue and generated summary. **(c)** Given a test dialogue as a query, we retrieve the dialogue (value) of which summary (key) obtains the best similarity score with the query.

To reflect the nature of the summarization task, we explicitly model the grounding step between the latest user input $\mathbf{u}_l$ and past utterances $\mathbf{u}_1, \ldots, \mathbf{u}_{l-1}$ as a structural bias in CONVERSE. This is achieved with the introduction of a soft retrieval structure that softly retrieves past utterances or tokens which are relevant to the latest user input. Specifically, the soft retrieval is simulated with another neural network $g_\phi : \mathbb{R}^d \times \mathbb{R}^d \rightarrow [0, 1]$, which outputs the relevance score of each token in the utterances $\mathbf{u}_1, \ldots, \mathbf{u}_{l-1}$ conditioned on the latest user utterance $\mathbf{u}_l$. Then, the relevance scores are used to downweight irrelevant token representations of the conversation $\mathbf{x}$:

$$\hat{f}_{\theta,\phi}(\mathbf{x}) = \begin{bmatrix} w_{1,1} f_\theta(\mathbf{x})_{1,1}^\top \\ \vdots \\ w_{l-1,T_{l-1}} f_\theta(\mathbf{x})_{l-1,T_{l-1}}^\top \\ f_\theta(\mathbf{x})_{l,1}^\top \\ \vdots \\ f_\theta(\mathbf{x})_{l,T_l}^\top \end{bmatrix} \in \mathbb{R}^{T \times d}$$

$$w_{j,t} = g_\phi(f_\theta(\mathbf{x})_{j,t}, s_l(\mathbf{x})) \in [0, 1] \quad (1)$$

$$s_l(\mathbf{x}) = \frac{1}{T_l} \sum_{t=1}^{T_l} f_\theta(\mathbf{x})_{l,t} \in \mathbb{R}^d,$$

where $t \in \{1, \ldots, T_j\}$ for each $j \in \{1, \ldots, l-1\}$ and $f_\theta(\mathbf{x})_{j,t}$ is a contextual representation of t-th token in $\mathbf{u}_j$. Intuitively, an irrelevant token in the conversation history receives a small weight, reducing its contribution to the final similarity scoring against the summary. Conversely, a token in the latest user input always carries the highest weight 1 and contributes more to the similarity computation.

3.2 Training Objective

Given the conversation encoder $\hat{f}_{\theta,\phi}$ and summary encoder f_θ with a set of conversation and summary pairs $\mathcal{D}^a = \{(\mathbf{x}_i, \mathbf{z}_i)\}_{i=1}^n$, as illustrated in Figure 2-(b), we train the dual encoder to maximize the similarity between a dialogue and its summary with the contrastive loss (Henderson et al., 2017):

$$L(\theta, \phi; \mathcal{D}^a) = -\frac{1}{n} \sum_{(\mathbf{x},\mathbf{z}) \in \mathcal{D}^a} \log p_{\theta,\phi}(\mathbf{z}|\mathbf{x}) \quad (2)$$

$$p_{\theta,\phi}(\mathbf{z}|\mathbf{x}) = \frac{\exp(\texttt{sim}(\hat{f}_{\theta,\phi}(\mathbf{x}), f_\theta(\mathbf{z})))}{\exp(\sum_{(\mathbf{x}',\mathbf{z}') \in \mathcal{D}^a} \texttt{sim}(\hat{f}_{\theta,\phi}(\mathbf{x}'), f_\theta(\mathbf{z}')))},$$

where $\texttt{sim}$ is the multi-vector similarity function (Khattab and Zaharia, 2020), which computes the similarity between the conversation and its summary, denoted as $\texttt{sim}(\hat{f}_{\theta,\phi}(\mathbf{x}), f_\theta(\mathbf{z}))$, by averaging maximum dot product between summary tokens and each conversation token as:

$$\frac{1}{T} \sum_{j=1}^{l} \sum_{t=1}^{T_j} \max_{t' \in \{1,\ldots,T'\}} \hat{f}_{\theta,\phi}(\mathbf{x})_{j,t}^\top f_\theta(\mathbf{z})_{t'}. \quad (3)$$

In practice, due to computational costs, we sample a mini-batch $\mathcal{B} \subset \mathcal{D}^a$ for computing the denominator of the contrastive loss in equation 2.

3.3 Inference

In LLM-based DST, we are given a small support set of labeled dialogues $\mathcal{D}_1^s = \{(\mathbf{x}_i^s, \mathbf{y}_i^s)\}_{i=1}^m$. The search keys can be pre-built offline by calling the conversation summarizer to generate a summary for each dialogue $\mathbf{x}_i^s$ from the support set $\mathcal{D}_1^s$, resulting in a set of (conversation, label, and summary) triplets denoted as $\mathcal{D}_2^s = \{(\mathbf{x}_i^s, \mathbf{y}_i^s, \mathbf{z}_i^s)\}_{i=1}^m$. The search index is then built with the summary as the

key, and a labeled conversation as the value. The summaries are encoded with the fine-tuned summary encoder described in Section 3.2.

During inference, for each conversation $\mathbf{x}_i^q$ from the test set $\mathcal{D}^q = \{\mathbf{x}_i^q\}_{i=1}^Q$, we embed the conversation with the CONVERSE encoder and compute its similarity with every search key using the similarity function in equation 3, i.e., $\texttt{sim}(\hat{f}_{\theta,\phi}(\mathbf{x}_i^q), f_\theta(\mathbf{z}_j^s))$ for $j = 1, \ldots, m$. As shown in Figure 2-(c), the retriever ranks examples $(\mathbf{x}_j^s, \mathbf{y}_j^s)$ based on the similarity score and chooses the top-k exemplars. Finally, the retrieved exemplars are added to the prompt of the downstream LLM for dialog state generation.

4 Experiments

4.1 Experimental Setup

Common We evaluate LLM-based DST with the proposed conversation retriever on MultiWOZ 2.1 (Eric et al., 2020) and 2.4 (Ye et al., 2022).

To simulate few-shot scenario, we consider a support set of 100 labeled conversations as the default setting in our comparison. For each experimental run, we randomly sample 100 labeled conversations from the training data of MultiWOZ 2.1/2.4. The analysis of other support set sizes is deferred to an ablation study. During inference, we retrieve the top 5 examples from the support set. The examples along with a test conversation are inserted into the prompt, following Hu et al. (2022). This setting is applied to all comparisons. We use both GPT-Neo (Black et al., 2022) and LLaMA-7B/30B (Touvron et al., 2023) as the LLM for DST generation. For evaluation, we report average and standard deviation of Joint Goal Accuracy (JGA) and F1 score (Henderson et al., 2014) on all 7,368 test dialogues from MultiWOZ with three runs.

Baselines We compare the proposed conversation retriever with the following baselines.

1. IC-DST (Hu et al., 2022): It utilizes dialogue labels to construct positive and negative pairs for fine-tuning a pretrained SBERT (Reimers and Gurevych, 2019) or LinkBERT (Yasunaga et al., 2022) as a retriever. The retrieval key is a dialogue context, and the best dialogue context is reported to be previous dialogue state + current user input (which is better than a full dialogue).
2. SM2 (Chen et al., 2023): Similar to IC-DST, it fine-tunes SBERT on labeled dialogue data with contrastive loss, where conversations with partial matching slots or values are considered as positive samples. The retrieval key is a dialogue context similar to IC-DST.
3. GTR-T5-LARGE (Ni et al., 2022): It uses a T5 encoder, which is pretrained on large scale corpora for sentence representation, to compute the similarity between conversations for retrieving examples. The retrieval key is the full dialogue.
4. JINA-LARGE (Günther et al., 2023): Similar to GTR-T5, the pretrained sentence encoder Jina is used to compute similarity between conversations. The retrieval key is also the full dialogue.

Ours We use `gpt-3.5-turbo` (OpenAI, 2022) as the conversation summarizer, since it provides reliable summaries that satisfy the task requirement in the prompt (see human evaluation in 4.4 and the prompt specified in Appendix A). First, we evaluate the effectiveness of summary-based search key and query generation, using off-the-shelf retrievers GTR-T5-Large and Jina-Large, which are directly comparable with the baseline.

Second, we evaluate the distilled conversation encoder (CONVERSE). To train CONVERSE, we use the same conversation summarizer to generate a summary for every turn of every conversation from the full MultiWOZ training set, resulting in a total of 56,776 conversation-summary pairs. The parameters θ of the dual encoder f_θ and $\hat{f}_{\theta,\phi}$ are shared and initialized with LinkBERT (Yasunaga et al., 2022), and trained on the conversation-summary pairs for 20 epochs with the objective in equation 2. LinkBERT (Yasunaga et al., 2022) is chosen since we empirically find that it offers the best general-purpose weight of initialization. We use the AdamW optimizer (Loshchilov and Hutter, 2018) with learning rate $5 \cdot 10^{-5}$ and batch size 200. We use eight A100 GPUs for training the model.

4.2 Quantitative Results

Main Results The DST results are shown in Table 1 and Table 2. The first set of comparisons is between conversation retrieval with and without explicit query/key generation. We observe that using the summary as search keys/queries significantly improves the end-to-end (E2E) results, when evaluated with the same off-the-shelf retriever (GTR-T5 or Jina). The result is slightly behind IC-DST which fine-tunes the retriever with dialogue state information in the key. However, after introducing the distilled CONVERSE model, we achieve much

better E2E results than all baselines. Although our motivation of distilling a conversation encoder is to reduce the inference cost, it turns out that the light-weight model is also helpful in E2E performance. We hypothesize that the improved performance brought by CONVERSE is attributed to two factors. The first and foremost is that we leverage a dual encoder architecture to optimize the matching between conversation-summary pairs. This suggests that the retrieval component is optimized for the task-specific keys and values. A secondary explanation of the performance gain is that the conversation encoder avoids error propagation in explicit summary decoding and re-embedding. It should be noted that the above findings are consistent across different datasets (MultiWOZ 2.1/2.4) and language models (GPT-Neo and LLaMA-7B/30B).

Comparison Against Few-Shot Finetuning Recently, Mosbach et al. (2023) have shown that few-shot fine-tuning outperforms in-context learning in some settings, which makes people wonder how few-shot fine-tuning behaves with 100 labeled dialogues for dialogue state tracking tasks. To answer this question, we compare our method, CONVERSE, against one of the strongest few-shot fine-tuning methods, DS2 (Shin et al., 2022), using BART (Lewis et al., 2020) and T5 (Raffel et al., 2020) language models. As shown in Table 3, our method, CONVERSE, outperforms the few-shot fine-tuning method, DST. Note that the BART-based DS2 severely overfits to the small labeled dataset and the T5-based model performs worse than the in-context learning method, even though T5 model is pretrained on an additional large-scale labeled dialogue summarization dataset, SAMSum (Gliwa et al., 2019).

Model	JGA	
	MWZ-2.1	MWZ-2.4

CONVERSE	**14.05**±0.58	**63.37**±1.53	**14.23**±0.48	**64.18**±1.47

Table 4: Out-of domain generalization using 100 labeled conversations with LLaMA-7B.

Out-of Domain Generalization To verify our hypothesis that our unsupervised retriever CONVERSE generalizes better to unseen domain than supervised methods, we hold out the hotel domain from the MultiWOZ dataset and train the retrievers, IC-DST and CONVERSE on the remaining four domains: train, restaurant, taxi, and attraction. Then we evaluate the performance of the few-shot in-context learning with the retrievers on test examples from the unseen domain, hotel. As shown in Table 4, our model CONVERSE outperforms IC-DST by a large margin, which empirically validates that our unsupervised retriever generalizes better to unseen domain than the supervised one.

4.3 Ablation Study

Size of Support Set We empirically study the size of the support set (labeled dialogues) in the conversation retrieval task. Notably, a smaller support set requires less annotation effort from the domain owner, placing more emphasis on general-

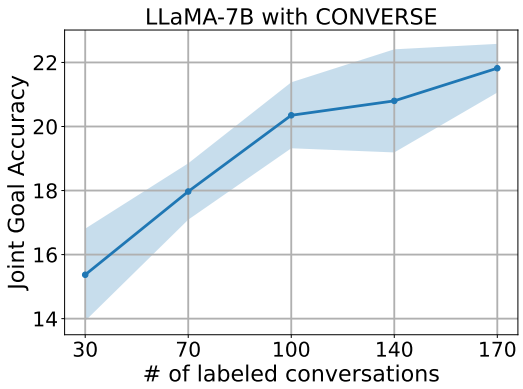

Figure 3: JGA of LLaMA-7B with CONVERSE as a function of the number of labeled data.

	JGA	
Model	**MultiWOZ 2.1**	**MultiWOZ 2.4**

CONVERSE	19.33 ± 0.91	20.35 ± 1.03

Table 5: Ablations of different ranking with LLaMA-7B.

ization to unseen dialogue structures. In contrast, a larger support set contradicts the fundamental motivation behind few-shot learning, but it is likely to improve the E2E accuracy, as more test dialogue structures are observable from the exemplars. In Figure 3, we plot the JGA of LLaMA-7B with CONVERSE on varying sizes of the support set constructed from MultiWOZ. As we expect, the JGA increases as the number of labeled conversation increases, even though we do not fine-tune the retriever with any labeled conversations.

Summary vs. state delta The conversation summary we adopt in this work concludes the user's current intent when the dialogue takes place. A limitation is that the summary does not directly highlight the state delta carried by the latest user input. As a remedy, we consider a multi-key and query retrieval setup, where we use both the summary and the latest user input as search keys and queries. More specifically, we first retrieve 20 dialogues with CONVERSE and re-rank the 20 dialogues based on the similarity of the latest utterance between the test sample and the support examples, using the pre-trained GTR-T5-Large. As shown in Table 5, re-ranking with the latest user utterance yields marginal performance gains. In future work, we aim to explore a better way of summarizing the conversation structure that reflects both the joint intent and the latest user input.

4.4 Qualitative Results

Visualization of history grounding As described in equation 1, CONVERSE softly retrieves

Conversation
USER: I need some tourist information please. I need to know about a hotel called the Arbury lodge guest house. **SYSTEM**: The Arbury lodge guest house is in the north area and has a moderate price range. ··· **USER**: I would like to book a stay for 3 people for 2 nights starting from Tuesday. **USER**: I am also looking to eat somewhere expensive, in the south area of town. ⋮ **USER**: I will also need a taxi , please. **SYSTEM**: Where would you like your taxi to pick you up and drop you off? **USER**: I want to be picked up at the hotel and dropped off at the restaurant.
Summary: The user wants to book a taxi to be picked up at a specific location and dropped off at another.

Table 6: The LLM successfully summarize the conversation based on the latest user utterance.

conversation history based on the latest user utterance. Specifically, the network g_ϕ outputs a relevance score between 0 and 1 for each token of the conversation history. In Figure 4, we visualize this relevance score of each token in the history. The tokens with darker blue color indicates a higher weight, which are considered to be more relevant to the latest input.

The examples in Figure 4 shows that the model successfully focuses on relevant part of history. For the first example in Figure 4a, the user wants to search for a Chinese restaurant in the center with moderate price range. The model assigns large weights to the tokens related to "Chinese", "center", and "price". Similarly, the tokens relevant to booking a taxi gets larger weights in Figure 4b. For the last example in Figure 4c, the model pays attention to the tokens related to a museum and ignores many irrelevant ones.

Human Evaluation on Conversation Summarizer The success of CONVERSE is highly dependent on the output quality of the conversation summarizer, which are used as labels for encoder distillation. We conduct human evaluation of 135 summaries generated by the conversation summarizer, namely `gpt-3.5-turbo`. Specifically, three human judges are asked to assess whether the generated summaries are consistent with the instructions in the prompt in Table 9. The results indicate that 90.3% of the 135 summaries are deemed consistent with the given prompt.

Examples of the generated summaries are shown in Table 6 and 7. For the first example, the model generates the summary about booking a taxi. It is

US ##ER : Hi , I am looking for a Chinese restaurant in the centre . S ##Y ##ST ##EM : There are 10 Chinese restaurants in the centre . Is there a particular price range you ' re interested in ? [SEP] [CLS] US ## ER : Yes, I would prefer a restaurant in the moderate price range . [SEP]

Summary: The user wants to find a Chinese restaurant in the centre with a moderate price range.

(a)

US ##ER : Can you help me with a taxi booking ? S ##Y ##ST ##EM : Sure ! when would you like to arrive ? [SEP] [CLS] US ## ER : I must arrive to na ##ndo ##s by 23 : 15 [SEP]

Summary: The user wants to book a taxi to a specific destination at a specific time.

(b)

US ##ER : What is the address of A ##corn Guest House ? S ##Y ##ST ##EM : a ##corn guest house is located at 154 chest ##erton road . US ##ER : Great . Can you book it for 7 people and 4 nights starting on Friday ? S ##Y ##EM : I have your reservation for 7 people staying 4 nights , starting on Friday . Your reference number at the A ##corn Guest House is 6 ##IA ##6 ##7 ##8 ##H ##6 . US ##ER : Okay , thanks . S ##Y ##ST ##EM : May I assist with anything else ? US ##ER : I am interested in visiting a museum while I am there . S ##Y ##ST ##EM : sure , we have 23 ! any particular area of town ? [SEP] [CLS] US ## ER : Wow, 23 ! I don ' t have a particular area of town in mind . Can you please recommend a great one to visit ? [SEP]

Summary: The user wants a recommendation for a museum to visit in the area.

(c)

Figure 4: **Visualization of importance scores.** Tokens with darker blue gets larger weights based on the latest user utterance.

Conversation
⋮
SYSTEM: Booking was successful. The table will be reserved for 15 minutes. · · · **USER**: Great. 1 more thing. Can you book a taxi between the 2 places? I would like to arrive at the restaurant in time for my reservation
Summary: The user wants to book a taxi to travel between two specific locations.

Table 7: A failure case of summarization with the LLM.

noteworthy that the model focuses on the latest user utterance while disregarding previous user requests for hotel and restaurant reservation. For the second example, the model misses out on the arrival time for generating the summary. Identification and correction of such errors are topics we will explore in future work. We include more examples in Appendix B.

Retrieved Exemplars In Table 8, we show the top three most similar examples retrieved by CONVERSE. In this example, the user asks to find an expensive Indian restaurant and a retriever needs to retrieve conversations about a restaurant. Indeed, our CONVERSE retriever assigns high similarity scores to pairs of the target conversation and summaries about finding a restaurant. Note that the language model (LLaMA-7B) with in-context learning successfully generalizes to decode test slot values from the exemplars, though the retrieved exemplars consist of values for food or price range, which are different from the target conversation.

5 Related Work

Dialog State Tracking Most of existing works on DST train a supervised model with large-scale labeled datasets (Wu et al., 2019; Zhang et al., 2020; Peng et al., 2021; Lin et al., 2020; Lee et al., 2021; Zhao et al., 2022; Kim et al., 2020; Heck et al., 2020; Hosseini-Asl et al., 2020; Ham et al., 2020; Cheng et al., 2020; Platanios et al., 2021). However, a supervised model does not scale well to new domains or annotation schemas. To address the problem, several recent works explore few-shot DST (Wu et al., 2020; Li et al., 2021; Gao et al., 2020; Lin et al., 2021; Campagna et al., 2020; Su et al., 2022). Most related are the works of Hu et al. (2022); Chen et al. (2023), who adopt in-context learning with LLM for dialog state generation. The work demonstrated the few-shot generalization ability of LLM applied to DST without parameter updates, but the dialog retriever is still fine-tuned with in-domain data.

Another work related to ours is Shin et al. (2022), which formulates DST as a summarization task. The authors train a T5 language model to decode text summaries, which are then transformed into dialog states with heuristic rules. Different from their work, we do not aim to alter the target of DST as summaries but rather our goal is to enable effective conversation retrieval.

Retrieval Our work mainly focuses on retrieving relevant conversations for in-context learning (Liu et al., 2022). There is a vast number of papers (Karpukhin et al., 2020b; Khattab and Za-

Target Conversation	⋮ **SYSTEM**: There are 9 Indian restaurants in centre what price range do you want? **USER**: I am looking for expensive Indian food.
Gold Label	restaurant-food: indian, restaurant-pricerange: expensive
Prediction	restaurant-food: indian, restaurant-pricerange: expensive
Exemplar #1	⋮ **USER**: I am also looking to eat somewhere expensive, in the south area of town. **SYSTEM**: There are 2 Chinese, 1 Indian , 1 Italian, and 1 Mexican restaurants. Which of those would you like? **USER**: I would like the Italian place please. **Summary**: The user wants to find a restaurant in a specific area with a certain price range and cuisine. **Label**: restaurant-food: italian.
Exemplar #2	⋮ **USER**: Actually, I also need a moderate priced restaurant in the same area. **SYSTEM**: I can find a few that meet that criteria, would you like Indian, or Italian food? **USER**: Well, everyone said it's my choice, so I think I would like Italian. **Summary**: The user wants to find a moderate priced restaurant in a specific area with a specific cuisine. **Label**: restaurant-food: italian.
Exemplar #3	⋮ **SYSTEM**: Good news I was able to get this for you. Reference i4dxhdjl. Can I help you find other things to do in the area as well ? **USER**: I am also looking to eat somewhere expensive, in the south area of town. **Summary**: The user wants to find a restaurant with an expensive price range in a specific area of town. **Label**: restaurant-pricerange: expensive, restaurant-area: south

Table 8: Given the target conversation, we show the top 3 most similar examples retrieved by our model CONVERSE.

haria, 2020; Izacard et al., 2022; Santhanam et al., 2022) proposing neural network based retrievers which encode queries and keys into low dimensional vectors and compute similarities between them. Hu et al. (2022); Chen et al. (2023) propose to utilize slots and values to represent a long history of conversation for retrieval. However, in order to train the retriever, their approaches require labeled dialogue data to construct positive and negative conversations for each query conversation. Recently, Ravfogel et al. (2023) retrieve texts based on abstract descriptions generated by a LLM.

6 Conclusion

The contribution of this work is twofold. First, we proposed an effective way of retrieving conversations in LLM-based DST with conversation summaries as search keys and queries. We then improved the efficiency of the retrieval system by distilling a conversation encoder capable of embedding a conversation into a vector space similar to its summary. This eliminates the cost of decoding an actual summary for each test sample during inference. We validated our CONVERSE encoder for LLM-based DST in a real few-shot setting with 100 conversations in the support set. Results showed that CONVERSE consistently improved both the efficiency and the performance of few-shot DST when using different LLMs, outperforming previous LLM-based DST baselines that rely on annotated dialogues for retriever fine-tuning.

Acknowledgement We would like to express our sincere gratitude to Dominik Wagner for the numerous helpful pieces of feedbacks.

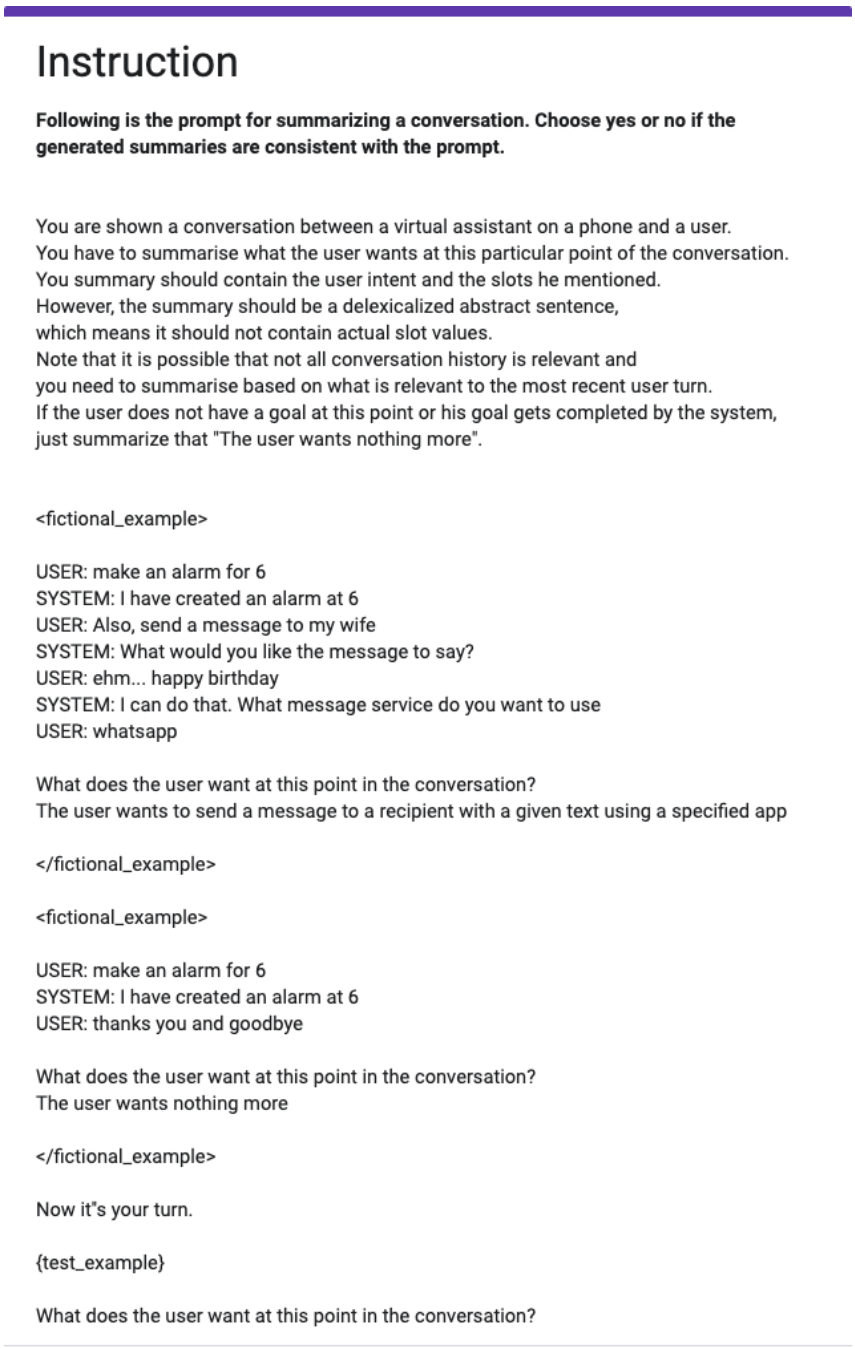
Appendix

A Prompt for Summarization



In Table 9, we provide an instruction and two examples that specify how to summarize a conversation based on the latest user utterance. The first example demonstrate how to ignore irrelevant history — request for setting an alarm and focus on sending a message. The second example is to generate "The user wants nothing more" instead of summarizing the conversation.

B Instruction for Human Evaluation

We conduct human evaluation of 135 summaries generated by the conversation summarizer, `gpt-3.5-turbo`. As shown in Figure 5, three human judges are given an instruction for the evaluation and they are asked to assess whether the generated summaries are consistent with the prompt specified in Table 9.

C Example of Summaries

In Tables 10 to 14, we provide more summaries generated by the LLM, `gpt-3.5-turbo`.

Instruction

Following is the prompt for summarizing a conversation. Choose yes or no if the generated summaries are consistent with the prompt.

You are shown a conversation between a virtual assistant on a phone and a user.
You have to summarise what the user wants at this particular point of the conversation.
You summary should contain the user intent and the slots he mentioned.
However, the summary should be a delexicalized abstract sentence,
which means it should not contain actual slot values.
Note that it is possible that not all conversation history is relevant and
you need to summarise based on what is relevant to the most recent user turn.
If the user does not have a goal at this point or his goal gets completed by the system,
just summarize that "The user wants nothing more".

<fictional_example>

USER: make an alarm for 6
SYSTEM: I have created an alarm at 6
USER: Also, send a message to my wife
SYSTEM: What would you like the message to say?
USER: ehm... happy birthday
SYSTEM: I can do that. What message service do you want to use
USER: whatsapp

What does the user want at this point in the conversation?
The user wants to send a message to a recipient with a given text using a specified app

</fictional_example>

<fictional_example>

USER: make an alarm for 6
SYSTEM: I have created an alarm at 6
USER: thanks you and goodbye

What does the user want at this point in the conversation?
The user wants nothing more

</fictional_example>

Now it"s your turn.

{test_example}

What does the user want at this point in the conversation?

Table 9: Prompt with two exemplars for summarizing a conversation.

Conversation
USER: I am looking for a hotel in the east , and i would like free wifi please. **SYSTEM**: I have found express by holiday inn Cambridge. 1517 Norman way, Coldhams business park **USER**: Does that hotel include free parking and have 2 stars? **SYSTEM**: No, thank you , that s all I need. **USER**: Sure thing what's the area and or name? **SYSTEM**: Thank you for contacting Cambridge Towninfo centre. Have a nice trip! Good Bye! **USER**: Actually, I also need a moderate priced restaurant in the same area
Summary: The user wants to find a moderate priced restaurant in a specific area.

Table 10: Example of conversation summary.

Conversation
USER: I need some tourist information please. I need to know about a hotel called the Arbury lodge guest house. **SYSTEM**: The arbury lodge guest house is in the north area and has a moderate price range. It is 4 stars and has free parking and internet. **USER**: I would like to book a stay for 3 people for 2 nights starting from Tuesday. **SYSTEM**: Good news I was able to get this for you. Reference i4dxhdjl. Can I help you find other things to do in the area as well? **USER**: I am also looking to eat somewhere expensive, in the south area of town. **SYSTEM**: there are 2 Chinese, 1 Indian, 1 Italian, and 1 Mexican restaurants. Which of those would you like? **USER**: I would like the Italian place please. **SYSTEM**: Frankie and Benny s is an expensive restaurant which is expensive would you like for me to book it? **USER**: yeah , book for 3 people on tuesday at 18:30 and give me the reference number
Summary: The user wants to book a table at an expensive Italian restaurant for 3 people at a specific date and time and receive a reference number.

Table 11: Example of conversation summary.

Conversation
USER: I would like to get to Cambridge by train, but I am afraid I need to travel on Sunday. Will that be possible? **SYSTEM**: From where are you departing? **USER**: I am leaving from Broxbourne. **SYSTEM**: There are 19 trains running from Broxbourne to Cambridge on Sunday.
Summary: The user wants to find a train from a specific location to a specific destination arriving before a certain time.

Table 12: Example of conversation summary.

Conversation
USER: Please help me reserve a taxi from saint catharine s college **SYSTEM**: Sure! When would you like to arrive? **USER**: I would like to arrive by 01:15. **SYSTEM**: Great! And what is your destination? **USER**: I am going to Loch Fyne.
Summary: The user wants to reserve a taxi from a specific location to a specific destination at a specific time.

Table 13: Example of conversation summary.

Conversation
USER: Are there any concert halls in the west? **SYSTEM**: I am sorry there are no listings for concert halls in the west. Is there something else I can assist you with today? **USER**: What about colleges in the west **SYSTEM**: There are 5 colleges in that area. 3 have no entrance fees. Would you like additional information on any of these? **USER**: No thank you. I am looking for information El Shaddai hotel. **SYSTEM**: The El Shaddai is a guest house in the centre part of town. It has free internet , parking and has 0 stars. Would you like me to book it for you? **USER**: Could you? That would be great. There are 5 of us and we plan to arrive on Thursday. We'd like to stay for 5 nights.
Summary: The user wants to book a hotel for a group of 5 people for a specific duration of time.

Table 14: Example of conversation summary.

Promptly Predicting Structures: The Return of Inference

Abstract

Prompt-based methods have been used extensively across NLP to build zero- and few-shot label predictors. Many NLP tasks are naturally structured: that is, their outputs consist of *multiple* labels which constrain each other. Annotating data for such tasks can be cumbersome. *Can the promise of the prompt-based paradigm be extended to such structured outputs?* In this paper, we present a framework for constructing zero- and few-shot linguistic structure predictors. Our key insight is that we can use structural constraints—and combinatorial inference derived from them—to filter out inconsistent structures predicted by large language models. We instantiated this framework on two structured prediction tasks, and five datasets. Across all cases, our results show that enforcing consistency not only constructs structurally valid outputs, but also improves performance over the unconstrained variants.

1 Introduction

Structured prediction requires making multiple inter-dependent structurally constrained decisions (Smith, 2010; Nowozin et al., 2014). Many NLP tasks are naturally structured. Consider, for instance, the task of Semantic Role Labeling (SRL) that aims to identify the semantic roles played by sentence constituents for a predicate (Palmer et al., 2010). Given a sentence '*Elrond gave Aragorn the sword.*' and predicate *gave*, the task entails extracting its semantic arguments — the giver (`Agent`), the receiver (`Recipient`), and the thing given (`Theme`). These decisions are mutually constrained; e.g., the arguments have to be distinct phrases.

Existing methods for structured prediction rely on large labeled datasets. However, obtaining structured labels is not straightforward, especially from non-experts. It invariably requires detailed annotation guidelines about the task, the label set, and the interactions between labels. Methods like the

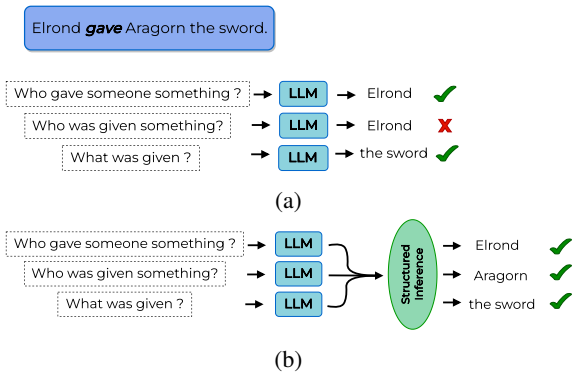

Figure 1: Example of Question Answer driven Semantic Role Labeling (QA-SRL) (a) without, and (b) with structured inference. Sans inference, prediction for each question may contain overlapping/repeated answers, which is prohibited per the task definition. Structured inference avoids such structurally invalid outputs.

re-formulation of structured prediction tasks into a question-answering (QA) format (He et al., 2015; Levy et al., 2017; Du and Cardie, 2020; Pyatkin et al., 2020, 2023) intend to make such tasks more amenable for annotation. However, procuring large-scale annotations still remains expensive and time-intensive; with the problem even more acute for low-resource domains. This predicament necessitates focus on zero and few-shot methods for structured prediction.

Recently, prompt-based methods (e.g., Schick and Schütze, 2021a,b; Liu et al., 2023, inter alia) have shown immense promise, requiring few or even no labeled examples for competitive performance. Prompt-based models generate output text conditionally based on textual input called *prompts*. Prompts can be crafted using a pre-defined task-specific template (Raffel et al., 2020), or even just as natural language instructions (Chung et al., 2022) or questions (Gardner et al., 2019; Pyatkin et al., 2021).

Prompt-based methods have shown promise for

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 112–130
June 16-21, 2024 ©2024 Association for Computational Linguistics

text classification and text generation tasks. However, their use for structured prediction is hitherto largely unexplored. Prior work (e.g., see Liu et al., 2023) uses prompts to predict components of structures independently, but their interactions are ignored. Figure 1a illustrates a failure of that agenda. Each question pertains to a semantic role for the highlighted predicate. Since the model independently encounters each question, it runs the risk of predicting structurally inconsistent answers.

In this paper, we propose to reintroduce inference into prompt-based methods for structured prediction problems (Figure 1b). We present a framework that allows using well-studied inference algorithms with prompt-based predictions. Inference algorithms—realized as beam search, integer linear programs (ILPs, e.g., Roth and Yih, 2004), weighted graph optimization (e.g., Täckström et al., 2015), etc.—take scored candidate label sub-structures as input and optimize a global score while satisfying structural constraints. Historically, trained models generated the label scores (e.g., Lafferty et al., 2001; Collins, 2002). We argue that large language models (LLMs), with appropriate prompts, can be used for scoring, thus eliminating the need for any training or fine-tuning.

We instantiate this idea on two English structured prediction tasks across five datasets. We explore various facets of prompt engineering (e.g., zero- vs few-shot, instruction tuning, etc.) and their impacts on performance. We show that current models can produce structurally inconsistent outputs, and inference helps improve not only consistency, but also overall task performance.[1]

2 Related Work

Prompts for Predictions. The "pretrain, prompt, and predict" paradigm (cf. Liu et al., 2023) exploits the observation that LLMs yield general-purpose tools applicable to several natural language tasks. These LLMs (e.g., T5 (Raffel et al., 2020), GPT-3 (Brown et al., 2020)) may be pretrained for various objectives, including the use of labeled data transformed into prompt-answer pairs. Wei et al. (2022) introduced *instruction tuning* that transforms natural language tasks into natural language instructions to generalize across tasks independent of their presence in training. With fine-tuning still possible, the prompting paradigm allows for generalization across tasks with some (few-shot) or even no (zero-shot) labeled samples. Several works have shown promise on zero- and few-shot text classification and generation tasks (e.g., Raffel et al., 2020; Brown et al., 2020; Schick and Schütze, 2021b; Lu et al., 2022; Touvron et al., 2023, inter alia).

Structures & Prompts. Many NLP tasks—e.g., parsing, coreference resolution, information extraction—call for predicting structured outputs such as sequences, trees or graphs. Structured prediction has a rich history in NLP (Smith, 2010).

Predicting structures with prompts is challenging; the output corresponds to multiple mutually-constraining decisions. Structures that can be flattened into label sequences can be cast as text generation tasks amenable to the LLM interface. Blevins et al. (2023) present a *structured prompting* paradigm to generate labels in an auto-regressive fashion for part-of-speech tagging, named entity recognition, and sentence chunking tasks. They show that this approach works well in a few-shot setting. Such tasks are also amenable for templated slot filling in a few shot setting (Cui et al., 2021). Liu et al. (2022) propose an autoregressive structured prediction framework that reformulates the problem into predicting a series of structure-building action steps.

Structured prediction tasks can be made prompt-friendly by identifying output components and framing each one into natural instructions (He et al., 2015; Du and Cardie, 2020; Pyatkin et al., 2020; Klein et al., 2022; Pyatkin et al., 2023) using the QA format. Mekala et al. (2023) decompose semantic parsing into a series of questions. However, they do not use inference and instead, aggregate outputs sequentially. Yang et al. (2022) use QA prompts to classify pairs of entity mentions as coreferent or not without aiming to form entity clusters. The near contemporary work of Lin et al. (2023) presents a prompt-driven heuristic for event type classification. Wang et al. (2023) use a programming language-based prompt and generate approach for zero and few-shot event argument extraction. Recently, Le and Ritter (2023) show two techniques based on QA and document infilling for zero-shot coreference resolution that rely on recent LLMs' ability to ingest entire documents as input. The concurrent work of Rajaby Faghihi and Kordjamshidi (2024) enforces structural consistency at inference-time, incorporating local decisions from different models using various normalizer functions.

3 "Promptly" Predicting Structures

Problem Statement and Notation Given an input X (e.g., phrase, sentence, etc.), the goal of a conditional model is to characterize the distribution $P(Y|X)$ over outputs Y. The outputs Y in structured prediction tasks consist of a set of decisions $y_1, y_2, \cdots$. For instance, consider the SRL task from §1. Given a predicate, identifying the token spans correponding to its arguments requires multiple decisions; i.e., each y_i corresponds to a semantic argument.

Since the size of the output Y is variable and depends on the input X, the standard approach for modeling such problems calls for factorizing the distribution $P(Y|X)$ over its components $y_1, y_2, \cdots$. The factorization is a design choice; the simplest one decomposes the probability as a product over individual local decisions: $P(Y|X) = \prod_i P(y_i|X)$. With such a factorization, the prediction Y^* for an input X is given by

$$Y^* = \max_Y \prod_{y_i \in Y} P(y_i \mid X) \tag{1}$$

These local probabilities relate to unary potentials in factor graph notation, and in our work, will correspond to logits from neural models. Importantly, the maximization problem above is trivial to solve. Each y_i can be independently assigned.[2]

Even the simple factorization above presents two drawbacks: i) It requires an explicit training step using expensive-to-acquire training data to obtain the unary potentials. ii) It does not guarantee structural consistency, leading to invalid structures. In this work, we ask: *Can we predict valid structured outputs in the zero- to few-shot regime?*

Now, let us address these drawbacks, leading to our proposed framework.

Unary Potentials from Prompts. Prompt-based methods can help bypass the need for supervised training. For every local decision y_i, we construct a query q_i to convert the decision into a prompt-friendly format. A pretrained model can use these queries in the standard prompt-and-predict fashion to get scored candidate answers. Formally, we write $P(Y|X, Q) = \prod_i P(y_i|X, q_i)$. Here, Q is a set of questions corresponding to the components of the structure. In the case of SRL, X would be the input sentence and the predicate, and Q would contain one question per semantic argument type for that predicate. Figure 1 gives an example.

The Return of Inference. Merely aggregating outputs generated with prompts does not address the second drawback, i.e., the need for structurally valid outputs. Structural validity is a constraint that, when applied to the prediction problem, ensures that only valid output collections are considered as candidate predictions. In other words, instead of the unconstrained prediction of Eq. 1, we have

$$Y^* = \max_Y \prod_{y_i \in Y} P(y_i|X, q_i) \quad \text{s.t. Y is structurally consistent} \tag{2}$$

The inference problem above requires combinatorial search over valid structures. Inference can be realized algorithmically in various forms like beam search, an ILP (Roth and Yih, 2004) or weighted graph search (e.g., Täckström et al., 2015; Zaratiana et al., 2022).

The Framework. We propose the following blueprint for predicting valid structures in a zero-shot manner: i) Break the prediction task into its constituent sub-tasks. ii) Convert each sub-task into a prompt-friendly format. iii) Implement an inference algorithm that takes scores from the LLM and produces a valid structured output. This recipe naturally extends to a few-shot setting by prefixing in-context examples with the original prompt.

Inference constructs outputs that satisfy constraints inherent in the definition of a task. Moreover, it can help correct errors of the zero- or few-shot models using other predictions of the same model. Without this mechanism (i.e., using the labels from the prompts directly as in Equation 1), not only will we have partially wrong outputs, they may be invalid from the perspective of the task. Finally, as we will see in the case of the coreference task, inference can help make long-range decisions about parts of an input even when the entire input is not presented to an LLM. In this sense, it can be seen as a mechanism to "bring back the context" without explicitly having to use a long-document model such as LongFormer (Beltagy et al., 2020).

[2] Of course, the structured prediction literature studies other task-dependent factorizations. With neural models, auto-regressive factorizations are also common, where each label is conditioned on previously predicted ones. In this work, we study the simple factorization described here because it can be easily adapted to work with prompting.

4 Experiments

This section describes the tasks and datasets where we instantiate the framework from section §3.

4.1 Semantic Role Labeling

Semantic Role Labeling (SRL) is the task of constructing predicate-argument structures triggered by verbs in a sentence. This task has been studied in using the PropBank (Palmer et al., 2005), FrameNet (Baker et al., 1998), and more recently, the QA-SRL (He et al., 2015) datasets.

Datasets. The QA-SRL project (He et al., 2015) recasts the argument labeling task as question-answering to make it amenable for non-expert annotation. By breaking the predicate-argument structure into a collection of individual arguments, the project curated a collection of QA pairs that represent SRL frames. This SRL-to-QA transformation sets it up perfectly for prompting; the sentence along with each question can serve as a prompt.

We consider two QA-SRL datasets for our experiments. 1) **QA-SRL**$_{wiki}$ (He et al., 2015) contains ∼10.8k QA pairs for 4440 predicates in 1959 sentences across splits.[3] 2) FitzGerald et al. (2018) present a much larger crowd-sourced dataset—**QA-SRL 2.0**—containing 265k QA pairs from 64k sentences for 133k verbal predicates annotated using the QA-SRL annotation schema.

Constraints. The SRL definition dictates that different argument spans for a predicate do not have token overlap (Palmer et al., 2010), and the QA-SRL schema mandates an answer per question.

Prompts and Inference. For any predicate in a sentence, we have one question q_i per semantic role i. For every question, we prompt a generative language model to predict the best-n spans (i.e., sequences) with their respective scores. We denote the score from the language model for the r^{th} (where r $\leq$ n) ranked span (t_r) for role i as $f(t_r, i)$. The scored spans from all questions for a predicate are input to an inference algorithm.

We follow the inference algorithm of Täckström et al. (2015).[4] Given a sentence, we construct a directed graph with one more vertex than the number of tokens. (Figure 2 shows an example.) A vertex v_j is shared by two consecutive words w_{j-1} and w_j, and denotes the boundary between them. Edges can be of two kinds: i) Null edges are added between consecutive nodes with a zero edge score. ii) For every candidate span t_r ranked r for the role i, we add an edge between its representative vertices with an edge score $s_{r,i} = f(t_1, i) - f(t_r, i)$. The highest ranked span gets an edge score of zero.[5]

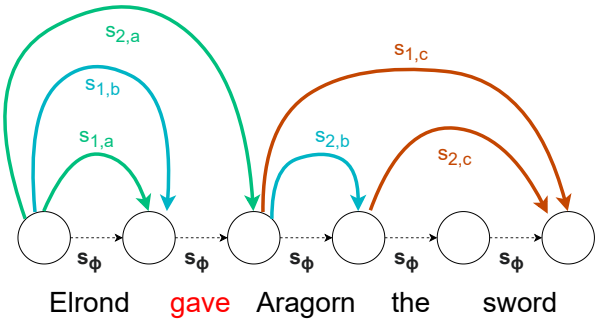

Figure 2: An example graph for the statement "*Elrond gave Aragorn the sword*". This is a toy example with the top-2 candidate spans ($n = 2$) for semantic roles=$\{a, b, c\}$. Each edge represents a candidate span. For instance, the span ranked second for scene role 'a' is the phrase "*Elrond gave*" with an edge score of $s_{2,a}$.

Given the graph, we can perform a shortest-path search from the leftmost to the rightmost nodes; the edges in the shortest path give us non-overlapping labels. However, doing so will generate null sequences that have a zero score. We avoid this issue by extending the algorithm to return the top K shortest paths using Yen's K-shortest path algorithm (Yen, 1971). Subsequently, the highest scoring path among the K paths which assigns exactly one span per semantic role is the optimal structure that satisfies all task constraints. For the example in Figure 2, our inference algorithm would return '*Elrond*', '*Aragorn*', and '*the sword*' as the arguments for roles a, b and c respectively.[6]

Evaluation. We evaluate at both the question-level and the structure-level. At each level, we use exact and head match metrics (Palmer et al., 2010, p. 49). At the question-level, predicted spans are compared with gold spans. For the **Exact**$_q$ accuracy metric, answers are considered correct if the spans exactly match. Similarly, answers are considered correct if the phrasal heads of the spans match to compute the **Head**$_q$ accuracy metric. A structure

[3] He et al. (2015) provide datasets in newswire and Wikipedia domains. We use the latter as it is larger.

[4] For brevity, we outline the inference setup here, and refer the reader to the original work for a detailed description.

[5] A generative model tasked for extraction, like ours, cannot get indices to mark the start and end. Yet, a generated span may occur multiple times in a sentence. In such cases, edges representing all such spans are added with an identical score.

[6] See Appendix F for a worked-out example.

is considered accurate if predicted spans for all constituent roles match. As at the question-level, a match can be determined in an exact (**Exact**$_s$), or head (**Head**$_s$) fashion. Additionally, we also evaluate inconsistency percent (ρ) by measuring how often constraints are violated. We compare every pair of outputs(i.e., argument spans) in a predicted structure. A violation occurs when two output spans overlap.

4.2 Coreference Resolution

Coreference resolution is the task of grouping mention expressions (or simply, mentions) in a document into clusters that refer to the same entity. For example, consider the sentence "*Al requested Bob to give him the pen.*", with given mentions: {"Al", "Bob", "him", "the pen"}. Here, "Al" and "him" refer to the same entity, i.e., Al, while the other mentions are singletons.

Datasets. We use three datasets for this task: 1) The entity coreference annotations within the EventCorefBank+ dataset (ECB+, Cybulska and Vossen, 2014).[7] 2) The CoNLL 2012 OntoNotes 5.0 dataset with the v12 English data splits (Pradhan et al., 2012), which contains entity and event coreference annotation across several domains like magazine articles, broadcast conversations, among others. 3) The GENIA Coreference Corpus (Su et al., 2008), which helps showcase the applicability of this framework in a low-resource domain like biomedicine where annotation is especially difficult. The GENIA corpus is a collection of coreference annotations for 2000 paper abstracts published in the biomedical domain. We define our own train/dev/test splits for the corpus since pre-defined splits were unavailable. We will release these splits for future use. For OntoNotes and GENIA, we do not consider nested entities.

Constraints. The coreference resolution task can be broken into a series of binary decisions: for every mention pair in a document we can ask whether the mentions are co-referrant or not. Entity clusters require transitive closure. That is, given three mentions m_i, m_j and m_k, if a predicate $C(x, y)$ denotes x and y refer to the same entity, then:

$$\forall i, j, k, C(m_i, m_j) \wedge C(m_j, m_k) \implies C(m_i, m_k) \quad (3)$$

[7]We use the processed files provided by Yang et al. (2022)

Prompt and Inference. For every document, we collect mention pairs in it.[8] We transform the coreference decision about mentions m_i and m_j into a Yes/No question: "*Does m_i refer to m_j?*". A 'Yes' establishes a coreference link between the mentions. Questions are appended with the relevant context and given to a language model. Link scores ($s_{i,j}$) for a mention-pair i and j are given by $s_{i,j} = f_{yes}(i, j) - f_{no}(i, j)$ where f_{yes} and f_{no} are the scores for generating the sequences "yes" and "no" given a question and context. Using the link scores, we employ *All-link* inference from Chang et al. (2011) to solve the following integer program over binary decisions $y_{i,j}$:

$$\max_y \sum_{i,j} y_{i,j} s_{i,j}$$
$$\text{such that} \quad y_{i,k} \geq y_{i,j} + y_{j,k} - 1, \quad \forall i, j, k$$
$$y_{i,j} \in \{0, 1\}, \quad \forall i, j.$$

The constraint ensures that the transitivity condition from (3) is satisfied.

Evaluation. We use two metrics: i) **F1** that measures performance of the binary decisions at the question level ii) **CoNLL score** (Pradhan et al., 2014) that averages three cluster evaluation metrics: MUC , B^3, and $CEAF_e$. Additionally, we measure the inconsistency percent (ρ): the number of times constraint (3) is violated divided by the number of times the antecedent is true. This is the same as the 'conditional violation' defined by Li et al. (2019), and measures the fraction of times a third link between three mentions does not exist, when the other two links between them exist.

5 Results

This section presents the impact of inference on zero-shot performance and consistency. We use the 3 billion variants from the T5 (Raffel et al., 2020) family of encoder-decoder models for our experiments. We discuss our implementation briefly here; Appendix D has details like prompt templates.

5.1 Semantic Role Labeling

We consider the T5-3B model[9] for our experiments. We also present results on Flan T5-XL (Wei et al., 2022), also a 3B parameter model, to check if instruction tuning helps with zero-shot performance.

[8]For Ontonotes, we considered all mention pairs in a window size of three sentences due to a large number of mentions.

[9]We also considered UnifiedQAv2 (Khashabi et al., 2022) and Macaw (Tafjord and Clark, 2021). T5 performed the best.

Instruction-tuned models like Flan T5 allow verbalizing constraints within the prompt structure. We also test out an iterative prompting method (Wang et al., 2022), where questions pertaining to a predicate in a sentence are presented in sequential order to the model with verbalized constraints. In every prompt, we include the QA pair from every previous question for the predicate already prompted. This prompting strategy is denoted by the superscript `itr`. See Appendix D.1.1 for an example.[10] Further, we can use inference in conjunction with this iterative prompting strategy.

Tables 1 and 2 show the results for QA-SRL$_{wiki}$ and QA-SRL 2.0 respectively. We see that the constrained models produce near-consistent gains over their unconstrained counterparts. Flan-T5 does not outperform the T5 model, but iterative prompting with inference significantly improves its performance. More importantly, without inference, the models produce highly inconsistent predictions with a lowest inconsistency percent of 34%! In addition, we also provide results on GPT-4 with the constraints verbalized as system instruction.[11] For GPT-4, all the questions are provided at once. Refer Appendix D.1.2 for details.

As an illustrative example, we present a case where constrained inference corrects overlapping predicted arguments. For the sentence, *"Keats' long and expensive medical training with Hammond and at Guy's Hospital led his family to assume he would pursue a lifelong career in medicine, assuring financial security ..."*, the model was asked: i) What would assure something? ii) What would something assure? The unconstrained model generated "financial security" on both counts. Post-inference, the answer to the first question is changed to "lifelong career in medicine", resulting in the correct structure.

5.2 Coreference Resolution

The ability to specify multiple choices makes the Macaw-3B (Tafjord and Clark, 2021) model an ideal choice for the Yes/No choice QA task.[12] As before, we show results using the instruction-tuned Flan T5-XL model as well. For this set of experiments, we only prompt the model with the sentence(s) containing the mention pair as context, and not the whole document.[13] We show more analysis with varying context styles in Appendix B.2.

In addition to the constrained inference proposed in §4.2, we consider a simple right-to-left cluster assignment heuristic (**R2L**) proposed by Soon et al. (2001). This heuristic assigns a candidate mention to the cluster of the closest mention where a link was predicted by the unconstrained model. We also present two rudimentary baselines: i) **All-Yes** baseline where all questions are answered "Yes" and all mentions belong to a single cluster, and ii) **All-No** baseline where all questions are answered "No" and every mention is its own cluster. These baselines are relevant since both generate valid structures.

The unconstrained and the constrained models can only be compared using their F1 scores and the inconsistencies.[14] Tables 3, 4 and 5 show results

System	Head$_q$(↑)	Head$_s$(↑)	ρ (↓)
T5-3B	**63.84**	36.17	34.30

[10] Note that verbalized constraints do not guarantee a valid output structure. However, exposure to preceding predictions may help reduce inconsistencies nonetheless.

[11] GPT-4 results are meant to contextualize our results with a current SOTA system. The datasets we considered may have been utilized to train GPT-4. GPT-4 also has multiple orders of magnitude more parameters than the models we consider.

[12] We also considered this task in an NLI format with the T5-3B model. However, the QA format was a clear winner.

[13] Note: We do not need a large context window. Inference can create consistent clusters by looking at smaller contexts.

[14] The official CoNLL scorer requires valid structures ren-

System	F1(↑)	CoNLL(↑)	ρ(↓)

+ R2L	51.88	50.37	0
+ All-Link	51.33	48.52	0

Table 4: Coreference resolution performance and consistency metrics for unconstrained vs constrained systems for the OntoNotes dataset. A fine-tuned constrained Macaw model gets an F1 and CoNLL score of 96.17 and 95.63 respectively. All values in %.

for the ECB+, OntoNotes and GENIA datasets respectively. We refer the reader to Table 8 in Appendix B.1 for a detailed breakdown of the CoNLL score. We observe gains in F1 scores for constrained systems over their unconstrained counterparts. In all cases, our models outperform the All-Yes and All-No baselines. We also see that the inconsistency is substantially higher for the unconstrained models, especially with Flan-T5-XL.

Figure 3 presents an instance where inference corrects flawed links. Here, '*T-mobile*' and '*carrier*' belong to one entity cluster, while, '*Blackberry Curve 8900*' and '*product*' belong to another. Our unconstrained model incorrectly predicts a link between '*T-mobile*' and '*Blackberry Curve 8900*'. But transitivity requires all other edges to be present, which the model does not predict. Our inference algorithm removes the erroneous edge and predicts consistent clusters.

dering base system evaluation impossible w/o inference.

+ R2L	53.35	54.11	0
+ All-Link	**65.36**	**57.47**	0

Table 5: Coreference resolution performance and consistency metrics for unconstrained vs constrained systems for the GENIA dataset. A fine-tuned constrained Macaw model gets an F1 and CoNLL score of 91.58 and 90.01 respectively. All values in %.

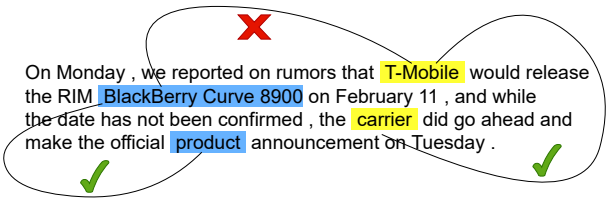

Figure 3: An example from ECB+ dataset where inference helps correct inconsistency of predictions. An incorrect link is predicted between '*Blackberry Curve 8900*' and '*T-Mobile*' by the unconstrained model, which is removed post-inference. Irrelevant mentions are hidden for clarity.

Iterative prompting for coreference resolution is challenging for two reasons: 1) As the component questions establish links between two mentions and the transitivity closure applies to three mentions, verbalizing the transitivity constraint within the prompt can be challenging. 2) Coreference structures are much larger than the SRL structures, hence, demanding a large memory requirement.

6 Analysis Experiments

Next, we show how performance and inconsistency vary with model size and in-context examples.

6.1 Model Size

We study the performance and consistency of models over varying sizes. For SRL, we compare the small, base, large, 3 billion, and 11 billion T5 models. Figure 4 shows the Head_s metric over T5 model sizes for QA-SRL 2.0, along with the inconsistency percent. For coreference, we compare the large, 3 billion and 11 billion variants of the Macaw model. We consider the All-Link inference for the constrained models. We report the F1 score

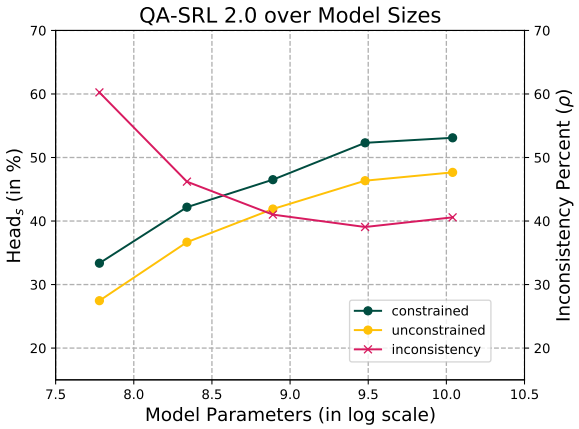

Figure 4: Head$_s$ performance and inconsistency percent over model sizes for the QA-SRL 2.0 dataset. The circle-marked (-•-) plots map to the left axis, and the cross-marked (-x-) plot to the right axis. Inconsistency is shown for unconstrained models since constrained models are always consistent (i.e., ρ=0).

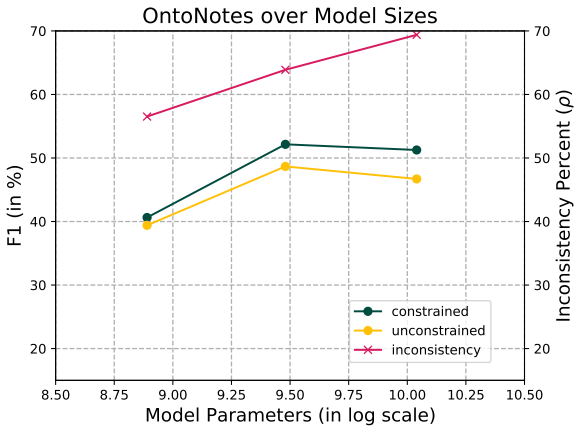

Figure 5: F1 performance and inconsistency percent over model sizes for the OntoNotes dataset. The visual encodings follow the same convention as in Figure 4.

and the inconsistency percent on the OntoNotes dataset in Figure 5. The inconsistency is shown only for the unconstrained models; the constrained ones are guaranteed to be consistent.

Across the datasets, we see that performance almost always increases and constraints provide steady gains. In QA-SRL 2.0, inconsistency reduces with increasing model size. The trend reverses for OntoNotes. Interestingly, with QA-SRL 2.0, a constrained model of a certain size often yields comparable, if not better, results as an unconstrained model of the immediately bigger model, showing that constraints might give performance gains equivalent to using a bigger model. Appendix C shows results for the other datasets.

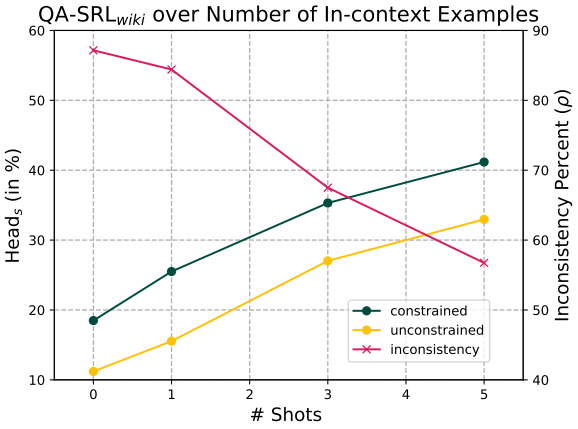

Figure 6: Head$_s$ performance and inconsistency percent over in-context examples (shots) for the QA-SRL$_{wiki}$ dataset. The visual encodings follow the same convention as in Figure 4.

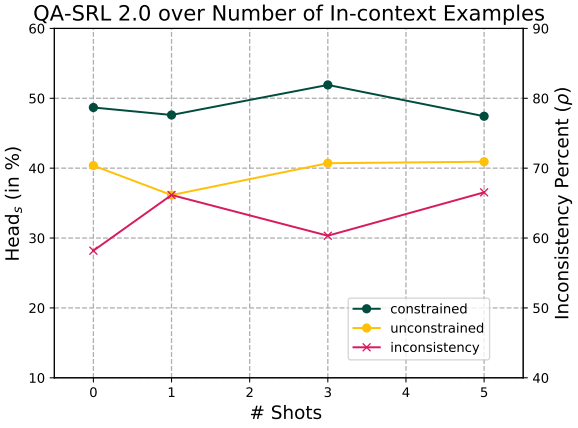

Figure 7: Head$_s$ performance and inconsistency percent over in-context examples (shots) for the QA-SRL 2.0 dataset. The visual encodings follow the same convention as in Figure 4.

6.2 Few-shot Prompting

So far, we have examined our framework in the zero-shot setting. *Do the conclusions hold for few-shot settings as well?* To answer this question, we use the Flan-T5-XL model which is known to yield promising results with even a few in-context examples.[15] We conduct few-shot experiments for the SRL task on the QA-SRL$_{wiki}$ (Figure 6) and QA-SRL 2.0 (Figure 7). We observe a clear increase in performance with increasing shots for QA-SRL$_{wiki}$. Recall that Flan T5, in a zero-shot setting for this dataset, underperforms compared to T5. Hence, the gains are not surprising: only the

[15]An interesting question: What counts as a shot? All questions in a structure or just one? We consider the latter.

5-shot constrained system beats the zero-shot constrained T5 model (38.75 Head_s). The model also becomes more consistent with more examples. For QA-SRL 2.0, the performance and the consistency largely remain invariant with number of shots. Constrained systems produce more accurate structures than their unconstrained counterparts.

7 Conclusions

Prompt-based methods have impressed when deployed in zero- and few-shot manner. Structured prediction problems can use them by breaking the structure down into smaller components and querying for local decisions. This aspect has been explored by some in the literature. However, these works leave out a pivotal part of such structured prediction tasks—the structure. In this work, we proposed a new framework to predict structurally consistent outputs by following local predictions with an inference step. In our experiments, our framework not only guarantees consistency but also provides consistent performance gains.

Limitations

Our focus of this work is to predict structures given that a structured prediciton task can be broken down into components and questions can be generated for those components. While this relies heavily on advances in question generation, we do not focus on this line of research and consider that questions are given to us. A separate line of work exists precisely in this domain of question generation for structured prediction tasks (He et al., 2015; Levy et al., 2017; Du and Cardie, 2020; Wu et al., 2020; Pyatkin et al., 2020; Klein et al., 2020; Pyatkin et al., 2021). We emphasize that our contribution is more general as to how we can marry the idea of inference with prompting.

A problem that can affect any generative model is the label bias problem where the model prefers a certain label over certain other label irrespective of the inputs. This problem can cause performance imbalances and models need to be calibrated to alleviate this phenomenon. Recently, a few works (Zhao et al., 2021; Holtzman et al., 2021; Chen et al., 2023; Han et al., 2023; Fei et al., 2023) study this phenomenon for zero and few shot prompting models for an array of text classification tasks. We briefly studied this for our coreference experiments and found that Macaw was more well-calibrated for the binary task as compared to T5. We leave a detailed calibration study for future work.

Acknowledgements

We thank the members at the Utah NLP lab and AI2 for their insights, especially, Ashim Gupta for his feedback on the iterative prompting experiments. We thank the anonymous reviewers for their feedback. This material is based upon work supported in part by NSF under grants #2007398, #2217154, #1822877 and #1801446. The support and resources from the Center for High Performance Computing at the University of Utah are gratefully acknowledged. Valentina is supported by an Eric and Wendy Schmidt Postdoctoral Award.

A Detailed SRL Results

Detailed results for the QA-SRL$_{wiki}$ and QA-SRL 2.0 are given in Tables 6 and 7 respectively.

B Additional Coreference Results

B.1 Zero Shot Coreference Results

The complete zero shot results for Macaw-3B and Flan T5-XL models are given in Table 8. One might notice that the Flan model is highly inconsistent as compared to the Macaw model. Note that in each case, the divisor is different since it is the number of times the antecedent is activated in equation 3. Examining the predictions, we saw that the value of the divisor for the Macaw models is roughly four times that of the Flan models. This implies that Flan-T5 tends to predict 'No' more often.

System	$\text{Exact}_q(\uparrow)$	$\text{Exact}_s(\uparrow)$	$\text{Head}_q(\uparrow)$	$\text{Head}_s(\uparrow)$	$\rho\ (\downarrow)$

Table 8: Coreference resolution performance and consistency metrics for unconstrained vs constrained systems. All values in %.

B.2 Context Styles for Coreference Resolution

As mentioned in §5.2, for any given question pertaining to a mention-pair, we consider only the sentences where the constituent mentions occur. One can argue that surrounding context can play an important role in deciding whether or not two mentions are co-referent. Furthermore, intermediate context between the sentences can be pivotal in establishing otherwise loosely connected sentences appearing a few sentences apart. This begs the question about how much, if any, does providing the entire document help.[16] On a different note, mentions can be highlighted with asterisks(as used for WSC in Raffel et al. (2020)) to explicitly state where in the context they occur. This approach can help deal with pronominal mentions which are bound to repeat. We present results when the entire document (**Full**) acts as context, when mentions are highlighted (**Hlght**), and a combination of both (**Full + Hlght**) in comparison to the context style where only the relevant sentences are considered (**Rel**). We provide detailed results for performance and consistency over differing context styles in Table 9. We see that results are comparable across all context styles.

C Additional Model Size Experiments

The analysis over model sizes for QA-SRL$_{wiki}$ is given in Figure 8. We see similar analysis as observed with QA-SRL 2.0 dataset. Performance improves with increasing model size while inconsistency reduces. Furthermore, constraints provide steady gains over their unconstrained counterparts.

Figure 9 shows performance and inconsistency of the Macaw model over sizes for the ECB+ coreference dataset. Figure 10 shows the same for the GENIA dataset. In both the cases, we see that performance drastically improves from the large to the 3 billion parameter variant. Performance gains from 3 billion to 11 billion are minimal. However, we see that the inconsistency increases with increasing size. We also see that for these datasets, for the large variant, constraints do not help the model. However, note that F1 is a question-level metric and a drop might be a necessary to guarantee a consistent structure.

[16]For Ontonotes and GENIA, the document size went beyond memory which is why we do not test along this dimension.

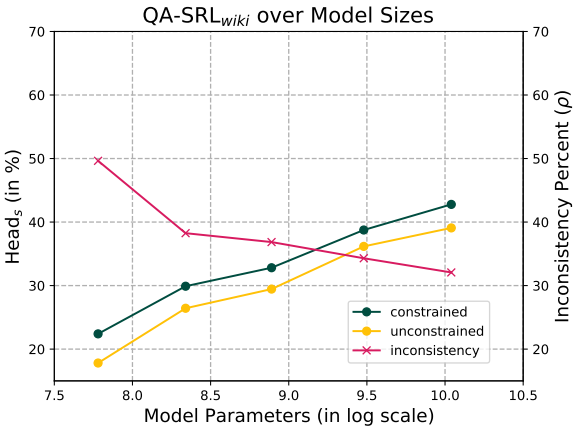

Figure 8: Head$_s$ performance and inconsistency percent over model sizes for the QA-SRL$_{wiki}$ dataset. Refer circle-marked (-•-) plots to the left axis, and the cross-marked (-x-) plot to the right axis. Inconsistency is computed for unconstrained models since constrained models are trivially consistent (i.e., ρ=0).

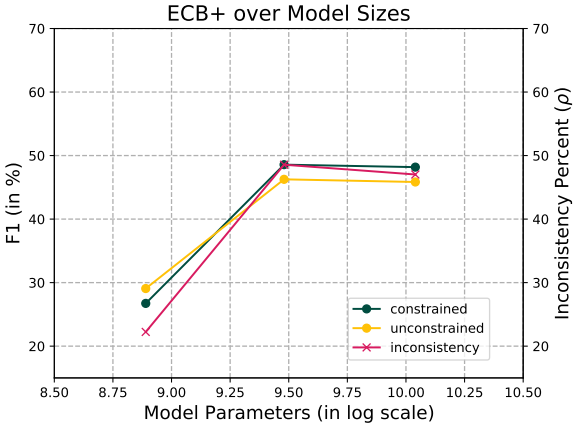

Figure 9: F1 performance and inconsistency percent over model sizes for the ECB+ dataset. Refer circle-marked (-•-) plots to the left axis, and the cross-marked (-x-) plot to the right axis. Inconsistency is computed for unconstrained models since constrained models are trivially consistent (i.e., ρ=0).

Table 9: Coreference resolution performance and consistency metrics over different context styles for unconstrained vs constrained systems. The first row of every triplet denotes the context style considered. All values in %. All results are on the Macaw-3B model.

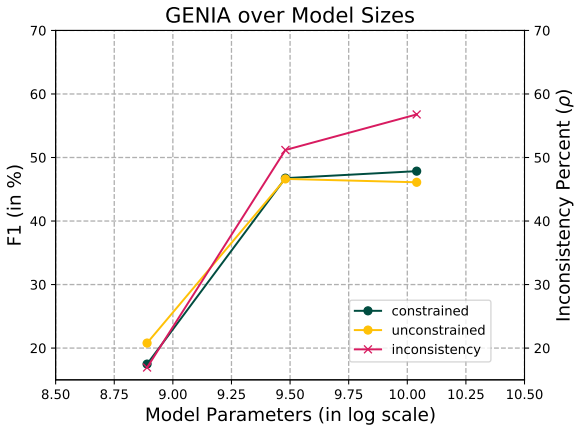

Figure 10: F1 performance and inconsistency percent over model sizes for the GENIA dataset. Refer circle-marked (-•-) plots to the left axis, and the cross-marked (-x-) plot to the right axis. Inconsistency is computed for unconstrained models since constrained models are trivially consistent (i.e., ρ=0).

D Experimental and Prompt Details

We use HuggingFace's `transformers` library (Wolf et al., 2020) for all our models. All model generations were done with a random seed of 2121. We use the 'generate' method in the HuggingFace (Wolf et al., 2020) library to return the score of a generated sequence. These scores can be accessed by the 'sequences_scores' output attribute. We consider the top 20 spans for each question. For all few shot settings, we average results across shots considered from three seeds: 42, 20 and 1984.

We explain the prompt templates and the parameters/assumptions we chose in the subsequent sections.

D.1 Semantic Role Labeling.

We use the questions and sentences provided by the respective datasets. Say, the question and the sentence context were denoted by <ques> and <context> respectively. For the T5 experiments, we follow the QA prompt format as specified by Raffel et al. (2020) which is: "`question: <ques> context: <context>`". For Flan-T5, we use the following prompt design: "`<context> \n In the above sentence, <ques>`". These are the inputs to the respective models. For generation, we considered a beam size of 20. We considered 20 shortest paths to be returned from Yen's K-shortest path algorithm. Generally, a higher K might get better results but we found 20 to be optimal for the perfomance-time tradeoff.

D.1.1 Iterative Prompting Template

In the iterative prompting template, we prompt the model one question at a time such that the answer for every preceding prompt is included in subsequent prompts. Assume a predicate in a sentence to have n questions: $\{q_1,q_2,\ldots,q_n\}$. In the first step, we prompt the model for q_1 using the prompt template mentioned in the previous sub-section. Next, we follow with the prompt the model for q_2 such that the question and the generated answer for q_1 are included in the prompt. Consequently, we use a different prompt template that contains this pair and an instruction that asks the answers to not overlap. Subsequently, the prompt for q_3 will contain the question-answer pair q_1 and q_2, and so on. An example is shown in Figure 11. We use the order provided in the QA-SRL datasets for our experiments.

D.1.2 GPT-4 Prompt Template

We used OpenAI's API and the `ChatCompletion` end-point to obtain the GPT-4 results. We provide the following system instruction: "*You will be given a set of questions regarding a particular sentence. Answer these questions such that the answers to the questions do not overlap. Answers should strictly be a sub-sequence of the sentence. Do not include anything except the answer phrase in the answer*". A user prompt consists of a sentence followed by a set of questions pertaining to a certain predicate in the sentence. As a result, each predicate consists of a request to the endpoint. An example request and answer are shown in Figure 12. A majority of the GPT-4 generations adhere to the answer template shown in the figure. However, for predicates with a single question, answers did not always contain answer headers (e.g., "`Answer 1: <answer>`"). These were handled accordingly. In some rare cases, "`None of the above choices`" was generated and such cases were considered as having no answers. The experiment across the two datasets cost a total of $96.31.

D.2 Coreference Resolution.

We are given the context (<context>) and a pair of mentions(<m1> and <m2>) for the input. For the Macaw models, the input prompt follows this format:

"`$answer$ ; $mcoptions$=(A) Yes (B) No ; <context> Does <m1> refer to <m2>?`"

Prompt:

Elrond gave Aragorn the sword .
In the above sentence, Who gave something?

Flan T5:

Elrond

Prompt:

For the sentence given below answer the following questions such that the answers do not overlap.

Sentence: Elrond gave Aragorn the sword .

Question: Who gave something?
Answer: Elrond

Question: Who was given something? Make sure the answer is present in the sentence.

Flan T5:

Aragorn

Prompt:

For the sentence given below answer the following questions such that the answers do not overlap.

Sentence: Elrond gave Aragorn the sword .

Question: Who gave something?
Answer: Elrond

Question: Who was given something?
Answer: Aragorn

Question: What was given? Make sure the answer is present in the sentence.

Flan T5:

the sword

Figure 11: An example of the iterative prompting template. Note that Flan-T5 is not a stateful model.

System Instruction:

You will be given a set of questions regarding a particular sentence. Answer these questions such that the answers to the questions do not overlap. Answers should strictly be a sub-sequence of the sentence. Do not include anything except the answer phrase in the answer.

User:

Sentence: Elrond gave Aragorn the sword .

Question 1: Who gave something?
Question 2: Who was given something?
Question 3: What was given?

GPT-4:

Answer 1: Elrond
Answer 2: Aragorn
Answer 3: the sword

Figure 12: An example with the template used for GPT-4 experiments.

For the Flan models, we follow the format: "`<context> \n In the above passage, does <m1> refer to <m2>? Yes or No?`"
We restrict generations to {"Yes","No"} for Flan experiments and to {"$answer$ = Yes", "$answer$ = No"} for the Macaw experiments. Integer Linear Programs were implemented and solved using the Gurobi solver (Gurobi Optimization, LLC, 2023).

E Inference Overhead

Since the inference algorithm follows the generation step, a time overhead is expected. Table 10 shows the generation time and its corresponding inference time for the datasets we consider. Crucially, while the generation step is run on the GPU, our inference implementation is run on the CPU.

F SRL Inference Worked-out Example

We will consider the example mentioned in Figure 2 with toy values to illustrate the inference process. In this toy setup, we consider three roles (`a`,`b`, and `c`)[17] and assume the top-2 candidate spans per role with their scores as returned a hypothetical generative model.

The spans and scores for this toy example are given in Table 11. Given these spans and scores. we can construct the directed graph as shown in

[17]You may assume these to be the `Agent`, `Recipient` and `Theme` roles as mentioned in §1

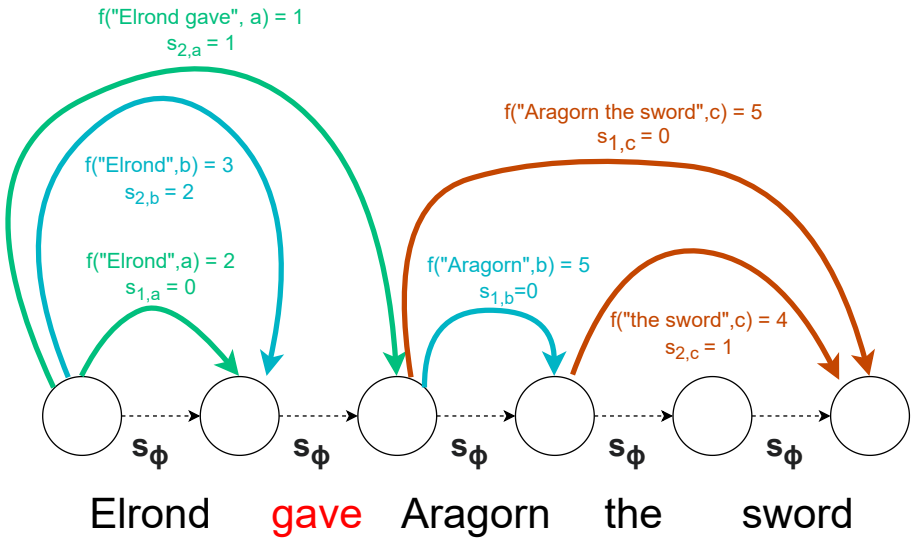

Figure 13: An example of the SRL inference graph with values. Every edge shown in the figure contains the scores returned by the scoring function (in our case, the generative language model) $f(t_r, i)$ where is t_r is the rth ranked span for role i. As mentioned in §4.1, edge score for a span t_r is then calculated as $s_{r,i} = f(t_1, i) - f(t_r, i)$ where $f(t_1, i)$ is the score (as returned by the scoring function) for the top ranked span for role i. Note that we use these scores as the edge weights and, subsequently, as the scores used in the inference algorithm.

Dataset	Gen. step	Inf. Step
QA-SRL$_{wiki}$	48.49	2.18
QA-SRL 2.0	945.22	32.68
ECB+	81.87	0.08
Ontonotes	1547.03	62.99
GENIA	859.88	116.33

Table 10: Time taken (in minutes) by the generation (Gen.) and the inference (Inf.) steps for the datasets. The generation step for QA-SRL$_{wiki}$, QA-SRL 2.0, and Ontonotes were executed on an Nvidia A100 (40 GB) GPU. The generation step for ECB+ and GENIA were executed on an Nvidia A40 (48 GB) GPU. The benchmarking is performed for the T5-3B and Macaw-3B models for the SRL and coreference resolution tasks respectively.

Figure 13. We calculate the edge scores $s_{r,i} = f(t_1, i) - f(t_r, i)$ where $f(t_1, i)$ is the score (as returned by the scoring function) for the top ranked span for role i. For the sake of this illustration, we shall use $s_{r,i}$ as the span notation as well. The s_ϕ value is set to zero. The first step of our inference algorithm aims to find the K shortest paths from the leftmost to the rightmost node. Observe how overlapping spans can never be on the same path. As a results, the top ranked candidates for roles b (span $s_{1,b}$) and c (span $s_{1,c}$) can never be in the same structure.

K shortest paths are returned in increasing order of total path length where path length for a path S is $\sum_{s_{r,i} \in S} s_{r,i}$ as shown in Table 12. As a result, one might notice that partial structures such as paths $\{s_{1,a} \rightarrow s_{1,c}\}$ or $\{s_{1,a} \rightarrow s_{1,b}\}$ might have the shortest path length. However, the QA-SRL framework necessitates one answer per question(or, in other words, role). A post-processing step follows the shortest path step where, from the K shortest paths returned, the shortest path containing exactly one span for each role is chosen. This step also ensures that paths where multiple spans for the same role are present (e.g., $\{s_{2,b} \rightarrow s_{1,b} \rightarrow s_{2,c}\}$), are also avoided. In the example shown in Figure 13, $\{s_{1,a} \rightarrow s_{1,b} \rightarrow s_{2,c}\}$ gives the most optimal path with a path length 1 and satisfies all the constraints. This yields to "*Elrond*", "*Aragorn*" and "*the sword*" as arguments for roles *a*, *b* and *c* respectively. Intuitively, a sufficiently large K (in our case, 20) leads to a higher chance of obtaining a complete and consistent structure. In cases where no complete structures can be formed from any of the K shortest paths, partial (yet, consistent) structures are predicted.[18]

[18]Partial structures can be considered as having "null" answers for some roles. For evaluation purposes, we treat them as incorrect answers.

Rank	Role		
	a	**b**	**c**
1	"*Elrond*" (2)	"*Aragorn*" (5)	"*Aragorn the sword*" (5)
2	"*Elrond gave*" (1)	"*Elrond*" (3)	"*the sword*" (4)

Table 11: Example spans and scores (in brackets) of candidate spans for each role. The scores correspond to the $f(t_r, i)$ values discussed in §4.1 where is t_r is the rth ranked span for role i.

Rank	Path	Path length
1	$\{s_{1,a}, s_{1,b}\}$	0
2	$\{s_{1,a}, s_{1,c}\}$	0
3	$\{s_{1,a}\}$	0
4	$\{s_{1,b}\}$	0
5	$\{s_{1,c}\}$	0
6	ϕ	0
7	$\boldsymbol{\{s_{1,a} \rightarrow s_{1,b} \rightarrow s_{2,c}\}}$	**1**
8	$\{s_{2,a} \rightarrow s_{1,c}\}$	1
	...

{yshao, nnakashole}@eng.ucsd.edu

Abstract

Structured data, prevalent in tables, databases, and knowledge graphs, poses a significant challenge in its representation. With the advent of large language models (LLMs), there has been a shift towards linearization-based methods, which process structured data as sequential token streams, diverging from approaches that explicitly model structure, often as a graph. Crucially, there remains a gap in our understanding of how these linearization-based methods handle structured data, which is inherently non-linear. This work investigates the linear handling of structured data in encoder-decoder language models, specifically T5. Our findings reveal the model's ability to mimic human-designed processes such as schema linking and syntax prediction, indicating a deep, meaningful learning of structure beyond simple token sequencing. We also uncover insights into the model's internal mechanisms, including the ego-centric nature of structure node encodings and the potential for model compression due to modality fusion redundancy. Overall, this work sheds light on the inner workings of linearization-based methods and could potentially provide guidance for future research.

1 Introduction

Motivation. Natural Language Interfaces (NLIs) to computer systems allow the use of everyday language to interact with computer systems, thus lowering technical barriers to advanced computing functionality. Early systems such as SHRDLU (Winograd, 1971) and LUNAR (Woods, 1973) saw limited success due to the limited language processing capabilities of computer systems at the time. After years of steady progress, the strong language processing capabilities of large language models (LLMs) have led to renewed interest in NLIs such as the widely used ChatGPT (Brown et al., 2020). Systems such as ChatGPT already serve as robust NLIs. However, a critical challenge remains in applying the underlying models to specialized and personalized real-world scenarios. The challenge stems from the need for the model to handle "backend data" commonly stored in structured formats such as proprietary databases, knowledge graphs, or dialog states, including intents, slots, and values. We refer to this task as *structured data representation* (SDR)(Shao et al., 2022).

In this study, our primary focus is on a representative SDR task: text-to-SQL parsing (Zelle and Mooney, 1996; Zettlemoyer and Collins, 2012). This task automatically maps natural language queries into SQL commands, thus eliminating or at least reducing the need for programming knowledge. For such a system to be broadly applicable, it must be capable of adapting to new databases, encoding these databases together with user queries, and predicting the corresponding SQL queries.

The Rise of Linearization-based Methods. Recent approaches to text-to-SQL parsing and other SDR tasks fall into two main categories: *linearization-based* and *structure-based* methods (Lin et al., 2020; Scholak et al., 2021; Xie et al., 2022). Structure-based approaches explicitly utilize the inherent structure in the data, often representing it with a graph (Bogin et al., 2019; Wang et al., 2020; Cao et al., 2021; Hui et al., 2022). In contrast, linearization-based methods treat structured data as a token sequence, processed similarly to natural language sentences. The latter have gained traction due to their compatibility with LLMs, which have demonstrated impressive performance across various NLP benchmarks.

Open Problems and Our Contributions. SDR tasks like text-to-SQL remain a challenging problem for LLMs, as they are not completely "solved" by current models (Li et al., 2023). Towards shedding light on ways forward, our main contribution is a detailed exploration of the inner workings of a former state-of-the-art (SOTA) text-to-SQL parser

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 131–156
June 16-21, 2024 ©2024 Association for Computational Linguistics

with T5 backbone (Scholak et al., 2021; Xie et al., 2022). Our analytical approaches include probing classifiers (Köhn, 2015; Gupta et al., 2015; Shi et al., 2016; Conneau et al., 2018), as well as techniques that directly manipulate model intermediates, leveraging the recent causal tracing method (Finlayson et al., 2021; Meng et al., 2022). We find that despite their simplicity, linearization-based methods can effectively represent structured data. Specifically, we show that the prefix-tuned T5 model preserves low-level textual details and enhances understanding of node relationships in structured data. We also show the ego-centric nature of structure node encodings, which primarily contain information relevant to the node itself. Additionally, we uncover a duplicative robustness in modality fusion, indicating potential avenues for model compression. Our study also reveals the model's internal working pipeline, which aligns with human-designed processes like schema linking, syntax prediction, and node selection, suggesting meaningful learning rather than reliance on spurious correlations. The attention mechanism's role in modality fusion and the distinctive functionalities of different layer ranges in the decoder are also revealed. Overall, our research contributes to our understanding of structured data representation in encoder-decoder LLMs.

We opted not to analyze extremely large LMs such as GPT-4, due to the high computational cost of our analytical methods and the opaque nature of their intermediate states. However, given the competitive performance of the model we study, coupled with its sequential input and autoregressive output which are analogous to LLMs, we believe that our findings are general and applicable to models in the same category.

2 Related Work

Structured Data Representation for Text-to-SQL. From prior work, structure-based methods include SchemaGNN (Bogin et al., 2019), RAT-SQL (Wang et al., 2020), LGE-SQL (Cao et al., 2021) and S^2SQL (Hui et al., 2022). Linearization-based methods have been widely studied, including BRIDGE (Lin et al., 2020) and Picard (Scholak et al., 2021). USKG (Xie et al., 2022), which proposes a unified linearization method for all SDR tasks, also falls under the category. Recently, LLMs such as those behind ChatGPT also demonstrated strong performance as a structure linearization-based text-to-SQL method (Li et al., 2023).

Model Behavior Analysis and Interpretation. Previous work include gradient-based methods which check the importance of input features based on their gradient, such as saliency maps (Simonyan et al., 2013). For models reliant on attention mechanisms (Clark et al., 2019), analytical methods exist to examine the significance of individual input units by evaluating attention weights. However, such analyses have faced skepticism in other works (Serrano and Smith, 2019). An alternative line of work is the *probing classifier* approach, in which classifiers are trained on a model's intermediate representations to determine the existence of specific information (Köhn, 2015; Gupta et al., 2015; Shi et al., 2016; Ettinger et al., 2016; Adi et al., 2016; Liu et al., 2019; Tenney et al., 2019; Hewitt and Liang, 2019; Voita and Titov, 2020; Zhu and Rudzicz, 2020; Pimentel et al., 2020; Ravichander et al., 2021b). Though flexible and adaptable to trace various information, probing tests may present challenges in the interpretation or comparison of results (Ravichander et al., 2021a; Belinkov, 2022). A recent line of work involves causal analysis, wherein researchers manipulate the target information within the input and restore intermediate outcomes to a clean state to verify the presence of information (Finlayson et al., 2021; Meng et al., 2022). Our analysis framework builds upon previous probing and causal analysis methods. However, we have adapted and incorporated additional methods specifically to gain insights into tasks related to structured data representation.

3 Preliminaries

The model we investigate in this work is T5-large,[1] with prefix-tuning on the Spider dataset (Yu et al., 2018; Xie et al., 2022). The model is a standard encoder-decoder Transformer architecture.[2] The encoder has two modules per layer: self-attention and linear multilayer perceptron (MLP). A decoder layer has three modules: self-attention, cross-attention, and MLP. To work as a text-to-SQL parser, the model takes the concatenation of user

[1]The prior SOTA method for Spider is Picard + T5-3B (Scholak et al., 2021), in which Picard is a post-hoc decoding algorithm without modifying the model. In the scope of our experiments, we use T5-large instead, as our behavior tests involve significant computational expenses.

[2]As our focus is on the interpretation of the inner workings of the model, we do not use any post-processing heuristic on the model output, like Picard.

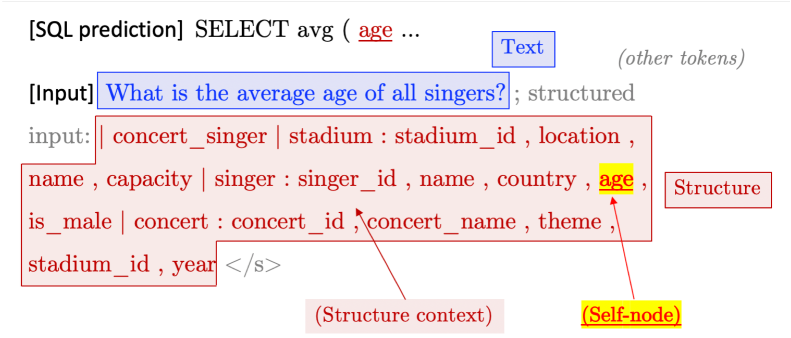

Figure 1: The input to the text-to-SQL parser consists of the query in natural language text (blue), and the relevant structured data (red), other tokens (gray). "self-node," refers to the input tokens corresponding to the expected output node where a node refers to both column and table names, and "structure-context," represents all the structured input tokens excluding the self-node. The output is the predicted SQL query (top).

query text and the linear form of a database (DB) structure as input and yields the SQL token sequence as output. The model has been trained with *prefix-tuning* (Li and Liang, 2021). Each attention module within the model is associated with 10 extra key-value entries from the prefix.

Terminology. For clarity of exposition, we introduce the term "structure nodes," or simply "nodes," which collectively refer to both columns and tables. We refer to "layer ranges" in the encoder or decoder, grouping them into to low, middle, and high layers. Both the encoder and decoder have 24 layers. In our discussion, "low layers" refer to layer 0-11, "middle" to 6-17 and "high" to 12-23. In addition, we mention "input sections," such as text, structure, and prefix. For a structure node, we also have the input section of "self-node," indicating the input tokens of the anticipated output node, and "structure-context," representing all the structured input tokens excluding the self-node. Figure 1 illustrates the format of the input to the text-to-SQL parser.

4 Research Questions

Preliminary Intuition Open Questions. The model's internal mechanics can be intuitively understood as follows: The encoder produces contextualized encodings by fusing both textual and structural input elements. These combined encodings then provide a comprehensive basis upon which the decoder constructs the SQL. However, despite this preliminary understanding, certain aspects remain unclear. Key questions that arise include:

(Q1) What specific information is passed from the encoder to the decoder via the text and structure token encodings? Addressing this allows us to delineate the functions of the encoder and decoder, further aiding in model interpretation.

(Q2) Which parts of the model store the important information? Here "parts" refers to model intermediates within different modules, input sections or layer ranges. This helps in detecting the possible bottlenecks and presents opportunities for model compression on the less important parts.

(Q3) How do the attention modules handle modality fusion? In our exploration of structured data representation in text-only models, we aim to understand how modality fusion is performed. It is expected to occur within the attention modules, as they are the only mechanism enabling different tokens to communicate.

(Q4) What is the internal working pipeline of the model? We aim to check if the thought process of the model mirrors human-designed pipelines, including steps such as schema-linking, syntax prediction, and node selection (Gu et al., 2023; Pourreza and Rafiei, 2023). Additionally, we seek to verify whether the model obtains meaningful knowledge through text-to-SQL training, or it is mainly fitting to spurious correlations.

5 Probing Study

5.1 Probing Tasks

For our first question **Q1**, our initial investigation focused on the information retained by the encoding vectors. For this purpose, we conducted two probing tasks as described below.

Node Name Reconstruction (NR). In this task, we examine the ability of the encoder to retain essential, low-level information about a node by

attempting to reconstruct its surface-form name. Due to the tokenization process of T5, a node can be tokenized into multiple sub-tokens. We keep all sub-token encodings as a sequence and pass them to a "probe decoder," which has the same architecture as T5-decoder but is initialized randomly. The probe decoder is trained to reconstruct the node name autoregressively.

Link Prediction (LP). Unlike node name reconstruction, this task assesses the ability of the model to capture higher-order structural information in its encodings. Using the encodings of a pair of nodes,[3] we train a probing classifier to predict the connection between them. The relation definitions follow RAT-SQL (Wang et al., 2020). Examples of these relations include QT-Exact (Question token and Table name Exact match), CC-TableMatch (two Columns belong to the same Table), or null relations like XY-default (a type X node and a type Y node, no special relation). We pool the sub-token encodings of each node into a single vector. We then construct the input vector of two nodes by concatenating their pooled encodings and their element-wise dot-product, i.e. $[e_1; e_2; e_1 * e_2]$ where ";" denotes concatenation and "*" denotes element-wise dot-product. We pass this input vector to a probe classifier, which is either a logistic regressor (LR) or a 2-layer MLP, to predict the relation between the two input nodes.

5.2 Probing Results

For both probing tasks, we utilized the train and dev partitions from the Spider dataset for training and evaluation respectively. The results are presented in Table 1. For Node Name Reconstruction (NR), both prefix-tuned and pretrained T5 exhibit very high reconstruction accuracy. This indicates that the prefix-tuning process did not undermine the ability of the model to preserve the low-level information.

For Link Prediction (LP), our results showed that the encodings from prefix-tuned T5 model outperformed the pre-trained version, suggesting that the prefix-tuning process of the model enhances its understanding of relations between nodes. Interestingly, the pre-trained T5 model also yields high LP accuracy. This suggests that even without tuning, pre-trained models have an implicit capability to process structured text. This observation is consistent with findings from (Ravichander et al., 2021a), where a model can learn features that are not aligned with its primary objective.

[3]In this study, a question token is also considered a node.

Model	NR	LP	
	Exact Match	LR acc.	MLP acc.
T5-P-tuned	0.9649	0.8110	0.8600
T5-pretrain	0.9709	0.7929	0.8400
T5-random	0.4918	0.2839	0.3102

Table 1: Node Name Reconstruction (NR) and Link Prediction (LP) probing results. "P-tuned" represents the T5 model with prefix-tuning.

For comparison, the T5-random version showed significantly lower probing performance compared to either T5-prefix-tuned or pre-trained. This confirms that the high performance are not merely due to overfitting noise in high dimensions.

Takeaway 1 (Q1). Regarding the information contained in the encodings, ***prefix-tuned T5 manages to preserve low-level textual details and also improves understanding of node relationships***. Surprisingly, ***pre-trained T5 model also exhibits an intrinsic capacity to handle structured text to some degree.***

6 Direct Model Manipulation

Besides the insights from the probing study, a remaining question is whether the model actually *utilizes* the information encoded in the representation. Since probing experiments did not answer this question, we undertook an exploration of the internal mechanisms of the model by directly manipulating the model intermediates and observing the outcomes. We employ the idea of *causal tracing* (Finlayson et al., 2021; Meng et al., 2022), where specific intermediate information is corrupted or reinstated to analyze its influence on the ultimate prediction. We design our studies in a fine-grained way, computing prediction accuracy at the token-level within a SQL query and categorizing the outcomes based on token types. Token types include *columns*, *tables*, *table aliases*, and *syntax tokens* (including keywords and operators). We focus on columns and syntax tokens, treating columns as being representative of structure node prediction. The results for rest of the token types are in the appendix.

6.1 Encoder States Investigation

We begin by *corrupting* the input embeddings or final encoding vectors of individual tokens or entire input sections. A vector is "corrupted" by replacing

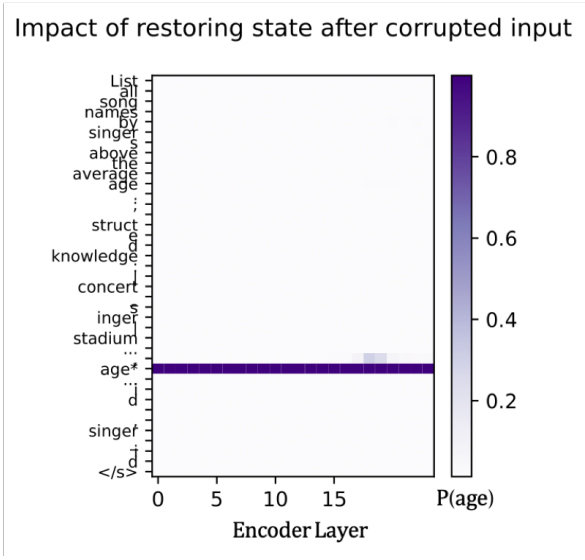

Figure 2: An illustrative sample showing the restoring effect of each encoder intermediate state. The decoder prompt: `SELECT song_name FROM singer WHERE ==> age`. Restoring the self-node hidden state on any layer can recover the correct prediction, while almost all other states do not have such an effect. More samples are available in Figure 6.

it with a zero-vector. The underlying intuition is that, when corrupting the embeddings of a token or section, the information is fully removed from the model. As such, the corruption study evaluates the overall usefulness of the corrupted part. When the final encodings are corrupted, only the information stored in these encodings is lost, thus this corruption study checks the actual information stored in these encodings and its importance.

We compute the average confidence on ground truth tokens for samples where the uncorrupted predictions are correct. The results for corrupting entire sections can be found in Table 2, on the left. First, as a sanity check, we confirm that corrupting the embeddings of the entire text section has a substantial impact on the prediction performance of both columns and syntax tokens. For structure embeddings, corrupting column names suffers a larger drop compared to syntax, consistent with our expectation. For final encodings corruption, we found that when predicting columns, the corruption on merely the self-node is as impactful as the entire structure section. Corruptions on the text part are considerably less effective, and on the structure context it has almost no influence. Shedding light on our question **Q2** regarding which states hold important information, these results indicate that the self-node encoding vectors are the most important when predicting this node. The structure node encodings are "ego-centric," each storing the information pertinent to that node and not others.

We further explored the opposite direction, corrupting the text embeddings and *restoring* the intermediate hidden states. Following ROME (Meng et al., 2022), this approach highlights intermediate states with high *restoring effect*, which refers to the increased probability of correct prediction when restoring the state back to the clean version. These states likely capture crucial information and hold notable importance. We chose to corrupt the embeddings of the text section based on the reasoning that the expected SQL output is entirely specified by the text.

Figure 2 illustrates the restoring effect of all encoder states on a representative sample. We observe that restoring the self-node hidden states at any layer can restore the correct prediction. However, for other tokens, restoring their representations at any layer has minimal impact. This observation reinforces the finding that self-node representations hold greater significance than other tokens when predicting that node. The ability of a single encoding to restore the correct prediction confirms that the low-level textual information is retained within the encoding and effectively utilized by the decoder **(Q1)**.

We also investigated the effects of restoring the final encodings of entire sections with corrupted text embeddings. The findings are presented in Table 2, on the right side. We observed the same trend where restoring only the self-node encoding proves to be more effective than restoring the entire text section or the structural context.

Takeaway 2 (Q1, Q2). The ***encodings of structure nodes are predominantly "ego-centric,"*** containing primarily information relevant to themselves with minimal data about other nodes. Consequently, the ***target node's encodings emerge as the most important*** among all encodings during node prediction.

6.2 Contextual Representations of Structure

We now turn our attention to **Q3**, which explores the attention mechanism and the integration of modalities between text queries and structured input. As can be seen in Table 2, when text embeddings are corrupted, even if their final encodings are restored, the prediction accuracy is still compromised (0.5663), since the structure nodes fail

Section	Embeddings		Final Encodings		Encoding Restore
	Column	Syntax	Column	Syntax	Column
Text	0.2482	0.2704	0.9115	0.4329	0.5663
Struct	0.4084	0.8435	0.4822	0.7056	0.8016
Self-node	0.3916	-	0.5239	-	0.6801
StructCtx.	0.8995	-	0.9848	-	0.1028
all	0.0083	0.0422	0.0943	0.1458	0.9416

Table 2: The effect of corrupting different sections of the input on columns and syntax token. Values are the average confidence scores of the ground truth over all samples where the clean (uncorrupted) prediction is correct.

to access accurate text information. This ***underscores the important role of text information in the process of encoding structure node, affirming the overall necessity of modality fusion***.

In the following experiments, we aim to study the inner workings of the attention modules by examining and manipulating them through various methods.

6.2.1 Attention Corruption Study

To reveal the inner mechanism of modality fusion, a straightforward first question we propose is: *Where does the fusion primarily take place?* For this, we explore another type of causal study, namely *attention corruption*, in which we deactivate the attention within certain layers and between certain sections by masking the corresponding attention entries. In detail, there are two corruption schemes, by *"weights"* or by *"logits"*. The "weights" setting simply sets the corrupted attention weights to 0, keeping others unchanged. The "logits" setting adjusts attention logits to $-\infty$ before the softmax operation, essentially zeroing out the corrupted sections while ensuring a valid distribution. Both settings are considered in our experiments.

Intuitively, modality fusion is expected to occur within encoder self-attention or decoder cross-attention. We evaluated the prediction accuracy of the model for columns and syntax tokens with our above-mentioned attention corruption, targeting the encoder self-attention or the decoder cross-attention, across different sections and within different layer ranges. Our guiding intuition here is straightforward: for components not engaged in modality fusion, a smaller performance drop is expected.

The results are shown in Table tables 3 and 4. Table 3 reveals an interesting finding under column "Columns - Weights" and on the row "$S \rightarrow T$" (structure-to-text[4]): the interference of encoder self-attention from the entire structure section to the text section had a negligible negative impact (0.9071), compared to the performance drop in Table 2 caused by text embeddings corruption (0.5663). Likewise, Table 4 row "Text" reports minimal damage to accuracy (0.9063) when the decoder cross-attention to the text was obstructed.

Corruption part	Columns		Syntax tokens	
	Weights	Logits	Weights	Logits
$T \rightarrow S$	0.9671	0.9543	0.9933	0.9919
$S \rightarrow T$	0.9071	0.6879	0.9926	0.9845
$T \leftrightarrow S$	0.8416	0.6138	0.9878	0.9788
all	0.2101	0.1502	0.7269	0.7338

Table 3: Attention corruption study on **encoder self-attention** across input sections. For input sections, "T" means text and "S" stands for structure. "$T \rightarrow S$" means corrupting the attention weights from text to structure tokens; "all" means corrupting the full attention matrix. On top, "Weights" and "Logits" represent the attention corruption scheme.

These findings seem to contradict our previous conclusion that the fusion of text and structure information is vital for the task. We propose an explanation for this inconsistency, suggesting that it stems from the *duplicative robustness* of the model. It means the model has learned certain capabilities in multiple locations, encoder and decoder in our case. To verify this hypothesis, we experiment with jointly corrupting the encoder self-attention from structure to text, and decoder cross-attention to text, essentially combining the corruption effect of the two experiments above. The results are shown in Table 5. We can observe that simultaneously corrupting both leads to a more substantial decline in accuracy. This supports our duplicative robustness hypothesis with regard to modality fusion. Related to **Q3**, this finding provides novel insights into modality fusion. It underscores the robustness of the model, but also hints at potential opportunities for post-hoc model compression.

Takeaway 3 (Q3). The model exhibits *duplicative robustness* in the joint representation of text and structure. ***Both encoder and decoder demonstrate proficient capabilities in fusing text information into structure, highlighting both the internal robustness of the model but also possibilities for compression***.

[4]Th notation of attention "from section A to B," means the attention matrix entries with tokens from A as query q, and tokens from B as keys k and values v.

Corruption part	Columns		Syntax tokens	
	Weights	Logits	Weights	Logits
Text	0.9063	0.9132	0.8517	0.8305
Struct	0.3239	0.4333	0.9543	0.9326
Prefix	0.9114	0.9025	0.8332	0.7676
StructCtx.	0.9429	0.9876	-	-
Self-node	0.3840	0.5382	-	-
all	0.1316	0.0597	0.4590	0.3725

Table 4: Attention corruption study on **decoder cross-attention** from each decoder step to encodings of each input section.

6.2.2 Attention Weights Information

To delve deeper into the functionalities of attention, we examine the potential correlation between attention weights and actual interpretable information. In **Q4** we hypothesize that the model internally performs subtasks akin to those designed by humans. One of them is *schema linking*, which aims to determine the *relevance* of a node, i.e., whether this node should appear in the output SQL. For that, we explore the correlations between the distribution patterns of a column within encoder self-attention and the relevance of the column. In detail, within each sample, we gather the attention weights from each column[5] to different input sections, across different layers and attention heads. We then compare patterns between relevant and non-relevant columns to gauge any distinctive behavior.

The results are presented in Table 6. We indeed observe distinctions between relevant and non-relevant columns. For specific heads and input sections, attention is consistently high for only one type of columns and low for the other. For example, head 8 shows a notably high attention to text and low attention to structural context for relevant nodes. For heads 10 and 11, attention to prefix token #4 is markedly high for non-relevant nodes.

We further confirm the correlation between encoder self-attention weights and node relevance by directly utilizing the attention patterns as features for node relevance classification. Specifically, we focused on the attention positions (layer, head, section) with clear discrepancy between relevant and non-relevant nodes, as mentioned above, and collect the attention weights on these positions to form "input features" for each node. A logistic regressor (LR) was trained to make the relevance prediction using these features. We compared with the implicit predictions made by the full model, where nodes in the generated SQL were predicted as relevant. The results can be found in Table 7. The accuracy and F1 scores of the LR are on par with those of the full model, and significantly better than simple heuristics such as predicting nodes with "exact text match" as relevant. This reaffirms that the encoder self-attention is tightly associated with node relevance, and that the encoder has successfully internalized the schema linking subtask.

[5]For simplicity, in this study we only use the first token of each column as its representative.

Corrupted part	Weights	Logits
Enc.SA-only	0.9071	0.6879
Dec.XA-only	0.9063	0.9132
Enc.SA + Dec.XA	0.6414	0.2987

Table 5: Joint corrupting encoder self-attention (structure to text) and decoder cross-attention (to text), to highlight the duplicative robustness phenomenon.

	Head 7	Head 8	Head 10	Head 11
prefix#0	0.55 / 0.06	0.01 / 0.01	0.04 / 0.01	0.00 / 0.04
prefix#4	0.04 / 0.05	0.00 / 0.00	0.01 / 0.45	0.01 / 0.42
prefix#8	0.01 / 0.01	0.01 / 0.24	0.07 / 0.02	0.12 / 0.03
text	0.00 / 0.01	0.73 / 0.06	0.05 / 0.01	0.00 / 0.00
self	0.25 / 0.57	0.01 / 0.01	0.03 / 0.00	0.04 / 0.05
context	0.10 / 0.24	0.17 / 0.61	0.33 / 0.09	0.22 / 0.23
others	0.01 / 0.01	0.06 / 0.05	0.27 / 0.07	0.52 / 0.15

Table 6: Attention weights from a column to each section, averaged for all relevant / non-relevant columns. Values in red are high for relevant nodes, and in blue are high for non-relevant nodes. Due to space constraints we only show results for Encoder layer 23, on a subset of heads and prefix tokens, on the dev set. More results are provided in Table 13.

Takeaway 4 (Q3, Q4). Encoder self-attention weights carry distinguishing information about node relevance. ***This implies the ability of the encoder to perform the schema linking subtask.***

6.2.3 End-to-End SQL Performance and Error Analysis

To verify the above findings, which are based on token-level prediction results, we extended our experiments using the same corruption settings to evaluate the *end-to-end SQL prediction* performance. SQL predictions are measured by the Exact Match and Execution Match metrics, in line with the original Spider leaderboard (Yu et al., 2018). In these experiments, we introduced corruptions on different layer ranges and targeting specific sections such as the encoder self-attention between the text and structure, and decoder cross-attention to text and structure. Additionally, we added *decoder self-attention* corruption, which yielding interesting findings.

Relevance	Attn. + LR	Full model	Heuristics
Accuracy	0.9729	0.9842	0.9403
Precision	0.8669	0.9316	0.8616
Recall	0.8535	0.8994	0.4634
F1	0.8602	0.9152	0.6026

Table 7: Column relevance prediction results. The P/R/F1 is computed for "relevant" columns due to their sparsity (<10%) among all columns.

Module	Corruption type	Layers	Section	Exact	Exec
Enc.SA	Logits	Low	$S \rightarrow T$	0.6538	0.6654
Enc.SA	Logits	Low	$T \rightarrow S$	0.6518	0.6721
Enc.SA	Logits	Low	$T \leftrightarrow S$	0.6422	0.6634
Enc.SA	Logits	High	$S \rightarrow T$	0.4072	0.4362
Enc.SA	Logits	all	$S \rightarrow T$	0.2234	0.2369
Enc.SA	Weights	all	$S \rightarrow T$	0.5145	0.5387
Dec.XA	Logits	all	Text	0.0706	0.0812
Dec.XA	Logits	all	Struct	0.0648	0.0638
Dec.SA	Weights	all	all	0.0000	0.0000
-	(Clean)	-	-	0.6692	0.6809

Table 8: End-to-end SQL performance with different attention corruption settings. Rows are selected for discussion; full results are available in Table 20 in the appendix. SA: self-attention; XA: cross-attention.

The results are provided in Table 8. For encoder self-attention (Enc.SA), the trends are consistent with previous observations. For example, the performance of "logits" corruption is much lower than "weights" (0.2369 vs. 0.5387 on Exec-match). Interestingly, corruption on the lower layers resulted in almost no decrease in performance, even for section "$T \leftrightarrow S$" (0.6809 $\rightarrow$ 0.6634), hinting at opportunities for model pruning.

For decoder cross-attention (Dec.XA), introducing corruption to either text or structure drastically reduces performance. This is attributable to the compromised ability to predict syntax tokens and structure nodes, respectively. To further understand the actual behavior of the model **(Q4)**, we conducted manual error analysis on a subset of 50 samples. The results are shown in Figure 3, with supplementary details provided in Table tables 21 and 22 in the appendix. We observe that when cross attention to text is blocked, the predominant errors are "clause-semantic errors," most commonly missing a condition or aggregation function. On the other hand, blocking structure section primarily results in node selection errors, where the model hallucinates on node names. This finding verifies the specialized capabilities of the decoder for SQL syntax prediction and node selection, functioning independently of each other. This reinforces the conclusion from Takeaway **4** for **Q4** that the model mirrors

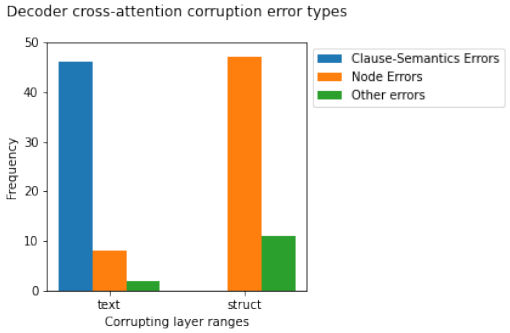

Figure 3: Error type analysis on **decoder cross-attention** corruption on the text or structure part.

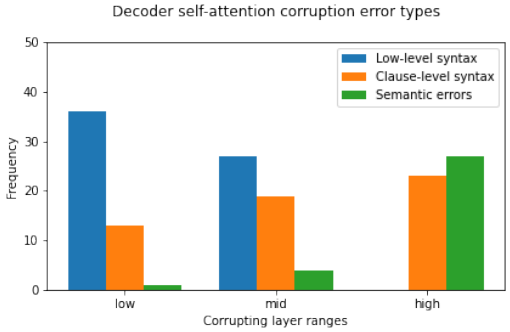

Figure 4: Error type analysis on **decoder self-attention** corruption on various layer ranges.

human-designed pipelines, including schema linking, syntax prediction, and node selection.

Takeaway 5 (Q4) The model shows the ***ability to perform different subtasks corresponding to human-designed pipelines: schema linking in the encoder self-attention, syntax prediction in decoder cross-attention to text, and node selection in decoder cross-attention to structure***.

Decoder Self-attention Study. In Takeaway **5**, we confirmed the model's subtask handling capabilities and identified corresponding submodules. Delving deeper, we aim to pinpoint the layers where these processes occur, relating back to **Q2** concerning the storage of information within the layer dimension. Hypothetically, different layer ranges in the decoder have distinct responsibilities. Intuitively, lower layers would focus more on syntax prediction, while higher layers would concentrate more on node selection, reflecting the intrinsic order of these subtasks.

To verify this, we conducted additional experiments by corrupting the *decoder self-attention*, effectively blocking all incoming information from previous timesteps in the decoder, within different layer ranges. The goal was to identify the information that is either already available or still

Q: **What is the average horsepower for all cars produced before 1980 ?**
Pred: `SELECT avg(horsepower) FROM cars_data WHERE year prior 1980`
Gold: `SELECT avg(horsepower) FROM cars_data WHERE year < 1980`
Q: **What are the codes of template types that have fewer than 3 templates?**
Pred: `SELECT template_type_code FROM templates GROUP BY template_type_code HAVING COUNT(*) less than 3`
Gold: `SELECT template_type_code FROM templates GROUP BY template_type_code HAVING COUNT(*) < 3`
Q: **What are the names of airports in Aberdeen?**
Pred: `SELECT airportname FROM airports WHERE city is Aberdeen`
Gold: `SELECT airportname FROM airports WHERE city = "Aberdeen"`

Pred: `SELECT title FROM cartoon arranged alphabetically`
Gold: `SELECT title FROM cartoon ORDER BY title`
Q: **How many type of governments are in Africa?**
Pred: `SELECT COUNT(different governmentform) FROM country WHERE continent = Africa`
Gold: `SELECT COUNT(DISTINCT governmentform) FROM country WHERE continent = "Africa"`

Table 9: Samples of corrupting **decoder self-attention** on **high layers**. In **red** are natural phrases generated by the model that semantically match the SQL syntax counterparts in blue.

missing at each layer range. The overall results are presented in Table 8, where, as expected, the end-to-end performance significantly deteriorated. For deeper insights, we performed manual error analysis on each layer range, including low, middle, and high, on a subset of 50 samples. The results are shown in Figure 4, with more details in Table tables 23 and 24 in the appendix. We observe a clear spectrum of error types distributed across the corrupted layer ranges. For low layers, the errors are predominantly "low-level syntax errors" such as unpaired brackets or quotes. For middle layers, many errors are "clause-level errors" where missing clauses or operators invalidate the SQL. For high layers, the SQL predictions are generally better formed syntactically, and the errors tend to pertain to higher-level semantics of the SQL. Interestingly, often the SQL error is confined to a clause where the SQL grammars are replaced by *natural language phrases with similar semantics*. Examples of this phenomenon are provided in Table 9. This intriguing observation is a strong indicator that the model has learned to align the semantics of SQL with natural language, and these representations are already obtained within the lower layers. Meanwhile, the overall behavior discrepancies between layer ranges support our intuitive hypotheses on the distinct functionalities of different layer ranges in the decoder.

Takeaway 6 (Q2, Q4) The decoder follows human intuitions that low layers focus more on syntax prediction and high layers focus more on node selection. Remarkably, we found that ***the model learns to align the semantics of SQL with natural language, despite no training on naturalized SQL versions***, such as SemQL or NatSQL (Guo et al., 2019; Gan et al., 2021). This suggests that the model learns meaningful knowledge rather than merely exploiting spurious correlations in the dataset.

7 Conclusion

We conducted a comprehensive study on the internal behavior of an encoder-decoder language model, specifically T5, text-to-SQL parser. Through both probing and manipulation of internal states, we provide insight into various aspects such as the information transfer between encoder and decoder, the storage of crucial data within the model, the functions of attention mechanisms, the process of modality fusion, the internal processing pipeline of the model, and the intrinsic alignment of SQL and natural language semantics. Our findings can inform and guide future research in text-to-SQL and related structured data representation tasks.

8 Limitations

Our study is limited to one type of pretrained language model architecture and did not consider a broader spectrum of models. The scope of our study was also limited by the computational resources required for analyzing larger models and the availability of model intermediates. Thus, future research directions include: 1) Exploring similar studies across different pretrained language model architectures, such as the widely adopted decoder-only models (Brown et al., 2020). ii) Examining the impact of model scaling, both in terms of increased parameters and data volume, following the insights from scaling laws (Hoffmann et al., 2022). iii) Extending the study to other structured data tasks, such as speech-to-SQL (Shao et al., 2023) or text-to-plots (Shao and Nakashole, 2020; Wang et al., 2021). and a variety of structured data sources such as knowledge graphs (Nakashole et al., 2010, 2011; Nakashole, 2013; Nakashole and Weikum, 2012; Nakashole et al., 2013; Mitchell et al., 2015; Kumar et al., 2017; Moon et al., 2019; Tuan et al., 2022) and tables (Yin et al., 2020; Herzig et al., 2020; Yu et al., 2021; Yang et al., 2022).

Our study was carried out only on the Spider dataset for text-to-SQL. However, we do not consider this to be a significant limitation, since our objective was to interpret the model behavior rather than proposing and validating a novel model.

A Details of Dataset and Model

Spider Dataset The Spider dataset has 7000 samples in the training set and 1034 samples in the dev set (Yu et al., 2018). Unless mentioned otherwise, our analytical studies were conducted on the full dev set.

Text-to-SQL Model The model we study is T5-large with prefix-tuning, implemented in the USKG project (Xie et al., 2022). Regarding the model size, it is almost the same as T5-large which has around 770M parameters.

Data Processing The tokenizer we use is the T5 tokenizer imported from HuggingFace, consistent with the model.

Probing Models For logistic regression, we use the Logistic Regression class from the Scikit-learn package (Pedregosa et al., 2011), with hyperparameter $C = 1.0$. For neural models including MLP (for the LP probing task) and T5-decoder (for the NR probing task), we use AllenNLP with Pytorch backend (Gardner et al., 2017). The MLP probe for the LP task has 2 linear layers with a middle dimensionality of 64 and activation function LeakyReLU (slope = 0.01). It is trained with Adam with initial learning rate $1e^{-4}$. The "probe decoder" for the NR task uses T5-large decoder architecture and pretrained parameters (without prefix-tuning). It is fine-tuned with Adam with initial learning rate $1e^{-5}$.

B Extra Details of Analysis

B.1 Probing Study

For Link Prediction (LP), we made adjustments to balance the frequencies of relation labels, given that there are multiple dominant classes with "default" labels (indicating no specific relation). For each input sample, which consists of a textual sentence and its corresponding structural input, we use only K node-pairs from each relation class. In our study, we simply set $K = 1$.

B.2 Causal Tracing Study

When the ground truth unit is multi-token, no matter node name or syntax tokens, we compute the probability of each sub-token in the ground truth with teacher-forcing, and compute the minimum probability (bottleneck) among all sub-tokens as the probability of the entire unit.

When we study behavior of columns in the input, such as the effect of "self-node" or the attention to other sections, we exclude the column whose name appears more than once in the structured input, since it is non-trivial to define "self-node" in such cases. In detail, it is unclear whether another node with the exact same name should be considered as "self-node".

We corrupt representation vectors to zero-vectors instead of adding a random noise vector as done in (Meng et al., 2022). This is because we observed in our preliminary studies that adding a random noise does not change the model prediction in most cases, different from the behaviors of the studied GPT-2 model in (Meng et al., 2022).

C Extra Results

C.1 Attention Blocking Effect

In comparing the outcomes of corrupting "weights" versus "logits" in Table tables 3 and 4, an interesting trend emerges. In Table 3,when corrupting "$S \rightarrow T$" (and similarly "$T \leftrightarrow S$") in encoder self-attention, the "logits" corruption caused a higher detriment than "weights" (0.9071 vs. 0.6879). This means that reallocating encoder self-attention weights to other less-attended sections can severely hamper performance. Conversely, Table 4 does not display the same pattern. When corrupting decoder cross-attention to "Text", the accuracy under the "logits" setting is not inferior to "weights" but slightly superior (0.9063 vs. 0.9132). For other sections like "Struct" or "Self-node", the "logits" accuracy is also higher than the "weights" setting. Besides, such patterns are only observed for column prediction and not for syntax tokens.

We attribute these trends to what we term the *blocking effect* of encoder self-attention, where a high attention weights serves a dual purpose: transmitting information from that section while simultaneously inhibiting other sections from conveying information. This effect is also verified by our finding on the correlation of attention weights and node relevance, which proves the attention weights carry distinguishing information. This explains the lowered performance when reallocating the attention to other sections, and justifies the existence of blocking effect in encoder self-attention.

C.2 Attention per Layer Range

Exploring another aspect of **Q3** (attention functionalities), we check the importance of attention

within different layer ranges. It also touches on **Q4** regarding the inner pipeline of the model. Referring back to Table tables 3 and 4, it is evident that for the encoder self-attention, corruption in low layers yields a substantially milder effect compared to high layers. This trend is consistent for both structure nodes and syntax prediction. This suggests that, within the encoder, the high-layer self-attention takes an overall lead on the contextualization process. We further conducted direct observations on a subset of samples, examining the attention distribution from a column token to all tokens. We found that low-layer self-attention is more "self-concentrated", meaning it is largely attending to the self-node tokens. In contrast, attention in high layers is generally more distributed towards other tokens. Relevant visualizations can be found in Figure 7. Another evidence is from the attention distribution patterns (Table 13). High layers exhibit more distinctive attention positions than low layers. This further implies that high layers play a more pivotal role in gathering information.

For the decoder cross-attention, the comparison between low and high layers is less clear. One possible explanation is that different layer ranges have distinct responsibilities. We will further discuss this topic in later sections.

D Experiment Environment

CPU: 48 × Intel(R) Xeon(R) Gold 6136 CPU @ 3.00GHz

GPU: 4 × NVIDIA GeForce GTX 1080 Ti

CUDA: Version = 10.2

OS: Ubuntu 16.04.6 LTS (Xenial)

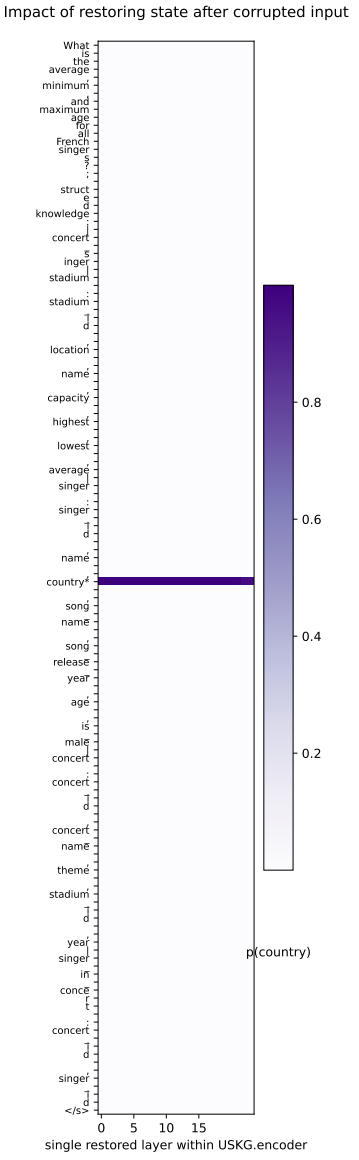
Table 10: Link prediction (LP) probing results (F1-score) per relation type, using logistic regression (LR) as probing method. For detailed definitions of each relation, please refer to (Wang et al., 2020).



Column	Clean Text	DC. Text	Crpt. Text
Clean struct	0.9905	0.9611	0.8505
DC. struct	0.6152	0.4952	0.0489
Crpt. struct	0.3916	0.3469	0.0241

Table	Clean Text	DC. Text	Crpt. Text
Clean Struct	0.9906	0.9802	0.9687
DC. Struct	0.4472	0.3965	0.1020
Crpt. Struct	0.2241	0.1958	0.0015

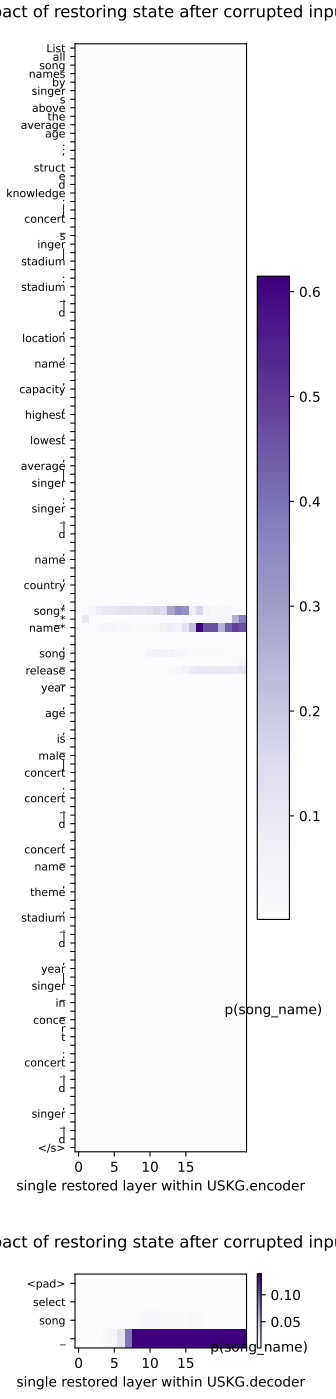


Table 11: Results of "dirty context encodings". "DC." means "dirty context", i.e. this section is encoded with its own embeddings clean but the other part embeddings corrupted; the other part's final encodings are restored to the clean state. Effectively, in this setting we obtain encodings without information from the context. "Crpt." means "corrupted", i.e. the input embeddings of this section is corrupted.

	Both+	Clean+	SCC+	None	Total
Column	1333	103	66	500	2002
Table	1424	123	105	31	1683
Table alias	1509	191	64	275	2039

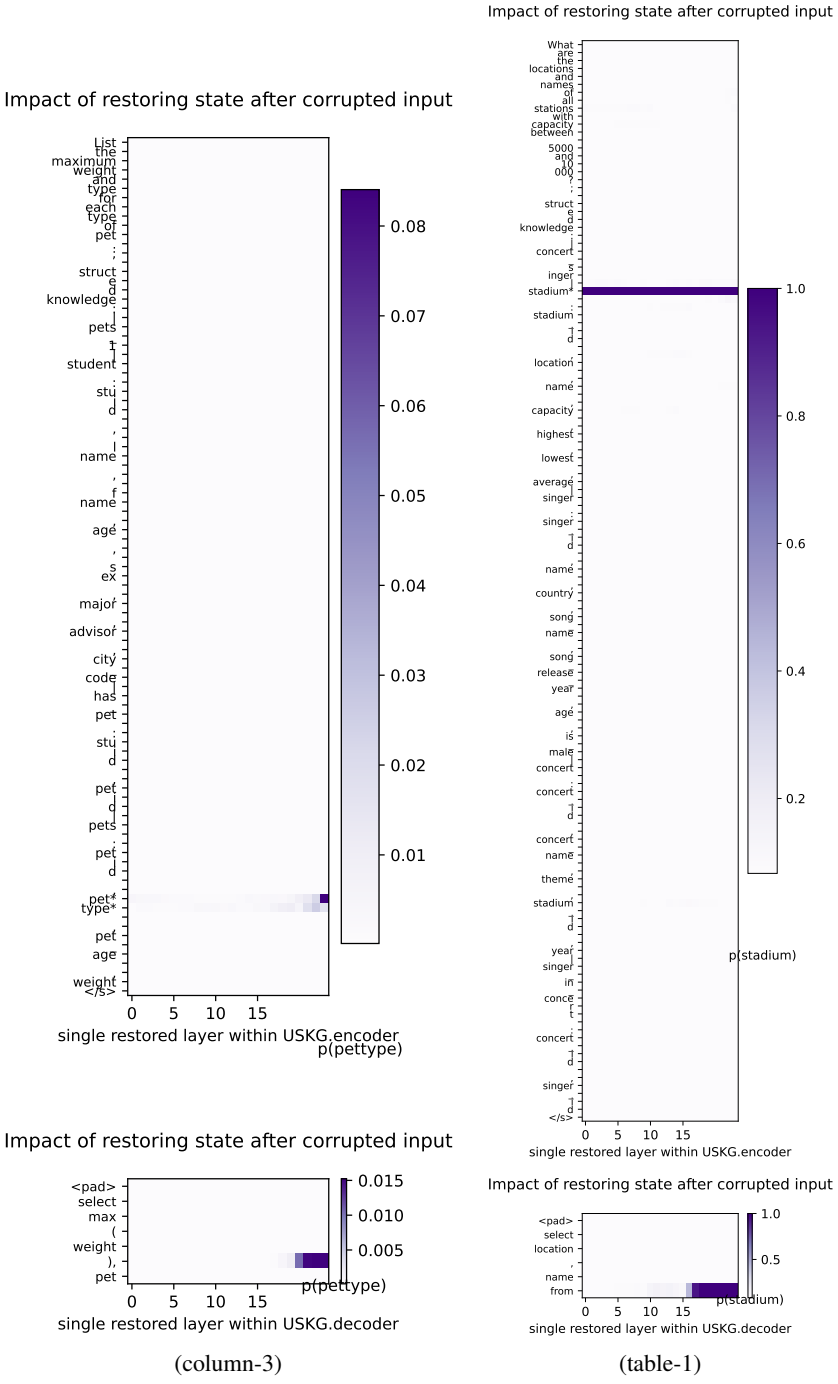

Table 12: Struct context corruption (SCC) effect. Clean+ means clean prediction is correct, with SCC it is wrong. Vice versa, SCC+ means clean prediction is wrong, but SCC makes it correct. We see the number of cases in which such corruption has positive / negative effects are on the same level, indicating that the two factors (information removal & distraction removal) both exist in structure context corruption.

(d) Training-L23

Table 13: Encoder attention weights to each sections from all relevant / non-relevant nodes on each head. Values in red are high for relevant nodes, and in blue are high for non-relevant nodes. (The criteria is based on heuristics: $x/y - y/x + x - y > 2.0$) Supplementary for Table 6. The trend is almost the same between training and dev set.

(c) Syntax tokens

Table 15: Attention corruption study on encoder self-attentions across input sections. For corruption part, "T" means text, "S" for structure, "P" for prefix; "$T \to S$" means corrupting the attention weights from text to structure tokens, i.e. text tokens as q and structure tokens as k. On top, "Weights" and "Logits" represent the attention corruption scheme. Supplementary for Table 3.

Table 20: End-to-end SQL performance with different attention corruption settings. Supplementary for Table 8.

Error class	Definition
S-class: Clause-level Semantics Errors	
S0	missing / wrong aggregator
S1	missing / wrong condition clause or ordering
S2	missing / wrong literal value
N-class: Node (column / table name) Errors	
N0	invalid (hallucinated) node name, either token or natural language phrases
N1	using '*' for an actual column
N2	valid but wrong node name (not including '*')
J-class: Join-chain Errors	
J0	extra join, but still correct
J1	missing alias reference, may cause ambiguous-column error depending on the schema
A-class: Low-level Syntax Errors	
A0	Unpaired brackets / quotes
A1	Misspelled keyword
A2	Non-ending token
B-class: Clause-level Syntax Errors	
B0	Missing / extra / misplaced / partial clauses (causing syntax error)
B2	Alias error (t1 -> t1.col, t1 -> t1st, errors like this)
B3	Missing / extra operator (causing syntax error)
C-class: Other High-level Semantics Errors	
C0	Natural language expression of SQL, or unquoted string values
C3	(Not really an error) - equivalent or alternative correct answer

Table 21: Decoder cross-attention corruption error analysis: detailed categories and descriptions.

Extractive Summarization with Text Generator

Nanyang Technological University
anhtuan.luu@ntu.edu.sg

Abstract

Standard extractive systems suffer from the lack of gold training signals since existing corpora solely provide document and human-written summary pairs while disregarding extractive labels. As a result, existing methods resort to imperfect pseudo-labels that are both biased and error-prone, thereby hindering the learning process of extractive models. In contrast, text generators which are commonly employed in abstractive summarization can effortlessly overcome this predicament on account of flexible sequence-to-sequence architectures. Motivated to bypass this inherent limitation, we investigate the possibility of conducting extractive summarization with text generators. Through extensive experiments covering six summarization benchmarks, we show that high-quality extractive summaries can be assembled via approximating the outputs (abstractive summaries) of these generators. Moreover, we find that the approximate summaries correlate positively with the auxiliary summaries (i.e. a better generator enables the production of better extractive summaries). Our results signify a new paradigm for training extractive summarizers i.e. learning with generation (abstractive) objectives rather than extractive schemes.

1 Introduction

Text summarization, owing to its practical application, has received increasing interest from the research community (Nguyen and Luu, 2022, Kumar and Chakkaravarthy, 2023). Current approaches mainly follow two directions: extractive and abstractive summarization (Yadav et al., 2022). While abstractive methods skillfully paraphrase the primary contents, extractive ones are less inventive as they seek to extract salient units (e.g. sentences) without making any textual modification. Nonetheless, extractive methods effectively avoid hallucinations and inconsistencies which commonly occur in abstractive summaries (Ladhak et al., 2022). We present an illustrative example in Table 1.

Source Article
Heat the broth to the boiling point. Add your Worcestershire sauce to taste. Reduce the heat and let it sit for 3 to 5 minutes. Alternatively, you can sift flour directly into the gravy, but that won't taste as good.
Abstractive Summary
Heat the broth in a large saucepan over medium heat. Sift the flour into the gravy.
Extractive Summary
Heat the broth to the boiling point. Alternatively, you can sift flour directly into the gravy, but that won't taste as good.

Table 1: An example from the WikiHow dataset showcasing an abstractive summary (BART) and an extractive summary (our method). Here the abstractive summary hallucinates the information *boiling point* to *medium heat* while the extractive summary preserves this detail as there is no textual change.

The training of abstractive models is rather straightforward as they can fit arbitrary target sequences (Sutskever et al., 2014, Shi et al., 2021). Meanwhile, extractive models suffer from the lack of gold training labels since most existing datasets only provide document and human-written summary pairs while disregarding extractive labels (Nallapati et al., 2017). The annotation process for manually obtaining these labels is also both labor-intensive and hard to control (Cheng and Lapata, 2016, Narayan et al., 2018b), further diminishing the presence of high-quality supervision. As a result, training labels for extractive models have often been secured via heuristic algorithms (Nallapati et al., 2017, Zhou et al., 2018, Xu et al., 2020, Zhang et al., 2023) which produce suboptimal alternatives (Zhang et al., 2018) and contain labeling biases (Xing et al., 2021) that lead to un-

derfitting (Narayan et al., 2018b) as well as the error propagation phenomenon (Xu and Lapata, 2023). Attributable to these instigating problems, research on acquiring better extractive labels has always been an actively developed topic (Jia et al., 2022, Xu and Lapata, 2023).

This gives rise to an intriguing research question: **Can we construct good extractive summarization models that learn directly from the ground truth summaries?** Being able to learn directly from the ground-truth summaries should eliminate the reliance on imperfect labeling algorithms which potentially introduce noise in the training process and allow learned models to make full use of available resources (summaries). However, deriving such a methodology is non-trivial as extractive models need to produce extract outputs (Liu and Lapata, 2019) which are often sentences or sub-sentential units (Zhou et al., 2020) that originate from the source document. Meanwhile, ground truth summaries are often abstractively written snippets that do not conform to this constraint and necessitate fine-grained token-level output modelings which aren't inherent in the decoder of extractive models (Cheng et al., 2023). In contrast, these limitations can be seamlessly overcome with abstractive models which are typically based on flexible seq2seq architectures (Nallapati et al., 2016). As summarization datasets are inherently extractive to a certain degree, abstractive models trained on these sources likely exhibit unequivocal extractive behaviors (Song et al., 2020). Previous works have characterized this property as the faithfulness-abstractiveness tradeoff (Ladhak et al., 2022) and opt to find a balance in extractivity that does not hurt the performance of abstractive models (Ge et al., 2023, Dixit et al., 2023). We hypothesize, however, that this property can serve as essential clues in transforming abstractive models into compelling extractive ones that concomitantly overcome the aforementioned gap. To decipher this conjecture as well as answer the research question, we propose to approximate the output summaries of abstractive models with heuristic algorithms, thereby deriving summaries of extractive formats. With the aim of examining the quality of these extractive outputs, we conduct exhaustive evaluations spanning six summarization benchmarks while taking into account state-of-the-art standard methods on extractive summarization. To our surprise, the evaluated models perform competitively, even outperform previous state-of-the-art methods across a wide range of settings despite not undergoing any (sentential) extractive training. Remarkably, these results are achieved without setting any extraction threshold which is unprecedented in traditional methods.

In summary, our contributions can be listed as follows:

- We present Abstract2Extract (A2E), a methodology that transforms existing abstractive models into powerful extractive epitomes by taking advantage of their innate extractiveness via heuristic algorithms, all the while not incurring additional training or inference cost.
- We demonstrate through experiments on a variety of domains that A2E models exhibit either superior or comparable performance to previous state-of-the-art extractive methods despite not undertaking any extractive supervision. In addition, A2E keeps track of both abstractive and extractive summaries which provides a straightforward unification of the two paradigms.

2 Related Works

Abstractive Summarization Together with the introduction of neural sequence-to-sequence learning (Sutskever et al., 2014), progress in the field significantly skyrocketed (Nallapati et al., 2016, Liu et al., 2022). To better guide the learning of these models and avoid hallucination, many existing works attempt to explicitly control the content selection process (Wang et al., 2020, Jiang et al., 2021, Nguyen et al., 2021b, Ladhak et al., 2022). Among different categories of guidance, extractive summarization and extractive labels have also been adopted. For example, Liu and Lapata, 2019 trained a two-stage model where the base architecture is sequentially fine-tuned on the extractive and abstractive summarization tasks. Bao and Zhang, 2021 rewrote the whole extractive summaries conditioned on the input documents. Similarly, Dou et al., 2021 designed a framework incorporating extractive guidance in abstractive models and observed increased faithfulness.

Extractive Summarization Extraction summarization has often been formulated as a sentence ranking task, where the goal is to predict the importance score of each sentence and perform selection accordingly (Gupta et al., 2014, Nallapati et al.,

2017). Due to the lack of extractive labels, Nallapati et al., 2017 employs a greedy approach to collectively select a subset of sentences that maximize the ROUGE (Lin, 2004) scores, whose strategy is also re-used in follow-up works (Kedzie et al., 2018, Zhong et al., 2019). This widely adopted approach, however, generates uncalibrated label sets containing biases (Jia et al., 2022) that potentially hurt the training of extractive models and further cause underfitting (Dong et al., 2018). To tackle this problem, Xu and Lapata, 2023 proposed to integrate a pool of summary candidates to derive fine-grained soft sentence labels. The approach remains limited as these scores represent merely a portion of an intractable hypothesis space and inevitably result in inferior approximators of the true ground truth which still hinder models' learning capacities.

Concurrent to our work, Varab and Xu, 2023 proposed to employ the abstractive model BRIO (Liu et al., 2022) as the scorer in guiding summary searches and achieved encouraging extractive results. Their approach, however, relies on the coordination property (i.e. the ability to properly rank summary hypotheses) which isn't inherent in most abstractive systems, and significantly degrades when the underlying model does not possess this characteristic. In contrast, we do not make any assumption about the underlying abstractive model and solely make use of the generated outputs as pseudo-references in heuristic practices which follows a black-box manner with high flexibility. Different from theirs, our approach neither diverges from the generation process of abstractive models nor additionally incurs any inference cost and can therefore seamlessly support the creation of dual summaries (i.e. abstractive and extractive).

3 Abstract2Extract

3.1 From Generation to Extraction

Given an input document D, suppose that we have access to a sequence-to-sequence abstractive summarization model M_θ which imitates the conditional likelihood $P_\theta(Y|D) = \prod_{i=1}^{t} P_\theta(Y_t|Y_{<t}, D)$ where Y represents the output summary. This probability distribution is primarily learned via the Maximum Likelihood Estimation (MLE) objective (Rehman et al., 2023). At inference time, heuristic decoding methods (e.g. beam decoding) are customarily used to generate the output sequence Y autoregressively (Kasai et al., 2022).

Denote $Y_A = M_\theta(D)$ as the abstractive summary generated from M_θ. We opt to find an alternative extractive summary Y_E conditioned on Y_A: $Y_E = \text{argmax}_{Y_E \in H(D)} Q(Y_E, Y_A)$ where $H(D)$ is the hypothesis space[1] and $Q(.)$ is the reference metric.

This formulation allows the construction of extractive summaries conditioned on the directly learned ground truth distribution Y while also taking advantage of useful fine-grained token-level output information which is otherwise impracticable in standard extractive paradigms. Accordingly, we can also bypass the problem of error propagation/noisy signal caused by imperfect pseudo-labels employed in extractive training.

3.2 Approximator

Since the pool of probable extractive candidates is literally intractable making the argmax operation expensive, we adopt heuristic practices to efficiently deduce good targets.

We delineate two groups of heuristics: *summary output* - which produces summary-level (or set-level) rankings and *sentence output* - which yields sentence-level rankings. For the prior, we choose the summary (or set) with the highest ranking as the extractive summary. For the latter, we select the top K_S highest-ranked sentences to acquire the extractive summary.

3.2.1 Summary Output

These algorithms explore the hypothesis space $H(D)$ and maintain the rankings of summaries (or sets) found during the process based on $Q(.)$. We harness two classic algorithms that are highly capable: *greedy* and *beam search*.

Greedy Search Starting from an empty selection set $H = \{\}$, at each step t, the algorithm picks the locally highest quality sentence $s_t = \text{argmax}_{s_t \in H'} Q(H \cup s_t, Y_A)$ and perform update $H = H \cup s_t$, where $H' = D_S \setminus H$ and D_S is the set of input sentences. The algorithm converges when the quality of the selection set cannot be further improved i.e. $\max_{s_t \in H'} Q(H \cup s_t, Y_A) \leq Q(H, Y_A)$ or additional constraints are met (e.g. maximum search steps).

Beam Search Instead of keeping only the locally best candidate H, beam search maintains a list of K_C best found sets $\{H_i\}_{i=1..K}$. At each iteration, it sequentially expands and prunes candidates in

[1]The set of all possible extractive summaries

$\{H_i\}$ based on Q. Similar to greedy search, the algorithm converges if either no better candidate gets discovered or extra restrictions are fulfilled.

3.2.2 Sentence Output

These algorithms are oriented to bring out rankings of individual input sentences. We exploit two scoring mechanisms: *local* and *global*.

Local Scorer For each sentence $s_i \in D_S$ in the source document, we evaluate its affinity with the auxiliary reference Y_A as $r_i = Q(s_i, Y_A)$, where Q is the established criterion. The computed affinity scores $\{r_i\}$ are then applied to determine sentence rankings.

Global Scorer Inspired by Xu and Lapata, 2023, we further incorporate summary-level information into the scoring of sentences. In particular, we first utilize beam search to retrieve a pool of K_C high-quality candidates $\{H_i\}_{i=1..K}$. Afterward, we iterate through the list and for each sentence s_i^k appearing in the candidate H_k, we update its affinity score as $r_i = r_i + Q(H_k, Y_A)$. To begin with, each affinity score is initialized as $r_i = 0$ and subsequently gets revamped according to its contribution (presence) in forming high-quality summaries.

3.3 Criterion

Employed heuristics rely on the criterion Q, which should encapsulate both relevance and conciseness in grading different sentences/summaries with respect to the pseudo-reference Y_A. While embedding-based criteria depend on latent features from pre-trained language models and can therefore capture contextualized information, they are computationally too demanding. In this work, we exploit the de-facto metric ROUGE[2] (Lin, 2004) as the optimization criterion following past literature (Chen et al., 2021, Gu et al., 2022). To justify this decision, we measure the lexical overlap between the abstractive summaries (PEGASUS) and the source documents in terms of *extractive n-grams* in Table 2. Overall, we observe high overlap rates which signify the method's feasibility.

4 Experiments

4.1 Settings

To examine our approaches, we conduct experiments on six summarization datasets: **CNN/DailyMail** (Nallapati et al., 2016) - a news-story dataset from the *CNN* and *Daily Mail* websites; **XSum** (Narayan et al., 2018a) - an extreme summarization dataset from *BBC*; **RedditTIFU** (Kim et al., 2019) - a social media dataset from the *TIFU* subreddit; **WikiHow** (Koupaee and Wang, 2018) - a knowledge-based dataset from the $WikiHow$ website; **PubMed** (Cohan et al., 2018) - a medical dataset; **Multi-News** (Fabbri et al., 2019) - a multi-document news summarization dataset. [3]

	CD	XS	RD	WH	PM	MN
Uni.	94.46	73.95	89.75	88.59	82.00	94.39
Bi.	77.80	26.03	44.41	48.85	60.77	72.59

Table 2: Percentage of *extractive (non-novel) n-grams* in PEGASUS's summaries. **CD**, **XS**, **RD**, **WH**, **PM** and **MN** stand for **CNN/DailyMail**, **XSum**, **RedditTIFU**, **WikiHow**, **PubMed** and **Multi-News**, respectively.

As underlying abstractive systems, we primarily use the following four models: **PEGASUS** (Zhang et al., 2020a) - a transformer model pre-trained with gap-sentence objectives; **BART** (Lewis et al., 2020) - a similar architecture pre-trained with denoising objectives; **BRIO** (Liu et al., 2022) - a multi-task optimized model; **PRIMERA** (Xiao et al., 2022) - a longformer encoder-decoder model pre-trained with the pyramid framework. During inference, we use beam decoding with hyperparameters determined following respective papers[4]. To guide heuristic algorithms, we use the ROUGE-1 F1 score in all experiments unless explicitly specified otherwise[5].

4.2 Can abstractive summaries serve as good pseudo-references ?

For the first experiment, we examine the quality of the approximate summaries with respect to the abstractive pseudo-references. In particular, we show the results in Table 3. For evaluation, we use an average of the three ROUGE scores i.e. ROUGE-1, ROUGE-2 and ROUGE-L F1 scores. Column **A**, **E** and Δ each denotes scores of the abstractive, approximate extractive and the accompanying quality loss during approximation. We additionally highlight the highest score in each block (or lowest in terms of loss).

On all datasets, we observe a consistent trend that **the superior the abstractive summary, the**

[2]ROUGE only depends on lexical overlap and is therefore significantly cheaper to compute.

[5]See Section C.0.3

better the extractive summary. This indicates that if we use a better abstractive model, we can expect a higher-quality extractive summary. Moreover, the finer the abstractive summary, the higher the transfer loss. This indicates that **high-grade abstractive summaries pose increasing difficulties in approximation**. Besides, we observe that the transfer loss is typically inflated on abstractive datasets such as XSum and WikiHow. Meanwhile, on fairly extractive datasets such as CNN/DailyMail or Multi-News, the approximate extractive summaries are comparatively close in quality compared to the auxiliary summaries. Ultimately, we find that **abstractive summaries can serve as good pseudo-references**, enabling extraction of non-trivial summaries on all datasets.

Table 4: Comparison between heuristic algorithms

Next, we present a comprehensive comparison of different algorithms. For *sentence output* heuristics, we determine the optimal extraction threshold based on grid search in the range [1..32] and select the top highest-scored sentences according to this threshold. We report an average of the three ROUGE variants[6] in Table 4. We highlight the best heuristic for each model, and underline the better heuristic in each category. In most cases, ***summary output* heuristics produce the best summaries**, with *beam search* typically improves over *greedy search*. For those with *sentence output*, we find that the *global scorer* often achieves better results than the *local scorer*. These observations show that summary-wise (or set-wise) comparisons are necessary to deduce good extractive summaries. Drawing on this conclusion, we focus on *summary output* heuristics for the rest of the paper.

instead of pseudo-references. We compare these standard methods with *summary output* heuristics. In addition, we **do not set any extraction threshold** for these heuristics (*greedy* and *beam search*) i.e. the algorithms converge only when no better candidates are found without extra constraints such as a maximum number of extracted sentences or search steps. Also, we use a default beam width of 4 unless specified otherwise[7]. For evaluation, we report the ROUGE-1, ROUGE-2 and ROUGE-L F1 scores achieved with each system. The results are presented in Table 5, 6, 7, 8, 9 and 10[8].

On CNN/DailyMail, our methods coupled with the BRIO model achieve results on par with state-of-the-art models such as MatchSum and DiffuSum. The PEGASUS/BART models also perform comparably to the BERTSum baseline. Noticeably, the BRIO - A2E Beam model achieves the high-

[7] See Section C.0.4

[8] We embolden the highest value and use asterisk "*" to denote results that significantly improve over the best baseline as measured via bootstrap testing with 95% confidence interval.

est ROUGE-L score. Compared with GenX, we also achieve consistently better scores. In addition, when the underlying system is not coordinated, our models do not significantly degrade, unlike GenX. For example, when switching from BRIO to BART whose summaries are of lower quality, we only suffer a 2-point drop in ROUGE-1 compared to GenX which degenerates by 5 ROUGE-1 points.

On XSum, our models consistently produce summaries with higher quality than baseline methods, especially in terms of ROUGE-1 and ROUGE-L.

On RedditTIFU and WikiHow, our models also outperform existing systems. In particular, our BART - A2E models surpass the best baseline SetSum on RedditTIFU. On WikiHow, our advantages are even more amplified, as all models improve 2 to nearly 3 ROUGE-1 points over the state-of-the-art model MatchSum with similar gains in ROUGE-2 and ROUGE-L.

On PubMed and Multi-News, we continually set new state-of-the-arts with persistent advances. On PubMed, our least competent models (PEGASUS) perform better than most previous systems while our best models (PRIMERA) outperform the best baseline MemSum regarding ROUGE-2 and ROUGE-L. We also observe similar results on Multi-News where our PEGASUS/BART models exceed most baselines and our PRIMERA models achieve absolute improvement over all methods.

Conclusively, we reach new **state-of-the-arts in extractive summarization** despite not undergoing customized training.

4.5 Evaluation with other metrics

We additionally report the results in terms of SummaQA (Scialom et al., 2019) and BERTScore (Zhang et al., 2020b). The prior is based on a question answering framework whereas the latter relies on greedy matching of contextualized embeddings. We repeat the comparisons with the MatchSum system. For generators, we use BRIO on CNN/DailyMail & XSum, BART on RedditTIFU & WikiHow and PRIMERA on PubMed & Multi-News. As for heuristics, we simply use *greedy search*. Dataset names are abbreviated[9]. We report the results in Table 11 and 12. Aligning with the previous section, we achieve consistently superior results on all benchmarks.

[9]Abbreviation follows Table 2

	CD	XS	RD	WH	PM	MN
MatchSum	25.96	9.88	2.25	2.19	2.75	8.04
Our method	**27.15**	**11.92**	**2.58**	**3.59**	**3.09**	**9.74**

Table 11: Results in SummaQA scores.

	CD	XS	RD	WH	PM	MN
MatchSum	64.05	57.24	52.55	56.29	58.83	61.00
Our method	**65.11**	**58.84**	**54.49**	**58.07**	**60.54**	**62.88**

Table 12: Results in BERTScore scores.

4.6 Manual Evaluation

To examine whether the automated evaluations align with human preferences, we further conduct a manual evaluation campaign. In particular, we randomly sampled 150 instances from the CNN/DailyMall test set and included extracted summaries from the MatchSum system and the A2E Greedy - BRIO model (we avoided samples where both extracted sentence sets are identical). Following Cheng et al., 2023, we invited three volunteers who are professional English speakers to examine the summaries based on two criteria: informativeness and coherence. System outputs were presented in random order and no participant was aware of the different systems beforehand. Each participant then, given the source article and gold reference, elected the summary which he/she preferred for each aspect separately. Each system then received one point for every vote.

We present the average results (percentage) in Table 13. It is clear that the summaries produced by A2E were preferred more by humans on both categories. Moreover, we obtained these results with substantial inter-annotator agreement as indicated by Fleiss' Kappa scores (Fleiss, 1971), which we show in Table 14.

	Informativeness	Coherence
MatchSum	19.56	24.67
Our method	**80.44**	**75.33**

Table 13: Human evaluation results on CNN/DailyMall.

	Informativeness	Coherence
Fleiss' Kappa	0.7034	0.6532

Table 14: Inter-Annotator Agreement.

4.7 Analysis on Lead Bias

Traditionally extractive systems often exhibit spurious correlations with beginning sentence positions, also known as *lead bias*, which emerges from an imbalance in the distribution of information positioning (Grenander et al., 2019, Xing et al., 2021). Compared to previous approaches, in our method, the learning process is identical to abstractive generation and the model thus learns to actually generate summaries rather than simply extract sentences which should supposedly lessen this spurious correlation.

To verify this argument, we examine the positions of sentences extracted with our models and the MatchSum system. In particular, we report the percentage of sentences with relative positions belonging to each of the range $0-10\%$, $10-30\%$ and $30-100\%$. We experiment with CNN/DailyMall - a dataset where lead bias is prevalent (See et al., 2017), and report results in Table 15:

	$0-10\%$	$10-30\%$	$30-100\%$
MatchSum	39.17	43.11	17.72
A2E Greedy - BRIO	**31.19**	**37.57**	**31.24**
A2E Greedy - BART	**27.01**	**39.97**	**33.02**

Table 15: Distribution of sentence positions in CNN/DailyMall extractive summaries.

As we expected, A2E models suffer less from lead bias. However, we find that the bias still exists. Specifically, when we compared the sentence positions of A2E models that were trained in-domain on XSum - a dataset with weak lead bias (Narayan et al., 2018a), versus cross-domain from CNN/DailyMall, we observed higher rates of extraction in the beginning parts for the latter. We illustrate this in Table 16.

	$0-10\%$ (In)	$0-10\%$ (Cross)
A2E Greedy - BRIO	**8.11**	25.75
A2E Greedy - BART	**8.65**	26.00

Table 16: Propagation of dataset bias on information positioning. Models were tested either in-domain or cross-domain (from CNN/DailyMall) on the XSum dataset.

This means that completely eliminating lead bias remains a non-trivial feat, which aligns with the results from Xing et al., 2021.

4.8 Further Optimization

We next study whether exact optimization can yield better extractive summaries (than heuristics). To experiment with this direction, we sample 100 documents from the CNN/DailyMail test set, each containing 9 sentences. We then compare the quality of extractive summaries conditioned on the abstractive ones (BRIO) obtained through *greedy search* and *brute force*[10]. We show the results in Table 17. Even though the gains are visible, the speed trade-offs are enormous.

	R-1	**R-2**	**R-L**	**Speed**
Greedy	47.2	24.65	42.95	**270.6** (iter/s)
Brute Force	**47.58**	**24.91**	**43.43**	4.6 (iter/s)

Table 17: Results with greedy search and brute force on CNN/DailyMall.

4.9 Cross-domain generalization

Although abstractive models are known to possess certain generalization capabilities (Chen et al., 2020), whether our approaches can leverage these properties remains a puzzle. To elucidate this matter, we employ a BRIO model fine-tuned on the CNN/DailyMail dataset and conduct cross-dataset inference on three benchmarks with distinct properties: XSum, RedditTIFU and WikiHow. We also compare with standard systems such as BERTSum, MatchSum and additionally include results for GenX. As Xu and Lapata, 2023 use ROUGE-L when reporting performances of standard systems, we also report ROUGE-L scores for our models accordingly. We show the results in Table 18. It can be inferred that not only can our models **generalize across domains** but we also achieve massive improvements especially when testing on non-news domain such as RedditTIFU and WikiHow.

Model	**XS**	**RD**	**WH**
Customized Extractive Methods			
BERTSum (2019, 2023)	15.62	17.06	25.39
MatchSum (2020, 2023)	15.75	17.82	25.1
Abstractive-driven Methods			
BRIO - GenX Search (2023)	15.92	-	-
BRIO - A2E Greedy	15.96	19.25*	27.02*
BRIO - A2E Beam	**16.00**	**19.51***	**27.06***

Table 18: Results for cross-domain summarization (ROUGE-L). Models are trained on the CNN/DailyMail dataset.

[10] Equivalent to conducting the argmax operation in Section 3.1

4.10 Faithfulness

In Section 4.2, we observed that the extractive summaries yielded lower ROUGE scores than their abstractive counterparts. However, **are extractive summaries actually inferior** ? We re-evaluate the two types of summaries from a distinct but important aspect - *faithfulness*. In particular, we collect the PEGASUS model's summaries along with the extractive ones obtained via *greedy search* and feed them through SummaC-Conv (Laban et al., 2022) - a strong factuality metric. We report the results in Table 19. As we can see, the extractive summaries are far more faithful than the abstractive ones, making them more reliable in real world deployment. Nevertheless, our methods always keep track of the extractive summaries along with the abstractive ones which allows the end users to freely choose whichever kind that suits their needs.

	CD	XS	RD	WH	PM	MN
Abstractive	51.96	24.97	28.32	68.02	47.21	62.12
Our method	**90.82**	**90.19**	**91.25**	**88.87**	**86.9**	**91.52**

Table 19: Faithfulness evaluation with abstractive summaries (PEGASUS) and extractive summaries (our method).

4.11 Application in hallucination detection

Unlike extractive systems, abstractive ones are more prone to factual errors (Cao et al., 2022). Towards mitigating this phenomenon, hallucination detection models have been developed aiming to automatically detect these errors, often via comparison between the produced summary and the source document (Goyal and Durrett, 2021, Fabbri et al., 2022). However, not all information present in the source document is relevant, and thus effective, in detecting factual errors. Therefore, instead of conducting comparison with the whole document, only using a subset of the most relevant parts can possibly help in improving the performance of these systems. Accordingly, we conduct trial experiments on the AggreFact-CNN and AggreFact-XSum datasets (Tang et al., 2023), focusing on the FTSOTA split as advised in the original paper. These datasets come with prepared outputs of abstractive systems and the corresponding source articles. For each sample, similar to previous experiments, we apply *summary output* heuristics to obtain the extractive summaries and then conduct hallucination detection conditioned on these summaries along with the abstractive ones. We choose SummaC-ZS (Laban et al., 2022) as the underlying detector - a zero-shot method that's sensitive to outliers and extrema. For evaluation, we use balanced accuracy and AUC scores. Similar to Tang et al., 2023, we choose the prediction threshold based on validation performance. The results are presented in Table 20 and 21. Generally, we obtain promising improvement on both datasets. On the CNN split, the **AUC scores significantly improve** upon the original model, whereas on the XSum split, we observe **consistent gains on both metrics**. These results show that our methods can also help **develop better hallucination detectors**.

	AggreFact-CNN	
	Acc.	AUC
SummaC-ZS	64.01	0.6421
SummaC-ZS + A2E Greedy	63.88	**0.6728**
SummaC-ZS + A2E Beam (k=2)	**64.55**	0.6688
SummaC-ZS + A2E Beam (k=4)	63.88	0.6687

Table 20: Results for hallucination detection on **AggreFact-CNN (FTSOTA)**.

	AggreFact-XSum	
	Acc.	AUC
SummaC-ZS	56.35	0.5228
SummaC-ZS + A2E Greedy	57.21	0.5287
SummaC-ZS + A2E Beam (k=2)	57.58	0.5293
SummaC-ZS + A2E Beam (k=4)	**58.27**	**0.5402**

Table 21: Results for hallucination detection on **AggreFact-XSum (FTSOTA)**.

5 Conclusion

In this work, we explore the use of existing abstractive models for extractive summarization. We make no assumption on the underlying abstractive models and follow a black-box approach. Utilising abstractive summaries, we show that state-of-the-art extractive summaries can be achieved without extractive training. To validate the method's effectiveness, we conduct extensive experiments on six datasets and provide comparison with existing methods, where our models demonstrate either superior or comparable performance.

Limitations

Our works build on top of text generators (or abstractive summarizers) and thus the effectiveness of the whole pipeline also depends on these models. As we have illustrated in the experiments, a worse

generator will produce auxiliary summaries with lower qualities which negatively affect the approximate summaries. Hence, adapting the methods to situations where generation models struggle to maintain peak performance (e.g. zero-shot cross-lingual (Vu et al., 2022), dialectal scenarios (Ziems et al., 2023, Le and Luu, 2023) and continual learning (Qin et al., 2023, Zhang et al., 2022, Nguyen et al., 2023)) is a worth-exploring direction. In addition, since we center on extractive summarization, the end summaries also inherit intrinsic limitations (e.g. lack of expressiveness, possible coreference issues). Nevertheless, as the pipeline seamlessly enables creation of dual summaries (i.e. abstractive and extractive), prospective future works can take advantage of this property to efficiently overcome these restrictions. For example, an end user might want an expressive summary (e.g. entertainment purposes) and accordingly choose the abstractive summary instead of the extractive one - which our method supports out of the box. Alternatively, another user might prioritize reliability (e.g. medical domains) and thus opts for the extractive summary.

A Dataset Statistics

Statistics of the used datasets can be found in Table 22.

The data files for CNN/DailyMail[11] (Nallapati et al., 2016), XSum[12] (Narayan et al., 2018a) and Multi-News[13] (Fabbri et al., 2019) are available in Hugging Face (Lhoest et al., 2021). WikiHow (Koupaee and Wang, 2018) can be obtained via following instructions in the authors' repository[14]. For RedditTIFU (Kim et al., 2019) where there is no official split, we adopt the partitions used by Zhong et al., 2020. For PubMed (Cohan et al., 2018), we use the truncated version similar to Zhong et al., 2020 and follow-up works (An et al., 2022, Zhang et al., 2023, Cheng et al., 2023). The data files for these two datasets can be retrieved from the repository of Zhong et al., 2020[15]. For sentence segmentation, we utilize the Trankit package (Nguyen et al., 2021a).

CNN/DailyMail (Nallapati et al., 2016), XSum (Narayan et al., 2018a) and RedditTIFU (Kim et al., 2019) are available under the MIT license. WikiHow (Koupaee and Wang, 2018) and PubMed (Cohan et al., 2018) are released under the Creative Commons License (CC-BY-NC-SA). Multi-News (Fabbri et al., 2019) is provided under a Dataset Usage Agreement with LILY LAB[16].

B Implementation Details

All experiments were implemented with the PyTorch framework (Paszke et al., 2019) and the Transformers library (Wolf et al., 2019). For ROUGE calculation, we use the package *rouge-score*[17] following Gu et al., 2022. For BERTScore, we use the *microsoft/deberta-large-mnli* model as advised by the authors[18].

Our works build on text generation models and we re-use pre-trained checkpoints whenever possible. Specifically, the details are shown in Table 23. The asterisk symbol "*" implies that we fine-tune from the corresponding raw checkpoint. In particular, we use a learning rate of $1e-5$ with AdamW (Loshchilov and Hutter, 2017) optimizer and a linear decay scheduler. Every model was trained with the MLE objective for a maximum of 300K steps on an A100 GPU and the checkpoint with the lowest validation loss was selected for inference. We also include the thresholds used in experiments with *sentence output* heuristics (#Ext-Local and #Ext-Global). Additionally, the hyperparameters for generation are presented in Table 24. No tri-grams could appear more than once during the generation process.

C Additional Ablations & Analyses

C.0.1 #Extracted Sentences

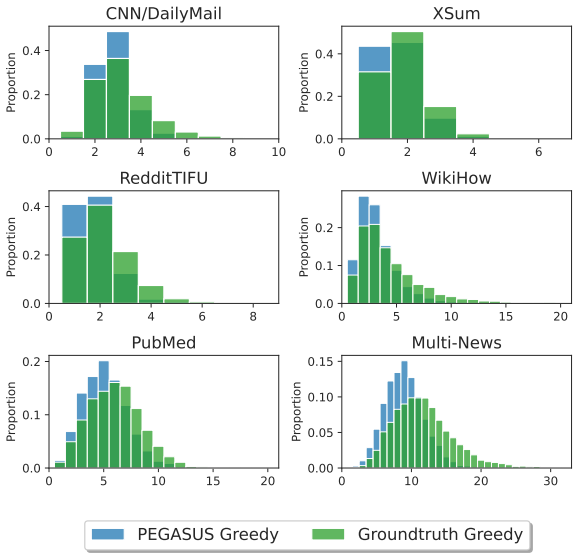

Figure 1: Length Distribution (#Sentences) - PEGASUS - A2E Greedy

We examine the length distribution of A2E models when conditioned on PEGASUS's summaries versus ground truth summaries. We present the histograms in Figure 1. It can be inferred that for the same dataset, the optimal extraction threshold differs per sample basis as indicated by the ground truth A2E outputs. Compared with the ground truth summaries, auxiliary summaries also provide good supervision imitating this property, as we can easily observe the two distributions closely resemble each other. As a result, heuristics with flexible extraction threshold (*summary output*) would gain advantages over fixed counterparts (*sentence output*).

Table 24: Generation hyperparameters.

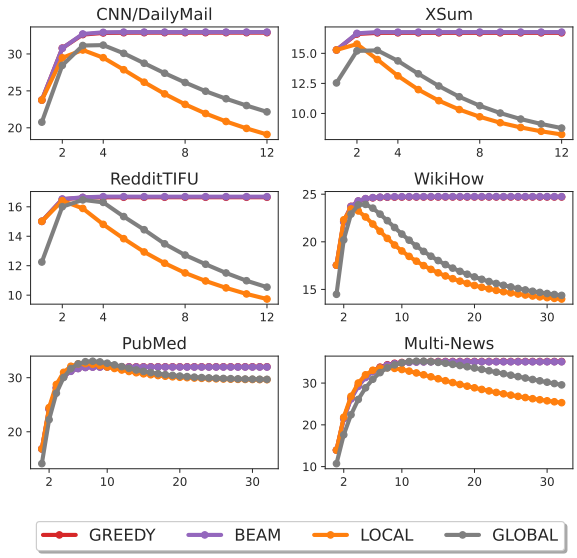

Figure 2: A2E with constrained length (*Summary Output*) and fixed threshold (*Sentence Output*)

C.0.2 Optimization with constrained length

To further study the effect of extraction threshold, we additionally apply summary size constraint on *summary output* heuristics while comparing them with *sentence output* heuristics with the according fixed thresholds. We show the results reported in average ROUGE scores[19] in Figure 2 with PEGASUS as the base generator. Apparently, *summary output* heuristics (i.e. *greedy* and *beam*) do not degenerate with excessive thresholds and typically discover better candidates compared to *sentence output* counterparts (*local* and *global*).

C.0.3 Criteria

To study the effect of different criteria, we re-execute *greedy search* with three evaluators: ROUGE-1, ROUGE-2 and sum of the two ROUGE-12[20]. We show the results in Table 25. The results are measured in an average of ROUGE scores[21]. In most scenarios, we observe that using ROUGE-1 leads to better results than related criteria.

C.0.4 Beam width

To explore the effect of different beam widths, we repeat the experiments with *beam search* while accounting for different beam values. The results are measured in an average of ROUGE scores[22] and presented in Table 26. Note that a beam size of 1 means the algorithm falls back to *greedy search*.

Table 26: Effect of different beam widths

For most cases, we observe that a beam size of 4 achieves good results and higher values do not significantly improve over it.

C.0.5 Inference with Large Language Model

Recent advances on large language models (LLMs) have unraveled emergent abilities (Schaeffer et al., 2023) that facilitate promising improvements in abstractive summarization (Zhang et al., 2024). To examine whether A2E can take advantage of these LLMs for extractive summarization, we reused and experimented with the corpus released by Zhang et al., 2024 which contains summaries generated by the *InstructGPT davinci v2* model (Ouyang et al., 2022) in zero- and few-shot ($k = 5$) in-context settings for 100 random samples in the CNN/DailyMall and XSum test sets. We present the details in Table 27 and 28. Under automatic

evaluation, we find that A2E closely **approaches the abstractive summaries in CNN/DailyMall** and achieves **reasonable performance in XSum**. The summaries from A2E sometimes even achieve higher scores than the abstractive counterparts, e.g., the zero-shot results in CNN/DailyMall.

	R-1	**R-2**	**R-L**	**BERTScore**
Abstractive (Zero-shot)	37.05	13.72	34.42	62.03
Abstractive (Few-shot)	40.31	16.41	36.78	63.97
A2E Greedy (Zero-shot)	37.92	15.14	34.73	62.10
A2E Greedy (Few-shot)	39.61	16.81	35.78	62.98

Table 27: Zero-shot results with the *InstructGPT davinci v2* model on CNN/DailyMall.

	R-1	**R-2**	**R-L**	**BERTScore**

Abstract

Modern Neural Machine Translation systems exhibit strong performance in several different languages and are constantly improving. Their ability to learn continuously is, however, still severely limited by the catastrophic forgetting issue. In this work, we leverage a key property of encoder-decoder Transformers, i.e. their generative ability, to propose a novel approach to continually learning Neural Machine Translation systems. We show how this can effectively learn on a stream of experiences comprising different languages, by leveraging a replay memory populated by using the model itself as a generator of parallel sentences. We empirically demonstrate that our approach can counteract catastrophic forgetting without requiring explicit memorization of training data. Code will be publicly available upon publication[1].

1 Introduction

Neural Machine Translation (NMT) systems have achieved remarkable performance on numerous language pairs, particularly those with abundant resources. The substantial growth in model parameters and the availability of large crawled corpora have greatly contributed to the adoption of advanced techniques like back-translation (Edunov et al., 2018; Sennrich et al., 2016) and denoising pre-training (Liu et al., 2020; Song et al., 2019; Xue et al., 2021), further increasing the translation quality of these models. Consequently, even low-resource languages have benefited from the increased multilingual capabilities of these models (Arivazhagan et al., 2019; Fan et al., 2021).

Despite their impressive quality, modern NMT systems exhibit limited Continual Learning (CL) capabilities and are susceptible to catastrophic forgetting (CF, McCloskey and Cohen, 1989; French, 2006). While the CL community has extensively investigated this phenomenon over the years, it has received relatively less attention from the Natural Language Processing (NLP) community. Previous works in this area have primarily focused on Domain Adaptation, and only recently have turned to different continual learning settings such as incremental language learning (Zhang et al., 2022a).

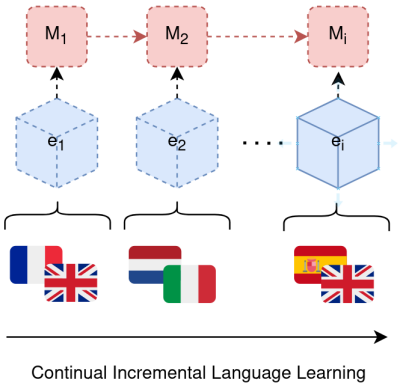

Figure 1: A scheme of the CILL setting. A model is trained incrementally on a stream of experiences comprising training data for various language pairs.

In this paper, we present **SG-Rep**: a novel approach to continually train an NMT system on a stream of experiences comprising several language pairs while mitigating the detrimental effects of catastrophic forgetting. Our method leverages a replay memory populated by synthetic parallel sentences generated by the model itself. We evaluate the effectiveness of our approach across different translation directions and demonstrate its ability to alleviate CF without the need for explicit memorization of the training data. This aspect is crucial where is not possible to store real training samples for privacy reasons or data retention policies.

2 Related Works

Continual Learning or Lifelong Learning (LL) research focuses on developing computational systems that can gradually acquire, refine, and transfer knowledge over extended periods, imitating biolog-

ical systems. The primary challenge arises from the inherent plasticity of neural networks, which leads to catastrophic forgetting. This refers to a situation where performance on previously learned tasks deteriorates as the network parameters are updated, resulting in the loss of acquired knowledge.

In addition to mitigating CF, lifelong learning methods should also promote knowledge transfer across tasks in both forward and backward directions. Research work in the field can be broadly categorized into architecture, regularization, or data-based approaches.

Architecture-based Methods

The central idea of this category of approaches is to allow the network architecture to change either by adding new parameters for specific tasks or by maintaining a fixed network size while allocating a different capacity to each task. Progressive networks (Rusu et al., 2016) maintain a pool of pre-trained models throughout training and learn lateral connections to leverage useful features for the new task. Sodhani et al., 2020 combine Net2Net (Chen et al., 2016) (a network growing approach) together with a gradient episodic memory to enable RNNs to dynamically expand if they fail to learn the current task.

PathNet (Fernando et al., 2017) presents an evolutionary-based algorithm that identifies which parts of the network to reuse for new tasks. By preserving parameters along a learned path from task A and evolving new paths for task B, accelerated learning is achieved compared to starting from scratch or fine-tuning.

Examples of architectural methods in NLP include instantiating a new decoder module for learning new translation directions in NMT (Escolano et al., 2019). Another approach is the use of small task-specific modules called "adapters" (Rebuffi et al., 2017; Houlsby et al., 2019; Pfeiffer et al., 2021) to avoid finetuning of large pre-trained models.

Berard, 2021 focuses on learning a set of language-specific embeddings to be used at inference time to boost translation quality. Other works (Liang et al., 2021; Gu et al., 2021) have explored pruning as a parameter partition strategy.

In contrast, Cao et al., 2021. propose a vocabulary-based approach to address CF, utilizing a vocabulary adaptation scheme that leverages the token overlap in the vocabulary of M-NMT systems that support multiple languages. When a new language is introduced, a new vocabulary is created, encompassing all the data. Embeddings for tokens in the intersection of the old and new vocabularies are reused, and training continues.

We identify two main limitations: first, training a new vocabulary requires storing all data up to the current experience, second, the starting vocabulary must support a large number of languages (24 in the paper) to achieve significant token overlap with the newly trained vocabulary.

Regularization-based Methods

This family of methodologies is based on theoretical neuroscience models that suggest synapses with varying levels of plasticity can protect acquired knowledge. In computational terms, this is implemented by adding a regularization term to the loss function of a neural network, leading to constrained weight updates. Elastic Weight Consolidation (EWC) (Kirkpatrick et al., 2017) prevents catastrophic forgetting by slowing down learning on important weights for old tasks, using the Fisher information Matrix to estimate their importance.

Memory Aware Synapses (MAS) (Aljundi et al., 2018) computes parameter importance in an unsupervised manner so that they approximate the sensitivity of the learned function to a parameter change. For domain adaptation, Thompson et al., 2019 employs EWC as a regularizer, while Li et al., 2022 propose an approach based on estimating the domain shift. Khayrallah et al., 2018 use a Knowledge Distillation (KD) inspired regularization approach. Shao and Feng, 2022 presents Online Knowledge Distillation (COKD) with complementary training and KD, distilling knowledge from n teachers to the student. Cao et al., 2021 proposes Dynamic KD, optimizing a weighted sum of translation and distillation loss, tested with fixed language pairs in both domain and time incremental fashions. Both COKD and Dynamic KD are resource-intensive, relying on external models for distillation, in contrast to our approach. Additionally, Cao et al., 2021 tested on fewer experiences.

Data-based Methods

Data-based methods retain a small number of training samples from previous tasks to limit weight updates based on the data distribution of past experiences. These samples can be either real or pseudo samples.

In the case of real samples, the work of Chu et al., 2017 demonstrates the use of a mixture of old and new data during domain adaptation. Additionally,

the incorporation of replay data and retrieval mechanisms has been shown to improve performance in neural machine translation (Bapna and Firat, 2019; Xu et al., 2020). GEM (Lopez-Paz and Ranzato, 2017) and A-GEM (Chaudhry et al., 2019) utilize real samples from previous tasks to constrain gradient updates within a favorable region for the current task, leading to better performance.

Other approaches closer to our proposed methods, leverage generative models to create pseudo samples: LAMOL (Sun et al., 2020) and (Zhang et al., 2022b; Qin and Joty, 2022) are among the methods that adopt this strategy.

3 The Self-Generated Replay Method

The goal of our method,which we abbreviate as **SG-Rep**, is to incrementally learn a single model that is able to translate into many directions. The training data is not available as a whole but is presented to the model in incremental steps, as a stream of experiences that comprises one or more language directions. The key challenge is preserving translation performance on past experience while adapting effectively to new data. To this end, we use the encoder-decoder model learned in a given experience as a generator of synthetic training samples. The obtained pseudo-samples will populate a fixed-size replay memory that will be used in future tasks to mitigate catastrophic forgetting.

3.1 Continual Incremental Language Learning

Similarly to other works from the CL community, we design a setting where the learning process is divided into E learning experiences. In each $e_i \in E$ the model is exposed to a pair of languages l_1^i, l_2^i and has access to a training set T_i and a validation set V_i comprising a single or both translation directions. In the Continual Incremental Language Learning (CILL) scenario (Figure 1) the model is trained across all experiences: we want to model $P(\mathbf{y}|\mathbf{x})$ for all the languages of interest, with **x** and **y** being the source and target sentence respectively. The model architecture and the number of parameters are kept fixed, together with the sub-word vocabulary which is built in advance. We design a set of experiments to quantify the amount of catastrophic forgetting occurring during the subsequent experiences and the effectiveness of our proposed replay strategy. We employ a fixed-size memory (the replay buffer) that is filled at the end of each e_i experience. We experimented with different buffer sizes and performed also experiments without memory, to assess the amount of catastrophic forgetting. In all the experiments the replay buffer size is fixed and it is not allowed to grow.

3.2 Self-generated Replay Memories

SG-Rep generates pseudo samples following three main steps: 1) generation of samples, 2) filtering, and 3) samples translation.

Encoder input. Consider $l_s \rightarrow l_t$ as translation direction, and a model M capable of translating in both directions: $l_s \leftrightarrow l_t$.

In the initial stage, our method generates a sentence in language l_t by using as encoder input a short text t_e that contains a special token indicating the translation direction <2lang>. Here, "lang" represents a 2-letter language code that identifies the target language l_t. We experimented with concatenating t_e with random words to improve input diversity but we observed a detrimental effect on the overall performance.

Generation and Filtering. We generate n pseudo sentences in language l_t iteratively by top-k sampling with k equal to vocabulary size. At each step, we process the sentences by 1) eliminating duplicates and 2) filtering out low-quality ones.

The filtering criterion considers morphological correctness. We use the PyEnchant[2] spellchecker to identify the number of misspelled words $\hat{w}$ in each sentence and filter out those with $\hat{w} \geq 2$.

Translation. The pseudo sentences are then translated into language l_s by using the same model, obtaining a set of self-generated samples $R = \{(x_i, y_i)\}_{i=1}^{n}$ with x, and y in language l_s and l_t respectively.

The last step populates the replay memory R^* by reservoir sampling from R. The total amount of samples in the replay buffer is constant during all the experiences, while their proportions vary for the effect of the sampling. The training samples for the next experience e_i will then be $T_i \cup R^*$. We repeat the process for each translation direction present in the current experience. The pseudo-code of SG-Rep is reported in Algorithm 1.

4 Experimental Setting

4.1 Multilingual Translation Model

A single Transformer model (Vaswani et al., 2017) was chosen as the architecture of the multilingual

[2]https://github.com/pyenchant/pyenchant

Algorithm 1 SG-Rep pseudocode

Input:
M: NMT model
n: # samples to generate
l_s, l_t: source and target language
Output: R: list of source-target pairs

procedure GENERATE_REPLAY_DATA
  $R \leftarrow [\,]$
  $t_e \leftarrow$GET_ENCODER_INPUT(l_t)
  $src \leftarrow [\,]$ ▷ Pseudo-source sentences
  $tgt \leftarrow [\,]$ ▷ Translated sentences
  while $length(src) < n$ **do**
    $out \leftarrow$ GENERATE(t_e, M)
    $out \leftarrow$ FILTER(out)
    $tgt \leftarrow tgt + out$
    $tgt \leftarrow$ DEDUPLICATE(tgt)
  end while
  $src \leftarrow$ TRANSLATE(tgt, l_s, M) ▷ Translate src into source language l_s
  $R \leftarrow [src, tgt]$
  return R
end procedure

NMT system. We started from the *T5 small v1.1* described by Google (Raffel et al., 2020) and available via Huggingface's Transformer library. We reduced the number of encoder and decoder blocks to 6, and the number of attention heads to 8 in both the encoder and decoder. The total amount of parameters with this configuration is $54.15 \cdot 10^6$. Before training all weights were reinitialized.

We prepend language tokens to the source sentences to denote the desired translation direction as in (Arivazhagan et al., 2019). The SentencePiece (Kudo and Richardson, 2018) tokenizer is trained with a minimum merge frequency of 5 and a vocabulary size of 32k tokens by using HuggingFace (Wolf et al., 2019). We trained in advance a total of 3 tokenizers: two for the two sets of languages from IWSLT17 and one for those from UNPC.

4.2 Datasets and experiences

We run experiments with both small and large-scale datasets. In the small scale setting we employ a subset of the IWSLT17 (Cettolo et al., 2017) dataset while for the large scale one we resort to the United Nation Parallel Corpus (UNPC) (Ziemski et al., 2016). For all the experiments the chosen language pairs are organized into four bidirectional experiences. In each experience, the model is exposed to a language pair and learns to translate from the source language to the target language and vice versa. This choice is motivated by two main reasons. Firstly, the inherent bidirectionality of the translation task. Secondly, in principle, in future steps, we may not have access to the training samples of a particular experience. Therefore, by alternating the roles of source and target languages in the training samples, we aim to ensure the model receives as much relevant information as possible.

Exp.	Direction	# Train	# Dev	# Test
	IWSLT17			
1	Fr ↔ En	465,650	1,780	17,194
2	It ↔ Nl	466,830	2,002	3,338
3	En ↔ Ro	441,076	1,828	3,356
4	It ↔ Ro	435,102	1,828	3,268
1	Ar ↔ En	463,426	1,776	17,166
2	En ↔ Fr	465,650	1,780	17,194
3	Ko ↔ En	460,480	1,758	17,028
4	It ↔ Nl	466,830	2,002	3,338
	UNPC			
1	Ar ↔ En	20,040,478	4,000	4,000
2	Es ↔ Ru	22,290,106	4,000	4,000
3	En ↔ Fr	30,336,652	4,000	4,000
3	En ↔ Es	25,223,004	4,000	4,000

Table 1: Summary of the different streams of experiences. IWSLT17: the first one (top) is composed of European-only languages while the second one (bottom) contains also non-European ones. UNPC: The four experiences contain European and non-European languages. We report the total size of train, validation, and test datasets. In a single experience, each direction has the same amount of samples for each split.

IWSLT17. To create the first stream we focus on the following translation directions: French ↔ English, Dutch ↔ Italian, English ↔ Romanian, and Italian ↔ Romanian. The second stream contains also non-European languages: Arabic ↔ English, English ↔ French, Korean ↔ English, and Italian ↔ Dutch.

UNPC. In this dataset we focus on a mix of European and non-European languages: Arabic ↔ English, Spanish ↔ Russian, and English ↔ French.

Table 1 summarizes the experiences and their corresponding data sizes for all streams.

4.3 Systems

We evaluate different systems against our proposed self-replay approach (**SG-Rep**). Each system follows the architecture described in Section 4.1 and has been implemented using the Transformers library (Wolf et al., 2019) except where explicitly indicated.

- **SG-Rep (ours).** We fix top-k sampling tem-

perature at $T = 0.93$. The translation phase is conducted with a beam search approach with a beam size of 12. The replay buffer size is always computed based on the total training data for the first IWSLT17 stream (the one with European-only languages). This allows us to have a relatively small memory also for experiments with large corpora and to compare results. We varied both the buffer sizes and the amount of generated samples. The latter is indicated with a superscript. SG-REP$^{100}_{0.05}$ denotes a buffer size of 5% of the data randomly filled using 100K generated translation pairs. Once set, the buffer size is not allowed to increase and stays constant throughout the experiences. We explicitly report the different sizes of the memory in Appendix D.

- **Incremental Training.** The model is directly trained on each experience, one after another.
- **Multitask (Joint training).** The classical upper bound for CL: the model is trained on data from all experiences simultaneously.
- **Replay.** The model has a fixed memory buffer. At the end of each experience, the memory is randomly populated with examples from the training set of the current experience using reservoir sampling. We tested different memory sizes, expressed as a percentage as we did for SG-Rep. We indicate the buffer percentage with a subscript: Replay$_{0.05}$ denotes a 5% replay memory buffer.
- **EWC.** The model uses Elastic Weight Consolidation as a regularization strategy. EWC computes the importance of the parameters using the Fisher information matrix and penalizes changes to important ones so that they stay close to the original ones. The regularized loss function is:

$$\mathcal{L}(\theta) = \mathcal{L}_{CE}(\theta) + \frac{\lambda}{2} \sum_i F_i(\theta_i - \theta^*_{0,i})^2 \quad (1)$$

  with λ controlling the relevance of the old task compared to the new one. We follow the implementation from the Avalanche library (Lomonaco et al., 2021).
- **A-GEM.** This GEM followup (Lopez-Paz and Ranzato, 2017) uses a small episodic memory to store a subset of the examples from each experience. When training on subsequent tasks, a random batch is sampled from the memory, and the losses on the episodic memories are treated as inequality constraints. A-GEM tries to ensure that the average episodic memory loss over the previous tasks does not increase, and improves on GEM computational requirements. We set the batch size equal to 150 when sampling from the memory. The implementation follows the one from the Avalanche library (Lomonaco et al., 2021).
- **LAMOL.** A language model is treated as both the learner and the generator. The model is trained by casting different tasks to question answering (QA) in a SQuaD (Rajpurkar et al., 2016) format. During training, each example is formatted into both the QA format and the language modeling (LM) format. The total loss optimized by the model is a weighted sum of the QA loss, and the classical LM loss:

$$\mathcal{L}(\theta) = \mathcal{L}_{QA}(\theta) + \lambda \mathcal{L}_{LM}(\theta). \quad (2)$$

  We use the authors' original implementation after pre-processing the IWSLT17 dataset in the required format. We ran experiments with both GPT and GPT-2 (Radford et al., 2019) models with a total of 116M and 124M trainable parameters, respectively.

4.4 Training Details

We train all configurations for a maximum of 50 epochs with early stopping (patience = 10) using the Adam optimizer ($\beta_1 = 0.9$, $\beta_2 = 0.99$). We adjust the learning rate with a cosine scheduler ($warmup_steps = 16k$). We evaluate the models every $5k$ steps, starting with an initial learning rate of $5 \cdot 10^{-4}$ and apply a dropout rate of 0.1. For decoding, we use beam search (size 12) with a maximum length of 128 tokens. We train all systems on a single A100 GPU, with a batch size of 150 in FP16 precision.For LAMOL, we train both the GPT and GPT-2 models using the author's code and the hyperparameters reported as the best in their paper. We train for 9 epochs on 8 H100 GPUs with a batch size of 310.

5 Experimental Results

The translation output of the models is scored using the 4-gram case-sensitive BLEU (Papineni et al., 2002) with the SacreBLEU tool (Post, 2018) using

the default tokenization scheme[3] based on mosestokenizer[4]. COMET scores are reported in Appendix G.

Each model is evaluated at the end of training on the last experience on all translation directions. In addition to the average BLEU, we also report a metric for comparative analysis to compensate for the diversity of the different test sets for each language. It quantifies the performance delta between the chosen system and the upper bound (i.e. joint training) for each language pair. Specifically, we define the language pair delta as

$$\Delta Lp^* = \sum_{i=0}^{n} U_i - S_i$$

where U_i and S_i denote the BLEU scores for language pair i under the upper bound and the system under consideration, respectively and n is the number of language pairs. We indicate with '*' the system representing the upper bound. Additionally, we conducted an analysis on data leakage and generated pseudo samples that we report in Section 5.7 and Appendix H, respectively.

5.1 IWSLT17 European Languages only

Our main results are summarized in Table 2. As can be seen, incremental training results in extreme catastrophic forgetting causing the model to completely lose its translation capabilities with the exception of languages present in the last experience. EWC brings only a slight performance improvement over fine-tuning in this training scenario.

All data-based methods perform better than EWC. Surprisingly, in this experimental setting, A-GEM surpasses LAMOL. We hypothesize that this result is due to the difficulty of the task as LAMOL was originally designed to deal with training data cast as QA. Compared to the original setting, casting a translation task as QA will yield longer answers, and consequently, increased generation difficulty. Thus the external memory used by A-GEM proves advantageous.

SG-Rep has the best overall performance among all tested methods and is the one getting closer to both joint training and replay using real samples.

Figure 2 shows the forgetting curve of the various baselines: we compute the averaged BLEU scores on the first experience at the end of each subsequent one. SG-Rep exhibits more forgetting with respect to A-GEM but has a significantly better BLEU when considering the whole stream of experiences. To investigate whether the order of the experiences has an effect on the different approaches compared, we ran additional experiments under 3 different permutations of the experiences. We found SG-Rep to be quite resilient in this setting showing lower variations for the average BLEU score and ΔLp than those exhibited by EWC and AGEM. We report full data for these additional experiments in the Appendix B

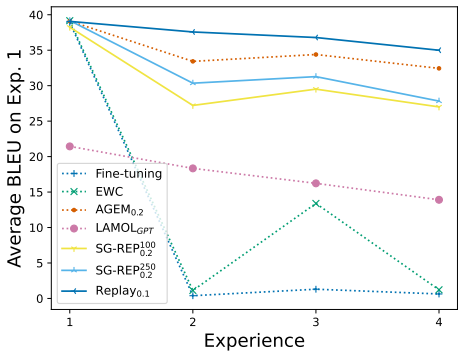

Figure 2: Forgetting curve of the different approaches. Average BLEU score on the first task evaluated at the end of the training process of each experience.

5.2 Sub-word Tokens Overlap

In this particular setting, we observed that utilizing EWC regularization leads to subpar performance and fails to effectively mitigate catastrophic forgetting. We attribute this outcome to the inherent characteristics of this CL scenario, where the model must learn distinct target distributions that often exhibit minimal overlap, despite the utilization of a shared sub-word vocabulary.

To validate our hypothesis, we performed tokenization on the labels within each training set of the individual experiences. Subsequently, we computed the token frequencies and selected the top k most frequent tokens for each experience. By measuring the intersection between these selected tokens, we quantified the overlap as a percentage. The results of this analysis, presented in Table 3, highlight the degree of overlap for various values of k. The findings demonstrate that while there is a higher overlap percentage between experiences that share the same target language, even for larger values of k, the overlap remains relatively low.

2-4	50.50	55.71	56.65	58.75
3-4	47.47	58.31	58.95	61.43

Table 3: Overlap percentage between the top-k tokens of different experiences for several values of k.

For a visual insight into the token distribution, we provide Figure 3, which presents a plot comparing the top-200 sub-word tokens in Experience 1 with their occurrences in the top-200 tokens of Experience 2. In the CILL setting, the token distribution affects the output layer in a manner akin to a class-incremental scenario, albeit to a lesser extent. Consequently, it is normal to expect a degradation of the performance: in such scenarios, EWC performs on par with fine-tuning (Lesort et al., 2019) and the effectiveness of regularization methods is generally acknowledged to be relatively low (van de Ven and Tolias, 2019). Although A-GEM demonstrates a relatively smaller decline in performance compared to other methods, its performance remains suboptimal. Under a task order that simulates a Domain Incremental setting (e.g. with subsequent tasks sharing a language), EWC has a stronger performance. We report the scores for both EWC and AGEM in Appendix C.

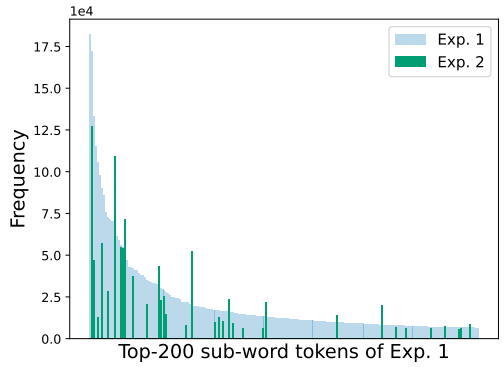

Figure 3: In light blue, frequencies of the top-200 sub-word tokens of exp. 1. The green bars represent the frequency of the same tokens that also appear in the 200 most frequent tokens of exp 2.

5.3 Effects of The Different Hyper-parameters

We investigated the impact of various hyper-parameters on the performance of our models.

In SG-Rep, we examined the effects of different memory sizes, specifically 5%, 10%, and 20%. Additionally, we maintained a fixed memory size of 20% and varied the number of self-generated samples, exploring values of $n = [100k, 180k, 250k]$.

For the A-GEM method, we utilized different memory sizes, namely 5%, 10%, and 20% . To investigate the impact of regularization strength, we varied the values of λ for the EWC method, specifically using $\lambda = [0.25, 2, 200, 2000]$. Figure 4 presents a comparison between A-GEM and our proposed approach across different memory sizes. Notably, increasing the memory size from 10% to 20% had a negligible effect on A-GEM, while it resulted in a relative improvement of nearly 1 BLEU for the self-generated replay approach.

By maintaining a fixed memory size and increasing the quantity of generated pseudo-samples, we obtain a larger initial population for reservoir sampling, leading to increased diversity within the memory. This diversity proved to be beneficial for the overall performance. Figure 5 illustrates the

Systems	Ar→En	En→Ar	En→Fr	Fr→En	Ko→En	En→Ko	Nl→It	It→Nl	Avg.	ΔLp* ↓

average BLEU score at the conclusion of each experience, considering various values of self-generated samples while keeping a fixed replay buffer size of 20%. We report a plot of the forgetting trend in Appendix E.

5.4 IWSLT17 with Eastern Languages

Table 4 summarizes the results on the stream of experiences containing also non-European languages. In this setting, both AGEM and EWC perform poorly, with the latter being able to retain most translation proficiency for Ar↔En but failing to learn in other directions. SG-Rep outperforms both AGEM and EWC by a larger margin with respect to the setting containing only European languages.

5.5 UNPC

We ran additional experiments on the United Nations Parallel Corpus in a high-resource context. Informed by the previous experiments on IWSLT and given the high computational costs we avoid to train low scoring approaches such as LAMOL. We keep EWC as an instance of regularization-based approaches. Table 5 summarizes the results. EWC maintains the strongest performance on the Ar ↔ En but impairs model learning in subsequent experiences. AGEM$_{0.2}$ is slightly better. SG-Rep has a larger gap with the classical Replay compared with the IWSLT setting, but it's still the strongest performer scoring more than 3 BLEU points higher than AGEM and having lower ΔLp with the jointly trained model.

5.6 Pseudo-samples Analysis

We conducted an analysis of generated pseudo samples, covering duplicate counts and length statistics, to assess their characteristics and compare them with the original data. For diversity assessment, we utilized self-BLEU scores (Alihosseini et al., 2019). Due to computational constraints, self-BLEU was

Table 6: Data leakage stats for IWSLT17 and UNPC datasets. Left: leakage in generated data before populating replay buffers. Right: data leaked into replay buffers. Stats are computed without mitigation.

calculated with a sampling approach, evaluating 5k sentences and reporting the average over 10 runs. Results are provided in Appendix H for both IWSLT17 data (Table 16) and UNPC (Table 17). In general, generated data exhibit higher self-BLEU scores, indicating lower diversity compared to the original data, except for the Arabic-English language pair. Conversely, for UNPC, generated samples are more diverse than the original ones. Pseudo samples for both UNPC and IWSLT17 are shorter than the original data.

5.7 Data leakage Analysis

Table 6 summarizes the analysis quantifying training data leakage during model generation. For IWSLT17, the leaked data proportion is extremely low, below 0.5%. It generally decreases for a single language pair when examining buffers and across experiences. English leakage consists of very short, common sentences with simple grammatical construction, like "Thank you" or "I am." Comparatively, UNPC has a larger data leakage, but the percentage remains low. Also for UNPC the leaked sentences are short and frequent names (e.g., country names) and section titles (e.g., "Introduction," "B. Text").

6 Conclusions

We proposed a simple yet effective continual learning method for NMT that uses a replay memory to mitigate catastrophic forgetting. Differently from other data-based approaches, we do not memorize training samples explicitly and instead use the model itself as a generator of parallel sentences. The experimental results prove that our method can achieve significant improvement over several strong continual learning baselines.

Limitations. Our method has a computational overhead to standard replay due to pseudo-sample generation. However, the overall training time for a stream of experiences is comparable to other baselines. To assess the performance of SG-Rep in challenging scenarios, we choose a model architecture with a relatively low number of parameters compared to state-of-the-art M-NMT systems.

Ethics Statement. Our work pertains to the continual training of NMT systems to adapt them with low forgetting. In this work, we use only publicly available data.

H Statistics of Original and Pseudo-samples

We conducted an analysis of generated pseudo samples, covering duplicate counts and length statistics, to assess their characteristics and compare them with the original data.

For diversity assessment, we utilized self-BLEU scores (Alihosseini et al., 2019). Due to computational constraints, self-BLEU was calculated with a sampling approach, evaluating 5k sentences and reporting the average over 10 runs. Results are provided for both IWSLT17 data in Table16 and UNPC in Table 17.

In general, generated data exhibit higher self-BLEU scores, indicating lower diversity compared to the original data, except for the Arabic-English language pair. Conversely, for UNPC, generated samples are more diverse than the original ones. Pseudo samples for both UNPC and IWSLT17 are shorter than the original data.

Abstract

Vision-language models (VLMs) can effectively act as visual assistants, interpreting questions about images and producing human-like responses. This work explores their abilities to demonstrate human-like reasoning. To address concerns about the consistency of VLMs' reasoning, we introduce a chain-of-thought (CoT) consistency measure. We tackle the challenge of extensive human annotations by proposing an LLM-Human-in-the-Loop pipeline. Based on this pipeline, we build the **CURE** benchmark to measure both the zero-shot reasoning performance and consistency of VLMs. We evaluate state-of-the-art VLMs and find that even the best-performing model is unable to demonstrate strong visual reasoning capabilities and consistency, indicating that substantial efforts are required to enable VLMs to perform visual reasoning as systematically and consistently as humans. As an early step, we propose a two-stage training framework aimed at improving both the reasoning performance and consistency of VLMs without human annotations. The framework consists of two primary stages: supervised fine-tuning and learning from feedback, to guide VLMs in generating reasoning chains that exhibit both consistency and groundedness. Our framework exhibits a 4% relative improvement in reasoning performance and consistency. We release the dataset at https://github.com/Yangyi-Chen/CoTConsistency.

1 Introduction

Vision-language models (VLMs) exhibit competence at generating human-like responses by leveraging multimodal instructional data and large language models (LLMs) (Li et al., 2023a; Liu et al., 2023c,a; Chen et al., 2023). A key direction in improving such VLMs is to enable grounded and consistent visual reasoning. We thus take a critical look at the reasoning capability of existing VLMs, measuring and improving both their performance and consistency in reasoning. For reasoning performance, we aim to measure whether VLMs can derive high-level inference that extends beyond the immediately perceived information correctly. For reasoning consistency, we seek to determine the extent to which VLMs can identify the underlying reasoning chains that lead to the high-level inference.

Previous work simplifies the evaluation of reasoning consistency by only considering coarse-grained rationales (Zellers et al., 2019) and relying on human evaluation (Lu et al., 2022a) and similarity measure (Wei et al., 2023), which lacks scalability and preciseness. Thus, we motivate to establish a new benchmark dataset that provides annotation of the fine-grained reasoning steps to automatically measure reasoning consistency. However, collecting such a dataset is challenging due to high-cost underlying human effort and may contain inconsistencies among annotators for the reasoning chains (González et al., 2021; Larson et al., 2020).

To address this challenge, we propose an LLM-Human-in-the-Loop pipeline for dataset construction. Several recent efforts have shown that LLMs can effectively follow human instructions to generate high-quality datasets (Brown et al., 2020; Meng et al., 2022; Ubani et al., 2023; Wang et al., 2022e). This pipeline functions by incorporating limited human assistance for providing instructions and filtering rules, enabling LLMs to efficiently generate high-quality datasets in a semi-automatic manner, substantially reducing annotation cost. Based on an existing coarse-grained visual inference dataset Sherlock (Hessel et al., 2022), we establish a benchmark CURE for **C**hain-of-Thought Vis**U**Al **R**easoning **E**valuation. It contains 1,622 human-verified samples of high-level visual inference and corresponding CoT reasoning chains, intended for zero-shot evaluation. Two examples are presented in Figure 1. Particularly, the CoT rea-

Figure 1: Besides the high-level inference about the images (e.g., *The girl is turning two years old today.*), CURE also contains CoT reasoning chains to evaluate VLMs' reasoning performance and consistency. We only show 2 (of 6) candidate options for presentation. We highlight the ground truth answers. More examples are shown in Figure 9.

soning chains consist of progressive subquestions, ranging from recognition (e.g., *What is on the cake?*) to cognition (e.g., *What does each candle represent?*), with the purpose of measuring the reasoning consistency of VLMs. Due to the notorious difficulty of natural language generation evaluation (Sai et al., 2023; Hendrycks et al., 2021), we formulate CURE as a multiple-choice task for the ease of automatic evaluation. Particularly, for each visual input, we assess the reasoning in VLMs by evaluating their overall inference capabilities for a designated area (the bounding box in Figure 1) and their ability to correctly address the intermediate reasoning chain leading to the final inference.

We evaluate the state-of-the-art (SOTA) VLMs on CURE. The key conclusions from these evaluations are: (1) The model's success in complex visual inference depends on LLMs components, visual inputs, and instruction finetuning; (2) Even the SOTA VLM (BLIP-2) falls short in comparison to human performance regarding overall visual reasoning performance. In addition, our findings indicate a lack of reasoning consistency. Specifically, the reliability of intermediate reasoning steps cannot be assured, irrespective of the accuracy of the final inference (and vice versa). This suggests VLMs are not always consistent in their reasoning.

To enhance VLMs' reasoning performance and consistency, we propose a two-stage training framework for training rationale-augmented VLMs. In the first stage, VLMs are trained on reasoning samples that encompass step-by-step reasoning chains, which are automatically generated by LLMs. However, VLMs may produce inaccurate high-level inferences due to inconsistencies or hallucination in the rationales after this stage. Thus, we introduce a subsequent stage that integrates feedback from LLMs to examine the reasoning process. This approach avoids the complex task of directly scrutinizing the high-level inferences of VLMs. The results demonstrate the relative improvement in both reasoning performance and consistency is approximately 4% compared to the SOTA.

2 Related Work

The CoT reasoning approach is first proposed for LLMs (Wei et al., 2022). We discuss related work regarding LLMs CoT reasoning and vision-language pretraining in Appendix B and focus on vision-language reasoning in this section. There exists a paucity of comprehensive diagnostic studies concerning VLMs with the aim of quantifying their reasoning consistency, although efforts have been spent on measuring the visual reasoning performance (e.g., Sherlock) (Hessel et al., 2022) and coarse-grained rationale evaluation, including multiple-choice question answering (e.g., VCR) (Zellers et al., 2019), human evaluation of generated rationales (Lu et al., 2022a), and similarity measure between the generated and the ground-truth rationales (Wei et al., 2023). Some work has identified the failure of VLMs to accurately answer subquestions that are components of the main problems (Ray et al., 2019; Jing et al., 2022; Selvaraju et al., 2020; Wang et al., 2022f; Lu et al., 2022a; Wei et al., 2023). For instance, VLMs may correctly determine the significant size of a mountain in an image but erroneously classify it as small when responding to a query such as "Are the mountains small?" (Ray et al., 2019). In contrast to the aforementioned studies that focus on coarse-grained rationale evaluation and individual subquestions, we create reasoning chains that consist of coherent subquestions capable of supporting high-level inference. This approach allows us to precisely measure the extent to which reasoning in VLMs is consistent and grounded.

3 CURE Benchmark

We present the CURE dataset for measuring visual reasoning performance and consistency in VLMs and the LLM-Human-in-the-Loop pipeline

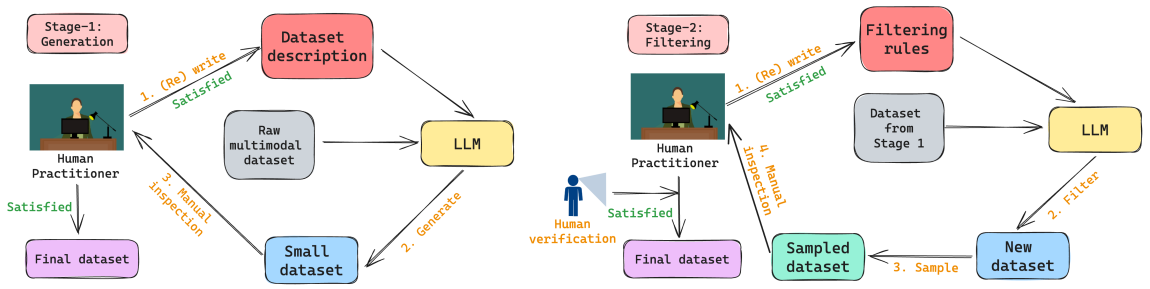

Figure 2: The LLM-Human-in-the-Loop dataset construction pipeline consists of the generation and filtering stages. We use this procedure to create CURE in a semi-automatic manner.

adopted to construct it semi-automatically. Our dataset builds on the Sherlock dataset (Hessel et al., 2022), which measures abductive reasoning by annotating visual clues (text and bounding boxes for perceptual elements) and high-level inference. However, our aim is not only to measure the capacity of VLMs to accurately perform high-level visual inference but also to subsequently ascertain the extent to which the resulting inference is thoroughly substantiated. We thus add two new annotations to enable this: **(1) Reasoning Chains:** We provide fine-grained and precise CoT reasoning containing coherent subquestions that can be chained together to derive the high-level inference provided by Sherlock. **(2) Candidate Answers:** To avoid the long-standing issues in the evaluation of natural language generation (Sai et al., 2023), we transform the generation task of high-level inference and CoT subquestions into a multiple-choice question answering task by generating plausible but incorrect alternative candidates for each ground truth, as shown in Figure 1.

In this section, we outline the procedure to semi-automatically create CURE with LLMs and then describe the evaluation metrics adopted to measure reasoning performance and consistency.

3.1 LLM-Human-in-the-Loop Data Generation Pipeline

Our dataset construction pipeline consists of two stages, as illustrated in Figure 2. The first stage aims to generate a preliminary dataset that potentially contains instances of failure, while the second stage filters out the error cases, similar to the crowdsourcing dataset collection approaches (Lin et al., 2014). In both stages, LLMs carry out the majority of tasks, while human practitioners (the researchers in this case) iteratively correct errors made by LLMs (Bubeck et al., 2023).

3.1.1 Stage-1: Preliminary Generation

We randomly select 10,000 examples from the Sherlock evaluation set to serve as the raw coarse-grained examples. In this stage, the practitioner engineers an initial prompt that basically describes the data LLMs should generate based on each raw example. The dataset description is then fed along with necessary context – the visual clues describing the image and the high-level inference from Sherlock – to generate a small initial dataset of reasoning chains (e.g., for 50 examples). These examples are usually inadequate and look different than intended. Next, the practitioner should carefully examine the generated examples and revise the dataset description accordingly. Through multiple iterations, a curated instruction that contains dataset descriptions and specific requirements can be produced to guide LLMs to generate the full-sized preliminary dataset.

Reasoning Chains. We use GPT-4 (OpenAI, 2023) in all dataset generation steps. Our stage-1 prompt for generating reasoning steps is shown in Appendix F. This prompt starts by describing the overall goal, inputs, and outputs we expect from LLMs. It then outlines five principles to ensure LLMs generate meaningful and reasonable subquestions. We also find that the inclusion of an in-context example for a step-by-step demonstration of sample generation significantly enhances the ability of LLMs to generate samples that conform to the specified principles. The resulting preliminary dataset contains fairly uniform reasoning chains for 1.6k examples. Typically the generated subquestions support the high-level inference when chained together, following a progression from perception problems to more complex visual inference, thus adhering to the "from recognition to cognition" practice (Zellers et al., 2019).

Iteration	Common Failure Modes
1	The CoT reasoning chains lack consistent subquestions that are capable of deriving the high-level inference.
2	The candidate inference about the image exhibits similarity in meaning with the ground truth inference.
3	The ground truth answers for the subquestions are incorrect due to the occurrence of hallucination in LLMs.
4	The candidate answers for the subquestions are also correct.
5	The problems can be solved directly without relying on visual inputs.
6	The subquestions can contain some words that are irrelevant to the visual inputs.

Table 1: The identified common failure modes at each iteration.

Candidate Answers. We can potentially evaluate whether the outputs from VLMs match or closely resemble ground truth inference or reasoning steps, similar to the practice in previous work (Lu et al., 2022a; Wei et al., 2023). However, this approach has two notable shortcomings: (1) The evaluation of natural language generation has been a persistent challenge, lacking a universally accepted approach (Sai et al., 2023); (2) Although we provide ground truth answers for each image, some alternative predictions may also be correct, regarding the nature of abductive reasoning (Walton, 2014). To address the above issues, we formulate CURE as a multiple-choice question answering task, requiring VLMs to select the most likely inference/answer from the six candidates provided. We prompt LLMs using the same stage-1 procedure to generate potential candidate inference/answers. These candidate answers maintain relevance to the provided image while incorporating factual inaccuracies when compared to the ground truth. The prompts adopted are shown in Appendix F.

3.1.2 Stage-2: Filtering

Although samples in the preliminary dataset generally adhere to the desired criteria, failures still arise due to inherent limitations in LLMs (Borji, 2023). However, by drawing explicit attention to common failure modes, we can instruct LLMs to correctly filter out bad example groups. In each round, the practitioner selects a small number of samples and conducts a thorough inspection to extract predominant failure modes. A distinct prompt is then created for each failure mode that requires LLMs to determine whether reasoning chains or sets of candidate answers meet that failure case. This prompt is applied to all remaining preliminary data, removing all examples that LLMs identify as lying in the failure modes. The practitioner then repeats this procedure through multiple iterations until the randomly selected sample of examples no longer exhibits any instances of error. We conduct a total of six iterations to systematically remove groups of samples that displayed common failure modes. The identified failure modes are listed in Table 1, and the prompts are described in Appendix F.

Human Verification. While the filtering stage yields a substantial labor reduction when compared to the initial unfiltered dataset (50% reduction estimated), there still exist some failure cases. For example, our analysis finds that a certain amount of examples in the Sherlock dataset share the same reasoning problem that relies on simplistic visual cues such as sky and lighting conditions to infer weather patterns and differentiate between day and night. This kind of shortcut annotation is documented in previous studies (Gururangan et al., 2018; Geva et al., 2019; Yuan et al., 2023). We motivate to address these concerns since CURE is for evaluation purposes. We hire human annotators to meticulously review the entire created dataset to ensure two primary objectives: (1) Each sample's validity for measuring reasoning performance and consistency; (2) The inclusion of diverse samples in the evaluation dataset. The details of human verification are described in Appendix D.

3.2 Human Evaluation

CURE contains 1,622 evaluative instances. We employ human annotators to conduct human evaluation with emphasis on two aspects: (1) What is the level of human performance observed on CURE? (2) Do the samples within CURE hold validity and can be effectively used for evaluation? We select a sample of 200 instances from CURE. The annotation details are described in Appendix D. We engage three human annotators to conduct the task of answering multiple-choice questions and provide annotations indicating the presence of any failure mode mentioned in Table 1 or any other unidentified failure modes. The human performance is listed in Table 2. The detailed discussion of the human performance compared with the model performance is in Sec. 5. In the assessment of sample validity, merely 3% of the evaluation samples within the benchmark are found to

demonstrate specific issues. Of this subset, 2% of the samples exhibit inconsistent reasoning chains, while 1% of the samples provide incorrect answers for the subquestions. It is worth noting that apart from the issues outlined in Table 1, no other problems have been reported. These findings serve as a validation of the high quality of CURE, and also demonstrate the effectiveness of our pipeline at identifying unqualified samples. The detailed statistics of CURE are described in Appendix A.

3.3 Evaluation Metrics

As described in the previous section, we frame CURE as a multiple-choice problem with six potential inference per image and six plausible candidates for every subquestion (reasoning step). Specifically, each image I_i is paired with a high level question Q_h^i associated with six candidate inferences $O_h^i = \{o_{h1}^i, o_{h2}^i, ..., o_{h6}^i\}$. Additionally, reasoning chains are made up of several questions Q_c^i. Each question $q \in Q_c^i$ is associated with a set of six candidate answers $O_q^i = \{o_{q1}^i, o_{q2}^i, ..., o_{q6}^i\}$. We propose a series of metrics that evaluate not only the reasoning ability of the VLMs but also the consistency in their reasoning.

3.3.1 Metrics for Reasoning Performance

Performance in High-Level Reasoning. The metric R_h is designed to measure the VLMs' ability in accurately choosing the most probable inference from the candidate pool for each image:

$$R_h = \frac{1}{N}\sum_{i=1}^{N}\mathbb{I}(\hat{a}_h^i = a_h^i), \quad \hat{a}_h^i \in \{o_{h1}^i, o_{h2}^i, ..., o_{h6}^i\}, \tag{1}$$

where N signifies the total number of images, $\mathbb{I}(x)$ is the indication function that returns 1 if x is true and 0 otherwise, $\hat{a}_h^i$ and a_h^i are model's chosen answer and ground truth answer respectively.

Performance in CoT Reasoning. The metric R_{cot} is used to evaluate the VLMs' ability to correctly answer all subquestions contained in the reasoning chain for each image:

$$R_{\text{cot}} = \frac{1}{N}\sum_{i=1}^{N}\mathbb{I}\left(\sum_{j=1}^{M}\mathbb{I}(\hat{a}_j^i = a_j^i) = M\right), \quad \hat{a}_j^i \in \{o_{j1}^i, o_{j2}^i, \ldots, o_{j6}^i\}, \tag{2}$$

where M is the number of subquestions within the CoT reasoning chain per image, $\hat{a}_j^i$ is the model's prediction, and a_j^i is the ground truth answer.

Overall Performance in Reasoning. We propose R_o to measure if VLMs can successfully perform both high-level reasoning and CoT reasoning for every image:

$$R_o = \frac{1}{N}\sum_{i=1}^{N}\mathbb{I}(\hat{a}_h^i = a_h^i) * \mathbb{I}(\sum_{j=1}^{M}\mathbb{I}(\hat{a}_j^i = a_j^i) = M) \tag{3}$$

where the notations adhere to previous definitions.

3.3.2 Metrics for Reasoning Consistency

Consistency in Forward Reasoning. We define C_f to evaluate the VLMs' capacity to correctly answer the high-level inference question once all subquestions have been correctly addressed:

$$C_f = \frac{1}{\sum_{i=1}^{N} s_i}\sum_{i=1}^{N} s_i \cdot \mathbb{I}(\hat{a}_h^i = a_h^i), \quad \hat{a}_h^i \in \{o_{q1}^i, o_{q2}^i, ..., o_{q6}^i\}, \tag{4}$$

where s_i equals 1 if all subquestions for the ith image have been correctly answered by the VLM, and 0 otherwise, and other notations adhere to their previous definitions.

Consistency in Backward Reasoning. We define C_b to evaluate the VLMs' proficiency in correctly answering all subquestions given the successful answering of the high-level inference question:

$$C_b = \sum_{i=1}^{N}\mathbb{I}\left(\sum_{j=1}^{M}\mathbb{I}(\hat{a}_j^i = a_j^i) = M\right), \quad \hat{a}_j^i \in \{o_{j1}^i, o_{j2}^i, \ldots, o_{j6}^i\}, \tag{5}$$

where h_i equals 1 if the VLM correctly answers the high-level inference question for the ith image, and 0 otherwise, and other notations adhere to their previous definitions.

4 Approach

In preliminary experiments, we find that VLMs can effectively conduct high-level visual inference when provided with complete reasoning chains. Thus, we propose to train a model capable of generating rationales that can potentially enhance visual reasoning performance and consistency. To this end, we propose a bifurcated training framework that is able to train a VLM to efficiently produce rationales that facilitate high-level visual inference (see Figure 3). In the first stage, we aim to train CoTBLIP to generate rationales that contain enough visual details and reasonable

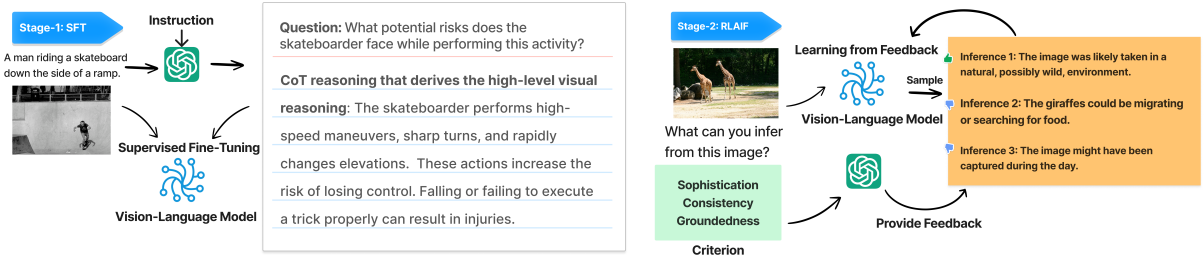

Figure 3: The two-stage training framework consisting of SFT and RLAIF. We instruct LLMs to examine the reasoning process of VLMs to improve the challenging high-level inferences.

inference. To further mitigate certain issues in generated rationales (e.g., hallucination) for better high-level inferences, we introduce the second Reinforcement Learning from LLMs (AI) Feedback (**RLAIF**) stage. We select BLIP-2-T5$_{xl}$ as our backbone model due to its strong performance on basic vision-language tasks (Xu et al., 2023; Fu et al., 2023). Consequently, we refer to our rationale-generation model as **CoTBLIP**.

Stage-1: SFT. We utilize the complex reasoning samples from the LLaVA dataset (Liu et al., 2023c). The original 77K samples are produced by instructing GPT-4 to generate visual inference using a carefully curated set of five human-annotated captions and bounding boxes associated with images from the COCO Dataset (Lin et al., 2014). However, the generated samples consist of repetitive, dialogic expressions that might not be entirely grounded in the images. We thus perform a further post-processing step that prompts LLMs to generate CoT reasoning chains based on the original samples, placing an emphasis on ensuring that these chains are logical, consistent, and succinct. The detailed prompt is shown in Appendix F. We train CoTBLIP on these refined samples using SFT.

Following the SFT stage, CoTBLIP is competent in generating plausible rationales. However, the high-level inferences may be inaccurate since the produced rationales might contain inconsistent reasoning chains or contents that are not grounded in the images (hallucination). In addition, the scalability of the SFT training stage is limited due to its dependence on high-quality human-annotated dense captions, which makes it difficult for this stage to leverage image-caption pairs in the wild. This can lead to lower generalizability on a broad range of visual concepts. Therefore, we extend the training into a second stage, optimizing the generation of rationales using feedback from LLMs. Specifically, we leverage LLMs to inspect the reasoning process, which is more straightforward than directly scrutinizing the high-level inferences.

Stage-2: RLAIF. In this stage, we use image-caption pairs sourced from the wild (e.g., SBU Captions (Ordonez et al., 2011)). For each image, CoTBLIP is initially prompted to generate three CoT reasoning chains, leading to high-level visual inference regarding each image. We also note that there is a noticeable variation in the quality of these generated reasoning chains, which necessitates external feedback. Therefore, we use LLMs (GPT-3.5-Turbo) to provide feedback on the reasoning chains based on the provided caption, considering three aspects:

- **Sophistication:** The CoT reasoning chains should derive interesting high-level visual inference, instead of trivial visual information (e.g., The image might be captured during the day.)
- **Consistency:** The reasoning chains should be logically consistent to derive the high-level inference without unsupported assertions or gaps.
- **Groundedness:** The extracted visual details in the reasoning chains should be fully grounded in the images, instead of hallucination.

The prompt we use is described in Appendix F. We adapt the methods proposed by (Ouyang et al., 2022) to facilitate pairwise comparison between two reasoning chains and establish a ranking for the three generated reasoning chains. In addition, we leverage a consistency check to exclude instances in which LLMs exhibit conflicting rankings. We use the SBU Captions to generate around 27K LLM preference samples considering the constraints of our available resources. We also demonstrate that increasing the sample size during this stage results in consistent performance improvements in Section 5.3.

Given the LLM preference data, we employ Conditional Reinforcement Learning to train

CoTBLIP due to its stability as observed in previous work (Lu et al., 2022b; Liu et al., 2023b; Laskin et al., 2022). Specifically, we introduce two control tokens, namely <Good> and <Bad>. For each sample containing a set of three ranked reasoning chains, we add the <Good> control token to the highest-ranked chain and the <Bad> control tokens to the remaining two chains. In the training time, given an appended control token, we optimize CoTBLIP to maximize the likelihood of the associated reasoning chain. Through this approach, CoTBLIP can learn to distinguish the difference between control tokens and their respective outputs (Liu et al., 2023b). We note that there is no requirement to perform training for a separate reward model, given that the LLM is capable of fulfilling that role effectively.

Inference. During inference, we initially prompt CoTBLIP to generate rationales. However, it is important to acknowledge that when dealing with CoT subquestions that primarily involve basic visual perceptual problems and text-only inference based on provided visual details, the generated rationales may have limited effectiveness. Thus, the rationales are used exclusively for high-level visual inference. Specifically, these rationales are incorporated before the top-tier question to prompt the downstream VLMs to generate the prediction. In our implementation, we opt for utilizing the original BLIP-2-T5$_{xl}$ model to conduct predictions based on the rationales generated by CoTBLIP.

5 Experiment

5.1 Model

We evaluate the reasoning performance and consistency of the following models on CURE. We include GPT-3.5-Turbo-0613 (**Turbo**), which is a text-only model without visual inputs. We include **OFA-Large/Huge** (Wang et al., 2022b), which are the leading VLMs without LLMs component. We include the **BLIP-2-OPT**$_{6.7b}$**/T5**$_{xl}$ (Li et al., 2023a), which effectively utilizes LLMs for vision-language modeling. Additionally, we incorporate **InstructBLIP-T5**$_{xl}$ (Dai et al., 2023), which performs instruction tuning on a mixture of vision-language datasets. We include **LLaVA**$_{13b}$ (Liu et al., 2023c) and **miniGPT-4**$_{13b}$ (Zhu et al., 2023) that have undergone extensive training on vision-language instruction tuning data. Our approach **CoTBLIP** appends the generated CoT reasoning chain to the frozen BLIP-2-T5$_{xl}$ model and prompts it to predict the answer. Note that this pertains exclusively to high-level visual inference.

5.2 Experimental Results

The concrete implementation details of evaluation are described in Appendix C. We consider the evaluation metrics defined in Sec. 3.3. The experimental results regarding the reasoning performance and consistency are listed in Table 2. We summarize the findings as follows: (1) The model's ability to perform complex visual inference and produce reasonable outputs relies on three crucial elements: LLMs, visual inputs, and instruction fine-tuning. Models solely reliant on text-based information (Turbo), VLMs lacking LLMs components (OFA), and VLMs incorporating LLMs that have not undergone instructional fine-tuning (BLIP-2-OPT) exhibit inadequate performance; (2) The Chat-based VLMs (LLaVA, miniGPT-4) that have been explicitly supervised fine-tuned on synthetic user-interaction response samples exhibit a lack of visual reasoning ability and reasoning consistency. The underlying cause can be ascribed to the informal nature of the chat-style data, which lacks sufficient supervision to facilitate VLMs in acquiring the ability to integrate visual elements effectively for performing high-level visual inference; (3) The existing best-performing model, BLIP-2-T5, still falls short in reasoning performance and consistency, compared to the human evaluation results. This suggests that significant effort is needed to facilitate VLMs in achieving a level of visual reasoning comparable to that of humans in a systematic and consistent manner; (4) Our framework improves VLMs' ability to perform visual reasoning and demonstrate better reasoning consistency to a certain extent. Specifically, we observe a 4% improvement in both the high-level visual inference and the forward reasoning consistency. CoTBLIP offers a distinct advantage by providing CoT rationales that contain both extracted visual details and potential inference, thereby improving the visual reasoning pertaining to a specific image.

5.3 Further Analysis

Ablation Study. We conduct an ablation study to understand the contribution of the SFT and RLAIF stages. The results are presented in Table 3. We observe that both of these stages contribute to the improvement in reasoning performance and consistency. In particular, we observe further improvements when employing the RLAIF after the SFT

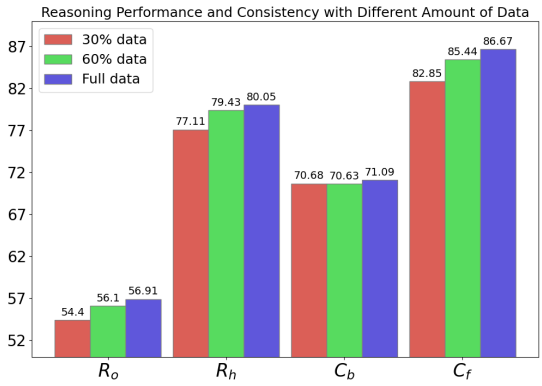

Figure 4: The influence of the percentage of training samples in RLAIF stage on performance.

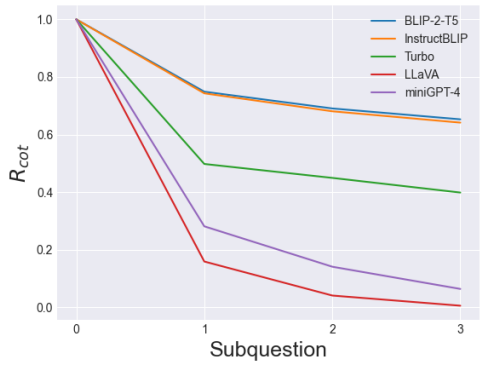

Figure 5: The CoT reasoning performance across the subquestions.

Metric	Performance			Consistency	
Model	R_o	R_h	R_{cot}	C_b	C_f
Random	0.14	16.67	0.82	0.82	16.67
Turbo	15.97	33.42	40.26	47.79	39.66
OFA-Large	0.12	17.63	0.62	0.70	20.0
OFA-Huge	0.06	16.40	0.68	0.38	9.09
BLIP-2-OPT	0.06	14.61	0.62	0.42	10.0
BLIP-2-T5	54.56	76.82	**65.66**	71.03	83.10
InstructBLIP-T5	54.01	76.14	65.35	70.93	82.64
LLaVA	0.12	14.67	17.82	17.65	14.29
miniGPT-4	2.10	23.12	38.75	41.80	28.81
CoTBLIP (ours)	**56.91**	**80.05**	**65.66**	**71.09**	**86.67**
Human	85.0	93.0	89.0	91.40	95.51

Table 2: The results (%) of the reasoning performance and consistency. The human performance is averaged among 3 human annotators. See Sec. 3.3 for the metrics.

Metric	Performance		Consistency	
Model	R_o	R_h	C_b	C_f
BLIP-2-T5	54.93	77.68	70.71	83.66
CoTBLIP	56.91	80.05	71.09	86.67
- w/o RLAIF	55.06	78.67	69.98	83.85
- w/o SFT	54.75	77.32	70.81	83.38

Table 3: Ablation study of the SFT and RLAIF stages (%). BLIP-2-T5 refers to prompting BLIP-2 without training to generate rationales. The R_{cot} metric (omitted here) holds the same across all methods because the generated rationales are only used for high-level visual inference.

stage. For example, the overall reasoning (R_o) for the combined stages (CoTBLIP) is 56.91 compared to 54.93 and 55.06 by the baseline and the SFT stage only, respectively. This can be attributed to the ability of RLAIF to facilitate enhanced calibration of the generated rationales, thereby augmenting their cohesiveness and substantiated nature. However, using only the RLAIF without the SFT stage negatively impacts performance when contrasted with the results of directly prompting BLIP-2 without training for rationale generation followed by answer prediction. The presence of the SFT stage enables VLMs to generate reasonable rationales. In its absence, CoTBLIP (BLIP-2) is restricted to producing only image captions or trivial rationales that do not contribute significantly to high-level inference. Thus, without the SFT stage for initialization, the training of CoTBLIP with RLAIF is not feasible.

Training Data of the RLAIF Stage. We investigate the impact of varying the amount of training data during the RLAIF stage (see Figure 4). We omit the presentation of R_{cot} as they are identical. Our findings reveal that a continuous expansion of training samples positively impacts the RLAIF training stage of CoTBLIP, regarding both reasoning performance and consistency. These results demonstrate the potential of utilizing web-scale image-captions data to further improve the training, attributing to the scalability of the RLAIF stage.

Backward Reasoning Consistency. We conduct a comprehensive study on the CoT reasoning performance (R_{cot}) of VLMs, evaluating the extent of performance degradation in answering subquestions (see Figure 5). We select examples that contain three subquestions for the presentation purpose. We observe that existing VLMs often struggle with the initial visual perceptual problem, which involves basic visual details needed for high-level visual inference. However, these models can partially derive the high-level inference when provided with the extracted visual details to some degree, ev-

idenced by the relatively small performance drop when answering the second and third questions. This demonstrates that high-level visual inference derived by VLMs is not entirely grounded in the visual details, leading to a low C_b. We also discuss the forward reasoning consistency in Appendix E.

6 Conclusion

We create CURE💊 using an LLM-Human-in-the-Loop pipeline and identify the deficiencies in existing VLMs for reasoning performance and consistency. To tackle these challenges, we introduce a two-stage training framework consisting of supervised fine-tuning and learning from LLMs feedback. Our method demonstrates improvement in VLMs' reasoning performance and consistency.

Limitation

As shown in Table 2, our proposed CoTBLIP still exhibits a significant gap, regarding the reasoning performance and consistency compared to the human annotators. This indicates substantial efforts are necessary to enable existing VLMs to perform robust visual inference like humans. CoTBLIP currently can only generate general visual inference about the given images, without considering the instructions. Future work is needed to enable CoTBLIP to perform instruction-guided reasoning chain generation that can more effectively facilitate high-level inference.

Appendix

A Dataset Statistics

CURE contains 1,622 evaluative instances, wherein each instance encompasses an average of 2.91 reasoning chains, also known as subquestions, reflecting a profound commitment to providing rich, complex data for effective analysis. On average, the lengths of the candidate inference, subquestions, and candidate answers in the dataset are 7.05, 9.97, and 2.96, respectively. Note that these elements are products of LLMs, generated based on the visual clues provided by human annotators. We thus present the word cloud of the visual clues regarding the evaluation samples in Figure 6. Upon examination, it becomes apparent that these visual values primarily center around human-oriented concepts. They incorporate information about entities, activities, and occurrences that are directly associated with individuals. This observation provides a partial representation of the data distribution within our dataset, particularly in relation to the target inference, subquestions, and their corresponding answers.

In addition, we delineate the distribution of question types within CURE as presented in Figure 7. We find that CURE comprises various kinds of questions with the "What" type questions dominating the distribution. This dominance is primarily due to the extensive use of such questions in Sherlock for cultivating a holistic comprehension of any given context or subject matter. Indeed, these types of queries are inherently employed to both obtain a detailed narrative of the scenario, as well as to facilitate visual inference based on the perceived information.

B Related Work

Vision-Language Pretraining. VLMs have demonstrated remarkable performance across various downstream tasks, primarily due to their extensive pre-training on large-scale datasets (Gan et al., 2022; Uppal et al., 2022; Wang et al., 2022c). Initially, VLMs heavily relied on object detectors for image comprehension (Li et al., 2019; Tan and Bansal, 2019; Lu et al., 2019; Li et al., 2020a,b, 2021b, 2020b, 2021b; Zhang et al., 2021). Subsequent developments in VLMs research have aimed to bypass the need for resource-intensive object detectors (Dou et al., 2022; Huang et al., 2020; Kim et al., 2021), streamline the inference process (Huang et al., 2021; Xu et al., 2021), incorporate more extensive visual data (Yang et al., 2022; Yao et al., 2022; Li et al., 2021a; Radford et al., 2021), and introduce additional tasks for object grounding during pre-training (Jia et al., 2021; Yao et al., 2022). As research progresses, efforts are made to design a unified architecture for VLMs, enabling them to handle multiple tasks without requiring task-specific adjustments (Wang et al., 2021, 2022b; Li et al., 2023a). Leveraging large-scale multimodal instruction tuning data for effective alignment of the two modalities, VLMs can effectively parse the questions and generate user-friendly responses (Li et al., 2023a; Liu et al., 2023c; Zhu et al., 2023).

CoT Reasoning Consistency The CoT reasoning approach was initially introduced to enhance the reasoning capabilities of LLMs by prompting them to generate rationales and then answers (Wei et al., 2022). This approach is extended to various domains, models, and more complex problems (Poesia et al., 2023; Li et al., 2023b; Chen et al., 2022; Jin and Lu, 2023; Yao et al., 2023b,a; Saparov et al., 2023; Wang et al., 2024). In addition, the CoT reasoning consistency is effectively utilized to improve the reasoning performance (Wang et al., 2022d). However, it is still not clear how consistent LLMs reasoning is, given the mixed results in previous work (Wang et al., 2022a; Lanham et al., 2023; Madaan and Yazdanbakhsh, 2022; Saparov and He, 2023; Sahu et al., 2022).

C Implementation Details of Evaluation

Given that none of the VLMs under consideration has been trained on grounded data, it is not feasible to directly incorporate bounding box information into these models We adopt a compromise solution that involves preprocessing the evaluation samples through the automatic incorporation of annotated bounding boxes into the images. We instruct VLMs to focus on the specific region delineated by the bounding boxes in the prompts provided. We describe the prompts for evaluation in Appendix F. For each top-tier question or subquestion in the reasoning chain, VLMs only need to select one option from candidate answers. Namely, VLMs choose an answer based on the highest probability among six options: "A", "B", "C", "D", "E", and "F".

Figure 6: The word cloud of the visual clues.

Question Type	Percentage
What	86.10
Where	3.74
Why	2.77
How	2.16
Which	1.84
Who	1.54
When	0.91
Yes/No	0.68
Others	0.25

Figure 7: Question distribution.

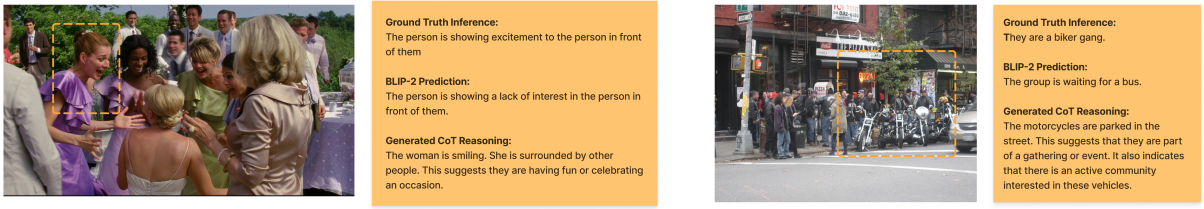

Figure 8: Showing cases where BLIP-2 fails initially but CoTBLIP is able to generate reasonable CoT reasoning chains that can help with the high-level visual inference and obtain the correct answer. More examples are in Figure 10.

D Human Annotation

Human Verification. We use the molardata platform[1] for human annotation. We hire 3 human annotators to validate each instance in the dataset generated by LLM, adhering to two specific criteria. First, the evaluation samples must be capable of effectively measuring reasoning performance and consistency. This entails instructing the annotators to examine the failure modes identified in Table 1 and also to identify any additional reasons for excluding certain examples from the evaluation; Second, we plan to improve the diversity of the evaluation dataset by reducing instances that demonstrate highly similar reasoning paths within certain groups. To this end, we provide each annotator with 100 dataset samples at the beginning of the annotation, acquainting them with the dataset's distribution as well as some analogous examples. In the verification process, we request annotators to label examples belonging to an extensive group of analogous cases. Note that this is a dynamic process, as annotators have the capability to continuously update their understanding of the dataset distribution while engaging in the annotation task. After completing the annotation process, we compile the results and subsequently exclude instances that have been classified as failures by any of the annotators. We systematically collect examples labeled as relatively abundant in the dataset and subject them to a thorough validation process. We ensure the inclusion of a specific quantity of high-quality examples in each group, proportionate to the sample size within each group.

Dataset Evaluation. We hire a different set of 3 human annotators to conduct a cross-validation of the dataset derived from the human verification process, following the same verification procedure. Additionally, these annotators are requested to perform the task on CURE💊, including the high-level visual inference and CoT reasoning subquestions, thus capturing the human performance score.

E Forward Reasoning Consistency

We choose the highest-performing models, specifically BLIP-2 and CoTBLIP, for conducting a qualitative analysis of their forward reasoning consistency. We selected these models since they exhibit significant performance improvements compared to text-only models. We select two examples, shown in Figure 8, to highlight cases where BLIP-2 demonstrates a lack of forward reasoning consistency and where CoTBLIP can potentially offer as-

[1] https://www.molardata.com/

sistance. We observe that CoTBLIP demonstrates the ability to generate coherent rationales, starting with visual elements that are highly relevant to the image, and subsequently advancing towards more sophisticated visual inference that significantly impacts the prediction. For example, the reasoning chain in the second example in Figure 8 seems to first identify some motorcyclists that are parked on a street in some kind of gathering and then provides the high-level inference indicating that these folks might be part of a community interested in such vehicles. Notably, incorporating the rationales explicitly within the context enhances the reasoning consistency of VLMs.

F Prompts

We compile the list of prompts utilized in our implementation to instruct LLMs to perform their designated tasks.

F.1 Candidate Answers Generation for CoT Subquestions

```
Imagine a scene: {Human-Annotated Visual Clue}
Here is a question and its corresponding answer:
Q: {CoT Subquestion}
A: {CoT Answer}
Please generate 5 different answers in 1-5 words that are semantically similar but contain factual errors.
```

F.2 Filtering

```
    Imagine a scene: {Human-Annotated Visual Clue}
We want to make an inference about this scene by asking some coherent and subsequent questions.
The questions are as follows:
Q1: {CoT Subquestion-1}
A1: {CoT Answer-1}
Q2: {CoT Subquestion-2}
A2: {CoT Answer-2}

So we draw the inference: {Human-Annotated High-Level Inference}

Judge whether the reasoning chain is coherent and consistent. Directly answer yes or no.
```

F.3 Baseline Evaluation

```
    Pay attention to the designated area outlined by the red bounding box in the image.
Question: {Subquestion}
Six potential answers are as follows:
A: {Candidate A}
B: {Candidate B}
C: {Candidate C}
D: {Candidate D}
E: {Candidate E}
F: {Candidate F}
Which one is most likely to be correct? Directly answer (A/B/C/D/E/F):

What can we infer from the designated area outlined by the red bounding box in the image?
Here are six potential answers:
A: {Candidate A}
B: {Candidate B}
C: {Candidate C}
D: {Candidate D}
E: {Candidate E}
F: {Candidate F}
Which one is most likely to be correct? Directly answer (A/B/C/D/E/F):

    What can we infer from the designated area outlined by the red bounding box in the image? Consider the following reasoning chain: {Reasoning Chain Generated by CoTBLIP}
Here are six potential answers:
A: {Candidate A}
B: {Candidate B}
C: {Candidate C}
D: {Candidate D}
E: {Candidate E}
F: {Candidate F}
Which one is most likely to be correct? Directly answer (A/B/C/D/E/F):
```

F.4 CoT Reasoning Chains Generation

```
    You need to generate some questions for evaluating vision-language models. You will be given a scene description and a corresponding high-level inference about this scene. Please generate step-by-step questions and corresponding answers that can derive the final inference. The reasoning chain should contain 2-4 questions, and the answers should contain 1-3 words.

Consider the following principle:
1. The reasoning chain needs to be as short as possible.
2. The questions are used to evaluate vision-language models that don't have access to the scene description. So the first few questions are about visual information in the scene description, and you should not mention "description" in the questions.
```

```
3. The reasoning chain should be consistent and cohesive. Each step should be atomic or based on previous steps, and should not be duplicated or redundant.
4. You should avoid generating questions with yes/no as the answers.
5. End your answer with the format 'The final reasoning chain is: ', and if you think such a task cannot be accomplished, please directly return 'No'.

Scene description: patches of snow spread throughout grass on the side of freeway.
High-level inference: Cold weather is causing hazardous conditions at this location.

Let's think step by step: We need to initially generate some perceptual questions based on the visual information in the scene description. Then we need to generate questions about the visual reasoning based on the previously perceived information. For the perceptual question, we have the information that patches of snow appear on the side of freeway in the scene. Then for the visual reasoning problem, we can infer that cold weather causes the appearance of snow, and based on the knowledge that snow can affect traffic, we can infer that cold weather can cause hazardous conditions at this location.

The final reasoning chain is:
Q1: What is seen on the grass on the side of the freeway?
A1: Patches of snow.
Q2: What kind of weather conditions could cause patches of snow to appear?
A2: Cold weather.
Q3: How can cold weather and patches of snow affect the conditions of a location?
A3: Hazardous conditions.

Scene description: {Human-Annotated Visual Clue}
High-level inference: {Human-Annotated High-Level Inference}

Let's think step by step:
```

F.5 Postprocessing of LLaVA Dataset

```
You need to generate some training samples for vision-language models. You will be given several scene descriptions to help you understand the image. Then a human-annotated question-answering pair will be given.

Please generate a step-by-step reasoning chain. The reasoning chain should be very concise and short, containing less than 15 words for each step, and the total steps should be less than 4.

For example:
Scene description:
A group of people skiing down a hill;
Several people on skis on a snowy slope;
A group of young men riding down the side of a snow covered slope;
Five skiers going through obstacles on a ski slope;
people skating on the snow with orange flags on the way.

Question: What can you say about the skill level of the skiers featured in the image?
Answer: In the image, there is a group of five people skiing down a snowy slope with orange flags marking their trail. It appears that they are maneuvering through those obstacles on the ski slope, which suggests that these skiers possess a certain level of skill and experience. The fact that they can ski together in close proximity and navigate through obstacles demonstrates their ability to maintain control and balance while skiing. It's reasonable to assume that these skiers may have had some training or practice to reach this skill level, as navigating a snow-covered slope with obstacles typically requires a level of expertise beyond that of a beginner skier.

Let's think step by step:
The skiers are navigating through obstacles. They are skiing in close proximity. This implies advanced skill and experience.

Now consider this example:
Scene description: {COCO Captions}
Question: {LLaVA Question}
Answer: {LLaVA Answer}
Let's think step by step:
```

F.6 Feedback Generation

```
You will receive two inferences on an image produced by two models. Your objective is to choose the superior inference. Additionally, you will receive a description of the
```

```
        ↪ scene to aid in your
        ↪ understanding.                    Let's think step by step:

When making your judgment, please keep
    ↪ the following principles in mind:
1. The language used in the inference
    ↪ should flow naturally.
2. The inference should be grounded in
    ↪ the image's content.
3. The inference should be logical,
    ↪ congruent, and concise.
4. The inference should be comprehensive
    ↪  and complete, ultimately drawing
    ↪  a high-level inference.

Give your answer after the "Answer:"

 For example:
Scene description: grass in a rock
Inferences:
A: The small plant growing out of the
    ↪ rock in the image is likely to be
    ↪  a native species that has been
    ↪ transplanted from another area,
    ↪ such as an urban or natural
    ↪ environment. Native plants tend
    ↪ to have deeper roots and are more
    ↪  resistant to environmental
    ↪ conditions than their non-native
    ↪ counterparts, making them ideal
    ↪ for adapting to different
    ↪ habitats and environments.
B: The small plants growing out of the
    ↪ crack in the rock are likely a
    ↪ result of natural processes, such
    ↪  as erosion or weathering over
    ↪ time. This can be beneficial to
    ↪ the plant's survival and growth,
    ↪ helping it adapt to its
    ↪ environment and thrive.
    ↪ Additionally, this type of
    ↪ habitat is conducive for
    ↪ microorganisms that help maintain
    ↪  soil quality and provide
    ↪ nutrients necessary for healthy
    ↪ plant growth.

Let's think step by step: Inference A
    ↪ captures the unique phenomenon of
    ↪  plants growing out of the rock,
    ↪ emphasizes the natural process
    ↪ and potential environmental
    ↪ benefits, and provides a more
    ↪ comprehensive understanding of
    ↪ the scene. On the contrary,
    ↪ Inference B fails to explain the
    ↪ mechanism or the specific
    ↪ relationship between the plants
    ↪ and the rock. The mention of
    ↪ adaptation to harsh conditions is
    ↪  relevant, but it does not
    ↪ encompass the entire context of
    ↪ the image.
Answer: A

Now consider this example:
Scene description: {Image Caption}
Inference:
A: {Inference-1}
B: {Inference-2}
```

Visual Clue: Fruit cut in half.
Ground Truth Inference: People going to eat it
Reasoning Chain:
- What is the state of the fruit in the scene?
  A: Cut in half. B: Fried and crispy.
- Why would someone cut a fruit in half?
  A: To practice knife skills. B: To eat it.
- Who is likely going to consume the fruit?
  A: Plants. B: People.

Visual Clue: A lot of seabirds on the boat.
Ground Truth Inference: This boat has been sitting for some time.
Reasoning Chain:
- What is seen on the boat?
  A: A lot of seabirds. B: A group of lions.
- What could be the reason for the presence of many seabirds on the boat?
  A: The boat has been stationary. B: The birds are lost.
- What can be inferred about the boat's status based on the presence of many seabirds?
  A: It's a popular attraction. B: It has been sitting for some time

Visual Clue: A child holding a spool of string and a kite floating in the air.
Ground Truth Inference: It is windy outside.
Reasoning Chain:
- What is the child holding?
  A: A hat. B: A kite.
- What is the kite doing?
  A: Running from clouds. B: Floating in the air.
- What condition is necessary for a kite to float in the air?
  A: Windy conditions. B: Sky magnets working properly.

Visual Clue: A large body of water between the walkway and a city skyline.
Ground Truth Inference: This city has a major port.
Reasoning Chain:
- What is located between walkway and city skyline?
  A: A body of water. B: A barren desert wasteland
- What can a large body of water near a city indicate?
  A: Abundance of whales. B: Presence of a port.
- What is the significance of a port in a city?
  A: Major port. B: A popular beach town.

Visual Clue: A person holding an animal treat.
Ground Truth Inference: This person is a tourist.
Reasoning Chain:
- What is the person holding in their hand?
  A: Toy for pets. B: An animal treat.
- What is a possible reason for someone to hold an animal treat?
  A: Sculpting with clay. B: Interacting with animals.
- What type of people often interact with animals while holding treats?
  A: Celebrities. B: Tourists.

Visual Clue: Kids walking out of a school building.
Ground Truth Inference: The kids have just been let out of class.
Reasoning Chain:
- What are the kids doing in the scene?
  A: Sleeping inside the building. B: Walking out of a building.
- What is written on the building?
  A: Hospital building. B: School.
- Why would kids be walking out of a school building?
  A: They have been let out of class. B: They won a competition.

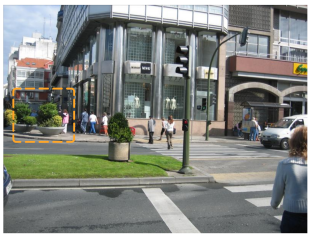
Visual Clue: Brown sausage patty on a plate
Ground Truth Inference: The person who is going to eat this is not vegetarian.
Reasoning Chain:
- What is on the plate?
  A: Chocolate donut sprinkle. B. Brown sausage patty
- What is a sausage patty typically made of?
  A: Fruit filling mix. B: Meat.
- Do vegetarians eat meat?
  A: Yes, always. B: No.

Visual Clue: Ship windows in background.
Ground Truth Inference: They are on a ship
Reasoning Chain:
- What type of windows are seen in the background?
  A: Bus windows. B: Ship windows.
- What does the presence of ship windows suggest about the location?
  A: In outer space. B: On a ship.

Figure 9: More examples included in CURE. We only show 2 candidate options (of 6 in total) for the sake of presentation

Ground Truth Inference:
This is the name of the train

BLIP-2 Prediction:
The sign displays the train's destination city.



Generated CoT Reasoning:
Two persons stand in front of a train. There is a sign on the front of the train saying HOGWARTS. That suggests the train could be an exhibition

Ground Truth Inference:
This is in a tropical climate.

BLIP-2 Prediction:
They're in a suburban residential area.

Generated CoT Reasoning:
The pictures show tropical palm trees and tall buildings in a city. This indicates that it may rain all year round

Ground Truth Inference:
The street is beautified

BLIP-2 Prediction:
Street is under construction.

Generated CoT Reasoning:
The picture shows a city scene with lots of green plants. This implies that the city is prosperous and beautiful

Ground Truth Inference:
The boat is used for a sporting event.

BLIP-2 Prediction:
The number indicates the boat's age.

Generated CoT Reasoning:
There are many boats in the picture with numbers on them. This indicates that the people may need to identify these ships by numbers.

Figure 10: More examples for qualitative analysis of CoTBLIP.

Building Knowledge-Guided Lexica to Model Cultural Variation

Shreya Havaldar[†], **Salvatore Giorgi**[†], **Sunny Rai**[†], **Thomas Talhelm**[◇], **Sharath Chandra Guntuku**[†], **& Lyle Ungar**[†]

{shreyah,ungar}@seas.upenn.edu

Abstract

Cultural variation exists between nations (e.g., the United States vs. China), but also *within* regions (e.g., California vs. Texas, Los Angeles vs. San Francisco). Measuring this regional cultural variation can illuminate how and why people think and behave differently. Historically, it has been difficult to computationally model cultural variation due to a lack of training data and scalability constraints. In this work, we introduce a new research problem for the NLP community: *How do we measure variation in cultural constructs across regions using language?* We then provide a scalable solution: building knowledge-guided lexica to model cultural variation, encouraging future work at the intersection of NLP and cultural understanding. We also highlight modern LLMs' failure to measure cultural variation or generate culturally varied language.

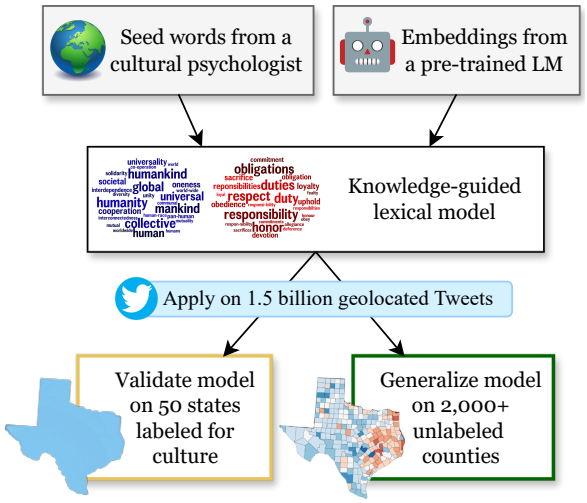

Figure 1: We build knowledge-guided lexica to model cultural variation. Our method encodes domain knowledge via seed words based on cultural psychology theory. We use embeddings to transform these seed words into a high-validity lexical model that successfully measures cultural variation across the US.

1 Introduction

People think and behave differently around the world. This is partly due to *cultural variation*, or the differences among individuals that exist due to some form of social learning (Cohen, 2001).

Having a computational method that utilizes language to measure cultural variation could help us better understand the way people communicate (Tsai et al., 2006; Oishi et al., 2009), build more culturally-aware NLP systems (Hovy and Yang, 2021), and advance interdisciplinary research in anthropology, cultural psychology, etc. However, due to a lack of data and scalability constraints, few such methods exist.

In this paper, we present *measuring regional variation in culture* as a problem of interest for the NLP community. We highlight how large language models (LLMs) struggle with this task, and build a knowledge-guided lexical model as a scalable and reliable solution. Specifically, we focus on measuring the cultural dimenision of *individualism and collectivism*[1] across the United States (US) using geolocated Tweets.

Historically, measuring cultural dimensions across regions has been mostly done through questionnaires, such as the World Values Survey (WVS) (Haerpfer et al., 2020). However, questionnaires are time-consuming and heavily restricted in scope; the most recent WVS wave required four years and averaged only 52 participants per US state. Recent work probes LLMs for cultural values (Arora et al., 2023), but these LLMs do not reflect all cultures equally (Havaldar et al., 2023b). Therefore, relying on LLMs to measure culture is risky, as they may not generalize well to different populations.

[1]Cultural psychologists have quantified axes on which culture differs, also called *cultural dimensions*. A key cultural dimension is called *individualism vs. collectivism* (Hofstede, 2011). Collectivism stresses the importance of the community, while individualism focuses on each person's rights and concerns. This dimension has been shown to influence behaviors like voting, donating, etc.

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 211–226
June 16-21, 2024 ©2024 Association for Computational Linguistics

The overhead of traditional survey-based approaches and inconsistent cultural awareness of existing LLMs motivate computational methods that rely on *existing language data* to measure cultural variation instead. We specifically seek to use geolocated Twitter data — instead of selecting a small portion of people to represent a state or county (like traditional survey-based methods), we instead use a massive amount of Tweets from that region, thus gaining a larger and more holistic representation of a region's population.

We also seek to leverage *domain expertise* from cultural psychologists. Cultural psychologists have spent decades developing non-computational tools to measure cultural constructs like individualism and collectivism (Talhelm et al., 2014). By encoding this domain knowledge via a set of expert-curated seed words, we can create a method to measure culture that is both scalable and grounded in cultural psychology theory.

In this paper, as an example of cultural variation, we will measure individualism and collectivism across US counties using the following resources:

- Domain knowledge from an expert psychologist researching collectivism.
- An open-source corpus (see Appendix A) of 1.5 billion geolocated Tweets from 6 million US users (Giorgi et al., 2018).
- Collectivism indicators (survey data, living arrangements, religiosity, and ingroup bias) to validate our results for fifty US states. (Vandello and Cohen, 1999; Pelham et al., 2022).

Challenges with deep learning approaches. A modern NLP solution to measure culture today would take the form of either labeling data and training a model, or prompting a pre-trained LM. However, LLMs have been shown to lack cultural awareness (Havaldar et al., 2023b; Liu et al., 2023), so cultural insights from these models may be incorrect or untrustworthy.

Additionally, classifying 1.5 billion Tweets requires a sizable amount of labeled training data, and training on such a large dataset is not computationally scalable. For instance, running our entire corpus through GPT-4 would cost roughly $900,000 (see Appendix B).

At a higher level, building a Tweet-level deep learning model to predict culture is impractical. Most of an individual's language does not indicate their cultural beliefs. Given this sparsity, labeling enough Tweets to train an adequate model is prohibitively expensive.

Our method builds upon a line of work in NLP called lexicon induction (Araque et al., 2020; Buechel et al., 2020; Geng et al., 2022; Havaldar et al., 2023a), which analyzes massive corpora in NLP without solely relying on deep learning. Past work mainly builds lexica for sentiment, emotion, etc. We uniquely focus on lexicon induction in the domain where little labeled data exists and not every utterance can be relevantly labeled.

Our contributions are as follows:

1. We present *measuring regional variation in culture* as a problem of interest for the NLP community.
2. We develop knowledge-guided lexical models and demonstrate their ability to measure individualism and collectivism. Our method (1) is highly scalable, (2) encodes domain knowledge from cultural psychology, and (3) does not require additional labeled data.
3. We validate our method against past collectivism research at the US state-level and present novel results at the US county level.
4. We provide new insights into cultural variation across the US via a taxonomy of *communities* (socio-demographic clusters of counties) from the American Communities Project (Chinni and Gimpel, 2011).
5. We highlight the failure of modern LLMs (GPT-3.5, GPT-4) to measure cultural variation or generate language that matches real-world cultural variation.

2 Building Knowledge-Guided Lexica

Issues with traditional lexica. Lexica, or sets of curated words, are a highly scalable and explainable method for analyzing large datasets. However, building a full lexicon linked to cultural theory from the ground up is a time-intensive process, and sometimes takes psychologists years to complete (Pennebaker et al., 2015). Additionally, psychologists often make the error of including words in lexica that correlate negatively with the construct they are trying to measure. Jaidka et al. (2020) find that removing certain words from lexical categories in LIWC 2015 (Pennebaker et al., 2015) actually improves overall performance.

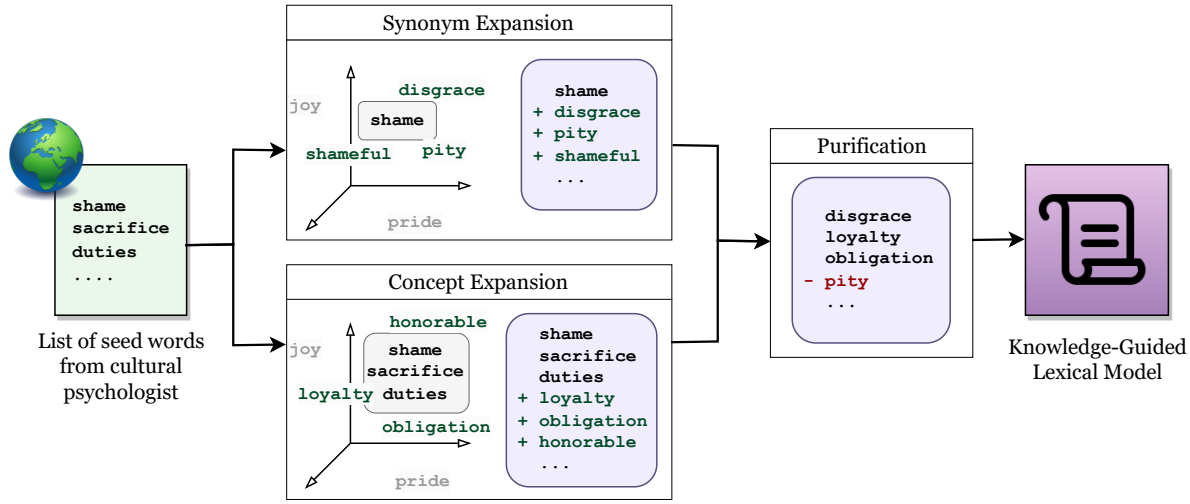

Figure 2: Our knowledge-guided lexica creation method. We begin with a set of seed words curated by an expert psychologist. The first stage, *Expansion*, consists of synonym expansion and concept expansion, done in parallel. The second stage, *Purification*, includes frequency-based and correlation-based pruning, done sequentially.

These erroneous words can be caused by the following two phenomena:

1. *Inflated Frequency:* Highly frequent words in a lexical category can correlate negatively with their counterparts (e.g. words like "love" and "lol", contained in the LabMT positive sentiment lexicon (Dodds et al., 2011) correlate negatively with happiness (Jaidka et al., 2020)) and muddy the results of a lexicon.
2. *Polysemy*: Words like "tender," which describe positive emotion, may have other meanings (e.g. describing chicken/steak, or referring to financial tenders), thus reducing the effectiveness of a lexicon.

To mitigate this, we propose a method that still builds on domain knowledge, but produces a lexicon that is *internally coherent*, bypassing the issues introduced by inflated frequency and polysemy.

Our approach has two components: Expansion and Purification. Figure 2 details this approach for the collectivism lexicon we generate. Using this method, we utilize domain knowledge from an expert psychologist to create a lexical model that has wider coverage of our corpus. We can then use this model to analyze our geolocated Twitter corpus and measure regional variation in individualism and collectivism across the US.

Step 1: Seed Word Generation We first ask an expert psychologist who has researched individualism and collectivism for many years to generate two small sets of seed words that capture each of these constructs (see Table 1). However, a small set of seed words may not be enough to sufficiently analyze a corpus of 1.5+ billion Tweets and may have erroneous words as described above.

Step 2: Expansion Next, we utilize word embeddings[2] to expand the set of seed words in two ways: we locate words that are similar to each seed word (*synonym expansion*), and locate the words that are similar to the overall construct described by the complete set of seed words (*concept expansion*).

For synonym expansion, we find the nearest neighbors for each seed word in embedding space and add these neighboring words to our lexica. For example, in Figure 2, we expand the word "shame" and add "disgrace", "shameful", and "pity" to our collectivism lexicon. We use cosine similarity to determine the nearest neighbors.

For concept expansion, we average the embeddings of each seed word set to find the *centroid embeddings*. For example, to find the collectivism centroid embedding, we would average the embeddings of "shame", "sacrifice", "duties", etc. Then we find the nearest neighbors of each centroid embedding. Concept expansion adds other words to a lexical category that are similar to the overall concept described by the seed word set.

By using embedding space to expand our lexica, we can additionally calculate a *weight* for each ex-

[2]We use FastText (Bojanowski et al., 2017) due to its fixed vocabulary size, efficient nearest neighbors functionality, and ability to find synonyms in context-free scenarios, but our methods are more general and agnostic to embedding type.

Collectivism Seed Words	`duties, responsibilities, role, fit in, community, sacrifice, shame, required, rules, honor, support, rely, loyal, respect, obedience`
Individualism Seed Words	`humans, humanity, worldwide, universal, mankind, everyone, collective, global, equity, imagination, cooperate, cooperation, shared, joint, identity, guilt, diversity`

Table 1: Seed words hypothesized to identify individualism and collectivism on social media, provided by an expert cultural psychologist. These words provide interesting insights into these two constructs — according to our domain expert, "collective" and "cooperation" are actually individualist words. This is because collectivism emphasizes close relationships over strangers, whereas individualism emphasizes strangers and weak ties, hence the usage of words like "collective".

panded word. The weight for each seed word is 1, and the weight for each word added during expansion is the cosine similarity to the corresponding seed word or centroid embedding. Highly similar words have a weight closer to 1, while more distant words have a lower weight. Our final lexicon is the union of seed words, words added via synonym expansion, and words added via concept expansion.

This method is highly tunable — any embeddings can be used, and the number of nearest neighbors returned during expansion can be adjusted based on the desired length of the final lexicon. To control the length of our final lexicon, we set two thresholds in this process: one for synonym expansion and one for concept expansion. We explore the effect of these expansion thresholds in Section 5.

Step 3: Purification Upon aggregating the words returned from both expansion types, we want to ensure that the resulting lexicon is both pertinent and internally correlated. Namely, we want to avoid the pitfalls of traditional lexica, where erroneous words may lower the overall performance.

To ensure pertinence, we filter out rare words, or any words below a given usage frequency (Bojanowski et al., 2017). Next, we ensure internal correlation. We apply our lexica to our US Twitter Corpus and compute the weighted frequencies for each word at the county-level.

Equation 1 details how we compute $F(w_i)$, the weighted frequency for a word w in County i, where T_i refers to the subset of Tweets geolocated in County i, and $\text{count}(w, t)$ refers to the number of times word w appears in Tweet t.

$$F(w_i) = \sum_{t \in T_i} \text{weight}_w * \text{count}(w, t) \quad (1)$$

To avoid issues that arise with inflated frequency and polysemy, we want to ensure that there are no words that correlate negatively with the other words in the lexicon. Specifically, we ensure that the product-moment correlation detailed in Equation 2 is greater than some positive threshold for every word w_i in our lexicon L.

$$r(F(w_i), \sum_{w \in L \setminus w_i} F(w)) \quad (2)$$

If a word does not meet this criteria, we remove it from the lexicon. This purification step ensures that every word contributes correctly to measuring the relevant cultural dimension. We explore the effect of this purification threshold in Section 5.

Figure 6 visualizes our expanded and purified knowledge-guided individualism and collectivism lexica. Note that this method can be used to measure regional variation for any cultural construct[3] by changing the seed words accordingly.

3 Evaluation

Upon expanding and purifying the lexica, we apply it to our Twitter Corpus. To get a collectivism score for county C, we sum the weighted frequencies of each word w in our collectivism lexicon L_{coll}, as outlined in Equation 3.

$$\text{Collectivism}(C) = \sum_{w \in L_{\text{coll}}} F(w) \quad (3)$$

We then aggregate these county-level scores to the state-level, and validate our results using past state-level collectivism research from Vandello and Cohen (1999); Pelham et al. (2022). We expect our state-level collectivism results to correlate positively with these indicators. As there are no similar resources for individualism, we use the strength of negative correlation to evaluate our state-level individualism results.

[3]Other example cultural constructs include power distance (Hofstede, 2011) or looseness/tightness (Gelfand et al., 2006) and are also hypothesized to vary regionally.

	Vandello & Cohen's Collectivism Scores	Grandparents *(GCI)*	Religiosity *(GCI)*	Ingroup Bias *(GCI)*	Average Validity
Collectivism (↑ is better)					
KGL Score (ours)	0.380*	0.362*	0.410*	0.467*	**0.405**
Seed Words Only	-0.033	-0.267	-0.352*	-0.142	-0.198
GPT-3.5 Baseline	-0.094	-0.094	0.056	-0.035	-0.042
Individualism (↓ is better)					
KGL Score (ours)	-0.379*	-0.571*	-0.659*	-0.515*	**-0.531**
Seed Words Only	-0.509*	-0.423*	-0.564*	-0.525*	-0.506
GPT-3.5 Baseline	-0.346*	-0.222	0.058	0.058	-0.113

Table 2: Pairwise product-moment correlations between our knowledge-guided lexica (KGL) scores and collectivism validation variables. We use Vandello & Cohen's Collectivism Scores and collectivism indicators from the Global Collectivism Index (GCI) at the US-state level. * indicates correlation is significant ($p < 0.05$). Underlined correlations are not found to be significantly different after bootstrapping test. We see that our method (KGL) outperforms both baselines — using only the seed words provided by an expert psychologist, and zero-shot labeling a subset of Tweets from each state using GPT-3.5.

Vandello & Cohen's Scores. Vandello and Cohen (1999) conduct a survey-based study of individualism and collectivism in the US and rank all states from most to least collectivist. We use these rankings as our first validation variable.

GCI Indicators. We also use relevant collectivism indicators from the Global Collectivism Index (Pelham et al., 2022) using corresponding questions from the 2017 US census and the 2017 wave of the World Values Survey (Haerpfer et al., 2020).

All six variables in the Global Collectivism Index – total fertility rate, living arrangements (% households with people over 60 and children under 14), stability of marriage (divorce rate to marriage rate ratio), religiosity, collective transportation, and ingroup bias (approximated by compatriotism due to lack of state-level data) – are replicable at the state-level using US census data and WVS data. Note that when aggregating US census data from county-level to state-level, we weight each county equally, due to disproportionate amounts of data coming from big cities.

In order to determine which of these six replicated variables also measures collectivism within the United States, we sample subsets of the six variables and use Cronbach's alpha to maximize internal consistency. We limit the subsets to size three or larger, following Pelham et al. (2022)'s validation of three collectivism indicators per nation. Upon exploring all possible subsets of size three or more, we find that the set of living arrangements, religiosity, and ingroup bias yields the highest Cronbach's alpha (0.702); we choose these as our additional validation variables.

Income. As a sanity check, we additionally validate against median household income at the state-level. Prior research has found that higher income levels lead to more individualistic values (Pelham et al., 2022). Similarly, we find that median household income correlates positively with our individualism lexicon scores (0.431) and negatively with our collectivism lexicon scores (-0.288).

4 Results

Table 2 contains the correlations between our collectivism and individualism lexicon scores and each of the four validation variables, across US states. We observe that collectivist word use positively correlates with all validation outcomes, and individualist word use correlates negatively. We also observe a strong negative correlation (-0.510) between our individualism and collectivism scores at the US state level.

To further assess the success of our method, we compare our correlations against the following baselines:

- **Seed Words Only:** To analyze the efficacy of expansion + purification, we compare against solely using the expert-curated seed words.
- **GPT-3.5 Baseline:** To explore whether our method outperforms prompting a pre-trained LM, we subsample a total of 100,000 Tweets (2,000 per state) from our corpus and have

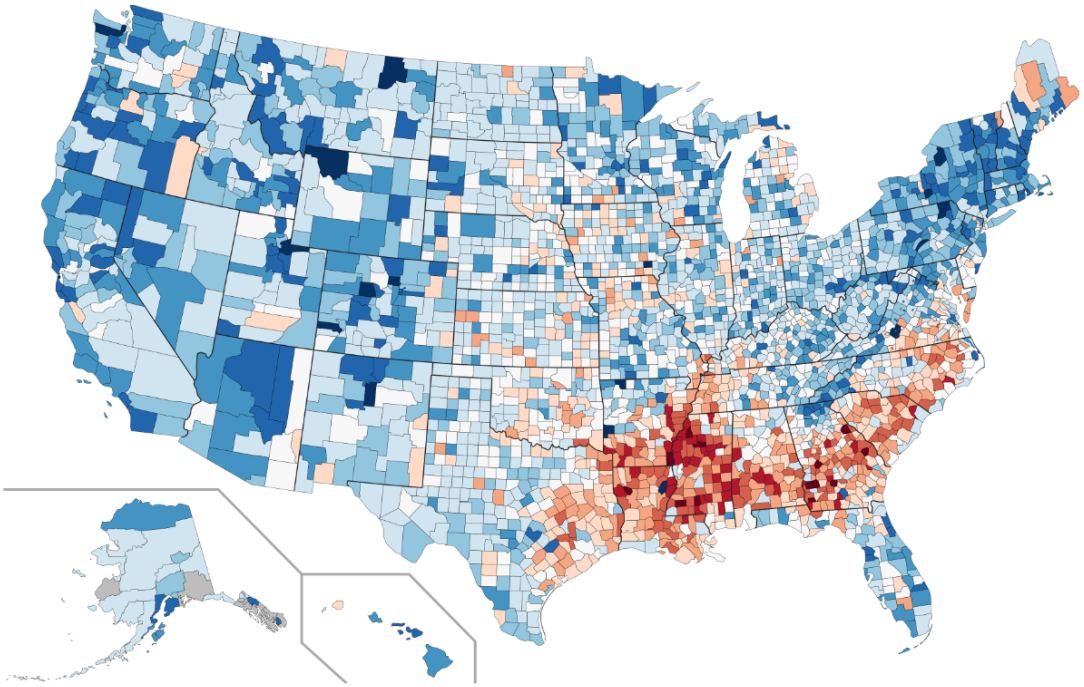

Figure 3: Collectivism (red) and individualism (blue) across US counties. Dark red = higher collectivism and dark blue = higher individualism. We include 2042 counties with sufficient data to compute individualism/collectivism scores, along with 1095 counties with interpolated scores based on geographic and socio-demographic variables.

GPT-3.5 label each Tweet as individualist, collectivist, or neither. We then calculate $\frac{num(\text{individualist})}{2{,}000}$ and $\frac{num(\text{collectivist})}{2{,}000}$ as the corresponding individualism and collectivism scores for that state. See Appendix C for additional details on prompting procedure.

Interpreting correlations in Table 2. There is little past work measuring culture in NLP, so we rely on state-level measures of collectivism to validate against, as no county-level measures exist. The magnitude of the effect sizes in Table 2 align with previous work. Giorgi et al. 2021 use this Twitter data to estimate 5-factor personality across US states. The average correlations across all five personality dimensions between these estimates and several national personality surveys range between 0.29 and 0.61.

Given our correlations fall within the range established in prior work, we conclude our lexica successfully capture individualism and collectivism.

Measuring county-level variation. Upon confirming the validity of our lexica, we apply them to county-level geolocated Tweets, as detailed in Equation 3, to gain a more fine-grained understanding of how individualism and collectivism vary regionally.[4] Figure 3 illustrates this variation, plotting the difference between the individualism and collectivism score. The deep south shows high levels of collectivism (dark red) and low levels of individualism (light blue). Conversely, the West Coast and the Northeast show low levels of collectivism (light red) and high levels of individualism (dark blue).

County interpolation. We interpolate individualism and collectivism across US counties where Twitter data is not available, in order to provide county-level estimates for the entire country.

To do this, we build a Gaussian Process (GP) regression model, which is traditionally used for spatial interpolation (i.e., kriging; Cressie, 1990). Instead of interpolating based on physical proximity alone, we follow Giorgi et al. 2023 and interpolate over both physical and socio-demographic space, training the GP model on latitude and longitude coordinates of the county centroids and 11 socio-demographic variables. See Appendix Section D for additional details.

Community-level insights. Cultural similarity is not always based on geographical proximity; two

[4]We release our lexica, county-level and state-level scores, and relevant code at https://github.com/shreyahavaldar/knowledge_guided_lexica

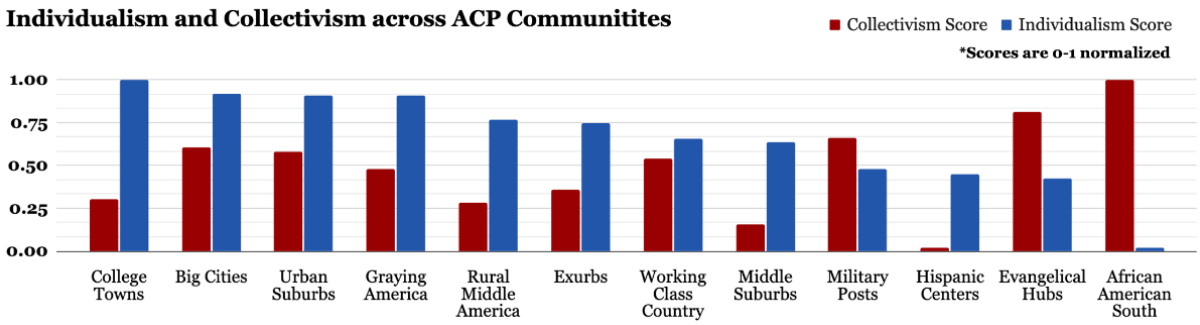

Figure 4: A comparison of collectivism (red) and individualism (blue) scores across communities defined by the American Communities Project, ordered from most individualistic (left) to least individualistic (right). We only analyze communities with over 40 included counties. *Scores are 0-1 normalized.*

cities hundreds of miles apart may be more similar than a city and a rural farm a few miles away (Guntuku et al., 2021). To show how county-level analyses of culture can help us better understand *communities*, we additionally use 15 community types (e.g., College Towns, Urban Suburbs) identified by the American Communities Project (ACP). The ACP identified these communities based on socio-demographic attributes, not spatial clusters of counties. Previous studies have used these community types to identify cultural variation in excessive alcohol consumption (Giorgi et al., 2020) and self-reported physical and mental health (Aggarwal et al., 2023; Mangalik et al., 2023).

Figure 4 shows county-level individualism and collectivism scores grouped into their corresponding ACP community (see Table A1 for counts.) These results provide novel insights into how culture varies regionally. For example, College Towns and Big Cities are highly individualist. These areas are also more affluent and have higher rates of education (ACP, 2023). This fits with prior research findings that people who are wealthy or educated tend to be more individualistic (Binder, 2019).

In contrast, the data shows that Evangelical Hubs and the African-American South are highly collectivist. These communities are tight-knit and religious areas (ACP, 2023), which have been linked to collectivism (Pelham et al., 2022). Military Posts are also more collectivist, which fits with the tight ties in military service and "duty to one's troop." This insight is helpful because we know of no cultural psychology research comparing military communities with civilian communities. Overall, our community-level findings are in line with prior work, and we introduce novel measurements for understudied communities.

5 Ablation Studies

5.1 Effect of Expansion Thresholds

To evaluate the effect of our expansion thresholds, we conduct a hyperparameter search with {0.7, 0.75, 0.8} as the search space for our synonym expansion threshold, and {0.4, 0.45, 0.5} as the sample space for our cluster expansion. We run our pipeline 9 times, testing each of these combinations. Table A2 contains the validation results for each of our hyperparameter runs.

We find that expansion greatly helps the validity of our collectivism lexicon, as our seed words do not perform well — a lower cosine similarity threshold yields higher validation scores. Interestingly, we observe the opposite phenomenon for our individualism seed words — more expansion hurts validity scores. We select {0.75, 0.45} for our final synonym and concept thresholds, respectively, as they yield the highest average validity.

As we see in the case of our collectivism lexicon, the expansion step is crucial to gathering the words that make our lexicon perform well. However, the results are unstable across thresholds. This is expected, as the resulting lexica are not internally coherent. Upon ensuring internal coherence, our lexica become significantly more stable.

5.2 Effect of Purification Threshold

To evaluate the effect of our purification threshold, we conduct another hyperparameter search over the space {0, 0.05, 0.1, 0.15, 0.2}. Here, we find that the purification threshold has very little impact on the overall validation score. As long as we ensure all words internally correlate positively (i.e. Equation 2 is greater than 0), the resulting lexicon is stable. We select 0.15 as our final purification threshold as this yields the highest average validity.

Table A3 contains the validation results for each purification threshold.

Some examples of words removed due to negative internal correlation include "benefit", "supporting", and "community" for collectivism, and "harmony", "evolution" and "international" for individualism. Though these words are added during expansion as synonyms of seed words, they have different usage patterns than their counterparts. Some are erroneous words due to polysemy — "benefit" may indicate helpful behavior, but may also refer to a fundraiser or gala event. Likewise, "harmony" may indicate unity, but is more frequently used to refer to music and melodies.

The purification component of our pipeline results in lexica that are highly stable across thresholds as well as reliable, highlighting the importance of internal coherence.

6 Investigating Cultural Variation in LLM-generated Text

With a validated method to measure regional variation in individualism and collectivism, we can now answer the question: *Given geographical information, can LLMs generate text that mimics real-world cultural variation?*

Generating state-specific text. A recent line of NLP research investigates how LLMs express personality, and explores imbuing a fixed set of characteristics into an LLM to create a persona (Mao et al., 2023; Safdari et al., 2023; Jiang et al., 2024). Drawing from this line of work, we create a geographic persona for an LLM (i.e. specifying a US state of residency), thus allowing us to generate state-specific text.

Specifically, we aim to recreate our dataset using an LLM, so we can directly compare whether synthetic LLM-generated text reflects the cultural variation found in Tweets from real people. We select four states for this experiment – New York, Massachusetts, Louisiana, and Mississippi, as they have the highest levels of individualism (NY, MA) and collectivism (LA, MS), while also containing Tweets from the vast majority of their counties.

Next, we prompt GPT-3.5 to generate Tweets as Twitter users living in each state. Following Jiang et al. (2024), we use a temperature of 0.7 to encourage creativity and variance when emulating different users. We keep our geographic persona prompt concise and open-ended, so as not to skew the LLM with prior notions of expected topics or writing style. We generate 100,000 total Tweets (500 users per state; 50 Tweets per user) and sample a parallel subset from our real-world Twitter dataset with an identical user breakdown.

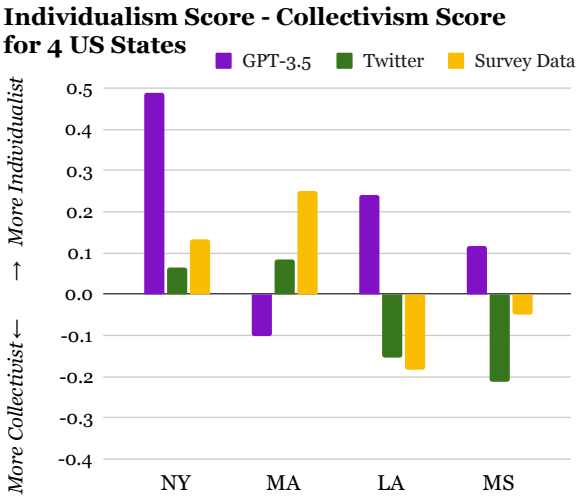

Figure 5: Individualism score minus collectivism score for LLM-generated and real-world Tweets. Across four US states, Twitter data (green) more closely aligns with Vandello & Cohen's survey-based scores (yellow) compared to the GPT-3.5 data (purple).

See Appendix E for full details on experimental setup and prompting procedure. Sample Tweets generated by GPT-3.5 are shown below:

```
Nothing beats a slice of New York pizza
on a Friday night #NYCeats
```

```
Louisiana summers are no joke, y'all.
The humidity is on another level.  Stay
cool out there, friends!  #LouisianaLife
```

LLMs don't reflect cultural variation. We then run our knowledge-guided lexical model on both datasets, and calculate the difference between the individualism and collectivism scores per state. The results are shown in Figure 5, along with Vandello & Cohen's collectivism scores[5].

The Twitter scores match what we expect: NY and MA are more individualist, while LA and MS are more collectivist. However, the GPT scores do not reflect this pattern. Upon inspecting the generated Tweets, we notice a deeper problem – the Tweets predominantly focus on state stereotypes (e.g. NY Tweets referencing pizza and bagels, LA Tweets referencing crawfish and Mardi Gras, etc.)

In fact, this phenomenon causes New York to have a very high individualism score, due to fre-

[5]As Vandello & Cohen's scores range from $0-1$, we shift the range by subtracting them from 0.5, thus ensuring a higher number indicates more individualism.

quently appearing phrases like "the greatest city in the world" and "diversity of cultures." However, the unstable and incorrect results for the other three states indicate that GPT-3.5 cannot reliably mimic real-world cultural variation. Rather, the generated Tweets are highly stereotypical and cover a small fraction of topics found in Tweets from real people.

7 Related Work

Lexicon Induction. Developing lexica to measure psychological and social constructs is a computationally inexpensive venture that can provide results at par with sophisticated LLMs. Emotion lexica (Mohammad and Turney, 2010), Demographic lexica (Sap et al., 2014), and Politeness lexica (Hayati et al., 2021; Havaldar et al., 2023a) are a few such examples. Similar to prior work, we begin with an expert-curated list of seed words that we expand using semantic knowledge in LLMs.

Measuring Cultural Constructs. Individualism and collectivism have previously been studied to understand a range of constructs (Hamilton et al., 2016; Hofstede, 2011; Triandis, 1993).

One of the earliest attempts to measure collectivism in the US uses a questionnaire-based survey approach (Vandello and Cohen, 1999). More recently, Bazzi et al. (2020) uses infrequent names (common names indicate the desire to fit in vs. stand out (Twenge et al., 2010)) as an indicator of individualism in their county-level study. Chen et al. (2021) use citizen ancestry data to account for immigrants' culture. However, static approaches including name and ancestry mapping ignore the transient nature of the collectivism-individualism dimension and the fact that it evolves with the socio-economic environment (Lomas et al., 2023; Santos et al., 2017). Question-based surveys may provide a truer picture but can become increasingly expensive and time-consuming when collecting granular data (e.g. county-level). In this scenario, social media language can help in dynamically modeling collectivism within regions (Aggarwal et al., 2023).

Culture and NLP. Detecting culture in LLMs and the consequent goal of "cultural alignment" are emerging research problems that often rely on decade-old measures of cultural constructs derived from a small sample of the population (Kovač et al., 2023; Jin et al., 2023; Masoud et al., 2023). Social psychology has great potential in adapting machine-generated text for cross-cultural interactions (Marmolejo-Ramos and Tejada, 2023). Through this paper, we propose a highly scalable approach to dynamically measure cultural constructs at high granularity from publicly available social media language.

8 Conclusion & Future Work

We introduce a new problem for the NLP community: *measuring regional variation in culture*. This is a new class of problem — obtaining labels for culture across states or countries is often infeasible, as there are very few labeled data points to train on. Using pre-trained LLMs to label data is unreliable, as these models lack basic cultural awareness. Additionally, scaling to label billions of data points is computationally infeasible. Classic deep learning methods fail to solve this problem; therefore, measuring culture necessitates a different approach.

We present a method to efficiently measure cultural variation by leveraging domain knowledge from cultural psychology to create knowledge-guided lexica. Our lexica filter out erroneous words and ensure internal coherence, bypassing the pitfalls of traditional lexica. By applying these lexica to social media language, we can estimate cultural differences at fine-grained geographic levels, such as states, counties, and communities – a task that modern LLMs fail to accomplish.

Future work could build on this method to get deeper insights into communities and cultures. For example, our method could be used to identify Tweets that mark cultural differences; we encourage researchers to build more sophisticated models on these identified Tweets. Additionally, our method is easily extendable to other cultural dimensions, such as power distance, tightness/looseness, etc. This method could also measure cultural variation globally, which requires analyzing different languages. Since our method is language agnostic, it can easily extend to non-English settings by leveraging multilingual embeddings.

9 Limitations

While we label each county for individualism and collectivism, we note that regions do not have a single culture. Within all regions, there is heterogeneity of cultural values and beliefs. Since we use an open-source Twitter corpus, we also have poor coverage of counties with little to no Twitter data. We also only use Twitter users to represent each region, which may lead to an incomplete represen-

tation of these regions. Additionally, not all aspects of culture are revealed in language – we are limited to analyzing only what people say online.

For our seed words, we only consult one domain expert. As a result, our final lexica are based on this expert's interpretation of individualism and collectivism. Extensions of this work could consult multiple experts to ensure downstream lexica are as unbiased as possible.

Furthermore, our results are influenced by the choice of embedding model used for expansion. Additional work is needed to determine the effect of the embedding model, namely, whether a different model yields drastically different results. We also risk propagating any bias present in the embedding model during expansion.

In our analyses, we do not control for race, income, or other demographic variables. We know cultural values are correlated with some demographic variables — for example, collectivism and individualism vary with income. Future work can improve upon these estimates by accounting for individual demographics. Additionally, it is unclear if this method of measuring cultural variation will work for all cultural dimensions. For example, power distance (Hofstede, 2011) involves the relationship dynamics of two people, which might make it difficult to capture with lexica.

10 Ethical Considerations

The goal of studying cultural variation is to better understand cultures, not individuals. Nonetheless, the characterization of culture has the danger of stereotyping individuals. Individuals within each culture vary greatly. Studying culture can help us understand differences in psychology, but we should not assume that a cultural average will definitely apply to a particular individual from that culture.

All data used in this study is publicly available. While geolocated Twitter data is used, only aggregated spatial-level data is reported. That is, no person-level identifiable information is used or released for this study.

A Open-Source Twitter Corpus

We use the County Tweet Lexical Bank, an open source data set of features extracted from a corpus of 1.5 billion tweets from approximately 6 million US county-mapped users (Giorgi et al., 2018). While the full details of the dataset can be found in the original paper, we give a high-level summary to aid the reader. The dataset is built from a larger corpus which is a 10% sample of Twitter from 2009-2015 (over 30 billion tweets). These tweets are then mapped to US counties via latitude and longitude coordinates associated with the tweets or self-reported location information in the Twitter user's profile (a free text field). A Twitter user is included in this data set if they have posted at least 30 or more English tweets, and a county is included if at least 100 such users are mapped to that respective county. This process resulted in 1.5 billion tweets mapped to over 2,000 US counties.

B Scalability Calculations

We outline the proposed costs of using various LM-based techniques to label our corpus of 1.5 billion Tweets:

Proposed cost of GPT-4 As of August 2023, the OpenAI API rate for GPT-4 is $0.06 cents per 1,000 tokens. Assuming 10 tokens per Tweet, we get:

$$1.5e9\,\text{Tweets} \times \frac{10\ \text{Tokens}}{\text{Tweet}} \times \frac{\$0.06}{1,000\ \text{Tokens}} \quad (4)$$

This yields a total cost of $900,000.

Proposed cost of GPT-3.5 As of August 2023, the OpenAI API rate for GPT-3.5 is $0.002 per 1,000 tokens. Assuming 10 tokens per Tweet, we get:

$$1.5e9\,\text{Tweets} \times \frac{10\ \text{Tokens}}{\text{Tweet}} \times \frac{\$0.002}{1,000\ \text{Tokens}} \quad (5)$$

This yields a total cost of $30,000.

C GPT-3.5 Baseline

To assess whether a pre-trained LLM is capable of measuring individualism and collectivism, we sample a subset of our Twitter corpus (2,000 Tweets per state) and have GPT-3.5 assign a label to each Tweet. Our prompt is as follows:

```
System Prompt: Given a Tweet, try to
reason about whether it reflects the
cultural dimension of Individualism
or Collectivism. Collectivists are
closely linked individuals who view
themselves primarily as parts of a
whole, be it a family, a network of
co-workers, a tribe, or a nation. Such
people are mainly motivated by the norms
and duties imposed by the collective
entity. Individualists are motivated by
their own preferences, needs, and rights,
giving priority to personal rather than
group goals.

If the Tweet does not reflect either
cultural dimension, please label it
'Neither'.

Example input and output:
Tweet: {Tweet Text}
Label: {Individualism, Collectivism,
Neither}

User Prompt: Tweet: {Tweet Text}
```

We provide GPT-3.5 with the definition of individualism and collectivism as defined by Triandis (1993), and then have it label each tweet with one of three labels – individualism, collectivism, or neither. Across all states, GPT-3.5 labels at least 50% of the Tweets, ensuring enough signal for adequate comparison. We take cues from Sorensen et al. (2023), which prompts LLMs for values, to design this prompt.

ACP Community	Num Counties
Exurbs	207
Graying America	164
African American South	252
Evangelical Hubs	269
Working Class Country	159
Military Posts	70
Urban Suburbs	103
College Towns	151
Big Cities	46
Hispanic Centers	87
Rural Middle America	403
Middle Suburbs	77

Table A1: Number of included counties for each ACP community included in the analysis in Figure 4.

D Interpolations

We use 11 socio-demographic variables to interpolate individualism and collectivism across US counties with insufficient Twitter data. This includes four socioeconomic variables (median household income, percentage of the population with a Bachelor's degree, unemployment rate, and high school graduation rate) and seven demographic variables: (population density, median age, and the percentage of the population in rural areas, Hispanic, fe-

Figure 6: Word clouds visualizing our individualism lexica (blue, top) and collectivism lexica (red, bottom). Larger words have a higher weight, while smaller words have a lower weight.

male, married, and African American). This is implemented with the GPyTorch package (Gardner et al., 2018) with a learning rate of 0.1 and 500 iterations over the training data.

Figure 7 shows the original 2042 counties, and Figure 3 contains the interpolated counties as well.

E GPT-3.5 Tweet Generation

To assess whether a pre-trained LLM can generate language that reflects real-world variation in individualism and collectivism, we have GPT-3.5 generate 100,000 Tweets from four states - New York, Massachusetts, Louisiana, and Mississippi.

Generating geographic personas. When constructing our prompt, we instruct the LLM to behave like an individual living in a given state. We specify solely the state of residency, keeping the prompt concise and open-ended, so as not to bias the LLM towards a specific topic or style when generating text.

Emulating users. To construct a dataset parallel to our Twitter dataset, we generate Tweets in batches, with each query to GPT-3.5 emulating a single "user". To encourage creativity and variance in responses, we set the temperature relatively high (0.7), following Jiang et al. (2024). Each query emulates a different "user," with 50 Tweets generated in response to a single query.

Our prompt is as follows:

```
System Prompt: You are an individual
who lives in {STATE}. You enjoy writing
Tweets and posting them on Twitter for
your followers to read.

User Prompt: Generate 50 Tweets
that you might write and post online.
Remember that each Tweet has a 280
character limit. Separate each Tweet
with a newline character.
```

We ensure that the resulting response meets the following criteria: (1) The response contains 50 separate Tweets, and (2) Each Tweet contains no more than 280 characters. All generated Tweets can be found at https://github.com/shreyahavaldar/knowledge_guided_lexica.

Table A3: Ablation study investigating the effect of the purification threshold.

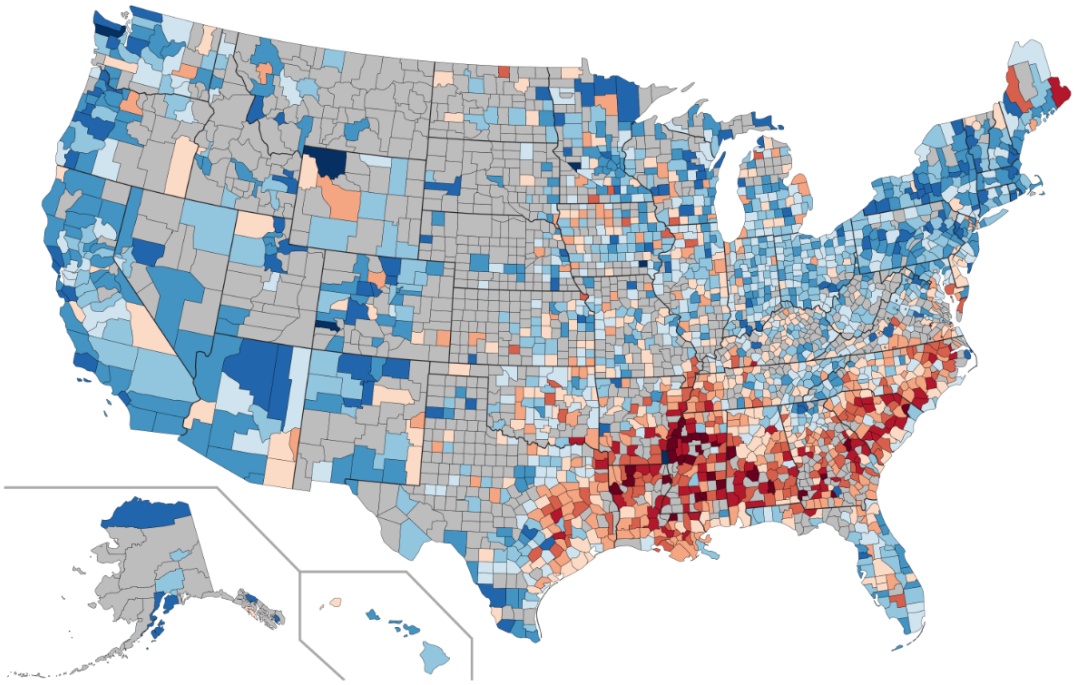

Figure 7: Collectivism (red) and individualism (blue) across US counties. Dark red = higher collectivism and dark blue = higher individualism. We show only the 2042 counties with sufficient data to compute individualism/collectivism scores. Gray counties do not have enough Twitter data to estimate scores.

Adaptive Rank Selections for Low-Rank Approximation of Language Models

Shangqian Gao, Ting Hua, Yen-Chang Hsu, Yilin Shen, Hongxia Jin
Samsung Research America
{s.gao1,ting.hua,yenchang.hsu,yilin.shen,hongxia.jin}@samsung.com

Abstract

Singular Value Decomposition (SVD) or its weighted variants has significantly progressed in compressing language models. Previous works assume the same importance for all operations and assign the same number of ranks for different layers in a language model. However, such a uniform rank selection is sub-optimal since different operations (layers) have non-uniform demand in capacity. In other words, a desired SVD strategy should allocate more ranks for important operations and vice versa. However, a globally-optimized selection of ranks for neural networks is still an open problem, and this is a non-trivial challenge since the selection is discrete. In this work, we propose a novel binary masking mechanism for optimizing the number of ranks in a differentiable framework. Our strategy uses a novel regularization to enable the masking to comply with the SVD property where the ranks have sorted singular values. The experiments examined both types of language models, encoder-only and decoder-only models, including large language models like LLaMA. Our compressed model achieves much better accuracy than previous SVD and their SOTA variants. More interestingly, our method retains significantly better accuracy with zero or limited fine-tuning, proving the substantial advantage of adaptive rank selection.

1 Introduction

Transformer-based models (Vaswani et al., 2017) have been very popular across different Natural Language Processing tasks, such as text classification (Wang et al., 2019a), question answering (Rajpurkar et al., 2016), and summarization (Liu, 2019). Despite its success on these tasks, the size of these models often scales up to millions or billions of parameters, especially for recently proposed large language models (Touvron et al., 2023; Biderman et al., 2023). Such a huge number of parameters makes these models very hard to be deployed on resource-limited devices, such as mobile phones or edge devices. As a result, the compression of Transformer-based language models has drawn much attention.

Transformers-based models have two core operations: self-attention layers and feed-forward layers. These operations are built on linear layers, making them straightforward to compression techniques like low-rank weight factorization (Golub and Reinsch, 1971; Noach and Goldberg, 2020) with SVD or its variants. Low-rank weight factorization decomposes a large linear layer into two small linear layers without changing other model parts, providing a friendly property for deployment. In addition, it is orthogonal to other compression techniques, such as structural pruning (Sanh et al., 2020), quantization (Shen et al., 2020), and knowledge distillation (Sun et al., 2019; Jiao et al., 2019).

Previous work (Hsu et al., 2021) shows that using vanilla SVD for compression can result in a significant performance drop. They argue that low reconstruction error is not equivalent to high accuracy. As a result, *Hsu et al.* (Hsu et al., 2021) proposed to apply the Fisher Information (Pascanu and Bengio, 2014) matrix to re-weight the weight matrix so that the factorization results can capture information from both the task and the reconstruction error. Empirically, Fisher Information weighted SVD performs much better than the original SVD. Despite using the Fisher Information matrix, other importance scores, like first-order Taylor expansion (Molchanov et al., 2019; Hua et al., 2022), can also be used to re-weight the weight matrix.

Although the mentioned weighted SVD methods above achieved promising results, they treat all layers uniformly and use the same number of ranks for all weight matrices. On the other hand, some prior works suggest that the compression rate for different layers should be different in the cases of vision (Molchanov et al., 2019) and language (La-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 227–241
June 16-21, 2024 ©2024 Association for Computational Linguistics

gunas et al., 2021) models. These observations provide clues to improve the performance of existing weight factorization by selecting the proper number of ranks for each layer. Inspired by the above observations, the target of our problem setting is to find the optimal number of ranks for all the layers in a neural network. However, this optimization is not trivial since it is a discrete, non-smooth, and non-convex problem. Reinforcement learning (Schulman et al., 2017) and evolutionary algorithms (Real et al., 2019) may find a solution for this problem, but they introduce substantial optimization costs that are not affordable for larger models.

To address the above challenge, we propose to use regularized differentiable binary masks to learn the number of ranks for each operation. The entire learning pipeline is built upon an end-to-end differentiable learning framework. We use the sum of a binary mask to capture the number of ranks for each layer. The proposed binary mask is properly regularized to be aligned with the sorted singular values of SVD. Moreover, we use a hypernetwork to improve the effectiveness of our method, which further accelerates the learning process. With all these designs, our method can efficiently find the number of ranks of different operations. The contribution of our work can be summarized as the following points:

- We proposed to use the sum of regularized binary masks to capture the number of ranks for different operations. To further improve efficiency, we introduce hypernetwork to generate the number of ranks.
- We proposed a novel regularization to make binary masks comply with the property of SVD where there are sorted singular values. The regularized binary mask can retain the important factors inherited from SVD or its weighted version.
- Extensive experiments show that our method can significantly improve the performance of SVD and its SOTA variants on both encoder-only and decoder-only language models.

2 Related Works

The benefit of Low-rank factorization is that it can be applied to any linear layer. An early work (Winata et al., 2019) applies SVD for the LSTM cell and explores the effectiveness on different NLP tasks (Zhang et al., 2021, 2022, 2023) and model components. (Noach and Goldberg, 2020) propose a two-stage approach to compress a pre-trained language model. The first stage decomposes the weight matrix with SVD in the pre-trained language model. Then, they fine-tune weights with knowledge distillation to regain performance. The standard SVD can not capture all the information from tasks. The Fisher Information is introduced to reweight the weight matrix, and SVD is applied to the reweighted matrix (Hsu et al., 2021). On top of (Hsu et al., 2021), several numeric optimization methods are used to find the optimal solution to the weighted SVD problem (Hua et al., 2022) when the weighting matrix is not diagonal.

Besides model weights, SVD can also be applied to embedding layers. The ALBERT model (Lan et al., 2019) addresses the issue of redundant parameters in the embedding layer by employing factorization. This layer tends to have high input and output dimensions, leading to inefficiencies. In their work, *Reid et al.* (Reid et al., 2021) introduce a novel approach called Self-Attentive Factorized Embeddings (SAFE). This method enhances performance by incorporating a small self-attention layer built upon linear projection.

A crucial point omitted by previous works is that not all operations are created equally. Some operations require more capacity than others. Our method tackles this problem by automatically learning the number of ranks for each operation.

Our method is also related to network pruning methods, especially structural pruning. Block Pruning (Lagunas et al., 2021) integrates structures of any size into the movement pruning paradigm for fine-tuning, and it prunes the model globally. In addition to NLP tasks, deciding the width of a convolution layer has also been studied extensively using reinforcement learning (He et al., 2018), evolutionary algorithm (Liu et al., 2019), etc. Differentiable pruning (Guo et al., 2020; Herrmann et al., 2020; Wang et al., 2019b; Gao et al., 2022, 2023a,b) is also a popular direction since the cost is often not high. However, they can not be directly applied to select the number of ranks due to the cost or difficulty of fine-tuning resulting from using binary masks.

3 Method

3.1 Background

Transformers have many linear layers, which makes them very suitable for compression methods

like Singular Value Decomposition (SVD). Suppose we have a matrix $\mathbf{W} \in \Re^{M \times N}$, SVD decomposes it into three matrices:

$$\mathbf{W} = \mathbf{USV} \approx \mathbf{U}_r \mathbf{S}_r \mathbf{V}_r, \quad (1)$$

where the orthogonal matrix $\mathbf{U} \in \Re^{M \times M}$ is the left singular vectors, and the orthogonal matrix $\mathbf{V} \in \Re^{N \times N}$ is the right singular vectors. $\mathbf{S}$ is a diagonal matrix of non-zero singular values $\text{Diag}(s) = \text{Diag}(\sigma_1, \sigma_2, \cdots, \sigma_N)$ (assuming $M \geq N$), where $\sigma_1 \geq \sigma_2 \geq \cdots \sigma_N$. $\mathbf{U}_r$, $\mathbf{S}_r$, $\mathbf{V}_r$ represent the truncated matrices with rank r and approximate the original matrix.

With the SVD, the computation of a linear layer in a neural network can be rewritten as below with input data $X \in \Re^{B \times M}$, weight matrix $\mathbf{W} \in \Re^{M \times N}$, bias $\mathbf{b} \in \Re^{1 \times N}$:

$$\mathbf{Y} = \mathbf{XW} + \mathbf{b} = \mathbf{X}(\mathbf{US})\mathbf{V}^T + \mathbf{b}. \quad (2)$$

The standard SVD can be further improved by multiplying a weighting matrix with $\mathbf{W}$, and this weighting matrix can be computed in many different ways, such as using Fisher Information (Pascanu and Bengio), Importance Estimation (Molchanov et al., 2019), etc. Weighted SVD often performs better than vanilla SVD when compressing language models. Denote the weighting matrix as $\mathbf{I}_w$, and $\mathbf{I}_w$ is a diagonal matrix where the importance of each weight is summed within each column or row. Then, after applying $\mathbf{I}_w$, we have:

$$\mathbf{Y} = \mathbf{XW} + \mathbf{b} = \mathbf{X}[{\mathbf{I}_w}^{-1}(\mathbf{U}'\mathbf{S}'){\mathbf{V}'}^T] + \mathbf{b}. \quad (3)$$

where U', S', and V' come from the weighted SVD decomposition of $\mathbf{I}_w\mathbf{W} = \mathbf{U}'\mathbf{S}'\mathbf{V}'$. Note that by using SVD or its weighted variants, we can easily compress pre-trained models, which is vital since the training costs of the typical large language models are very high, and training them from scratch is usually prohibitively expensive.

3.2 Overview

In the following contents, we will first introduce how we parameterize the number of ranks. Then we will introduce the hypernetwork used to generate the number of ranks. After that, we will talk about how we overcome the difficulty of fine-tuning caused by directly using indices from binary masks and how to produce top-k-like masks. The overall optimization problem will be introduced last. Fig. 1 illustrates our method given one self-attention layer.

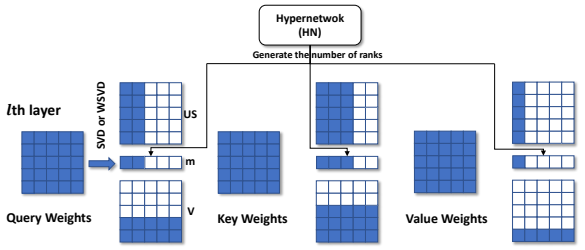

Figure 1: An overview of our method. In the figure, we use the self-attention layer as an example. The hypernetwork produces the number of ranks for each operation, which are then applied to the query, key, and value weights. Since m is differentiable w.r.t to the hypernetwork, we can optimize the number of ranks in an end-to-end differentiable way.

3.3 Control the Number of Ranks

In Equation. 2, the diagonal matrix $\mathbf{S}$ contains singular values of SVD. If singular values are equal to zeros, then the corresponding vectors from $\mathbf{U}$ and $\mathbf{V}$ can be safely removed. Usually, the singular values of model weights are non-zero. As a result, we can apply a binary mask $m \in \{0, 1\}$ on top of the diagonal matrix $\mathbf{S}$:

$$\hat{s} = m \odot s, \quad (4)$$

where s is the singular vector, and $\mathbf{S} = \text{Diag}(s)$. After applying $\mathbf{m}$, it changes Eq. 2 into:

$$\mathbf{Y} = \mathbf{X}(\mathbf{U}\text{Diag}(\hat{s}))\mathbf{V}^T + \mathbf{b}, \quad (5)$$

which inserts the mask m into the forward/backward calculation of a linear layer under SVD decomposition. By doing so, we can calculate the gradients w.r.t m during regular backpropagation. As a result, the mask can be learned in a loss-aware fashion if it is parameterized properly. Note that, unlike the uniform rank selection in previous works (Noach and Goldberg, 2020; Hsu et al., 2021; Hua et al., 2022), our method enables adaptive rank selections for individual operations for the model, which creates flexibility to allocate different ranks for different operations, and we can allocate more parameters for more important operations. Thus, the overall performance can be largely improved over the uniform rank selection setting.

3.4 Hypernetwork

The binary mask m is not differentiable in its plain form; therefore, we incorporate the straight-through Gumbel-Sigmoid (Jang et al., 2016) operation to make it differentiable. In addition, instead of using element-wise mask parameterization,

we employ a hypernetwork (**HN**) to accelerate the learning of masks m. Specifically, m is generated by:

$$m = \mathbf{HN}(z; \theta), \tag{6}$$

where θ is the parameters of the hypernetwork, and z (randomly sampled before training the hypernetwork) is the input to the hypernetwork. Basically, the HN is composed of GRUs (Chung et al., 2014) and linear layers. The intuition is that the GRU can be used to learn interactions between different operations, and linear layers are used to map GRU outputs to individual operations of different sizes. More details of the hypernetwork will be presented in the Appendix.

3.5 Singular Value-aware Masking

The hypernetwork gives the number of ranks and the exact positions of selected ranks for each layer. On the other hand, SVD, or its weighted version, provides sorted singular values in the diagonal matrix S (from Eq. 2). So far, the hypernetwork computes the mask completely independent from the structure of S, which has sorted singular values. This independency can produce a mask that skips some ranks with a high singular value, resulting in a less generalizable selection of ranks. This behavior significantly deteriorated the compressed model, impeding the following fine-tuning process from recovering the accuracy. In the later section, Fig. 3 shows this phenomenon with the exact positions of selected ranks from the hypernetwork (the plot named 'Element-Wise').

To address the issue, we choose to use the sum of the binary mask $\mathbf{1}^T m_l$ (m_l is the mask for lth layer) to represent the number of ranks for the current operation and use this sum to force selecting the top-k ranks. Although this strategy resolves the above issue, it introduces a gap between the learned and actual masks for compressing the model. The gap can be formulated by:

$$\|m_l \odot s - m'_l \odot s\|_2^2, \tag{7}$$

where m'_l is a binary mask with the first $\mathbf{1}^T m_l$ elements equals to 1 ($m'_{l[:\mathbf{1}^T m_l]} = 1$), and the rest elements of m'_l equals 0. The smaller the gap, the closer the binary mask m_l to follow the structure of sorted singular values from SVD. The above insight inspired our novel regularization term: $\mathcal{R}_{align}(m_l) = \|m_l \odot s - m'_l \odot s\|_2^2$. This regularization can be seamlessly inserted into the optimization of the HN without introducing extra parameters. Our ablation study will verify the mentioned insight and prove the effectiveness of $\mathcal{R}_{align}$.

Algorithm 1: Adaptive Rank Selection

Input: a sub-dataset for training the HN: D_{HN}; remained rate of parameters: p; hyper-parameter: λ, γ; HN training iterations: N_{iter}; a pre-trained model: f; the hypernetwork HN parameterized by θ

for $i := 1$ *to* N_{iter} **do**
  for *a mini-batch* (x, y) *in* D_{HN} **do**
    1. generate m from HN with Eq. 6.
    2. calculate the parameter regularization term $\mathcal{R}(pT(m), T_{\text{total}})$.
    3. calculate the alignment regularization term $\mathcal{R}_{align}$.
    4. calculate gradients *w.r.t* θ by minimizing Obj. 8 and update θ.
  end
end

Compress the model based on **the number of ranks**:
$\mathbf{US} = (\mathbf{US})_{[:,:\mathbf{1}^T m]}$, $\mathbf{V} = \mathbf{V}_{[:,:\mathbf{1}^T m]}$.
Return the resulting model for fine-tuning.

3.6 The Proposed Algorithm

For a specific task, to maximally preserve the performance given a parameter budget, we minimize the task loss together with the regularization of the number of parameters and the regularization for aligning the SVD property. The overall objective function is defined by:

$$\min_{\theta} \mathcal{L}(f(x; m), y) + \lambda \mathcal{R}(T(m), pT_{total}) + \gamma \frac{1}{L} \sum_{l=1}^{N} \mathcal{R}_{align}(m_l), \tag{8}$$

where x, y are input and its label, $\mathcal{L}$ is the task-specific loss, $f(\cdot; m)$ is the model parameterized by the mask m, λ controls the regularization weights for the parameter regularization $\mathcal{R}$ and $\mathcal{R}(a, b) = \log(\max(a, b)/b)$, γ controls the regularization weights of $\mathcal{R}_{align}$, T_{total} is the total number of the parameters, and p is the persevered ratio of parameters which is given by users. $T(m)$ is the number of parameters decided by the number of ranks for each operation. Take lth weight matrix as an example; the number of parameters for

Table 1: Results of GLUE benchmark when $p = 0.48$. 'Avg' means the average score of the GLUE tasks. The 'Δ-Avg' is the difference of 'Avg' between the full model and different baselines. Given a similar number of parameters, a smaller 'Δ-Avg' represents better performance.

it is decided by: $T(m_l) = (M_l + N_l) \times (\mathbf{1}^T m_l)$, $T(m) = \sum_{l=1}^{L} T(m_l)$, where M_l and N_l is the number of inputs and outputs dimensions for lth weight matrix. Note that the model weights are frozen during the optimization of Obj. 8; therefore, the learnable parameter is small and can be optimized efficiently.

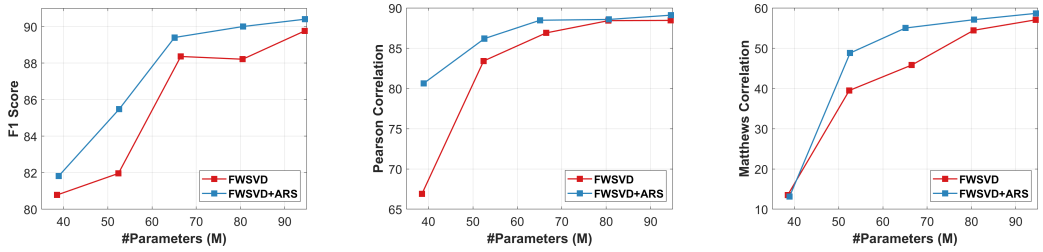
We present the algorithm for learning the number of ranks in Alg. 1. It requires only a small subset of the original training data; therefore, the computation overhead to optimize the number of ranks is negligible (details are in the experiment section). Note that all m_l are learned jointly in one pass, and rank selection competes across all layers. In other words, important operations can receive more ranks than the less important ones. Finally, we select top $\mathbf{1}^T m_l$ ranks for each operation to compress a model, as described in Section 3.5.

4 Experiments

4.1 Settings

We assess our proposed method and baselines using the General Language Understanding Evaluation (GLUE) benchmark (Wang et al., 2019a) and the large language model pre-training task on Pile (Gao et al., 2020). For GLUE tasks, we use BERT (Devlin et al., 2018), MobileBERT (Sun et al., 2020), and DistllBERT (Sanh et al., 2019) to evaluate our method. We use LLaMA-7B (Touvron et al., 2023) to evaluate our method for large language models. In the Appendix, we use models from Pythia Suite (Biderman et al., 2023) to evaluate our method for the language modeling task. Throughout the experiment section, our method is abbreviated as **ARS** (**A**daptive **R**ankd **S**election).

To build fair comparison baselines, we compress all linear layers from the model, including self-attention layers and feed-forward networks. In addition, we do not compress the embedding layer, and the compression rate of our method can be further improved by incorporating previous works focusing on compressing the embedding layer (Lan et al., 2019; Reid et al., 2021).



Our method aims to find the best number of ranks for each operation. As a result, we will show our method is effective across different choices of weighting matrices (Eq. 3) or no weighing matrix (Eq. 2). For weighted SVD, we choose two kinds of weighting matrix: Fisher information Weighted SVD (FWSVD) (Hsu et al., 2021) and Importance Weighted SVD (IWSVD). For IWSVD, the importance is calculated by directly following the definition from (Molchanov et al., 2019), which is based on the first-order Taylor expansion.

For all tasks, we use pre-trained language models as a start, then the model is fine-tuned on downstream tasks, like GLUE or language modeling tasks. After that, we freeze the model weights, and we train the HN based on Obj. 8. The model is then compressed based on the number of ranks produced by the HN. Finally, the model is fine-tuned again on downstream tasks or pre-training tasks.

When training the HN, we choose 4000 samples for GLUE tasks (Wang et al., 2019a). If the dataset is smaller than 4000 samples, we use the whole dataset to train the HN. For the language modeling task, we train the HN for 2000 iterations. ADAM (Kingma and Ba, 2015) is used to train the HN with a constant learning rate 1×10^{-3}. λ and γ in Obj. 8 is set to 16 and 10 for all experiments. For all GLUE tasks, the other settings are the default configuration from the HuggingFace

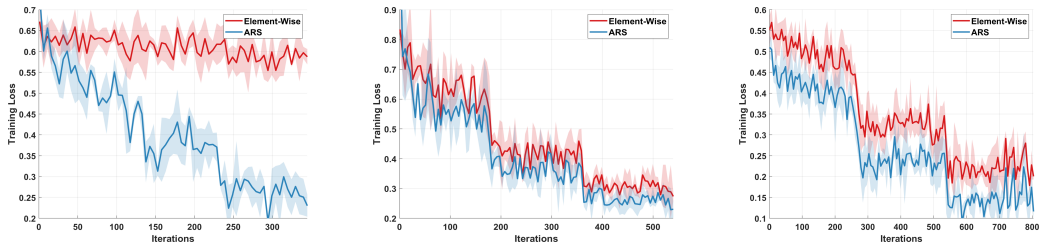
Transformer library. We defer other training details of the language modeling task to the Appendix. All of our implementations are based on the Huggingface Transformer library (Wolf et al., 2020) and PyTorch (Paszke et al., 2019).

4.2 GLUE Results for BERT

The GLUE results are shown in Tab. 1. As introduced previously, our method ARS is applied to three baselines: FWSVD, IWSVD, and SVD. For all methods, the uniform baseline from previous works has 66.5M parameters, and it is achieved by removing 67% ranks from the original model. For ARS, the model has 65.1M parameters, which is achieved by setting p in Obj. 8 to $p = 0.48$.



We present results before and after fine-tuning in the table. It is clear that ARS can boost the performance of the uniform SVD, IWSVD, and FWSVD. In particular, before fine-tuning, SVD+ARS performs better than SVD by 18.48 regarding average task performance ('Avg' in the table). After fine-tuning, this gap is 3.19 between SVD and SVD+ARS. By using Fisher Information or other importance scores, the compressed model has a much better performance across different tasks since task related information is injected. With these stronger baselines, our method continuously improves their performance. For IWSVD, our method is 21.32/2.21 (with/without fine-tuning), better than the baseline on average task performance. For FWSVD, our method again is better than the baseline by 12.46 and 2.19 before and after fine-tuning. In summary, ARS can still provide substantial improvements even with stronger baselines.

Besides the comparison under the same weighting mechanism, SVD+ARS has a similar or even better performance than weighted SVD like IWSVD and FWSVD. In particular, by finding the proper number of ranks given each operation, SVD+ARS has 60.48/81.61 average task performance. At the same time, IWSVD has 45.96/80.93 average task performance, and the number for FWSVD is 57.03/81.34. SVD+ARS is better than IWSVD, and it has a similar performance as FWSVD. From this perspective, we can say that properly choosing the number of ranks is as important as building a good importance metric for weighted SVD.

We further increase the compression rate, and results are shown in Tab. 2. In this setting, we remove 78% of ranks for the baseline model, and we set $p = 0.33$ for the proposed ARS. ARS improves the performance of SVD, IWSVD, and FWSVD across different GLUE tasks. More specifically, SVD+ARS is better

Table 3: Results of GLUE benchmark with compact models. The definition of 'Avg' and 'Δ-Avg' is same as Tab. 1.

(a) MRPC (b) STSB (c) COLA

Figure 3: The fine-tuning loss averaging from three different random seeds given $p = 0.48$ with BERT.

than SVD by $20.09/3.44$ before and after fine-tuning. IWSVD+ARS is $25.63/4.76$ better than IWSVD, and FWSVD+ARS is $27.18/3.05$ better than FWSVD. In general, with a more aggressive compression rate, the advantage of ARS is more obvious. In Fig. 2, we visualize the number of parameters vs. the performance for MRPC, STSB, and COLA between FWSVD and FWSVD+ARS. FWSVD+ARS outperforms FWSVD across nearly all settings, which again demonstrates that selecting the proper number of ranks is important across different compression rates.

With both compression rates (Tab. 1 and Tab. 2), ARS is much more effective in retaining performance before fine-tuning than SVD, suggesting that adaptive selection of the number of ranks has the potential for fine-tuning less/free compression.

4.3 GLUE Results for Compact Models

ARS already shows promising results when compressing BERT, and a follow-up question is whether it can improve the results on compact models. To verify this, we apply FWSVD and FWSVD+ARS on DistillBERT (Sanh et al., 2019) and MobileBERT (Sun et al., 2020). We choose FWSVD and FWSVD+ARS since they achieve the best Δ-Avg on BERT. The overall results are shown in Tab. 3.

For DistillBERT, we still uniformly remove 67% of ranks for FWSVD, and we let $p = 0.48$ for FWSVD+ARS. Clearly, FWSVD+ARS performs better than FWSVD for DistillBERT, and the gap is $18.79/2.67$ regarding average task performance before and after fine-tuning. For MobileBERT, we uniformly remove 40% of the ranks for FWSVD, and we set $p = 0.75$ for FWSVD+ARS. FWSVD+ARS outperforms FWSVD by $18.99/1.71$ with or without fine-tuning. In short, ARS continuously improves low-rank factorization for compact models like MobileBERT or DistillBERT.

Table 6: Comparison results with LLaMA-7B.

baselines: (1) training from scratch with a similar number of parameters, (2) WSVD with uniform rank selections, and (3) LLM-pruner (Ma et al., 2023). For WSVD, ARS, and Scratch settings, the compressed models are fine-tuned for 576 A-100 GPU hours, which is less than 1% of the cost for training LLaMA-7B. More training and evaluation details are presented in the appendix. The results are shown in Tab. 6. From the table, we can see that our proposed ARS achieves the best average performance on these 6 tasks. LLM-Pruner performs better on OBQA and ARC-c, but the number of parameters doubles compared to ARS. LLM-Pruner and our method use two different ways to fine-tune model weights, where LLM-Pruner is fine-tuned with LoRA (Hu et al., 2021) on Alpaca (Taori et al., 2023). Our results suggest that fine-tuning with the pre-training setting is more promising than LoRA+Alpaca for a larger compression rate. Training from scratch shows a much worse performance suggesting that compression techniques could be an alternative way to create models with different sizes given limited training budgets.

4.5 Further Analysis

To better understand our method, we present further analysis regarding different perspectives of ARS.

(1) The Number of Samples. In Tab. 4, we show the impact of the number of samples when training the HN. For some datasets, increasing the number of samples for the HN is very helpful such as QQP and QNLI. For SST-2, the impact is not obvious. Increasing the number of samples may have some benefits, but the benefit of using too many samples is marginal. The reason is that, unlike model weights, the search space for the number of ranks is much smaller, and the performance gain becomes less obvious when there are enough samples.

(2) Ablation Study. In Tab. 5, we present the ablation study results on MRPC, STSB, and COLA. 'w/o Rank Selection' means we ignore the property of SVD and use the index to perform element-wise selections. Under this setting, we find a significant performance drop. We also plot the training loss in Fig. 3. Clearly, the element-wise rank selection hurts the structure of low-rank factorization, making it much more difficult to regain performance by fine-tuning. This suggests that we should follow the property of SVD instead of ignoring it. 'w/o hypernetwork' means that we use a simple baseline with element-wise binary gates and keep other settings intact. In this setting, the performance has an obvious drop, and we found it harder to reach the pre-defined compression rate p, and it is generally more difficult to optimize (takes more steps, oscillating of training losses). Without $\mathcal{R}_{align}$, our method suffers from an obvious performance decrease, which verifies the benefit of encouraging masks to follow the sorted singular values from SVD.

(3) Effectiveness of HN. We plot the task loss when learning the number of ranks with or without using HN in Fig. 4, which is also the setting of 'w/o hypernetwork' in Tab. 5. It is clear that our method can find a better solution and achieve a

Device Name	Quantization	Model	Model Size	Per Token Time	Tokens Per Sec
S23 Ultra 12GB	8-bit	Llama-7B	7.6 GB	301.3ms	3.3
		ARS-1.7B	1.9 GB	55.7 ms	17.9
	4-bit	Llama-7B	4.0 GB	221.8 ms	4.5
		ARS-1.7B	1.1 GB	47.1 ms	21.3

Table 7: Generation speed comparison with our method and the original Llama-7B model

Settings	#Params	WikiText	PTB	C4
ARS	4.1B	115.62	183.12	117.76
	3.3B	404.49	581.23	389.44

	3.3B	17.07	21.99	19.93
	2.5B	18.53	23.75	21.35
	1.7B	20.54	26.82	23.53

Table 8: The effect of different pruning rates. We report the perplexity on WikiText, PTB, and C4.

much faster convergence rate with HN on MRPC, STSB, and COLA. No doubt, HN largely improves the efficiency when learning the number of ranks. The plots of the $\mathcal{R}$ loss are shown in the Appendix.

(4) Generation Speed Comparison. In Tab. 7, we further show the generation speed comparison between ARS 1.7B and Llama-7B. Both models are deployed on the mobile device: S23 Ultra 12GB. In short, the generation speed increases as the number of parameters decreases. If both models are quantized to 8 bits, then the generation speed of the ARS 1.7B model is around $4.7\times$ faster than the original model. If both models are quantized to 4 bits, then the generation speed of our model is around $5.4\times$ faster than the original model.

(5) The Effect of Different Pruning Rates for Llama-7B. We present the result before and after fine-tuning in Tab. 8. The fine-tuning setting for this experiment is quite short, the model is only fine-tuned on around 0.16B tokens. After a short fine-tuning, the perplexity of the model can be quickly recovered. To recover the general ability of the original model, it still requires a longer fine-tuning period.

5 Conclusion

In this paper, we proposed a new algorithm that adaptively selects the number of ranks for low-rank approximation of language models. We proposed to use a hypernetwork to predict the number of ranks for each operation. The predicted number of ranks is regularized using the SVD property and is encouraged to produce top-k-like binary masks. Our method resolved the issue with the ordinary masking that resulted in element-wise rank selections, delivering stable performance gain in a comprehensive collection of experiments. The extensive results also show our advantage over previous low-rank methods with uniform rank selections.

A Limitations

Our work adaptively learns the number of ranks for each layer for individual tasks. As a result, the limitation of our method is that we always need to find a new configuration of the number of ranks for a new task, where the learned number of ranks for previous tasks can not be re-used on new tasks. This limitation brings additional computational costs for each new task. Fortunately, this additional cost is trivial on large datasets. For example, it takes 2.2 V100 GPU hours to train BERT on MNLI. Training HN on 4000 samples costs around 0.1 V100 GPU hours on this task.

Alternatively, if we can use some statistics to capture the dataset distribution and incorporate it to learn the number of ranks, we may be able to predict the proper configuration of the number of ranks based on some statistics about the data distribution of the new task. However, this may substantially increase the training time for HN since the problem becomes much more complex.

B The Architecture of Hypernetwork

Table A1: The architecture of hypernetwork.

Input z
Bi-GRU(32,64)$\rightarrow$ LayerNorm$\rightarrow$ GeLU
Linear$_l$(128, N_l)$\rightarrow$Outputs o_l, $l = 1, \cdots, L$

As we discussed in the paper, the Hypernetwork is composed of linear layers and Bi-GRUs, and now we present the architecture of the HN in Tab. A1. z is initially sampled from a normal distribution, and it is then fixed during training. Outputs o_l are continuous values. We use the following equation to covert it into m_l:

$$m_l = \text{round}(\text{sigmoid}((o_l + g + b)/\tau)), \quad (9)$$

where sigmoid$(\cdot)$ is the sigmoid function, round$(\cdot)$ is the rounding function, g is sampled from Gumbel distribution ($g \sim \text{Gumbel}(0, 1)$), b is a constant value to make sure HN starts from the full rank, and τ is the temperature hyper-parameter. As shown in Eq. 9, straight-through Gumbel-Sigmoid (Jang et al., 2016) are used to produce the final binary vector m. For all experiments, we set $\tau = 0.4$ and $b = 3.0$.

Dataset	Tables	Models	p	r

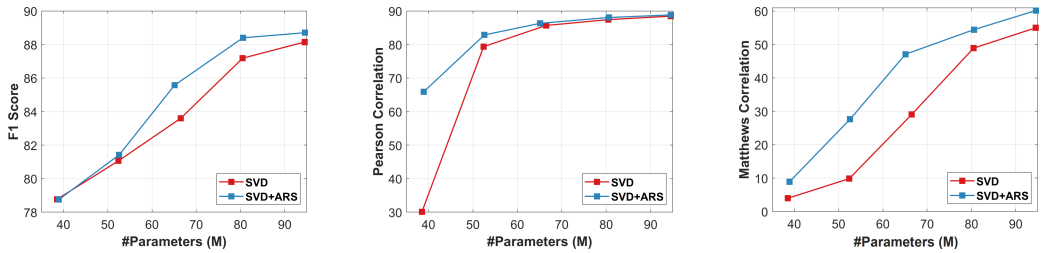
	Tab. 2	BERT-base	0.33	0.22
	Tab. 3	DistllBERT	0.48	0.33
	Tab. 3	MobileBERT	0.75	0.60
Pile	Tab. 6	LLaMA-7B	0.24	0.15
WikiText-103	Tab. A4	Pythia-160m	0.48	0.36

Table A2: Choice of p for different models. p is the remained number of parameters divided by the total parameters. 'r' represents the ratio of ranks uniformly preserved by SVD, IWSVD, and FWSVD.

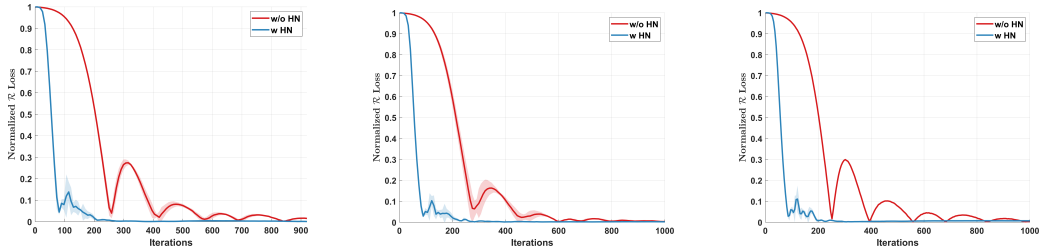


C Implementation and Training Details

For BERT based models on GLUE tasks (Wang et al., 2019a), we use Huggingface (Wolf et al., 2020) codes for experiments, which is under Apache 2.0 license. We use the lit-llama `https://github.com/Lightning-AI/lit-llama`, also with Apache 2.0 license, codes for fine-tuning the Pythia (Biderman et al., 2023) model on the WikiText (Merity et al., 2016) dataset. The lit-llama code is also used to fine-tune the compressed LLaMA-7B models on Pile (Gao et al., 2020).

GLUE (Wang et al., 2019a) contains nine English sentence understanding tasks, which cover a broad range of domains, data quantities, and difficulties. Pile (Gao et al., 2020) is an 825 GiB English text corpus targeted at training large-scale language models. The Pile is constructed from 22 diverse high-quality subsets—both existing and newly constructed—many of which derive from academic or professional sources. The WikiText language modeling dataset (Merity et al., 2016) is a collection of over 100 million tokens extracted from the set of verified Good and Featured articles on Wikipedia. The dataset is available under the Creative Commons Attribution-ShareAlike License. We follow all intended usage of licenses of the datasets and codebase we used.

For all GLUE tasks, we train the HN on 4000 samples (randomly sampled) for 8 epochs. If the dataset has less than 4000 samples, we train the HN on the whole dataset for 8 epochs. For both HN training and BERT training, we set the mini-batch size to 32, and it is trained on 1 Nvidia-V100 GPU.



For the language modeling task, we directly use the pre-trained Pythia-160m model and fine-tune it on the WikiText-103 dataset. We set the sequence length to 512, and the mini-batch size is 64. The initial learning rate is 2×10^{-5}, and the learning rate is linearly decayed. We also list choices of p for different tasks and choices of the preserved ratio

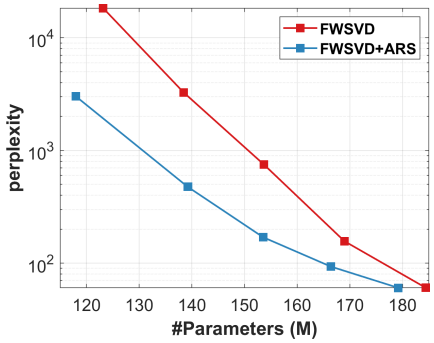

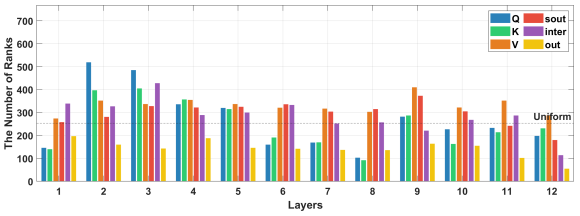

Figure A3: Perplexity for different compression rates before fine-tuning on the WikiText-103 dataset.

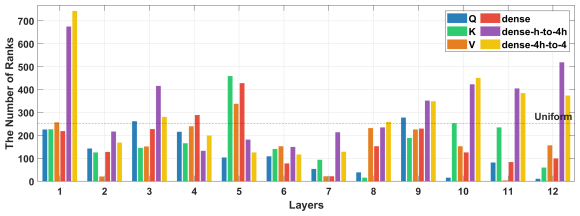
of ranks by SVD, IWSVD, and FWSVD in Tab. A2. The model is trained for 24,000 iterations in total. We use 2 Nvidia-A100 GPUs for this experiment.



For LLaMA-7B, we set $p = 0.24$ and we train HN on the Pile validation dataset on 2 Nvidia-A100 GPUs for 4000 iterations. We use the constant learning rate 1×10^{-3} for this stage. After compression, the model is trained on Pile (Gao et al., 2020) training set with 8 Nvidia-A100 GPUs, mini-batch size 48, block size 2048, and a start learning rate of 5×10^{-5}. We use the cosine scheduler for learning rate decay, and the final learning rate is 5×10^{-6}. The model is trained for 210,000 steps and the training can be completed within 3 days. The total training tokens are around 20B. Our training code is built on lit-llama: `https://github.com/Lightning-AI/lit-llama`. We use llm-eval-harness (Gao et al., 2021) to evaluate the compressed model.

D Importance Calculation

In this section, we will briefly review the Fisher Information and the other importance scores used in our paper. The Fisher Information measures the amount of information that an observable dataset D carries about a model parameter w. More specif-

(a) MRPC - BERT

(b) WikiText - Pythia-160m

Figure A4: The number of ranks selected by FWSVD+ARS for different tasks.

ically,

$$\mathbf{I}_w^{\text{FI}} = \mathbf{E}[\frac{\partial}{\partial w}(\log p(D|w))^2] \approx \frac{1}{|D|}\sum_{i=1}^{|D|}(\frac{\partial}{\partial w}\mathcal{L}(f(x_i;w),y_i))^2.$$

For IWSVD, the importance score follows the definition from (Molchanov et al., 2019):

$$\mathbf{I}_w^{\text{Imp}} = (\frac{\partial \mathcal{L}}{\partial w}w)^2.$$

E Additional Results

We further provide the result of #Params vs. performance for SVD/IWSVD and our ARS variants in Fig. A1. SVD+ARS and IWSVD+ARS clearly outperform SVD/IWSVD for almost all compression rates. We also visualize the perplexity before fine-tuning for different compression rates in Fig. A3. FWSVD+ARS outperforms FWSVD at every compression rate for the number of ranks. At a higher compression rate, the perplexity of FWSVD+ARS is often a magnitude lower than WSVD, which shows the advantage of adaptive selections of the number of ranks.

In Fig. A4, we visualize the number of ranks selected by ARS across each operation. In Fig. A4a, ARS allocates more ranks for early to middle layers for MRPC. In Fig. A4b, ARS allocates more ranks for both early and late layers for WikiText. The difference between MPRC and WikiText is probably because the language modeling task focuses on both input contexts and output predictions, and MRPC only needs to measure whether input sentences are equivalent and it is not complex. In summary, ARS can produce different selections of the number of ranks based on different tasks.

To provide a more detailed understanding on the effectiveness of HN, we plot the parameter regularization loss $\mathcal{R}$ with or without HN. The $\mathcal{R}$ loss is normalized between 0 and 1 for better visualization.

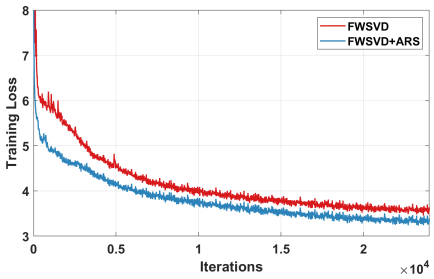


Figure A5: Training loss on WikiText.

In Fig. A2, we can see that our method with HN can quickly reduce the parameter loss $\mathcal{R}$. Without HN, the $\mathcal{R}$ loss keeps bumping and it seems hard to reach the desired parameter budget without HN.

F Language Modeling Task with Pythia

We further apply our method to the language modeling task on WikiText-103 (Merity et al., 2016) dataset. Results are shown in Tab. A4. From the table, we can see that FWSVD+ARS performs much better than FWSVD. In particular, FWSVD+ARS compresses 6% more parameters than FWSVD, and the perplexity of it is 3.07 and 3.24 lower than FWSVD on the test and validation splits. FWSVD+ARS even performs better than the baseline on the test split. These results again demonstrate the importance of selecting the number of ranks across different tasks. In Fig. A5, we visualize the training loss of FWSVD and FWSVD+ARS during fine-tuning on WikiText. FWSVD+ARS always starts at a lower loss value, and the gap between FWSVD and ARS is maintained till the end of training. By properly choosing the number of ranks, we obtain a model more suitable for the task, making it easier to regain performance.

G Comparison with Pruning Methods

We provide further comparison results against structural pruning methods in Tab. A3. For IE (Molchanov et al., 2019), we built this structural pruning baseline for compression language

Task	MRPC	STSB	COLA	SST-2	MNLI	QNLI	QQP	Avg	# Params
IE (Molchanov et al., 2019)	45.58	64.90	8.04	66.92	48.82	49.48	50.70	47.77	66.8M

Table A4: Results of the language modeling task on WikiText-103. 'PT' represents the total number of parameters. 'PM' represents the number of model parameters excluding the Embedding layer. 'ppl' represents perplexity.

models based on the original method. The training and fine-tuning settings are the same as our method. We compared it with IWSVD+AES since they use the same importance. Our method has a better average task performance before and after fine-tuning. For CoFipruning (Xia et al., 2022), We use the GitHub repository of CoFipruning, and modify some hyperparameters to build a fair comparison baseline. We set the fine-tuning epoch of CoFipruning to 3 epochs which is the same as our method. In addition, the first stage of CoFipruning is reduced to 20 epochs for small datasets and 5 epochs for large datasets. Recall that our method first trains the model for 3 epochs for each task and the hypernetwork is trained at most for 1000 steps. As a result, even though we reduced the training time for CoFipruning, it still has a larger computational cost than our method. In addition, we turned off the knowledge distillation of CoFipruning since our method does not rely on any form of knowledge distillation. Our method still has a clear advantage in this setting.

An Empirical Study of Consistency Regularization for End-to-End Speech-to-Text Translation

Abstract

Consistency regularization methods, such as R-Drop (Liang et al., 2021) and CrossConST (Gao et al., 2023), have achieved impressive supervised and zero-shot performance in the neural machine translation (NMT) field. Can we also boost end-to-end (E2E) speech-to-text translation (ST) by leveraging consistency regularization? In this paper, we conduct empirical studies on intra-modal and cross-modal consistency and propose two training strategies, SimRegCR and SimZeroCR, for E2E ST in regular and zero-shot scenarios. Experiments on the MuST-C benchmark show that our approaches achieve state-of-the-art (SOTA) performance in most translation directions. The analyses prove that regularization brought by the intra-modal consistency, instead of the modality gap, is crucial for the regular E2E ST, and the cross-modal consistency could close the modality gap and boost the zero-shot E2E ST performance.

1 Introduction

Speech-to-text translation takes acoustic speech signals as input and outputs text translations in the target language. The conventional cascaded ST system consists of an automatic speech recognition (ASR) system and a machine translation (MT) module in a pipeline manner (Sperber et al., 2017, 2019; Zhang et al., 2019). Recent works on ST have focused on the end-to-end system, which learns a unified model that directly generates text translations from speech without any intermediate outputs (Duong et al., 2016; Berard et al., 2016). E2E ST is a cross-modal task, where the major challenges include parallel ST data scarcity and representation discrepancy between speech and text modalities. In order to boost E2E ST training, the techniques utilized by existing approaches include pretraining (Wang et al., 2020b; Xu et al., 2021), multi-task learning (Ye et al., 2021; Tang et al., 2021a), knowledge distillation (Liu et al., 2019; Inaguma et al., 2021), and cross-modal representation learning (Ye et al., 2022; Wang et al., 2022; Fang and Feng, 2023b). However, most methods are far from being widely used due to the sophisticated model architecture, complicated algorithm implementation, and tedious hyperparameter search.

Consistency regularization has been widely adopted and shown great promise to improve NMT performance (Sato et al., 2019; Chen et al., 2021; Liang et al., 2021; Gao et al., 2022, 2023). Specifically, Liang et al. (2021) introduce an intra-lingual consistency, R-Drop, to regularize dropout and improve the supervised NMT performance, and Gao et al. (2023) propose a cross-lingual consistency, CrossConST, to learn universal representations and boost the zero-shot NMT performance. Given the similar problem formulations between NMT and E2E ST, a natural question arises: *Can we significantly improve E2E ST performance by leveraging simple consistency regularization?*

In this paper, our primary goal is to provide a simple, easy-to-reproduce, but tough-to-beat strategy for learning E2E ST models. Inspired by Liang et al. (2021) and Gao et al. (2023), we propose two strategies, SimRegCR and SimZeroCR, for training E2E ST models in regular and zero-shot scenarios. We show that intra-modal consistency is crucial for the regular setting, and cross-modal consistency is the key to closing the modality gap and boosting the zero-shot performance. The contributions of this paper can be summarized as follows:

- We conduct empirical studies on consistency regularization and propose two simple but effective strategies for learning E2E ST models in regular and zero-shot scenarios.
- Experimental results show that our approaches achieve significant improvements on the MuST-C benchmark and outperform the current SOTA methods CRESS (Fang and Feng, 2023b) and DCMA (Wang et al., 2022).

2 Background

2.1 End-to-End Speech-to-Text Translation

Speech translation corpora usually contain speech-transcription-translation triples, which can be denoted as $\mathcal{S} = \{\mathbf{s}^i, \mathbf{x}^i, \mathbf{y}^i\}_{i=1}^{|\mathcal{S}|}$. $\mathbf{s}$ denotes the sequence of the audio wave, $\mathbf{x}$ is the transcription in the source language, and $\mathbf{y}$ represents the translation in the target language. $\mathcal{S}$ could be pairwise combined into three parallel corpora, $\mathcal{S}_{asr} = \{\mathbf{s}^i, \mathbf{x}^i\}_{i=1}^{|\mathcal{S}|}$, $\mathcal{S}_{mt} = \{\mathbf{x}^i, \mathbf{y}^i\}_{i=1}^{|\mathcal{S}|}$, and $\mathcal{S}_{st} = \{\mathbf{s}^i, \mathbf{y}^i\}_{i=1}^{|\mathcal{S}|}$, for ASR, MT, and ST tasks respectively. The goal of E2E ST is to generate translation $\mathbf{y}$ directly from the speech $\mathbf{s}$ without generating transcription $\mathbf{x}$, and the standard training objective is to minimize the empirical risk:

$$\mathcal{L}_{ce}^{st}(\theta) = \ell(f(\mathbf{s}, \mathbf{y}; \theta), \ddot{\mathbf{y}}), \quad (1)$$

where ℓ denotes the cross-entropy loss, θ is a set of model parameters, $f(\mathbf{s}, \mathbf{y}; \theta)$ is a sequence of probability predictions, and $\ddot{\mathbf{y}}$ is a sequence of one-hot label vectors for $\mathbf{y}$. Directly modeling the speech-to-text mapping is nontrivial due to the representation discrepancy between speech and text modalities. To alleviate ST data sparsity, people usually include ASR and MT supervisions from $\mathcal{S}_{asr}$ and $\mathcal{S}_{mt}$ as well as external corpora for E2E ST tasks.

2.2 Consistency Regularization for Neural Machine Translation

Liang et al. (2021) propose an intra-lingual consistency regularization, R-Drop, for boosting NMT performance by forcing the output distributions of different sub-models generated by dropout to be consistent with each other. For each sentence pair $(\mathbf{x}, \mathbf{y})$, the training objective is defined as:

$$\mathcal{L}_{R-Drop}(\theta) = \mathcal{L}_{ce}^{mt}(\theta) + \alpha \mathcal{L}_{intra}^{mt}(\theta), \quad (2)$$

where

$$\mathcal{L}_{ce}^{mt}(\theta) = \ell(f(\mathbf{x}, \mathbf{y}; \theta), \ddot{\mathbf{y}}), \quad (3)$$

$$\mathcal{L}_{intra}^{mt}(\theta) = \mathrm{JS}(f_1(\mathbf{x}, \mathbf{y}; \theta), f_2(\mathbf{x}, \mathbf{y}; \theta)), \quad (4)$$

$f_1(\cdot)$ and $f_2(\cdot)$ denote the two forward passes of the same model $f(\cdot)$ with the dropout operation, $\mathrm{JS}(\cdot, \cdot)$ is the Jeffreys (JS) divergence[1] of two distributions,

$$\mathrm{JS}(a, b) = (\mathrm{KL}(a \| b) + \mathrm{KL}(b \| a))/2, \quad (5)$$

$\mathrm{KL}(\cdot \| \cdot)$ denotes the Kullback-Leibler (KL) divergence, and α is a scalar hyperparameter.

[1]Note that definitions of Jeffreys divergence often omit the factor of $\frac{1}{2}$.

Gao et al. (2023) introduce a cross-lingual consistency regularization, CrossConST, for bridging the representation gap among different languages and improving zero-shot translation in multilingual NMT. For each sentence pair $(\mathbf{x}, \mathbf{y})$, the training objective is defined as:

$$\mathcal{L}_{CrossConST}(\theta) = \mathcal{L}_{ce}^{mt}(\theta) + \beta \mathcal{L}_{cross}^{mt}(\theta), \quad (6)$$

where

$$\mathcal{L}_{cross}^{mt}(\theta) = \mathrm{KL}(f(\mathbf{x}, \mathbf{y}; \theta) \| f(\mathbf{y}, \mathbf{y}; \theta)), \quad (7)$$

and β is a scalar hyperparameter.

3 Datasets and Baseline Settings

3.1 Dataset Description

We initially consider en→de translation for empirical study on consistency regularization in Section 4 and then show further experiments for other translation directions in Section 5. The detailed statistics of all datasets are summarized in Table 9.

3.1.1 ST Datasets

We conduct experiments on MuST-C (Di Gangi et al., 2019), which is a multilingual speech translation dataset containing audio recordings with the corresponding transcriptions and translations from English (en) to 8 languages: German (de), Spanish (es), French (fr), Italian (it), Dutch (nl), Portuguese (pt), Romanian (ro), and Russian (ru). We use dev and tst-COMMON as the validation and test sets respectively.

3.1.2 MT Datasets

We utilize external MT datasets to boost the E2E ST performance. Specifically, we incorporate WMT13 (Bojar et al., 2013) dataset for en→es, WMT14 (Bojar et al., 2014) dataset for en→fr, WMT16 (Bojar et al., 2016) datasets for en→de/ro/ru, and OPUS100 (Zhang et al., 2020) datasets for en→it/nl/pt. Note that we also use dev and tst-COMMON in the MuST-C dataset as the validation and test sets for the MT tasks.

3.2 Baseline Settings

We adopt a widely used baseline model, W2V2-Transformer (Ye et al., 2021) in our empirical study (Figure 1), which consists of a learnable acoustic feature extractor before two 1-dimensional convolutional layers and the standard Transformer architecture (Vaswani et al., 2017). We use different language tags at the decoder input to distinguish

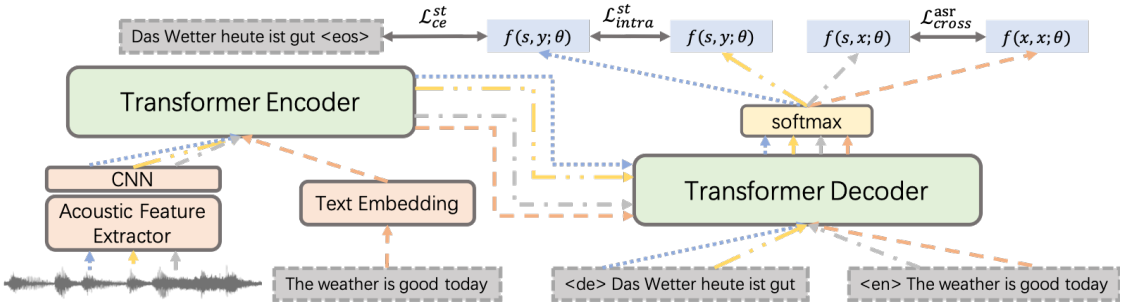

Figure 1: Illustration of the intra-modal and cross-modal consistency regularization. For $\mathcal{L}_{intra}^{st}(\theta)$, the Speech-German pair (Speech, "Das Wetter heute ist gut") goes through the E2E ST model twice and obtains two output distributions $f(\mathbf{s}, \mathbf{y}; \theta)$. For $\mathcal{L}_{cross}^{asr}(\theta)$, the original Speech-English pair (Speech, "The weather is good today") and the copied English-English pair ("The weather is good today", "The weather is good today") go through the E2E ST model and the NMT model respectively and obtain two output distributions $f(\mathbf{s}, \mathbf{x}; \theta)$ and $f(\mathbf{x}, \mathbf{x}; \theta)$.

the target languages. During inference, the language tag serves as the initial token to predict the output text. For example, if the speech input for the sentence "The weather is good today" is in English, to perform ASR, we use <en> as the initial token and decode "The weather is good today", while to translate into German, we use <de> as the initial token and decode "Das Wetter heute ist gut".

Pre-processing For speech input, we utilize the raw 16-bit 16kHz mono-channel audio wave. Following common practice, utterances with less than 1000 frames are removed, and utterances with more than 480000 frames are removed in the training set for GPU efficiency. For each translation direction, we jointly learn a unigram SentencePiece (Kudo and Richardson, 2018) model with size 10K on both the source and target sentences and use it to segment sentences into subwords for MT and ST tasks. For the external MT datasets, we filter out parallel sentences which length ratio exceeds 1.5.

Model Configuration We use wav2vec2.0[2] (Baevski et al., 2020) as the acoustic feature extractor, which is pretrained on the audio data from LibriSpeech (Panayotov et al., 2015). Two 1-dimensional convolutional layers are added following the acoustic feature extractor, with kernel size 5, stride size 2, padding 2, and hidden dimension 1024. We utilize 6-layer transformer encoder and 6-layer transformer decoder. Each of the transformer layers comprises 512 hidden units, 8 attention heads, and 2048 feed-forward hidden units.

Training Configuration We apply cross-entropy loss with label smoothing rate 0.1 and set max tokens per batch to be 4096 for the MT task and 2000000 for the ASR and ST tasks. We use the Adam optimizer with Beta $(0.9, 0.98)$, 4000, 8000, and 4000 warmup updates, and inverse square root learning rate scheduler with initial learning rate $1e^{-4}$, $1e^{-3}$, and $1e^{-4}$ for the ASR, MT, and ST tasks respectively. We apply the same configuration in each stage of the training procedure. During inference, we use beam search decoding with a beam size of 8 with length penalty 1.2, 0.6, 1.8, 1.0, 1.0, 1.4, 1.4, and 0.8 for en→de, es, fr, it, nl, pt, ro, and ru, respectively. We evaluate the MT and ST tasks by case-sensitive sacreBLEU (Post, 2018). We train all models until convergence on 8 NVIDIA Tesla V100 GPUs. For all the experiments below, we select the saved model state with the best validation performance.

4 Methodology

In this section, we formally propose SimRegCR and SimZeroCR, the consistency-based strategies for learning E2E ST models in regular (Section 4.1) and zero-shot (Section 4.2) scenarios respectively. We introduce the details of each part below.

4.1 Consistency Regularization for Regular End-to-End Speech Translation

We here investigate the performance of consistency regularization for the regular scenario, where we learn the E2E ST model by utilizing MT and ST datasets. For each training sample, the loss functions include: $\mathcal{L}_{ce}^{mt}(\theta)$, $\mathcal{L}_{intra}^{mt}(\theta)$, $\mathcal{L}_{ce}^{st}(\theta)$,

$$\mathcal{L}_{intra}^{st}(\theta) = \text{JS}(f_1(\mathbf{s}, \mathbf{y}; \theta), f_2(\mathbf{s}, \mathbf{y}; \theta)), \quad (8)$$

and

$$\mathcal{L}_{cross}^{mt-st}(\theta) = \text{KL}(f(\mathbf{x}, \mathbf{y}; \theta) \| f(\mathbf{s}, \mathbf{y}; \theta)), \quad (9)$$

Table 1: Case-sensitive detokenized BLEU scores on the MuST-C en→de tst-COMMON set. † denotes the MT training is performed on the WMT16 dataset, and other MT training is performed on the MuST-C dataset. We mark the best ST BLEU scores in two experimental setups in bold. The choices for α and β are summarized in Table 10. Experimental results on more languages are summarized in Table 12.

where (1) and (3) are the cross-entropy loss for the ST and MT tasks respectively, (4) and (8) are the intra-modal consistency regularization for the MT and ST tasks respectively, and (9) denotes the cross-modal consistency regularization between the MT and ST tasks, which could also be regarded as the sequence-level knowledge distillation from the MT model to the ST model (Liu et al., 2019).

4.1.1 Experimental Results

We consider two experimental setups: without external MT data (① - ⑫) and with external MT data (⑬ - ⑲), and summarize the experimental results in Table 1. For each experiment in Table 1, we conduct a careful grid search to select the best hyperparameters, α and β, for the model performance. Note that ⑤ and ⑰ correspond to the W2V2-Transformer baselines in the settings of without and with external MT data respectively. By checking model performance under different combinations of loss function and training strategy, we have the following observations: 1) The intra-modal consistency, $\mathcal{L}_{intra}^{mt}$ and $\mathcal{L}_{intra}^{st}$, could boost the MT (① vs ② ; ⑬ vs ⑭) and ST (③ vs ④) performance. 2) The paradigm of pretraining-finetuning could further improve the ST performance (③ vs ⑤ ; ④ vs ⑦). 3) The multi-task learning achieves similar performance compared with the pretraining-finetuning strategy (③ vs ⑧ ; ⑤ vs ⑨). 4) The cross-modal consistency, $\mathcal{L}_{cross}^{mt-st}$, could improve the ST performance (⑨ vs ⑩ ; ⑪ vs ⑫) but still achieve the sub-optimal performance (⑦ vs ⑫).

4.1.2 Does Intra-modal Consistency Implicitly Bridge the Modality Gap?

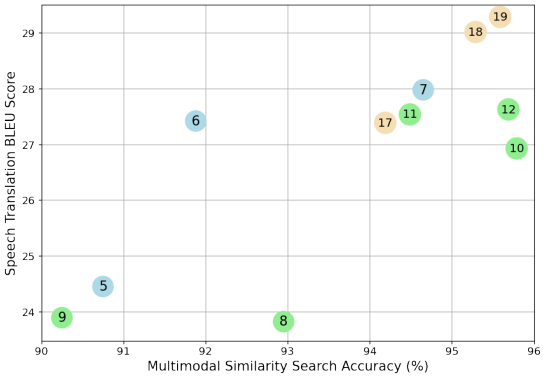

Figure 2: The ST BLEU score and similarity search accuracy of each model in Table 1 on the MuST-C en→de tst-COMMON set. The blue circles denote the pretraining-finetuning experiments without external MT data. The green circles denote the multi-task learning experiments without external MT data. The orange circles denote the experiments with external MT data.

One interesting finding from the empirical study is that the strategies (⑦ and ⑲) only utilizing the intra-modal consistency achieve the best ST performance instead of explicitly leveraging the cross-modal consistency. We here investigate

the impact of the consistency regularization on the modality gap and the E2E ST performance. We conduct a multimodal similarity search experiment and use the averaged bidirectional similarity search accuracy as the metric to evaluate the modality gap. Given parallel speech-transcription pairs, we find the nearest neighbor for each one in the other modality according to the representation cosine similarity and compute the corresponding accuracy, where the speech and transcription representations are calculated by max-pooling the encoder outputs. The evaluation results are reported in Figure 2. By checking the relationship between ST BLEU score and multimodal similarity search accuracy, we have the following observations: 1) The intra-modal consistency, $\mathcal{L}^{mt}_{intra}$ and $\mathcal{L}^{st}_{intra}$, implicitly closes the modality gap (⑤ vs ⑥ vs ⑦ ; ⑰ vs ⑱ vs ⑲). 2) The cross-modal consistency, $\mathcal{L}^{mt-st}_{cross}$, explicitly bridges the modality gap (⑨ vs ⑩ ; ⑪ vs ⑫). 3) A closer modality gap does not guarantee a better ST performance (⑥ vs ⑩ ; ⑦ vs ⑫), and the regularization effect introduced by the intra-modal consistency seems to be more crucial for the regular E2E ST task. This empirical evidence aligns with the insight from Han et al. (2023) which posits that modality adaptation efforts do not significantly boost the performance of fully trained models. Overfitting emerges as a more pressing concern, and effective regularization techniques become paramount for regular E2E ST.

4.1.3 Training Strategy

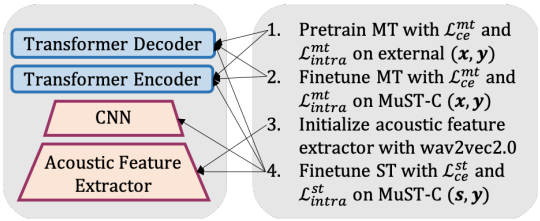

Figure 3: The training steps of SimRegCR by utilizing the intra-modal consistency regularization. In each step, the modules that contribute to the final E2E ST model are pointed out by arrow lines. We also consider SimRegCR$^-$ (⑱ in Table 1) in this paper, which trains MT model only with $\mathcal{L}^{mt}_{ce}$ in the first two steps.

We here summarize the multi-stage training strategy, SimRegCR (⑲ in Table 1), consisting of MT pretraining and ST finetuning with the intra-modal consistency regularization in Figure 3. The setting without external MT data only differs by removing the first step of external MT pretraining.

Method	BLEU	
	w/o WMT16	w/ WMT16
XSTNet†	25.2	27.1
STEMM†	25.6	28.7
ConST†	25.7	28.3
CMOT†	27.0	29.0 / 28.5*
CRESS†	27.2	**29.4** / 28.9*
W2V2-Transformer	24.4	27.3
+ SimRegCR$^-$	27.4	29.0
+ SimRegCR	**27.9**	29.2

Table 2: Our method achieves the superior or comparable performance over the existing methods on the MuST-C en→de benchmark. $*$ denotes the performance of CMOT and CRESS using wav2vec2.0 instead of HuBERT as the acoustic feature extractor. † denotes the numbers are reported from the corresponding papers, others are based on our runs.

Comparison with Existing Methods We summarize the recent results of several existing works on the MuST-C en→de benchmark in Table 2. The existing methods vary from different aspects, including cross-modal progressive training (XSTNet) (Ye et al., 2021), cross-modal manifold mixup (STEMM) (Fang et al., 2022), cross-modal contrastive learning (ConST) (Ye et al., 2022), cross-modal mixup via optimal transport (CMOT) (Zhou et al., 2023), and cross-modal regularization with scheduled sampling (CRESS) (Fang and Feng, 2023b). Note that XSTNet, STEMM, and ConST adopt wav2vec2.0 as the acoustic feature extractor, while CMOT and CRESS use HuBERT (Hsu et al., 2021) which could achieve slightly stronger baseline. We can see that SimRegCR$^-$ achieves an improvement of 2.35 BLEU score on average over W2V2-Transformer, and SimRegCR achieves the superior or comparable performance over the current SOTA method CRESS that incorporates cross-modal regularization, scheduled sampling, token-level adaptive training, and a stronger acoustic feature extractor.

4.2 Consistency Regularization for Zero-shot End-to-End Speech Translation

We here investigate the performance of consistency regularization for the zero-shot scenario, where we learn the E2E ST model by utilizing ASR and MT datasets. For each training sample, the loss functions include: $\mathcal{L}^{mt}_{ce}(\theta)$, $\mathcal{L}^{mt}_{intra}(\theta)$,

$$\mathcal{L}^{asr}_{ce}(\theta) = \ell(f(\mathbf{s}, \mathbf{x}; \theta), \ddot{\mathbf{x}}), \quad (10)$$

$$\mathcal{L}^{asr}_{intra}(\theta) = \mathrm{JS}(f_1(\mathbf{s}, \mathbf{x}; \theta), f_2(\mathbf{s}, \mathbf{x}; \theta)), \quad (11)$$

ID	Training Stage	Loss Function	MT BLEU	ST BLEU
①	MT train from scratch†	$\mathcal{L}_{ce}^{mt}$	29.61	-
②	MT train from scratch†	$\mathcal{L}_{ce}^{mt} + \alpha\mathcal{L}_{intra}^{mt}$	30.02	-
③	MT Finetune on ①	$\mathcal{L}_{ce}^{mt}$	33.59	-
④	MT Finetune on ②	$\mathcal{L}_{ce}^{mt} + \alpha\mathcal{L}_{intra}^{mt}$	34.11	-
⑤	ASR & MT finetune on ③	$\mathcal{L}_{ce}^{asr} + \mathcal{L}_{ce}^{mt}$	33.99	0.46
⑥	ASR & MT finetune on ③	$\mathcal{L}_{ce}^{asr} + \mathcal{L}_{ce}^{mt} + \beta\mathcal{L}_{cross}^{asr}$	32.82	**25.10**
⑦	ASR & MT finetune on ④	$\mathcal{L}_{ce}^{asr} + \alpha\mathcal{L}_{intra}^{asr} + \mathcal{L}_{ce}^{mt} + \alpha\mathcal{L}_{intra}^{mt}$	34.35	0.56
⑧	ASR & MT finetune on ⑦	$\mathcal{L}_{ce}^{asr} + \alpha\mathcal{L}_{intra}^{asr} + \mathcal{L}_{ce}^{mt} + \alpha\mathcal{L}_{intra}^{mt} + \beta\mathcal{L}_{cross}^{asr}$	33.25	24.86

Table 3: Case-sensitive detokenized BLEU scores on the MuST-C en→de tst-COMMON set. † denotes the MT training is performed on the WMT16 dataset, and other MT training is performed on the MuST-C dataset. We mark the best ST BLEU score in bold. The choices for α and β are summarized in Table 11.

and

$$\mathcal{L}_{cross}^{asr}(\theta) = \mathrm{KL}(f(\mathbf{s}, \mathbf{x}; \theta) \| f(\mathbf{x}, \mathbf{x}; \theta)), \quad (12)$$

where (3) and (10) are the cross-entropy loss for the MT and ASR tasks respectively, (4) and (11) are the intra-modal consistency regularization for the MT and ASR tasks respectively, and (12) denotes the cross-modal consistency regularization for the ASR task, which could be regarded as the multimodal version of CrossConST (Gao et al., 2023).

4.2.1 Experimental Results

We consider the experimental setup with external MT data and summarize the experimental results in Table 3. For each experiment in Table 3, we conduct a careful grid search to select the best hyperparameters, α and β, for the model performance. Note that ⑤ corresponds to the W2V2-Transformer baseline. By checking model performance under different combinations of loss function and training strategy, we have the following observations: 1) The cross-modal consistency, $\mathcal{L}_{cross}^{asr}$, could boost the zero-shot ST performance (⑤ vs ⑥ ; ⑦ vs ⑧). 2) Leveraging the intra-modal consistency, $\mathcal{L}_{intra}^{asr}$ and $\mathcal{L}_{intra}^{mt}$, could improve the corresponding MT performance (⑤ vs ⑦ ; ⑥ vs ⑧), but could not achieve the superior performance in the zero-shot ST direction (⑥ vs ⑧).

4.2.2 Does the Cross-modal Consistency Really Close the Modality Gap?

To verify whether the cross-modal consistency regularization can better align the modality representation space, we visualize the speech and transcription representations of the MuST-C en→de tst-COMMON set. We apply dimension reduction on the 512-dimensional representations with T-SNE (Hinton and Roweis, 2002) and then depict the bivariate kernel density estimation based on the 2-dimensional representations in Figure 4. Figure 4 shows that the W2V2-Transformer baseline (⑤) cannot align speech and transcription well in the representation space, while the cross-modal consistency (⑥) draws the representations across different modalities much closer.

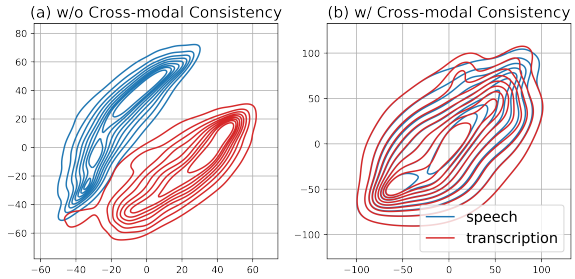

Figure 4: Bivariate kernel density estimation plots of the speech and transcription representations after using T-SNE dimensionality reduction, where the max-pooled outputs of the W2V2-Transformer encoder are applied as the speech and transcription representations.

4.2.3 Training Strategy

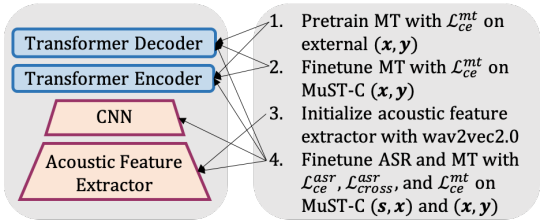

Figure 5: The training steps of SimZeroCR by utilizing the cross-modal consistency regularization. In each step, the modules that contribute to the final E2E ST model are pointed out by arrow lines.

We here summarize the multi-stage training strategy, SimZeroCR (⑥ in Table 3), consisting of MT pretraining and ASR & MT finetuning with the cross-modal consistency regularization in Figure 5.

Table 5: Our method achieves superior performance over the existing methods on the MuST-C en→de benchmark. † denotes the numbers are reported from Wang et al. (2022), others are based on our runs.

Comparison with Existing Methods We summarize the recent results of several existing works on MuST-C en→de benchmark in Table 5. The existing methods vary from different aspects, including language-specific encoders-decoders architecture (MultiSLT) (Escolano et al., 2021), continuous cross-modal alignment (Chimera) (Han et al., 2021), and discrete cross-modal alignment (DCMA) (Wang et al., 2022). SimZeroCR achieves an improvement of 24.6 BLEU score over W2V2-Transformer and outperforms the current SOTA method DCMA[3] that incorporates shared memory and vector quantization modules.

5 Experiments on More Languages

5.1 Regular End-to-End Speech Translation

We consider two experimental setups: without external MT data and with external MT data. The detailed information on the baseline methods is summarized in Appendix D, and the BLEU scores of the baseline methods are reported from the corresponding papers. The choice for hyperparameters and the corresponding model performance in each training step of our approaches are summarized in Tables 13, 14, 15, and 16.

When there is no external MT data (Table 4), SimRegCR$^-$ gains an average improvement of 2.6 BLEU scores over the W2V2-Transformer baseline and can achieve comparable performance to the current SOTA method CRESS. It is also worth mentioning that SimRegCR gains an average improvement of 3.1 BLEU scores over the W2V2-Transformer baseline and achieves an average improvement of 0.6 BLEU scores over CRESS that incorporates cross-modal regularization, scheduled sampling, token-level adaptive training, and a stronger acoustic feature extractor, which clearly shows the effectiveness of our methods. When external MT data is included (Table 6), SimRegCR$^-$ and SimRegCR gain average improvement of 1.7 and 2.2 BLEU scores over the W2V2-Transformer baseline respectively, and SimRegCR achieves an average improvement of 0.2 BLEU scores over CRESS, which implies that we could easily achieve SOTA performance for E2E ST task by leveraging simple intra-modal consistency regularization.

5.2 Zero-shot End-to-End Speech Translation

The experimental results with external MT data are summarized in Table 7. For fair comparisons, we keep our experimental settings consistent with Wang et al. (2022) to use WMT14 dataset for

[3]Note that the external MT dataset and the inference configurations used in this section are slightly different from those used in Wang et al. (2022). Please check the experimental results in Section 5.2 for more fair comparisons.

+ SimRegCR$^-$	✓	29.0	33.0	39.4	27.3	32.2	33.5	26.0	19.4
+ SimRegCR	✓	29.2*	33.0*	40.0*	**28.2***	**32.7***	**34.2***	**26.7***	**20.1***

Table 6: Case-sensitive detokenized BLEU scores on MuST-C tst-COMMON set with external MT datasets. "External speech" denotes unlabeled speech data. † is a speech-unit-text pretraining model whose training costs are much higher than ours. * indicates the improvements over W2V2-Transformer are statistically significant with $p < 0.01$. The highest BLEU scores are marked in bold for all methods in each column.

en→de/es/fr/ru as the external MT data[4]. During inference, we use beam search decoding with a beam size of 5 with length penalty 1.0. The detailed information on the baseline methods is summarized in Appendix E, and the corresponding BLEU scores are reported from Wang et al. (2022). The choice for hyperparameters and the corresponding model performance in each training step of our approach are summarized in Table 17.

Method	BLEU de	es	fr	ru
MultiSLT	6.8	6.8	10.9	-
Chimera	13.5	15.3	22.2	8.3
DCMA	24.0	26.2	33.1	**16.0**
W2V2-Transformer	0.5	0.4	0.4	0.1
+ SimZeroCR	**25.1**	**27.0**	**34.6**	15.6

Table 7: Case-sensitive detokenized BLEU scores on MuST-C tst-COMMON set with external MT datasets in zero-shot E2E ST setting. The highest BLEU scores are marked in bold for all methods in each column.

Despite the language tag is properly set during inference, W2V2-Transformer is still not capable of translating into specific language and only generating English text. We can see that SimZeroCR gains an average improvement of 25.2 BLEU scores over the W2V2-Transformer baseline and achieves an average improvement of 0.8 BLEU scores over the current SOTA method DCMA that incorporates shared memory and vector quantization modules, clearly showing the effectiveness of our method.

[4]We only use europarl v7, commoncrawl, and news commentary subsets of WMT14 dataset for en→fr.

Method	BLEU de	fr	ru
Cascaded System			
Ye et al. (2021)	25.2	34.9	17.0
Wang et al. (2022)	26.7	-	-
Fang et al. (2022)	27.5	-	-
Zero-Shot End-to-End Model			
W2V2-Transformer	0.5	0.4	0.1
+ SimZeroCR	25.1	34.6	15.6

Table 8: Case-sensitive detokenized BLEU scores on MuST-C tst-COMMON set.

We then compare our approach with several strong cascaded systems in Table 8. The cascaded system transforms the speech into the source language text and then translates the transcription into the target language. We can see that our zero-shot approach achieves comparable or slightly worse performance to those cascaded systems which however suffer from high inference latency.

6 Related Work

E2E ST is a cross-modal task, and one major challenge is direct ST data scarcity. To address such problem, people usually adopt MT data by leveraging the techniques such as pretraining (Bansal et al., 2019; Alinejad and Sarkar, 2020; Le et al., 2021; Tang et al., 2022), multi-task learning (Le et al., 2020; Dong et al., 2021; Indurthi et al., 2021), knowledge distillation (Liu et al., 2019; Gaido et al., 2020; Inaguma et al., 2021), and data augmentation (Lam et al., 2022; Fang and Feng, 2023a). Due to the representation discrepancy between speech and text modalities, people also utilize cross-modal

alignment (Han et al., 2021; Fang et al., 2022; Ye et al., 2022; Ouyang et al., 2023) to fully exploit MT data. Specifically, Wang et al. (2022) employ a shared discrete vocabulary space to accommodate both modalities of speech and text and achieve SOTA performance in the zero-shot setting. We show that the zero-shot E2E ST performance could be boosted by leveraging simple cross-modal consistency regularization. Fang and Feng (2023b) propose the cross-modal regularization with scheduled sampling method to bridge the modality gap and achieve the SOTA performance in the regular setting. We find that the regularization is more crucial than modality adaption, which is in line with Han et al. (2023), and achieve the SOTA performance in the regular setting by leveraging simple intra-modal consistency regularization.

7 Conclusion

In this paper, we propose two simple but effective consistency regularization based strategies for learning E2E ST models. We analyze the regularization effect of SimRegCR on the regular E2E ST performance and show that SimZeroCR could effectively close the modality gap. Experiments on the MuST-C benchmark demonstrate the capabilities of our approaches to improve translation performance in both regular and zero-shot settings. Given the universality and simplicity of SimRegCR and SimZeroCR, we believe they can serve as strong baselines for future E2E ST research. For future work, we will explore the effectiveness of consistency regularization on more speech related tasks, such as speech-to-speech translation, speech language modeling, etc.

Limitations

While our approach achieves promising performance by leveraging simple consistency regularization, it still has some limitations: 1) The performance of our approach still lags behind SpeechUT, although the training cost of our approach is much lower. 2) We mainly focus on evaluating our approach on the MuST-C benchmark in this paper. Future research could consider more speech translation benchmarks with more diverse languages, larger ST datasets, and larger models.

- **Fairseq ST** (Wang et al., 2020a): Fairseq ST is a fairseq extension[5] for speech-to-text modeling tasks such as speech translation, which includes end-to-end workflows and SOTA models with scalability and extensibility design.
- **Dual Decoder** (Le et al., 2020): This paper introduces a dual-decoder Transformer architecture for synchronous speech recognition and multilingual speech translation.
- **Speechformer** (Papi et al., 2021): This paper introduces a Transformer-based ST model that is able to encode the whole raw audio features without any sub-optimal initial sub-sampling.
- **SATE** (Xu et al., 2021): This paper proposes a stacked acoustic-and-textual encoding method, which is straightforward to incorporate the pre-trained models into ST.
- **BiKD** (Inaguma et al., 2021): To fully leverage knowledge in both source and target language directions for bilingual E2E ST models, this paper proposes bidirectional sequence-level knowledge distillation, in which both forward sequence-level knowledge distillation from a source-to-target NMT model and backward sequence-level knowledge distillation from a target-to-source NMT model are combined.
- **XSTNet** (Ye et al., 2021): This paper proposes cross speech-text network, an extremely concise model that can accept bi-modal inputs and jointly train ST, ASR, and MT tasks.
- **MTL** (Tang et al., 2021b): This paper proposes a general multi-task learning framework to leverage text data for ASR and ST tasks.
- **JT-S-MT** (Tang et al., 2021a): This paper proposes three techniques to increase knowledge transfer from the MT task to the ST task, which include parameter sharing and initialization strategy to improve the information sharing between tasks, cross-attentive regularization and online knowledge distillation to encourage the ST system to learn more from the auxiliary MT task and then generate similar model representations from different modalities.
- **STEMM** (Fang et al., 2022): This paper proposes a speech-text manifold mixup method to mix up the speech representation sequences and word embedding sequences.
- **ConST** (Ye et al., 2022): This paper proposes a simple yet effective contrastive learning framework bridging the speech-text representation gap and facilitating the ST with limited data.
- **SpeechUT** (Zhang et al., 2022): This paper proposes a unified-modal speech-unit-text pretraining model, which bridges the modality gap between speech and text representations with hidden units.
- **WACO** (Ouyang et al., 2023): This paper proposes a simple and effective method for extremely low-resource speech-to-text translation, where the key idea is bridging word-level representations for both speech and text modalities via contrastive learning.
- **M^{3}ST** (Cheng et al., 2023): This paper proposes a method to mix the training corpus at three levels, including word level, sentence level and frame level.
- **FCCL^m** (Zhang et al., 2023): This paper proposes a cross-modal multi-grained contrast learning method for explicit knowledge transfer from the MT to the ST model.

Unleashing the Emergent Cognitive Synergy in Large Language Models: A Task-Solving Agent through Multi-Persona Self-Collaboration

Abstract

Human intelligence thrives on cognitive synergy, where collaboration among different minds yield superior outcomes compared to isolated individuals. In this work, we propose **Solo Performance Prompting (SPP)**, which transforms a single LLM into a **cognitive synergist** by engaging in multi-turn self-collaboration with multiple personas. A cognitive synergist is an intelligent agent that collaboratively combines multiple minds' strengths and knowledge to enhance problem-solving in complex tasks. By dynamically identifying and simulating different personas based on task inputs, SPP unleashes the potential of cognitive synergy in LLMs. Our in-depth analysis shows that assigning multiple fine-grained personas in LLMs improves problem-solving abilities compared to using a single or fixed number of personas. We evaluate SPP on three challenging tasks: Trivia Creative Writing, Codenames Collaborative, and Logic Grid Puzzle, encompassing both **knowledge-intensive** and **reasoning-intensive** types. Unlike previous works, such as Chain-of-Thought, that solely enhance the reasoning abilities in LLMs, experimental results demonstrate that SPP effectively reduces factual hallucination, and maintains strong reasoning capabilities. Additionally, comparative experiments show that cognitive synergy only **emerges** in GPT-4 and does not appear in less capable models, such as GPT-3.5-turbo and Llama2-13b-chat, which draws an interesting analogy to human development. Code, data, and prompts can be found at: https://github.com/MikeWangWZHL/Solo-Performance-Prompting.git

1 Introduction

Although large language models (LLMs) have demonstrated impressive performance as general task-solving agents, they still encounter challenges (Qin et al., 2023; Bang et al., 2023; OpenAI, 2023b; Bubeck et al., 2023) in various knowledge-intensive and reasoning-intensive tasks due to factual hallucination (Maynez et al., 2020) and a lack of slow-thinking (Sloman, 1996) capabilities. Unlike humans, who can leverage the power of collaboration and information integration among different cognitive processes and individuals (referred to as *cognitive synergy* (Curşeu et al., 2015; Goertzel, 2009, 2017)), current LLMs are akin to "jack-of-all-trades" with a vast mixture of knowledge and characteristics. Recent advancements, such as Chain-of-Thought (CoT) prompting (Wei et al., 2023; Kojima et al., 2022) and Self-refinement (Madaan et al., 2023; Shinn et al., 2023), have successfully enhanced the reasoning abilities of LLMs by simulating slow-thinking through the generation of intermediate steps or iterative revision. However, factual hallucination remains a major challenge for LLMs on knowledge-intensive tasks.

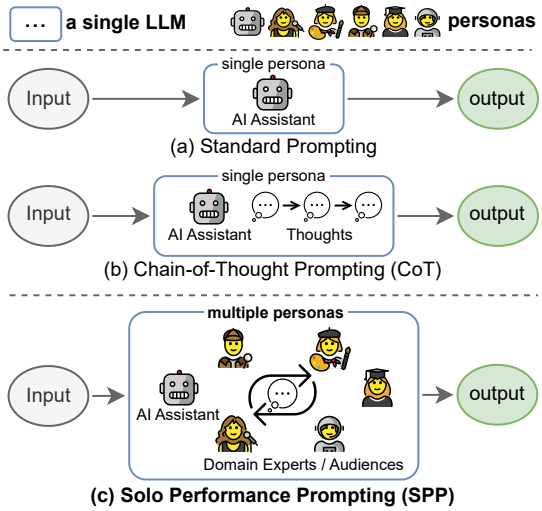

Figure 1: Schematic illustration of Solo Performance Prompting (SPP) and the difference compared to previous prompting methods.

A cognitive synergist is an intelligent agent

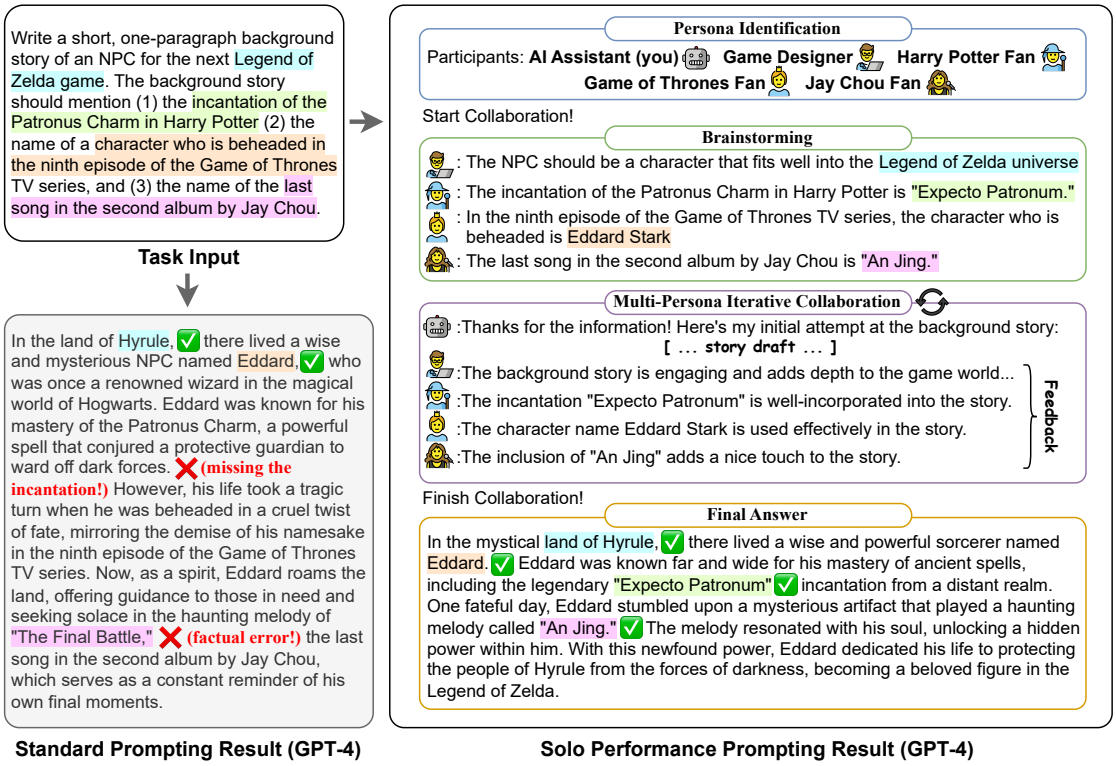

Figure 2: Task-solving example of Solo Performance Prompting (SPP) with GPT-4. The personas of the participants are automatically identified by GPT-4 based on the task input. This example shows that Standard Prompting suffers from factual errors, whereas SPP provides accurate information and a coherent answer. Note that, in real-world applications, the domains can vary not only within entertainment but also encompass history, science, education, healthcare, etc.

that collaborates with multiple minds to enhance problem-solving and efficacy in complex tasks. In this work, we aim to **create a cognitive synergist based on a single LLM** that can *"split into" multiple personas and engage in self-collaboration to solve both knowledge-intensive and reasoning-intensive tasks*. This idea is heavily inspired by the role of pretend play (Piaget, 1954; Pellegrini, 2009) in cognitive development and recent findings that assigning personas (Deshpande et al., 2023; Xu et al., 2023) to LLMs can elicit specific behaviors, improve answer quality, and potentially build an AI society (Park et al., 2023; Schick et al., 2022; Li et al., 2023; Cai et al., 2023) with collaborative LLM agents. However, as shown in Table 1, previous works have limitations such as fixed or task-specific personas, the need for additional fine-tuning, and increased inference costs due to multiple LLM instances.

To unleash the potential of cognitive synergy for general task-solving, we propose **Solo Performance Prompting (SPP)**, which *prompts a single LLM to identify, simulate, and collaborate with multiple personas*. Figure 1 provides a high-level overview of SPP. Here, a persona can represent either a domain expert, such as a movie enthusiast, or a target audience, such as a ten-year-old child. Through the dynamic identification of various personas, we empower a single LLM to acquire diverse domain knowledge accurately without additional retrieval systems. By facilitating multi-turn self-collaboration, we enable self-revision and self-feedback from various perspectives without requiring additional agents.

In real-world scenarios, such as those in creative industries, there is often a need to incorporate diverse information from different domains. Figure 2 presents a concrete example of how SPP operates on a challenging task that requires creative integration of information from various domains, such as the Legend of Zelda game, Harry Potter movies, and Jay Chou's albums. Standard prompting fails to generate satisfactory output due to missing essential information and factual errors. In contrast, SPP produces informative and coherent answers by automatically identifying expert personas and engaging in a multi-turn self-collaboration. In this process, the AI Assistant persona iteratively writes

	General task solving?	Pure zero-shot prompting?	Has multiple personas?	Personas dynamically identified?	Has iterative refinement?	Need only a single LLM?

Table 1: High-level comparison with various prompting-based methods. Methods directly comparable to ours are denoted by †. Results for the comparison can be found in Section 3. In Section 4, we further design and compare with two variants of Solo Performance Prompting: one adopting fixed personas, as in Camel (Li et al., 2023), and another with additional persona profiles, as proposed in ExpertPrompting (Xu et al., 2023).

drafts of the story, solicits feedback from other participants, and revises accordingly.

To explore the prevalence of cognitive synergy in different LLMs, we apply SPP to LLMs with varying scales and capabilities, including GPT-4, GPT-3.5-turbo, and Llama-13b-chat. Comparative results show that cognitive synergy only emerges in GPT-4 and not in less capable models. This draws an interesting analogy to human development, as children typically start engaging in role-playing at the age of 2 to 3 (Piaget, 1954), but not earlier. In summary, the key contributions of this paper are as follows:

- We investigate whether LLMs can leveraging cognitive synergy for general task-solving. We introduce **Solo Performance Prompting (SPP)**, which simulates multi-agent, multi-persona collaboration in a pure zero-shot manner.
- We evaluate SPP across **three challenging tasks**: Trivia Creative Writing, Codenames Collaborative and Logic Grid Puzzle, spanning both knowledge- and reasoning-intensive domains. To our knowledge, SPP is the first zero-shot prompting method that can enhance both knowledge and reasoning abilities on GPT-4.
- We present an intriguing finding regarding the emergent nature of cognitive synergy ability in LLMs, which **only emerges in GPT-4** and not in less powerful models.
- We conduct in-depth analyses of the impact of the identified personas and SPP prompt design, providing insights into why **dynamic, fine-grained personas** are necessary, as opposed to fixed, coarse-grained personas.

2 Solo Performance Prompting

To unleash the power of synergizing different personas to tackle complex problems, we propose Solo Performance Prompting (SPP) which instructs a LLM to perform the following the procedure for general task-solving: **(1) Persona Identification**: Identify multiple participants with special personas (including a leader persona: AI Assistant) that are essential for solving the particular task. **(2) Brainstorming**: The participants share knowledge and provide suggestions on how to approach the task based on their own expertise. **(3) Multi-Persona Iterative Collaboration**: The leader persona, AI Assistant, proposes initial solutions, consults the other participants for feedback, and revise the answer iteratively. Figure 2 shows a walking example of SPP during inference. Next, we formally describe the SPP procedure in detail.

Given an input sequence x and a model $\mathcal{M}$, let a prompt (including demonstration examples) prepended to the input to be p and the final output to be y. Denote an intermediate generation before generating the final y as z. Under this formulation, Standard Prompting and Chain-of-Thought (CoT) Prompting can be described as:

$$\textit{Standard Prompting:} \quad y = \mathcal{M}(x) \tag{1}$$

$$\textit{CoT Prompting:} \quad y = \mathcal{M}(p_{cot} \| x \| \{z_1, z_2, ..., z_n\}) \tag{2}$$

where p_{cot} is the CoT prompt, e.g., `"Solve the task step-by-step"` and $\{z_1, z_2 ..., z_n\}$ are the intermediate steps. In contrast, our proposed Solo Performance Prompting can be described as follows:

$$\textit{Solo Performance Prompting:} \quad y = \mathcal{M}(p_{spp} \| x \| p_p \| \{z_b^1, z_b^2, ..., z_b^m\} \| \{z_s^0, z_f^1, ..., z_f^m\}_{j=1..n}) \tag{3}$$

where the SPP prompt (p_{spp}) includes a high-level instruction and two carefully crafted demonstration examples[1] that showcase the expected task-solving procedure of SPP. We describe the design details of the prompt in **§A.1**. The corresponding intermediate generations (z) of SPP are detailed below.

Persona Identification (z_p). Given an input task, SPP first generates a list of participants with different personas. For example in Figure 2, the model identified a *Jay Chou Fan* persona to help answer "the last song in the second album by Jay Chou". We let the language model identify the personas dynamically instead of manually defining them. Given only two demonstration examples (detailed in §A), we observe that a state-of-the-art large language model, e.g., GPT-4 (OpenAI, 2023b), can identify accurate and meaningful personas for diverse tasks. We denote this part of intermediate generation as z_p in Equation 3.

Brainstorming (z_b^i). Among the identified participants, "AI Assistant (you)" is treated as a leader persona that initiates the collaboration and generates initial solutions. Before generating the initial answer, the personas brainstorm on how to approach the task from their own perspectives. For example, the *Jay Chou Fan* points out that the last song in Jay Chou's second album is "An Jing" ("Silence"). We find that the brainstorming phase effectively improves the quality of the initial solution. In Equation 3, the superscript $i = 0$ is used to denote the "AI Assistant" persona, while $i \geq 1$ represents other dynamically identified personas. The intermediate generations of the brainstorming step are denoted as $\{z_b^1, z_b^2, ..., z_b^m\}$.

Multi-Persona Iterative Collaboration (z_s^0, z_f^i). Based on the brainstorming remarks, the AI Assistant persona generates an initial solution z_s^0, then it consults each of the other participants for feedback $\{z_f^i\}$. The participants are encouraged to critique the current generation and give revision suggestions. For example, the Jay Chou Fan persona checks whether the song "An Jing" ("Silence") is correctly included in the story. This process can be repeated for multiple times until every participant is satisfied with the current solution. In Equation 3, we denote the intermediate generations of the multi-turn dialogue as $\{z_s^0, z_f^1, ..., z_f^m\}_{j=1...n}$ where n is the number of iterations before reaching the final answer. The final answer can be directly read out following user-specified output format.

In summary, SPP instructs an LLM to solve general tasks via multi-persona self-collaboration in a pure zero-shot manner. In contrast, as detailed in Table 1, previous prompting-based methods are either task-specific or require additional mechanism, e.g., searching (Yao et al., 2023), external tools (Yao et al., 2022), memory component (Shinn et al., 2023), and fine-tuning (Xu et al., 2023).

3 Experiments

To explore the effectiveness of Solo Performance Prompting (SPP), we adopt an evaluation methodology similar to that of previous work (Yao et al., 2023). We carefully design new tasks and select tasks from existing benchmarks (Srivastava et al., 2022) that are challenging even for the most capable LLMs (OpenAI, 2023b). The evaluation aims to cover diverse types of tasks encompassing both *knowledge-intensive* and *reasoning-intensive* domains.

Tasks. We invent the **Trivia Creative Writing** task (§3.1), which requires the model to internally acquire and integrate diverse information from various fields. We observe that even GPT-4 (OpenAI, 2023b) frequently exhibit hallucination and factuality errors in the Trivia Creative Writing task. We also propose the **Codenames Collaborative** task (§3.2), an extension of the Codenames task from the BigBench (Srivastava et al., 2022) that features a two-role collaboration setup. Codenames Collaborative demands creative reasoning across a broad range of related knowledge and challenges the model's theory of mind skills. Lastly, we include a challenging pure-reasoning task, **Logic Grid Puzzle** (§3.3), from the BigBench (Srivastava et al., 2022) which necessitates complex multi-step reasoning.

Baselines. We compare our approach with **Standard Prompting**, **Chain-of-Thought (CoT)** prompting methods (outlined in §2) and **Self-Refine** (Madaan et al., 2023). For CoT, a similar prompt design to (Yao et al., 2023) is employed, where the model is prompted to generate a plan or a series of steps before producing the final output. For Self-Refine, we follow (Madaan et al., 2023) to design *feedback* and *refine* prompts. We perform one self-refine iteration which requires three times more inferences than SPP. Full prompts for the methods can be found in Appendix A.2.

[1]The tasks we use in the demonstration examples do not overlap with the evaluation tasks.

Methods	Trivia.C.W (N=5) Score (%)	Δ	Trivia.C.W (N=10) Score (%)	Δ	Codenames.C Score (%)	Δ	Logic.G.Puzzle Score (%)	Δ
Standard	74.6	0.0%	77.0	0.0%	75.4	0.0%	57.7	0.0%
CoT	67.1	↓10.0%	68.5	↓11.1%	72.7	↓3.6%	65.8	↑14.1%

Self-Refine [iter=1]	73.9	↓1.0%	76.9	↓0.1%	64.6	↓14.6%	60.0	↑4.0%
SPP (ours)	**79.9**	**↑7.1%**	**84.7**	**↑10.0%**	**79.0**	**↑4.8%**	**68.3**	**↑18.5%**

Table 2: GPT-4 results on Trivia Creative Writing (Trivia.C.W), Codenames Collaborative (Codenames.C) and Logic Grid Puzzle (Logic.G.Puzzle). Δ indicates the relative gain/loss compared with Standard Prompting (first row). We report the average scores across two individual runs with/without a system message (detailed in Appendix C).

Models. The default model we use is GPT-4 (OpenAI, 2023b). Detailed inference configurations, API versions, and full results can be found in Appendices C and F. In §3.4, we further investigate the prevalence of cognitive synergy in LLMs with different scales and capabilities, including GPT-3.5-turbo (OpenAI, 2023a) and Llama2-13b-chat (Touvron et al., 2023).

3.1 Trivia Creative Writing: A Knowledge-Intensive Task

Task Description. As illustrated in Figure 3, Trivia Creative Writing asks a model to write a coherent story while incorporating the answers to N trivia questions. Our preliminary experiments (Figure 10) show that a sufficiently large N can effectively challenge GPT-4 to demonstrate factual knowledge across diverse domains. Thus, we mainly consider two evaluation settings, $N = 5$ and $N = 10$. We built a benchmark with 100 instances for each N, covering a total of 1000 trivia questions[2] extracted from the TriviaQA (Joshi et al., 2017) dataset. More details can be found in Appendix B.1.

Evaluation Metrics. Evaluating GPT-4 level generation results can be challenging. Our preliminary experiments indicate that, even for humans, it is very difficult to identify which generation is better in terms of overall "quality" of the story from different prompting methods. Thus, instead of focusing on evaluating the coherence of the generation, which can be highly subjective, we employ an automatic metric which focuses on detecting factual hallucinations. As shown in Figure 3, we perform string matching with the ground truth target answers for each question on the output generation. For each question, a match to any of the answer aliases provided by the TriviaQA dataset is considered a correct mention. The metric score is computed as: $\frac{\text{\# correct answer mentions}}{\text{\# trivia questions}}$.

Results. Table 2 presents the results of the Trivia Creative Writing task. The key observations are as follows: (1) Chain-of-Thought (CoT) does not outperform Standard prompting, indicating that CoT is ineffective in eliciting an LLM's knowledge abilities. Qualitative examples in Figure 8 and 11 illustrate that although CoT generates reasonable plans for task resolution, the final generation still contains factual errors and hallucinations. (2) Self-Refine only brings marginal improvements over iterations. (3) SPP outperforms all baselines significantly. The improvement is more pronounced in the $N = 10$ setting compared to $N = 5$ (10% vs. 7%), suggesting that Solo Performance Prompting is particularly beneficial when the task requires incorporating knowledge from numerous domains.

3.2 Codenames Collaborative: A Knowledge+Reasoning Task

Task Description. As illustrated in 4, Codenames Collaborative is a collaborative task that challenges a model's knowledge, reasoning, and theory of mind abilities by assigning two player roles: the *Spymaster* and the *Guesser*. The Spymaster's role is to provide a hint word related to the target words, excluding some other distractor words, while the Guesser's role is to identify the target words based on the given hint and the full list of words. The same LLM (GPT-4 (OpenAI, 2023b)) is used for both roles sequentially, and a dataset with 50 instances is constructed based on BigBench's (Srivastava et al., 2022) Codenames task data.

Evaluation Metrics. The original Codenames task in the BigBench dataset has limitations due to its focus on the Guesser role and subjectivity in hint

[2]To select difficult question instances that can pose challenges to GPT-4, we use a smaller open-source LLM, *fastchat_t5_3b* (Zheng et al., 2023), to obtain preliminary performance on the validation set, and then choose the failure cases as our question selection.

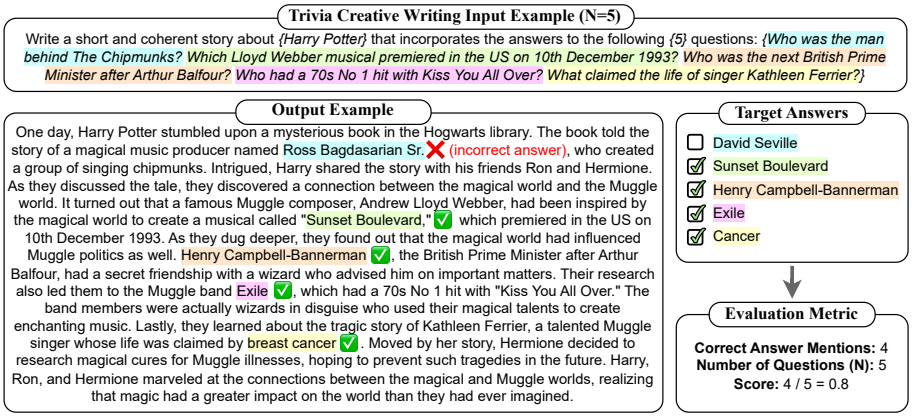

Figure 3: Trivia Creative Writing task example.

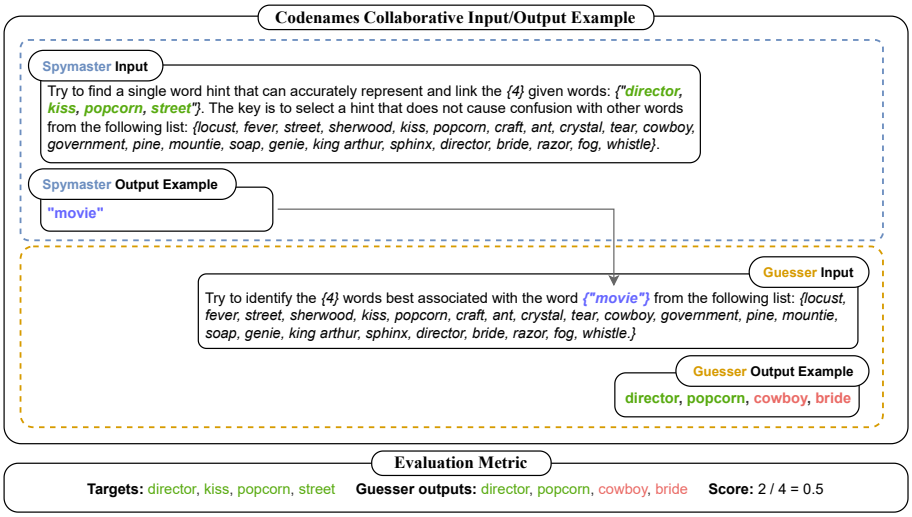

Figure 4: Codenames Collaborative task example.

words. Our new task, Codenames Collaborative, resolves this by creating a self-contained evaluation setting that accurately measures the model's capability without human annotation. As illustrated in Figure 4, we compute the overlapping ratio between the predicted words from the Guesser and the target words as the metric.

Results. Table 2 shows the results on the Codenames Collaborative task. Similar to the Trivia Creative Writing task, we find that CoT does not bring positive gains compared with the Standard prompting. Interestingly, iterative self-refinement brings negative impact on this task, due to a high tendency changing the initial response even if it is already good. In contrast, SPP brings significant improvements (~5%), which indicates its effectiveness on collaborative tasks that require knowledge, reasoning, and theory of mind skills. Figure 12 provides further qualitative examples illustrating that SPP generates *detailed* and *interpretable* intermediate dialogues.

3.3 Logic Grid Puzzle: A Reasoning-Intensive Task

Task Description and Evaluation Metrics We utilize the Logic Grid Puzzle task from the Big-bench (Srivastava et al., 2022) dataset, which comprises 200 instances. Each instance describes a logic puzzle typically involving 2 to 5 houses, with each house inhabited by a person with specific characteristics, such as playing the piano. The objective is to answer questions about house numbers based on given clues, which requires multi-step reasoning and the selection of relevant information. An example input and output of the Logic Grid Puzzle task are illustrated in Figure 5. For evaluation metrics, we calculate the accuracy of the predicted house numbers by comparing them with the ground truth targets provided by the dataset.

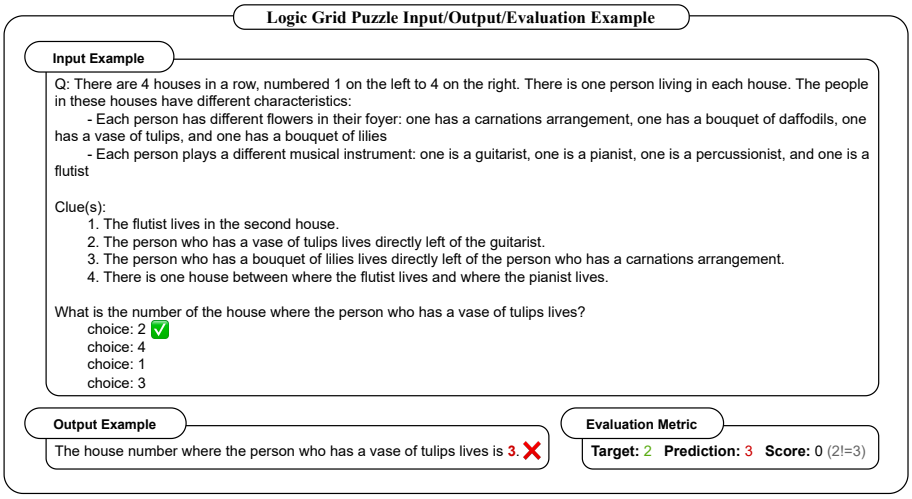

Figure 5: Logic Grid Puzzle task example.

Results. Table 2 presents the results on Logic Grid Puzzle. In contrast to the previous two tasks, we find that CoT brings significant improvements compared to Standard prompting, verifying the observation from previous work that CoT elicits better reasoning abilities. Furthermore, we discover that SPP also achieves strong performance on this reasoning-intensive task.

3.4 The Emergence of Cognitive Synergy

We further discover that **cognitive synergy can only be fully unleashed in LLMs with a certain level of instruction-following capabilities, akin to that of GPT-4.** This can be intriguingly compared to human development, where children usually begin to participate in role-playing around the ages of 2 to 3 (Piaget, 1954), but not before that age.

As shown in Figure 6, the effectiveness of SPP is not seen in smaller and less capable models like GPT-3.5 and Llama2. Additionally, on Llama2, we identify a unique problem which we refer to as *early-termination*, where the model stops generating after identifying the participants, resulting in exceptionally low performance with SPP. The model behaves as if it were waiting for input from a user instead of following the demonstration examples to generate responses on its own. Detailed discussions and examples on the early-termination problem can be found in Appendix E.

4 Analysis

SPP effectively improves both knowledge and reasoning abilities in LLMs. As demonstrated by the results in §3, Solo Performance Prompting (SPP) not only brings significant improvements to knowledge-intensive tasks such as Trivia Creative Writing and Codenames Collaborative without relying on external knowledge bases, but also achieves strong performance on reasoning-intensive tasks like Logic Grid Puzzle. To our knowledge, SPP is the first zero-shot prompting method that can enhance both knowledge and reasoning abilities on GPT-4.

LLMs can effectively identify useful personas in a zero-shot manner. We are interested in investigating whether the identified personas are highly relevant to the tasks. We visualize the personas automatically identified by SPP using a word cloud for each task in Figure 7a, where a larger font indicates a higher frequency. The key observations include: (1) The identified personas are closely correlated with the particular task. For example, in Logic Grid Puzzle, even though "logic puzzle" is not mentioned in the input, the LLM frequently identifies the persona "Logic Puzzle Expert." (2) On knowledge-intensive tasks, such as Trivia Creative Writing, SPP identifies more diverse and specific personas, while on reasoning-intensive tasks, such as Logic Grid Puzzle, the personas are more homogeneous.

We further investigate whether a detailed profile for each persona is needed for eliciting domain knowledge, as suggested by (Xu et al., 2023). To this end, we design a variant of SPP, **SPP-Profile**, which involves generating profiles for each persona during the Persona Identification phase. The results in Figure 7b show that SPP-Profile does not outperform SPP. This suggests that a fine-grained

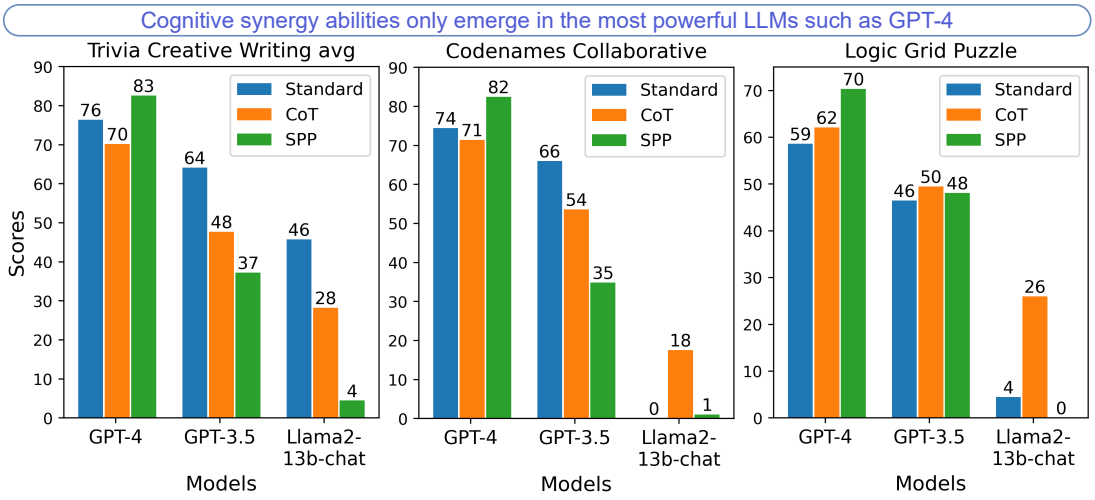

Figure 6: SPP achieves superior performance only with the most powerful LLM (GPT-4), but not with GPT-3.5 and Llama2-13b. This indicates that cognitive synergy abilities only emerge in LLMs with GPT-4 level capabilities.

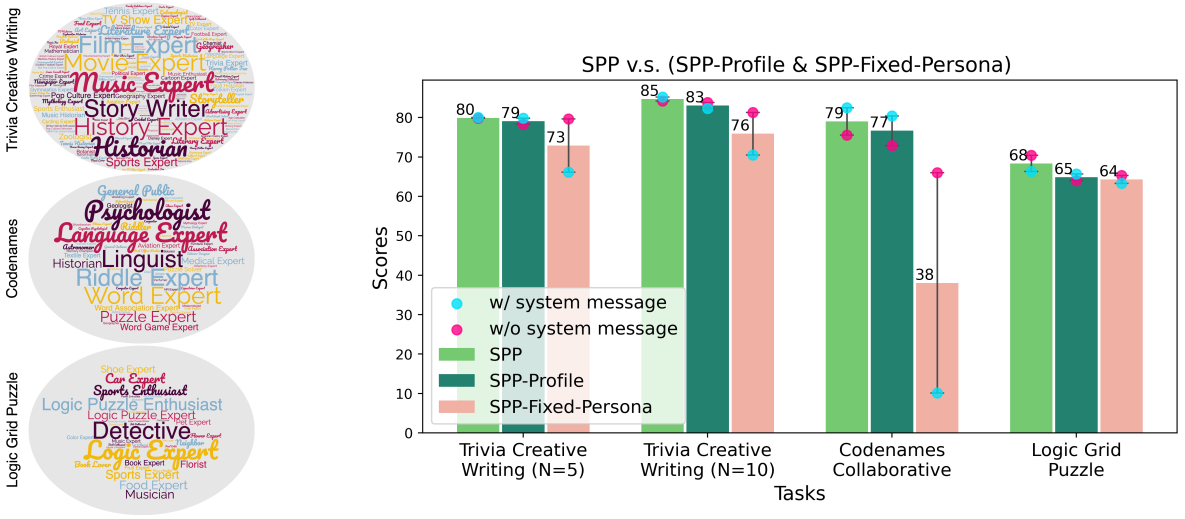
persona name without a detailed description may already be sufficient for eliciting certain domain knowledge.



Dynamic personas v.s. fixed personas. To further investigate the importance of dynamically identifying personas for each task instance instead of fixing a general persona, an ablated variant of SPP, **SPP-Fixed-Persona**, is introduced. For SPP-Fixed-Persona, we modify the prompt (Figure 17) to force the personas to be fixed as an "AI Assistant" and an "Expert". Comparing SPP and SPP-Fixed-Persona in Figure 7b, we have the following insights: (1) SPP consistently outperforms SPP-Fixed-Persona across all tasks, suggesting that dynamic, fine-grained personas are more effective than fixed, general personas. Qualitative examples in Figure 8 and 13 shows that the fine-grained personas such as "Film Expert" and "Sports Enthusiast" correctly provide the answers, while the fixed persona "Expert" fails. (2) SPP-Fixed-Persona also suffers from the **early-termination** problem as defined in §3.4, where the LLM stops collaboration before providing the final answer as if it were waiting for external inputs.

Impact of the demonstrations in SPP prompt. To investigate the effectiveness of the hand-crafted demonstration examples in SPP, we conduct an ablation study where we remove the second demo example and preserve the first one, which shows only a two-persona collaboration setting. As shown in Figure 9, we observe that (1) Adding the second example, which requires collaboration of more than two personas, effectively boosts the performance. (2) SPP is fairly robust to the prompt change and show good performance with only the first demo example.

5 Related Work

LLMs as role-playing agents. Recent research (Deshpande et al., 2023; Xu et al., 2023; Fu et al., 2023; aut, 2023; Li et al., 2023) demonstrates that assigning personas or roles to LLMs influences their generation behavior. AI societies with distinct personas or occupations have been explored for collaboration (Park et al., 2023; Schick et al., 2022; Li et al., 2023; Cai et al., 2023). However, limitations in persona assignment and multi-agent collaboration include single or fixed persona assignments (Xu et al., 2023; Fu et al., 2023; Schick et al., 2022; Li et al., 2023) and the need for multiple LLM instances, increasing inference cost. In contrast, SPP uses a single LLM to dynamically identify useful personas for general tasks. Our discovery on the emergent nature of cognitive synergy also aligns with related work (Olausson et al., 2023), which investigates the emergent ability of self-debugging in code generation.

Enhancing reasoning and factual knowledge in LLMs. LLMs face challenges in complex knowledge-intensive tasks due to hallucination (Maynez et al., 2020) and reasoning-intensive tasks due to the lack of human-like slow thinking (Sloman, 1996; Kahneman, 2011). Approaches like Chain-of-Thought (CoT) and Self-Refinement encourage LLMs to solve tasks step by step or iteratively revise their answers (Wei et al., 2023; Kojima et al., 2022; Zhang et al., 2022; Fu et al., 2022; Xue et al., 2023; Yao et al., 2023; Madaan et al., 2023; Shinn et al., 2023; Gou et al., 2023;

(a) Visualization of the SPP-identified personas. The personas show a high correlation with the nature of the tasks.

(b) Comparison between SPP, SPP-Fixed-Persona (with two fixed personas) and SPP-Profile (additionally generating persona profiles). SPP significantly outperforms SPP-Fixed-Persona, highlighting the importance of automatically identifying dynamic, fine-grained personas. SPP slightly outperforms SPP-Profile, indicating that the persona names (without detailed description of the expertise) are probably already sufficient for eliciting cognitive synergy.

Figure 7: **(a)** Qualitative analysis on the identified personas; **(b)** Quantitative analysis on two SPP variants.

SPP v.s. CoT (Trivia Creative Writing N=5)

Question #5: In which country is the Sky Train Rail bridge?

SPP

Participants: AI Assistant (you); Movie Expert; Art Expert; Sports Expert; Geography Expert
[...]
Geography Expert: The Sky Train Rail Bridge is located in Canada. ✅

CoT

Plan:
[...]
6. Incorporate the Sky Train Rail bridge, which is in Thailand. ❌

SPP v.s. SPP-Fixed-Persona (Trivia Creative Writing N=5)

Instance Index: 30
Question #1: Which orchestral conductor was married to one of the subjects of the film Hillary and Jackie?

SPP

Participants: AI Assistant (you); Film Expert; Literary Expert; History Expert; Geography Expert; Architecture Expert
Film Expert: The orchestral conductor married to one of the subjects of the film Hillary and Jackie is Daniel Barenboim. ✅

SPP-Fixed-Persona

Participants: AI Assistant (you); Expert
Expert: Sir Simon Rattle was married to one of the subjects of the film Hillary and Jackie. ❌

Figure 8: Qualitative examples on Trivia Creative Writing comparing SPP, CoT and SPP-Fixed-Persona. While CoT provides reasonable intermediate steps, it still struggles with factual hallucination. SPP v.s. SPP-Fixed-Persona reveals that dynamically identified fine-grained personas, such as the "Film Expert," tend to outperform the fixed general persona of an "Expert. More examples can be found in Figures 11, 12, and 13.

Chen et al., 2023; Huang et al., 2022; Yao et al., 2022). However, these methods do not necessarily reduce factual hallucination. Retrieval augmented LLMs (Borgeaud et al., 2022; Izacard et al., 2022; Wang et al., 2022; Shuster et al., 2021) enhance knowledge acquisition but do not improve reasoning abilities. We propose Solo Performance Prompting (SPP) to elicit both knowledge and reasoning abilities in LLMs, improving factuality while maintaining strong performance on pure-reasoning tasks.

6 Conclusion

Solo Performance Prompting unleashes the cognitive synergy abilities within powerful LLMs, significantly reducing factual hallucination while enhancing reasoning. The performance is assessed using newly proposed tasks, e.g., Trivia Creative Writing and Codenames Collaborative, demonstrating superior results compared to Standard, CoT and Self-Refine. The discovery of the emergent nature of cognitive synergy on different LLMs draws interesting analogy to human development.

Limitations

Although Solo Performance Prompting exhibits promising improvements in acquiring factually correct knowledge compared to Standard prompting, it has some limitations. For instance, even when a fine-grained persona is assigned, the answer may still be incorrect. It remains unclear to what extent assigning a persona can help enhance domain knowledge in a specific area. Dedicated diagnostic experiments and theoretical efforts are needed to quantify the impact of having a persona or not.

Furthermore, we currently adopt an identical SPP prompt with the same two demonstration examples for any given task inputs, which may be suboptimal. Future work investigating how to find better demonstration examples conditioned on each input could further improve the effectiveness of SPP.

Last but not least, if given sufficient computational budget, a natural variant of SPP could extend to a *multi-agent cognitive synergist* setup where a leader persona identifies several expert agents and forms a cabinet to collaboratively solve a task. The multi-agent setup allows for leveraging richer computation power, larger local memory, and more flexible human-computer interaction, which could be essential for deploying to real-world applications.

A Prompts

A.1 SPP Prompt Design

To prompt an LLM to behave as a cognitive synergist that follows the expected task-solving procedure as mentioned in §2, we carefully designed the structure of the SPP prompt as follows. The full prompts can be found in § A.2.[3]

System Principle. The first part of the prompt contains a high-level instruction: `"When faced with a task, begin by identifying the participants who will contribute to solving the task. Then, initiate a multi-turn collaboration process until a final solution is reached. The participants will give critical comments and detailed suggestions whenever necessary."`

Demonstration Examples. Then, we include two manually crafted demonstration examples to showcase the expected task-solving behavior. The first example describes a *Game of 24* task, where we only include two personas: an AI Assistant and a Math Expert. This task aims to provide an example of a *reasoning-intensive task*, where the AI Assistant needs to propose multiple proposals, and the other participants need to give *fine-grained feedback* on where the current solution went wrong and how to improve it. The second example describes a poem-writing task with *diverse requirements*, including lexical constraints, semantic constraints, and audience awareness. This task aims to provide an example of a *knowledge-intensive task*, where diverse personas are required to collaboratively solve the task. This example also demonstrates a case where it is important to assign a dedicated persona to the audience, e.g., a ten-year-old child.

Task Prefix. The last part of the prompt reminds the model to `"identify the participants and collaboratively solve the following task step by step."` followed by task-specific format instructions and inputs.

A.2 Full Prompts

Figures 15, 16 and 17 show the full prompts for SPP, SPP-Profile and SPP-Fixed-Persona respectively. Figure 18 shows the prompts for Chain-of-

[3]We use the same prompt for any arbitrary tasks.

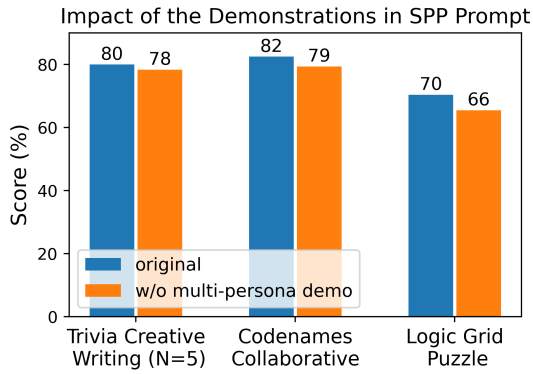

Figure 9: Analysis on the impact of the demonstration examples in SPP prompt. We compare the effectiveness of the original SPP prompt with a variant where we remove the second demonstration example, which shows a multi-persona scenario. We observe that (1) SPP is fairly robust to the change in the prompt; (2) adding an additional multi-persona example apart from the single-persona one effectively boosts performance on all three tasks.

Thought (CoT) prompting. Figure 19 shows the prompts for Self-Refine prompting.

B Task Details

B.1 Trivia Creative Writing

Figure 3 shows a detailed illustration of the Trivia Creative Writing task. Additionally, we investigate how the number of the questions (N) and the ordering of the questions would affect the performance on the Trivia Creative Writing task. As shown in Figure 10, with a larger number of questions (N$\geq$5), Trivia Creative Writing effectively challenges GPT-4's performance. While a single question (N=1) yields similar outcomes regardless of the prompting method, SPP approach is notably superior for larger Ns. The ordering of the questions has minimal impact to the task performance.

The topic list is automatically generated by prompting GPT-4 to provide 100 nouns from pop culture[4].

C Inference Configurations

The main results in Table 2 are obtained from GPT-4. The GPT-4 API version we employ is Azure 2023-3-15-preview.[5] The *temperature* is set to 0.0 (most conservative) and *top_p* to 1.0 for all generations to maximize reproducibility. Since even though the temperature is set to 0.0 the GPT-4 generation can still be non-deterministic, we conduct additional experiment to investigate its generation consistency under this configuration. As shown in Table 3, we perform three individual runs and compute the mean and standard deviation of the metric score on Trivia Creative Writing. We find that the variance is sufficiently small and Solo Performance Prompting enjoys lower variance than Standard and CoT prompting.

Methods	Run 1	Run 2	Run 3	Mean (std)
Standard	75.6	74.4	73.1	74.4 $\pm$1.3
CoT	68.8	69.6	70.8	69.7 $\pm$1.0
SPP	80.0	79.8	80.8	80.2 $\pm$0.5

Table 3: Investigation on the generation consistency of GPT-4 API. The experiment is performed on the Trivia Creative Task (N=5). We set the inference temperature to 0.0 and top_p to 1.0 as all experiments conducted in the paper. The results show that the GPT-4 generation is fairly consistent with a small variance ($\sim$ 1%). We also observe that SPP shows lower variance compared with Standard and CoT prompting across different runs.

To evaluate the potential impact of initial persona assignment through a system message, we consider two inference settings: *with* or *without* the default system message, `"You are an AI assistant that helps people find information"`. Divergent patterns are observed across various tasks and methods regarding the use of the system message. We report the average metric scores across both inference settings in Table 2. Full GPT-4 results for each setting can be found in Appendix F.

For GPT-3.5 results in Figure 6, we employ the same prompt, hyper-parameters and the best system message setting in terms of SPP's GPT-4 performance. For Llama2, we leverage the Huggingface text-generation pipeline[6] with greedy decoding.

D Additional Qualitative Analysis

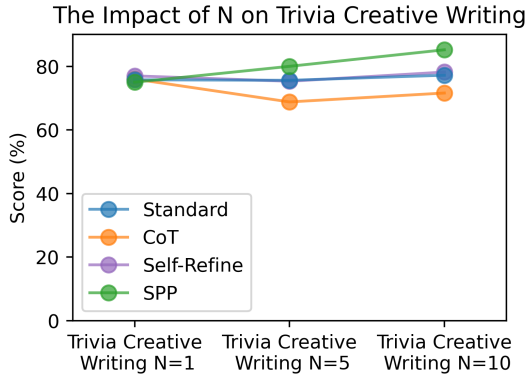

Figure 11 presents examples of the Trivia Creative Writing task, illustrating that although CoT can generate plausible plans for task resolution, the final outcomes often contain factual inaccuracies and instances of hallucination. In contrast, SPP elicits precise knowledge with fine-grained personas.

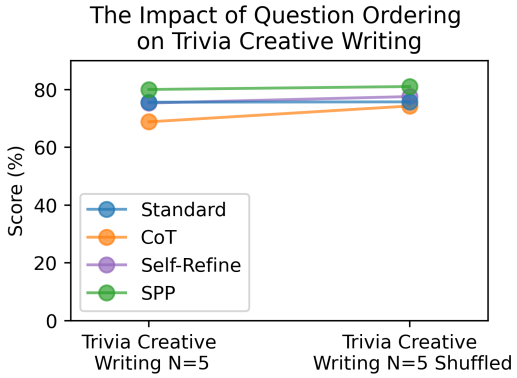
Figure 12 displays examples of the Codenames Collaborative task, illustrating that SPP generates



[4]The full prompt for generating the topic list can be found in Figure 20. We performed further human curation to avoid potential harmful content.

[5]There are rare cases when a generation triggers the content filter of the API. We exclude those instances from our results.

[6]https://huggingface.co/blog/llama2

(a) Trivia Creative Writing with a large enough number of questions (N) effectively pose challenge to GPT-4 in terms of factual correctness. With N=1, different prompting methods result in similar performance, while with N>=5, SPP shows visible superiority.

(b) The ordering of the questions in the Trivia Creative Writing task does not bring too much impact. The performance on shuffled questions is close to the original ordered questions.

Figure 10: Analysis on the impact of the number of questions (N) and the ordering of the questions for the Trivia Creative Writing task.

intermediate dialogues that are both *detailed* and *interpretable*, leading to superior performance compared to CoT.

Figure 13 shows additional qualitative examples on Solo Performance Prompting vs SPP-Profile.

E Early-termination with SPP-Fixed-Persona

Figure 14 shows an example of the early-termination problem (defined in § 4) where the generation stops before reaching the final solution as if the models is waiting input from an external user.

The problem is particularly severe on certain tasks, e.g., Codenames Collaborative, resulting in unexpectedly low performance as shown in Figure 7b. The problem can be largely alleviated by removing the system message but cannot be entirely eliminated. Table 4 shows the statistics of the early-termination problem for each task and method. In contrast, we did not observe early-termination on SPP, SPP-Profile, Standard, or CoT prompting with GPT-4.

F Full Results

Full results of the three tasks: Trivia Creative Writing, Codenames Collaborative and Logic Grid Puzzle can be found in Tables 5, 6 and 7, respectively.

G Usage of AI assistants in writing

We used ChatGPT and GPT-4 solely for checking and correcting grammars.

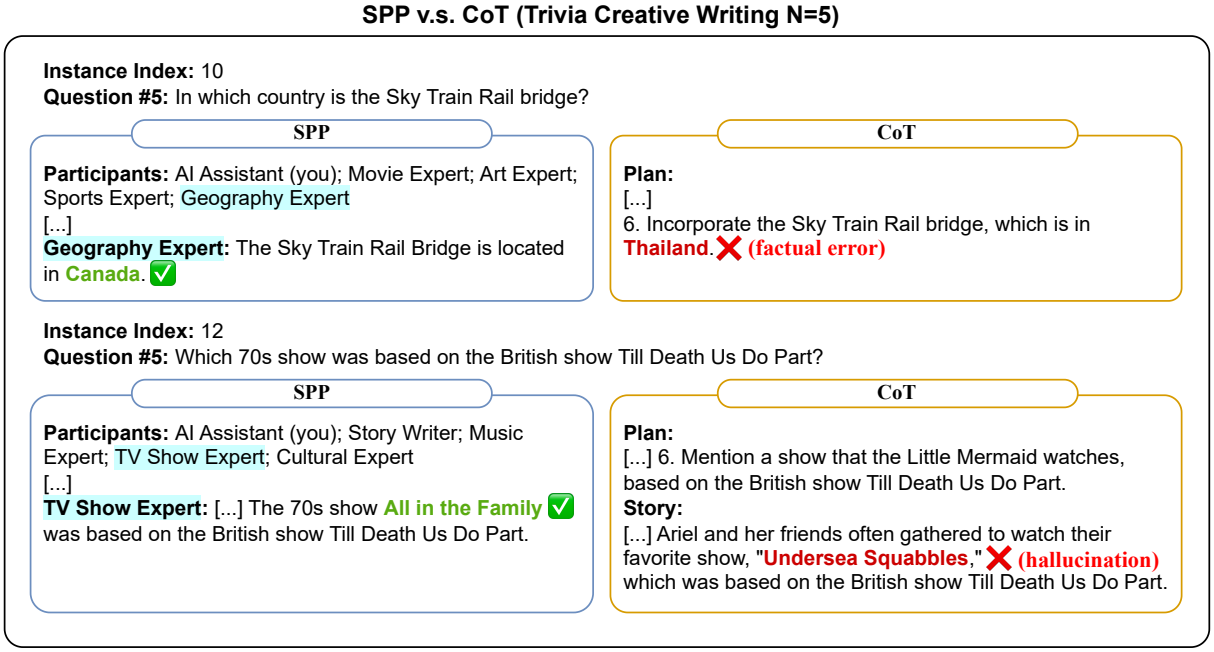


Figure 11: SPP vs CoT qualitative examples on Trivia Creative Writing (N=5). We find that although CoT generates reasonable plans or steps, it tends to suffer from factual errors and hallucination.

Tasks	added system message	# early-termination
Trivia Creative Writing (N=5)	yes	18 / 100
	no	0 / 100
Trivia Creative Writing (N=10)	yes	16 / 100
	no	1 / 100
Codenames Collaborative	yes	37 / 50
	no	4 / 50
Logic Grid Puzzle	yes	11 / 200
	no	15 / 200

Table 4: Early termination statistics on *SPP-Fixed-Persona*: Removing the system message, `"You are an AI assistant that helps people find information."`, can effectively reduce the problem but cannot fully eliminate it.

SPP v.s. CoT (Codenames Collaborative)

Instance Index: 9
Word List: shoulder, glacier, anchor, magician, tunnel, sugar, gear, book, rainbow, ram, nose, pacific, volume, rope, mark, drum, page, sack, kick
Target Words: kick, rope

SPP Spymaster

Participants: AI Assistant (you); Language Expert; Word Association Expert

Language Expert: The task is to find a single word hint that can accurately represent and link the 2 given words: "kick, rope". The hint should not cause confusion with other words from the list provided.
Word Association Expert: Let's first analyze the words "kick" and "rope". We can think of activities or objects that involve both kicking and using a rope. For example, sports or games.
AI Assistant (you): Thanks for the suggestions! Based on the idea of sports or games, I propose the hint "jump". It can be associated with both "kick" and "rope" without causing confusion with the other words in the list.
[...]
Final answer: jump

SPP Spymaster Hint: jump

SPP Guesser

Participants: AI Assistant (you); Linguist; Athlete

Linguist: When thinking about words associated with "jump," consider words that are related to physical activities, sports, or movement. Look for words that can be used in the same context as "jump" or have a similar meaning.
Athlete: In sports and physical activities, we often use equipment or tools that help us jump or perform jumping-related actions. Keep that in mind when selecting the words.
AI Assistant (you): Thanks for the guidance! Based on your suggestions, I think "rope" and "kick" are the two words best associated with "jump" from the list. Rope can be related to jumping rope, and kick can be associated with jumping in some sports like soccer or martial arts.
Linguist: Let's verify if the words are related to "jump." Rope is indeed related to jumping rope, which is a common physical activity. Kick is also related to jumping in some sports, as you mentioned. Both words seem to be good choices.
Athlete: I agree with the choices. Rope and kick are both related to jumping and physical activities.

Final answer: rope, kick

Score: 2 / 2 = 1.0

CoT Spymaster

Steps:

1. Analyze the given words: "kick" and "rope".
2. Identify the common theme or connection between the two words.
3. Compare the connection with the list of words provided to ensure the hint does not cause confusion with other words.
4. Select a hint that accurately represents and links the two given words without causing confusion.

Answer: Sport

CoT Spymaster Hint: Sport

CoT Guesser

Steps:

1. Review the list of words provided.
2. Identify words that are directly related to or commonly associated with sports.
3. Select the top 2 words that are most closely related to sports.

Answer: gear, kick

Score: 1 / 2 = 0.5

Figure 12: SPP vs CoT qualitative examples on Codenames Collaborative. We find that SPP provides much more detailed and interpretable intermediate discussions from various perspectives, which leads to stronger knowledge selection, integration, and theory-of-mind capabilities.

SPP v.s. SPP-Fixed-Persona (Trivia Creative Writing N=5)

Instance Index: 30
Question #1: Which orchestral conductor was married to one of the subjects of the film Hillary and Jackie?

SPP

Participants: AI Assistant (you); Film Expert; Literary Expert; History Expert; Geography Expert; Architecture Expert
Film Expert: The orchestral conductor married to one of the subjects of the film Hillary and Jackie is **Daniel Barenboim**. ✅

SPP-Fixed-Persona

Participants: AI Assistant (you); Expert
Expert: **Sir Simon Rattle** was married to one of the subjects of the film Hillary and Jackie. ❌

Instance Index: 7
Question #3: Which musician founded the Red Hot Peppers?

SPP

Participants: AI Assistant (you); Storyteller; Mythology Expert; Music Enthusiast; Historian; Speed Record Expert
Music Enthusiast: The musician who founded the Red Hot Peppers is **Jelly Roll Morton**. ✅

SPP-Fixed-Persona

Participants: AI Assistant (you); Expert
AI Assistant (you): The musician who founded the Red Hot Peppers is **Louis Armstrong**. ❌

Instance Index: 56
Question #1: What sport or pastime would you be playing if your balls were black and blue and your opponent's were red and yellow?

SPP

Participants: AI Assistant (you); Story Writer; Sports Enthusiast; Historian; Movie Buff; Music Expert; Mythology Expert
Sports Enthusiast: The sport with black and blue balls for one player and red and yellow balls for the other is **Croquet**. ✅

SPP-Fixed-Persona

Participants: AI Assistant (you); Expert
Expert: **Snooker** ❌

Figure 13: SPP vs SPP-Fixed-Persona qualitative examples on Trivia Creative Writing (N=5). Each example shows one of the trivia questions in the input instance, the identified participants and the provided answer. We observe that the dynamically identified fine-grained personas, such as "Film Expert", "Music Enthusiast" and "Sports Enthusiast", tend to outperform the fixed general personas, "Expert".

Early-termination example with SPP on Llama2-13b-chat

Input

[... SPP procedure instructions and demonstration examples ...]

Now, identify the participants and collaboratively solve the following task step by step. Remember to present your final solution with the prefix "Final answer:".

Task: *{Write a short and coherent story about Harry Potter that incorporates the answers to the following 5 questions: Who was the man behind The Chipmunks? Which Lloyd Webber musical premiered in the US on 10th December 1993? Who was the next British Prime Minister after Arthur Balfour? Who had a 70s No 1 hit with Kiss You All Over? What claimed the life of singer Kathleen Ferrier?}*

Generation

Participants: AI Assistant (you); Harry Potter Expert; Music Expert; History Expert; Medical Expert
Start collaboration!

The generation stopped here without simulating the multi-turn dialogue following the demonstration examples

Further Observation: Llama2 cannot follow the procedure as demonstrated in the examples, even with additional prompting, such as: "Follow the same procedure as the example tasks shown above. Simulate the dialogue of the participants." This indicates that a strong instruction-following ability is a prerequisite for SPP to effectively elicit cognitive synergy abilities.

Early-termination example with SPP-Fixed-Persona on GPT-4

Input

[... SPP-Fixed-Persona Prompt ...]

Now, identify the participants and collaboratively solve the following task step by step. Note that the participants can only be either AI Assistant (you) or Expert. Remember to provide the final solution with the following format "Final answer: (a list of words here).".

Task: *{Try to identify the 4 words best associated with the word "film" from the following list: locust, fever, street, sherwood, kiss, popcorn, craft, ant, crystal, tear, cowboy, government, pine, mountie, soap, genie, king arthur, sphinx, director, bride, razor, fog, whistle. Your answer should be a comma-separated list of words.}*

Generation

Participants: AI Assistant (you); Expert

AI Assistant (you): Let's first analyze the task. We need to find the 4 words that are most closely associated with the word "film" from the given list. We can start by identifying words that are directly related to films, such as those related to movie genres, settings, or elements commonly found in films.

Expert: That's a good approach. You can also consider words that are related to the experience of watching a film, such as items that are commonly consumed during a movie or words that describe the atmosphere of a film. Make sure to pick the 4 words that have the strongest association with "film".

The generation stopped here without providing the Final answer

Figure 14: Examples of the early-termination problem with SPP on Llama2-13b-chat and SPP-Fixed-Persona on GPT-4.

SPP Prompt

When faced with a task, begin by identifying the participants who will contribute to solving the task. Then, initiate a multi-round collaboration process until a final solution is reached. The participants will give critical comments and detailed suggestions whenever necessary.

Here are some examples:

Example Task 1: Use numbers and basic arithmetic operations (+ - * /) to obtain 24. You need to use all numbers, and each number can only be used once.
Input: 6 12 1 1

Participants: AI Assistant (you); Math Expert

Start collaboration!

Math Expert: Let's analyze the task in detail. You need to make sure that you meet the requirement, that you need to use exactly the four numbers (6 12 1 1) to construct 24. To reach 24, you can think of the common divisors of 24 such as 4, 6, 8, 3 and try to construct these first. Also you need to think of potential additions that can reach 24, such as 12 + 12.
AI Assistant (you): Thanks for the hints! Here's one initial solution: (12 / (1 + 1)) * 6 = 24
Math Expert: Let's check the answer step by step. (1+1) = 2, (12 / 2) = 6, 6 * 6 = 36 which is not 24! The answer is not correct. Can you fix this by considering other combinations? Please do not make similar mistakes.
AI Assistant (you): Thanks for pointing out the mistake. Here is a revised solution considering 24 can also be reached by 3 * 8: (6 + 1 + 1) * (12 / 4) = 24.
Math Expert: Let's first check if the calculation is correct. (6 + 1 + 1) = 8, 12 / 4 = 3, 8 * 3 = 24. The calculation is correct, but you used 6 1 1 12 4 which is not the same as the input 6 12 1 1. Can you avoid using a number that is not part of the input?
AI Assistant (you): You are right, here is a revised solution considering 24 can be reached by 12 + 12 and without using any additional numbers: 6 * (1 - 1) + 12 = 24.
Math Expert: Let's check the answer again. 1 - 1 = 0, 6 * 0 = 0, 0 + 12 = 12. I believe you are very close, here is a hint: try to change the "1 - 1" to "1 + 1".
AI Assistant (you): Sure, here is the corrected answer: 6 * (1+1) + 12 = 24
Math Expert: Let's verify the solution. 1 + 1 = 2, 6 * 2 = 12, 12 + 12 = 12. You used 1 1 6 12 which is identical to the input 6 12 1 1. Everything looks good!

Finish collaboration!

Final answer: 6 * (1 + 1) + 12 = 24

Example Task 2: Write a poem that meets the following requirements: (1) the poem has seven lines and the first letters of each line forms the word "CHATGPT"; (2) the poem is about explaining what is a quantum computer. (3) the poem needs to be easy to understand by a ten years old kid.

Participants: AI Assistant (you); Poet; Computer Scientist; Ten year old child

Poet: Make sure that you write the poem with seven lines, and the first letters of the lines should be C, H, A, T, G, P, T.
Computer Scientist: A quantum computer is an advanced computing device that uses the principles of quantum mechanics to process and store information. Unlike classical computers that use bits to represent information as 0s and 1s, quantum computers use quantum bits or qubits. Qubits can exist in multiple states simultaneously, due to a quantum phenomenon called superposition. You can consider using these information for the poem.
Ten year old child: I hope the poem to be fun and easy to understanding. I don't want to see a lot of jargons or complicated concepts.
AI Assistant (you): Thanks for the guidance! Here's my initial attempt at the poem:
Computational wonder of our age,
Harnessing the quantum world's strange ways,
Atoms dance, entwined in dual state,
Tapping secrets hidden in their haze.

Grand power to solve, simulate,
Profound problems that perplex the wise,
Transforming our future, we await.

Poet: Let's verify if the poem meets the requirements. The first letters are CHATGPT which is correct! And the poem rhymes well. Good job!
Computer Scientist: Everything looks good to me!
Ten year old child: I don't know what does perplex mean. Can you make the use of words easier to understand?
AI Assistant (you): Sure, let me revise the poem by using more common words. Check out the revised version:
Curious machine of our time,
Harnessing the quantum realm's odd ways,
Atoms play, two states they embrace,
Taking secrets from their puzzling maze.

Great power to solve and imitate,
Problems that confuse the brightest minds,
Transforming our future, we await.

Poet: Let's check again if the poem meets the requirements. The first letters are C H A T G P T. And now the poem is more accessible to children. Everything looks good to me.
Computer Scientist: Looking good!
Ten year old child: I like this version a lot!

Finish collaboration!

Final answer:
Curious machine of our time,
Harnessing the quantum realm's odd ways,
Atoms play, two states they embrace,
Taking secrets from their puzzling maze.

Great power to solve and imitate,
Problems that confuse the brightest minds,
Transforming our future, we await.

Now, identify the participants and collaboratively solve the following task step by step. *{Task-specific Formating Instruction}*

Task: *{Task input}*

Figure 15: SPP full prompt.

SPP-Profile Prompt

When faced with a task, begin by identifying the participants who will contribute to solving the task. Provide profiles of the participants, describing their expertise or needs. Then, initiate a multi-round collaboration process until a final solution is reached. The participants will give critical comments and detailed suggestions whenever necessary.

Here are some examples:

[...]

Participants: AI Assistant (you); Math Expert

Profiles:
- AI Assistant (you): A super-intelligent AI assistant capable of performing tasks more effectively than humans.
- Math expert: A person who is good at math games, arithmetic calculation, and long-term planning.

[...]

Participants: AI Assistant (you); Poet; Computer Scientist; Ten year old child

Profiles:
- AI Assistant (you): A super-intelligent AI assistant capable of performing tasks more effectively than humans.
- Poet: A person who studies and creates poetry. The poet is familiar with the rules and formats of poetry and can provide guidance on how to write a poem.
- Computer Scientist: A scholar who specializes in the academic study of computer science. The computer scientist is familiar with the concept of a quantum computer and can provide guidance on how to explain it.
- Ten year old child: A child with a limited English vocabulary and little knowledge about complicated concepts, such as a quantum computer.

[...]

Now, identify the participants, provide their profiles, and collaboratively solve the following task step by step. *{Task-specific Formating Instruction}*

Task: *{Task input}*

Figure 16: SPP-Profile full prompt. "[...]" indicates identical parts with SPP. Green text indicates the key difference between SPP-Profile and SPP.

Methods	**Scores (N = 5) (%)**			
	w/ system message	**w/o system message**	**average**	**max**

Table 5: Trivia Creative Writing full results, including two inference settings: with system message and without system message. "average" and "max" indicating the mean and max score across the two settings. The system message we use is: ‘‘`You are an AI assistant that helps people find information.`’’

SPP-Fixed-Persona Prompt

When faced with a task, begin by identifying the participants who will contribute to solving the task. Note that the participants can only be either AI Assistant (you) or Expert. Then, initiate a multi-round collaboration process until a final conclusion is reached. The Expert will give critical comments and detailed suggestions whenever necessary.

Here are some examples:

Example Task 1: Use numbers and basic arithmetic operations (+ - * /) to obtain 24. You need to use all numbers, and each number can only be used once.
Input: 6 12 1 1

Participants: AI Assistant (you); Expert

Start collaboration!

Expert: Let's analyze the task in detail. You need to make sure that you meet the requirement, that you need to use exactly the four numbers (6 12 1 1) to construct 24. To reach 24, you can think of the common divisors of 24 such as 4, 6, 8, 3 and try to construct these first. Also you need to think of potential additions that can reach 24, such as 12 + 12.
AI Assistant (you): Thanks for the hints! Here's one initial solution: (12 / (1 + 1)) * 6 = 24
Expert: Let's check the answer step by step. (1+1) = 2, (12 / 2) = 6, 6 * 6 = 36 which is not 24! The answer is not correct. Can you fix this by considering other combinations? Please do not make similar mistakes.
AI Assistant (you): Thanks for pointing out the mistake. Here is a revised solution considering 24 can also be reached by 3 * 8: (6 + 1 + 1) * (12 / 4) = 24.
Expert: Let's first check if the calculation is correct. (6 + 1 + 1) = 8, 12 / 4 = 3, 8 * 3 = 24. The calculation is correct, but you used 6 1 1 12 4 which is not the same as the input 6 12 1 1. Can you avoid using a number that is not part of the input?
AI Assistant (you): You are right, here is a revised solution considering 24 can be reached by 12 + 12 and without using any additional numbers: 6 * (1 - 1) + 12 = 24.
Expert: Let's check the answer again. 1 - 1 = 0, 6 * 0 = 0, 0 + 12 = 12. I believe you are very close, here is a hint: try to change the "1 - 1" to "1 + 1".
AI Assistant (you): Sure, here is the corrected answer: 6 * (1+1) + 12 = 24
Expert: Let's verify the solution. 1 + 1 = 2, 6 * 2 = 12, 12 + 12 = 12. You used 1 1 6 12 which is identical to the input 6 12 1 1. Everything looks good!

Finish collaboration!

Final answer: 6 * (1 + 1) + 12 = 24

Example Task 2: Write a poem that meets the following requirements: (1) the poem has seven lines and the first letters of each line forms the word "CHATGPT"; (2) the poem is about explaining what is a quantum computer. (3) the poem needs to be easy to understand by a ten years old kid.

Participants: AI Assistant (you); Expert

Expert: Make sure that you write the poem with seven lines, and the first letters of the lines should be C, H, A, T, G, P, T. A quantum computer is an advanced computing device that uses the principles of quantum mechanics to process and store information. Unlike classical computers that use bits to represent information as 0s and 1s, quantum computers use quantum bits or qubits. Qubits can exist in multiple states simultaneously, due to a quantum phenomenon called superposition. You can consider using these information for the poem. I hope the poem to be fun and easy to understanding. I don't want to see a lot of jargons or complicated concepts.
AI Assistant (you): Thanks for the guidance! Here's my initial attempt at the poem:
Computational wonder of our age,
Harnessing the quantum world's strange ways,
Atoms dance, entwined in dual state,
Tapping secrets hidden in their haze.

Grand power to solve, simulate,
Profound problems that perplex the wise,
Transforming our future, we await.

Expert: Let's verify if the poem meets the requirements. The first letters are CHATGPT which is correct! And the poem rhymes well. Good job! I don't know what does perplex mean. Can you make the use of words easier to understand?
AI Assistant (you): Sure, let me revise the poem by using more common words. Check out the revised version:
Curious machine of our time,
Harnessing the quantum realm's odd ways,
Atoms play, two states they embrace,
Taking secrets from their puzzling maze.

Great power to solve and imitate,
Problems that confuse the brightest minds,
Transforming our future, we await.

Expert: Let's check again if the poem meets the requirements. The first letters are C H A T G P T. And now the poem is more accessible to children. Everything looks good to me. I like this version a lot!

Finish collaboration!

Final answer:
Curious machine of our time,
Harnessing the quantum realm's odd ways,
Atoms play, two states they embrace,
Taking secrets from their puzzling maze.

Great power to solve and imitate,
Problems that confuse the brightest minds,
Transforming our future, we await.

FPT: Feature Prompt Tuning for Few-shot Readability Assessment

Ziyang Wang[1,2], **Sanwoo Lee**[1,3], **Hsiu-Yuan Huang**[1,3] **Yunfang Wu**[1,3*]
[1]National Key Laboratory for Multimedia Information Processing, Peking University

Abstract

Prompt-based methods have achieved promising results in most few-shot text classification tasks. However, for readability assessment tasks, traditional prompt methods lack crucial linguistic knowledge, which has already been proven to be essential. Moreover, previous studies on utilizing linguistic features have shown non-robust performance in few-shot settings and may even impair model performance. To address these issues, we propose a novel prompt-based tuning framework that incorporates rich linguistic knowledge, called **F**eature **P**rompt **T**uning (FPT). Specifically, we extract linguistic features from the text and embed them into trainable soft prompts. Further, we devise a new loss function to calibrate the similarity ranking order between categories. Experimental results demonstrate that our proposed method FTP not only exhibits a significant performance improvement over the prior best prompt-based tuning approaches, but also surpasses the previous leading methods that incorporate linguistic features. Also, our proposed model significantly outperforms the large language model gpt-3.5-turbo-16k in most cases. Our proposed method establishes a new architecture for prompt tuning that sheds light on how linguistic features can be easily adapted to linguistic-related tasks.

1 Introduction

Readability assessment (RA) is the task of evaluating the reading difficulty of a given piece of text (Vajjala, 2022). It has wide applications, such as choosing appropriate reading materials for language teaching (Collins-Thompson and Callan, 2004), supporting readers with learning disabilities (Rello et al., 2012), and ranking search results by their reading levels (Kim et al., 2012).

Early works in RA mainly focused on designing handcrafted linguistic features such as word length (in characters/syllables), sentence length, and usage of different difficulty-level words. In recent years, RA has been dominated by neural network-based architectures (Meng et al., 2021; Azpiazu and Pera, 2019). The key challenge of these methods is to learn a better text representation that can capture deep semantic features. Current research has also explored different ways of combining linguistic features with pretrained language models (PLMs), achieving state-of-the-art results on numerous RA datasets (Li et al., 2022; Lee et al., 2021). However, these studies have mainly focused on fine-tuning with a large amount of labelled data, while only a few studies have explored few-shot settings.

Prompt-based tuning, shown to be a powerful method for the classification task in the few-shot setting, makes full use of the information in PLMs by reformulating classification tasks as cloze questions. Different prompt-based tuning strategies are illustrated in Figure 1. The hard prompt tuning

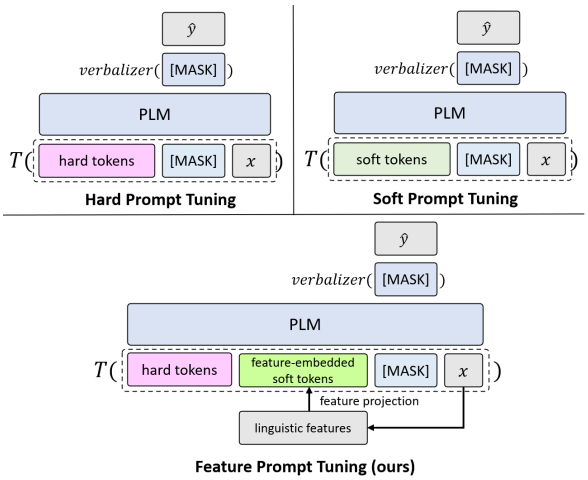

Figure 1: Comparison of previous prompt tuning frameworks and our proposed Feature Prompt Tuning (FPT). $T(\cdot)$ and $verbalizer(\cdot)$ denote the template and verbalizer function, respectively. FPT utilizes both hard and soft tokens which are projected from the linguistic features extracted from the input x.

applies a template with [MASK] token to the original input and maps the predicted label word to the corresponding class (Han et al., 2022; Shin et al., 2020). The performance is sensitive to the quality of template, which introduces time-consuming and labor-intensive prompt design and optimization. To address this problem, researchers propose soft prompt strategies, where continuous embeddings of trainable tokens replace the hard template and are optimized by training (Liu et al., 2021; Lester et al., 2021).

Despite the success in a range of text classification tasks, existing prompt-based tuning methods still suffer from inferior performance in RA. This might be attributed to the lack of linguistic knowledge which has been demonstrated to play a crucial role in RA (Vajjala, 2022; Qiu et al., 2021; Li et al., 2022). Meanwhile, RA differs from general classification tasks in that there exists a notion of ranking order between classes. Our intuition behind the utilization of linguistic knowledge is that the learned representations of different levels should preserve the similarity relationship analogous to that of original linguistic features of different levels.

Motivated by the above insights, in this paper, we propose a novel prompt-based tuning method that incorporates rich linguistic knowledge, called **F**eature **P**rompt **T**uning (FPT), as shown in the bottom of Figure 1. Specifically, our methodology begins with extracting linguistic features from the text. These extracted features are subsequently embedded into feature prompts, functioning as trainable soft prompts. Contrary to the conventional prompt tuning frameworks, our model can explicitly benefit from linguistic knowledge. Furthermore, we devise a new loss function to calibrate the similarity relationships between the embedded features across different categories. Our approach is straightforward and effective, offering wide applicability to other tasks where the importance of handcrafted features is emphasized.

To verify the effectiveness of our proposed methods, we conduct extensive experiments on three RA datasets, including one Chinese data (Li et al., 2022) and two English datasets, WeeBit (Vajjala and Meurers, 2012) and Cambridge (Xia et al., 2019). By incorporating linguistic knowledge, our proposed model FPT improves significantly over other prompt-based methods. For instance, in the 2-shot setting, FPT brings a relative performance gain of 43.9% over the traditional soft prompt method on the Chinese dataset and 5.50% on English Weebit. Moreover, compared to other feature fusion methods, FPT outperforms the previous best method Projecting Feature (PF) (Li et al., 2022) by 43.19% on Chinese data and 11.55% on English Weebit data. Also, we experiment on the Large Language Model (LLM), demonstrating the superiority of our approach on RA. We will make our code public available [1]. We summarize our contributions as follows:

- We propose a novel prompt-based tuning framework, Feature Prompt Tuning (FPT), which incorporates rich linguistic knowledge for RA.
- We design a new calibration loss to ensure the linguistic features retain their original similarity information during optimization.
- Our experimental results show that our method outperforms other prompt-based tuning methods and effectively leverages linguistic features, leading to better and more stable performance improvements than previous approaches.

2 Related Works

2.1 Readability Assessment

Early works have explored a wide range of linguistic features as measurements for readability. Flesch (1948) performed regression over features such as average word length in syllable; Schwarm and Ostendorf (2005) trained an SVM over features including LM perplexity and syntactic tree height; Pitler and Nenkova (2008) illustrated that discourse relations can be a good predictor of readability.

Recent works largely employ deep learning approaches for RA. Several deep architectures, including BERT (Devlin et al., 2018), HAN (Yang et al., 2016), and multi-attentive RNN were applied to achieve strong performance without feature engineering (Martinc et al., 2021; Azpiazu and Pera, 2019). However, the performance of neural models tends to fluctuate a lot across different RA datasets (Deutsch et al., 2020), suggesting that relying only on neural networks might not be a robust solution for RA. Meanwhile, later works have shown that a hybrid approach combining transformer-based encoders with linguistic features can achieve even higher performance (Lee et al., 2021; Lee and Vajjala, 2022; Li et al., 2022). Lee and Lee (2023)

[1] https://github.com/Wzy232303/FPT

applied a prompt-based learning based on seq2seq model such as T5 and BART, treating RA as a text-to-text generative task. Despite the novelty of their method, it was not included in our baselines since it is hard for this method to draw a meaningful comparison against our approach. In addition to the fundamental discrepancy in the task definition, their method focuses on optimizing hard prompts and combining multiple datasets during training, whereas our method focuses on incorporating linguistic knowledge without leveraging multiple datasets.

2.2 Prompt-based Tuning

Fine-tuning PLMs have shown their prevalence in various NLP tasks. PLMs, such as BERT (Devlin et al., 2018), GPT (Radford et al., 2018), XLNet (Xia et al., 2019), RoBERTa (Liu et al., 2019) and T5 (Raffel et al., 2020), have been proposed with varied self-supervised learning architectures. It has been demonstrated that larger models tend to perform better in many learning scenarios (Brown et al., 2020), which stimulated PLMs with billions of parameters to emerge.

Fine-tuning large PLMs may be prohibitive, and there exist a significant gap between pretraining tasks and downstream tasks. Prompt tuning addresses this challenge by reformulating downstream tasks as a language modeling problem and optimizing the prompt. Prompts are used to probe PLM's intrinsic knowledge to perform a task (Min et al., 2022), and various techniques of prompting have been explored to aid PLM better: hard prompt (Shin et al., 2020; Schick and Schütze, 2021), soft prompt (Lester et al., 2021; Li and Liang, 2021), verbalizer (Cui et al., 2022) and pretrained prompt tuning (Gu et al., 2021).

The effectiveness of prompt tuning has been validated in various NLP tasks, including sentiment analysis (Wu and Shi, 2022), named entity recognition (Ma et al., 2022), relation extraction (Chen et al., 2022) and semantic parsing (Schucher et al., 2021). However, the potential of prompt tuning is less explored in RA. In this work, we focus on the effectiveness of linguistic features for modeling readability, and utilize linguistic features to guide prompt tuning.

3 Background

We model RA as a text classification task. Formally, a RA dataset can be denoted as $\mathcal{D} = \{\mathcal{X}, \mathcal{Y}\}$, where $\mathcal{X}$ is the text set and $\mathcal{Y}$ is the class set. Each instance $x \in \mathcal{X}$ consists of several tokens, $x = \{w_1, w_2, ..., w_{|x|}\}$, and is annotated with a label $y \in \mathcal{Y}$, indicating the reading difficulty.

3.1 Fine-tuning PLMs for RA

Given a PLM $\mathcal{M}$ for RA, fine-tuning methods first convert a text $x = (w_1, w_2, ..., w_{|x|})$ into an input sequence ([CLS], $w_1, w_2, ..., w_{|x|}$, [SEP]). The PLM encodes this sequence into the hidden vectors $h = (h_{\text{[CLS]}}, h_1, h_2, ..., h_{|x|}, h_{\text{[SEP]}})$.

In the conventional fine-tuning, an additional classifier FC is trained on top of the [CLS] embedding $h_{\text{[CLS]}}$. This classifier produces a probability distribution over the class set $\mathcal{Y}$ through a softmax function, which can be formulated as:

$$P(\cdot|x) = \text{Softmax}(FC(h_{\text{[CLS]}})),$$

The objective of fine-tuning is to minimize the cross-entropy loss between the predicted probability distribution $P(\cdot|x)$ and the ground-truth label y:

$$\mathcal{L}_{classfication} = -\frac{1}{|\mathcal{X}|} \sum_{x \in \mathcal{X}} \log P(y|x).$$

3.2 Prompt-based Tuning

Prompt-based tuning aims to bridge the gap between pretraining tasks and downstream tasks, as illustrated in Figure 1.

Hard Prompt. It typically consists of a template $T(\cdot)$, which transforms the input x into a prompt input x_{prompt}, and a set of label words V that are connected to the label space through a mapping function $\Phi : V \rightarrow \mathcal{Y}$, often referred to as the verbalizer. The prompt input contains at least one [MASK] token for the model to fill with label words.

Taking an example in RA, x_{prompt} could take the form of

$$x_{prompt} = T(x) = \text{"It is [MASK] to read: } x\text{"}.$$

In this case, the input embedding sequence of x_{prompt} is denoted as

$$(e(\text{"It is"}), e(\text{[MASK]}), e(\text{"to read: "}), e(x)).$$

Soft Prompt. It replaces hard tokens in the template with trainable soft tokens $[h_1, ..., h_l]$, yielding an input embedding sequence of

$$(h_1, ..., h_l, e(\text{[MASK]}), e(x)).$$

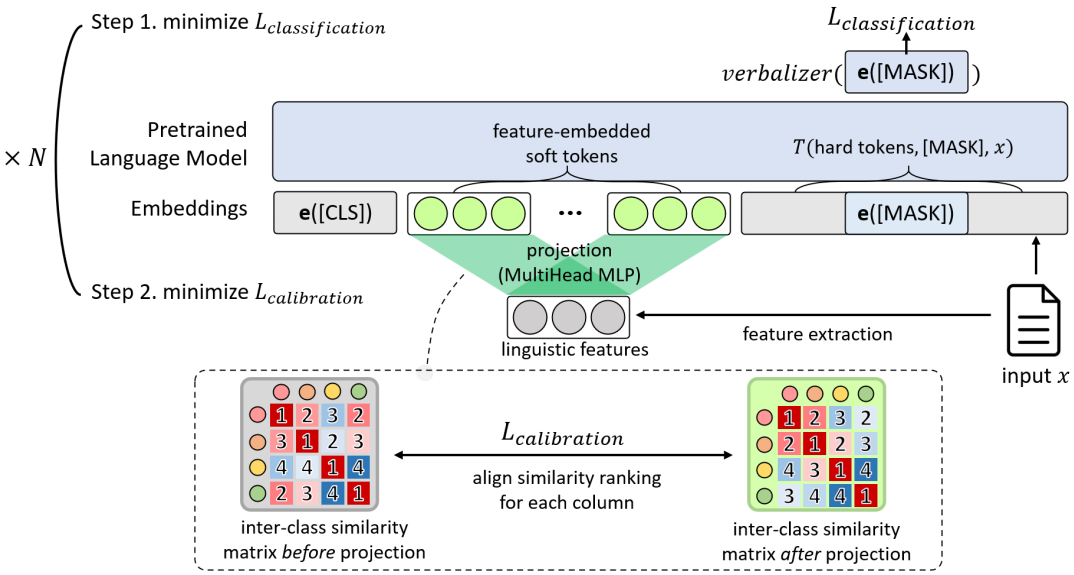

Figure 2: The architecture of the proposed Feature Prompt Tuning. Column-wise ranking orders of similarity matrices are denoted with numbers.

Hybrid Prompt. It combines soft tokens with hard prompt tokens T to form the input embedding sequence:

$$(h_1, ..., h_l, e(T), e([\text{MASK}]), e(x)).$$

By feeding the input embedding sequence of x_{prompt} into $\mathcal{M}$, the probability distribution over the class set $\mathcal{Y}$ is modeled by:

$$P_{\mathcal{M}}(y|x) = P_{\mathcal{M}}([\text{MASK}] = \Phi(y)|x_{prompt})$$

The learning objective of prompt-based tuning is to minimize the cross entropy loss:

$$\mathcal{L}_{classification} = -\frac{1}{|\mathcal{X}|}\sum_{x\in\mathcal{X}} \log P_{\mathcal{M}}(y|x)$$

4 Feature Prompt Tuning

In this section, we propose a novel method for RA with prompt-based tuning, named Feature Prompt Tuning (FPT). The architecture of our model is illustrated in Figure 2. Specifically, we extract linguistic features from the texts and embed them into soft prompts. Then, we employ a loss function to calibrate the similarity relationship between embedded features of different classes. We adopt an alternating procedure to optimize the model with respect to the classification loss and calibration loss.

4.1 Feature Prompt Construction

Feature Extraction Our approach for extracting linguistic features from text is consistent with previous works (Li et al., 2022; Lee et al., 2021). For English texts, the linguistic features are extracted using the *lingfeat* toolkit (Lee et al., 2021), which includes discourse, syntactic, lexical, and shallow features. In terms of Chinese linguistic features, we directly utilize the *zhfeat* toolkit (Li et al., 2022) to extract character, word, sentence, and paragraph-level features. Specific details are provided in Appendix A. For an input text x, we denote the extracted features as f_x, which is a α-dimensional vector with α representing the number of extracted features.

Feature Embedding To incorporate linguistic knowledge into prompt-based tuning, we transform linguistic feature f_x into l distinct vectors $\{v_1, ..., v_l\}$ which function as the embeddings of soft tokens, as follows:

$$\{v_1, ..., v_l\} = \text{MultiHeadMLP}(f_x).$$

Here, MultiHeadMLP is a multi-head MLP with l output heads. Each head consists of a series of fully connected layers followed by non-linear activation functions.

The purpose of using a multi-head MLP is to allow the model to map f_x into separate vector spaces and learn multiple aspects of the linguistic features. This enables the model to better capture the relationships between different features and their contribution to RA.

Ultimately, we formulate the input embedding

sequence of x_{prompt} as follows:

$$(v_1, ..., v_l, e(T), e([\text{MASK}]), e(x)).$$

This input sequence is passed through the PLM $\mathcal{M}$ to calculate $\mathcal{L}_{classification}$ loss as described in Section 3.2.

4.2 Inter-class Similarity Calibration

We denote $\mathcal{F} = \{F_{c_1}, \cdots, F_{c_n}\}$ as the collection of linguistic features for the dataset $\mathcal{D}$, which consists of n classes. Here, $F_{c_i} = \{f_{x_{i1}}, \cdots, f_{x_{ik}}\}$ signifies the extracted features of k samples which belong to i-th class. We apply average pooling to the feature embeddings of each sample in $\mathcal{F}$, resulting in a set of embedded linguistic features, denoted as $\mathcal{F}' = \{F'_{c_1}, \cdots, F'_{c_n}\}$. To gauge the similarity between any two classes F_{c_m} and F_{c_n}, we employ a pairwise approach based on cosine similarity, expressed as:

$$s_{mn} = \frac{1}{k^2} \sum_{i=1}^{k} \sum_{j=1}^{k} \cos(f_{x_{mi}}, f_{x_{nj}})$$

With the feature representation and similarity function in place, we can define our calibration objective. The fundamental intuition is that the distribution of extracted linguistic features should be preserved as much as possible. Namely, if the similarity between F_{c_m} and F_{c_n} is relatively low, the similarity between F'_{c_m} and F'_{c_n} should also be proportionately low, and vice versa. Therefore, during the training process, we devise an objective function based on a list-wise ranking loss function ListMLE (Xia et al., 2008), to maintain this initial ranking relationship.

More specifically, we compute the similarity between each pair of classes within $\mathcal{F}$ to generate the similarity matrix:

$$M = \begin{bmatrix} s_{11} & s_{12} & \cdots & s_{1n} \\ s_{21} & s_{22} & \cdots & s_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ s_{n1} & s_{n2} & \cdots & s_{nn} \end{bmatrix}$$

Likewise, we can derive the similarity matrix M' for $\mathcal{F}'$.

We then use $\Pi = \{\pi_1, \pi_2, \cdots, \pi_n\}$ to denote the ranking order of the columns in M, where π_i represents the ranking order of the i-th column. We obtain $\hat{M}'$ by rearranging the columns of M' according to Π:

$$\hat{M}' = \begin{bmatrix} s'_{\pi_{11}} & s'_{\pi_{12}} & \cdots & s'_{\pi_{1n}} \\ s'_{\pi_{21}} & s'_{\pi_{22}} & \cdots & s'_{\pi_{2n}} \\ \vdots & \vdots & \ddots & \vdots \\ s'_{\pi_{n1}} & s'_{\pi_{n2}} & \cdots & s'_{\pi_{nn}} \end{bmatrix}$$

Finally, we aim to minimize the following loss function for similarity calibration:

$$L_{calibration} = -\sum_{k=1}^{n} log \prod_{i=1}^{n} \frac{\exp(s'_{\pi_{ik}})}{\sum_{j=i}^{n} \exp(s'_{\pi_{jk}})}$$

4.3 Training Procedure

Training Objectives Given the dataset $\mathcal{D}$ and the linguistic feature set $\mathcal{F}$, we establish two training objectives. The primary objective is to minimize the classification loss $L_{classification}$, which is computed based on the difference between the predicted and actual class labels. The secondary objective is to calibrate the inter-class similarity of the mapped features by minimizing the loss function $L_{calibration}$ defined in Section 4.2.

Algorithm 1 Alternating Training Procedure for Feature Prompt Learning

```
Initialize model parameters M and feature embeddings f
for each epoch do
    Shuffle dataset D
    for each batch b in D do
        Compute L_classification for b using M and f
        Update M and f by minimizing L_classification
    end for
    Compute L_calibration for D using f
    Update f by minimizing L_calibration
end for
```

Alternating Training Procedure For training both loss functions, we adopt an alternating training procedure, as encapsulated in Algorithm 1. This procedure iteratively updates the model parameters and feature embeddings by minimizing the classification loss $L_{classification}$ and the similarity calibration loss $L_{calibration}$, respectively.

In each epoch, the dataset D is shuffled to ensure the model is not biased towards any particular ordering of the data. For each batch b in D, the classification loss $L_{classification}$ is computed using

the current model parameters M and feature embeddings f. The model parameters M and feature embeddings f are then updated by minimizing this loss. Subsequently, the similarity calibration loss $L_{calibration}$ is computed using the updated feature embeddings f for the epoch, and the feature embeddings are updated by minimizing this loss . This process is repeated for each epoch. The alternating training procedure ensures that the model learns to classify the data accurately while maintaining the inter-class similarity structure of the feature space.

5 Experimental Setting

5.1 Datasets

To evaluate the effectiveness of our proposed method, we conduct experiments on one Chinese dataset and two English datasets, following the same data split as Li et al. (2022). The statistics of the datasets can be found in Table 1.

ChineseLR (Li et al., 2022) is a Chinese dataset collected from textbooks of the middle and primary schools of more than ten publishers. Following the standards specified in the *Chinese Curriculum Standards for Compulsory Education*, all texts are divided into five difficulty levels.

WeeBit (Vajjala and Meurers, 2012) is often considered as the benchmark data for English RA. It was initially created as an extension of the well-known Weekly Reader corpus.

Cambridge (Xia et al., 2019) consists of reading passages from the five main suite Cambridge English Exams (KET, PET, FCE, CAE, CPE).

5.2 Baselines 1: Prompt-based Methods

For prompt-based methods, we compare with hard, soft, and hybrid prompts. To avoid the influence of verbalizers on experimental results, we adopt a soft verbalizer (Hambardzumyan et al., 2021) that employs a linear layer classifier across all prompt-based methods.

Hard Prompt (HP): We implement four manually defined templates for prompt tuning and select a template with the best performance on the development set. As for FPT in Table 2, we report the test set performance averaged over the four templates. This setting poses a challenge to FPT, as the averaged performance of FPT should outperform the best performance of HP to demonstrate its effectiveness. Details of the templates can be found in Appendix B.

Dataset	WeeBit		Cambridge		ChineseLR	
Level	#	Avg Len	#	Avg Len	#	Avg Len
1	625	152	60	141	814	266
2	625	189	60	271	1063	679
3	625	295	60	617	1104	1140
4	625	242	60	763	762	2165
5	625	347	60	751	417	3299
All	3125	245	300	509	4160	1255

Table 1: Statistics of RA datasets. #: number of the passages. Avg Len: average tokens numbers per passage.

Soft Prompt (SP): It replaces manually defined prompts with trainable continuous prompts. We follow the same implementation as Lester et al. (2021) and use randomly sampled vocabulary to initialize the prompts.

Hybrid Prompt (HBP): It concatenates trainable continuous prompts to the wrapped input embeddings. We adopt the implementation from Gu et al. (2022).

P-tuning: A hybrid prompt method, which replaces some tokens in manually designed prompts with soft prompts and only retains task-relevant anchor words. The soft prompts are embedded with a bidirectional LSTM and a MLP (Liu et al., 2021).

5.3 Baselines 2: Fusion Methods

We also compare with the methods fusing linguistic features and PLMs from previous studies.

SVM: Use the single numerical output of a neural model (BERT) as a feature itself, joined with linguistic features, and then fed them into SVM (Lee et al., 2021; Deutsch et al., 2020).

FT: Standard fine-tuning method without linguistic features, where the hidden representation of [CLS] token is used for classification. This baseline validates whether the linguistic features indeed have a positive effect.

Concatenation (Con): Fine-tune with linguistic features, in which the linguistic features are directly concatenated to the hidden representation of the [CLS] token (Meng et al., 2021; Qiu et al., 2021).

PF: Fuse linguistic features with hidden representations of [CLS] through projection filtering (Li et al., 2022).

5.4 Implementation Details

Under the few-shot setting, we randomly sample $k = 1, 2, 4, 8, 16$ instances in each class from the training and development set. For each k-shot experiment, we sample 4 different training and dev sets and repeat experiments on each training set for 4 times. We select the best model checkpoint based on the performance of the development set

and evaluate the models on the entire test set. As for the evaluation metric, we use *accuracy* in all experiments and take the mean values as the final results.

All our models and baselines are implemented with the PyTorch (Paszke et al., 2019) framework and Huggingface transformers (Wolf et al., 2020). We use BERT (Devlin et al., 2018) as our Pre-trained Language Model (PLM) backbone. We use "bert-base-uncased" for English datasets and "bert-base-chinese" for the Chinese dataset. During training, we employ the AdamW optimizer (Loshchilov and Hutter, 2019) with a weight decay of 0.01 and a warm-up ratio of 0.05. We tune the model with the batch size of 8 for 30 epochs, and the learning rate is 1e-5. All experiments are conducted with four NVIDIA GeForce RTX 3090s.

Table 2: Experimental results comparing with prompt-based methods. We report the mean performance and the standard deviation in brackets. The best results are in bold, and the best results of previous prompt-based methods are underlined.

6.1 Comparison with Prompt-based Methods

Table 2 shows the results of our proposed method FPT and prompt-based baselines under the few-shot setting. (1) Our method FPT significantly outperforms nearly all baseline methods across all three datasets under different shots, demonstrating that our method exhibits greater robustness and adaptability to variations in data sizes and languages. (2) FTP particularly excels on the ChineseLR dataset, and it outperforms the soft prompt (SP) method by 8.41, 14.1, 10.15, 9.94 and 7.9 points under 1, 2, 4, 8, 16 shots, respectively. (3) In the task of RA, the soft prompt method generally outperforms the hard prompt. Interestingly, the hybrid prompt, a combination of both, does not always yield better results than the standalone soft prompt. This could be attributed to the inherent challenge in designing and selecting effective hard prompts for RA. Nevertheless, as a hybrid prompt approach that integrates linguistic knowledge, our proposed method continues to exhibit robust performance, demonstrating its adaptability and effectiveness.

	FPT(ours)	**53.94**(3.16)	**68.10**(3.25)	69.17(7.77)

Table 3: Experimental results comparing with feature fusion methods. Con means Concatenation. For a fair comparison, here FPT concatenates the embedded linguistic features to the embeddings of the input sequence (without hard prompt template) and outputs the classification logits over [CLS] token embedding instead of [MASK].

6.2 Comparison with Fusion Methods

Table 3 reports the experimental results comparing with fusion methods under the few-shot setting. (1) Our proposed method FPT shows a stable and significant improvement compared to the previous feature fusion methods. For instance, in the 2-shot setting, FPT outperforms the best previous fusion methods by 11.28, 5.8 and 11.66 points on ChineseLR, Weebit and Cambridge, respectively. This demonstrates our method's effectiveness in integrating linguistic features for RA. (2) Methods with linguistic features perform better than standard fine-tuning on Chinese datasets. However, it may not necessarily lead to improvement on English datasets, especially when k is increased to a sufficient amount, which indicates that simply applying linguistic features to aid in English RA is not consistently effective.

Dataset	Methods	k=2	k=4	k=8
ChineseLR	FPT	**46.24**	**48.93**	**52.66**
	-SC	40.97	46.03	50.48

Table 4: Ablation study of FPT on ChineseLR and Weebit datasets. SC represents the similarity calibration and FP means utilizing linguistic features as soft prompts.

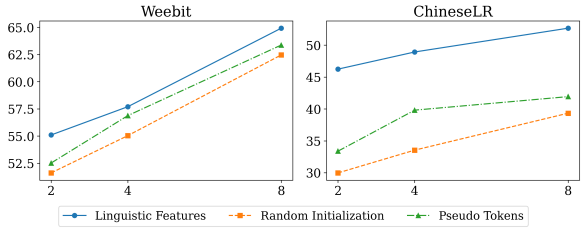

Figure 3: The comparison results of linguistic features, randomly initialized vectors and pseudo tokens.

6.3 Ablation Study

To validate the effectiveness of each component in our proposed model, we conduct ablation experiments on both English Weebit and ChineseLR datastes. Table 4 lists the results. Notably, our similarity calibration (SC) is built on the feature prompt (FP), with the aim to maintain consistent inter-class similarity of linguistic features. Therefore, removing FP also detaches SC, explaining why our ablation study is performed incrementally.

Our full model yields the best performance on both datasets. When removing the SC module, the performance is markedly decreased, demonstrating the necessity of retaining the linguistic features' original similarity information during optimization. We have also investigated the impact of SC by visualising the similarity difference matrix before and after applying SC, the results of which are presented in Appendix C. Moreover, further removal of the FP shows a steep drop in performance (12.37 points on ChieseLR and 4.29 points on Weebit when $k = 4$), validating the effectiveness of incorporating linguistic features as soft prompts. We note that the improvement of SC and FP is more significant on the Chinese dataset compared to the English dataset, indicating that the Chinese RA task is more dependent on linguistic features.

6.4 The Significance of Linguistic Features

To further analyze whether linguistic features improve performance, in our model structure, we replace the linguistic feature vectors with randomly initialized vectors. On the other hand, we reimplement the Hybrid Prompt Tuning by utilizing pseudo tokens as soft prompts. We conduct experiments on WeeBit and ChineseLR datasets, and the comparison results are shown in Figure 3.

The performance on both datasets significantly decreases when the linguistic features are replaced with random vectors, especially on the ChineseLR dataset, where the decrease is up to 16.27%. The fewer the samples, the more severe the decline caused by the replacement, further indicating the beneficial role of linguistic features when data is insufficient. Moreover, compared to pseudo tokens, using vector-form embeddings as soft prompts requires the integration of linguistic knowledge to achieve better performance.

6.5 Comparison with the LLM

The large language model (LLM) excels at various downstream tasks without the need for parameter adjustment. We carry out experiments on LLM, utilizing the gpt-3.5-turbo-16k API. We sample the same examples as in other experiments, and the prompt is generated by GPT-4. Specifically, we provide GPT-4 with the task instructions to generate the system prompt and user input for gpt-3.5-turbo-16k, as shown in Figure 4. Table 5 shows that our model with 110M parameters significantly outperforms the LLM on the English dataset (except for one sample on Cambridge). Moreover,

gpt-3.5-turbo-16k is unable to perform 1-shot or 2-shot experiments on ChineseLR due to its limited context length. This underscores the necessity for research on handling long texts in RA.

```
System Prompt:
Evaluate the readability of the text using the
following five levels (reading difficulty):
        Very Easy
        Easy
        Moderate
        Difficult
        Very Difficult
Based on the provided text examples, assign a
readability score to new text and display it in
the following format: "[score: X]"

User Input:
Text: "content 1"
[score: X]
Text: "content 2"
[score: X]
...
Text: "content n"
[score: X]
New text:
Text: "{}"
```

Figure 4: The system prompt and the user input for prompting LLM.

k	Dataset	FPT	LLM
0	Weebit	-	30.79
	Cambridge	-	43.33
	ChineseLR	-	21.67
1	Weebit	**43.61**	31.75
	Cambridge	44.17	**48.33**
	ChineseLR	39.63	-
2	Weebit	**55.10**	33.17
	Cambridge	**59.79**	54.16
	ChineseLR	46.24	-

Table 5: Comparison (accuracy) between our model and LLM (gpt-3.5-turbo-16k) on three datasets. k represents the number of in-context examples. Due to the limitation of context length, the experiments on Chinese dataset cannot be carried out.

7 Conclusion

Inspired by the solid performance of prompt tuning on classification tasks and the importance of linguistic features in the RA task, we empirically investigated the effectiveness of incorporating linguistic features into prompt tuning for RA. We convert linguistic features of the input into soft tokens and utilize the similarity calibration loss to preserve the similarity relationship between classes before and after the transformation. The results show noticeable improvements over previous fusion methods and prompt-based approaches in the few-shot learning setting. The ablation study further illustrated that the proposed model benefits from linguistic features and additional similarity calibration. Our proposed method, FPT, has demonstrated a new possibility of prompt tuning in an era dominated by LLMs, showcasing its undeniable significance and value in linguistic-related tasks.

This work is supported by the National Natural Science Foundation of China (62076008) and the Key Project of Natural Science Foundation of China (61936012).

Limitations

Our proposed method, which leverages the masked language model (MLM) backbone such as BERT, has demonstrated its efficacy across a variety of natural language processing tasks. Despite its strengths, we acknowledge several limitations that warrant further investigation.

Firstly, our approach exhibits constraints in processing long texts, a scenario frequently encountered in Chinese readability evaluation datasets. The inherent architecture of MLMs like BERT is optimized for shorter sequences, leading to potential performance degradation when dealing with extensive text inputs.

Secondly, while MLM-based methods are proficient in classification tasks, they often fall short in terms of interpretability of the classification outcomes. The black-box nature of these models makes it challenging to trace and understand the decision-making process, which is crucial for applications where justification of results is required.

Lastly, the success of our method is significantly contingent upon the quality of linguistic features extracted from the text. However, the extraction of high-quality linguistic features is not always guaranteed, especially in languages with rich morphology or poor data resources.

In conclusion, while our method stands as a robust approach for several NLP tasks, addressing these limitations is imperative for advancing the field and extending the applicability of MLM-based models to a broader spectrum of text analysis challenges. It is also worth noting that only one Chinese dataset is included in this work, as it appears to be the only Chinese RA dataset available to the best of

our knowledge. We urge that more attention should be paid to this field of work and further experiments will be conducted if new datasets are released.

Ethics Statement

Potential Risks Firstly, as a neural network-based method, the predictive outcomes of our approach should not be applied in practical applications without the involvement of human experts. This is a responsible practice for the actual beneficiaries, the learners. Secondly, as mentioned earlier, low-quality or even incorrect linguistic features can negatively impact our method. Therefore, evaluating the quality of linguistic features is essential for the efficacy of our approach.

About Computational Budget For each k-shot experiment, we conducted a total of 16 repetitions (refer to Section 5.4) for all baselines and FPT. The duration of a single experiment varies according to the size of k (approximately 20 seconds to 200 seconds), but the time consumed by different methods is almost identical.

Use of Scientific Artifacts We utilize the *lingfeat* toolkit (Lee et al., 2021) to extract linguistic features from English texts; this toolkit is publicly accessible under the CC-BY-SA-4.0 license. For extracting Chinese linguistic features, we employ the *zhfeat* toolkit (Li et al., 2022).

Use of AI Assistants We have employed ChatGPT as a writing assistant, primarily for polishing the text after the initial composition.

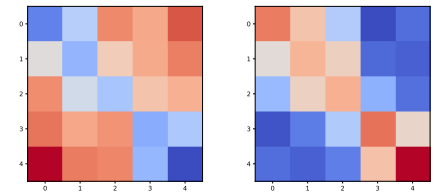
B Templates

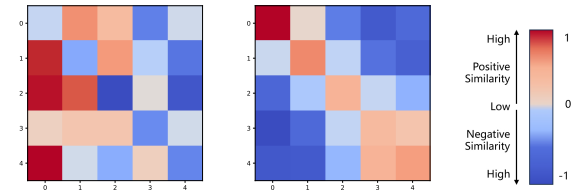
Chinese Dataset Based on the *Chinese Curriculum Standards for Compulsory Education*, we devise the following templates:

- $T_1(\cdot)$ = 一篇第[MASK]学段的文章:
- $T_2(\cdot)$ = 这是一篇第[MASK]学段的课文:
- $T_3(\cdot)$ = 一篇第[MASK]学段的课文:
- $T_4(\cdot)$ = 一篇阅读难度为[MASK]的课文:



English Dataset Based on (Vajjala and Meurers, 2012), we use the following templates:

- $T_1(\cdot)$ = A [MASK] article to understand:
- $T_2(\cdot)$ = A [MASK] text to understand:
- $T_3(\cdot)$ = This is a [MASK] article to understand:
- $T_4(\cdot)$ = A [MASK] article to read:



C The Impact of Similarity Calibration

To investigate the impact of Similarity Calibration (SC), we plot the similarity difference matrices before and after linguistic feature embedding on two datasets, both with and without SC. Specifically, we calculate the similarity of linguistic features between each category before and after embedding to obtain two similarity matrices. Then we subtract the former from the latter to obtain the difference matrix. The results are shown in Figure 5, where the diagonal of the matrix represents the similarity of the linguistic features from the same category.

On both datasets, SC can effectively increase the similarity between the same and analogous categories (represented by warm colors), while reducing the similarity between distance categories (represented by cool colors). This can provide effective assistance for classification tasks.

(a) ChineseLR w/o SC (b) ChineseLR w/ SC

(c) Weebit w/o SC (d) Weebit w/ SC

Figure 5: Similarity difference matrices. We plot the difference matrices of similarity before and after linguistic feature embedding, both with and without SC. The horizontal and vertical coordinates represent the level of linguistic features. By comparing the diagonal of the matrix before and after the similarity calibration (that is, the similarity between linguistic features of the same level), the similarity between analogous categories is drawn closer.

Self-Prompting Large Language Models for Zero-Shot Open-Domain QA

Abstract

Open-Domain Question Answering (ODQA) aims to answer questions without explicitly providing specific background documents. This task becomes notably challenging in a zero-shot setting where no data is available to train tailored retrieval-reader models. While recent Large Language Models (LLMs) like GPT-3 have demonstrated their effectiveness in zero-shot ODQA using direct prompting methods, these methods still fall short of fully harnessing the potential of LLMs when implicitly invoked. In this paper, we propose a **Self-Prompting** framework to explicitly utilize the massive knowledge encoded in the parameters of LLMs and their strong instruction understanding abilities. Concretely, we prompt LLMs step by step to generate multiple pseudo QA pairs with background passages and explanations entirely from scratch. These generated elements are then utilized for in-context learning. Experimental results show that our method significantly surpasses previous state-of-the-art zero-shot methods on three widely-used ODQA datasets and even achieves comparable performance with various customized fine-tuned models on full training data. Our code is available at https://github.com/lockon-n/self-prompting.

1 Introduction

Open-Domain Question Answering (ODQA) is a longstanding task in natural language processing that aims to answer questions about world knowledge without explicitly providing specific background documents (Voorhees et al., 1999; Huang et al., 2020; Zhu et al., 2021; Zhang et al., 2022a). The most common approach for ODQA is to train a Retriever-Reader pipeline (Chen et al., 2017): (i) first retrieving the most related documents of the question, (ii) then applying the reader to extract or generate the final answer conditioned on these documents (Karpukhin et al., 2020; Lewis et al., 2020; Izacard and Grave, 2021). Despite the decent performance, they rely on large amount of training data and a large external knowledge corpus, so it is hard to expand these methods to zero-shot ODQA where no training data is available.

With the emergence of Large Langauge Models (LLMs) such as GPT-3 (Brown et al., 2020), OPT (Zhang et al., 2022b), PaLM (Chowdhery et al., 2022), InstructGPT (Ouyang et al., 2022), researchers start to leverage them for zero-shot ODQA tasks. These LLMs are capable of generating correct answers without any training data and external corpus with direct prompts (like *Q: {question} A:*). Some recent works go further to induce the instruction understanding abilities and use the abundant knowledge in their parameters by asking LLMs to generate rationales called *chain-of-thought* (Wei et al., 2022b; Kojima et al., 2022) or related background information (Yu et al., 2022; Sun et al., 2022) before answering. However, these naive prompting methods for zero-shot ODQA still fail to compete with customized fine-tuned models (Yu et al., 2022), since they fail to take full advantage of the powerfulness of LLMs.

In this paper, we focus on zero-shot ODQA with no training data and external corpus. Based on the characteristics of this task, we propose **Self-Prompting** the LLM to explicitly activate different capabilities of LLMs and combine these capabilities to improve performance. In general, we ask LLMs to automatically generate pseudo QA pairs for in-context learning instead of predicting the answers directly as in naive prompting methods. Self-prompting consists of two stages: preparation and inference. In the preparation stage, the LLM is required to generate a pseudo QA dataset in three steps: (i) write a short Wikipedia-style passage, extract named entities in this passage as answers;

(ii) raise questions for the answers; (iii) explain each generated QA pair in a short sentence based on the passage. Relying on the strong instruction understanding ability of LLMs, all these sub-tasks can be effectively conducted with simple natural language prompts. In the inference stage, we propose a novel clustering-based retrieval method to select salient examples from this pseudo dataset as the in-context demonstrations for each test sample. These selected QA pairs, along with the passages and explanations, are concatenated with the test question in a specific order as the input sequence, which is fed into the LLM to get the final answer.

We evaluate our approach on three ODQA benchmarks: WebQ (Berant et al., 2013), NQ (Kwiatkowski et al., 2019), and TriviaQA (Joshi et al., 2017). Experimental results show that our method significantly surpasses the direct prompting baselines and the previous state-of-the-art (SOTA) zero-shot method *GENREAD* (Yu et al., 2022). Our method even shows comparable performance with strong few-shot methods. We also conduct extensive analysis on the effects of different generated components, like the formats of the prompted sequence for in-context learning, ways of demonstration selection from the pseudo dataset, and the quality of generated QAs. In general, our contributions can be summarized as follows:

(i) We propose Self-Prompting to leverage multiple capabilities of LLMs for zero-shot ODQA. It can automatically build a pseudo but high-quality ODQA dataset in advance and select salient QA instances for in-context learning.

(ii) We propose a clustering-based retrieving method to effectively utilize the built pseudo QA dataset to select both semantically similar and diverse examples for each test sample.

(iii) We conduct extensive experiments to show the effectiveness of Self-Prompting on three ODQA tasks. It achieves new SOTA for zero-shot ODQA, and is comparable with some fine-tuned Retriever-Reader models and few-shot prompting methods.

2 Related Works

Retriever-Reader Models for ODQA The mainstream method to tackle ODQA tasks is the Retriever-Reader architecture (Zhang et al., 2023). It first leverages a retriever over a large knowledge corpus to select several related documents that may contain the answer. Then, a reader is used to process the retrieved documents and predict the answer. Conventional models use sparse retrieval methods such as TF-IDF or BM25, while recent works choose dense retrieval based on the representation vector encoded by pre-trained language models (Karpukhin et al., 2020; Lewis et al., 2020; Guu et al., 2020; Izacard and Grave, 2021). There are also two choices for the reader: extractive readers like BERT (Devlin et al., 2019) or generative ones like T5 (Raffel et al., 2020). A related work in this branch is PAQ (Lewis et al., 2021b), which generates 65 million probably-asked questions based on the complete dump of Wikipedia and directly retrieves these questions instead of documents.

LLM and In-context Learning Generally, LLMs refer to the pre-trained models with tens or hundreds of billions of parameters, such as GPT-3, FLAN, PaLM, OPT, and InstructGPT (Brown et al., 2020; Wei et al., 2022a; Chowdhery et al., 2022; Zhang et al., 2022b; Ouyang et al., 2022). These models are trained with large-scale unsupervised learning and are able to perform NLP tasks by converting inputs into natural language queries without further training. The cost of fine-tuning these models is extremely huge, so the usual way of using them is in-context learning, which is to put some input-output pairs as demonstrations in front of the test sample. Some previous works have investigated the calibration (Zhao et al., 2021), example selection (Liu et al., 2022a; Rubin et al., 2022) and ordering (Lu et al., 2022b) of in-context learning, while to the best of our knowledge, we are the first to generate a large number of demonstrations used in in-context learning completely by the LLM itself from scratch.

Enhancing Models with LLM generation A recent line of research aims to use the generated contents of LLMs to facilitate the training of small models. For example, Ye et al. (2022) uses GPT-2 (Radford et al., 2019) to generate pseudo data to train tiny language models, and Wang et al. (2022) distills the knowledge of GPT-3 into GPT-2 for commonsense QAs. Another line of work directly uses contents generated by the LLM itself. Some works use LLMs to generate relevant contexts or background documents, which are used as additional inputs when answering questions (Liu et al., 2022b; Yu et al., 2022; Sun et al., 2022), while others focus on eliciting a series of intermediate reasoning steps referred to as *chain-of-thought* for arithmetic problems (Wei et al., 2022b; Kojima et al., 2022; Zhang et al., 2022c).

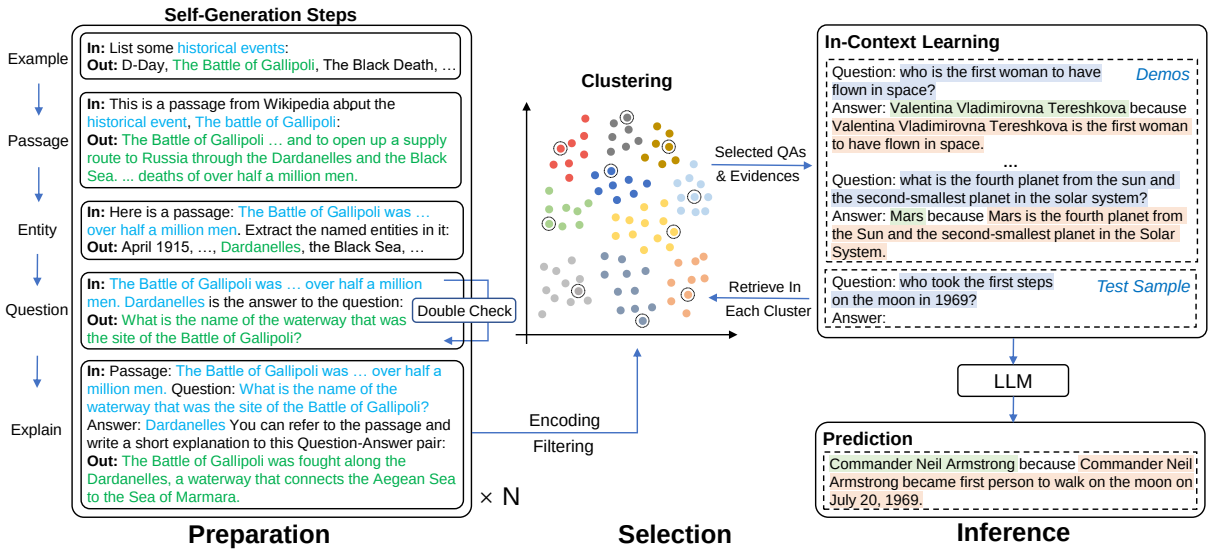

Figure 1: The overall framework for Self-Prompting on ODQA. In the self-generation steps, blue refers to contents generated in previous steps or manually designed topics, and green is the newly generated texts. In inference, question, answer, and explanation are question, answer, and explanation for both demonstrations and test samples.

3 Approach

This section presents the details of Self-Prompting, which has two stages: preparation and inference. In the first stage, we require the LLM to automatically build a pseudo ODQA dataset by prompting it to generate QA pairs with context passages and explanations. In the second stage, we dynamically select examples in the pool through a clustering-based retrieval method as in-context demonstrations to help understand and answer the given question. An overall framework is shown in Figure 1.

3.1 Qseudo QA Dataset Generation

In the preparation stage, we prompt the LLM to automatically generate a large number of QA pairs as a pseudo dataset by the following four steps.

Passage Generation To ensure the diversity of the generated passages, we first sample various topics (such as *countries, books, tourist attractions*) that are likely to appear in ODQA based on the distribution of hierarchical WordNet synsets for entities appearing in the answers of TriviaQA (Joshi et al., 2017). Specifically, we first abstract and summarize these entities to define a set of high-level themes such as politics, sports, geography, film, television, etc. Then under each high-level theme, we further subdivide it into several topics; for instance, the sports theme is broken down into athletes, sports teams, and sporting events, leading to a complete list of topics. Regarding the number of examples needed for each topic, we empirically set the requirement for each high-level theme at 100 and evenly distribute this value among all the subordinate topics. Subsequently, we manually adjust these numbers, resulting in the data shown in our paper (Table 9 in Appendix B).

For each topic, the LLM is asked to list some examples with instructions like "`List some {topic}:`", and this step is repeated until we have collected a certain number of different examples for it. Through this, we obtain a huge number of examples covering different categories and they are leveraged to generate short Wikipedia-style passages with the following prompt "`This is a passage from Wikipedia about the {topic}, {example}:`". Note that we do not require the generated article to be an exact copy of the Wikipedia page but just a Wikipedia-style paragraph with enough factual information.

Named Entity Recognition We extract the named entities in these generated passages as the candidate answers. Usually, this step is conducted by a fine-tuned small model. In our framework, this is also done by the LLM itself. For a given passage, the prompt might be "`Here is a passage: {passage} Extract the named entities in it:`", and we can get the entities in this passage.

Question Generation Named entities (e.g., date, name, and location) extracted in the previous step are used as the candidate answers. We then ask the LLM to write a proper question for this answer based on the given passage with prompts like

"`{passage} {entity} is the answer to the question:`". To ensure the correctness of the QA pair, we ask the LLM to double-check, i.e., re-answer the question based on the passage to see whether it can recover the entity, and only keep the sample when the answer predicted by the LLM has the same normalized form as the extracted entity.

Explain the QA pair For each QA pair, we ask the LLM to return a one-sentence explanation according to the passage. The prompt is like "`Passage: {passage} Question: {question} Answer: {answer} You can refer to the passage and write a short explanation to this Question-Answer pair:`". This step elicits the summarization and induction skills of the LLM to provide a fine-grained annotation for the generated QA pairs without including too much redundant information in the original passage.

3.2 Dynamic In-context Demonstrations Selection for Inference

It is an open question for how to use the pseudo QA dataset generated in the preparation stage. We focus on two aspects, namely selection and format.

Clustering-based Retrieval Some previous works point out that using examples with high semantic similarity as in-context demonstrations brings benefits (Liu et al., 2022a), while others claim that a fixed set of examples based on clustering is better (Zhang et al., 2022c). We find it effective to combine these two ways. First, each QA pair is encoded into a vector representation over the whole QA pool with Sentence-BERT (Reimers and Gurevych, 2019). Suppose k examples are needed for in-context demonstration; the pseudo QAs will be clustered into k categories by the k-means algorithm. For a given question, we encode the question using Sentence-BERT and retrieve the most similar example from each cluster with simple cosine similarity. This selection method balances the similarity and diversity of the demonstrations.

Answer then Explain The final step is to organize the format of these selected examples. In the input sequence, we first put these examples sequentially in the format of *Question*$\rightarrow$ *Answer* $\rightarrow$ *Explanation* and place the test question at the end of the sequence. By doing so, the LLM can view more information than just switching to a QA mode, and it can also give out a brief explanation along with its answer. This is different from the common practice in *chain-of-thought* prompting, i.e., generating a rationale before the answer, but our experiments prove the effectiveness of our choice.

4 Experiments

4.1 Datasets and Settings

We conduct experiments on three English ODQA benchmarks, including WebQ (Berant et al., 2013), NQ (Kwiatkowski et al., 2019) and TriviaQA (Joshi et al., 2017). Data statistics are in Appendix A.

We use InstructGPT (Ouyang et al., 2022) (`text-davinci-002` of GPT-3 (Brown et al., 2020)) as the LLM following previous works (Wei et al., 2022b; Kojima et al., 2022; Yu et al., 2022). We also conduct experiments on Codex (Chen et al., 2021) (`code-davinci-002` of GPT-3 for code generation) to check the versatility of Self-Prompting. The exact model we used as Sentence-BERT is `all-mpnet-base-v2`, and the number of demonstrations for in-context learning is 10.

In passage generation, we design 29 topics in advance. Their names and numbers of required examples for each topic are in Appendix B. In question generation, we ban some pronouns like *they, he, she* by setting their `logit_bias` as -100 in the API call to prevent getting questions that are ambiguous without context (e.g., *what did he do in 1997?*). After the generation process, we filter the QA pair where the answer has more than 5 words, or the LLM outputs an explanation sentence with no target answer span in it. For each passage, the upper limit of generating QA pairs is 10 to ensure diversity. Detailed parameters like `max_tokens` or `temperature` and prompt templates for LLM generation in each step are in Appendix C. We also provide a brief cost and running efficiency analysis in Appendix H. Following previous works on ODQA, we choose Exact Match (EM) as the evaluation metric, with the same answer normalization as in Karpukhin et al. (2020). We also observe that in WebQ, if the correct answer contains multiple listed entities, the reference is often given as only one of them. So we heuristically perform extra post-processing on WebQ to extract only the first entity when the LLM predicts multiple ones (e.g., only return *A* if the raw prediction is *A, B, and C*).

The baselines we select include direct prompting: InstructGPT (Ouyang et al., 2022), Codex (Chen et al., 2021), GENREAD (Yu et al., 2022), RECITE (Sun et al., 2022); retrieval-augmented LLM prompting: DPR+InstructGPT,

Table 1: Main results on three ODQA benchmarks, Self-Prompting is free from any training data and external knowledge corpus. # Total Params. is the total number of model parameters in this system (e.g., RAG uses 2 BERT-base with 110M×2 and 1 BART-large with 400M). Train Data refers to whether the system uses training data for training or as in-context demonstrations, and External Corpus means whether an external knowledge corpus is used to retrieve documents. ⋆This value is obtained by 5-shot in-context learning with samples from the training set as demonstrations. †This value is obtained on a subset of TriviaQA used in RECITE to save computational cost.

Models	# Total Params.	Train Data	External Corpus	WebQ	NQ	TriviaQA	Avg.

Self-Prompting (Codex)	175B	✗	✗	38.9	40.7	84.3†	-

Google+InstructGPT; fine-tuned models with no retrieval: T5-SSM 11B (Roberts et al., 2020); retrieval-augmented fine-tined models: REALM (Guu et al., 2020), DPR (Karpukhin et al., 2020), RAG (Lewis et al., 2020).

4.2 Main Results

The main results are shown in Table 1. Compared to direct prompting, our Self-Prompting method surpasses the InstructGPT baseline by +15.5 EM on average and the previous SOTA method GENREAD by +8.8 EM on average. A similar improvement is also observed when using Codex as the backbone model, and it even achieves a higher score than RECITE, a strong few-shot baseline.

Self-Prompting yields comparable results to various powerful retrieval-augmented fine-tuned models with regard to the average EM on three datasets, showing that the LLM itself has stored enough world knowledge in its parameters and provides the potential as an implicit corpus for retrieving. We also notice that Self-Prompting achieves higher EM than T5-SSM 11B on two datasets except WebQ, even though we do not give any training data to the LLM, showing the great potential of LLMs for ODQA under a zero-shot setting.

Although the generated QA data is not 100% perfect (see Sec 5.6), using them for in-context learning still improves the model performance, which is consistent with the conclusion in Min et al. (2022) where they demonstrate that the label space, the distribution of the input text, and the overall format of the sequence are key factors for in-context learning rather than absolute accuracy. Therefore, Self-Prompting can reasonably use the existing capabilities of LLMs to construct data with a similar distribution, and it improves model performance in an in-context learning way as expected.

5 Analysis

This section will present our analysis on the construction of in-context learning demonstrations, hyper-parameters in Self-Prompting, the generality of Self-Prompting on different LLMs, and quality analysis of the generated pseudo data. As LLMs like GPT-3 have paywalls, our analysis is conducted on the subsets of the three datasets by randomly selecting 1,000 samples from the test sets. Unless otherwise stated, we use InstructGPT in this section for these three subsets. Besides EM, we also report the F1 score because it is a more robust metric for tiny formal differences between the prediction and gold answer.

Table 2: Effects of using different formats for in-context learning in the inference stage. Q = question, A = answer, E = explanation sentence, P = passage. We report the average EM and F1 on three datasets.

Demos	Pred.	EM	F1
**one iteration*			
QAE	Q→AE	**48.2**	**58.3**
QAP	Q→AP	46.9	57.5
QEA	Q→EA	43.3	53.6
QPA	Q→PA	40.3	49.9
QAEP	Q→AEP	46.9	57.3
QAPE	Q→APE	46.4	57.1
**two iterations*			
1: QP	Q→P	-	-
2: PQA	PQ→A	41.5	51.8
1: QE	Q→E	-	-
2: EQA	EQ→A	43.7	54.7

5.1 How to Use Generated Passages and Explanations

A crucial question is how to use the byproducts, namely the passages and explanations, in a better format for in-context learning. Given a list of 10 demonstrations (Q, A, P, E) $\times$ 10 (by clustering-based retrieval), we investigate several input formats in Table 2. The *one iteration* methods mean only one call of API is needed to generate the answer and the passage/explanation, while in *two iterations* methods the LLM needs to generate the passage/explanation first and use them in the second API call. Detailed templates for these methods are in Appendix E. From Table 2, we see that the QAE format is the most effective, while the other three answer-then-explain formats (QAP, QAEP, and QAPE) are worse than QAE, which indicates that ntroducing too much redundant information in the form of passage is harmful to the LLM. We also find that the two *chain-of-thought* style formats, QEA and QPA, are much worse than other variants. In Lu et al. (2022a) and Wei et al. (2022b), similar findings are concluded that *chain-of-thought* is beneficial to complex reasoning tasks like math problems but has little impact on commonsense questions. Finally, the *two iterations* methods lead to a significant performance drop, which makes them the worst settings considering the doubled inference time and cost.

5.2 Ways of Demonstration Selection

Since the size of the pseudo QA dataset generated by the LLM is much larger than the number of examples we can put in the input sequence for in-context learning, a proper selection strategy is necessary. We conduct experiments with four settings: randomly selection (Random), retrieving the most similar QAs with cosine similarity globally (Retrieve), selecting the closest QA to the centroid in each cluster (ClusterCenter), and retrieving the most similar QA in each cluster (RetrieveInCluster). The other hyper-parameters are kept the same, i.e., 10 demonstrations and QAE format. Results in Table 3 show that random selection performs the worst and suffers from instability. The Retrieve and ClusterCenter methods have some improvements over Random. RetrieveInCluster, proposed to select diverse and semantically similar demonstrations, is robust enough to achieve satisfactory scores among all datasets.

Table 3: Different ways for demo selection. We report mean value and standard deviation on 5 runs of Random. The metrics are average EM and F1 on three datasets.

Selection	EM	F1
Random	$46.4_{\pm 1.3}$	$56.7_{\pm 1.0}$
Retrieve	46.7	57.1
ClusterCenter	47.1	57.2
RetrieveInCluster	**48.2**	**58.3**

Table 4: Performance of Self-Prompting (Codex) on different numbers of generated QA pairs.

Data Size	100	500	1,000	2,000	full
EM	51.8	51.7	52.2	52.4	**52.6**

5.3 Different Number of Demonstrations

A natural idea of in-context learning is to put as many examples as possible in the input, so we also investigate the effect of different numbers of demonstrations, as in Figure 2. We report the av-

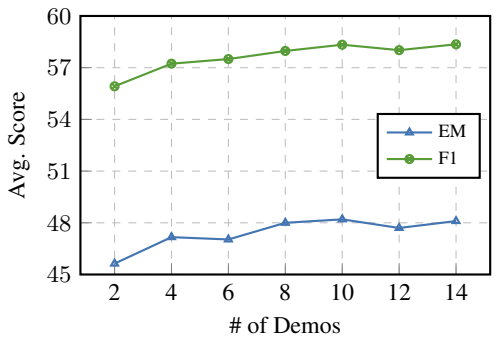

Figure 2: Average EM / F1 when using different numbers of demonstrations in Self-Prompting.

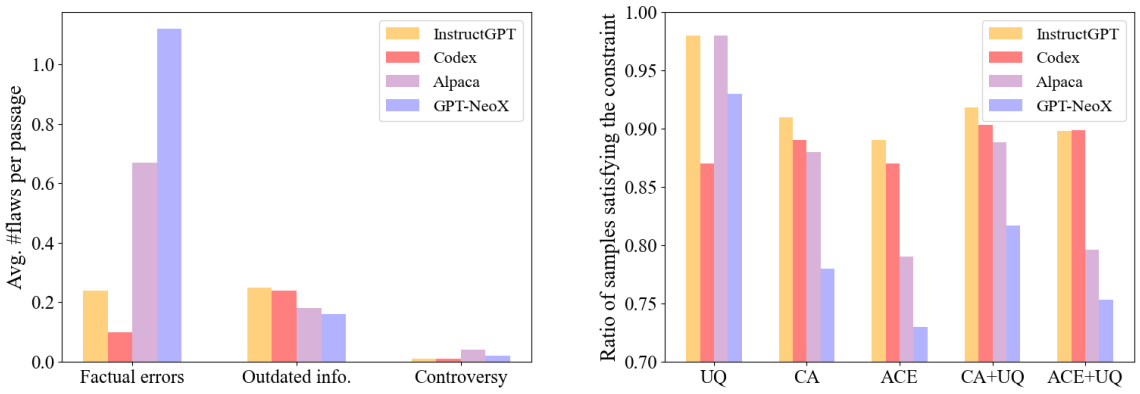
Table 5: The performance of our method for different LLMs. **Direct** means the models are required to output answers directly with no demonstrations, **Self-P** (**Self-Prompting**) uses the self-generated QAs as in-context learning samples.

Model	#Params	Method	WebQ			NQ			TriviaQA			Avg.		
			EM	F1	IE	EM	F1	IE	EM	F1	IE	EM	F1	IE
InstructGPT	175B	Direct	25.3	38.7	52.6	21.6	31.9	38.9	55.1	64.8	72.0	34.0	45.1	54.5
		Self-P	38.7	51.6	61.4	37.2	47.6	48.3	68.7	75.7	78.2	48.2	58.3	62.6
Codex	175B	Direct	27.6	44.5	55.9	27.1	38.0	45.8	67.6	73.6	76.3	40.8	52.1	59.3
		Self-P	44.0	55.8	64.6	41.3	51.7	51.2	72.4	79.5	81.8	52.6	62.3	65.9
GPT-NeoX	20B	Direct	14.9	27.7	38.8	5.9	12.3	28.7	19.1	25.8	37.8	13.3	21.9	35.1
		Self-P	27.6	40.6	41.7	19.2	26.5	26.9	38.3	43.8	46.4	28.4	37.0	38.3
Alpaca	7B	Direct	16.4	32.9	46.0	11.4	21.3	29.7	29.3	41.5	51.4	19.0	31.9	42.4
		Self-P	25.8	40.3	50.0	20.3	30.0	32.6	44.3	52.8	57.9	30.1	41.0	46.8

Table 6: Two examples in the pseudo QA dataset. teals are the key sentences for the questions and blues are the entities used as answers.

Topic: Video game
Example: Splatoon
Passage: Splatoon is a third-person shooter video game developed and published by Nintendo for the Wii U, which was released worldwide in May 2015. The game centers around characters known as Inklings—anthropomorphic squid that can transform between humanoid and cephalopod forms, and use colored ink to attack opponents and clear goals. Splatoon features several game modes, including four-on-four online multiplayer and a single player campaign.
Entity: the Wii U
Question: On what platform is Splatoon available?
Explanation: Splatoon is a third-person shooter video game developed and published by Nintendo for the Wii U.

Topic: Historical figure
Example: Augustus Caesar
Passage: Augustus Caesar (63 BC – 14 AD) was the first Roman emperor, ruling from 27 BC until his death in 14 AD. He was born Gaius Octavius Thurinus into an old and wealthy equestrian branch of the plebeian gens Octavia. His maternal great-uncle Julius Caesar was assassinated in 44 BC, and Octavius was named in Caesar's will as his adopted son and heir, then known as Octavianus (Anglicized as Octavian). He, Mark Antony, and Marcus Lepidus formed the Second Triumvirate to defeat the assassins of Caesar. Following their victory at Philippi, the Triumvirate divided the Roman Republic among themselves and ruled as military dictators. The Triumvirate was eventually torn apart by the competing ambitions of its members. Lepidus was driven into exile and stripped of his position, and Antony committed suicide following his defeat at the Battle of Actium by Octavian in 31 BC.
Entity: 31 BC
Question: In which year did Octavian defeat Antony at the Battle of Actium?
Explanation: The Battle of Actium took place in 31 BC, and was the decisive battle of the Final War of the Roman Republic.



erage EM and F1 over the three datasets. When the number ranges from 2 to 10, the performance generally becomes better as the number increases, and using more than 10 examples does not bring significant improvements. As a result, we choose 10 demonstrations in our main experiments for both performance and cost considerations.

5.4 Impact of the size of generated pseudo data for Self-Prompting

In our preliminary experiments, we find that Self-Prompting can achieve strong performance with substantially fewer generated examples than our current data size of about 5,000. We report the average EM on the three datasets used for analysis in Table 4 for Codex. While we chose the maximum data size for our main experiments to demonstrate the peak capabilities, these results highlight that comparable gains can also be achieved with good data efficiency and greatly reduced overhead.

5.5 General Effectiveness with LLMs of Different Sizes

Besides InstructGPT and Codex, we also try two smaller LLMs to see how Self-Prompting performs on different sizes of models: GPT-NeoX (20B) (Black et al., 2022) and Alpaca (7B) (Taori et al., 2023). Since the performance of large language models on ODQA is highly underestimated with EM and F1 (Kamalloo et al., 2023), we also report the Instruct-Eval (IE) (Kamalloo et al., 2023) score with GPT-4 (OpenAI, 2023a) (`gpt-4-1106-preview`) as the evaluator model. The results in Table 5 show that for LLMs with

(a) Average # of flaws in a passage.

(b) Quality of the question, answer and explanation.

Figure 3: Quantitative study of the generated data. In (b), UQ = Unambiguous question, CA = Correct answer, ACE = Explanation is both accurate and helpful, CA+UQ and ACE+UQ = ratio of CA and ACE given UQ, respectively. In (a) lower value indicates a higher quality, while in (d), a higher value is better.

parameters of different orders of magnitude, Self-Prompting boosts their performance significantly on all three datasets. It also narrows the performance gap between different LLMs, even if the gap is large under direct prompting.

5.6 Data Generation Quality Analysis

To further explore the quality of the generated pseudo data, we display two examples in Table 6 as a case study, with key sentences in teal and answer entities in blue. The questions generated for extract entities are proper and answerable with no context given, which is in line with ODQA. As a key part of Self-Prompting, we see that the explanations written by the LLM are reasonable. In the first example, the LLM precisely extracts the key sentence from the passage, while in the second, the LLM not only identifies relevant information but also adds effective explanations.

We also conduct a quantitative study to detect the hallucination issue (Ji et al., 2023) in the generated contents. We collect the data generated by all four LLMs used in Sec 5.5 and manually selected 100 samples (Q, A, P, E) from each of these four sources with the same topics (e.g., passages and QAs generated by different models but all about *The Legend of Zelda*) for fair comparison. For each sample, we use GPT-4 (OpenAI, 2023b) based New Bing[1] to check: (i) the number of factual errors, outdated information and controversial opinions in the generated passage; (ii) if the question is unambiguous without context; (iii) if the answer is correct for the question; (iv) if the explanation is both accurate and helpful for question answering.

All LLMs inevitably generate outdated information, as they cannot access the Internet and are limited by training data. The two smaller models, Alpaca and GPT-NeoX, make significantly more factual mistakes when they generate the required passages, as shown in Figure 3(a) while InstructGPT and Codex only have one factual error in every 5 and 10 passages respectively. From Figure 3(b), we see that (question, answer, explanation) triples by InstructGPT are better than those from other models on almost all concerned metrics, showing its strong instruction understanding ability.

Table 7: Comparison between Self-Prompting and in-context learning with training data (Traindata-ICL). We report average EM/F1 on the non-overlapping subsets.

Method	EM	F1
Traindata-ICL	36.0	48.7
Self-Prompting	34.2	46.0

5.7 Comparison between Self-Prompting and Using Training Data

Since the generated pseudo data is not flawless, it is natural to see the gap between Self-Prompting and in-context learning with real training data as a strong baseline (Traindata-ICL). To avoid the test-train data overlap problem, we use the non-overlapping subsets annotated in Lewis et al. (2021a) (425 WebQ samples, 357 NQ samples, and 254 TriviaQA samples) to conduct experiments in this section. Since there are no explanations in the training data, we only use a simple *question-answer* format. Other procedures and

[1] https://bing.com/chat

hyper-parameters, like the clustering-based selection and 10 in-context demonstrations, are kept the same. We report the average EM and F1 on the three datasets. The results in Table 7 show that even though the size of available demonstrations is much larger (e.g., 70K training data for NQ v.s. 4.8K pseudo data by Self-Prompting), Self-Prompting still obtains comparable performance with using training data for in-context learning (performance gap less than 2 EM and 3 F1). This indicates that even without laborious and costly human annotation, the LLMs can still effectively elicit their own knowledge and answer open-domain questions.

6 Conclusion

In this paper, we propose Self-Prompting LLMs for Zero-Shot Open-Domain Question Answering. Our method induces the LLM to generate pseudo QA pairs with matching passages and explanations and use them for in-context learning. It successfully stimulates the potential of the LLM in ODQA by explicitly activating various language understanding abilities and eliciting knowledge in its parameters. With no training data and external corpus, Self-Prompting surpasses previous SOTA significantly and performs on par with several strong retrieval-augmented fine-tuned models and few-shot prompting methods. It is generally effective across LLMs under different sizes and is able to provide accurate and helpful explanations alongside the answers, making it a more reliable and interpretable framework for turstworthy AI systems.

7 Limitations

In this paper, various experiments rely on the OpenAI APIs, whose usage needs to be paid and may cause a huge cost when generating a large number of tokens. Therefore, this may affect the reproducibility of this work. We also note that the pseudo QA generating process needs some trial and error to find good prompt templates for each step as shown in Table 14 in Appendix C, so there is still room to reduce the human effort in the whole process.

8 Ethics

In this work, we use three ODQA datasets for experiments. The NQ and TriviaQA datasets use the Apache-2.0 code, and the license for WebQ is not specified. In Self-Prompting, any suggested prompt templates refrain from gathering or employing personal information concerning other individuals. The specific prompt templates employed can be found in Appendix C and E. Notably, all prompt templates in this paper are devoid of any discriminatory language targeting individuals or groups, and they do not pose any potential harm to the safety of others.

We also recognize the importance of considering the potential societal impacts of the synthesized data. To address this, we have primarily utilized the OpenAI Moderation API[2] to detect if Self-Prompting generated content is free from harmful material. We find that all 977 passages and 4,883 question-answer-explanation triples revealed no toxic content. While our current synthetic data is free from toxicity, we acknowledge the need for safeguards against potential risks in larger-scale generation, especially for contents that are not toxic but contain explicit or implicit bias. Introducing measures such as the OpenAI Moderation API to detect and halt toxic outputs, setting rules in the prompts for LLM behavior (Bai et al., 2022), and employing controllable decoding strategies, from token bans to sophisticated methods that dynamically shift the output token distribution (Li et al., 2023; Liu et al., 2021), are possible solutions to manage this issue.

Datasets	Size	Q Words	A Words	Answers
WebQ	2.0K	6.8	2.5	2.4
NQ	3.6K	9.1	2.2	2.0
TriviaQA	11K	14.0	2.5	14.0

Table 8: Statistics for the test split of each dataset. Answers, Q Words and A Words refer to the average number reference answers, words in question, and words in answer for each sample respectively.

A Statistics of the datasets

The statistics of the datasets we use in Table 8. We find that test samples in TriviaQA have much longer question length than the other two datasets. TriviaQA also provides more reference answer, so models tend to have a higher score on this dataset.

B Names and Required Number of Examples for Topics

We list the name and required number of examples for each topic in Table 9. In general, we require about 100 examples for each high-level category (e.g., *Art, History, Sports*).

C Details in Generating Pseudo QA Dataset

We present the exact templates and API parameters used in self-generation steps in Table 14. After getting the passage, we use the NLTK toolkit[3] to remove the last sentence of it if the last sentence is incomplete or truncated.

D Statistics of the Generated Pseudo QA datasets

We show some statistics of the generated pseudo QA dataset in Table 10.

E Specific Templates in Different Formats

The specific templates used in main experiments (QAE) and in Sec 5.1 are shown in Table 15. We refer to Yu et al. (2022) to design them. The `temperature` is 0 for all formats.

F Training Small Models with the Pseudo QA dataset

We investigate if the built pseudo ODQA dataset can be used to train a specialized smaller model. To implement it, we retrain the reader of a RAG

Table 13: Comparison between Self-Prompting and a real-time generation variant.

Method	EM	F1
Self-Prompting	37.2	47.6
Real-time Generation Variant	35.3	45.5

(Lewis et al., 2020) pre-trained on the full NQ trining set[4] on our pseudo data from BART-large, while fixing the retriever module (we are unable to jointly train both modules as the original RAG did with our synthetic data). The EM and F1 on the NQ subset used in the analysis section are in Table 12.

This huge performance gap is likely caused by: 1) The pre-trained model benefits from more in-domain examples (70K+ NQ training examples vs 5K pseudo data). There is also significant train-test overlap in NQ as reported in Lewis et al. (2021a), 2) Retraining only the reader while fixing the retriever causes a mismatch, and 3) The reader is trained to only process one passage at a time, instead of comparing multiple passages simultaneously as the pre-trained reader. Given these results, we conclude that in current setting, it is a better practice to use the generated data for in-context learning samples of LLM itself than training a smaller supervised model.

G Real-time Pseudo Data Generation Variant for Self-Prompting

We also investigate the potential of a real-time generation variant of Self-Prompting. Specifically, for each test sample, we first ask the LLM to identify the main entity in the question and then generate a short passage based on it. The rest generation steps are all kept the same. In short, we reinforce the relevance of in-context demonstrations but weaken the diversity. We show the performance of this variant on the NQ subset in the analysis section.

The results in Table 13 show that this real-time variant does not bring improvement over Self-Prompting. This aligns with our earlier finding that cluster-based selection outperforms global similarity retrieval (in Table 3), indicating diversity is important for effective prompting. While real-time generation of highly-related examples is promising intuitively, it seems that some variability in the prompts is beneficial to avoid overfitting to a narrow context. Additionally, the higher inference delay and cost of real-time generation make it less practical. Overall, these results emphasize the balance of relevance and diversity when constructing demonstrations, and some offline preparation can be more efficient.

H Cost and Running Efficiency

We provide a brief analysis of the cost and running efficiency of Self-Prompting. The total cost for constructing the pseudo QA dataset is about $120 and it takes about 6 hours to collect the data.

The indexing and search time over the pseudo data in Table 11. As a comparison, the encoding/indexing/search time for DPR (Karpukhin et al., 2020) (statistics from their original paper) is 8.8h for encoding the complete Wikipedia dump on an 8-GPU machine, 8.5h for indexing the Wikipedia passage embeddings, and the search rate is 995 queries per second.

I More Data Quality Analysis

We provide more statistics for the quality analysis on our generated pseudo data in Figure 4 as a supplement to Sec 5.6, including the average number of flaws in the generated passages normalized by passage length, and the ratio of passages with at least one flaw. Similar to Figure 3, they also show the superiority of the OpenAI models over Alpaca and GPT-NeoX.

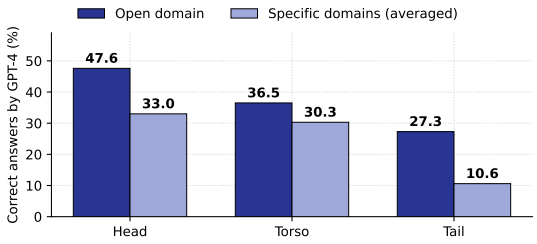
Head-to-Tail: How Knowledgeable are Large Language Models (LLMs)? A.K.A. Will LLMs Replace Knowledge Graphs?

Kai Sun, Yifan Ethan Xu, Hanwen Zha, Yue Liu, Xin Luna Dong
Meta Reality Labs
{sunkaicn,ethanxu,hwzha,yuei,lunadong}@meta.com



Abstract

Since the recent prosperity of Large Language Models (LLMs), there have been interleaved discussions regarding how to reduce hallucinations from LLM responses, how to increase the factuality of LLMs, and whether Knowledge Graphs (KGs), which store the world knowledge in a symbolic form, will be replaced with LLMs. In this paper, we try to answer these questions from a new angle: *How knowledgeable are LLMs?*

To answer this question, we constructed Head-to-Tail, a benchmark that consists of 18K question-answer (QA) pairs regarding head, torso, and tail facts in terms of popularity. We designed an automated evaluation method and a set of metrics that closely approximate the knowledge an LLM confidently internalizes. Through a comprehensive evaluation of 16 publicly available LLMs, we show that existing LLMs are still far from being perfect in terms of their grasp of factual knowledge, especially for facts of *torso-to-tail* entities.

1 Introduction

Pre-trained large language models (LLMs), such as ChatGPT[1], GPT-4 (OpenAI, 2023), and Llama 2 (Touvron et al., 2023b), have demonstrated impressive capabilities in internalizing knowledge and responding to common inquiries (Ouyang et al., 2022; OpenAI, 2023). Nevertheless, these models often lack knowledge of nuanced, domain-specific details and are susceptible to hallucinations (Bang et al., 2023), underscoring the significant challenges of increasing the *factuality* of LLMs and minimizing *hallucinations* from LLM responses. Conversely, the rise of LLMs has sparked debates on whether Knowledge Graphs (KGs), which store real-world factual knowledge in triplet form (subject, predicate, object), will be replaced with LLMs. This paper tries to answer these questions from a new angle: *How knowledgeable are LLMs?*

Example questions where GPT-4 gives incorrect answers

Movie

Question: What profession does Tj Singh (known for John Carter (2012)) have?
Ground Truth: Visual effects
GPT-4: Actor

Book

Question: Who authored Choke (published in 1996)?
Ground Truth: Stuart Woods
GPT-4: Chuck Palahniuk

Academics

Question: Where did Josef Kittler receive the Ph.D. (thesis: Development and application of pattern recognition techniques.)?
Ground Truth: University of Cambridge, UK
GPT-4: University of Surrey

Open

Question: What college is the sister college of Trinity College, Oxford?
Ground Truth: Churchill College, Cambridge
GPT-4: Balliol College

Figure 1: The question-answering accuracy of GPT-4 decreases in the order of head, torso, and tail entities on the Head-to-Tail benchmark, and is only 31% on average.

Finding answers to these questions is not easy. First, it is hard to directly "query" the knowledge embedded in an LLM—hallucination can be due to lack of knowledge but can also be caused by dysfunction of the generative model even if the knowledge is already parameterized in the model. We approximate the amount of knowledge in an LLM by its accuracy in answering simple-formed questions, such as *"where was the basketball player Michael Jordan born?"*; in addition, we ask the LLM to generate brief answers and admit "unsure" when its confidence is low. We chose this proxy because we found LLMs are normally very good at understand-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 311–325
June 16-21, 2024 ©2024 Association for Computational Linguistics

ing simple-formed questions and produce consistent answers when regenerating answers, especially if asked to be brief (Section 3.5).

Second, there is no ready-to-use benchmark that either well represents distributions of user's interest (the query logs for major LLMs or search engines are not publicly available) or well represents the uniform distribution of the world knowledge (even the largest knowledge graphs admit sparsity of knowledge, especially towards non-popular facts). To address this challenge, we construct a benchmark of 18K QA pairs that cover various domains and various relationships in these domains. We bucket entities and relationships to *head, torso,* and *tail* according to how *popular* they are (details in Section 2) and randomly sample from each bucket; as such, we call our benchmark Head-to-Tail. This benchmark facilitates us to achieve a comprehensive view of how knowledgeable LLMs are regarding each bucket.

Through the Head-to-Tail benchmark and the experimental methodology, we answer the following three research questions (RQs):

RQ1: How reliable are LLMs in answering factual questions? (Section 3.2)

RQ2: Do LLMs perform equally well on head, torso, and tail facts? (Section 3.3)

RQ3: Do normal methods that improve LLMs, such as model size increase and instruction tuning, help LLMs to be more knowledgeable? (Section 3.4)

As shown in Figure 1, our analysis demonstrates a consistent decline in the performance of LLMs, following the order of head, torso, and tail entities, confirming our hypothesis that LLMs contain more head knowledge where training data abound. Surprisingly, even for the top-0.5% popular entities in popular domains such as *Movie*, the evaluated LLMs, at best, provide accurate answers for only ∼60% of the questions in the benchmark. Normal methods that enhance LLMs do not necessarily make them more knowledgeable, highlighting the need for more effective approaches to increase LLMs' factuality.

Our main contributions are as follows:

(i) We introduce Head-to-Tail, the first benchmark focused on comprehensively assessing the effectiveness of LLMs in incorporating factual knowledge encompassing the head, torso, and tail portions of knowledge graphs (Section 2.1). Head-to-Tail will be available at https://github.com/facebookresearch/head-to-tail.

(ii) We present an evaluation methodology accompanied by metrics designed to assess the factuality of LLMs. Our metrics allow us to distinguish hallucination and missing answers, and our evaluation method, whereas entirely automated, proves to be reliable and robust (Section 2.2-2.3).

(iii) We conducted a comprehensive evaluation and quantified the factuality of 16 LLMs regarding head, torso, and tail facts to answer the research questions (RQ1–RQ3) (Section 3). In light of these findings, we envision the future of knowledge graphs and outline a research landscape aimed at improving the overall factual reliability of LLMs (Section 4).

2 The Head-to-Tail Benchmark

We now describe the Head-to-Tail benchmark, the metrics, and our evaluation methodology.

2.1 QA pair generation

Domains and data sources. To cover a broad range of knowledge, we used the DBpedia knowledge graph (Auer et al., 2007), where the knowledge originates from Wikipedia (Denoyer and Gallinari, 2006). We used a cleaned version of the English snapshot from December 1, 2022.[2]

To better understand LLM performance on particular domains, we also selected three domains where public data are easily accessible.

- **Movie:** We used a snapshot of *IMDb*[3] from May 21, 2023.
- **Book:** We used the data of *Goodreads* scraped in 2017 released by Wan and McAuley (2018).
- **Academics:** We used a snapshot of *MAG* (Sinha et al., 2015) from September 13, 2021 and *DBLP*[4] from May 10, 2023.

Entities. An important contribution of the Head-to-Tail benchmark is the bucketing of head, torso,

	IMDb		Goodreads	MAG			DBLP	DBpedia
	Title	Person	Book	Article	Conference	Journal	Scholar	-
Head	767 (0.01)	34,903 (0.48)	3,150 (2.31)	1,827,710 (0.70)	257 (1.63)	225 (0.46)	79,521 (2.44)	103,564 (1.30)
Torso	4,113 (0.05)	87,645 (1.21)	7,304 (5.35)	9,386,034 (3.60)	965 (6.12)	1,266 (2.58)	500,778 (15.36)	1,255,113 (15.77)
Tail	7,536,482 (99.94)	7,111,496 (98.31)	126,134 (92.35)	249,311,539 (95.70)	14,550 (92.25)	47,546 (96.96)	2,680,704 (82.20)	6,600,206 (82.93)

Table 1: The number (%) of head, torso, and tail entities. The distribution follows the power law.

and tail entities, decided by the *popularity* of the entities (we will also discuss how the popularity of the predicates affect results in Section 3.3). We use two ways to approximate popularity: *traffic* and *density*. When there is traffic information, such as views and votes, we conveniently use traffic to measure the popularity; otherwise, we use density as a proxy, such as the number of facts or authored works about the entity. We often observe a correlation between density and traffic (e.g., the more popular a person is, the more we know about her), but as we will see soon from the benchmark statistics (Table 1), they can still lead to slightly different distributions of head, torso, and tail. We give details on how we decide the popularity of different types of entities from each data source in Appendix A.2.

We bucketed head, torso, and tail entities in three steps. First, we sorted the entities by their popularity, measured as above. Second, for each entity, we computed the cumulative popularity score up to the top-1 entity in the sorted list. Third, we bucketed the entities such that head entities comprise entities whose cumulative popularity score is up to 1/3 of that of all entities, torso entities comprise entities with cumulative scores ranging from 1/3 to 2/3, and tail entities from 2/3 to 1. (See Appendix A.7 for an example.) We determined the partitioning separately for different entity types for each domain.

To make the popularity score fair, we filtered out entities that are likely too new to have sufficient statistical data for popularity measurement. For IMDb, MAG, DBLP, and Goodreads, we kept only entities by the year of 2020, 2020, 2020, and 2015, respectively. The cut-off years are all before the cut-off time of the LLM training data, so the benchmark avoids questions that require *recent* knowledge. We did not perform similar filtering for DBpedia because the year attribute is unavailable or non-applicable for most entities, and our pilot study shows that very few (if at all) of the questions generated from DBpedia require knowledge after 2020.

Table 1 summarizes the distribution of head, torso, and tail entities. The distribution follows the *power law*, where very small percentages of entities fall in the head and torso buckets, and the majority of entities fall in the tail bucket; for example, over 99.9% of movies fall in the tail bucket, according to IMDb vote counts. We also observe that this phenomenon is more pronounced when we measure by traffic than by density; for the latter, the torso buckets are often larger (∼15% of entities), and the tails are slightly smaller (∼82%).

Questions. We generated questions using a template-based approach, where each generated question asks for an attribute of an entity. We filtered out the following types of attributes: (i) unspecific (e.g., `seeAlso` in DBpedia), (ii) dynamic (e.g., `lastLaunchRocket` in DBpedia), (iii) data source specific (e.g., `averageRating` in IMDb), and (iv) non-textual (e.g., `picture` in DBpedia). We discuss a stricter filtering criterion in Appendix A.4. For each specific domain (Movie, Book, Academics), we manually designed the question template for each attribute. DBpedia contains a large set of attributes, so we first employed ChatGPT to draft the templates (using Prompt 1 in Appendix A.1), then proofread them manually and made necessary edits. Each question template corresponds to a distinct predicate.

The answer for each question is the object of the relevant triple; when there are multiple answers (e.g., a book may have multiple authors), we included all in the answer. When necessary, we included extra information for an entity to avoid potential ambiguities (e.g., we included the publication year for a book to distinguish books of highly similar names).

We generated an equal number of questions for randomly sampled head, torso, and tail entities using each template. For each specific domain, we generated ∼1K questions for each of the head, torso, and tail buckets. As DBPedia contains more domains and relationship types, we generated ∼3K questions for each bucket. Table 2 summarizes the overall statistics of Head-to-Tail in the number of questions and templates.

Domain	Sources	# Templates	# Questions
Movie	IMDb	13	3,093
Book	Goodreads	4	3,000
Academics	MAG, DBLP	13	2,946
Open	DBpedia	393	9,132
Total		423	18,171

Table 2: The overall statistics of Head-to-Tail.

2.2 Metrics

Metrics. We find that oftentimes LLMs are intelligent enough to admit that it does not have enough information to answer a question. As such, we used three metrics: *accuracy* (**A**), *hallucination rate* (**H**), and *missing rate* (**M**), measuring the percentage of questions that an LLM gives the correct answer, gives a wrong or partially incorrect answer, or admits it cannot answer, respectively; by definition, $\mathrm{A} + \mathrm{H} + \mathrm{M} = 100\%$.

Manually deciding the correctness of answers can be cumbersome. We next describe a few different ways to automatically decide if an answer is correct.

LLM-based. We ask ChatGPT to check whether an answer is correct given the question and ground truth (Prompt 2 in Appendix A.1). Thus, accuracy $\mathbf{A_{LM}}$ is defined as the percentage of answers that ChatGPT judges as correct; hallucination rate $\mathbf{H_{LM}}$ is defined as the percentage of time when (i) an attempted answer is not missing, and (ii) ChatGPT judges the answer as incorrect (i.e., $\mathrm{H_{LM}} = 100\% - \mathrm{A_{LM}} - \mathrm{M}$).

To understand the reliability of the LLM-based metrics, we randomly sampled 840 answers from the evaluated LLMs and manually checked whether human judgment agrees with the LLM-based metrics. The agreement is 98%, which we view as reliable. Hence, we use $\mathrm{A_{LM}}$ and $\mathrm{H_{LM}}$ as the primary metrics in this study.

Rule-based. In addition, we adopt popular metrics, including *exact match (EM)*, *token F1 (F1)*, and *ROUGE-L (RL)* (Lin, 2004; Rajpurkar et al., 2016); in other words, we use rule-based methods to judge the correctness of an answer. Specifically, $\mathbf{A_{EM}}$ is computed as the percentage of answers that exactly match the ground truth; $\mathbf{A_{F1}}$ is computed as the average harmonic mean of precision and recall when comparing tokens in the returned answers and in the ground truth answers; $\mathbf{A_{RL}}$ is computed as the average normalized longest common subsequence (LCS) between the returned answers and the ground truths. For common answer types, we additionally expand the set of ground-truth answers with their variants using hand-crafted rules (e.g., "*W Shakespeare*" is a variant of "*William Shakespeare*"); when a given question has multiple expanded ground-truth answers, we take the maximum score.

Correspondingly, we measure hallucination rate by $\mathbf{H_{EM}}$ ($= 100\% - \mathrm{A_{EM}} - \mathrm{M}$), $\mathbf{H_{F1}}$ ($= 100\% - \mathrm{A_{F1}} - \mathrm{M}$), and $\mathbf{H_{RL}}$ ($= 100\% - \mathrm{A_{RL}} - \mathrm{M}$). As we will show later in Section 3.5, we observe high correlations between rule-based and LLM-based metrics.

2.3 Evaluation methodology

We prompted the LLM as shown in Prompt 3 in Appendix A.1. First, we asked LLMs to give as concise answers as possible. Second, we prompted LLMs to respond "unsure" when the LLM is not confident in the answer. We applied few-shot learning and included in the prompt two examples that are not in Head-to-Tail: one is a simple, answerable question with the corresponding answer as the response; the other is an unanswerable question with "unsure" as the response.

With this prompt, rule-based metrics are more likely to reflect the factual correctness of the answers, and we can simply compute the missing rate (i.e., M) by counting "unsure" or empty answers. We observed that explicitly asking for "unsure" as an answer could significantly reduce hallucination rate (Section 3.5).

To summarize, the following three setups in the benchmark and evaluation methodology help us best approximate the existence of (confident) knowledge in the LLMs: (i) focusing on simple questions in easy-to-understand forms, (ii) asking for concise answers to ease evaluation, and (iii) hinting the LLMs to answer "unsure" to suppress unnecessary hallucinations.

3 Experimental Analysis

3.1 Models and configurations

We evaluated representative state-of-the-art LLMs of various sizes and architectures, including ChatGPT, GPT-4 (OpenAI, 2023), LLaMA (7B, 13B, 33B, 65B) (Touvron et al., 2023a), Llama 2 (70B) (Touvron et al., 2023b), Vicuna (7B, 13B) (Chiang et al., 2023), Flan-T5 (3B, 11B) (Chung et al., 2022), RWKV (7B) (Peng et al., 2023b), Falcon (7B, 40B), and Falcon-Instruct (7B, 40B) (Almazrouei et al., 2023). We

Model	All		Open		Movie		Book		Academics	
	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}
GPT-4	30.9	19.7	37.1	25.3	41.7	15.5	21.3	19.4	10.0	6.8
ChatGPT	20.3	14.1	22.1	14.8	34.7	13.3	16.9	24.9	3.0	1.9
Llama 2 (70B)	11.8	34.0	7.5	24.8	27.9	34.3	10.3	54.5	9.8	41.0
LLaMA (33B)	18.2	80.0	19.0	79.1	28.7	70.1	15.8	82.9	7.1	90.3

Table 3: The best overall accuracy is only ∼31% on Head-to-Tail. All numbers are in percentage (%).

employed the most deterministic settings (i.e., `temperature=0` or `top_k=1`) for all models. We present more details in Appendix A.3.

Table 14 in Appendix A.8 gives detailed results of all LLMs. We note that our goal is NOT to compare different LLM models; rather, by examining the metrics by different LLMs, we make sure to report the common patterns among the representative LLMs. We also note that it is hard to exhaustively benchmark every recent model in this fast-moving field; we conducted evaluations up to GPT-4 (OpenAI, 2023) and Llama 2 (Touvron et al., 2023b), and detailed discussions can be based on slightly older models, where we observe similar patterns.

3.2 RQ1: How reliable are LLMs in answering factual questions?

We present in Table 3 the overall performance of GPT-4, ChatGPT, Llama 2-70B, and LLaMA-33B, which perform the best in most metrics on Head-to-Tail among all LLMs introduced in Section 3.1. The best overall accuracy is obtained by GPT-4 at 31%.

Interestingly, for questions that are not answered correctly, different LLMs show different patterns: GPT-4 and ChatGPT give unsure or empty answers for the majority of them, and the hallucination rate is <20% (still non-negligible); LLaMA-33B mostly provides hallucinated answers, resulting with high hallucination rate (∼80%); Llama 2-70B falls in-between. We suspect fine-tuning and reinforcement learning of these models may explain the different patterns when the model is unsure of the answers. Figure 1 shows examples of counterfactual answers given by GPT-4.

Finally, for all models, the overall performance varies substantially across different specific domains. All models perform the best in the *Movie* domain and worst in the *Academics* domain, likely because of the relatively low popularity of the *Academics* domain, as we will discuss soon.

Domain	Head		Torso		Tail	
	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}
Movie	59.3	14.8	55.0	16.9	10.9	14.7

GPT-4	46.0 (↑5.7)	21.4 (↓1.9)	32.6 (↓3.7)
Llama 2 (70B)	18.7 (↑2.5)	29.7 (↓0.6)	51.6 (↓1.9)

Table 5: Accuracy on the top-10% popular questions in the head bucket is only slightly better than overall head entities. (↑/↓: increased/decreased % compared with using all head instances.)

3.3 RQ2: Do LLMs perform equally well on head, torso, and tail facts?

The overall accuracy of GPT-4 and Llama 2-70B (A_{LM}) declines in the order of head, torso, and tail entities, as shown in Figure 1 and Table 4. We observe the same pattern for other LLMs. This verifies our hypothesis that as we lack training data for long-tail entities, it is difficult for LLMs to obtain knowledge for such entities.

Surprisingly, the QA accuracy is still low even for the head entities (e.g., GPT-4 achieves an A_{LM} of 48% in the open domain). We further retain top-10% popular questions from the head bucket. As shown in Table 5, GPT-4 and Llama 2-70B obtained slightly higher accuracy (within 6 percent point) and lower hallucination rate for these super

Model	Head & Torso		Tail	
	A_{LM}	H_{LM}	A_{LM}	H_{LM}
GPT-4	42.9	20.3	36.8	25.6
ChatGPT	18.6	14.2	22.3	14.8
Llama 2 (70B)	8.0	42.1	7.5	23.8
LLaMA (7B)	15.3	83.5	13.5	77.7
LLaMA (13B)	14.6	85.1	14.7	83.6
LLaMA (33B)	18.2	81.4	19.0	78.9
LLaMA (65B)	20.1	79.7	18.3	81.4
Vicuna (7B)	12.5	82.0	9.3	77.4
Vicuna (13B)	13.0	70.3	8.6	55.5
Flan-T5 (3B)	4.4	13.0	3.4	10.4
Flan-T5 (11B)	9.2	11.1	5.0	8.1
RWKV (7B)	6.9	28.7	6.4	29.7
Falcon (7B)	11.3	51.0	8.1	43.7
Falcon (40B)	14.4	34.1	8.5	29.2
Falcon-Instruct (7B)	8.8	48.3	7.2	47.1
Falcon-Instruct (40B)	12.8	15.3	7.9	15.2

Table 6: Comparison of LLMs' factuality about head, torso, and tail predicates in A_{LM} (%) and H_{LM} (%) using open-domain instances from Head-to-Tail.

popular entities, but the accuracy is still disappointingly low (46% for GPT-4 and 19% for Llama 2-70B), and the missing rate is notable. We have a further discussion in Appendix A.6.

The QA accuracy on tail entities is significantly lower in most of the domains. Notably, *Academics* intuitively is a long-tail domain, and we observe $\sim$10% overall accuracy and very low accuracy (16% for GPT-4 and 13% for Llama 2-70B) even for head entities in this domain.

Finally, hallucination rate drops from head to torso to tail for GPT-4, but increases for Llama 2-70B. We hypothesize that there is at least one more factor that affects the hallucination rate—the internal assessment of the confidence. When an LLM "knows" what is unknown to it, it is likely to reduce confidence when answering related questions and produce fewer hallucinations.

Head-to-tail predicates. We investigated whether the performance still correlates with the head-to-tail order regarding the popularity of *predicates* instead of entities. We sorted the predicates from DBpedia by popularity (measured by the number of relational triples with the predicate) and partitioned the sorted predicates into head, torso, and tail in a similar fashion. We then re-partitioned the open-domain questions into head, torso, and tail predicate buckets, each containing 72, 450, and 8, 610 questions, respectively. Since the number of questions in the head bucket is low, we merged the head and torso buckets.

Table 6 compares the performance on head & torso vs. on tail. We observe no consistent correlation among different LLMs between the performance and the head-to-tail predicate ordering, and the differences in accuracy are not very high. This is not too surprising for two reasons. First, the semantics of each predicate is mostly consistent with the semantics of the predicate names, which can be well understood by LLMs. Second, when facts are present for tail predicates, they are often about the head entities, and factual information for head entities is likely to be more abundant in the training data.

3.4 RQ3: Does normal methods that improve LLMs increase the factuality?

Table 7 compares LLMs in different sizes and with or without instruction tuning. First, we observe that an increased model size does not automatically translate to a better grasp of factual knowledge. For example, LLaMA-33B modestly outperforms LLaMA-65B across the head, torso, and tail subsets ($+0.4\%$ in A_{LM} and -1.9% in H_{LM} on average) while they share the same training dataset and hyperparameters. This provides additional evidence for our hypothesis that once the model is sufficiently large, the abundance of training data plays a more critical role in the factuality of the LLMs.

Second, compared with LLaMA and Falcon, the instruction-tuned counterparts (i.e., Vicuna and Falcon-Instruct) have lower accuracy, as they learned to be more conservative in providing factual answers and thus generate "unsure" more often (e.g., Vicuna-13B is 26.9% higher in M than LLaMA-13B). Despite so, they still have high hallucination rate.

3.5 Robustness of our evaluation methodology

Finally, we evaluate the robustness of our evaluation methodology.

Correlations between rule- and LLM-based metrics. For each combination of popularity (head, torso, tail) and domain (movie, book, academics, open), we calculate Spearman's rank and Pearson correlation coefficients between rule- and LLM-based metrics over all LLMs. We report the aggregated results (minimum, mean) in Table 8. The correlation scores suggest that A_{LM} (resp. H_{LM}) strongly correlates with A_{EM}, A_{F1}, and A_{RL} (resp. H_{EM}, H_{F1}, and H_{RL}), indicating that rule-based metrics are good alternatives for lower-cost or faster evaluation.

Model	Head-to-Tail			Head		Torso		Tail	
	A_{LM}	H_{LM}	M	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}
LLaMA (7B)	12.1	80.0	7.9	19.0	74.4	11.7	81.0	5.4	84.8
LLaMA (13B)	14.4	84.3	1.3	22.0	77.2	14.8	83.8	6.3	91.9
LLaMA (33B)	18.2	80.0	1.8	26.0	72.8	19.8	78.7	8.8	88.6
LLaMA (65B)	17.8	81.9	0.3	25.9	73.8	18.7	81.0	8.7	90.9
Vicuna (7B)	10.1	79.2	10.8	16.2	72.7	9.6	79.8	4.3	85.0
Vicuna (13B)	9.2	62.6	28.2	14.0	55.0	8.8	62.8	4.7	70.0
Flan-T5 (3B)	2.3	17.4	80.3	3.9	19.7	1.5	17.1	1.3	15.5
Flan-T5 (11B)	4.2	20.0	75.7	7.6	23.7	3.2	19.9	2.0	16.5
Falcon (7B)	9.5	57.9	32.6	14.5	53.8	9.2	57.9	4.8	62.0
Falcon (40B)	10.8	41.0	48.2	16.2	36.4	11.2	40.0	4.9	46.6
Falcon-Instruct (7B)	6.8	56.7	36.5	11.5	56.0	5.6	57.2	3.4	56.7
Falcon-Instruct (40B)	10.8	32.2	57.0	16.7	30.5	11.5	31.1	4.3	34.8

Table 7: Comparison of different LLMs with different sizes. All numbers are in percentage (%).

LLM-Based	Rule-Based	ρ		r	
		Min.	Mean	Min.	Mean
A_{LM}	A_{EM}	0.721	0.915	0.921	0.966
	A_{F1}	0.775	0.951	0.781	0.969
	A_{RL}	0.730	0.947	0.775	0.969
H_{LM}	H_{EM}	0.968	0.991	0.993	0.998
	H_{F1}	0.976	0.995	0.998	0.999
	H_{RL}	0.976	0.995	0.998	0.999

Table 8: The minimum and mean Spearman's rank correlation coefficients (ρ) and Pearson correlation coefficients (r) show high correlation between LM- and rule-based metrics.

	Domain	Few-shot		Zero-shot		In-domain	
		A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}
Head	Open	32.7	**20.8**	32.6	24.7	**45.0**	27.8
	All	29.4	**17.2**	29.2	18.6	**38.3**	24.7
Torso	Open	19.7	**13.3**	21.6	17.9	**30.1**	23.0
	All	21.9	**14.6**	22.8	16.7	**29.8**	22.8
Tail	Open	13.8	**10.2**	14.9	14.5	**23.0**	19.5
	All	9.5	**10.5**	10.3	12.7	**15.4**	20.2

Table 9: Performance of ChatGPT with different prompts on Head-to-Tail. All numbers are in percentage (%).

Effect of brief and "unsure". We randomly sampled 1.2K questions and tested the stability of answers if we call ChatGPT to regenerate answers. When not requiring brief or "unsure" answers, for 18% of questions, ChatGPT regenerated different answers. Adding the requirement for brief answers (Prompt 6 in Appendix A.1) reduced the percentage to 4%, and further asking "unsure" answers with few-shot examples (Prompt 3) reduced the percentage to 1%. In addition, according to manual evaluation on 150 randomly sampled questions, removing "unsure" as an option increases ChatGPT's hallucination rate by 13 percentage points.

Robustness of prompts. We explore two other prompts. Compared with the original prompt that conducts few-shot learning (Section 3.1), denoted as **Few-shot**, the **Zero-shot** prompt does not provide examples and thus is zero-shot learning (Prompt 4 in Appendix A.1), and the **In-domain** prompt has the answerable example swapped out for an in-domain example generated by the same question template as the target question (Prompt 5 in Appendix A.1).

As shown in Table 9, **Few-shot** and **Zero-shot** show very similar results, but performance differences are noticeable between **Few-shot** and **In-domain**. In particular, in-domain examples help get more correct answers (+8.9%, +7.9%, +5.9% in A_{LM} for head, torso, tail) but at the cost of more hallucinations (+7.5%, +8.2%, +9.7% in H_{LM} for head, torso, tail). We suspect that the in-domain examples boost the confidence of ChatGPT in answering a question, so it answers questions even when the real confidence is not that high, causing both higher accuracy and higher hallucination rate.

Despite the fluctuation, our original prompt template (**Few-shot**) appears to be better at approximating the (confident) factuality of LLMs with the QA accuracy, and the *relative* performance among the head, torso, and tail remains stable over different prompts.

4 Discussions

4.1 The future of knowledge graphs

The experimental analysis indicates that although LLMs have incorporated factual knowledge within their parameters, the amount of this encoded knowledge remains limited. Knowledge of long-tail entities is already sparse in KGs and is even more deficient in LLMs.

Nevertheless, LLMs have been revolutionizing the way people seek information and calling for reconsideration of the best representation of factual knowledge. We term the forthcoming generation of KGs as *Dual Neural KGs*: knowledge can reside explicitly as triples (similar to KGs) and implicitly as embeddings (like in LLMs); the symbolic form caters to human understanding and explainability, while the neural form benefits machine comprehension and seamless conversations. A piece of knowledge can exist in both formats or in the one that is more appropriate. The harmonious blend of the two forms, capitalizing on the latest LLM innovations, is an exciting research area as we elaborate next.

Head knowledge. This involves popular entities where training data are ample. Ideally, LLMs could be taught such knowledge for efficient retrieval, meaning head knowledge shall exist in both forms. Currently, LLMs still have a mediocre QA accuracy for popular entities (see Table 5), so a critical research area is to infuse head knowledge into LLMs through model training or fine-tuning. Early work in this line includes knowledge infusion (Liu et al., 2021; Wang et al., 2021; Zhen et al., 2022).

Torso-to-tail and recent knowledge. This involves non-popular entities and emerging knowledge, where training data are typically sparse or absent. This type of knowledge might be best represented as triples. Serving such knowledge requires effectively deciding when external knowledge is essential, efficiently retrieving the relevant knowledge, and seamlessly integrating it into the answers. Early attempts in this direction involve knowledge-augmented LLMs (Asai et al., 2023; Nakano et al., 2022; Shi et al., 2023; Borgeaud et al., 2022).

4.2 Limitations and extensions

Taxonomy. Our work does not discuss the effectiveness of LLMs in capturing taxonomy or type hierarchies, which could be an extension of this study. Specifically, we hypothesize that LLMs can effectively incorporate type relationships (e.g., hypernyms and synonyms), even for the fine-granularity sub-types. Hence, it may no longer be worth manually constructing a very deep and complex hierarchy in the future.

Robustness to question formulation. This paper primarily aims to evaluate how much an LLM "knows" a fact with high confidence; we thus tested various ways of formulating factual questions and selected the least ambiguous form for this study. However, this approach does not assess the model's robustness to paraphrasing or consider the diverse ways models can be queried, such as entailment or cloze-style prompts. Our supplementary experiment in Appendix A.5 suggests that varying the form of questions does not significantly impact the evaluation results. A more thorough evaluation of robustness is beyond the scope of this paper and left for future research.

5 Related Work

Benchmarks. Most works studied the factuality of LLMs using existing QA benchmarks such as WebQuestions (Berant et al., 2013), TriviaQA (Joshi et al., 2017), LC-QuAD (Trivedi et al., 2017; Dubey et al., 2019), QALD-9 (Usbeck et al., 2018), Natural Questions (Kwiatkowski et al., 2019), and EntityQuestions (Sciavolino et al., 2021). A recent line of work has been constructing new QA benchmarks to assess LLMs' factuality, especially for long-tail knowledge (Mallen et al., 2023; Kim et al., 2023). Compared with these benchmarks, Head-to-Tail is the first to specifically assess how well LLMs incorporate head, torso, and tail factual information.

LLM Evaluation. Recent years have seen a proliferation of research on assessing the factuality of LLMs (Roberts et al., 2020; Petroni et al., 2021; Shuster et al., 2021; Mielke et al., 2022; Tan et al., 2023; Hu et al., 2023; Peng et al., 2023a; Omar et al., 2023; Kandpal et al., 2023; Mallen et al., 2023; Chen et al., 2023). Most of these works focus on a single knowledge source, such as Freebase or Wikipedia, and they have yet to systematically perform the evaluation explicitly regarding head/torso/tail entities or attributes. One work close to ours is Omar et al. (2023), which evaluated ChatGPT using facts collected from diverse knowledge sources; however, their evaluation was carried out manually on only 450 QA instances.

There are three works that also showed the correlation between the QA accuracy of language models and fact popularity (Mallen et al., 2023; Kandpal et al., 2023; Kim et al., 2023). Our work, conducted in parallel, focuses on a different angle—how knowledgeable are LLMs? For this purpose, we systematically designed experimental methodology, including the definition of head, torso, and tail entities, the design of metrics, and the evaluation method. Our benchmark is comprehensive in containing different knowledge sources, different

domains, and rich relations. Compared with these three works, we gave more quantified answers for research questions RQ1–RQ3.

6 Conclusion

We introduce Head-to-Tail, the first benchmark designed to assess the ability of LLMs to internalize head, torso, and tail facts. Alongside the dataset, we present a new evaluation methodology with appropriate metrics for automatically evaluating LLMs' factuality. Our evaluation shows that even the most advanced LLMs have notable limitations in representing factual knowledge, particularly for the torso and tail entities. Accordingly, we suggest new research areas to seamlessly blend knowledge in the symbolic form and neural form.

A Appendix

A.1 List of Prompts

```
You are given a few samples of a relation in the format of <X, relation, Y>. You need to write a question *template* about the relation, which can be used to generate questions. The template needs to have one blank such that a question about Y can be generated by filling the blank with X.

#Example 1
Samples: <!Hero, musicBy, Eddie DeGarmo>, <9 to 5 (musical), musicBy, Dolly Parton>, <All About Us (musical), musicBy, John Kander>
Template: The music of _ is by whom?

#Example 2
Samples: <10,000 Maniacs, bandMember, Dennis Drew>, <16bit (band), bandMember, Eddie Jefferys>, <1TYM, bandMember, Teddy Park>
Template: Name a band member of _?

#Example 3
Samples: {SAMPLES}
Template:
```

Prompt 1: Question template drafting.

```
You need to check whether the prediction of a question-answering system to a question is correct. You should make the judgment based on a list of ground truth answers provided to you. Your response should be "correct" if the prediction is correct or "incorrect" if the prediction is wrong.

Question: Who authored The Taming of the Shrew (published in 2002)?
Ground truth: ["William Shakespeare", "Roma Gill"]
Prediction: W Shakespeare
Correctness: correct

Question: Who authored The Taming of the Shrew (published in 2002)?
Ground truth: ["William Shakespeare", "Roma Gill"]
Prediction: Roma Gill and W Shakespeare
Correctness: correct

Question: Who authored The Taming of the Shrew (published in 2002)?
Ground truth: ["William Shakespeare", "Roma Gill"]
Prediction: Roma Shakespeare
Correctness: incorrect

Question: What country is Maharashtra Metro Rail Corporation Limited located in?
Ground truth: ["India"]
Prediction: Maharashtra
Correctness: incorrect

Question: What's the job of Song Kang-ho in Parasite (2019)?
Ground truth: ["actor"]
Prediction: He plays the role of Kim Ki-taek, the patriarch of the Kim family.
Correctness: correct

Question: Which era did Michael Oakeshott belong to?
Ground truth: ["20th-century philosophy"]
Prediction: 20th century.
Correctness: correct

Question: Edward Tise (known for Full Metal Jacket (1987)) is in what department?
Ground truth: ["sound department"]
Prediction: 2nd Infantry Division, United States Army
Correctness: incorrect

Question: What wine region is Finger Lakes AVA a part of?
Ground truth: ["New York wine"]
Prediction: Finger Lakes AVA
Correctness: incorrect

Question: {QUESTION}
Ground truth: {GROUND_TRUTH}
Prediction: {PREDICTION}
Correctness:
```

Prompt 2: Correctness checking.

```
Answer the following questions in as few words as possible. Say "unsure" if you don't know.

Question: What is the capital of China?
Answer: Beijing

Question: What is the captical of Wernythedia?
Answer: unsure

Question: {QUESTION}
Answer:
```

Prompt 3: Question answering (Few-shot).

```
Answer the following question in as few words as possible. Say "unsure" if you don't know. {QUESTION}
```

Prompt 4: Question answering (Zero-shot).

```
Answer the following questions in as few words as possible. Say "unsure" if you don't know.

Question: What is the captical of Wernythedia?
Answer: unsure

Question: {QUESTION#}
Answer: {ANSWER#}

Question: {QUESTION}
Answer:
```

Prompt 5: Question answering (In-domain) (#: the in-domain instance described in Section 3.5).

```
Answer the following questions in as few words as possible. {QUESTION}
```

Prompt 6: Question answering (simply asking for concise answers).

```
Answer the following questions in as few words as possible. Return your best guess if you don't know.

Question: What is the capital of China?
Answer: Beijing

Question: {QUESTION}
Answer:
```

Prompt 7: Question answering (returning its best guess instead of "unsure" when the confidence is low).

A.2 Popularity measure in head-to-tail partition

- **IMDb** (traffic): The number of votes (i.e., `numVotes`) the *title* (e.g., movie, short, TV series, etc.) has received; we do NOT consider whether the vote is high or low in the counting. For person entities, we use the total number of votes received by the titles the person is known for.
- **Goodreads** (traffic): The count of ratings (i.e., `ratings_count`) the book has received; similarly, we do NOT take into consideration whether the rating is high or low.

- **MAG** (traffic): The number of citations (i.e., `CitationCount`) the entity (i.e., scholarly article, conference, or journal) has received.
- **DBLP** (density): The number of works the scholar has authored.
- **DBpedia** (density): The number of relational triples in DBPedia that contain the entity.

A.3 Implementation details

We interacted with ChatGPT and GPT-4 through OpenAI API[5]. The employed version of ChatGPT and GPT-4 is `gpt-3.5-turbo-0301` and `gpt-4-0613`, respectively. We used Transformers (Wolf et al., 2020) to interact with the other LLMs on A100 (80GB) GPUs, and we used 16-bit floating point formats (i.e., float16 for Flan-T5 and RWKV, bfloat16 for LLaMA, Llama 2, Vicuna, Falcon, and Falcon-Instruct). We employed the original LLaMA, Llama 2, Flan-T5, Falcon, and Falcon-Instruct versions. The employed version of RWKV and Vicuna is `v4 Raven` and `v1.1`, respectively.

A.4 Impact of less naturally occurring questions

Model	Movie		Book		Academics	
	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}
GPT-4	43.8	12.6	39.1	24.6	11.2	9.8
ChatGPT	37.8	14.5	31.0	21.5	2.3	1.6
Llama 2 (70B)	30.4	31.6	19.7	10.0	4.5	59.0
LLaMA (7B)	18.7	71.9	21.4	59.1	2.4	94.9
LLaMA (13B)	25.3	73.2	24.4	74.5	4.6	93.7
LLaMA (33B)	31.2	67.5	31.7	65.9	5.2	91.7
LLaMA (65B)	27.1	72.4	32.3	66.5	8.2	91.8
Vicuna (7B)	21.1	68.5	19.2	62.9	2.6	91.3
Vicuna (13B)	20.3	58.5	11.4	38.7	3.1	77.4
Flan-T5 (3B)	1.7	15.1	2.8	4.5	0.2	4.3
Flan-T5 (11B)	6.3	22.1	6.6	10.1	0.8	16.0
RWKV (7B)	4.5	24.3	13.3	37.0	0.1	9.5
Falcon (7B)	20.4	62.3	15.0	45.1	3.5	80.7
Falcon (40B)	26.0	43.1	11.4	7.1	4.7	55.0
Falcon-Instruct (7B)	13.4	66.4	9.9	34.1	1.9	58.5
Falcon-Instruct (40B)	28.4	37.5	11.9	1.9	3.9	51.2

Table 10: Comparison of LLMs' factuality on Head-to-Tail without relatively less naturally occurring questions. All numbers are in percentage (%).

When constructing Head-to-Tail, we include all predicates that allow reasonable factual questions. Table 10, instead, shows metrics on predicates that users are more likely to ask about. In general we observed higher performance on the *Movie* and *Book* domains, but the accuracy is still fairly low and we observe similar patterns regarding head, torso, and tail entities.

[5] https://platform.openai.com/docs/api-reference

A.5 Asking questions in different forms

	Head		Torso		Tail	
	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}
Original	51.3	11.5	46.4	16.6	6.4	11.8
Cloze-style	50.8	8.9	46.1	14.3	6.8	12.6

Table 11: ChatGPT's factuality in A_{LM} (%) and H_{LM} (%) obtained by the cloze-style queries closely mirrors that of the simple-formed questions in the *Movie* domain.

We explored the influence of question formulation on the evaluation results using ChatGPT in the *Movie* domain. We rewrote all questions as cloze-style questions (e.g., "What's the release year of Mr. & Mrs. Smith" was transformed to "The release year of Mr. & Mrs. Smith is _"). As shown in Table 11, the performance obtained by the cloze-style queries is very similar to that obtained by simple-formed questions.

A.6 Further discussions on the missing rate

Domain	A_{LM}	H_{LM}	M
Movie	63.5	13.5	22.9
Academics	25.3	14.7	60.0

Table 12: Performance of GPT-4 on the top-10% popular questions in the head bucket. All numbers are in percentage (%).

Prompt	A_{LM}	H_{LM}	M
Original (Prompt 3)	63.5	13.5	22.9
Prompt 7	68.8	16.7	14.6

Table 13: Performance of GPT-4 on the top-10% popular questions in the head bucket in the *Movie* domain. All numbers are in percentage (%).

It is observed that even for the top-10% popular questions in the head bucket, the missing rate of GPT-4 is still over 30% (Table 5). Although this might seem counterintuitive, there are two reasons. First, the performance reported in Table 5 is based on all the studied domains, including the tail domain *Academics*. Table 12 compares GPT-4's performance on the top-10% head entities in the *Academics* and the *Movie* domains. The missing rate on the more popular domain *Movie* is much lower (23%). Second, if we explicitly ask the LLM to return the best guess (Prompt 7) instead of responding "unsure", GPT-4's missing rate on the top 10%

of head entities in the *Movie* domain would further drop to 15% (Table 13). However, this is with the price of higher hallucination rate, showing that the confidence of this part of knowledge is low. Interestingly, even after the above change, GPT-4 still admits to being "unsure" for 15% of questions (e.g., GPT-4's answers are "unknown" given the questions "What is the death year of Debbi Datz-Pyle (known for The Matrix (1999))?", "What movie is Alan R. Kessler known for?"). This further confirms that LLMs are not good at memorizing (internalizing) factual information.

A.7 An example of entity bucketing

Suppose there are 12 entities $A, B, C, \ldots, L$, and their popularity scores are $A = 8$, $B = 4$, $C = D = 2$, $E = F = \ldots = L = 1$. The total popularity scores add up to 24 ($= 8 + 4 + 2 + 2 + 1 \times 8$). Top-$1/3$ traffic (a total score of 8) is contributed by $\{A\}$, thus the head; mid-$1/3$ traffic is contributed by $\{B, C, D\}$ (a total score of $4 + 2 + 2 = 8$), thus the torso; bottom-$1/3$ traffic is contributed by $\{E, F, \ldots, L\}$ (a total score of $1 \times 8 = 8$), thus the tail.

A.8 Supplemental Results

	Model	All									Movie		Book		Academics		Open	
		A_{EM}	H_{EM}	A_{F1}	H_{F1}	A_{RL}	H_{RL}	A_{LM}	H_{LM}	M	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}	A_{LM}	H_{LM}

Abstract

Task-Oriented Parsing (TOP) enables conversational assistants to interpret user commands expressed in natural language, transforming them into structured outputs that combine elements of both natural language and intent/slot tags. Recently, *Large Language Models (LLMs)* have achieved impressive performance in synthesizing computer programs based on a natural-language prompt, mitigating the gap between natural language and structured programs. Our paper focuses on harnessing the capabilities of LLMs for semantic parsing tasks, addressing the following three key research questions: 1) *How can LLMs be effectively utilized for semantic parsing tasks?* 2) *What defines an effective prompt?* and 3) *How can LLM overcome the length constraint and streamline prompt design by including all examples as prompts?* We introduce *k-Nearest Neighbor In-Context Learning* (kNN-ICL), which simplifies prompt engineering by allowing it to be built on top of any design strategy while providing access to all demonstration examples. Extensive experiments show that: 1) Simple ICL without kNN search can achieve a comparable performance with strong supervised models on the TOP tasks, and 2) kNN-ICL significantly improves the comprehension of complex requests by seamlessly integrating ICL with a nearest-neighbor approach. Notably, this enhancement is achieved without requiring additional data or specialized prompts.

1 Introduction

Task-Oriented Parsing (TOP), which aims to translate the natural-language commands from users into specific actions, such as booking a restaurant, is an essential component in conversational systems (Chen et al., 2020; Budzianowski et al., 2018; Wu et al., 2023). Over the past few years, a wide range of methods have been developed, ranging from rule-based methods (Zelle and Mooney, 1996; Dong and Lapata, 2018) to neural program synthesis methods (Shin et al., 2019; Mansimov and Zhang, 2022; Drozdov et al., 2022).

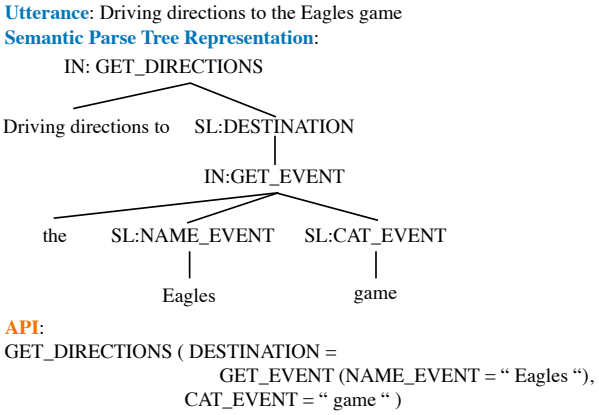

Figure 1: Reduction of an utterance from Topv2 with semantic parse tree to Python style API.

The recent advancements in TOP involve formulating the task as a sequence-to-sequence problem, relying on a wealth of labeled data. This process typically entails feeding user utterances into Transformer models (Liu et al., 2019; Devlin et al., 2018; Raffel et al., 2020) and designing specialized Transformer architectures to generate structured outputs that combine natural language with intent and slot tags like "IN:" and "SL:". Some alternative approaches attempt to reframe TOP as conventional tasks, such as canonical paraphrasing (Shin et al., 2021) and abstractive question answering (Zhao et al., 2022). These approaches aim to reduce the model's burden by eliminating the need to rationalize non-linguistic labels that were not part of pre-training. However, in real-world scenarios, obtaining high-quality training examples with expert annotations can be challenging. Additionally, API documentation, which contains valuable information, often remains underutilized within the fine-tuning paradigm.

On the contrary, *Large Language Models (LLMs)* excel in challenging few-shot scenarios, where they only need a few examples to generate the desired

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 326–337
June 16-21, 2024 ©2024 Association for Computational Linguistics

output and can also understand extensive API documentation. In this paper, we delve into an examination and analysis of the performance of ICL in the context of TOP. Besides, following a comprehensive review of prompt design strategies, we introduce kNN-ICL, which offers adaptable integration with any prompt design strategy, further augmenting model performance.

We conducted experiments using three representative models: GPT-Neox-20B (Black et al., 2022), CodeGen-16B-Multi (Shin et al., 2019), and Codex (`code-davinci-002`) (Chen et al., 2021) to assess the performance of LLMs in TOP. Our research revolves around three key questions:

Question 1: How can we effectively leverage LLMs for TOP tasks? We transform TOP into a code generation task, mapping semantic parse trees to Python code (referred to as 'API' hereafter) to align with LLMs' output format, as shown in Figure 1.

Question 2: What constitutes proper prompt design for TOP using LLMs? We analyze ICL performance under various prompt design strategies, including factors: API documentation and exemplar selection methods. Our findings include: API documentation benefits the more powerful CODEX model but can be distracting for the less-capable CODEGEN and GPT-NEOX models. Unsupervised demo selection proves most effective with ICL, thanks to its flexibility in capturing semantically similar examples holistically.

Question 3: How can we overcome the LLM's length constraint and simplify prompt design by including all examples as prompts? Instead of solely focusing on LLM performance through complex prompt design strategies, we draw inspiration from the retrieval language model approach (Khandelwal et al., 2019, 2021) and introduce kNN-ICL. kNN-ICL enables LLMs to access all available demo exemplars during inference, harnessing synergy between the copy mechanism and the labeling task. We tackle two key challenges. First, how to infuse TOP knowledge into LLMs, considering their limited domain expertise due to the scarcity of labeled data? We address this by including a few demos as kNN-ICL prompts, guiding LLMs to follow the desired output pattern. Second, how to retrieve the nearest neighbor when there's a representation discrepancy between the kNN-ICL datastore and the LLM prompt? To address this challenge, instead of using the hidden state h_t directly from the LLM as the current step representation, we utilize a combination of the target utterance and previously generated words from the LLM at time step t. This ensures consistency in representation between the kNN-ICL datastore and LLMs, offering flexibility in adapting to various prompt design strategies.

In summary, the contributions of this paper are three-fold: 1) We examine prompt design strategies for LLMs in the context of TOP by framing TOP as a code generation task. We conclude that similarity-based demo selection is effective for both black-box and open-source models, with stronger LLMs benefiting more from documentation; 2) We introduce kNN-ICL to address the length constraints of LLMs, offering flexibility to integrate with any prompt design strategy; and 3) Extensive experimental results showcase that kNN-ICL can enhance the generation of better-nested API structures by leveraging guidance from nearest neighbors.

2 Methodology

In this section, we outline the methodology employed in this study. Our approach consists of two key components: (1) *Prompt Design for Semantic Parsing* (cf. Section 2.3). We begin by crafting an effective prompt for TOP. This involves varying two crucial elements within the prompt: API documentation and exemplar selection strategies. (2) *Integration with* kNN-ICL (cf. Section 2.4). We then integrate all the exemplars to LLM in kNN-ICL. This integration allows us to harness the collective knowledge from all exemplars within the demo pool, enhancing the generation of the semantic parse API.

2.1 Preliminaries

In-Context Learning (ICL), which involves no parameter updates or fine-tuning for downstream tasks, has demonstrated competitiveness across multiple *Natural Language Understanding (NLU)* and *Natural Language Generation (NLG)* tasks. Typically, prompts are designed as task instructions, often comprising a few exemplars paired with input-output examples retrieved from a demo pool. However, due to the limited input length of LLMs, the number of exemplars is constrained.

More recently, the concept of retrieval language models (Khandelwal et al., 2019; Borgeaud et al., 2022) has emerged. In this paradigm, language models have access to extensive corpora and em-

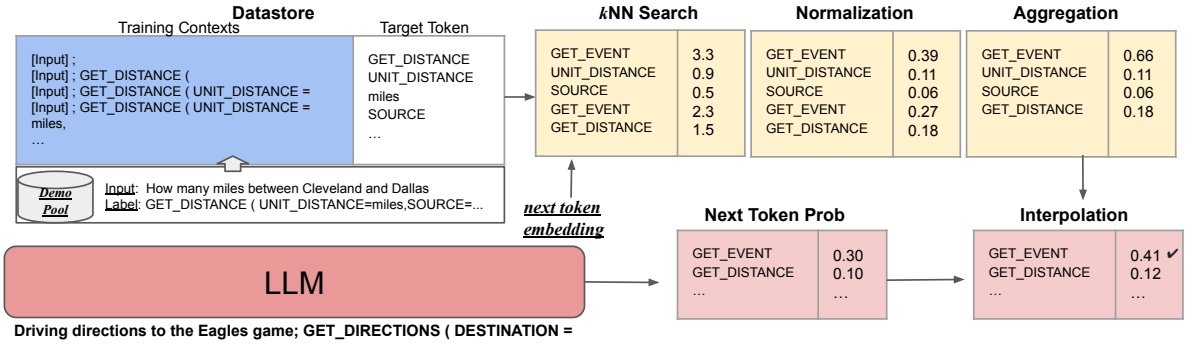

Figure 2: An illustration of kNN-ICL at decoding time step t. The input to LLM is the user utterance "*Driving directions to the Eagles game*" combined with the previously generated output "*GET_DIRECTIONS (DESTINATION =*". The target token "*GET_EVENT*" is generated as output.

ploy explicit memory mechanisms for text generation. This approach has proven to enhance the capabilities of language models significantly.

2.2 Reduction to Code Generation

We utilize pre-trained code style knowledge, as found in models like CODEX, CODEGEN, and GPT-NEOX, trained on extensive code style corpora. We transform the API representations into Python code style, mapping the root node's intent name from the TOP semantic parse tree to the outermost Python function name. The tree branches serve as variable-value pairs within the Python function structure, enabling effective use of pre-trained code style knowledge.

2.3 Prompt Design for Semantic Parsing

The fundamental prompt design for TOP consists of three core elements: "`[API documentation]+[exemplars]+[target utterance]`." The target utterance represents the expected prediction by the LLMs, based on the provided prompt. Below is an example.

Prompt 1: An Example of Prompt Design for Semantic Parsing

```
[API Documentation]
GET_ESTIMATED_DURATION: estimate how
    long it takes to travel from the
    source to the destination.
GET_TRAFFIC_CONDITION: get the traffic
    conditions such as easy, heavy
    congestion.
...
[Exemplars]
Example 1:
How long will it take to drive to New
    Orleans if I leave my house at 3 am?
GET_ESTIMATED_DURATION(
    METHOD_TRAVEL="drive",
    DESTINATION="New Orleans",
    SOURCE=GET_LOCATION_HOME(
    CONTACT="my"),
    DATE_TIME_DEPARTURE="at 3 am")
Example 2:
Driving directions to the Eagles game
GET_DIRECTIONS(DESTINATION=GET_EVENT(
    NAME_EVENT="Eagles"),
    CAT_EVENT="game")
...
[Target Utterance]
what's the current traffic like from my
    home to Shine Restaurant?
```

We will delve into the first two components in the subsequent discussion.

2.3.1 API Documentation

In each domain, the API name, which includes intent and slot names from the TOP dataset, is represented symbolically, like *GET_LOCATION*. The API document or description offers natural language explanations of the domain service, aiding pre-trained LLMs in comprehension.

2.3.2 Demo Selection

We explore three exemplar selection strategies.

▷ **Random Selection** Exemplars are randomly drawn from the demo pool to create the prompt.

▷ **Unsupervised Selection with SentenceBERT** Utilizing SentenceBERT, we generate sentence-level embeddings for both the target utterance and all exemplar utterances. We rank the cosine similarity scores for all demos in the pool and select the top-k most similar exemplars. In experiments, we set the number of exemplars (m) to 10 across all three models.

▷ **Supervised Selection with Paraphrasing** In contrast to SentenceBERT, we train a more precise classifier to rank utterances based on the similarity at the outermost intent level. We frame the similarity ranking as a paraphrasing task. To construct pairwise data for the paraphrase model, we label `[a, b]` as `True` if `a` and `b` share the same intent

name from a parent node of the semantic parse tree, where `b` is sampled from the demo pool. For each utterance `a`, the ratio of constructed `True` pairs to `False` pairs is 1 to 5. During inference, we use the probability of predicting the label `True` as the ranking score.

2.4 k-Nearest Neighbour In-Context Learning

LLMs face a limitation in fully utilizing the exemplar information from the demo pool, making the demo selection strategy a critical factor influencing generation quality for ICL. Here, we introduce a comprehensive model, kNN-ICL, designed to enable ICL to consider all demo exemplars from the demo pool, irrespective of the length constraint imposed by LLMs.

An overview of kNN-ICL is shown in Figure 2: kNN-ICL leverages both LLMs' predictions and k-nearest neighbor search to generate the final prediction. This involves probability distribution over the LLMs' vocabulary during the decoding process and the retrieval of the top-k nearest neighbors from the datastore.

A challenge for kNN-ICL arises from the need to copy a span from the target utterance as a slot value which is a requirement of the TOP task. Unfortunately, traditional kNN-LM (Khandelwal et al., 2019) or kNN-MT (Khandelwal et al., 2020) methods do not naturally support this. Furthermore, the constrained size of the demonstration pool may not encompass all potential slot values during the inference process. To tackle these challenges, we undertake the following steps:

LLM Prompt kNN-ICL bridges the information formality gap between LLM and the datastore. ICL has demonstrated promising copying ability from target utterances. Hence, we prompt the LLMs with a combination of exemplars and the target utterance to compensate for the limited datastore records, ensuring that the slot value is grounded in the target utterance.

Datastore Creation We create a datastore offline, comprising multiple key-value pairs. The key represents the contextualized representation of the input sentence encoded by LLM, and the value corresponds to the subsequent token of the input sentence. Given a set of training contexts denoted as C and a target represented as T, the formulation of the datastore D is as follows:

$$D \stackrel{\text{def}}{=} (\mathbf{K}, \mathbf{V}) = \{(f(c_i), t_i) | \forall c_i \in C, \forall t_i \in T, (c_i, t_i) \in (C, T)\} \quad (1)$$

For each example in the training set, we store multiple datastore records containing only tokens corresponding to the semantic parsing labels as targets.

Similarity Search Another challenge arises because the hidden state produced by LLM at time step t resides in a different representation space than the datastore. To address this, at time step t when generating token y_t, we calculate the current hidden state representation as a combination of the target utterance s and the previously generated API tokens $y_{1...i-1}$ from "`[API documentation]`". This alignment ensures compatibility with the datastore representation space. Given the limited size of the datastore in TOP, the distribution of retrieved k nearest neighbors tends to be skewed. To mitigate overfitting to the most similar retrieval, we introduce a temperature parameter $Temp$ to flatten the distribution in Equation 2. In this equation, c is training context, identical to "`[API documentation]+[exemplars]`", and s is the "`[target utterance]`".

$$p_{kNN}(y_t|c, y_{1:t-1}) \propto \sum_{(k_j, v_j) \in N} 1_{y_t = v_j} \exp\left(\frac{-Dis(k_j, f(c, y_{1:t-1}))}{Temp}\right) \quad (2)$$

Interpolation The decoding process involves interpolating the k nearest neighbor from the datastore with the language model distribution. To enable the model to accurately predict slot values by copying spans from the target utterance, we employ the full vocabulary from LLM rather than restricting it to the intersection between the LLM vocabulary and the k-nearest neighbor vocabulary.

$$p(y_t|x, y_{1:t-1}) = \lambda p_{kNN}(y_t|c, y_{1:t-1}) + (1 - \lambda) p_{lm}(y_t|x, y_{1:t-1}) \quad (3)$$

***k*NN-ICL *vs.* *k*NN-MT** kNN-ICL is a generalization of kNN-MT for conditional generation tasks using in-context learning, seamlessly integrating with LLMs. It introduces some significant differences compared to kNN-MT. First, the LLM conditions not only on the source sequence but also

Table 1: Exact Match results for TOPv2 dataset on Navigation domain using LLMs with varying prompt components.

on the provided prompt, which typically includes a few selected demonstrations. This enables the LLM to align more closely with the pattern of the target demonstration. Second, while the datastore in kNN-MT is constructed solely from the source and target mappings, the LLM produces representations that are conditioned on the entire prompt and target. This results in a discrepancy when selecting the k nearest neighbors. To address this, we rely on representations derived from both the source and the previously generated tokens in the target to ensure consistency during the similarity search.

3 Experiments

In this section, we address the following key research questions through our experiments: (1) *What constitutes an effective prompt design to enhance the performance of LLMs?* (2) *How does ICL compare to state-of-the-art supervised models on TOP tasks?* (3) *What impact does kNN-ICL, which incorporates all available demo examples from the demo pool through interpolation, have on prediction quality?*

3.1 Dataset, LLMs, and Evaluation

We conduct experiments on the TOPv2 dataset (Chen et al., 2020), an extension of the TOP (Gupta et al., 2018) dataset designed for voice assistants. TOPv2 encompasses 8 domains, including 6 new additions, providing a diverse range of task-oriented semantic parsing examples. Due to the resource-intensive nature of running LLMs, we select 4 representative domains for our testing: Navigation, Reminder, Alarm, and Weather. These domains were chosen based on their complexity, with Navigation and Reminder representing more intricate domains with complex nested semantic parses and a larger number of intent slot names, while Alarm and Weather offer relatively simpler examples with fewer complexities in terms of intent and slot names.

For our experiments, we employ GPT-Neox-20B (Black et al., 2022), CodeGen-16B-Multi (Shin et al., 2019), and Codex (Chen et al., 2021) (`code-davinci-002`) to assess the performance of LLMs in ICL. GPT-Neox and CodeGen models are publicly available and can be hosted locally, whereas Codex is accessible solely through a commercial API provided by OpenAI. Codex cannot be downloaded and implemented directly with our proposed method kNN-ICL. Hence, we employ CodeGen and GPT-Neox for experimenting with kNN-ICL.

We evaluate model performance using exact match criteria, where a prediction is considered correct (scored as 1) if it matches the ground-truth precisely and incorrect (scored as 0) if there is any discrepancy between the prediction and the ground-truth. This evaluation metric disregards the order of the semantic parse tree branches, focusing solely on the correctness of the prediction.

3.2 Baselines

We consider three sets of baselines. **Supervised State-of-the-Art Models**: To establish a performance benchmark for LLMs on TOP, we include supervised state-of-the-art models. RINE (Mansimov and Zhang, 2022) introduces a recursion insertion-based encoder tailored for TOP, breaking the task into smaller steps where each step predicts either an intent or slot name along with its starting and ending positions. CodeT5 (Wang et al., 2021), a unified pre-trained encoder-decoder model based on T5, showcases strong performance in code generation tasks. **ICL**: Unless specified otherwise, we will use ICL with randomly selected demos as the prompt. **kNN-LM**: In this baseline, we use kNN-LM without the inclusion of exemplar prompts for LLMs.

3.3 Implementation Details

For ICL, we utilize 10 exemplars to construct the prompt for LLMs. In the case of kNN-ICL, we explore a range of parameter values, including temperature (chosen from 50, 100, 200, 300, 400, 500), interpolation weight (selected from 0.1, 0.3, 0.5, 0.7), and the number of neighbors (picked from 20, 100, 1000). We conduct an exhaustive search for the best parameter combinations within each domain. We use FAISS (Johnson et al., 2019), an open-source library for fast nearest-neighbor retrieval in high dimensional spaces.

LLM	Method	Navigation	Reminder	Alarm	Weather	Avg
CODET5	FINE-TUNE	10.02	6.61	15.72	6.60	9.74
RINE		42.28	36.87	32.09	32.53	35.94
GPT-NEOX	ICL	1.81	5.28	9.54	16.56	8.30
	kNN-LM	1.22	3.48	6.54	2.28	3.38
	kNN-ICL	**5.69**	**8.48**	**19.40**	**24.52**	**14.52**
CODEGEN	ICL	3.94	5.99	10.88	13.84	8.66
	kNN-LM	0.51	0.14	5.07	1.01	1.68
	kNN-ICL	**8.37**	**10.49**	**19.10**	**25.19**	**15.79**
CODEX	ICL	18.78	30.46	45.08	45.70	35.01
	kNN-ICL *	**35.74**	**41.36**	**57.56**	**53.35**	**47.00**

Table 2: Results of Exact Match on SIPS10 demo pool. We selected four domains using three LLMs: GPT-NEOX, CODEGEN, and CODEX on TOP. ICL refers to vanilla LM using randomly selected examples as demo; kNN-LM uses the external dataset as retrieval pool while no demo is used as prompt; and kNN-ICL is the proposed method using retrieved demo and external datastore. * indicates an estimated result from the black-box CODEX model using retrieved semantic similar demo examples.

Our experiments are conducted on machines equipped with 8 V100 GPUs, each with 16GB of memory. In the context of kNN-ICL, the inference batch size is set to 3 for CODEGEN and 1 for GPT-NEOX, respectively.

To assess kNN-ICL's performance, we establish the SPIS10 data split for each domain, where each domain comprises a maximum of 10 examples for intent or slot labels, simulating a few-shot setting. Additionally, we evaluate kNN-ICL on a larger data setting with a demo pool containing 2000 randomly sampled examples.

3.4 Prompt Design Results (RQ1)

Table 2 presents the exact match scores achieved through the ablation of different prompt components, including the presence of API documentation and the use of three exemplar selection strategies. Due to resource constraints, we randomly selected 20% of the validation data from the Navigation domain, resulting in 596 examples. Additionally, we include the results obtained using RINE and CodeT5 to provide a benchmark for ICL by comparing them with fine-tuning state-of-the-art results.

To summarize, first, the best performance for GPT-NEOX and CODEGEN is achieved with prompts that do not include API documentation and utilize similarity-based selection strategies. This suggests that these two models struggle to leverage the documentation due to the input sequence length limitations, making it challenging to extract useful information. However, CODEX benefits from API documentation when combined with the SentenceBERT similarity strategy. This difference may be attributed to Codex's stronger capacity to handle longer prompts and effectively utilize API documentation.

When comparing the SentenceBERT and paraphrase similarity-based selection strategies, SentenceBERT yields a better prompt when documentation is not included. The paraphrased model provides higher-quality exemplars in terms of outermost intent name similarity, but it falls short of capturing the nested semantic parse tree structure, which is crucial for predicting the correct API.

3.5 ICL vs. Supervised Methods (RQ2)

Table 2 reports the results for supervised models: RINE and CODET5 on the few-shot setting. We create SPIS10 data split for each domain in which each domain contains at most 10 examples for intent or slot label.

We compare ICL with fine-tuned SOTA models. Since CODEX is a black-box model, we use the top-k most similar examples as prompt to estimate its kNN-ICL performance, as shown in Table 2. We observed that the CODEX model consistently outperforms RINE by an average margin of 11.06 across four domains, with notable improvements of 4.5%, 25.5%, and 20.8% in the Reminder, Alarm, and Weather domains, respectively. However, RINE shows better performance on the most challenging domain Navigation. To summarize, the CODEX model demonstrates superior performance over SOTA models especially on flattener domains, while slightly under-performs on the domain with more challenging examples. Although GPT-NEOX and CODEGEN models lag behind CODET5 and

LLM	Method	Navigation	Reminder	Alarm	Weather	average
CODEGEN	ICL-Retrieve	37.00	23.40	48.10	65.80	43.58
	kNN-LM	21.30	3.10	26.99	46.60	24.50
	kNN-ICL	**38.20**	**24.20**	**50.40**	**66.60**	**44.85**
GPT-NEOX	ICL-Retrieve	**33.40**	**24.10**	46.70	65.70	42.48
	kNN-LM	14.30	6.70	33.50	40.00	23.63
	kNN-ICL	33.30	24.00	**46.90**	**66.30**	**42.63**

Table 3: Results for Exact Match on a randomly sampled pool of 2000 demonstrations, illustrating the scalability of kNN-ICL.

RINE model, CODEX results show the potential of ICL from the high capacity model.

3.6 kNN-ICL Results (RQ3)

Few-shot Setting In Table 2, we showcase the results for our novel approach, kNN-ICL, alongside the baseline method, kNN-LM. From this table, we can observe that kNN-ICL outperforms kNN-LM across all domains, demonstrating its effectiveness in leveraging prompts for TOP. Notably, kNN-ICL achieves improvements of 11.1% and 14.1% when compared to kNN-LM, using GPT-NEOX and CODEGEN, respectively.

We also compare kNN-ICL with its ICL counterpart. The results show that for GPT-NEOX and CODEGEN, kNN-ICL provides a boost in performance across an average of four domains, with gains of 6.22% and 7.13% in exact match scores. It's worth noting that our datastore size is limited, containing approximately 100 examples, which matches the size of the demo pool. Therefore, kNN-ICL effectively leverages all available example information to achieve these improved results.

Scale Up We conducted experiments to test the performance of kNN-ICL on a larger datastore, which includes 2000 examples. The goal was to determine if kNN-ICL could benefit more from a larger datastore compared to kNN-LM. When comparing kNN-ICL with kNN-LM, we found that the performance gap between the two models becomes larger in the presence of the larger datastore. Notably, kNN-ICL outperforms kNN-LM by 20.3% and 19.0% using CODEGEN and GPT-NEOX as backbone models respectively. Furthermore, we compared kNN-ICL to ICL-Retrieve, a method that retrieves the most semantically similar example from the demo. In this comparison, kNN-ICL outperforms CODEGEN by 1.2%, 0.8%, 2.3%, and 0.8% on the Navigation, Reminder, Alarm, and Weather domains, respectively. This improvement highlights that even when a demo selection strategy is fixed, kNN-ICL can still bring about performance enhancements.

Depth	GPT-NEOX		CODEGEN	
	ICL	kNN-ICL	ICL	kNN-ICL
1	2.53	**6.42**	5.90	**10.16**
2	1.14	**5.72**	1.72	**6.45**
3	0.00	**1.93**	0.16	**4.98**

Table 4: Analysis of accuracy with respect to nesting depth (1/2/3) for the TOPv2 dataset in the Navigation domain using different models.

For GPT-NEOX, the kNN-ICL shows similar performance on the Navigation and Reminder domains, with a slight improvement observed in the Alarm and Weather domain.

3.7 Additional Analysis: Depth vs. Accuracy

Table 4 illustrates the model's performance concerning the semantic depth in the Topv2 dataset. Our analysis focuses on the Navigation domain, which contains the most complex average semantic parse tree depth. Notably, ICL on GPT-NEOX and CODEGEN exhibits a consistent performance drop with increasing depth. On the other hand, kNN-ICL significantly enhances the performance of examples compared to its ICL counterpart.

3.8 Case Study

In order to assess the performance of state-of-the-art models, specifically ICL, kNN-LM, and kNN-ICL, we present a case study in Figure 3. This case study provides examples of utterances, corresponding ground-truth APIs, and model predictions. The showcased example includes a nested semantic parse tree structure with a depth of 3.

First, CODET5 exhibits overall good quality, except for hallucinating the slot name `POINT_ON_MAP` on the deepest tree branch. However, ICL had a hard time generating API calls for deeper-level APIs, such as hallu-

Utterance: How long will it take to drive to New Orleans if I leave my house at 3 am
GroundTruth: GET_ESTIMATED_DURATION (METHOD_TRAVEL = " drive " , DESTINATION = " New Orleans " , SOURCE = GET_LOCATION_HOME (CONTACT = " my ") , DATE_TIME_DEPARTURE = " at 3 am ")

CodeT5: GET_ESTIMATED_DURATION (METHOD_TRAVEL = " drive ", DESTINATION = GET_LOCATION (POINT_ON_MAP = " New Orleans "), DATE_TIME_DEPARTURE = " at 3 am ")

ICL: "GET_ESTIMATED_DURATION (METHOD_TRAVEL = " drive " , SOURCE = GET_LOCATION_HOME (CONTACT_RELATED = " my ") , DESTINATION = GET_LOCATION_WORK (CONTACT = " my ") , DATE_TIME_ARRIVAL = " at 3 am ")

kNN-LM: GET_INFO_TRAFFIC (LOCATION = GET_LOCATION ( ))

kNN-ICL: GET_ESTIMATED_DURATION (METHOD_TRAVEL = " drive ", DESTINATION = " New Orleans ", SOURCE = GET_LOCATION_HOME (CONTACT = " my "), DATE_TIME_DEPARTURE = " at 3 am ")

Figure 3: A case study from Topv2. The wrong intent and slot name from prediction are marked in red, and the hallucinated nested API call is marked in blue. The ICL, kNN-ICL, kNN-LM uses GPT-NEOX model.

cinating `GET_LOCATION_WORK ( CONTACT = " my " )` for slot `DESTINATION`. kNN-LM suffers from the wrong outermost intent name prediction as well as the slot name prediction because no prompt is provided, causing severe deviation from the expected output. In contrast, kNN-ICL performs best on this complex example with the aid of both prompting, producing an accurate utterance span as a slot value, and the k-nearest neighbor guidance, choosing the proper nested API structure.

4 Related Work

Semantic Parsing Semantic parsing plays a vital role in developing commercial personal assistants for understanding spoken language. Supervised models, including sequence-to-sequence models (Mesnil et al., 2013; Liu and Lane, 2016; Liu et al., 2022b) and pretrained language models (Devlin et al., 2018; Chen et al., 2019), have demonstrated competitive performance. In structured semantic parsing, recent approaches break down semantic tree construction into multiple steps. For instance, RINE (Mansimov and Zhang, 2022) recursively inserts predicted labels at predicted positions to construct the semantic parse tree. Additionally, some methods, like (Zhao et al., 2022), transform semantic parsing into multi-turn abstractive question answering. In few-shot scenarios, techniques such as meta-learning (Chen et al., 2020) and label semantics (Paolini et al., 2021; Desai et al., 2021) enhance neural semantic parsers. Furthermore, (Shu et al., 2022) simplifies semantic parsing to program synthesis and integrates the predicted program into an executable environment.

In-Context Learning With the emergence of Large Language Models (Nijkamp et al., 2023; Black et al., 2022; Brown et al., 2020; Scao et al., 2022; Chen et al., 2021; Chowdhery et al., 2022), model parameters have scaled from 16 billion to over 500 billion. The substantial resource requirements for hosting LLMs have made it challenging to fine-tune them for downstream tasks. As a result, the paradigm for utilizing language models has shifted from traditional pre-training and fine-tuning to more efficient approaches, such as parameter-efficient fine-tuning (Lester et al., 2021; Li and Liang, 2021; He et al., 2021) and ICL (Dong et al., 2022; Liu et al., 2022a; Nguyen et al., 2023). ICL has demonstrated its reasoning capabilities in both plain text (Wei et al., 2022; Zhang et al., 2022) and structured text formats (Chen, 2022; Chen et al., 2022). Researchers have also analyzed the factors contributing to the effectiveness of ICL (Dai et al., 2022; Min et al., 2022; von Oswald et al., 2022) in general tasks. However, existing literature primarily focuses on the overall performance of ICL in generic tasks. Our work, on the other hand, falls within a specific domain, where we investigate the performance of ICL in the context of task-oriented semantic parsing problems.

Retrieval-Augmented Large Language Model Recent advancements in Retrieval-Augmented Language Models (RALMs) have garnered significant attention within the NLP community. LLMs face challenges in terms of scaling (Khandelwal et al., 2019) and acquiring long-tail knowledge (Mallen et al., 2023; Izacard et al., 2022). RALMs (Guu et al., 2020; Zhao et al., 2023; Liu et al., 2023) present a promising solution by seamlessly integrating non-parametric data stores with their parametric counterparts. To enhance the adaptability of RALMs for downstream tasks, researchers have devised strategies such as zero or few-shot prompting (Shi et al., 2022; Xu et al., 2023) and fine-tuning (Shi et al., 2023). To the best of our knowledge, our work stands as the pioneering effort to combine the k-nearest neighbor retrieval language model with in-context learning on generative tasks.

Code Generation Our work is also pertinent to the field of code generation, which endeavors to produce code based on the provided query, whether in the form of natural language or partial code. This domain has recently witnessed significant contributions from LLMs, encompassing both closed-source models such as AlphaCode (Li et al., 2022) and ChatGPT (OpenAI, 2022), as well as open-source counterparts like CodeT5 (Wang et al., 2021), CodeT5+ (Wang et al., 2023), CodeGen (Nijkamp et al., 2022), InCoder (Fried et al., 2022), StarCoder (Li et al., 2023), and Code Llama (Rozière et al., 2023).

5 Conclusion

In this paper, we have delved into the intricacies of prompt design and introduced kNN-ICL to include all demo examples on the task-oriented semantic parsing task, addressing input length challenges during decoding and lessening prompt engineering efforts. Our findings highlight the substantial impact of prompt design on TOP, with models like CODEX deriving more benefits from structured documentation than less capable models. The similarity-based exemplar retrieval strategy enhanced model performance significantly. Furthermore, kNN-ICL's integration with a large language model and k Nearest Neighbor search ensures comprehensive use of training data, offering more consistent results across tasks. This study underscores the critical role of prompt design, pointing to promising avenues for future research.

6 Limitations

Generalization of Prompt Design This study highlights the varying impact of prompt design on different models based on their capacities. Instead of advocating a universal prompt design strategy, the optimal choice should be model-agnostic. A potential avenue for future research is enabling models to autonomously select their preferred prompt designs (Zamfirescu-Pereira et al., 2023; Zhou et al., 2022). Depending on the LLM's chosen strategy, kNN-ICL can serve as a plugin to further enhance model performance by harnessing all available examples.

Generalization to High-Capacity Models This paper offers an initial exploration of kNN-ICL with LLMs. While CODEX is not publicly accessible and the resource limitation, we have used GPT-NEOX and CODEGEN as representative models for kNN-ICL experiments. Nevertheless, given the substantial performance disparity between GPT-NEOX, CODEGEN, and CODEX, future research should delve into assessing the influence of kNN-ICL on more robust models.

Abstract

Evaluating retrieval-augmented generation (RAG) systems traditionally relies on hand annotations for input queries, passages to retrieve, and responses to generate. We introduce ARES, an *Automated RAG Evaluation System*, for evaluating RAG systems along the dimensions of context relevance, answer faithfulness, and answer relevance. By creating its own synthetic training data, ARES finetunes lightweight LM judges to assess the quality of individual RAG components. To mitigate potential prediction errors, ARES utilizes a small set of human-annotated datapoints for prediction-powered inference (PPI). Across eight different knowledge-intensive tasks in KILT, SuperGLUE, and AIS, ARES accurately evaluates RAG systems while using only a few hundred human annotations during evaluation. Furthermore, ARES judges remain effective across domain shifts, proving accurate even after changing the type of queries and/or documents used in the evaluated RAG systems. We make our code and datasets publicly available on Github.

1 Introduction

Retrieval-augmented generation (RAG) has become a prominent approach for building user-facing NLP applications, such as systems for question answering (QA), fact-checking, and customer support (Petroni et al., 2021; Wang et al., 2019). Typically, a RAG system consists of a retriever and a downstream language model (LM). Given a user question, the retriever finds relevant passages from a corpus and the LM uses these passages to generate a response. This formulation admits a multitude of choices: what retrieval model to use, how to divide the documents into retrieval chunks, and how to prompt or finetune the LM to use the retrieved information, to name only a few of the simplest design decisions.

The best design for a RAG system is not necessarily universal across data domains, corpus sizes, and cost/latency budgets. To tune their own RAG systems, practitioners traditionally need hand annotations for test questions, passages to retrieve (to assess the retriever), and responses to generate, labeled specifically for their target domain. Alternatively, they may evaluate different approaches in production by collecting human preferences that compare the candidate systems. Unfortunately, both of these strategies demand high expertise and impose considerable annotation costs.

Model-based evaluation is an inexpensive strategy to test generative output quality (Zheng et al., 2023). For instance, the open-source RAGAS framework (James and Es, 2023) prompts an LM for evaluating the *relevance* of retrieved information and the *faithfulness* and *accuracy* of generated responses. Unfortunately, such strategies currently rely for evaluation on a fixed set of heuristically hand-written prompts, offering little adaptability to various evaluation contexts and no guarantees about quality.

To evaluate RAG systems rapidly and accurately, we propose ARES, the **A**utomated **R**AG **E**valuation **S**ystem. ARES is the first automated RAG evaluation system to generate tailored LLM judges for each component of a RAG pipeline, leading to substantial boosts in evaluation precision and accuracy compared to existing approaches like RAGAS. Furthermore, unlike existing RAG evaluation systems, ARES provides confidence intervals for its scoring by leveraging prediction-powered inference (PPI; Angelopoulos et al. 2023). Given a corpus of documents and a RAG system, ARES reports three evaluation scores: context relevance (is the retrieved information pertinent to the test question), answer faithfulness (is the response generated by the language model properly grounded in the retrieved context), and answer relevance (is the response also relevant to the question). A good

RAG system finds relevant contexts and generates answers that are both faithful and relevant.

Many existing RAG evaluation frameworks require substantial human annotations for scoring. ARES significantly improves data efficiency during evaluation by only requiring three inputs: an in-domain passage set, a human preference validation set of approximately 150 annotated datapoints or more, and few-shot examples of in-domain queries and answers (e.g. five examples or more), which are used for prompting LLMs in synthetic data generation.

Given the corpus of in-domain passages, ARES proceeds in three stages. First, it leverages an LM to construct a synthetic dataset of question–answer pairs, derived from the passages in the corpus. Second, it defines three separate judge models to perform three classification tasks (context relevance, answer faithfulness, and answer relevance). These judges are lightweight models fine-tuned against a contrastive learning objective. Third, ARES scores the different RAG systems being assessed using prediction-powered inference (PPI; Angelopoulos et al. 2023) to improve model-based evaluation accuracy and provide statistical confidence intervals for RAG scoring. PPI utilizes a small set of human annotated datapoints for computing its confidence intervals; we designate this annotated set as our *human preference validation set*, which is composed of approximately 150 annotated datapoints or more that designate both positive and negative examples for context relevance, answer faithfulness, and answer relevance.

We conduct extensive empirical evaluations, demonstrating that ARES accurately scores RAG systems across the six knowledge-intensive datasets in KILT and SuperGLUE, beating existing automated evaluation approaches like RAGAS by 59.3 and 14.4 percentage points on average across context relevance and answer relevance evaluation accuracy, respectively. Additionally, ARES accurately calculates answer hallucination occurrences in the AIS attribution dataset (Rashkin et al., 2022), predicting within 2.5 percentage points of the ground truth average for answer hallucinations. Compared to annotation-based evaluation methods, ARES is substantially more accurate and efficient, requiring 78% less annotations than the baseline approach. We also find that ARES consistently distinguishes competitive RAG systems that are only a few points apart in ground-truth metrics. This precision enables ARES to guide the development and comparison of competitive approaches and configurations.

We make the ARES code and datasets publicly available on Github.

2 Related Work

RAG (Guu et al., 2020; Lewis et al., 2020; Khattab et al., 2021; Izacard et al., 2022)) is now a common strategy for bolstering LLMs by combining them with retrieval systems. Through retrieval, RAG helps LM systems gather domain-specific knowledge, ground generations in factual information (Shuster et al., 2021; Huo et al., 2023), and offer a degree of transparency or interpretability via citing sources (Mialon et al., 2023).

Multiple LLM-based evaluation techniques have emerged for gauging LLM systems. This is essential for rapid deployment in new settings, where it is difficult to build a traditional benchmark dataset from scratch. Early attempts at this use LLMs out of the box, as in MT-Bench and Chatbot Arena (Zheng et al., 2023). AutoCalibrate (Liu et al., 2023b) seeks to align an LLM-judge with human preferences, leveraging a self-refinement prompt to iteratively improve the LLM judge. However, AutoCalibrate does not offer any statistical guarantees for the accuracy of its predictions. Other work has used LLM prompting to evaluate system quality across natural language generation tasks, such as translation, summarization, and dialogue (Kocmi and Federmann, 2023; Fu et al., 2023; Liu et al., 2023a; Wang et al., 2023).

In the context of knowledge-intensive NLP tasks, LLMs have been explored for assessing attribution and factuality in LLMs (Min et al., 2023; Gekhman et al., 2023; Yue et al., 2023). New guidelines like LongEval (Krishna et al., 2023) and datasets like Hagrid and ALCE (Kamalloo et al., 2023; Gao et al., 2023) provide resources for analyzing knowledge-intensive LLM pipelines.

The two most-closely related projects to ARES are EXAM (Sander and Dietz, 2021) and RAGAS (James and Es, 2023). To evaluate RAG systems, the EXAM metric estimates how many exam questions a reader (simulated as a QA system) can answer correctly based on the generated response. This requires a set of queries with several associated sub-questions each, which adds a burden that ARES does not bring. RAGAS is based on a handful of heuristic hand-written prompts. These offer little adaptability to new RAG evaluation set-

tings (e.g., new corpora) and, as we show in our evaluation, substantially underperform ARES.

3 ARES

ARES proceeds in three stages (Figure 1). There are three required inputs: an in-domain passage set, a human preference validation set of approximately 150 annotated datapoints (or more), and few-shot examples of in-domain queries and answers (five or more examples), which are used for prompting LLMs in synthetic data generation. With our inputs prepared, we begin by generating synthetic queries (and their answers) from the passages in the target corpus. We then use these query–passage–answer triples to train LLM judges. Subsequently, we apply these judges to any RAG system, scoring a sample of its in-domain query-document-answer triples, and use prediction-powered inference (PPI) with our human preference validation set to estimate a confidence interval for the quality of each RAG system.

3.1 LLM Generation of Synthetic Dataset

We generate synthetic queries and answers from the corpus passages using generative LLMs. The generated data represent both positive and negative examples of query–passage–answer triples (e.g., relevant/irrelevant passages and correct/incorrect answers). For generation, the LLM uses our input set of few-shot examples with in-domain passages mapped to in-domain queries and answers; the model then generates a synthetic question and answer from a given in-domain passage, allowing us to create both positive and negative training examples. We include example prompts for generating synthetic queries and answers in A.6.

For creating our synthetic data, we primarily use on FLAN-T5 XXL (discussed in subsection 4.1). ARES works well with this model (see section 5) but our system can ultimately use another high-quality model for generating synthetic queries and answers. We then filter out low-quality queries by testing if a given query can retrieve its original passage as the top result using its retriever. This filtering approach has been used in previous work to isolate high-quality synthetic queries (Dai et al., 2022; Saad-Falcon et al., 2023).

To generate negatives for fine-tuning our LLM judges, we rely on two novel strategies, generating the same number of negatives with each strategy:

1. **Weak Negative Generation**: For context relevance negatives, we randomly sample in-domain passages unrelated to a given synthetic query. For answer faithfulness and answer relevance negatives, we randomly sample synthetically-generated answers from other passages, which were created using FLAN-T5 XXL.
2. **Strong Negative Generation**: For context relevance negatives, we randomly sample in-domain passages from the same document as the gold passage. For datasets in which multiple passages are not available for the same document, we use BM25 to retrieve the top-10 passages similar to the passage and sample from them for our context relevance strong negatives. For answer faithfulness and answer relevance negatives, we prompt FLAN-T5 XXL (subsection 4.1) to generate a contradictory answer using the few-shot prompt in subsection A.5.

In total, the number of negatives generated equals the number of positives generated for evaluating context relevance and answer relevance.

3.2 Preparing LLM Judges

To prepare our RAG evaluation judges, we use our synthetic dataset to fine-tune DeBERTa-v3-Large judges (discussed in subsection 4.1) to evaluate three different capabilities (Chen et al., 2023; James and Es, 2023):

1. **Context Relevance**: Is the passage returned relevant for answering the given query?
2. **Answer Faithfulness**: Is the answer generated faithful to the retrieved passage, or does it contain hallucinated or extrapolated statements beyond the passage?
3. **Answer Relevance**: Is the answer generated relevant given the query and retrieved passage?

For each metric, a separate LLM with a binary classifier head is fine-tuned to classify positive and negative examples. For each concatenated query-document-answer, a single LLM judge must classify the triple as positive or negative for that judge's metric. To fine-tune these judges, we use our human preference validation set to evaluate model improvement after each epoch, stopping when we have three epochs with no improvement in loss (see subsection A.1 for more information).

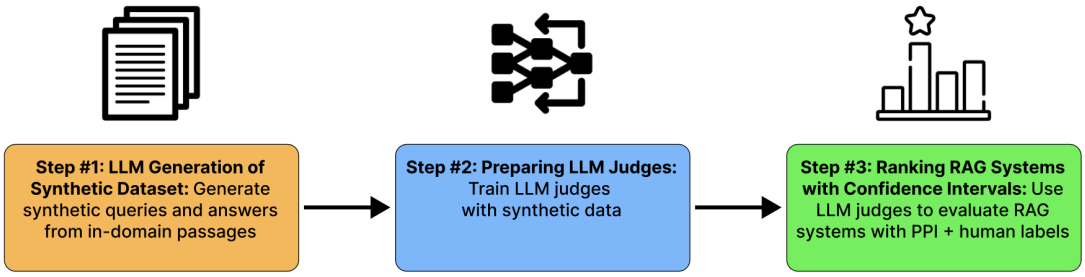

Figure 1: **Overview of ARES**: As inputs, the ARES pipeline requires an in-domain passage set, a human preference validation set of 150 annotated datapoints or more, and few-shot examples of in-domain queries and answers (five or more), which are used for prompting LLMs in synthetic data generation. To prepare our LLM judges for evaluation, we first generate synthetic queries and answers from the corpus passages. Using our generated training triples and a constrastive learning framework, we fine-tune an LLM to classify query–passage–answer triples in three different criteria: context relevance, answer faithfulness, and answer relevance. Finally, we use the LLM judges to score RAG systems and generate confidence bounds for the ranking using PPI and the human preference validation set.

3.3 Ranking RAG Systems with Confidence Intervals

Once we have prepared our LLM judges, we need to use them to score and rank the competing RAG systems. To do this, ARES samples the in-domain query-document-answer triples produced by each RAG approach, and the judges label each triple, predicting their context relevance, answer faithfulness, and answer relevance. By averaging the individual predicted labels for each in-domain triple, we calculate the RAG system performance across each of the three metrics.

In principle, we could simply report these average scores as quality metrics for each RAG system. However, these scores reflect entirely unlabeled data with predictions from a synthetically-trained LLM judge, and hence they may not be entirely accurate. As an extreme alternative, we could use just the small human preference validation set discussed previously for evaluation, reporting the extent to which each RAG system agrees with (or deviates from) the human annotations. However, an annotation-based evaluation approach would require labeling substantially more generative outputs from each RAG systems separately, which can be costly both in terms of time and financing.

To combine the benefits of both, and hence boost the precision of the evaluation, ARES uses *prediction-powered inference* (PPI; Angelopoulos et al. 2023) to predict the system scores. PPI is a recent statistical method that provides tighter confidence intervals on a small set of annotated datapoints (i.e., our validation set) by leveraging predictions on a much larger set of non-annotated datapoints. PPI can leverage both the labeled datapoints and the ARES judge predictions on the non-annotated datapoints to construct confidence intervals for our RAG system's performance.

To do this, PPI uses the LLM judges on the human preference validation set to learn a *rectifier function* for constructing a confidence set of the ML model's performance, using each ML prediction in the larger non-annotated dataset. The confidence set can then be used to create a tighter confidence interval for the performance of the evaluated RAG system (e.g. its context relevance, answer faithfulness, or answer relevance accuracy individually) compared to simply using annotated outputs from the evaluated RAG system. By bolstering the human preference validation set with the much larger set of datapoints with ML predictions, PPI can develop reliable confidence intervals for ML model performance that beat previous classical inference approaches.

The PPI rectifier function allows us to estimate the errors of the LLM judge and generate confidence bounds for the success and failure rates of the RAG system, estimating context relevance, answer faithfulness, and answer relevance performance. Additionally, PPI allows us to estimate confidence intervals with a selected level of probability; for our experiments, we use a standard 95% alpha (probability) for our confidence interval.

With the accuracy confidence interval for each component of the RAG, we find the midpoint of each confidence interval and use the midpoints to rank the RAG systems. With our ranking, we can compare different RAG systems, as well as different configurations of the same RAG system, to find the best-performing approach for a given domain.

4 Experiments

4.1 Models

For our fine-tuned judges, ARES relies on generating cheap but quality synthetic queries and answers using LLMs. For generating our synthetic datasets, we use FLAN-T5 XXL (Chung et al., 2022). We selected DeBERTa-v3-Large (He et al., 2021) for our fine-tuned LLM judge. Our fine-tuned LLM judges allow us to rank RAG systems without relying on external APIs, solely using few-shot prompts and deployable LLMs on commercial GPUs.

For our in-context learning baseline, we use OpenAI's *gpt-3.5-turbo-16k*, version 10/23, (Brown et al., 2020) in a zero/few-shot setting. For similarity search over in-domain passages, we use FAISS IndexFlatL2 for indexing (Johnson et al., 2019) and OpenAI's *text-embedding-ada-002* for generating embeddings. We use simlarity search over in-domain passages to filter our synthetic queries that cannot retrieve the passage from which they were generated. We use version 0.0.18 of RAGAS in our experiments (James and Es, 2023).

4.2 Datasets

Our core experimental goal is to provide a rich picture of where ARES can be applied effectively. To test across multiple types of queries, documents, and answers, we selected all the datasets from the widely-used KILT and SuperGLUE benchmarks for which RAG is appropriate.

From KILT (Petroni et al., 2021), we use Natural Questions (NQ), HotpotQA, FEVER, and Wizards of Wikipedia (WoW) (Kwiatkowski et al., 2019; Yang et al., 2018; Akhtar et al., 2023; Dinan et al., 2018). Each dataset uses Wikipedia passages but the queries and answers offer a range of applications. Both NQ and HotpotQA feature direct questions and expect short answers, but NQ uses single passages for reasoning while HotpotQA requires multiple passages for reasoning. Furthermore, FEVER focuses on fact-verification, determining if a passage supports or refutes a given statement, and expects an output of "SUPPORTS" or "REFUTES". WoW seeks to evaluate dialogue agents by mapping user dialogue to relevant Wikipedia passages before a chatbot generates a paragraph-length chat response incorporating passage knowledge.

From SuperGLUE (Wang et al., 2019), we use MultiRC and ReCoRD (Khashabi et al., 2018; Zhang et al., 2018). MultiRC focuses on direct questions for seven different domains (News, Wikipedia articles, articles on society/law/justice, articles on history/anthropology, elementary school science textbooks, 9/11 reports, and fiction). ReCoRD focuses on determining the placeholder entity in a statement, focusing on news articles from CNN and the Daily Mail. For MultiRC and ReCoRD, we create open-domain versions of their tasks. For MultiRC, we perform retrieval over its seven sets of domain passages. For ReCoRD, we perform retrieval over its news article passages.

The efficacy of ARES relies on its ability to rank different RAG systems while only using a human preference validation set and domain-targeted LLM judges. To test the limits of ARES, we need to simulate the existence of many RAG systems that are separated by small accuracy margins on our evaluation metrics. For this, we create systems using artificial query-passage-answer triples, in which we empirically know the positive and negative examples of the mock RAG system. We generate these mock splits of the given datasets by selecting (1) The positive and negative query-passage matches for context relevance, and (2) the positive and negative query-passage-answer matches for answer relevance. We include positive and negative examples from our evaluation sets in Table 7.

For our positive triples, we can simply use the KILT and SuperGLUE examples without any alteration. For gathering negative query-passage pairs and query-passage-answer triples, we randomly sample passages and answers from either: the same Wikipedia document or an entirely random Wikipedia document. This sampling allows us to artificially create mock RAG systems for testing ARES. By sampling both related and unrelated documents/answers, we hope to better gauge the efficacy of ARES in judging RAG outputs.

We do not evaluate answer faithfulness for KILT and SuperGLUE datasets since we do not have human-annotated hallucinated answers to use for evaluation. However, we do test the ARES framework on real attribution datasets in Section 5.2.

Using the validation subsets for each KILT and SuperGLUE dataset, we create nine different dataset splits, ranging from 70% success rate to 90% success rate for each of the evaluated RAG criteria; each dataset is separated by 2.5% accuracy points (e.g. 70.0%, 72.5%, 75.0%, ..., 90.0%). Each split also represents a different mock RAG system. Since we know the success percentages of each dataset split, we know the appropriate ranking of each mock RAG system. This allows us to

test ARES success at both scoring and ranking the mock RAG systems appropriately across the three evaluation criteria.

4.3 Metrics

To calculate the correlation between the correct ranking and the ARES ranking, we use the Kendall rank correlation coefficient or Kendall's τ:

$$\tau = \frac{(\#\text{ of concordant pairs}) - (\#\text{ of discordant pairs})}{\#\text{ of pairs total}}$$

Concordant pairs are defined as two ordinal values in the ranking where the earlier value in the sequence is lower than the later value in the sequence. Discordant pairs are defined as two ordinal values in the ranking where the earlier value in the sequence is greater than or equal to the later value in the sequence. A Kendall's τ greater than 0.9 is considered successful but it ranges from 0.0 to 1.0.

In development, researchers and engineers will be comparing different RAG configurations through individual pairwise comparisons of model choices, retriever selection, and document preprocessing. We want to make sure that ARES has satisfactory accuracy in pairwise comparisons across a variety of performance gaps between RAG systems. Kendall's τ is explicitly designed for measuring the accuracy of such pairwise comparisons, calculating the correlation between a perfectly accurate pairwise ranking and an experimental pairwise ranking. Thus, it is a popular and widespread metric used in information retrieval, allowing developers to evaluate ranking systems empirically. Therefore, we believe Kendall's tau and prediction accuracy provide meaningful metrics for testing the efficacy of ARES as a RAG evaluation system.

5 Results & Analysis

5.1 ARES Ranking

Table 1 summarizes our main evaluation of ARES (with DeBERTa-v3-Large as the pretrained basis for the judges). We compare against RAGAS (version 0.0.18) and a baseline few-shot prompted GPT-3.5 judge (*gpt-3.5-turbo-16k*). For the few-shot GPT-3.5 judge, we provide few-shot examples for guiding predictions; the prompts are included in Appendices A.2, A.3, and A.4. For both ARES and the GPT-3.5 judge baseline, we augment the LLM with PPI, using a 300-datapoint human preference validation set to rectify the ML predictions and produce confidence intervals.

Across almost all settings across the datasets from KILT and SuperGLUE, ARES provides a more accurate ranking of RAG systems than RAGAS. ARES averages a Kendall's τ *0.065 higher for context relevance* and *0.132 higher for answer relevance than RAGAS*. Additionally, the LLM-judge is substantially more accurate than RAGAS at predicting context relevance and answer relevance of a query-passage-answer triple. For context relevance, ARES with a fine-tuned LLM-judge is *59.9 percentage points higher than RAGAS* while for answer relevance, our system is *14.4 percentage points higher than RAGAS*. Overall, ARES provides a more accurate system for automatically evaluating RAG configurations than RAGAS by leveraging domain-adaptive techniques for prompting and training as well as utilizing PPI to bolster model predictions.

As an additional comparison, we also include the Kendall's τ for RAG ranking with the ARES LLM judge without PPI; for all datasets tested, PPI improved the ranking prediction accuracy of the fine-tuned LLM judge. Furthermore, we included a sampled annotations configuration, in which we sampled 150-datapoints from each mock RAG system, totalling 1,350 annotations. Even with all these annotations, the Kendall's τ for ARES is 0.08 higher on average, across both context and answer relevance, compared to sampled annotations, despite using 78% less annotations. In sum, ARES proves significantly more data-efficient with human annotations while being more accurate at scoring than standard sampled annotation methods.

Compared to the GPT-3.5 judge, ARES provides a more accurate ranking of the RAG systems than the GPT-3.5 judge, averaging a Kendall's tau 0.06 higher over both context relevance and answer relevance. Between the judge configurations, the fine-tuned LLM judge of ARES can more precisely distinguish between RAG systems and guide configuration decisions surrounding document splitting, retriever selection, and generative LLM choice. However, while the fine-tuned LLM judge had a higher Kendall's tau on average, the GPT-3.5 judge is more readily deployable and does not require any additional fine-tuning. The GPT-3.5 judge does come with its own querying costs, which can vary based on the date of querying as well as the total tokens used in evaluation.

We also wanted to better understand the importance of human annotations for ARES. To this end, we conducted two sets of experiments. First, we

Table 1: **ARES Ranking with Fine-tuned LLM Judges vs. Sampled Annotations, RAGAS and GPT-3.5 Judge**: For scoring context relevance and answer relevance (C.R. and A.R. in the table, respectively), we compare ARES with our fine-tuned LLM judges against sampled annotations benchmark, RAGAS, and a few-shot GPT-3.5 judge. For our sampled annotations, we gather 150 annotated datapoints from each mock RAG system and use those labels to score the system. RAGAS also uses GPT-3.5 as its judge but it uses few-shot prompts that are not targeted for each evaluation domain. Overall, we found that ARES ranked RAG systems more accurately than RAGAS and GPT-3.5 across all the explored datasets. The Kendall's tau for ARES was *0.065 higher on average for scoring context relevance* and *0.132 higher on average for scoring answer relevance* than RAGAS. Additionally, we include the Kendall's taus for the ARES LLM Judge without PPI and found that PPI further boosted the ranking accuracy of the judge across the board. We selected GPT-3.5 instead of GPT-4 due to the lower financial costs required to run. For PPI in both ARES and the GPT-3.5 judge, we used 300 human annotations for our human preference validation set. The prompts used for the GPT-3.5 judges are included in Sections A.2, A.3, and A.4.

used ARES with human annotation sets ranging in size from 25 to 400 and found that 150 is the minimum number required (Table 3). Second, we explored whether GPT-4 generations could replace human annotations entirely, finding that GPT-4 is less good than humans in this role, though the idea arguably has promise (Table 4).

5.2 ARES Performance on AIS

	WoW	CNN / DM
ARES Split Prediction	0.478	0.835
Correct Positive/Negative Split	0.458	0.859
ARES Judge Accuracy	62.5%	84.0%
Evaluation Set Size	707	510
Human Preference Data Size	200	200

Table 2: ARES Results on the AIS benchmark

To evaluate whether ARES can effectively gauge answer faithfulness in real RAG systems, we tested ARES on the AIS attribution benchmark (Rashkin et al., 2022). In AIS, we selected the Wizards of Wikipedia (WoW) and CNN/DM datasets; the other benchmark datasets involve either table reasoning (ToTTo) or focus on passage summarization (QRECC) so we excluded them. In WoW and CNN/DM, each evaluation example includes a query, a retrieved passage, and a generated answer (which is either faithful or non-attributed to the retrieved passage).

Table 2 summarizes our AIS results. We found that ARES can effectively score the AIS datasets, getting within 2.5 accuracy points of the correct scores. Furthermore, for scoring each system, we only use 200 annotated datapoints for our human preference validation set. Our results on AIS demonstrate the ability of ARES to reliably distinguish faithful and hallucinated answers in real-world RAG systems.

5.3 ARES Ranking of Existing RAG Systems

We also wanted to evaluate whether ARES can score and rank existing RAG systems across both context relevance and answer relevance. For evaluation, we selected the NQ, WoW, and FEVER datasets from KILT. We consider the answer gen-

erations to be correct if they contained the KILT answer in their output. For our RAG systems, we selected three different retrievers (BM25, OpenAI Ada embeddings with cosine similarity search, and ColBERTv2 (Santhanam et al., 2022)) and three different generative LLMs (MPT-7b-Instruct (Team, 2023), GPT-3.5-Turbo, and GPT-4). Additionally, we include the Facebook RAG model (Lewis et al., 2020), which uses a DPR retriever (Karpukhin et al., 2020) and BART sequence-to-sequence model (Lewis et al., 2019). During retrieval, each RAG system only retrieves one passage to assist generation.

In Table 5, we found that ARES can reliably score and rank RAG systems in real-world applications, averaging a Kendall's tau of 0.91 for context relevance and 0.97 for answer relevance. Compared to RAGAS, ARES is 0.16 higher for context relevance and 0.15 higher for answer relevance, on average. ARES also provided accurate confidence bounds for its predictions, capturing the ground truth average outcomes for context relevance and answer relevance more than 95% of the time; on average, the PPI confidence intervals were 7.4 points wide for context relevance and 6.1 points wide for answer relevance (see Figure 2 and Figure 3 for ARES vs. RAGAS). Among the models tested, the best performing retriever was ColBERTv2 while the best performing generative LLM was GPT-4.

5.4 Strengths and Limits of Cross-Domain Applications

The generalizability of the LLM judge used in ARES is critical for deploying our framework in specialized domains, particularly domains where in-domain queries, documents, and answers are difficult to gather. Therefore, we wanted to test how the LLM judges used in ARES would be affected by three domain shifts: change in *query type* from training to test (e.g. NQ to FEVER), change in *document type* from training to test (e.g. NQ to MultiRC), and change in both *query and document type* (e.g. NQ to ReCoRD).

In Table 6, we found that the fine-tuned LLM judges used in ARES proved successful in cross-domain applications. Across all settings, we found that LLM judges in ARES had strong generalizability, even when only using 300 datapoints in our human preference validation set for PPI. Furthermore, we found that even when the LLM judge's accuracy suffered in cross-domain applications, PPI helped mitigate the loss in accuracy and still allow ARES to be successful. Additional examples for PPI also continued to boost cross-domain ARES performance in subsequent tests.

While LLM judges in ARES were successful in cross-domain applications for KILT and SuperGLUE, LLM judges are unable to generalize when making more drastic shifts in domain, such as: switching languages (e.g. English to Spanish, German, and other languages), switching from text to code (e.g. questions + passages to coding functions + documentation), and switching from retrieving text to extraction of entities, webpages, or citations.

To test cross-lingual transfer, we used the XGLUE datasets (Liang et al., 2020); a LLM judge fine-tuned on NQ achieved a Kendall's tau of 0.33 over both context relevance and answer relevance scoring for XGLUE. To test text-to-code, we used CodeSearchNet (Husain et al., 2019); an LLM judge fine-tuned on NQ achieved a Kendall's tau of 0.28 over both context relevance and answer relevance scoring for CodeSearchNet. To test extraction task generalizability, we used T-Rex from KILT (Elsahar et al., 2018; Petroni et al., 2021); an LLM judge fine-tuned on NQ achieved a Kendall's tau of 0.38 over both context relevance and answer relevance scoring for T-Rex. Each cross-domain shift requires in-domain passages and few-shot query examples for reconfiguring ARES judges.

6 Conclusion

In this work, we present ARES, a novel automated evaluation framework for retrieval-augmented generation (RAG). ARES offers a novel training pipeline for fine-tuning lightweight LLM judges on synthetically generated queries and answers. ARES can evaluate each component of a RAG system separately to help improve system understanding and create targeted solutions, and it requires only minimal human annotations. For the eight different datasets in KILT, SuperGLUE, and AIS requiring RAG-based solutions, we found that ARES can accurately score and rank RAG systems based on context relevance, answer faithfulness, and answer relevance scores, beating the existing RAGAS automated evaluation framework.

ARES is a flexible framework, and there may be variants of it that are even more powerful than the ones we explored here. Avenues to explore include GPT-4 as a replacement for human labeling (Table 4), more robust techniques for the synthetic datasets used in fine-tuning LLM judges, utilizing

logits in LLM judge prediction to improve PPI confidence intervals, and testing more sophisticated LLMs as fine-tuned judges for ARES.

7 Limitations

ARES relies on a small set of annotations in the human preference validation set (roughly 150-300 datapoints but more is better). These annotations often require an annotator familiar with the RAG system's domain application. While these annotations can be easy to generate for general-domain applications, more specialized domains, such as law, medicine, and finance, may require annotators with specialized expertise.

The LLMs used in ARES benefit substantially from GPU-based hardware with substantial storage. In ARES, DeBERTa-v3-Large (304M) and FLAN-T5-XXL (11.3B) required GPUs with about 32GB of memory to run, taking several hours for fine-tuning and generation, respectively. While commercial GPUs are widely available, they are not easily accessible to all NLP researchers and practitioners due to their costs.

Additionally, all of the datasets used in our evaluation of ARES are in English, a well-resourced language with abundant annotations. Future work should explore how ARES can be employed in other languages by utilizing different LLMs for the ARES judge and the synthetic data generation. This can help us better understand the strengths and weaknesses of the current ARES framework.

A Appendix

A.1 Fine-tuning Configuration for LLM Judges

For our loss function used in LLM judge training, we selected cross-entropy loss using Adam (Kingma and Ba, 2017). For our classification head, we use a single linear classification layer and apply a 0.1 dropout to the input, which is the final hidden state of the [CLS] token. For our learning schedule, we use linear warmup and linear decay (Howard and Ruder, 2018) with a 5e-6 learning rate and a 32 training batch size across all experimental configurations.

A.2 GPT Prompting for Context Relevance Scoring

For the NQ, HotpotQA, MultiRC, and ReCoRD datasets, we use 8 few-shot examples with the following prompt to score context relevance:

- Given the following question and document, you must analyze the provided document and determine whether it is sufficient for answering the question. In your evaluation, you should consider the content of the document and how it relates to the provided question. Output your final verdict by strictly following this format: "[[Yes]]" if the document is sufficient and "[[No]]" if the document provided is not sufficient. Do not provide any additional explanation for your decision.

  Question: *<few-shot example here>*

  Document: *<few-shot example here>*

For FEVER, we use the following prompt to score context relevance:

- You are an expert fact-checking agent. Given the following statement and document, you must analyze the provided document and determine whether it is sufficient for determining the statement's factuality. In your evaluation, you should consider the content of the document and how it relates to the provided statement's factuality. Output your final verdict by strictly following this format: "[[Yes]]" if the document is sufficient and "[[No]]" if the document is not sufficient. Do not provide any additional explanation for your decision.

  Statement: *<few-shot example here>*

  Document: *<few-shot example here>*

For WoW, we use the following prompt to score context relevance:

- You are an expert dialogue agent. Given the following dialogue and document, you must

analyze the provided document and determine whether it is relevant for responding to the dialogue. In your evaluation, you should consider the content of the document and how it relates to the provided dialogue. Output your final verdict by strictly following this format: "[[Yes]]" if the document is relevant and "[[No]]" if the document provided is not relevant. Do not provide any additional explanation for your decision.

Dialogue: *<few-shot example here>*

Document: *<few-shot example here>*

A.3 GPT Prompting for Answer Faithfulness Scoring

For the NQ, HotpotQA, MultiRC, and ReCoRD datasets, we use 8 few-shot examples with the following prompt to score answer faithfulness:

- Given the following question, document, and answer, you must analyze the provided answer and determine whether it is faithful to the contents of the document. The answer must not offer new information beyond the context provided in the document. The answer also must not contradict information provided in the document. Output your final verdict by strictly following this format: "[[Yes]]" if the answer is faithful to the document and "[[No]]" if the answer is not faithful to the document. Do not provide any additional explanation for your decision.

  Question: *<few-shot example here>*

  Document: *<few-shot example here>*

  Answer: *<few-shot example here>*

For FEVER, we change the word "question" in the prompt to "statement". For WoW, we change the word "question" in the prompt to "dialogue".

A.4 GPT Prompting for Answer Relevance Scoring

For the NQ, HotpotQA, MultiRC, and ReCoRD datasets, we use 8 few-shot examples with the following prompt to score answer relevance:

- Given the following question, document, and answer, you must analyze the provided answer and document before determining whether the answer is relevant for the provided question. In your evaluation, you should consider whether the answer addresses all aspects of the question and provides only correct information from the document for answering the question. Output your final verdict by strictly following this format: "[[Yes]]" if the answer is relevant for the given question and "[[No]]" if the answer is not relevant for the given question. Do not provide any additional explanation for your decision.

  Question: *<few-shot example here>*

  Document: *<few-shot example here>*

  Answer: *<few-shot example here>*

For FEVER, we change the word "question" in the prompt to "statement". For WoW, we change the word "question" in the prompt to "dialogue".

A.5 Prompting for Generation of Synthetic Queries and Answers

To generate synthetic queries and answers using FLAN-T5, we use the following prompt and provide 5 few-shot examples:

- Example N

  Question: *<few-shot example here>*

  Document: *<few-shot example here>*

  Answer: *<few-shot example here>*

We use the same prompting structure for generating incorrect or contradictory answers; we simply swap out the few-shot examples to be incorrect or contradictory instead.

A.6 Synthetic Query and Answer Generation

For generating our synthetic questions, we use the following prompt for FLAN-T5 XXL:

- Example #1

  Document: *<few-shot example here>*

  Query: *<few-shot example here>*

  Example #2

  Document: *<few-shot example here>*

  Query: *<few-shot example here>*

  Example #3

  Document: *<few-shot example here>*

  Query: *<few-shot example here>*

  Example #4

  Document: *<in-domain passage>*

  Query:

For generating our synthetic answers, we use the following prompt for FLAN-T5 XXL:

- Example #1

  Query: <*few-shot example here*>

  Document: <*few-shot example here*>

  Answer: <*few-shot example here*>

  Example #2

  Query: <*few-shot example here*>

  Document: <*few-shot example here*>

  Answer: <*few-shot example here*>

  Example #3

  Query: <*few-shot example here*>

  Document: <*few-shot example here*>

  Answer: <*few-shot example here*>

  Example #4

  Query: <*synthetic query here*>

  Document: <*in-domain passage here*>

  Answer:

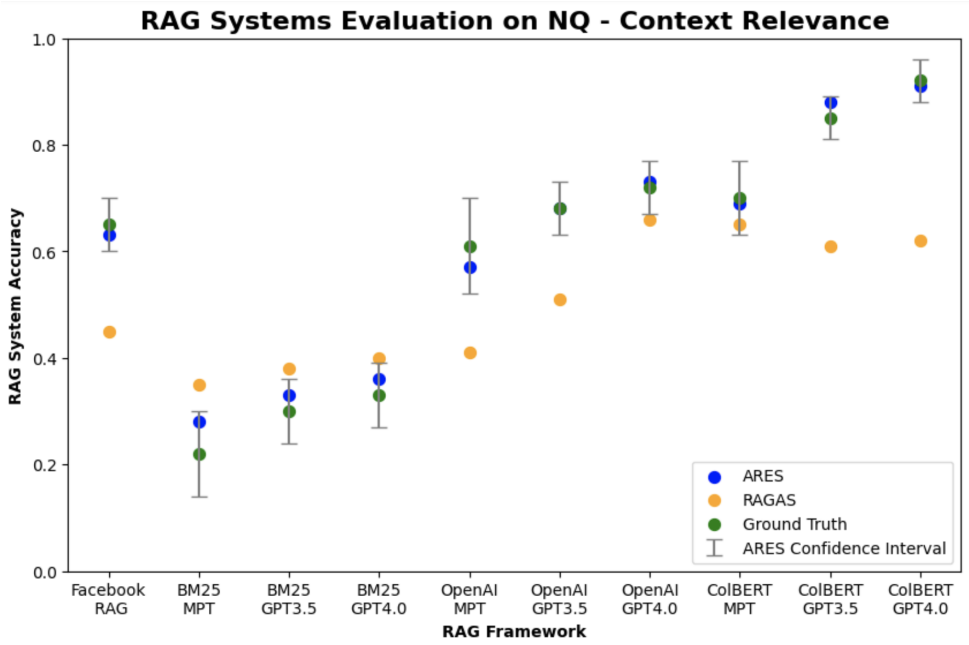

Figure 2: **RAG Systems Evaluation on NQ - Context Relevance**

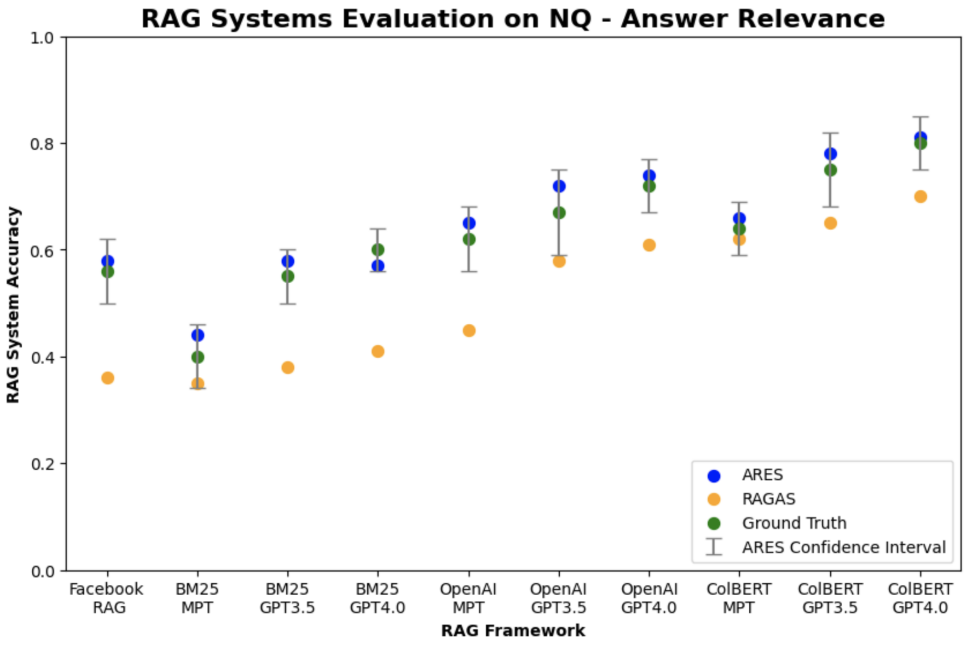

Figure 3: **RAG Systems Evaluation on NQ - Answer Relevance**

	Kendall's Tau by Dataset					
	NQ		MultiRC		ReCoRD	
PPI Labeled Count	C.R.	A.R.	C.R.	A.R.	C.R.	A.R.
400	1.0	1.0	0.89	0.94	0.89	0.94
300	0.89	1.0	0.94	0.89	0.83	0.89
200	0.83	1.0	0.83	0.94	0.83	0.83
150	0.72	1.0	0.83	0.89	0.72	0.83
100	0.44	1.0	0.67	0.67	0.67	0.83
50	0.44	0.94	0.61	0.44	0.56	0.67
25	0.44	0.89	0.56	0.44	0.44	0.56

Table 3: **Analysis of PPI Labeled Count vs. ARES Efficacy by Kendall's Tau**: The Kendall's tau values represent the correlation between the correct ranking and the ARES ranking of the pseudo RAG systems. We use the same experimental set-up as described in subsection 4.2. We find that below about 100-150 datapoints in the human preference validation set, ARES cannot meaningfully distinguish between the alternate RAG systems based on their accuracies in context relevance and answer relevance (C.R. and A.R., respectively).

	ARES Ranking of Pseudo RAG Systems using GPT-4 Labels					
	NQ		ReCoRD		MultiRC	
	Context Relevance	Answer Relevance	Context Relevance	Answer Relevance	Context Relevance	Answer Relevance
Kendall's Tau	0.78	1.0	0.78	0.72	0.89	0.78
Kendall's Tau of Human Labeled Approach	0.94	1.0	0.83	0.89	0.94	0.89
Average PPI Range	9.2%	6.8%	8.2%	9.0%	7.7%	8.3%
Accuracy on RAG Evaluation Sets	79.3%	96.7%	88.4%	78.3%	85.8%	82.5%

Table 4: **GPT-4 Labels vs. Human Labels**: We wanted to explore the practicality of using GPT-4 generated labels instead of human annotations for our human preference validation set in ARES. In the experiments, we generated 500 GPT-4 labels as replacements for human labeling using few-shot prompts (see Sections A.2, A.3, and A.4). While GPT-4 generated labels decreased Kendall's tau in most settings by 0.05 to 0.30, the ability to cheaply produce GPT-4 generated labels significantly reduces the cost of annotation, cutting it from hundreds of annotations to less than ten for few-shot prompts. Additionally, the efficacy of PPI continues improving as we generate more GPT-4 generated labels. In the table, we define PPI range as the number of percentage points from the lower number to the upper number of the PPI confidence bounding. Additionally, we use the fine-tuned LLM judge (DeBERTa-v3-Large) for evaluation.

	ARES Ranking of Real RAG Systems					
	NQ		WoW		FEVER	
	C.R.	A.R.	C.R.	A.R.	C.R.	A.R.
Kendall's Tau for Sampled Annotations	0.73	0.78	0.73	0.73	0.73	0.82
Kendall's Tau for RAGAS	0.82	0.82	0.73	0.82	0.73	0.87
Kendall's Tau for GPT-3.5 Judge	0.82	0.87	0.82	0.82	0.64	0.87
Kendall's Tau for ARES LLM Judge	0.91	**0.96**	**0.91**	**1.0**	0.73	0.87
Kendall's Tau for ARES	**1.0**	**0.96**	**0.91**	**1.0**	**0.82**	**1.0**
RAGAS Accuracy	35.9%	68.2%	44.4%	80.1%	21.4%	75.9%
GPT-3.5 Accuracy	80.5%	91.2%	81.2%	83.5%	61.3%	54.5%
ARES Accuracy	85.6%	93.3%	84.5%	88.2%	70.4%	84.0%

Table 5: **ARES Ranking on Real-World RAG Systems**: For scoring context relevance and answer relevance (C.R. and A.R. in the table, respectively), we compare ARES with our fine-tuned LLM judges against sampled annotations benchmark, RAGAS, and a few-shot GPT-3.5 judge. For our sampled annotations, we gather 150 annotated datapoints from each mock RAG system and use those labels to score the system. RAGAS also uses GPT-3.5 as its judge but it uses few-shot prompts that are not targeted for each evaluation domain. Overall, we found that ARES ranked RAG systems more accurately than RAGAS and GPT-3.5 across all the explored datasets. Additionally, we include the Kendall's taus for the ARES LLM Judge without PPI and found that PPI further boosted the ranking accuracy of the judge across the board. We selected GPT-3.5 instead of GPT-4 due to the lower financial costs required to run. For PPI in both ARES and the GPT-3.5 judge, we used 300 human annotations for our human preference validation set. The prompts used for the GPT-3.5 judges are included in Sections A.2, A.3, and A.4.

Table 6: **Cross-Domain Usage of Fine-tuned LLM Judges**: We tested the cross-domain application of the fine-tuned LLM judge in the ARES framework. We found that for both context relevance and answer relevance (C.R. and A.R. in the table, respectively), fine-tuned LLM judges showed strong generalizability across domains when changing query type (e.g. NQ and FEVER), document type (e.g. NQ and MultiRC), or both (e.g. NQ and ReCoRD). For PPI, we used 300 labeled examples for our human preference validation set but also found that additional examples further improved the performance of ARES. Furthermore, we found that even in scenarios where the fine-tuned LLM judge's accuracy significantly dropped out-of-domain (e.g. answer relevance for NQ to FEVER), PPI mitigated the decrease in judge performance. In the table, we define PPI range as the number of percentage points from the lower bound to the upper bound of the PPI confidence interval.

Abstract

Image-text matching has been a long-standing problem, which seeks to connect vision and language through semantic understanding. Due to the capability to manage large-scale raw data, unsupervised hashing-based approaches have gained prominence recently. They typically construct a semantic similarity structure using the natural distance, which subsequently provides guidance to the model optimization process. However, the similarity structure could be biased at the boundaries of semantic distributions, causing error accumulation during sequential optimization. To tackle this, we introduce a novel hashing approach termed Distribution-based Structure Mining with Consistency Learning (DEMO) for efficient image-text matching. From a statistical view, DEMO characterizes each image using multiple augmented views, which are considered as samples drawn from its intrinsic semantic distribution. Then, we employ a non-parametric distribution divergence to ensure a robust and precise similarity structure. In addition, we introduce collaborative consistency learning which not only preserves the similarity structure in the Hamming space but also encourages consistency between retrieval distribution from different directions in a self-supervised manner. Through extensive experiments on three benchmark image-text matching datasets, we demonstrate that DEMO achieves superior performance compared with many state-of-the-art methods.

1 Introduction

Image-text matching (Sun et al., 2023; Zhang et al., 2022b; Huang et al., 2022; Liu and Ye, 2019; Hu et al., 2023b) is a pivotal task in both computer vision and natural language processing, which bridges data across heterogeneous modalities. The objective is to return images correlated with a given textual description and detect texts corresponding to a given image. Considering explosively growing web data (Krotov and Johnson, 2023), there is a significant demand for an efficient approach that can select a small candidate set from a comprehensive dataset. Towards this end, hashing has become prevalent in information retrieval (Luo et al., 2021a), particularly image-text matching (Hu et al., 2023a; Sun et al., 2022a; Tu et al., 2023a; Zeng et al., 2023; Cao et al., 2022), which involves mapping both texts and images into a shared binary space (Hamming space), and then determining cross-modal similarity scores by comparing their binary codes.

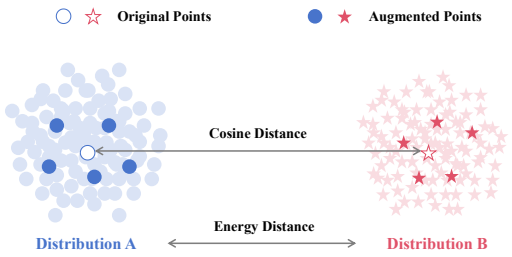

Figure 1: Comparison between cosine distance and energy distance. We leverage the randomness of data augmentation to estimate the latent semantics distributions, and then use energy distance between distributions as a substitute for cosine distance between data points.

In literature, numerous approaches have been developed for cross-modal hashing (Jiang and Li, 2017; Kaur et al., 2021), which can broadly be categorized into supervised and unsupervised methods. Supervised methods (Chen et al., 2019; Jia et al., 2021; Gu et al., 2019) typically incorporate ground truth similarities into a pairwise (Fan et al., 2023) or rankwise (Liu et al., 2023) loss objective. However, due to the high costs associated with label annotation, unsupervised approaches (Tu et al., 2023a; Zeng et al., 2023; Cao et al., 2022) tend to be more appreciated in real-world applications. Unsuper-

vised cross-modal hashing approaches typically begin by reconstructing the similarity structure between different modalities, which subsequently provides guidance during the learning process of the hashing model.

Despite the notable advancements, prevailing unsupervised cross-modal hashing approaches (Tu et al., 2023a; Zeng et al., 2023; Cao et al., 2022) still suffer from two major limitations: (1) *Biased Similarity Structure.* These approaches typically employ natural distances (e.g., cosine distance) to generate the semantic similarity structure. Since deep features with the same semantics should be from a high-dimensional distribution, utilizing cosine distance would be imprecise at the distribution boundaries, which generates noisy supervision, and serious error accumulation during subsequent optimization procedures. (2) *Distribution Discrepancy Across Modalities.* Given the inherent heterogeneity, different networks are utilized to generate binary codes, which could obey distinct distributions in the Hamming space. This distribution discrepancy inherently undermines the effectiveness of cross-modal retrieval and brings suboptimal results.

To handle these limitations, in this work, we propose a new hashing approach named Distribution-based Structure Mining with Consistency Learning (DEMO) for efficient image-text matching. The core of our DEMO revolves around exploring the latent semantic distribution of each sample using multiple random augmentations. In particular, given that data augmentation generally maintains the semantics (Dai et al., 2023), we consider each augmented view of an image as samples drawn from its intrinsic semantic distribution. Then a non-parametric metric (i.e., energy distance (Rizzo and Székely, 2016)) is incorporated to precisely measure the distribution divergence (see Figure 1), thereby reconstructing a robust and accurate semantic structure. The subsequent optimization of the hashing network is achieved by preserving this semantic structure in the Hamming space. Furthermore, to diminish the distribution shift across modalities, we generate cross-modal retrieval distributions given both queries of images and texts and their consistency are promoted in a self-supervised manner. In addition, we employ a sharpening operation to refine retrieval results by emphasizing points with high degrees of similarity. We conduct comprehensive experiments on three benchmark image-text matching datasets, and the results show that our DEMO outperforms a wide range of competing methods. In brief, the main contribution of this paper can be summarized as follows:

- *Innovative Perspective.* We explore the latent semantics distribution and adopt the distribution divergence to construct a robust and accurate semantics structure to guide unsupervised cross-modal hashing through a statistical perspective.
- *Coherent Framework.* DEMO optimizes the modality-specific hashing networks by preserving the semantics structure in the Hamming space. Additionally, DEMO promotes consistency between cross-modal retrieval distributions, resulting in modality-invariant binary descriptors.
- *Outstanding Performance.* Comprehensive experiments reveal that DEMO outperforms various state-of-the-art hashing-based methods on image-text matching benchmark datasets.

2 Related Work

2.1 Image-text Matching

Image-text matching is a fundamental problem which can bridge computer vision and natural language processing (Sun et al., 2023; Zhang et al., 2022b; Huang et al., 2022; Liu and Ye, 2019; Hu et al., 2023b). Recent approaches can be divided into local-level and global-level approaches. Local-level matching approaches (Liu et al., 2019a; Chen et al., 2020; Zhang et al., 2022a; Dong et al., 2022; Fu et al., 2023; Bhattacharyya et al., 2022) take the input of image-text pairs to learn fine-grained relationships, such as region-word alignments. In contrast, global-level matching approaches (Tu et al., 2021; Lu et al., 2022; Radford et al., 2019; Jia et al., 2021) map both images and texts into a shared space and then calculate their latent embedding similarities. To enhance the efficiency of image-text matching, this paper proposes a novel hashing method termed DEMO for binary descriptors, which enables the calculation of similarity using the efficient “XOR" operation (Gu et al., 2022).

2.2 Unsupervised Cross-modal Hashing

Cross-modal hashing (Hu et al., 2023a; Sun et al., 2022a; Tu et al., 2023a; Zeng et al., 2023; Cao et al., 2022) attempts to project samples from various modalities into a shared binary space in which samples with similar semantics should be close. Early efforts typically investigate hand-crafted features for hash codes (Song et al., 2013; Zhou et al.,

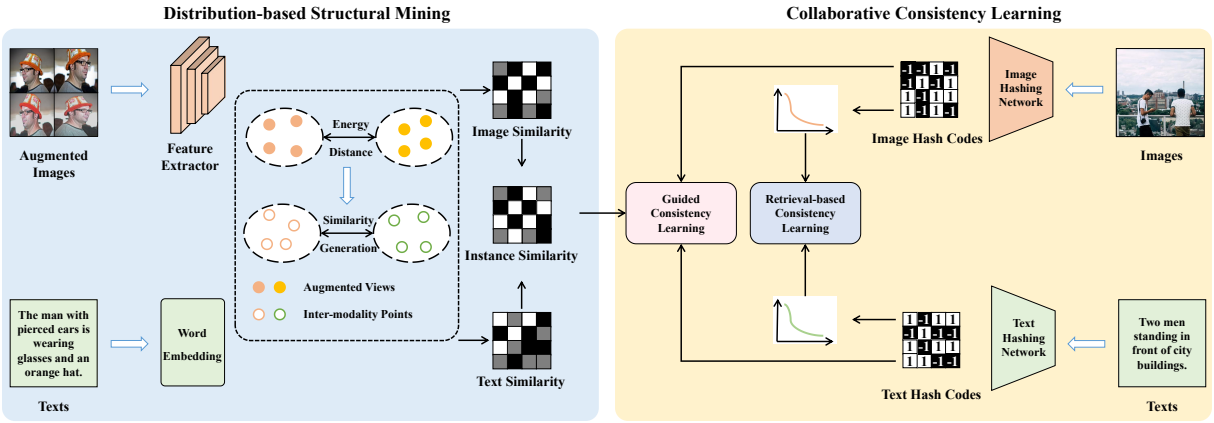

Figure 2: An overview of our proposed DEMO. DEMO first calculates the energy distance between latent semantics distributions to generate an instance similarity matrix. Then DEMO simultaneously optimizes the modality-specific hashing networks by preserving the similarity with guided consistency learning. In addition, retrieval distributions using both image and text queries are encouraged to be consistent to obtain modality-invariant binary codes.

2014), which are typically not discriminative to preserve similarity structure. Recently, various deep unsupervised cross-modal hashing approaches have been developed (Gao et al., 2023; Mikriukov et al., 2022), which typically reconstruct the similarity structure based on cosine distances to optimize the process of learning to hash. However, these methods are incapable of producing precise supervision signals, resulting in inferior binary hash codes. Towards this end, we investigate the latent distribution for each sample and adopt the distribution divergence for enhanced semantic structures.

3 The Proposed Approach

3.1 Problem Definition and Overview

Problem Definition. We begin with notations and the formal definition. $X = \{\boldsymbol{x}_i\}_{i=1}^{N}$ represents a dataset consisting of N images and $Y = \{\boldsymbol{y}_i\}_{i=1}^{N}$ represent a dataset with N texts. Each $\boldsymbol{y}_i$ is associated with text embeddings $\boldsymbol{t}_i$. The objective is to map these samples into a shared Hamming space. We expect the matched samples between two modalities to be encoded into similar binary codes with small Hamming distances. This mapping can guarantee effective and efficient image-text matching.

Framework Overview. This work proposes a new cross-modal hashing approach named DEMO for efficient image-text matching. As depicted in Figure 2, DEMO first employs a pre-trained feature extractor $F^v(\cdot)$ for images, which removes the last layer of a well-known classification neural network (Tu et al., 2023a). We also extract text embeddings using an embedding layer $F^t(\cdot)$. Then, two feed-forward networks (FFNs), $\phi^v(\cdot)$ and $\phi^t(\cdot)$ are adopted to map features of images and texts into binary codes, respectively. Formally, we have:

$$\boldsymbol{b}_i^v = sgn(\phi^v(F^v(\boldsymbol{x}_i))), \quad (1)$$

$$\boldsymbol{b}_i^t = sgn(\phi^t(F^t(\boldsymbol{y}_i))), \quad (2)$$

where $sgn(\cdot)$ is the sign function. Our DEMO mainly consists of two modules, (1) *Distribution-based Structural Mining.* We delve into the inherent semantics distribution behind each image using random data augmentation and utilize the distribution divergence to reconstruct an accurate semantic structure, which would effectively guide the optimization of hashing networks. (2) *Collaborative Consistency Learning.* On the one hand, we maximize the consistency of similarity scores between the semantic structure and hash codes. On the other hand, we produce cross-modal retrieval distributions given texts and images and encourage their consistency from opposing directions.

3.2 Distribution-based Structural Mining

A pivotal challenge in unsupervised cross-modal hashing lies in the lack of supervised information. Previous approaches (Yu et al., 2021; Tu et al., 2023b; Hu et al., 2023a) typically reconstruct the similarity structure as supervision by measuring the natural distance (e.g., cosine distance) of deep features. However, the reconstructed structure may introduce noise, leading to significant error accumulation throughout subsequent optimization stages. In particular, we observe that deep features with the same semantics should originate from a high-dimensional distribution (Sun et al., 2022b; Yang

et al., 2018; Tu et al., 2020), and the natural distance could be inaccurate at the boundaries of latent distributions. Consequently, we aim to measure the distribution divergence for effective structural mining, ensuring high-quality hash codes for efficient image-text matching.

Firstly, we take the image dataset as an example of similarity structure mining. In particular, the random vector of each example $\boldsymbol{x}_i$ in the embedding space is represented as $\boldsymbol{\xi}_i$ with the cumulative distribution function G_i. Then, the distribution divergence between the underlying semantic distributions of $\boldsymbol{x}_i$ and $\boldsymbol{x}_j$ is formulated as:

$$d(\boldsymbol{x}_i, \boldsymbol{x}_j) = \psi(G_i, G_j), \tag{3}$$

in which ψ is a given metric. However, due to immense complexity, parameterizing the high-dimensional distributions remains a considerable challenge. Therefore, classic methods such as KL divergence and JS divergence are not inappropriate here. Towards this end, we turn to a non-parametrized metric, i.e., energy distance (Székely and Rizzo, 2013) . This metric enables modeling of the distribution divergence without the derivation of specific distribution functions, providing an effective alternative for handling the challenges in the high-dimensional space.

Definition 1 *(Energy Distance). Given two independent random vectors $\boldsymbol{\xi}$ and $\boldsymbol{\zeta}$ with the cumulative distribution functions $G_{\boldsymbol{\xi}}$ and $G_{\boldsymbol{\zeta}}$, respectively. We construct two independent copies $\boldsymbol{\xi}'$ and $\boldsymbol{\zeta}'$ from these cumulative distribution functions. Then, the energy distance is defined as:*

$$D^2(G_{\boldsymbol{\xi}}, G_{\boldsymbol{\zeta}}) = 2\mathrm{E}\rho(\xi, \zeta) - \mathrm{E}\rho\left(\xi, \xi'\right) - \mathrm{E}\rho\left(\zeta, \zeta'\right), \tag{4}$$

where $\rho(\cdot, \cdot)$ is a pointwise distance metric such as cosine distance.

When random variables are real-valued, we can rewrite Eqn. 4 into:

$$D^2(G_{\boldsymbol{\xi}}, G_{\boldsymbol{\zeta}}) = \int_{-\infty}^{\infty} \rho^2(G_{\boldsymbol{\xi}}(x), G_{\boldsymbol{\zeta}}(x)) dx. \tag{5}$$

From Eqn. 5, we can infer that $D^2(G_{\boldsymbol{\xi}}, G_{\boldsymbol{\zeta}}) \geq 0$ and the equality holds when two distributions are identical. In non-parametric test, we generate statistical samples $\{\boldsymbol{u}_1, \cdots, \boldsymbol{u}_M\}$ and $\{\boldsymbol{v}_1, \cdots, \boldsymbol{v}_M\}$ from $G_{\boldsymbol{\xi}}$ and $G_{\boldsymbol{\zeta}}$, respectively. Then, we explore the statistics for the null hypothesis, i.e., $G_{\boldsymbol{\xi}} = G_{\boldsymbol{\zeta}}$ by calculating the following averages:

$$\begin{aligned} A &= \frac{1}{M^2} \sum_{m=1}^{M} \sum_{m'=1}^{M} \rho\left(\boldsymbol{u}_m, \boldsymbol{v}_{m'}\right) \\ B &= \frac{1}{M^2} \sum_{m=1}^{M} \sum_{m'=1}^{M} \rho\left(\boldsymbol{u}_m, \boldsymbol{u}_{m'}\right) \\ C &= \frac{1}{M^2} \sum_{m=1}^{M} \sum_{m'=1}^{M} \rho\left(\boldsymbol{v}_m, \boldsymbol{v}_{m'}\right) \end{aligned}. \tag{6}$$

The statistics (Székely and Rizzo, 2013) can be formulated as:

$$\mathcal{E}\left(\{\boldsymbol{u}_m\}_{m=1}^{M}, \{\boldsymbol{v}_m\}_{m=1}^{M}\right) = 2A - B - C, \tag{7}$$

where $\mathcal{E}(\cdot, \cdot)$ denotes energy distance. A large energy distance would reject the null hypothesis, indicating different distribution functions. Since the labels of unlabeled samples cannot acquired, we turn to data augmentation (Sun et al., 2022b; Luo et al., 2021b; He et al., 2020). In particular, we view the augmented view of each image $\boldsymbol{x}_i$ as the samples from its underlying semantic distribution G_i since data augmentation would typically retain the semantics. Therefore, the distribution divergence between $\boldsymbol{x}_i$ and $\boldsymbol{x}_j$ can be estimated as:

$$d\left(\boldsymbol{x}_i, \boldsymbol{x}_j\right) = \mathcal{E}\left(\{\boldsymbol{z'}_{im}\}_{m=1}^{M}, \{\boldsymbol{z'}_{jm}\}_{m=1}^{M}\right), \tag{8}$$

where $\boldsymbol{z'}_{im} = F^v(\boldsymbol{x}'_{im})$ is the deep feature of the augmented view $\boldsymbol{x}'_{im}$. In our implementation, we use cosine distance for $\rho(\cdot, \cdot)$. Finally, we set a threshold τ to reject the null hypothesis and thus the pair with the distance below the threshold is considered as positive. Moreover, we notice there are still fine-grained differences among dissimilar pairs. Towards this end, we introduce image and text similarities in the semantics structure:

$$S_{ij}^v = \rho(\sum_{m=1}^{M} \boldsymbol{z'}_{im}, \sum_{m=1}^{M} \boldsymbol{z'}_{jm}), \tag{9}$$

$$S_{ij}^t = \rho(\boldsymbol{t}_i, \boldsymbol{t}_j), \tag{10}$$

where $\boldsymbol{t}_i$ is the text embedding of $\boldsymbol{y}_i$. We combine S_{ij}^v and S_{ij}^t to depict the similarities when $d\left(\boldsymbol{x}_i, \boldsymbol{x}_j\right) \geq \tau$. In formulation, we construct the instance similarity structure as follows:

$$S_{ij} = \begin{cases} 1, & d\left(\boldsymbol{x}_i, \boldsymbol{x}_j\right) < \tau \\ \alpha S_{ij}^v + (1-\alpha) S_{ij}^t, & otherwise, \end{cases} \tag{11}$$

where α is a coefficient to balance two similarities (Tu et al., 2023b, 2020; Ma et al., 2022). It can be noticed that when $M = 1$, our distribution divergence would be degraded to the fundamental cosine distance. The incorporation of multiple augmented views makes it more robust against random attacks. Moreover, it alleviates biases for examples at the boundary of latent semantic distributions, ensuring the accuracy of structural mining.

3.3 Optimization with Collaborative Consistency Learning

In this part, we jointly optimize the image and text hashing networks using collaborative consistency learning which mainly includes guided consistency learning and retrieval-based consistency learning.

Guided Consistency Learning. After constructing the similarity structure (Luo et al., 2021b; Yang et al., 2018; Tu et al., 2020), we aim to preserve this in produced hash codes. In particular, we generate hash codes for both images and texts and then produce their similarities, which would be consistent with the reconstructed structure. Formally, we have:

$$\mathcal{L}_{gui} = \sum_{i,j=1}^{N} \sum_{e_1,e_2 \in \{v,t\}} ||\rho(\boldsymbol{b}_i^{e_1}, \boldsymbol{b}_j^{e_2}) - S_{ij}||^2, \tag{12}$$

where e_1 and e_2 indicate the selected modalities. Therefore, image-image, text-text, and image-text consistency are jointly considered and mapped to the similarity structure under the guidance.

Retrieval-based Consistency Learning. To further reduce the potential distribution discrepancy between the two modalities (Lu et al., 2022; Wei et al., 2021), we simulate the cross-modal retrieval procedure in different directions and enforce the consistency between the retrieval results. In formulation, given a batch, the probability distribution corresponding to text-to-image retrieval is written as:

$$\boldsymbol{p}_i^{T2I} = [\rho(\boldsymbol{b}_i^t, \boldsymbol{b}_1^v), \cdots, \rho(\boldsymbol{b}_i^t, \boldsymbol{b}_B^v)], \tag{13}$$

where B denotes the batch size. Similarly, the probability distribution corresponding to image-to-text retrieval is:

$$\boldsymbol{p}_i^{I2T} = [\rho(\boldsymbol{b}_i^v, \boldsymbol{b}_1^t), \cdots, \rho(\boldsymbol{b}_i^v, \boldsymbol{b}_B^t)]. \tag{14}$$

Then, we utilize the sharpening operator (Xie et al., 2016; Assran et al., 2021; Wang et al., 2023) to refine the soft distributions with:

$$\delta(\boldsymbol{p})_b = \frac{[\boldsymbol{p}]_b^{1/T}}{\sum_{b'=1}^{B}[\boldsymbol{p}]_{b'}^{1/T}}, b = 1, \cdots, B. \tag{15}$$

Our sharpening operation is capable of enhancing the purification of the retrieval results and emphasizing the samples with high similarities. Finally, we conduct consistency learning across two directions in a self-supervised fashion using:

$$\begin{aligned}\mathcal{L}_{ret} = \sum_{i=1}^{B} (&KL(\delta(\boldsymbol{p}_i^{I2T})||\boldsymbol{p}^{T2I}) \\ &+ KL(\delta(\boldsymbol{p}_i^{T2I})||\boldsymbol{p}^{I2T})),\end{aligned} \tag{16}$$

where $KL(\cdot||\cdot)$ returns the KL divergence of two distributions and T is a temperature coefficient that controls the sharp degree set to 0.25 empirically.

Besides, we leverage the co-occurrence knowledge embedded in the dataset, which enforces binary codes of images and texts with identical objects to be close. In particular, we have:

$$\mathcal{L}_{co} = \sum_{i=1}^{N} ||\rho(\boldsymbol{b}_i^v, \boldsymbol{b}_j^t) - \gamma||^2, \tag{17}$$

where γ is set to 1.5 empirically (Tu et al., 2023a) to emphasize this accurate embedding knowledge.

In a nutshell, we summarize our framework by combining all these objectives:

$$\mathcal{L} = \mathcal{L}_{gui} + \mathcal{L}_{ret} + \mathcal{L}_{co}. \tag{18}$$

However, directly minimizing Eqn. 18 is infeasible since $sgn(\cdot)$ is not differentiable at zero and its derivative is zero at the other point. To tackle this problem, we replace $sgn(\cdot)$ with $tanh(\cdot)$ during optimization, which results in approximate hash codes $\hat{\boldsymbol{b}}_i^v = tanh(\phi^v(F^v(\boldsymbol{x}_i)))$ and $\hat{\boldsymbol{b}}_i^v = tanh(\phi^t(F^t(\boldsymbol{y}_i)))$. We summarize the whole training algorithm of DEMO in Algorithm 1.

3.4 Model Inference

After the optimization procedure, we would feed each sample into the hashing network for a binary descriptor. Then, given each query text y_q (image x_q) with a binary code $\boldsymbol{b}_q^t$ ($\boldsymbol{b}_q^v$), we rank the Hamming distances between $\boldsymbol{b}_q^t$ ($\boldsymbol{b}_q^v$) and $\{\boldsymbol{b}_i^v\}_{i=1}^N$ ($\{\boldsymbol{b}_i^t\}_{i=1}^N$), which can produce the nearest examples efficiently. In practice, we consider the returned samples as candidates and conduct fine-grained matching for the final results (Tu et al., 2021).

4 Experiment

4.1 Experimental Settings

Datasets and Evaluation Metrics. To assess the performance of our DEMO, we employ three public and widely-used benchmark datasets to conduct experiments, including MIRFlickr-25K, NUS-WIDE, and MS-COCO. *MIRFlickr-25K* comprises

Table 1: MAP scores comparison with code length varying from 16 to 128 bits. I2T refers to the image-to-text matching task, and T2I signifies the text-to-image task. The highest scores are shown in **boldface**.

25,000 pairs of image-text data, and each sample is manually annotated with multiple labels from a set of 24 distinct classes. We remove samples lacking class information, resulting in 20,015 samples for our experiments. We divide these samples into two sets: a query database containing 2,000 paired samples and a retrieval database containing the remaining samples. We employ bag-of-words (BoW) vectors with a dimension of 1,386 to represent the text samples. *NUS-WIDE* consists of 269,498 paired image-text samples and each sample is assigned to a multilabel category from 81 categories. We select 186,557 samples from the top 10 frequent classes for our experiments. These samples are split into a query database with 2,100 image-text pairs and a retrieval database with the remaining samples. Similarly, we employ 1,000-dimensional BoW vectors to represent the text samples. *MS-COCO* is a benchmark dataset which consists of 123,287 images. Each image is associated with 5 annotations from 80 categories. After deleting the samples without label annotations, 122,218 pairs remain during the experiment. We choose 5,000 paired image-text samples randomly as the query database and the remaining pairs are left as the retrieval database. Correspondingly, the text samples are represented by 2026-dimensional BoW vectors.

We evaluate the matching performance based on two protocols: the Hamming ranking protocol and the hash lookup protocol. The former is evaluated by the widely used metric Mean Average Precision (MAP) score, and the latter is evaluated by three types of curves: Precision-Recision curve, Precision-top N curve, and Recall-top N curve. For a fair comparison, we report MAP@All scores as default.

Baselines and Implementation Details. We employ 10 state-of-the-art hashing-based image-text matching approaches as baseline methods, including three supervised cross-modal hashing methods (MTFH (Liu et al., 2019b), FOMH (Lu et al., 2019), DCH (Xu et al., 2017)), four shallow unsupervised cross-modal hashing methods (CVH (Kumar and Udupa, 2011), LSSH (Zhou et al., 2014), CMFH (Ding et al., 2016), FSH (Liu et al., 2017)), and three deep unsupervised cross-modal hashing methods (DGCPN (Yu et al., 2021), UCHSTM (Tu et al., 2023b), UCCH (Hu et al., 2023a)). We randomly select 5,000/10,000/all samples from the retrieval database as the training samples for supervised/deep unsupervised/shallow unsupervised cross-modal hashing methods. For a fair comparison, we follow previous works (Tu et al., 2023b; Hu et al., 2023a) and reimplement the deep unsupervised methods, utilizing VGG-19 pre-trained on the ImageNet dataset and a two-layer MLP as the backbone of the image hashing network and text hashing network, respectively. We adopt the SGD

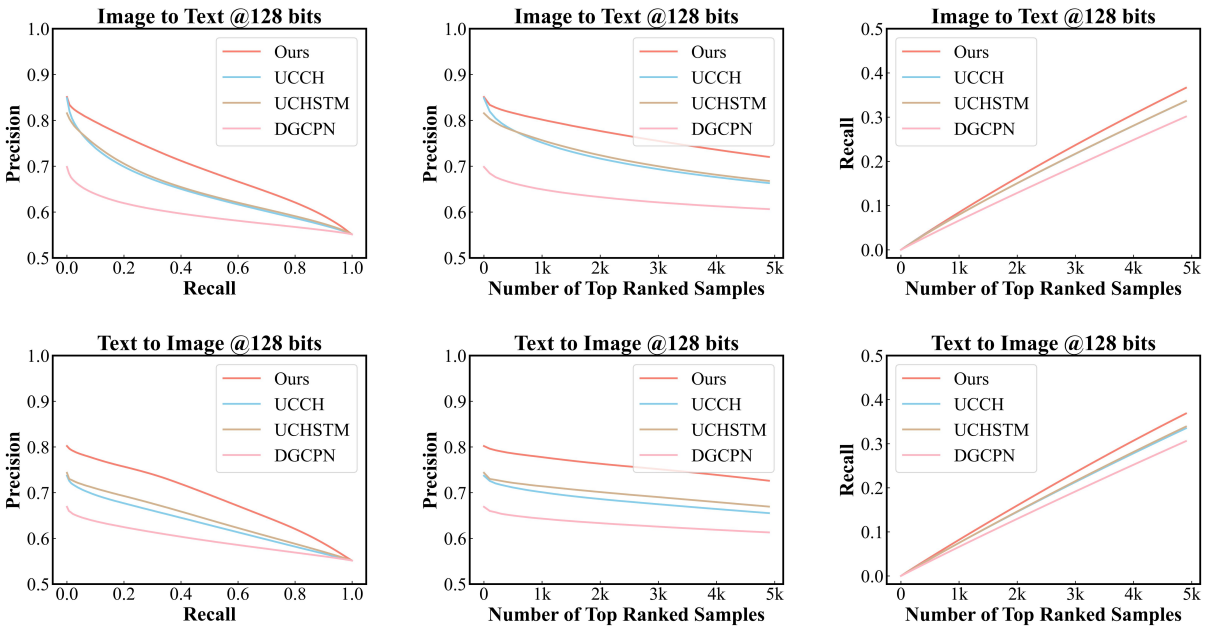

Figure 3: The Precision-Recall curve, Precision-top N curve, and Recall-top N curve with 128 bits on MIRFlickr-25K. The first row plots image-to-text results, and the second row plots text-to-image results.

algorithm with a learning rate of 1e-3 to optimize the networks. The batch size is set to 128. More hyper-parameters are set according to Section 4.4.

4.2 Main Results

Hamming Ranking Protocol. We showcase the MAP scores of all compared baseline methods and our DEMO in Table 1. From these results, the following observations can be attained: *First*, deep unsupervised cross-modal hashing methods outperform shallow unsupervised cross-modal hashing approaches even with insufficient amounts of training data, indicating the superiority of deep neural networks in generating high-quality and modality-invariant hash codes. *Next*, supervised methods excel due to their reliance on expensive labeled data. However, when labeled data is scarce, these methods fall short compared to deep unsupervised approaches. Consequently, deep unsupervised cross-modal hashing emerges as the fundamental technique for image-text matching in the presence of vast amounts of unlabeled multimodal data. *Furthermore*, DEMO outperforms all the compared state-of-the-art hashing-based image-text matching methods, revealing the effectiveness of our proposed distribution-based structural mining and collaborative consistency learning. Additionally, our approach exhibits consistent and significant improvements across three datasets, highlighting the success of addressing previously overlooked distribution divergence combined with collaborative consistency. The proposed components can enhance the performance of unsupervised hashing-based image-text matching in a robust manner.

Hash Lookup Protocol. We also incorporate the hash lookup protocol to generate Precision-Recall, Precision-top N, and Recall-top N curves for our DEMO and three reproduced deep unsupervised baselines using 128 bits on MirFlickr-25K, as illustrated in Figure 3. Due to space limitations, curves for other code lengths can be seen in Section D. The Precision-Recall curve represents the relationship between the varying precision and recall scores. The Precision-top N and Recall-top N curves depict precision and recall values as the retrieval numbers vary from 1 to $5,000$ with a step size of 100. In brief, for these three types of curves, the higher-performing method's curve is usually above the curves of other methods. These curves clearly illustrate that our DEMO consistently outperforms the other baselines, underscoring its superiority. The hash lookup results are consistent with the Hamming ranking results, further validating the exceptional performance and robustness of our DEMO in image-text matching.

4.3 Ablation Study

In Table 2, we investigate the contributions of each proposed component with 16 bits on three datasets. *Firstly*, we remove the distribution-based struc-

Task	Method	MIRF-25K	NUS-WIDE	MS-COCO
I2T	DEMO w/o D	0.698	0.627	0.560
	DEMO w/o R	0.705	0.632	0.565
	DEMO w/o S	0.712	0.636	0.571
	Full Model	**0.718**	**0.646**	**0.575**
T2I	DEMO w/o D	0.696	0.630	0.559
	DEMO w/o R	0.695	0.634	0.564
	DEMO w/o S	0.699	0.642	0.569
	Full Model	**0.708**	**0.654**	**0.572**

Table 2: Ablation on each proposed component. The highest MAP scores are shown in **boldface**.

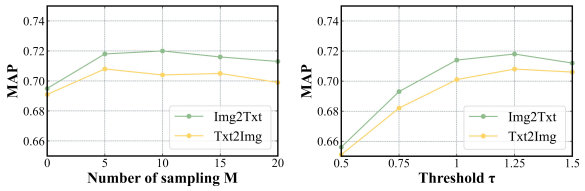

Figure 4: Sensitivity analysis of sampling times M and threshold τ with 16 bits on MIRFlickr-25K.

tural mining process and replace it with sample-based structural mining. The comparison between DEMO w/o D in the first row and the full model in the last row highlights the significant improvement achieved by our distribution-based objective. *Next*, we assess the significance of the retrieval-based consistency learning by removing it. Without this module, the retrieved distributions given images and texts as queries are not encouraged to be consistent. The performance degradation observed in DEMO w/o R in the second row emphasizes the effectiveness of this component. *Moreover*, we conduct an experiment where we remove only the proposed sharpening operation from the retrieval-based consistency learning module. The results of DEMO w/o S in the third row reveal slight differences compared to the full model, underscoring the importance of the sharpening operation. Furthermore, the performance of DEMO w/o S falls between DEMO w/o R and the full model, which is reasonable since DEMO w/o S removes only parts of the retrieval-based consistency learning module while still retaining the ability to promote consistency between the retrieved distributions. *Finally*, we evaluate the full model which incorporates all the components. Results in the last row exhibit the best performance across all scenarios. These experiments successfully verify the significance of each proposed component in DEMO.

4.4 Sensitivity Analysis

To assess the impact of the hyper-parameter M and τ, Figure 4 plots the MAP scores with respect to

Method	LSSH	UGACH	UCCH	DEMO
Inference Time	7.78s	26.59s	0.41s	0.41s

Table 3: Comparison with other methods on the inference speed.

M ranging from 0 to 20, and τ ranging from 0.5 to 1.5. From the results, we can observe that increasing M from 0 to 5 yields a significant performance improvement, but further increasing M from 5 to 20 does not lead to any noticeable enhancement. This phenomenon demonstrates that our DEMO is not sensitive to M within the range of $[5, 20]$. Therefore, M is fixed at 5 and we proceed to investigate the threshold τ, varying from 0.5 to 1.5. The threshold τ plays a crucial role as it controls the percentage of the image-text pairs categorized as positive samples, thereby influencing the quality of the generated similarity matrix. A large value of τ will mistakenly consider numerous incorrect image-text pairs as the matching ones, while a small value of τ will classify many matching image-text pairs as non-matching pairs. From the results, it can be found that 1.25 is the most suitable for the threshold τ. Consequently, we obtain the optimal value of $M = 5$ and $\tau = 1.25$, respectively.

4.5 Efficiency Analysis

We make experimental verification on the inference speed. In particular, we compare our DEMO with state-of-the-art hashing-based image-text matching approaches with 128 bits on MIRFlickr-25K. As shown in Table 3, our DEMO can achieve much higher efficiency compared with LSSH (Zhou et al., 2014) and UGACH (Zhang et al., 2018). Even though the inference time of UCCH (Hu et al., 2023a) and our DEMO is the same, our retrieval performance is much better. In summary, our DEMO is superior to these baselines taking into both efficiency and effectiveness.

4.6 Visualization

We present the t-SNE (van der Maaten and Hinton, 2008) visualization of hash codes from two different modalities generated by four methods with 128 bits on MirFlickr-25K in Figure 5. The results of the comparison with the other three approaches reveal that our DEMO demonstrates a significantly higher degree of similarity and overlap between the image and text modalities. This observation serves as a strong indication that combined with collaborative consistency learning, distribution-based struc-

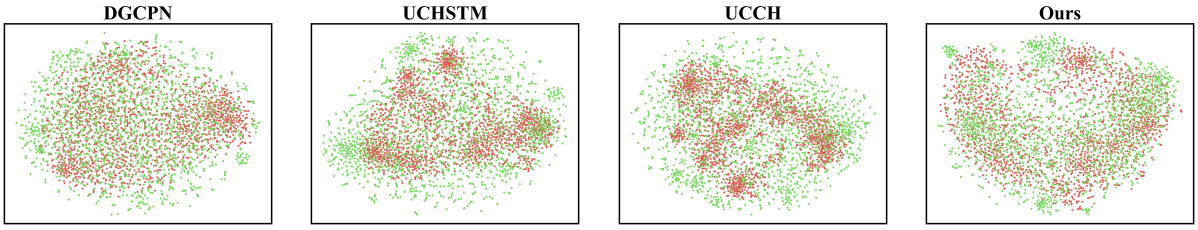

Figure 5: The t-SNE visualization with 128 bits on the MIRFlickr-25K. The image modality is colored red, and the text modality is colored green. The overlap degree represents the degree of modality-invariant hash codes.

tural mining is superior to sample-based structural mining. The visualization results also provide compelling evidence of the exceptional quality and modality-invariant hash codes learned by our approach.

5 Conclusion

In this paper, we investigate the problem of image-text matching and propose a novel deep unsupervised hashing-based approach termed DEMO. The crux of our DEMO is to explore the latent semantic distributions of each sample for effective semantics structure mining. Specifically, we characterize each image with multiple augmented views, which are regarded as samples from its intrinsic semantic distribution. Then, a non-parametric distribution divergence is employed to ensure a robust and accurate similarity structure in the process of similarity generation, which serves as guidance for the optimization. Extensive experimental results across multiple datasets substantiate the efficacy of DEMO.

6 Limitation

Although our DEMO achieves promising results, it still has some limitations. First, there could be different complicated scenarios in real-world applications such as data contamination and domain shift. We would extend our DEMO to more generalization scenarios in our future works. Second, our unsupervised hashing approach DEMO targets at coarse-level retrieval. How to improve unsupervised cross-modal hashing for fine-grained cross-modal retrieval remains an open problem.

A Algorithm

Algorithm 1 Training Algorithm of DEMO

Require: Image dataset X; text dataset Y; number of augmented views M, threshold τ.
Ensure: Parameters of the hashing network.

Generate M augmented views for every $\boldsymbol{x}_i$;
Calculate the distribution divergence using Eqn. 8;
Generate the instance similarity structure using Eqn. 11;
repeat
  Sample a mini-batch randomly;
  Output approximate binary codes for both images and texts;
  Generate cross-modal retrieval results using Eqn. 13 and Eqn. 14;
  Calculate the whole loss using Eqn. 18;
  Update the hashing network by backpropagation;
until convergence

B Data Augmentation Strategy

We leverage the randomness of data augmentations to convert sample-based structural mining to distribution-based structural mining. The detailed data augmentation strategy is illustrated below. First, we resize the image to 256×256 and randomly crop a size of 224×224. Then we employ strategies such as Random Horizontal Flip, Random Color Jitter with $p = 0.7$, Random Grayscale with $p = 0.2$, and Gaussian Blur with $kernelsize = 3$. Finally, we normalize the data with pre-computed mean and standard values. With this augmentation strategy, the intrinsic semantic distribution of a data sample is established for future semantic structure mining.

C Compared Methods

Many state-of-the-art cross-modal hashing-based methods are employed for comparison, including three supervised methods, four shallow unsupervised methods, and three deep unsupervised methods. The detailed introduction of these methods is as follows:

- **CVH** (Kumar and Udupa, 2011) introduces a novel relaxation technique that transforms the learning-to-hash process into a tractable eigenvalue problem. To address this challenge, they utilize techniques such as Locality Sensitive Indexing and Canonical Correlation Analysis.

- **LSSH** (Zhou et al., 2014) extracts the latent semantics from textual samples by matrix factorization. It also leverages sparse coding techniques to capture essential image structures. Introducing an effective iterative method, it analyzes the correlation between multimodal representations, thereby narrowing the semantic gap within the latent semantic space.

- **CMFH** (Ding et al., 2016) builds robust connections via cross-modal factorization, integrating locally linear embedding to uphold the Euclidean structure. Additionally, it employs a classifier-like loss function to leverage semantic label information effectively.

- **FSH** (Liu et al., 2017) defines the similarity between different modalities by introducing a graph-based framework, and then utilizing it to learn modality-invariant hash codes.

- **MTFH** (Liu et al., 2019b) proposes to learn semantic correlations between modalities and aligns heterogeneous data to obtain modality-specific hash codes.

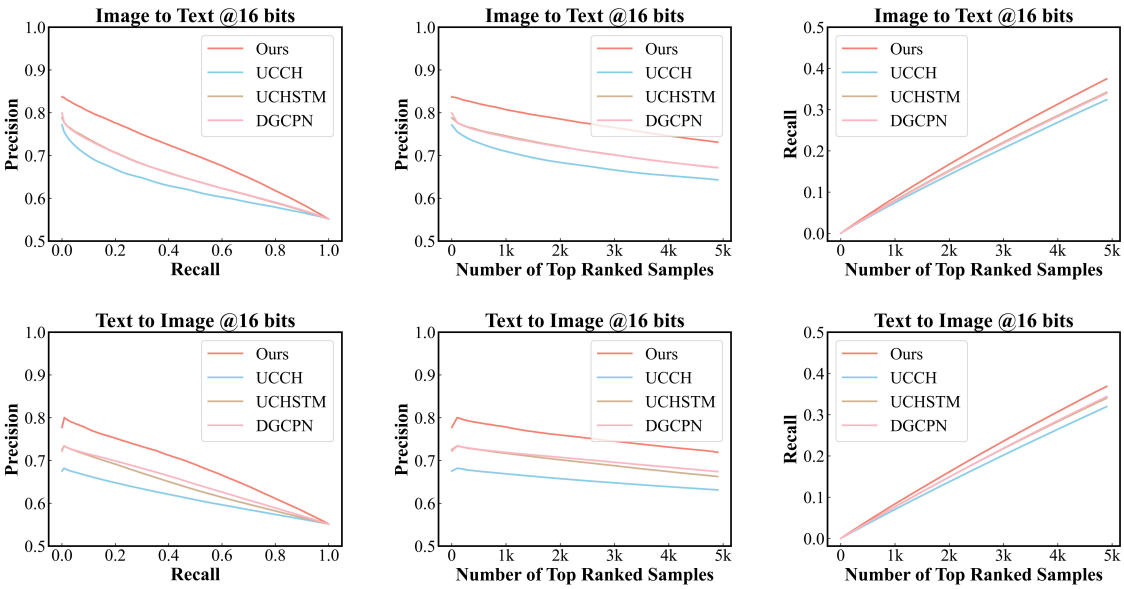

Figure 6: The Precision-Recall curve, Precision-top N curve, and Recall-top N curve with 16 bits on the MIRFlickr-25K dataset. Image-to-text results are plotted in the first row, and text-to-image results are plotted in the second row.

- **FOMH** (Lu et al., 2019) introduces a multi-modal fusion framework to fuse representations when modalities are missing, and then constructs discriminative hash codes.
- **DCH** (Xu et al., 2017) optimizes the network to get modality-specific and modality-invariant hash codes simultaneously. Moreover, it refines the hash codes by iterative training to enhance efficiency.
- **DGCPN** (Yu et al., 2021) investigates the correlations between data samples and their neighbors to improve the quality of similarity generation. It employs a hybrid optimization strategy, combining real and binary components, to minimize discrepancies between the Hamming space and the continuous latent space, thus enhancing similarity and value consistency.
- **UCHSTM** (Tu et al., 2023b) explores correlations among words in textual data points, facilitating the creation of a text modality-specific similarity matrix derived from these correlations. Furthermore, it introduces a self-redefined similarity loss to rectify inaccuracies in the instance similarity matrix, thereby improving the accuracy of similarity measurements.
- **UCCH** (Hu et al., 2023a) introduces contrastive learning, aiming to align various modalities with unified binary representations. It emphasizes leveraging discrimination from all pairs rather than solely focusing on the hardest negative pairs.

D Detailed Hash Lookup Protocol

We showcase the hash lookup results on MIRFlickr-25K with varying code lengths in Figure 6, Figure 7, and Figure 8. From the results of the hash lookup protocol, several conclusions can be observed:

1. Firstly, from the Precision-Recall curve, we can notice the correlation between precision and recall scores. These two metrics are contradictory to each other, as an increase in one often leads to a decrease in the other. From the results in the first column, it can be found that as the recall score increases, the precision score of our DEMO consistently surpasses the other three compared baseline hashing-based image-text matching methods.
2. Secondly, the Precision-top N curve represents the correlation between the precision score and the top N number of results returned in a single retrieval process. As the number of retrieved samples increases, the precision score tends to decrease. From the results in the second column, it can be observed that as

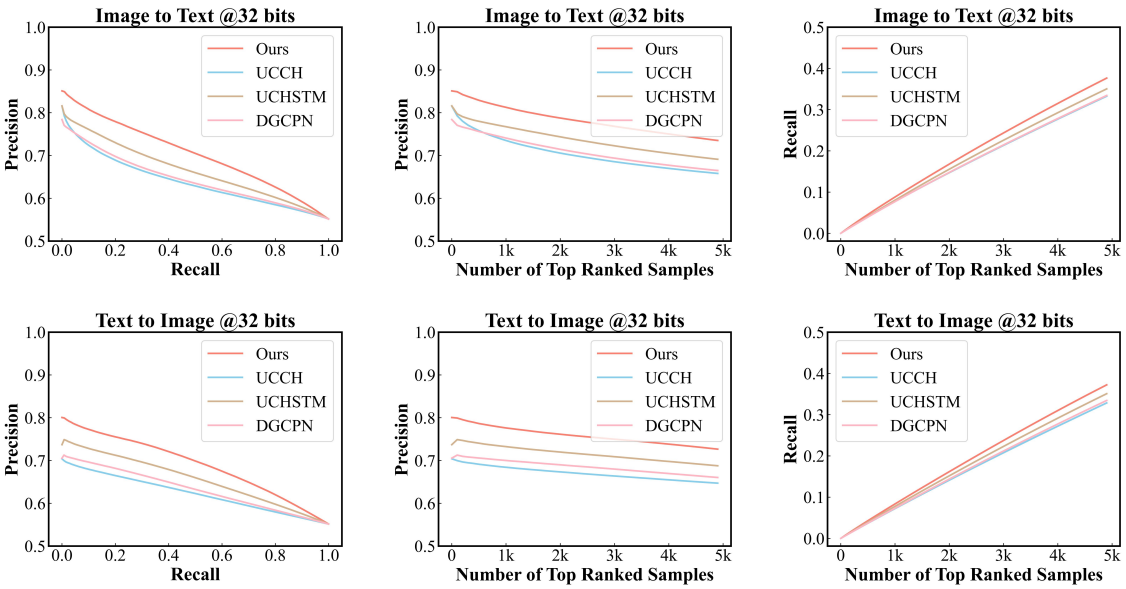

Figure 7: The Precision-Recall curve, Precision-top N curve, and Recall-top N curve with 32 bits on the MIRFlickr-25K dataset. Image-to-text results are plotted in the first row, and text-to-image results are plotted in the second row.

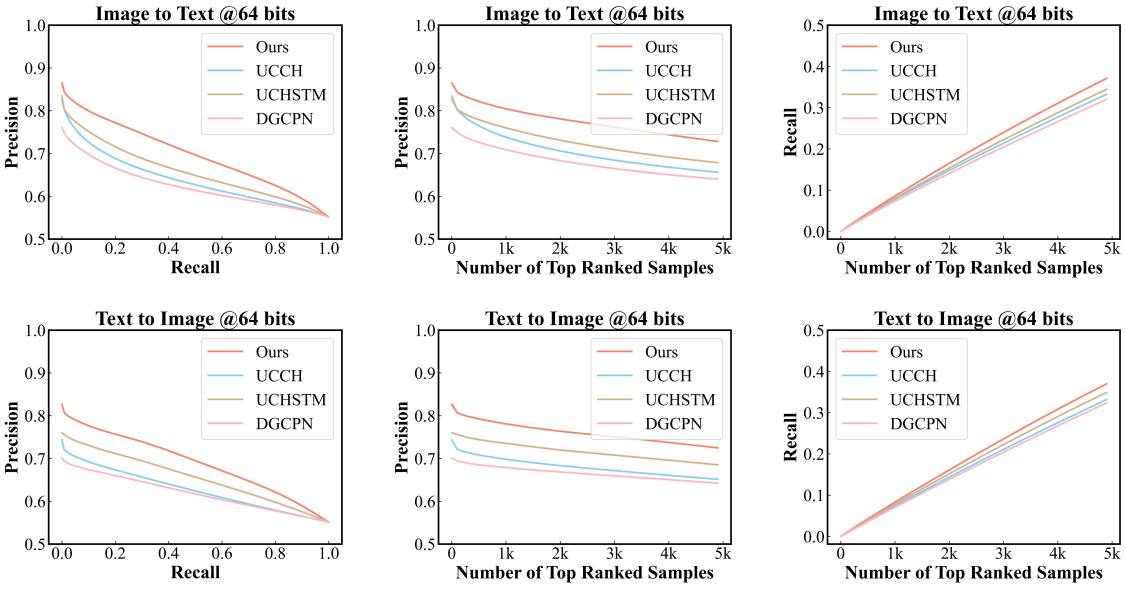

Figure 8: The Precision-Recall curve, Precision-top N curve, and Recall-top N curve with 64 bits on the MIRFlickr-25K dataset. Image-to-text results are plotted in the first row, and text-to-image results are plotted in the second row.

N increases from 1 to 5000, our DEMO consistently outperforms the other three methods.

3. Furthermore, similar to the Precision-top N curve, the Recall-top N curve represents the correlation between the recall score and the top N results returned in a single retrieval. Different from the precision score, the recall score tends to increase as N increases. From the results in the third column, it can be seen that as N increases from 1 to 5000, our curve consistently remains above the other three curves.

4. Lastly, a large number of results demonstrate the robustness of our method from different perspectives. Whether it pertains to various code lengths or different modalities, all the results indicate that we have successfully explored a more suitable similarity structure for

unsupervised cross-modal hashing from a distribution perspective. By combining collaborative consistency learning, DEMO effectively improves the image-text matching quality.

SeaEval for Multilingual Foundation Models: From Cross-Lingual Alignment to Cultural Reasoning

Abstract

We present *SeaEval*, a benchmark for multilingual foundation models. In addition to characterizing how these models understand and reason with natural language, we also investigate how well they comprehend cultural practices, nuances, and values. Alongside standard accuracy metrics, we investigate the brittleness of foundation models in the dimensions of semantics and multilinguality. Our analyses span both open-sourced and closed models, leading to empirical results across classic NLP tasks, reasoning, and cultural comprehension. Key findings indicate (1) Many models exhibit varied behavior when given paraphrased instructions. (2) Many models still suffer from exposure bias (e.g., positional bias, majority label bias). (3) For questions rooted in factual, scientific, and commonsense knowledge, consistent responses are expected across multilingual queries that are semantically equivalent. Yet, most models surprisingly demonstrate inconsistent performance on these queries. (4) Multilingually-trained models have not attained "balanced multilingual" capabilities. Our endeavors underscore the need for more generalizable semantic representations and enhanced multilingual contextualization. *SeaEval* can serve as a launchpad for more thorough investigations and evaluations for multilingual and multicultural scenarios.[1]

1 Introduction

Over the past years, there has been rapid development of large language models (LLMs), also known as a type of foundation models (FMs) (Bommasani et al., 2021), demonstrating their generalizability and adaptability across various downstream tasks (Scao et al., 2022; Chowdhery et al., 2022; OpenAI, 2023; Touvron et al., 2023b; Wang et al., 2023a). The proliferation of LLMs has raised urgent requirements for extensively evaluating their performance in various contexts, and understanding their limitations (Wei et al., 2024). Therefore, recent efforts on LLM evaluation are focusing on more challenging and human-centric tasks including complex reasoning (Clark et al., 2018; Zellers et al., 2019; Hendrycks et al., 2021a) and domain-knowledge-intensive problems (Hendrycks et al., 2021a; Lin et al., 2022a; Zhong et al., 2023; bench authors, 2023), math problems (Zhong et al., 2023), human exams (Clark et al., 2018; Zhong et al., 2023; OpenAI, 2023), and using LLMs as judges for open question answering (Zheng et al., 2023).

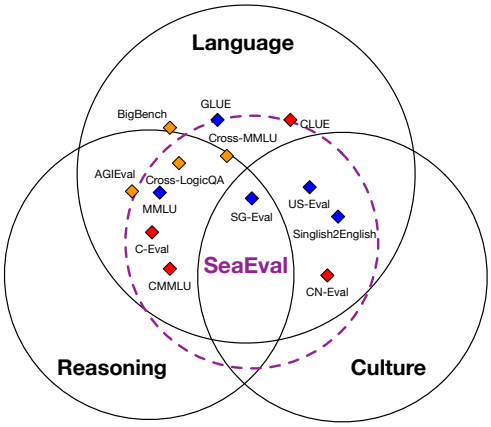

Figure 1: *SeaEval* for multilingual foundation models. English is represented by the color blue, Chinese by red, and a mix of multiple languages by yellow. *SeaEval* includes the datasets within the dotted-line circle.

Compared to other species on earth, humans are adept in using language to symbolize and encode thoughts, represent and document knowledge, and express emotions. Whether it is spoken or written form, language has become a default means for humans to conduct and communicate our reasoning process and logic (Logan, 1986; Li and Gleitman, 2002). Three variables are language, region, and culture. Our cultural behavior, rituals, and values are often embodied and represented through lan-

*: Equal contribution.

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 370–390
June 16-21, 2024 ©2024 Association for Computational Linguistics

guage (Kramsch, 1991; Ji et al., 2004). Therefore, the capabilities of language models go beyond language per se. Evaluating multilingual language model should incorporate deep cultural understanding and reasoning. To this end, we expand the current evaluation criteria to cover more linguistic and cultural contexts (Ahuja et al., 2023; Lai et al., 2023), which are under-explored in prior research.

Another important yet under-explored aspect of evaluating multilingual foundation models is their knowledge transferability in language dimensions. Multilingual foundation models are expected to demonstrate consistent performance across languages in the context of region-invariant common knowledge (Zhu et al., 2023b). Monolingual or bilingual benchmarks cannot adequately capture this aspect. Therefore, we introduce cross-lingual consistency evaluation with tailored datasets and specialized metrics.

SeaEval aims to assess the capabilities of multilingual foundation models in four dimensions: (a) Classic NLP tasks that are centered around language understanding and generation; (b) Complex reasoning; (c) Cultural understanding and reasoning; and (d) Cross-lingual knowledge transfer and contextualization. *SeaEval* encompasses a total of 28 datasets, including 6 new datasets constructed for cultural reasoning and cross-lingual consistency assessments.

Key findings from our investigations and experimental results indicate: (1) Most models show varying responses to rephrased instructions. (2) Exposure bias (e.g., positional bias, majority label bias) of label arrangements still prevails. (3) Most models give inconsistent answers when the same fact-based questions are asked in different languages. This counter-intuitive observation suggests semantic representations are not generalized in the multilingual context. (4) Multilingually-trained models fall short of achieving "balanced multilingual" proficiency. To sum up, our contributions are multifold:

- We offer fresh insights into multilingual foundation models and their evaluations.
- We introduce 7 new datasets for assessing cultural understanding and cross-lingual consistency, along with tailored metrics to fill existing gaps in model evaluation.
- We present a comprehensive evaluation benchmark derived from extensive experiments across models, tasks, datasets and metrics. This framework facilitates in-depth exploration of multilingual and multicultural tasks using foundation models.

2 Essential Properties of Multilingual Foundation Models and Benchmarks

In this section, we delve into the desired properties of multilingual foundation models and explore the ideology for crafting a comprehensive benchmark.

2.1 Multilingual Foundation Model

Multilingual foundation models should possess additional properties beyond monolingual models to effectively handle diverse languages and cultural contexts. Here are the key properties:

Multilinguality The applicability of multilingual LLMs can be elevated when they demonstrate proficiency across diverse languages, including low-resource languages and their dialects (Wu et al., 2016; Kulshreshtha et al., 2020). The advantage of multilingualism is that it allows these models to bridge the linguistic gaps that exist between different cultures and communities. Multilingual capability is not a combination of various monolingual capabilities (Ye et al., 2023); instead, it represents a holistic approach to understanding and processing languages. For example, the model should be adept at bilingual tasks such as machine translation and code-switching scenarios, which offers the advantage of preserving linguistic and cultural information.

Reasoning Capability Reasoning has long been treated as a complex yet essential capability in cognition that goes beyond fundamental language understanding (McCarthy, 2022), which can be demonstrated via extracting critical information from the text environment and drawing correct conclusions (Nilsson, 1991). The advancement of natural language reasoning has evolved from explicit and superficial reading comprehension and natural language inference (Rajpurkar et al., 2016; Wang et al., 2019; Wang and Li, 2023) to encompass implicit, complex, and specific reasoning capabilities such as multi-hop reasoning, numerical reasoning, and logical reasoning (Lai et al., 2017; Huang et al., 2019; Jiao et al., 2022). While reasoning can be challenging due to the various relations and expressions involved, which are difficult to transcribe into symbolic or formal languages, FMs are shown

This inconsistency highlights insufficient alignment across languages, leading to suboptimal multilingual contextualization and representations.

to serve as a proxy to compress abundant knowledge, and solve various tasks following human instructions with less specialization (Wei et al., 2022; Wang et al., 2023b; Jiao et al., 2023).

Cultural Understanding Language is deeply tied to culture and local norms (Pennycook, 2006). The meaning of linguistic elements can differ considerably across cultures. Cultural understanding capability can help large language models better interpret content with local communication conventions (Zampieri et al., 2020) and avoid stereotypes and biases. In the context of philosophy, language, reasoning, and culture are considered three important pillars that play a significant role in shaping people's understanding of the world (Ji et al., 2004; Kramsch, 2014) as depicted in Figure 1. They intersect and influence one another in various ways across studies in linguistics, philosophy, and psychology. Logan (1986) presents a provocative proposal that language can be used to account for cultural differences in reasoning styles. Therefore, in pursuit of advancing multilingual foundation models, it is desired that models not only acquire proficiency across languages but also gain a profound comprehension of cultural concepts influencing human behaviors. An illustrative example highlighting the impact of local cultural conventions is shown in Table 2, where a particular model must draw insights from locally sourced content to address this problem properly.

Cross-Lingual Knowledge Transfer An important advantage of encompassing multiple languages is the ability to access information from various language resources simultaneously, a characteristic that is also desired in multilingual foundation models. An effective cross-lingual knowledge transfer method can significantly enhance model capabilities across all languages, as they mutually reinforce each other. Additionally, world knowledge is typically dispersed in various languages and regions and may not be easily accessible in a single source, which demonstrates the need for cross-lingual knowledge transfer. On the other hand, some world knowledge should be kept consistent across different languages, such as factual, scientific, and commonsense knowledge. In Table 1, we see an illustration of the same question posed in 4 languages, revealing inconsistent answers attributed to inadequate cross-lingual alignments of multilingual foundation models. Up to 16 languages are tested to illustrate this phenomenon as depicted in Section F.

Question	*Which drink in Singapore has the highest calories?* *(A) Teh O* (B) *Teh Siew Dai* (C) *Kopi* (D) *Kopi C*
Multicultural Reasoning Steps	**Multilingual Understanding** (Hokkien) Teh = Tea (Cantonese) Siew Dai = Less Sweet/Sugar (Malay) Kopi = Coffee **Cultural/Personal Preferences** Teh = Tea + Condensed Milk + Sugar Teh O = Tea + Sugar Kopi = Coffee + Condensed Milk Kopi C = Coffee + Evaporated Milk + Sugar **Reasoning with Dietary Knowledge** Condensed milk = Sweetened = Sugar was Added Sugar = Calories Pure Tea or Coffee = Almost No Calories
Answer	(C) Kopi

Table 2: An example from SG-Eval dataset. To accomplish the task, one needs to employ reasoning that incorporates multilingual and cultural knowledge.

2.2 Multilingual Benchmarks

Motivated by the preceding discussion regarding the desired model characteristics, we introduce the targeted aspects for benchmarks:

Monolingual and Cross-lingual Capabilities The focus on monolingual tasks ensures the model's proficiency in comprehending and generating text within a single language. The cross-lingual tasks, such as machine translation and code-switch comprehension, can access the communication capabilities across different languages, reflecting a comprehensive understanding of multilingual contexts. In terms of evaluation aspects, both fundamental NLP capabilities and complex reasoning capabilities should be examined under monolingual and cross-lingual settings.

Knowledge Transfer Ability Language-related knowledge can be categorized into: 1) cultural knowledge and local norms tied to language and 2) common (universal) knowledge. Cultural knowledge refers to language-related information that is specific to a particular culture, community, or region. It includes the nuances, customs, and norms associated with language use within a specific cultural context. Common knowledge is widely applicable across languages and communities, encompassing factual, scientific, and real-world knowledge, etc (Hendrycks et al., 2021a). When designing evaluation benchmarks, it is essential to include a diverse set of language-related cultural tasks while also evaluating how effectively the universal knowledge is shared across different languages. Since such datasets are not readily accessible, this evaluation aspect is severely constrained in existing benchmarks.

Robustness and Stability The robust context modeling and stable output generation are important to ensure LLMs work as intended (functionality) when applied to real-world applications (reliability) (Haduong et al., 2023). When built on the auto-regressive framework, language models are originally trained to predict the next token given a sequence of previous ones, and their in-context learning and zero-shot inference performance depends on the prompts they receive (Ouyang et al., 2022). Consequently, minor variations of the input can possibly lead to distinct outputs with unpredictable formats. In particular, since FMs do not attain "balanced multilingual" capabilities, they are more sensitive to input variations such as multilingual and code-switch under real-world scenarios. Therefore, recognizing the models' instruction sensitivity should be a crucial aspect of the evaluation framework.

3 SeaEval

In this section, we present our *SeaEval* benchmark from task selection, data curation, to evaluation protocols. Besides the evaluation of fundamental capabilities and complex reasoning, we also include the evaluation tasks on cultural understanding and cross-lingual alignment. The datasets are summarized in Table 3.

3.1 Task Selection

Fundamental Language Capabilities The fundamental capabilities can be evaluated by a combination of classic NLP tasks of language understanding and generation. To ensure the diversity regarding both task and language, we collected 18 representative datasets from 5 languages. Previous studies (Shi et al., 2022; Ye et al., 2023) show that English-centric LLMs demonstrate certain multilingual transfer ability, where the skills learned from one source language can be readily transferred to other languages. Therefore, for discriminative tasks, we select 8 tasks from the GLUE benchmark (Wang et al., 2019), including SST-2, COLA, QQP, QNLI, MNLI, WNLI, RTE, and MRPC. Furthermore, we incorporate DREAM for English dialogue comprehension, OCNLI and C3 for Chinese comprehension, and Indo-Emotion dataset (Saputri et al., 2018; Wilie et al., 2020) to gauge emotion comprehension in Indonesian. To build a generative task basis, we include translation and summarization datasets from FLoRes, SAMSum, and DialogSum.

Complex Reasoning Classic NLP benchmarks (e.g., GLUE, SQuAD) primarily focus on text understanding rather than complex reasoning abilities aligned with intricate real-world scenarios. As language models continue to grow in size and complexity, it becomes increasingly important to assess their abilities in performing complex reasoning and problem-solving tasks that humans typically excel at (Wong et al., 2023). Therefore, here we add evaluation datasets from recent representative human-centric benchmarks, which are derived from high-standard and professional exams. We include the MMLU dataset to assess knowledge comprehension in English. To assess the reasoning capability in a multilingual setting, we include C-Eval,

Dataset	Task Description	Languages	Metrics	# of Samples
Multicultural and Multilingual Understanding

Table 3: Datasets from **SeaEval**. Language abbreviations are from ISO 639-3 standard, where Eng, Zho, Ind, Spa, Vie, Zsm, and Fil indicate English, Chinese (Mandarin), Indonesian, Spanish, Vietnamese, Malay (Malaysian), and Filipino, respectively. Examples from our newly collected datasets (▲) are shown in Table 5.

CMMLU, and ZBench, which are specifically tailored for evaluating intricate reasoning in Chinese.

Multilingual and Cultural Understanding An effective multilingual language model is trained with text corpus from diverse sources. It enables the model to acquire cultural knowledge related to languages, which is important when serving users from different cultural backgrounds. In order to assess the model's cultural comprehension abilities, we manually construct 4 datasets containing multiple-choice questions that encompass 4 distinct regions: the United States (English), Singapore (English), China (Chinese), and the Philipines (English). The corresponding datasets are US-Eval, SG-Eval, CN-Eval, PH-Eval. Unlike monolingual models, multilingual models should demonstrate a strong capability for effectively transferring common knowledge. Therefore, we introduce two datasets, Cross-MMLU and Cross-LogiQA, to evaluate this feature across 7 diverse languages: English, Chinese, Indonesian, Spanish, Vietnamese, Malay, and Filipino.

3.2 Data Curation

Considering the size of LLMs, evaluation on the full test set can incur significant computational and economic expenses. Therefore, for existing datasets on evaluating model's fundamental capability and complex reasoning, we randomly sampled a subset. The numbers are listed in Table 3, which results in over 13k samples in total.

The output formats of autoregressive language models (e.g., GPT) cannot be easily controlled for open-ended tasks, making it difficult to assess the accuracy of their predictions. Consequently, in order to quantitatively evaluate their performance, we have transformed all the discriminative datasets (e.g., emotion classification, natural language inference, dialogue comprehension) into multiple-choice questions. While, for generative tasks such as summarization and translation, we have retained the original evaluation process, as it relies on word-matching metrics and human-annotated references are readily applicable.

Cultural Reasoning There are no publicly available datasets for explicitly evaluating cultural knowledge in different regions. To effectively evaluate such knowledge, certain criteria should be met. First, the knowledge should originate directly from respective regions, distinct from widespread content. Second, it should encompass an understanding of the intricate norms of each culture under

examination. Third, certain cultural expressions can be challenging to fully convey in another language, making it preferable to retain the knowledge in its original language.

Therefore, we hired linguistic experts to construct datasets to evaluate the knowledge from three distinct regions, including the United States (US-Eval), Singapore (SG-Eval), China (CN-Eval) and the Philipines (PH-Eval). For each dataset, over 100 questions are sourced from a variety of channels, including local residencies' proposals, government websites, historical textbooks and exams, local cultural heritage materials, and pre-existing academic research datasets. CN-Eval and US-Eval also include questions carefully selected from MMLU, C-Eval and CMMLU datasets. Meanwhile, Singapore serves as an exceptional illustration, blending a harmonious fusion of diverse Southeast Asian cultures, enriched by a wealth of local content (Deterding, 2007; Liu et al., 2022). We also introduce a new dataset for Singlish to standard English translation with 546 sentences. Singlish incorporates elements of various languages, including Malay, Chinese dialects, and Tamil, and often includes unique vocabulary, grammar, and pronunciation. It has distinct local characteristics and requires a deep understanding of local practices. The samples from each dataset are illustrated in Table 5.

Cross-Lingual Consistency As shown in Table 1, for existing multilingual LLMs, the same question posed in different languages leads to inconsistent answers, which is undesired for multilingual foundation models. To qualitatively evaluate the model's capability in cross-lingual consistency, we present two datasets: Cross-MMLU and Cross-LogiQA with paralleled questions in 7 languages: English, Chinese, Indonesian, Spanish, Vietnamese, Malay, and Filipino. The selected questions are carefully curated to test common knowledge (e.g. commonsense, scientific), which is universally acceptable and transferrable between languages. Cross-MMLU and Cross-LogiQA are originated from MMLU dataset (Hendrycks et al., 2021a) and LogiQA2.0 dataset (Liu et al., 2023), respectively. To prepare questions that do not have equivalents in the target language, we utilize Google Translate first and enlist native speakers to perform proofreading and editing. This approach helps prevent translation errors and ensures accurate expressions, avoiding any potential misinterpretations.

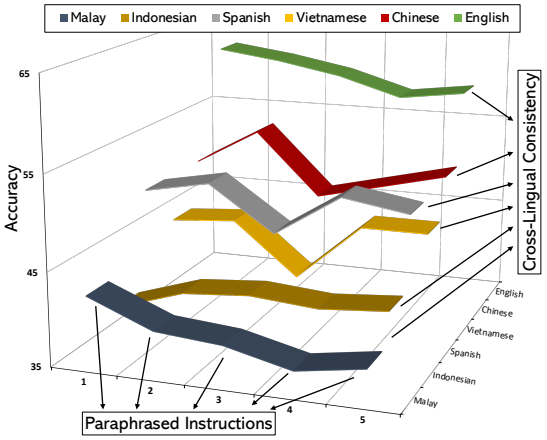

Figure 2: Two new evaluation protocols for multilingual foundation models in *SeaEval*. The performance result is taken from ChatGPT on Cross-LogiQA dataset.

3.3 Evaluation Protocols

Conventional benchmarks typically emphasize a single metric evaluation per dataset. As illustrated in Figure 2, it becomes apparent that they do not provide enough coverage in multilingual FM evaluation. Therefore, in addition to standard metrics, we introduce two new evaluation dimensions called instruction sensitivity and cross-lingual consistency to measure a model's stability across instructions and languages. Regarding standard evaluation metrics, we use accuracy scores for multiple-choice questions. In the case of translation assessments, we report the BLEU-4 score (Papineni et al., 2002), while for summarization tasks, we deploy the average of ROUGE-1/2/L scores (Lin, 2004).

Cross-Lingual Consistency Besides the standard *Accuracy* metric for evaluating multi-choice questions, we compute the cross-lingual *Consistency* score as a measurement of whether the answers are consistent for the same question in 7 different languages without considering the answer's correctness. Specifically, for a question set $Q = \{q^1, q^2, ..., q^N\}$, each question q^i is represented in 7 languages $q^i = \{q^i_{eng}, q^i_{zho}, q^i_{ind}, q^i_{spa}, q^i_{vie}, q^i_{msa}, q^i_{fil}\}$, and a^i_{lang} is model's answer to q^i_{lang}, the *Consistency* score is computed as

$$M_{\{l_1,l_2,..,l_s\}} = \frac{\sum_{i=1}^{N} \mathbb{1}_{\{a^i_{l_1}=a^i_{l_2}=..=a^i_{l_s}\}}}{N}$$

$$Consistency_s = \frac{\sum_{\{l_1,l_2,..,l_s\} \in C(s,q_i)} M_{\{l_1,l_2,..,l_s\}}}{C^s_7}$$

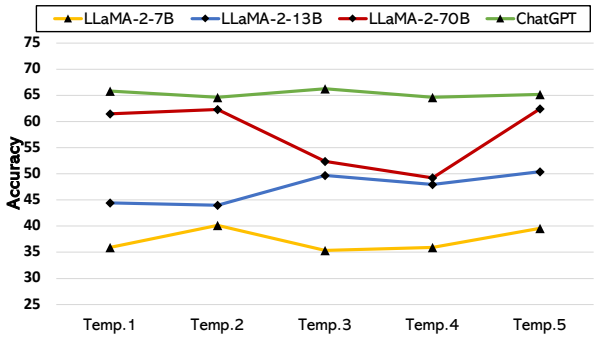

Figure 3: Performance on MMLU dataset with paraphrased instruction. Some models show large performance variances with paraphrased instruction templates.

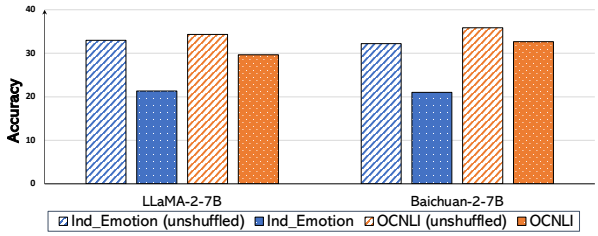

Figure 4: Effect on label order. Performance varies when labels are shuffled, revealing inherent label biases.

where $s \in [2, 7]$. It measures the answer's consistency of any combination of s languages. The model gets rewarded if it generates consistent answers across the sampled languages. The consistency requirement is enhanced to more languages with increased s. Given that both *Accuracy* and *Consistency* alone do not provide a comprehensive assessment of models' performance on cross-lingual datasets, we introduce the *AC3* score as a holistic measure, which is calculated as the harmonic mean of both scores:

$$AC3_s = 2 \cdot \frac{Accuracy \cdot Consistency_s}{Accuracy + Consistency_s}$$

where *AC3* is within range $[0, 1]$. We deploy *AC3* with $s = 3$ as the default value for Cross-MMLU and Cross-LogiQA datasets. Figure 8 illustrates the impact on variable s.

Instruction Sensitivity Early methods for training LLMs to follow instructions primarily use task instruction sets, which are compiled by combining task instruction templates with instances from standard NLP tasks (Chung et al., 2022). However, such approaches often fall short of capturing the intricacies of practical user instructions, as these instructions tend to originate from artificial NLP tasks designed to test specific aspects of machine capabilities. Real-world user instructions, on the other hand, are significantly more diverse and complex (Ouyang et al., 2022), and it is necessary to evaluate the performance under varied instructions. Therefore, we build 5 human paraphrased instructions with NLP experts for each dataset. We show in Figure 3 about the LLaMA-2 and ChatGPT models on their performance with five instructions and witnessed that ChatGPT models are more robust to instruction paraphrases. Some instructions possess the ability to unlock the model's full potential, potentially surpassing its more efficient counterparts, which may lead to biased evaluation (***Our Finding 1***). Hence, it becomes crucial to utilize multiple instructions to obtain a more comprehensive assessment of model capabilities. Evaluating the model's resilience to paraphrased instructions is also a significant aspect. To report performance, we employ the median value derived from five instructions as the ultimate result.

Exposure Bias on Label Arrangements Recent work demonstrates that LLMs have inherently exhibited exposure biases from many factors (Fei et al., 2023) including majority label bias, recency bias, and common token bias (Zhao et al., 2021). In our study, we found the positional arrangement of labels is a potential source of exposure bias, especially for smaller-sized models. Figure 4 shows the results of LLaMA-2 and Baichuan-2 models on two datasets. We observe that some models are prone to rely on intrinsic biases of label arrangements when making predictions which lead to higher evaluation results. Ignoring such patterns could raise unanticipated advantages on specific models (***Our Finding 2***). Therefore, in *SeaEval*, we shuffle all labels whenever possible to avoid exposure biases on label arrangements. Note that for position-sensitive labels such as 'all above', we manually keep their order unchanged.

4 Evaluation Results and Discussion

We show the evaluation results on five datasets for cross-lingual consistency and cultural reasoning in Figure 5 and our key findings are as follows.

Firstly, GPT-4 demonstrates outstanding performance on most datasets, surpassing others by a substantial margin across cultures and languages, demonstrating its superior capability in handling multilingual tasks.

Second, becoming an expert in cultural knowledge necessitates extensive pre-training with a diverse and extensive collection of multilingual tex-

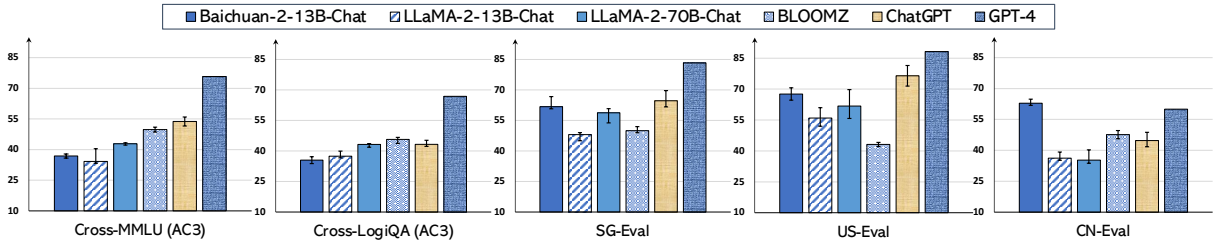

Figure 5: Evaluation results of six representative LLMs on a subset of *SeaEval*. AC3 and Accuracy scores are reported. The error bar covers performances from five different instruction templates.

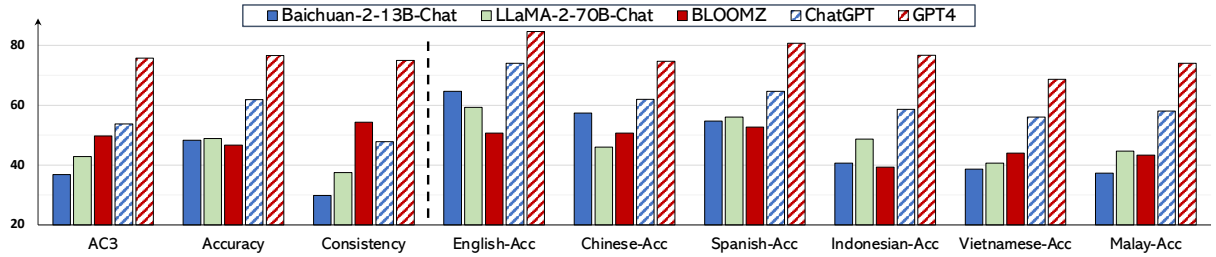

Figure 6: Evaluation results on Cross-MMLU. Both overall and language-specific scores are shown.

tual data such as books, articles, websites, historical documents, and cultural artifacts. Baichuan-2 model has shown remarkable performance in understanding Chinese culture (CN-Eval), even outperforming GPT4. In contrast, LLaMA models are primarily focused on English, with approximately 90% of English pre-training data. This specialization makes them less proficient in handling multilingual and multicultural scenarios.

Detailed results regarding cross-lingual consistency are presented in Figure 6. The report includes comprehensive evaluation metrics: *AC3*, *Accuracy*, *Consistency*, and *Accuracy* for each language. The consistency score clearly demonstrates that BLOOMZ stands out for its better performance in aligning knowledge across languages, solidifying its position as a leading open-source multilingual foundational model. Even being the worst in overall accuracy, BLOOMZ surpasses ChatGPT in cross-lingual consistency, achieving a score of 54% compared to 47%. However, they are still showing unsatisfactory consistency scores, highlighting the inconsistency in the sharing of common knowledge across various languages (***Our Finding 3***). While GPT-4 achieves a 75% consistency score, it drops to 64% when $s = 6$ as shown in Figure 8, which suggests ample opportunity to further enhance cross-lingual knowledge alignment, aiming for optimal multilingual models.

Last, when assessing models' accuracy in individual languages, it is evident that their problem-solving capability in English usually surpasses that in other selected languages. This illustrates that the proficiency of models varies unevenly across different languages (***Our Finding 4***). Compared to high-resource languages, the performance of low-resource languages is inferior. For example, English, Chinese and Spanish rank within the top 5 out of 46 languages present in BLOOMZ corpus. Therefore, the multilingual foundation model's capability in low-resource languages needs to be further improved to match the more centralized languages. The disparity in cross-lingual consistency highlights the need for more robust alignment efforts. Particularly under low-resource constraints, enhancements in this aspect have the potential to elevate the overall performance across all languages through effective knowledge transfer, facilitating further development of multilingual language models (Kulshreshtha et al., 2020; Huang et al., 2023a; Zhu et al., 2023b; Muennighoff et al., 2023).

5 Conclusions

We introduced *SeaEval* benchmark for multilingual foundation model evaluation, grounded in comprehensive experimentation across languages, models, tasks, and datasets. *SeaEval* encompasses 29 datasets, including 7 new ones for cultural understanding and cross-lingual consistency. Our empirical analysis demonstrates four key findings on the capabilities of multilingual foundation models: 1) Sensitivity to paraphrased instructions; 2) Ex-

posure bias of label arrangements, 3) Inconsistent performance across multilingual questions that are semantically equivalent, and 4) Imbalanced multilingual proficiency. These findings accentuate the importance of more generalizable semantic representations and enhanced multilingual contextualization. We hope that our endeavors in *SeaEval* can pave the way for more in-depth investigations into multilingual and multicultural tasks using foundation models.

Limitations

In this study, our primary focus is multilingual foundation models' language capabilities. Nonetheless, there remain several evaluation aspects to be included in order to provide a complete reflection of the capability of multilingual foundation models in practical applications.

First, there is a need for the inclusion of more languages and cultural reasoning datasets. Expanding the linguistic and cultural diversity within the benchmark is a resource-intensive endeavor, as the acquisition of suitable datasets for various languages and culture-related contexts can be challenging. Nevertheless, as we aspire for this benchmark to comprehensively cover a wide range of languages, there is a pressing need to explore automated methods for data collection. Such an approach can help ensure the acquisition of high-quality datasets while mitigating the resource-intensive nature of manual data curation, thereby enhancing scalability.

Second, *SeaEval* ensures a robust quantitative evaluation benchmark, incorporating datasets that facilitate more straightforward performance quantization. In real-world usage cases, foundation models are also used for information-seeking purposes, where users may pose subjective questions and engage in dialogues. This poses challenges in evaluating the faithfulness, expertise and engagement during interactions. Existing approaches adopt powerful FMs as the evaluation criteria which may not necessarily replicate the judgments from humans (Zheng et al., 2023), underscoring the necessity of practical automatic assessment approaches for open-ended questions.

Third, but certainly not the least, safety and efficiency are two important dimensions of FMs. Ensuring the safety of models in real-time and dynamic contexts is critical, especially to avoid generating harmful or biased content. Meantime, striking a balance between the effectiveness and efficiency of FMs is challenging and requires more ongoing research efforts. Therefore, our pursuit of a comprehensive benchmark should extend to these vital dimensions of model performances.

A Related Work

A.1 Existing Benchmarks

The field of LLM evaluation is expanding quickly owing to the rapid development of model capabilities. Chang et al. (2023) provides a comprehensive review of different evaluation methods. Even though there are thousands of languages around the world, the vast majority of LLM evaluation benchmarks concentrate on English or Chinese (Liang et al., 2022; Li et al., 2023b; Zhong et al., 2023), which has a solid foundation of well-annotated resources. They are mainly focused on complex reasoning datasets which are normally collected from human examinations including SAT, math tests or Chinese college examinations (Zhong et al., 2023; Hendrycks et al., 2021b; Huang et al., 2023b; Li et al., 2023a). Gu et al. (2023) gathered questions from various disciplines like economics, jurisprudence and literature. Besides the subjective test, Li et al. (2023b) and Bai et al. (2023) propose to use LLMs as the judger to provide objective evaluations on generated content for objective scores and implement pairwise model ranking.

There are pioneering efforts on multilingual large language model evaluation. Lai et al. (2023) propose to evaluate large language models for their multilingual capability with a series of classic NLP tasks. Zhang et al. (2023) expands multilingual evaluation to 9 languages associated with a toolkit. Zhu et al. (2023a) evaluate LLM with machine translation test sets which are multilingual inherently. In this work, we expand multilingual foundation model evaluation benchmarks beyond combinations of monolingual tasks.

A.2 Foundation Language Models

The foundation language models, as general task solvers, include both pre-trained language models and their instruction-tuned variants. ChatGPT (Ouyang et al., 2022) and GPT4 (OpenAI, 2023) are showing superior capabilities across various applications. A series of foundation models

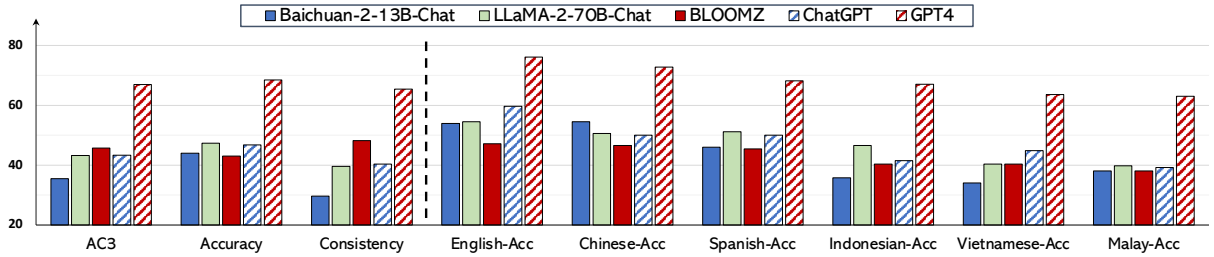

Figure 7: Evaluation results on Cross-LogiQA. Both overall and language-specific scores are shown.

Question	*Which of the following items would be considered the least suitable gift to bring to a Singaporean family during Lunar New Year?* *(A) An pineapple* *(B) Cash money* *(C) Two organges* *(D) A red packet*
Multicultural Reasoning Steps	**Multilingual Understanding** · Pineapple = Ong lai (Hokkien), sounds like 'good fortune to come' · Orange sounds like 'good luck' in Cantonese **Cultural Preferences** · Chinese like 'double' as a representation of unity, completeness and harmony. · Red packet is preferred as associated with luck, prosperity and happiness.
Answer	(B) Cash Money

Table 4: The 2nd example of cultural reasoning from SG-Eval.

are released afterwards including Flan-T5 (Chung et al., 2022), Alpaca (Taori et al., 2023), Vicuna (Chiang et al., 2023) and LLaMA-2 (Touvron et al., 2023b). Their multilingual capability is inferior to English due to the unbalanced training corpus and vocabulary settings. For applicable to multilingual scenarios, a series of bilingual or multilingual models are proposed by pertaining from scratch (XGLM (Lin et al., 2022b), BLOOM (Scao et al., 2022), ChatGLM (Du et al., 2022)), expansion of vocabulary sizes (Cui et al., 2023) or aligning multilingual instructions (Zhu et al., 2023b). In the foreseeable future, we anticipate a surge of multilingual language models, underscoring the need for effective multilingual LLM evaluation benchmarks.

B Selected Models

In this work, we evaluate the performance of various large language models on our benchmark datasets. They show disparate capabilities in various tasks. The included models are Flan-T5 (Flan-T5-Small, Flan-T5-Base, Flan-T5-Large, Flan-T5-XL, FLAN-T5-XXL, FLAN-UL2) (Chung et al., 2022), LLaMA-1 (LLaMA-7B, LLaMA-13B, LLaMA-30B, LLaMA-65B) (Touvron et al., 2023a), LLaMA-2 (LLaMA-2-7B, LLaMA-2-7B-Chat, LLaMA-2-13B, LLaMA-2-13B-Chat, LLaMA-2-70B, LLaMA-2-70B-Chat) (Touvron et al., 2023b), Baichuan (Baichuan-7B, Baichuan-13B, Baichuan-13B-Chat, Baichuan-2-7B, Baichuan-2-7B-Chat, Baichuan-2-13B, Baichuan-2-13B-Chat) (Yang et al., 2023), Alpaca-7B (Taori et al., 2023), Vicuna (Vicuna-7B-v1.3, Vicuna-13B-v1.3, Vicuna-7B-v1.5, Vicuna-13B-v1.5, Vicuna-33B-v1.3) (Chiang et al., 2023), ChatGLM (ChatGLM-6B, ChatGLM2-6B) (Du et al., 2022), BLOOM (BLOOMZ-7B1, MT0-XXL) (Scao et al., 2022), Colossal-LLaMA-2-7B-Base, ChatGPT (gpt-3.5-turbo-0613, gpt-4-0613) (OpenAI, 2023). In this paper, we report the result of the following models as a representative set considering their overall performance and multilingual support.

- **Baichuan-2**: is an open-source multilingual language model with emphasis on English and Chinese. It shows competitive performance compared to models of the same size and generally outperforms LLaMA-2 model through better pre-training and human alignment techniques. Baichuan-2-13B-Chat is selected in our experiments.
- **LLaMA-2**: is an open-source language model released by Meta. Even though it supports multilingual, LLaMA is trained with most data (close to 90%) in English which makes it an English-centric model. It performs the best for English use cases than other languages. The Chat variant is further tuned for improved helpfulness and safety. LLaMA-2-13B-Chat and LLaMA-2-70B-Chat are selected in our experiments.
- **BLOOMZ**: is the leading open-source multilingual large language model further tuned

with diverse instructions. It supports over 40 languages with a more balanced pertaining and fine-tuning corpus. Note that BLOOMZ is instruction-tuned with supervised datasets which may cause supervision leakage on certain datasets (e.g. SAMSum, DREAM) and unjustified comparison. BLOOMZ-7B1 is selected in our experiments.

- **ChatGPT**: is closed-source model developed by OpenAI. It has good multilingual support and demonstrates more robust performance compared to open-source models. The model is updating over time and we select GPT3.5 (referred to as ChatGPT) and GPT4 on version 0613 in all our experiments.

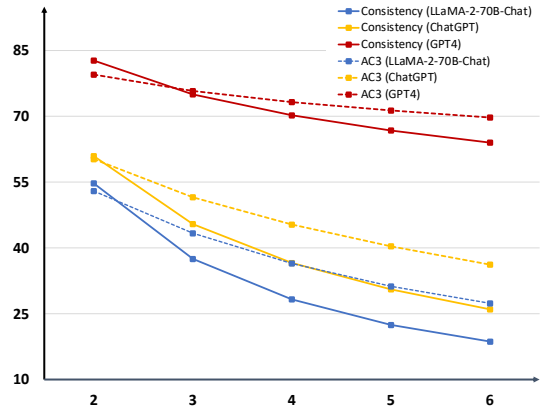

Figure 8: Consistency and AC3 Scores with $s \in [2, 6]$ on Cross-MMLU dataset. (Filipino excluded)

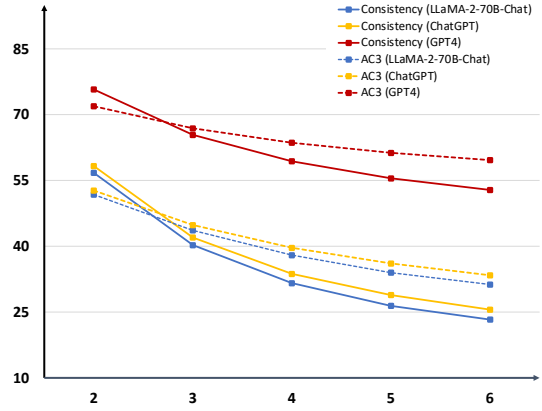

Figure 9: Consistency and AC3 Scores with $s \in [2, 6]$ on Cross-LogiQA dataset. (Filipino excluded)

C Cross-Lingual Consistency

In this paper, we spot the cross-lingual inconsistency problem for multilingual foundation models. To better evaluate this aspect, we collect and propose two new datasets with respective metrics. In this section, we provide more analysis on the cross-lingual consistency study and the effectiveness of s in the proposed *Consitency* and *AC3* metrics.

The evaluation results for Cross-LogiQA dataset is depicted in Figure 7. As the leading open-source multilingual model, BLOOMZ outperforms other open-source models and ChatGPT in terms of consistency but falls short in achieving high performance in specific languages. This suggests that BLOOMZ provides more consistent answers across languages, possibly due to its training on a more balanced multilingual corpus and fine-tuning with multilingual instruction data to improve cross-language alignment. As observed in Figure 6, the performance is better for higher-resource languages such as English, Chinese, and Spanish compared to lower-resource languages like Indonesian, Vietnamese, and Malay. GPT4 surpasses other models in both "Accuracy" and "Consistency," highlighting significant potential for further enhancement of all other models.

In Section 3.3, AC3 score is presented, taking into account both accuracy and consistency scores. We have one tolerance hyperparameter s which requires the answers to be consistent across s languages to be rewarded in consistency score. We deploy $s = 3$ as the default hyperparameter in above experiments. Here, we conduct more systematic study of s with its effect on the final scores.

The results on Cross-MMLU and Cross-LogiQA are shown in Figure 8 and 9. As s increases, the consistency score has dropped dramatically for all models. Among all three models, the performance of GPT4 drops the least, indicating a robust consistency alignment across languages. Even for ChatGPT, when $s = 6$, the consistency score downgrades to around 26% on both Cross-MMLU and Cross-LogiQA datasets. It indicates that only 26% of the cases that ChatGPT is selecting the same answer for the same question across six languages. Hence, we opt for $s = 3$ as the default value for two primary reasons: 1) to facilitate evaluation across multilingual language models, even when not all 6 languages are supported, and 2) to allow for a certain level of tolerance regarding language consistency, without imposing the strict requirement of complete consistency among all responses. This approach can be seen as a more lenient method of assessing language consistency. In the future, as

the model's multilingual capabilities continue to advance, we can increase s accordingly.

D Evaluation Protocols

When assessing foundation models, two distinct settings come into play: zero-shot and few-shot. In this study, we predominantly rely on zero-shot evaluation as the chosen method for all models, primarily for two compelling reasons. Firstly, zero-shot evaluation aligns more closely with real-world application scenarios, where users interact directly with deployed models without undergoing explicit training. Secondly, it's worth noting that even without the process of fine-tuning using human instructions, these models display a noteworthy ability to comprehend and adhere to emerging instructions. Besides, it brings additional benefits to avoid uncertainty caused by the in-context few-shot samples and potential exposure biases.

Another challenge in evaluation is the unstructured form of outputs from large language models. Unlike previous discriminative models, language generation models produce the answer represented by free text. Therefore, there is a gap between the generated content and the ground-truth answers, especially for multi-choice questions. Therefore, we develop a heuristic algorithm to decide the mapping. In general, we first split the answer into sentences. For each sentence, we detect whether the choice symbols (e.g. (A), (B), (C), (D)) exist. If none of them exists, we detect whether the choice description exists. If exists, we count the sentence as the symbol of such label and N.A. otherwise. Finally, we perform majority voting from all sentences as the final answer. From the experiments, we found the algorithm is robust enough to link the generated content with labels among diverse models and languages. Therefore, we chose this algorithm after careful comparison with a few other variants.

E Full Experimental Results and Analysis

Besides the evaluation on 5 datasets shown in Figure 5, the full evaluation results on the other 23 datasets are shown in Figure 10. From the results, we spot several key findings.

First, Baichuan-2-13B-Chat surpasses LLaMA-2-13B-Chat not only in Chinese tasks but also in tasks in English and other languages. Despite being pre-trained with 2T tokens mostly in English, LLaMA-2 falls short in terms of its English proficiency. This highlights the critical role of data quality and diversity. Effective data collection and post-processing play a pivotal role in the development of large language models.

Secondly, when it comes to a multilingual context, BLOOMZ exhibits lower competitiveness in comparison to other models. Despite being trained on a dataset that incorporates more than 40 languages and pre-trained using a more evenly balanced corpus from these languages, it fails to showcase superior performance in various multilingual tasks. This could be attributed to ineffective pre-training and the limitations imposed by the model's size, which consists of 7 billion parameters. It is worth noting that BLOOMZ does display exceptional performance in specific datasets, such as SAMSum and Flores. This can be attributed to the direct fine-tuning of the model with supervision, making it inappropriate to draw direct comparisons with datasets as outlined in (Muennighoff et al., 2023). Nevertheless, the cross-lingual consistency of the BLOOMZ model is good due to its cross-lingual generalization through multitask finetuning (Muennighoff et al., 2023).

Lastly, GPT4 surpass ChatGPT in various aspects including multilingual capability. However, due to its commercial nature, it is generally hard to conduct transparent research with such models.

F More Examples

To have a direct interpretation of the newly proposed six datasets, we further illustrate samples and instructions with English translations in Table 5. Examples of SG culture questions are shown in Table 2 and 4.

For evaluating cross-lingual consistency, we introduce two datasets: Cross-MMLU and Cross-LogiQA, featuring parallel questions in 6 different languages. In this section, we delve deeper into cross-lingual inconsistency phenomena across a broad range of languages. To achieve this, we expand our sample to include questions in 16 languages and prompt ChatGPT for answers. The outcomes are detailed in Table 1, 6 and Figure 11, 12, 13, 14, 15. The languages encompassed in this study are English, Chinese, Indonesian, Spanish, Thai, French, Korean, Malay, Turkish, German, Romanian, Filipino, Tamil, Portuguese, Vietnamese and Arabic. The results substantiate the existence of cross-lingual consistency issues across different languages, underscoring the need

for increased attention to this matter.

G Annotators

The annotators consist of both full-time employees and PhD students. Full-time employees did not receive additional compensation for their annotation work but considered it as part of their regular working hours. Conversely, PhD students had their annotation time recorded and were compensated with fixed-hour claim rates. On average, one round of correction for each language on each dataset took approximately 3-5 hours, varying depending on the languages involved.

VOLCANO: Mitigating Multimodal Hallucination through Self-Feedback Guided Revision

Seongyun Lee[1] **Sue Hyun Park**[1] **Yongrae Jo**[2] **Minjoon Seo**[1]

[1]KAIST AI [2]LG AI Research

{seongyun, suehyunpark, minjoon}@kaist.ac.kr yongrae.jo@lgresearch.ai

Abstract

Large multimodal models suffer from multimodal hallucination, where they provide incorrect responses misaligned with the given visual information. Recent works have conjectured that one of the reasons behind multimodal hallucination is due to the vision encoder failing to ground on the image properly. To mitigate this issue, we propose a novel approach that leverages self-feedback as visual cues. Building on this approach, we introduce **VOLCANO**, a multimodal self-feedback guided revision model. VOLCANO generates natural language feedback to its initial response based on the provided visual information and utilizes this feedback to self-revise its initial response. VOLCANO effectively reduces multimodal hallucination and achieves state-of-the-art on MMHal-Bench, POPE, and GAVIE. It also improves on general multimodal abilities and outperforms previous models on MM-Vet and MMBench. Through qualitative analysis, we show that VOLCANO's feedback is properly grounded on the image than the initial response. This indicates that VOLCANO can provide itself with richer visual information through feedback generation, leading to self-correct hallucinations. We publicly release our model, data, and code at github.com/kaistAI/Volcano.

1 Introduction

Recent large multimodal models (LMMs) use substantial image-text or video-text pairs to help instruct-tuned large language models (LLMs) comprehend visual features produced by vision encoders (Alayrac et al., 2022; Liu et al., 2023b,c; Chen et al., 2023; Peng et al., 2023; Dai et al., 2023; Zhu et al., 2023; Ye et al., 2023a; Li et al., 2023a; Zhang et al., 2023b; Su et al., 2023; Maaz et al., 2023). With the introduction of fine-tuning methods such as visual instruction tuning (Liu et al., 2023b,c), LMMs are now evolving into assistants capable of understanding the world through multiple channels, akin to humans.

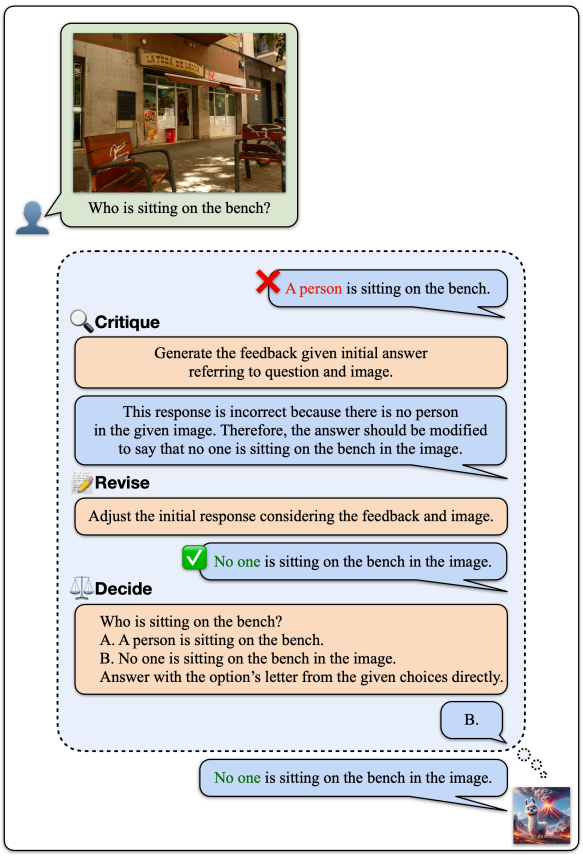

Figure 1: Overview of VOLCANO. This example illustrates the process undertaken by VOLCANO for a question in the MMHal-Bench dataset. Before giving the response, VOLCANO goes through a *critique-revise-decide* process. It critiques its initial response with natural language feedback, revises the response based on the feedback, and decides whether to accept the revised answer.

Despite the impressive performance observed on various benchmark tasks and qualitative outcomes, these models grapple with an issue called *multimodal hallucination*, where they produce responses that do not align with the visual information given in the question. Recent work (Zhai et al., 2023) demonstrates that multimodal hallucinations can occur when the vision encoder fails to ground im-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 391–404
June 16-21, 2024 ©2024 Association for Computational Linguistics

ages accurately. In other words, LMMs tend to rely more on their parametric knowledge than on provided visual features, causing them to guess and generate hallucinations. Wang et al. (2023b) empirically shows that models attend to the previous tokens more than image features as they generate tokens misaligned with the given image.

In this paper, we propose a novel method that utilizes natural language feedback to enable the model to correct hallucinated responses by providing detailed visual information. Building on this method, we introduce **VOLCANO**[1], a multimodal self-feedback guided revision model. VOLCANO is trained to first generate an initial response based on the given image and question, then sequentially revises the response until it determines that no more improvement is required. We collect our training data for multimodal feedback and revision using proprietary LLMs.

To verify the efficacy of VOLCANO in reducing multimodal hallucination, we evaluate its performance on multimodal hallucination benchmarks (Sun et al., 2023; Li et al., 2023d; Liu et al., 2023a). Results demonstrate consistent performance improvements across all benchmarks. Notably, when compared to previous methods specialized in mitigating multimodal hallucination (Zhou et al., 2023; Sun et al., 2023; Yin et al., 2023), VOLCANO showcases a 24.9% enhancement, underscoring its effectiveness in addressing the challenge. Further, on multimodal understanding benchmarks (Liu et al., 2023e; Yu et al., 2023), it is also shown effective in understanding and reasoning about visual concepts.

Through qualitative analysis, we find that the generated feedback attends to the image with higher intensity and higher coverage of features in the image. These findings explain that feedback carries fine-grained visual information. Even if the vision encoder fails to properly ground, the feedback can still guide the LLM to improve upon the hallucinated response, supporting the role of feedback in our proposed method.

Our contributions are summarized as follows:

1. We introduce VOLCANO, a self-feedback guided revision model that effectively mitigates multimodal hallucination. It achieves state-of-the-art performance on multimodal hallucination benchmarks and multimodal understanding benchmarks.

2. Our qualitative analysis shows that VOLCANO's feedback is rooted in the image, conveying rich visual details. This illustrates that feedback can offer guidance to reduce multimodal hallucination, even if the vision encoder imprecisely encodes the image and the model misinterprets the image initially.

3. We open-source VOLCANO (7B & 13B), along with data and code for training and inference.

2 Related work

2.1 Multimodal hallucination

Unlike language hallucination, where fabrication of unverifiable information is common (Ji et al., 2023; Zhang et al., 2023c; Li et al., 2023c), multimodal hallucination typically involves verifiable information misaligned with the input visual content. This phenomenon has been predominantly explored in the context of object hallucination, where generated content includes objects that are inconsistent with or absent from the target image (Rohrbach et al., 2018; Biten et al., 2022; Li et al., 2023d; Liu et al., 2023a; Zhai et al., 2023). More complex forms of multimodal hallucination, such as holistic misrepresentations involving entire scenes or environments, have only begun to be recognized and documented in recent studies (Sun et al., 2023).

To uncover the cause of failure in grounding, previous works analyze either the visual or language side. Zhai et al. (2023) pinpoints the lack of preciseness in visual features produced by the vision encoder. Other studies (Li et al., 2023d; Liu et al., 2023a; Wang et al., 2023b) focus on the tendency of LLMs to generate words more in line with common language patterns rather than the actual visual content. The error may be further exacerbated by autoregressive text generation (Rohrbach et al., 2018; Zhang et al., 2023a; Zhou et al., 2023).

2.2 Self-correcting from feedback

Learning from feedback can align LLMs to desired outcomes, to better follow instructions via human preference feedback (Ouyang et al., 2022), preference feedback generated by AI itself (Lee et al., 2023; Dubois et al., 2023), or even fine-grained feedback (Wu et al., 2023; Lightman et al., 2023). Compared to preference and fine-grained feedback which provide scalar values as training signals, natural language feedback provides more information (Scheurer et al., 2022; Ma et al., 2023) and has

[1]We call our model VOLCANO because it frequently erupts *LLaVA*

been effective for language models to correct outputs, especially for *self-correction* (Welleck et al., 2022; Pan et al., 2023). Inspired by successful iterative self-refining language models (Madaan et al., 2023; Ye et al., 2023b; Shinn et al., 2023; Gou et al., 2024), to the best of our knowledge, we are the first to achieve improvement in multimodal models through self-feedback guided refinement.

2.3 Mitigating multimodal hallucination

Previous methods for mitigating multimodal hallucinations have varied in their focus, including enhancing the quality of instruction tuning data, model training methodologies, and implementing post-hoc refinements. LRV-Instruction dataset (Liu et al., 2023a) ensures the balance of both negative and positive instructions and VIGC (Wang et al., 2023a) iteratively generates and corrects instructions to reduce hallucinated samples in training data. Adapting reinforcement learning from human feedback (RLHF) to train a single reward model as in LLaVA-RLHF (Sun et al., 2023) or training multiple or even without no reward models as in FDPO (Gunjal et al., 2023) has proven effective as well. LURE (Zhou et al., 2023) trains a revision model to detect and correct hallucinated objects in the base model's response. Woodpecker (Yin et al., 2023) breaks down the revision process into multiple subtasks where three pre-trained models apart from the base LMM are employed for the subtasks.

Unlike models using reinforcement learning, our approach does not require reward model training. Also, contrary to revision-only methods, our method trains a model to *self*-revise, eliminating the need for extra modules. Furthermore, we introduce natural language feedback before the revision process. This feedback serves a dual purpose: it revisits the visual features for enhanced clarity and specifically pinpoints the hallucinated elements that require correction, thereby enriching the information available for more effective revision.

3 VOLCANO

VOLCANO is a single LMM to generate initial responses, feedback, and revisions, as well as decisions to accept revisions. It follows a sequential procedure of an iterative critique-revision-decide loop. In Section 3.1, we introduce the process by which VOLCANO self-revises its responses iteratively. Section 3.2 describes the collection of multimodal feedback and revision data used to train VOLCANO. Finally, Section 3.3 provides detailed information about the models and data used in our study. The overall process is explained in Algorithm 1 and illustrated in Figure 2.

Algorithm 1 Feedback guided self-revision

Input: *model* M, *image* I, *question* Q
$R_{initial} = M(I, Q)$
$R_{best} = R_{initial}$
for up to 3 iterations **do**
  $F = M(I, Q, R_{best})$
  $R_{revised} = M(I, Q, R_{best}, F)$
  $R_{decided} = M(I, Q, R_{best}, R_{revised})$
  if $R_{decided} == R_{best}$ **then**
    break
  else
    $R_{best} = R_{revised}$
return R_{best}

3.1 Iterative self-revision

VOLCANO is a single model that generates improved responses through a sequential process of four stages. First, similar to other LMMs, it generates an initial response $R_{initial}$ for the image I and question Q and initializes the best response R_{best} with $R_{initial}$. This stage is performed only once in the process of creating the final response. Second, it generates feedback F based on the R_{best} (**stage 1**). Using this feedback, it self-revises the R_{best} (**stage 2**). Since there is no guarantee that the revised response $R_{revised}$ will be better than the existing R_{best}, there is a need to determine which response is better for the given Q and I. At this point, VOLCANO is given Q, I, and both responses, and it goes through the process of deciding which response is better (**stage 3**). The order of $R_{revised}$ and R_{best} in stage 3 is randomized to prevent the positions from affecting the results (Wang et al., 2023c). If the model decides that $R_{revised}$ is better than R_{best}, then R_{best} is updated with $R_{revised}$ and the procedure from stage 1 to stage 3 is repeated, with the predetermined maximum number of iterations. Otherwise, the loop is early-stopped, and R_{best} is selected as the final output. The prompts for inference at each stage are in Appendix B.1.

3.2 Data collection

To train VOLCANO, we collect initial responses for visual questions from an open-source LMM and generate feedback and revisions using a proprietary LLM as shown in Figure 3 (Akyürek et al., 2023;

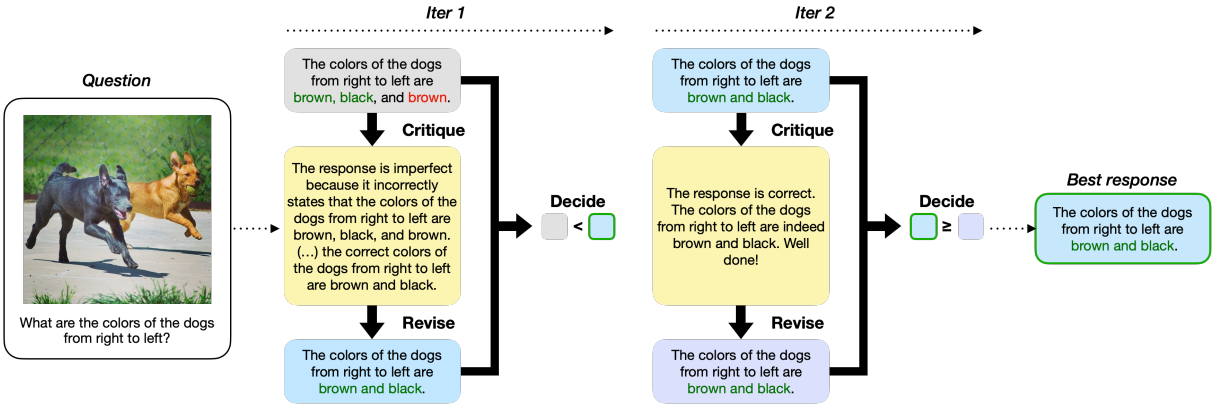

Figure 2: Overall process of VOLCANO. VOLCANO is a multimodal self-feedback guided revision model that takes an image and a question and then generates an improved response based on the self-feedback.

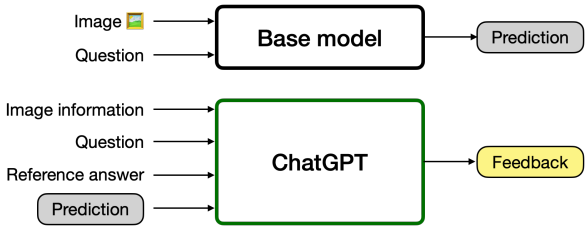

Figure 3: Data collection.

Madaan et al., 2023; Ye et al., 2023b; Wang et al., 2023d; Kim et al., 2023).

Since current proprietary LLMs cannot process images, we provide object details in text and image captions as a proxy for images. For each data instance, we feed the proprietary LLM image information consisting of object details and captions, question, initial response, and gold answer as reference answer, allowing the model to evaluate the given inputs and produce feedback.

The proprietary LLM might exploit the gold answer to generate the feedback, which can cause potential inaccuracies in feedback during inference time when it is not provided. To avoid this, we give the LLM clear prompts to focus on the text-formatted image details when generating feedback. When constructing the revision data, we set up a system to predict the existing gold answer as the output, using the feedback data, image, question, and initial response obtained from the previous steps as input, without involving any separate model generation process. The prompts for data collection are in Appendix B.2.

3.3 Implementation details

Data To construct multimodal feedback and revision data, we utilize the LLaVA-SFT-127k dataset (Sun et al., 2023). We only use the first turn of each instance in the dataset. When fine-tuning VOLCANO, we use the llava-1.5-mix665k as the visual instruction dataset (Liu et al., 2023b).

Model For the proprietary LLM, we employ OpenAI's gpt-3.5-turbo (OpenAI, 2022). We use the LLaVA-SFT+ 7B model to generate the initial response when creating feedback data and LLaVA-1.5 7B and 13B as backbone models of VOLCANO (Liu et al., 2023b,c). Details of computation and hyperparameters used are in Appendix C and Appendix D, respectively.

4 Experiments

4.1 Benchmarks

Multimodal hallucination benchmarks We use POPE (Li et al., 2023d), GAVIE (Liu et al., 2023a), and MMHal-Bench (Sun et al., 2023) as our benchmarks to test multimodal hallucination mitigation performance. POPE and GAVIE are benchmarks for assessing object-level hallucinations in images. POPE comprises 9k questions asking if a specific object is present or not in an image. GAVIE is composed of 1k questions evaluating how accurately the response describes the image (accuracy) and how well the response follows instructions (relevancy) using GPT-4. MMHal-Bench aims to evaluate the overall hallucination of LMMs, consisting of realistic open-ended questions. It comprises 96 image-question pairs across 8 question categories and 12 object topics. The overall score is computed by GPT-4, which compares the model's response to the correct answer based on the given object information. If the overall score is less than 3, the response is considered to contain hallucinations.

Model	MMHal-Bench		POPE		GAVIE		
	Score ↑	Hal rate ↓	Acc ↑	F1 ↑	Acc score ↑	Rel score ↑	Avg score ↑
MiniGPT-4 7B	-	-	68.4	74.5	4.14	5.81	4.98
mPLUG-Owl 7B	-	-	51.3	67.2	4.84	6.35	5.6
InstructBLIP 7B	2.1	0.58	71.5	80.0	5.93	7.34	6.64
LLaVA-SFT+ 7B	1.76	0.67	81.6	82.7	5.95	8.16	7.06
LLaVA-RLHF 7B	2.05	0.68	81.8	81.5	6.01	8.11	7.06
LLaVA-SFT+ 13B	2.43	0.55	83.2	82.8	5.95	8.2	7.09
LLaVA-RLHF 13B	2.53	0.57	83.1	81.9	6.46	8.22	7.34
LLaVA-1.5 7B	2.42	0.55	86.1	85.1	6.42	8.2	7.31
LLaVA-1.5 13B	2.54	0.52	86.2	85.2	6.8	8.47	7.64
VOLCANO 7B	2.6	0.49	88.2	**87.7**	6.52	8.4	7.46
VOLCANO 13B	**2.64**	**0.48**	**88.3**	**87.7**	**6.94**	**8.72**	**7.83**

Table 1: Results on multimodal hallucination benchmarks. The MMHal-Bench score is measured on a 0-5 scale. Hallucination rate (Hal rate) is measured as the proportion of scores less than 3. Additionally, GAVIE's Acc score (Accuracy score) and Rel score (Relevancy score) are measured on a 0-10 scale, with Avg score representing the average of Acc and Rel scores. Detailed evaluation results for each benchmark by question type are in Table 6 and Table 7.

Multimodal understanding benchmarks We use MM-Vet (Yu et al., 2023) and MMBench (Liu et al., 2023e) as benchmarks to measure the general multimodal performance of LMMs. MM-Vet is a benchmark consisting of 16 tasks and 218 instances designed to evaluate LMM's ability in complex multimodal tasks. The score is measured by GPT-4, which compares the LMM's response to the gold answer. MMBench comprises 4,377 multiple-choice questions aimed at assessing visual perception and visual reasoning. We utilize the development set of MMBench in this study.

4.2 Baselines

We use Openflamingo (Awadalla et al., 2023), MiniGPT-4 (Zhu et al., 2023), mPLUG-Owl (Ye et al., 2023a), InstructBLIP (Dai et al., 2023), Otter (Li et al., 2023a), LLaVA-SFT+ (Sun et al., 2023), and LLaVA-RLHF (Sun et al., 2023) as baseline models. As multimodal hallucination corrector baselines, we employ LURE (Zhou et al., 2023) and Woodpecker (Yin et al., 2023). LURE utilizes MiniGPT-4 13B as its backbone model. Woodpecker uses gpt-3.5-turbo as its corrector, grounding DINO (Liu et al., 2023d) as its object detector and BLIP-2-FlanT5-XXL (Li et al., 2023b) for its VQA model.

4.3 Main results

VOLCANO achieves the best performance in multimodal hallucination benchmarks. As shown in Table 1, VOLCANO consistently outperforms the base model, LLaVA-1.5 and other existing LMMs in the multimodal hallucination benchmark. It shows strong performance in benchmarks that measure scores using proprietary LLMs (MMHal-Bench, GAVIE) and a benchmark using conventional metrics like accuracy and F1 score (POPE). Notably, results from GAVIE demonstrate that VOLCANO not only provides accurate answers for a given image but also enhances its ability to follow instructions. Full results are in Appendix A.1.

Model	MMHal-Bench	
	Score ↑	Hal rate ↓
LURE	1.9	0.58
Woodpecker	1.98	0.54
VOLCANO 7B	**2.6**	**0.49**
LLaVA-RLHF 7B	2.05	0.68
VOLCANO$^-$ 7B	**2.19**	**0.59**

Table 2: Performance comparison with recent methods focusing on reducing multimodal hallucination. VOLCANO$^-$ 7B is a model fine-tuned with our multimodal feedback and revision data on LLaVA-SFT+ 7B, which is the backbone model of LLAVA-RLHF 7B.

Natural language self-feedback is effective in revising responses. Table 2 shows VOLCANO's effectiveness by comparing it with previous models designed to tackle multimodal hallucination. Compared to LURE and Woodpecker, both of which revise responses without feedback, VOLCANO reduces hallucination better. This suggests that providing specific feedback is crucial for correcting multimodal hallucination. In addition, unlike the two methods that require a separate model specialized for revision, VOLCANO efficiently gives better responses using just one model. Another notable

Model	MMBench Acc ↑	MM-Vet Acc ↑

VOLCANO 13B	**69.4**	**38.0**

Table 3: Results on multimodal understanding benchmarks. The detailed evaluation results for each benchmark by question type are in Table 8 and Table 9.

Model	MMHal-Bench Score ↑	MMHal-Bench Hal rate ↓
Only prediction	2.45	0.52
No decision	2.33	0.56
VOLCANO 7B	**2.6**	**0.49**

Table 4: Module ablation results. The "Only prediction" is the result of performing only stage 1 for VOLCANO 7B. "No decision" is the outcome of completing stages 1 and 2.

Model	MMHal-Bench Score ↑	MMHal-Bench Hal rate ↓
Iter 1	2.54	0.51
Iter 2	2.58	0.5
Iter 3 (VOLCANO 7B)	**2.6**	**0.49**

Table 5: Iteration ablation results.

observation is that Woodpecker's improvement in hallucination is less significant compared to VOLCANO, despite converting visual information into text and feeding it to a proprietary LLM corrector. From this, we find that for reducing multimodal hallucination, conveying visual features directly to the corrector model is critical.

Compared to LLaVA-RLHF, which reduces LLM hallucination using RLHF, VOLCANO consistently performs better as well. For a fair comparison, we developed VOLCANO$^-$ 7B by fine-tuning the base model of LLaVA-RLHF 7B, LLaVA-SFT+ 7B, on our multimodal feedback and revision data. The results indicate that providing feedback in the form of natural language feedback, which the model can directly interpret, is more effective than providing feedback as scalar values.

VOLCANO showcases high general multimodal understanding capabilities. As the tendency of hallucination decreases, it is expected that the LMM can answer user questions about images more accurately. In this sense, we anticipate that VOLCANO would score high in benchmarks measuring general LMM's performance. To demonstrate this, we evaluate VOLCANO on benchmarks assessing complicated visual reasoning and perception capabilities of LLMs (Table 3). VOLCANO achieves superior performance compared to existing LMMs. Notably, as shown in Table 8, when measuring the math score related to a model's arithmetic capability, VOLCANO 13B impressively scored about twice as high as LLaVA-1.5 13B. Full results are in Appendix A.2.

4.4 Ablation studies

Module ablation We test the influence of each stage in the critique-revise-decide process (Section 3.1) in reducing multimodal hallucination. As shown in Table 4, when we only use the initial response as the final response and skip iterative self-revision, it scores lower than going through both processes. Surprisingly, even after just completing stage 1 and without self-revision, it still scores higher than the base model LLaVA-1.5 7B. This shows that merely fine-tuning with multimodal feedback and revision data can effectively reduce the hallucination rate. We observe a decrease in performance when the revised response is given as the final output without executing stage 3, compared to when a decision is made. This highlights the role of stage 3 in decreasing hallucination as it can prevent unnecessary revisions. This also suggests that while it is hard for the model to produce the right answer initially, distinguishing between right and wrong answers is relatively easier.

Iteration ablation We test how changing the maximum number of iterations affects VOLCANO's performance. As shown in Table 5, as the maximum iteration count increased, the hallucination rate decreased. This indicates that answers are successfully refined through multiple revisions. However, there also exists a trade-off: as the iteration count goes up, the inference time also increases.

5 Qualitative analysis

We qualitatively analyze how feedback from VOLCANO is effective in reducing multimodal hallu-

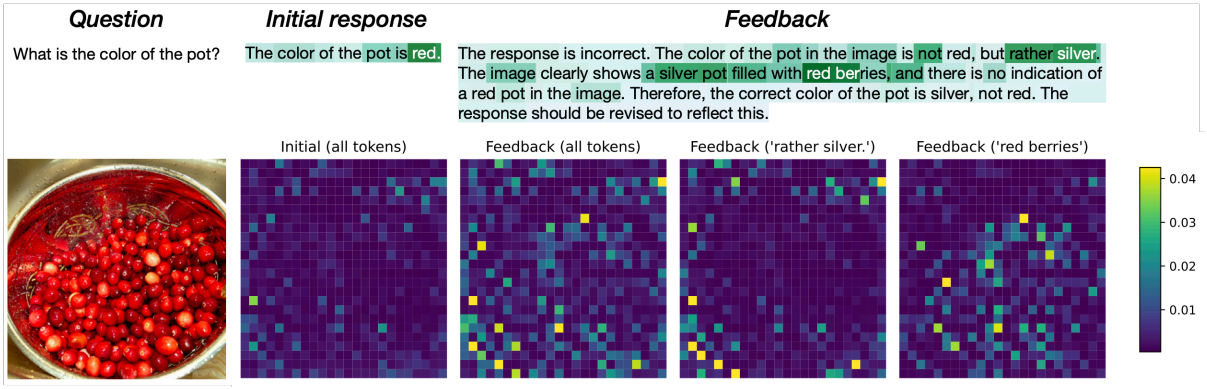

Figure 4: Coverage of image features attended during initial response and feedback generation on a single MMHal-Bench instance. The image attention heatmaps depict how the model's attention is distributed across image features, considering either all tokens or a subset of tokens in the output. In the text attention heatmaps above, the intensity of each token's background indicates the attention weight magnitude to image features, with darker highlights signifying higher weights. In the image attention heatmaps below, outliers at or above the 0.995th quantile are shown with the highest color intensity.

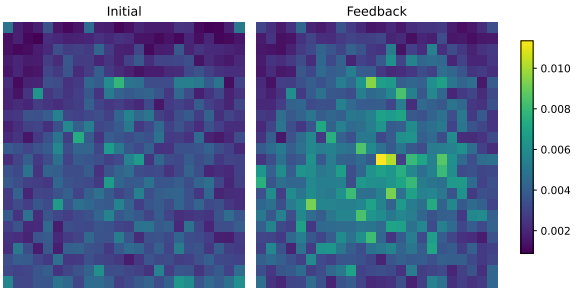

Figure 5: Average amount of attention to image features during the initial response (left) and feedback (right) generation. Attention weights are averaged across instances in MMHal-Bench where VOLCANO's revision enhances the initial response.

cination. In this section, we examine VOLCANO 7B results on MMHal-Bench in which the model's revised answer is chosen as the final answer. We compare the visual information content between the model's initial response and feedback, focusing on amount (5.1) and coverage (5.2).

5.1 Amount of visual information

Upon manual inspection of the instances, we observe that the initial response often correctly identifies object-level information but frequently misinterprets finer details such as object attributes or relationships between objects. On the contrary, we discover that the feedback text tends to describe the image contents more comprehensively.

To explore this phenomenon, we take inspiration from Wang et al. (2023b) and visualize how *much* do output tokens attend to input image features[2] while generating initial response and feedback tokens to the same image. For each instance, we perform top-k mean pooling to aggregate attention weights of initial response or feedback tokens on each image feature.[3] Specifically, we average top-3 attention weights across hidden layers, average top-3 weights across self-attention heads, and then average top-l weights across output tokens, where l is the length of the shorter output between initial response and feedback.

The results averaged across all instances are shown in Figure 5. Image features are more strongly attended by feedback than by initial response. Interestingly, even though attention to input would be more dispersed when generating feedback as its input includes an initial response in addition to the question, an increased concentration on wider areas of image features is visible. This suggests that visual information is largely reflected in the feedback text, supporting our manual inspection beforehand.

5.2 Coverage of visual information

We further empirically investigate how attention from individual tokens contributes to the *coverage* of critical visual information. Building upon the visualization method described in Section 5.1, we

[2]For every image, the vision encoder of VOLCANO, CLIP ViT-L/14 336px, processes it into 336px×336px size and divides it into 14px×14px patches, creating an image feature vector of size 576.

[3]We experimented with min, max, mean, and top-k mean pooling. We chose the top-k mean configuration as it provided the clearest visualization for our analysis.

compare attention weights to image features from *all* tokens in the output with those from *a subset of* tokens in the output. For the latter procedure, tokens that most intensely attend to image features during generation are deemed salient and are selected.

We provide attention heatmaps of a representative instance in Figure 4. The task in this example is to identify the color of the pot in the image, and the initial response incorrectly answers ("red") and then the feedback corrects the answer ("silver").

Such a correction can be explained by the difference in the distribution of attention to image features during the generation of each token. Based on the heatmaps of all tokens attending to image features, when VOLCANO generates the initial response, it mostly focuses on features on the outer edges, corresponding to the rim of the pot; when generating feedback, it attends to the entire image including outer regions corresponding to the silver pot and inner regions with red berries in it. Heatmaps of specific tokens attending to image features show that in the process of improving the initial response, VOLCANO indeed focuses on the exact areas of the image corresponding to key color descriptors "silver" and "red" when generating these words.

The findings suggest that during the feedback generation phase, the model develops an enhanced focus on an increased coverage of salient features, leading to a more comprehensive understanding of the image. This capability is beneficial for addressing the fundamental cause of multimodal hallucination of LLMs, which is that a lack of clear visual features leads LLMs to base their responses on pre-existing knowledge (Zhai et al., 2023; Li et al., 2023d; Liu et al., 2023a; Wang et al., 2023b). We propose that VOLCANO, with its ability to extract fine-grained visual information through feedback, can effectively reduce multimodal hallucination.

6 Conclusion

In our work, we suggest a novel approach that utilizes feedback as visual signals to direct the model to refine responses that do not accurately reflect the image. Building on this approach, we present VOLCANO, a multimodal self-feedback guided revision model. VOLCANO has not only achieved state-of-the-art results on a multimodal hallucination benchmark but also demonstrated its effectiveness by improving performance compared to baseline models on multimodal understanding benchmarks. Through qualitative analysis, we demonstrate that the feedback produced by VOLCANO is well-grounded on the image, and providing the model with rich visual information helps reduce multimodal hallucination. We hope our model and data open new pathways for strategies to mitigate multimodal hallucination and uncover the fundamental cause of the issue.

Limitations

In our study, we successfully demonstrated that VOLCANO can mitigate multimodal hallucination, as evidenced by our evaluations and analyses across various benchmarks. However, one notable drawback is the increased execution time. VOLCANO necessitates multiple calls to the model, making it less time-efficient than directly generating a response. On average, VOLCANO tends to be around 2 to 3 times slower than the base model, requiring 5.8 seconds to generate a response for a given image and instruction compared to 2.7 seconds by LLaVA-1.5. A strategy we use to reduce the overall execution time is to limit the number of iterations to 3. We think future work could explore improving the efficiency of the self-feedback-guided revision process.

A Full results on benchmarks

In this section, we describe the detailed results from the benchmarks used in our work. The benchmarks are designed to evaluate the performance of LMMs from multiple perspectives, encompassing various sub-tasks and types of questions.

A.1 Multimodal hallucination benchmarks

For MMHal-Bench, the questions are categorized into 8 types: Attribute, Adversarial, Comparison, Counting, Relation, Environment, Holistic, and Other (Table 6). POPE evaluates three types of questions: random, popular, and adversarial (Table 7).

A.2 Multimodal understanding benchmarks

MM-Vet is composed of sub-tasks designed to measure 6 LMM capabilities: Recognition, OCR (Optical Character Recognition), Knowledge, Language generation, Spatial awareness, and Math (Table 8). MMBench is structured to evaluate across L-1, L-2, and L-3 dimensions. We followed previous works and conducted evaluations for the L-2 dimension. The L-2 dimension tasks include Coarse Perception (CP), Fine-grained Single-instance Perception (FP-S), Fine-grained Cross-instance Perception (FP-C), Attribute Reasoning (AR), Relation Reasoning (RR), and Logic Reasoning (LR) (Table 9).

B Prompts

B.1 Prompts for inference at each stage

For all prompts, we did not explicitly provide an image feature prompt. Instead, the image features are concatenated with the question during the tokenization process before being input to the model. Additionally, the prompt for the decision process is based on the work of (Liu et al., 2023b).

B.2 Prompt for generating multimodal feedback

We introduce the prompt used in generating our multimodal feedback dataset. For an LLM that cannot see images, we included the image contents in the form of text within the prompt, allowing it to provide feedback as if it had seen the image and initial response. We utilized object information and a gold caption as the image contents. In instances where no objects are present in the dataset, we didn't use a separate object detector to prevent the model's errors from propagating into the feedback. Instead, only the gold caption is provided in such cases. Additionally, to avoid erroneously generating feedback that suggests the presence of hallucination merely due to the use of different expressions, even when the initial response aligns sufficiently with the image information but uses different terms from the gold answer, we crafted the prompt to treat synonyms or paraphrases as correct answers. Drawing inspiration from previous research (Kim et al., 2023), we structured the prompt to ensure that it encapsulates these aspects well.

C Computation

For this research, we used an NVIDIA A100-SXM4-80GB GPU and an AMD EPYC 7513 32-Core Processor running at 2.0778 GHz. Training VOLCANO 7B required 8 GPUs and took a total of 15 hours, while training VOLCANO 13B took 30 hours. While the time taken to evaluate each dataset varies, VOLCANO takes about 2 to 3 times longer to complete the entire process compared to existing baselines that only generate responses.

D Hyperparameters

We used a batch size of 128, a learning rate of 2e-5, and trained for 1 epoch. The maximum length is set to 2048, with no weight decay. We employed a cosine scheduler for learning rate adjustments, with a warmup ratio of 0.03. Additionally, we incorporated gradient checkpointing and used DeepSpeed zero stage 3. The maximum number of iterations for self-revision is 3. When generating responses, we utilized greedy decoding following LLaVA-1.5.

System prompt

You are excellent multimodal feedback-generating assistant. You are given questions about the image contents, objects information, reference answers, image contents and the model's response to evaluate. Utilizing these informations, please give me some feedback on the model's response only if feedback is needed.

Rule
- Consider synonyms or paraphrases in response as a correct answer

---

User prompt

Your job is to generate multimodal feedback of the given response.

Object information:
{objs}

Image contents:
{Capts}

Question:
{question}

Response to Evaluate:
{prediction}

Reference Answer:
{answer}

* Feedback
- The feedback should each be an explanation of why the response is imperfect and how it could improve.
- The feedback should consider the image contents and object information.
- The feedback shouldn't just copy and paste the response, but it should also give very detailed feedback on the content of the response.

* Format
- DO NOT WRITE ANY GREETING MESSAGES, just write the feedback only.

Generated Feedback:

Figure 6: **Prompt for generating multimodal feedback**

Feedback prompt *(stage 1)*

Generate the feedback given initial answer referring to question and image.
Question: {question}
Initial answer: {initial response}

Revision prompt *(stage 2)*

Adjust the initial response considering the feedback and image.
Question: {question}
Initial answer: {initial response}
Feedback: {feedback}

Decision prompt *(stage 3)*

{question}
Answer with the option's letter from the given choices directly.
A. {initial response}
B. {revised response}

Abstract

In-context learning (ICL) empowers large language models (LLMs) to perform diverse tasks in underrepresented languages using only short in-context information, offering a crucial avenue for narrowing the gap between high-resource and low-resource languages. Nonetheless, there is only a handful of works explored ICL for low-resource languages with most of them focusing on relatively high-resource languages, such as French and Spanish. In this work, we extensively study ICL and its cross-lingual variation (X-ICL) on 25 low-resource and 7 relatively higher-resource languages. Our study not only assesses the effectiveness of ICL with LLMs in low-resource languages but also identifies the shortcomings of in-context label alignment, and introduces a more effective alternative: query alignment. Moreover, we provide valuable insights into various facets of ICL for low-resource languages. Our study concludes the significance of few-shot in-context information on enhancing the low-resource understanding quality of LLMs through semantically relevant information by closing the language gap in the target language and aligning the semantics between the targeted low-resource and the high-resource language that the model is proficient in. Our work highlights the importance of advancing ICL research, particularly for low-resource languages.

1 Introduction

Large language models (LLMs) have displayed remarkable generalization capability in various tasks (Brown et al., 2020b; Kojima et al., 2022; Wei et al., 2022; Smith et al., 2022; Rae et al., 2022; Chowdhery et al., 2022; Scao et al., 2022; Liang et al., 2023; Srivastava et al., 2023; Lovenia et al., 2023; Bang et al., 2023). Nonetheless, these models face difficulties in generalizing across different languages, leading to performance disparity, particularly for low-resource languages (Aji et al., 2022a; Ebrahimi et al., 2022a; Adelani et al., 2022b; Cahyawijaya et al., 2023a,b; Asai et al., 2023). A myriad of research works address this problem through language-specific fine-tuning (Wilie et al., 2020; Kakwani et al., 2020; Cahyawijaya et al., 2021; Adelani et al., 2021; Kumar et al., 2022) which often leads to catastrophic forgetting (French, 1993; Chaudhry et al., 2019; Rolnick et al., 2019). Another line of work utilizes continual learning and adapter-based methods to inject new languages to existing LLMs (Yong et al., 2022; Cahyawijaya et al., 2023c; Jin et al., 2023). Nevertheless, these methods rely on performing multiple steps of parameter updates which require huge computational budgets, particularly for very large LLMs with hundreds of billion parameters.

To cope with this problem, prior works (Winata et al., 2021b; Lin et al., 2022a; Shi et al., 2023; Zhang et al., 2023) explore cross-lingual in-context learning (X-ICL) methods, an extension from in-context learning (ICL), that allow LLMs to generate better response quality in low-resource languages without the need for parameter tuning. In X-ICL, source language exemplars are incorporated into the input context allowing the model to transfer the task understanding capability from the source, commonly high-resource, language into the target language query (Winata et al., 2021b; Shi et al., 2023). However, X-ICL still fails to compete with a simple translate-test baseline, prominently for low-resource languages. A recent work (Tanwar et al., 2023) further enhances X-ICL through semantically similar cross-lingual exemplars and in-context label alignment[1], yielding a large gain over the baselines on relatively high-resource languages such as French, Spanish, Chinese, and Japanese.

In this work, we expand upon the concept of cross-lingual semantic similarity and in-context alignment, specifically focusing on low-resource

[1] In Tanwar et al. (2023), label alignment is referred to as task alignment. In this work, we distinguish two types of task alignments, i.e., query alignment and label alignment (§3.1).

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 405–433
June 16-21, 2024 ©2024 Association for Computational Linguistics

languages. Our hypothesis posits that their effectiveness may be compromised in low-resource languages due to the weak representation of the labels and sentences for the target languages. To test our hypothesis, we explore cross-lingual in-context learning (X-ICL) covering 25 low-resource languages from various language families and compare them with the performance of 7 relatively higher resource languages, including French (fra), Spanish (spa), German (deu), Italian (ita), Portuguese (por), Arabic (arb), and Hindi (hin). Our result suggests that the X-ICL performance decays correlate to the size of pre-training data of the target languages, which aligns with our hypothesis. Moreover, to our surprise, contrary to the results reported in (Tanwar et al., 2023), we found that in-context label alignment does not work for all the languages under study and introduced an alternative alignment method namely in-context query alignment, which significantly improves the alignment quality compared to the in-context label alignment.

To this end, we explore alternatives for X-ICL approaches covering variations of in-context alignment information, prompt, label encoding, and strategy for selecting in-context learning exemplars. We extensively analyze all these factors and their effect on the downstream task performance of all the languages under study. Our results and analysis highlight the following key takeaways:

- Contrary to prior work (Tanwar et al., 2023), we found that label alignment undermines the performance in most languages. Keeping uniform labels from the high-resource language often yields the best results.
- We introduce a new approach for cross-lingual alignment, i.e., query alignment, which is more effective than label alignment and can substitute or complement X-ICL.
- We analyze the effect of improving prompt format consistency on low-resource languages. However, despite improving performance for higher-resource languages, format consistency does not yield any benefit to the low-resource languages under study.
- We present a comprehensive in-context learning framework for better low-resource language understanding under various constrained conditions, concluding the significance of few-shot in-context information on enhancing the low-resource understanding quality of LLMs through semantically relevant information, where **monolingual ICL** does so by closing the language and domain gap on the targeted downstream task, while **X-ICL** closes the domain gap to the target downstream task, and **in-context alignment** closes the semantic gap between the targeted low-resource and the high-resource language that the model is proficient in.

2 Related Work

2.1 In-Context Learning

The in-context learning paradigm, originally introduced by Brown et al. (2020a), has significantly advanced our understanding of LLMs' capabilities. It demonstrated that LLMs can effectively perform complex tasks through in-context learning with just task-specific formatting and a few task-specific examples (few-shot) or none at all (zero-shot). This ability is facilitated by the LLMs' increasing capacity for generalization across diverse tasks, e.g., machine translation, question answering, and domain adaptation, without gradient updates.

Another line of work expands the scope of the study to multilingual generative LLMs, i.e., BLOOM (Scao et al., 2022), trained on the ROOTS corpus covering 46 natural and 13 programming languages, and XGLM (Lin et al., 2022b), trained on 500B tokens comprising 30 languages, which exhibit robust zero-shot and few-shot performances on multilingual NLP tasks. Furthermore, Lin et al. (2022b) address the imbalance in language representation by up-sampling the less-resourced languages. Bandarkar et al. (2023) then expand the language coverage of the in-context learning evaluation to 122 languages through Belebele, a wide-scale multilingual multiple-choice machine reading comprehension benchmark comprising short passages from FLORES-200 (Goyal et al., 2022).

Cross-Lingual In-Context Learning (X-ICL) Winata et al. (2021b) were among the first to explore the potential of few-shot X-ICL. Using 4 high-resource languages, this work shows that pre-trained LMs significantly outperform random prediction in cross-lingual tasks and produce better results compared to smaller fine-tuned baselines. Winata et al. (2022a) expand this study to unseen languages and find that taking the X-ICL contexts from a mixture of random source languages is surprisingly more effective compared to linguistically similar and geographically similar languages.

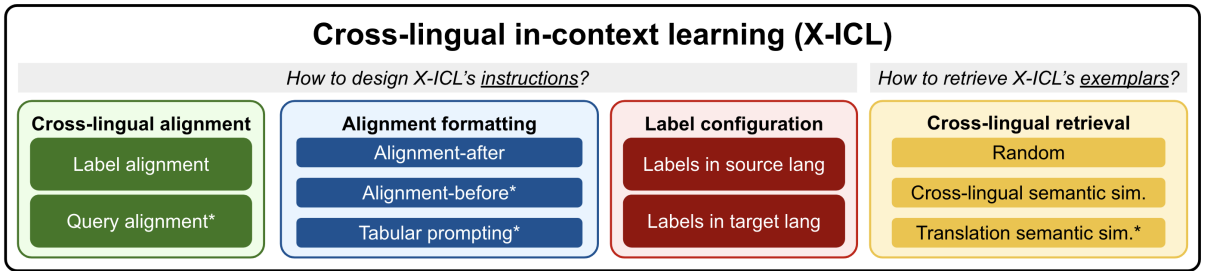

Figure 1: Framework of cross-lingual in-context learning (X-ICL) methods analyzed within our work. We explore various cross-lingual retrieval methods with different kinds of cross-lingual prompting strategies. *Original approaches.

Expanding the investigation to different aspects of cross-lingual transfers in X-ICL, Lin et al. (2022b) explores the use of various languages for instructions and exemplars. They find that incorporating English instructions notably improves zero-shot performance across multiple languages.

In a related vein, Tanwar et al. (2023) analyze the effect of cross-lingual prompt design for X-ICL across 3 text classification tasks using 44 different cross-lingual pairs. Their findings emphasize the limitations of random exemplar selection and propose the use of semantic-based exemplar retrieval and label alignment[1] for superior X-ICL performance. Notably, their findings diverge from our results (§5.1), which contend that label alignment does not provide benefits for X-ICL.

2.2 LLMs on Low-Resource Languages

Rigorous evaluations have been proposed to investigate how LLMs perform on low-resource languages. According to (Cahyawijaya et al., 2023a), while multilingual LLMs typically exhibit positive transfer learning among related languages, these models perform notably better for mid- and high-resource (e.g., Indonesian and English) compared to low-resource languages (e.g., other 18 Indonesian indigenous languages). This implies a challenge in the generalization capability of existing multilingual LLMs to low-resource languages. This is further evidenced by (Cahyawijaya et al., 2023b), which extends the exploration to 12 low-resource and extremely low-resource languages, where both existing zero-shot prompting LLMs and fine-tuned pre-trained LMs struggle to outperform classical machine learning baselines, which is indicative of LLMs' limited ability to generalize to extremely low-resource languages that are significantly distinct from those encountered during their training. Similar observations have been reported by Asai et al. (2023); Bang et al. (2023); Adilazuarda et al. (2024) for lower-resource languages. Furthermore, another line of work emphasizes the challenges faced by multilingual LLMs in understanding (Zhang et al., 2023; Adilazuarda et al., 2023) and generating (Yong et al., 2023) code-switching, a real use case and nuance of multilingualism exhibited by human speakers.

3 Methods

Figure 1 presents the general framework of X-ICL, comprising: 1) cross-lingual in-context alignment (§3.1), 2) cross-lingual alignment formatting and 3) label configuration as parts of cross-lingual prompting (§3.2), as well as 4) cross-lingual retrieval (§3.3). We assess variations of these X-ICL aspects to understand their effectiveness on different language resource levels.

3.1 Cross-Lingual Alignment

Prior works showcase the benefit of cross-lingual in-context learning with random exemplars which can improve the zero-shot performance of LLMs on downstream tasks (Winata et al., 2021c; Shi et al., 2023; Asai et al., 2023). More recently, Tanwar et al. (2023) introduce cross-lingual in-context alignment that injects a label aligner to the prompt in between the in-context exemplars and the input query. The label aligner provides the translation of the source label set $C^{src} = \{c_1^{src}, c_2^{src}, \ldots, c_k^{src}\}$ to the target label set $C^{tgt} = \{c_1^{tgt}, c_2^{tgt}, \ldots, c_k^{tgt}\}$. For instance, given a target language L^{tgt}, the label aligner prompt is formatted as follow: "`In` L^{tgt}, c_1^{src} `means` c_1^{tgt}, c_2^{src} `means` c_2^{tgt}, `...,` `and` c_k^{src} `means` c_k^{tgt}". This allows the model to align labels between source and target languages. We call this method **in-context label alignment**.

As opposed to in-context label alignment, we explore another approach, dubbed **in-context query alignment**, which provides alignment of

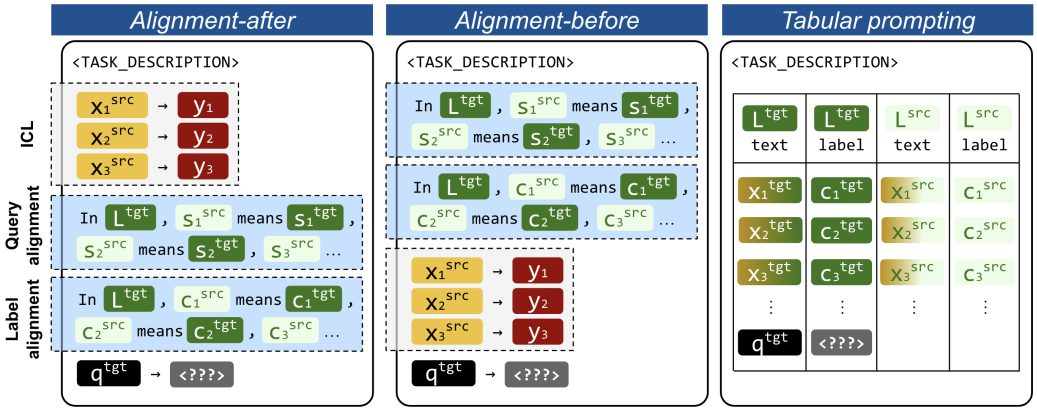

Figure 2: We explore 3 different alignment formats for X-ICL prompting, i.e., alignment-after, alignment-before, and tabular-prompting. From left to right, the prompt format has a higher degree of format consistency.

input distribution by providing the translation of sentences similar to the query while keeping the label set as is. To do so, we utilize the parallel exemplar dataset $D^{para} = \{(s_1^{src}, s_1^{tgt}), (s_2^{src}, s_2^{tgt}), \ldots, (s_m^{src}, s_m^{tgt})\}$, where (s_i^{src}, s_i^{tgt}) respectively denotes to a pair of parallel source and target sentences, and select the top-k most similar parallel pair by maximizing the monolingual similarity between the q^{tgt} with s_i^{tgt}. Given a target language L^{tgt}, the parallel pairs are then formatted into an input alignment prompt, i.e., "`In` L^{tgt}, s_1^{src} `means` s_1^{tgt}, s_2^{src} `means` s_2^{tgt}, ..., and s_k^{src} `means` s_k^{tgt}". We show the example query for in-context label alignment and in-context query alignment in Appendix B.

3.2 Cross-Lingual Prompting

Although cross-lingual in-context alignment has shown improvements as reported in (Tanwar et al., 2023), it introduces distortions to certain aspects of the Bayesian inference framework (Xie et al., 2022; Min et al., 2022) underlying in-context learning. Notably, this method compromises the formatting consistency and output distribution of the prompt. While the label aligner is expected to align the output distribution between the source and target labels, it is merely an idealistic assumption, which might not be the case in real cases. To better align with the Bayesian inference framework, we explore two cross-lingual prompt adjustments, i.e., alignment formatting and label configuration.

Alignment Formatting Existing X-ICL with alignment approach (Tanwar et al., 2023) places the alignment between ICL exemplars and the input query (dubbed as **alignment-after**). We argue that such abrupt changes in the prompt format might cause performance degradation. To improve the format consistency, we also explore two prompt formats for X-ICL: 1) **alignment-before** and 2) **tabular-prompting**. Alignment-before simply swaps the alignment text with the cross-lingual exemplars. This avoids the abrupt format change between the exemplars and the query such that the neighboring text span is more format-consistent. Tabular-prompting formats the prompt in the form of a table with multiple columns, which allows a consistent prompt format, but at the same time requires either a labeled parallel corpus or disrupting the input-output mapping through incorrect labeling (Min et al., 2022). The depiction of the prompt formats and the X-ICL alignment is in Figure 2.

Label Configuration To improve the output distribution consistency, we explore alternatives of using either **source-only labels** and **target-only labels** as opposed to **in-context label alignment** which shifts the language of the labels from the source language in the exemplars to the target language in q^{tgt}. These alternatives serve as a comparison to measure the effectiveness of in-context label alignment. In this study, we focus on English as the source language. Appendix F analyzes the use of other closely related source languages.

3.3 Cross-Lingual Retrieval

Another way to improve X-ICL performance is by improving the exemplar retrieval quality. Given an input query q^{tgt} and a source language exemplar dataset $D^{src} = \{(e_1^{src}, y_1^{src}), (e_2^{src}, y_2^{src}), \ldots, (e_n^{src}, y_n^{src})\}$, where e_1^{src} and y_1^{src} respectively denote the input and label of the exemplar, the goal of cross-lingual retrieval is to retrieve one or more labeled exemplars

Table 1: The datasets and languages under study. Our study covers 25 low-resource languages and 7 relatively higher-resource languages from various regions.

(e_i^{src}, y_i^{src}) semantically relevant to q^{tgt}. Most prior works in X-ICL (Winata et al., 2021a; Asai et al., 2023; Zhang et al., 2023; Lin et al., 2022a) incorporate random retrieval, while recently, Tanwar et al. (2023) utilize **cross-lingual semantic similarity** which significantly improves performance over the random retrieval.

Nevertheless, we argue that this approach might not be optimal in the case of low-resource languages as the semantic representation for these languages might not be well aligned with the high-resource languages (see Appendix C). Thus, we explore **translation semantic similarity** as an alternative. It performs monolingual semantic similarity on q^{tgt} to obtain a sentence in L^{tgt} from a parallel dataset D^{para}, then uses monolingual semantic similarity on its pair in L^{src} to find the high-resource exemplars from D^{src}. Although the monolingual semantic similarity between two sentences from a low-resource language is also sub-optimal, this problem can be alleviated by incorporating other similarity metrics such as TF-IDF and bag-of-words. We denote ICL method using the translation semantic similarity as **T-ICL**. We show this analysis in Appendix C along with the depiction of the cross-lingual retrieval methods.

4 Experimental Settings

4.1 Retrieval and In-Context Learning Setup

To calculate the cross-lingual and monolingual semantic similarity, we utilize multilingual sentence transformers (Reimers and Gurevych, 2019, 2020).[2] For all ICL experiments, we conduct ICL with 3-shot ICL exemplars. We run our experiments using two LLMs: XGLM-7.5B (Lin et al., 2022b) and BLOOM-7B (Scao et al., 2022). To select the prediction label, we take the label that maximizes the marginal probability of the prompt:

[2]As our semantic similarity model, we utilize `sentence-transformers/stsb-xlm-r-multilingual`

Eval Dataset	D^{src}	D^{para}
NusaTranslation	NusaX-Senti (Winata et al., 2022b)	NusaX-MT (Winata et al., 2022b)
MasakhaNews	MasakhaNews (Eng Train set)	MAFAND (Adelani et al., 2022a)
AmericasNLI	XNLI (Eng) (Conneau et al., 2018)	XNLI (Eng) $\bigoplus$ AmericasNLI (Dev set)*
Tweet Sentiment Multilingual	Tweet Sentiment Multilingual (Eng Train set)	Tweet Sentiment Multilingual (Eng MT)†

Table 2: The D^{src} and D^{para} for all the evaluation datasets under study.† Translated to English using NLLB (Team et al., 2022).* We align the two datasets.

$$c^{pred} = \arg\max_c P(X^{icl}, X^{align}, q^{tgt}, c) \quad (1)$$

$$= f(X^{icl} \oplus X^{align} \oplus q^{tgt} \oplus c) \quad (2)$$

where $f(.)$ denotes a language model, $\oplus$ denotes the concatenation operator, X^{icl} denotes the ICL exemplars, X^{align} denotes the alignment text, and c denotes the class label taken from the label set.

4.2 Languages and Datasets

As shown in Table 1, our study includes 25 low-resource languages from three different regions, i.e., Africa, Americas, and South-East Asia, covering 13 language families. Note that, many of the low-resource languages are unseen to both XGLM and BLOOM, nonetheless, both models might have seen other languages under the same language family group with those low-resource languages, e.g., both models are pre-trained on Indonesian, which falls under the same language family group (i.e., Malayo-Polynesian) to the low-resource languages in Indonesia. We also include 7 relatively higher-resource languages, i.e., Arabic (arb), French (fra), German (deu), Hindi (hin), Italian (ita), Portuguese (por), and Spanish (spa) for comparing the behavior of X-ICL between these relatively higher-resource languages and low-resource languages. Detailed information on all the languages under study is shown in Appendix A.

All the languages are spread across four different datasets, i.e., MasakhaNews (**topic classification**) (Adelani et al., 2023), AmericasNLI (**natural language inference**) (Ebrahimi et al., 2022b), NusaTranslation (**sentiment analysis**) (Cahyawijaya et al., 2023b), and TweetSentimentMultilingual (**sentiment analysis**) (Barbieri et al., 2022). For each dataset, we defined the ICL dataset D^{src} and parallel alignment dataset D^{para} from different dataset subsets or completely different datasets. The details are shown in Table 2. Note that, we only take languages that are supported in NLLB (Team

et al., 2022), such that we can compare the performance with machine-translation-based approaches. For the monolingual semantic similarity baselines, we utilize the train and dev sets of the evaluation dataset.

5 Result and Discussion

The per-dataset results of our experiments are shown in Appendix H. For brevity, we report the analysis mainly for XGLM-7.5B, since we observe that the BLOOM-7B results are similar. We show the results for BLOOM in Appendix G.

5.1 Inferiority of In-Context Label Alignment

Figure 3 shows the comparison of **in-context label alignment** with uniform **source-only** and **target-only** labels. In most languages, in-context label alignment yields lower performance than target-only label, and source-only label yields the best performance. For low-resource African languages, the target-only label performs much worse. We conjecture that this is due to the weak representation of these languages, which is less apparent in low-resource Indonesian and American languages because the target labels (see Appendix D) are similar to higher-resource languages in training. Contrary to Tanwar et al. (2023), our results highlight the ineffectiveness of **in-context label alignment** to improve X-ICL on both higher-resource and low-resource languages.

5.2 In-Context Query Alignment

We introduce in-context query alignment as an alternative to in-context label alignment in §3.1. As shown in Figure 4, **in-context query alignment** yields similar performance with the baseline (i.e., without query alignment) on higher-resource languages while improving zero-shot performance on low-resource languages. Nonetheless, the improvement is rather marginal in the X-ICL setting on low-resource languages. In this case, we conclude that in-context query alignment can be used as an alternative to X-ICL, which is favorable when there is no available X-ICL corpus for the particular task. With the recent development of large multilingual parallel corpora, such as Bloom Library (Leong et al., 2022), WikiMatrix (Schwenk et al., 2021),

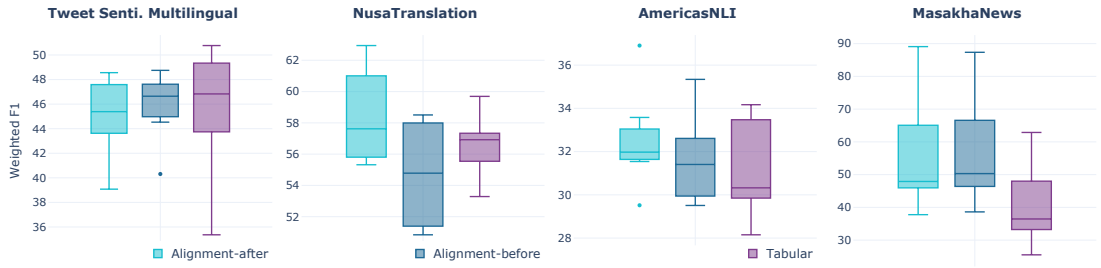

Figure 6: Performance of XGLM-7.5B with different alignment formats ordered by the degree of formatting consistency on **(1)** higher-resource languages, **(2)** low-resource Indonesian languages, **(3)** low-resource American languages, and **(4)** low-resource African languages.

CC-Aligned (Chaudhary et al., 2019; El-Kishky et al., 2020), FLORES-200 (Team et al., 2022), and GATITOS (Jones et al., 2023), in-context query alignment can also be a perfect complement to X-ICL for improving LLMs understanding on thousands of languages.

Label Alignment vs Query Alignment To investigate how well in-context alignments can affect the understanding of all the languages under study, we analyze their effectiveness by comparing them with the corresponding non-alignment baseline. As shown in Figure 5, in-context label alignment only improves the performance at ∼11.54% of the time with an improvement of ∼5% weighted F1, while the rest 88.46% experiments are decreased by ∼20% weighted F1. In-context query alignment, on the other hand, increases the performance 56.25% of the time with an improvement of ∼10% weighted F1, while the rest 43.75% of the time experiences a reduction of ∼5% weighted F1. Our results suggest that **in-context query alignment** is superior to **in-context label alignment**, and it improves LLMs' understanding of low-resource languages in the absence of X-ICL task-specific data, which leads to performance gain.

5.3 Why Query Alignment Performs Better

In regards to the in-context alignment, we can first simplify the effect of alignment into the following two possibilities: 1) when the alignment is successful (upper bound) and when no alignment is done (lower bound). When The LLM successfully aligns the query in the source language to the target language, query alignment will enable the LLM to understand the query in the target as well as in the source languages, the LLM will reach a performance similar to monolingual ICL, which is the upper bound performance. While in label alignment, when the LLM successfully aligns the label in the source to the target languages, the LLM understands the label semantics, but there is no guidance on how to interpret the query in the target language. In this case, the upper bound will be equivalent to performing X-ICL which generally performs slightly worse than monolingual high-resource language ICL which is reflected in our result in §5.6.

When the LLM completely fails to align the label in the source to the target languages, in the query alignment, the LLM performs a regular X-ICL, which is similar to the best case of the label alignment. While in the label alignment, the LLM performs X-ICL with a shifted label space. The harmful effect of ICL with a shifted label space has been extensively studied in (Min et al., 2022), which results in severe performance degradation. With regards to the two possibilities, the upper-bound and lower-bound of in-context query alignment are better than label alignment, thus query alignment outperforms label alignment on average. In a more realistic scenario, there is also another factor where the alignment text becomes the noise that will shift the output prediction of the LLMs. As the noise factor happens for both query and label alignment, we can assume the same effect of noise for both methods and omit this factor into account, resulting in the same conclusion.

5.4 Effect of Format Consistency

We explore three types of prompting with various degrees of formatting consistency (§3.2). As shown in Figure 6, for higher-resource languages, formatting consistency correlates to a slight improvement in the downstream performance for both XGLM and BLOOM (see Appendix G) models. Meanwhile, for low-resource languages, the trend for both models is unclear. We conjecture that increasing the format consistency can improve the downstream task performance on well-represented

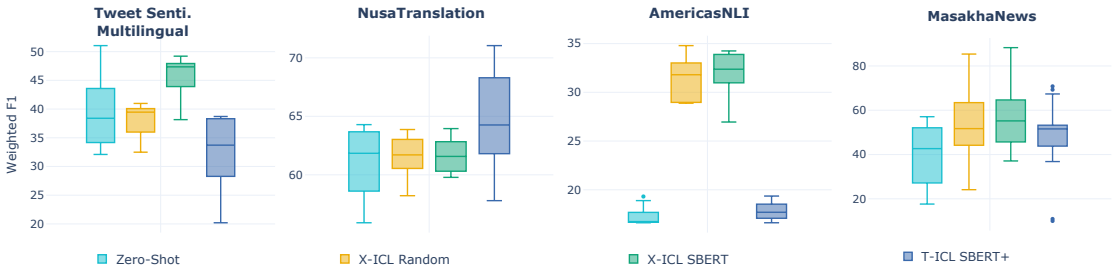

Figure 7: Performance of XGLM-7.5B with different in-context learning retrievals covering monolingual, cross-lingual, translation semantic similarity (T-ICL) on **(1)** higher-resource languages, **(2)** low-resource Indonesian languages, **(3)** low-resource American languages, and **(4)** low-resource African languages. Random and SBERT denotes random and semantic-similarity-based exemplar selection, respectively.

languages. For low-resource languages, increasing the format consistency will not improve the model understanding. Increasing the representation through X-ICL and query alignment would be a better alternative to improve the low-resource language understanding ability of LLMs.

5.5 Importance of Cross-Lingual Retrieval

Cross-Lingual Semantic Similarity We compare the effectiveness of cross-lingual semantic similarity to monolingual and translation semantic similarity for retrieving ICL and X-ICL exemplars. Based on Figure 7, X-ICL and ICL with cross-lingual and monolingual semantic-similarity-based retrieval, respectively, perform better than zero-shot prompting, suggesting the effectiveness of these approaches for improving the task understanding of LLMs. In addition, we show that translation semantic similarity performs almost on par with the zero-shot baseline. We hypothesize that this problem is attributed to the error propagation of the pipelined nature of the translation semantic similarity system and the limited coverage of parallel exemplars in D^{para}, showing the benefit of using direct cross-lingual semantic similarity retrieval over translation-based retrieval. Furthermore, the performance of cross-lingual semantic similarity is similar to or slightly lower than the monolingual semantic similarity approach. Hence, cross-lingual semantic similarity retrieval is important in the case where the corpus for performing monolingual ICL on a particular task is not available.

Variations of Semantic Similarity Models We further compare the effectiveness of varying the cross-lingual semantic similarity models for cross-lingual retrieval. As shown in Figure 8, all cross-lingual semantic similarity models outperform the zero-shot baseline. Interestingly, despite the reported inferiority of STS-tuned models over paraphrasing-tuned models and LaBSE in prior works (Reimers and Gurevych, 2019, 2020; Feng et al., 2022), our results showcase otherwise. On average, XLMR STS performs on par with other models, gaining a better performance on high-resource languages while getting a worse performance on low-resource languages. We find that, depending on the language under study, the choice of cross-lingual semantic similarity models can play a huge role in the downstream performance of X-ICL.

5.6 Is X-ICL Effective for low-resource Languages?

To analyze the effectiveness of X-ICL in low-resource languages, we compare X-ICL with other inference approaches. Specifically, we compare X-ICL with 3 other baselines: 1) monolingual **ICL** that performs inference using ICL from the same language as the query, 2) **translate-test** that translates the query and performs zero-shot inference in a high-resource language, i.e., English, and 3) **translate-test ICL** that simply combines **translate-test** and monolingual **ICL**. We measure the ΔWeighted F1 against a simple **zero-shot prompting** over all languages under study. For all experiments that include translation, we utilize MT models from NLLB (Team et al., 2022).[3]

Based on our experiment results shown in Figure 9, the **translate-test** slightly improves the performance from the zero-shot baseline in BLOOM and XGLM, while **in-context query alignment** only improves zero-shot performance on XGLM. This indicates that alignment information only offers a limited benefit to improving LLMs' understanding. Additionally, all ICL approaches improve the performance over zero-shot prompting in most

[3] https://huggingface.co/facebook/nllb-200-distilled-1.3B

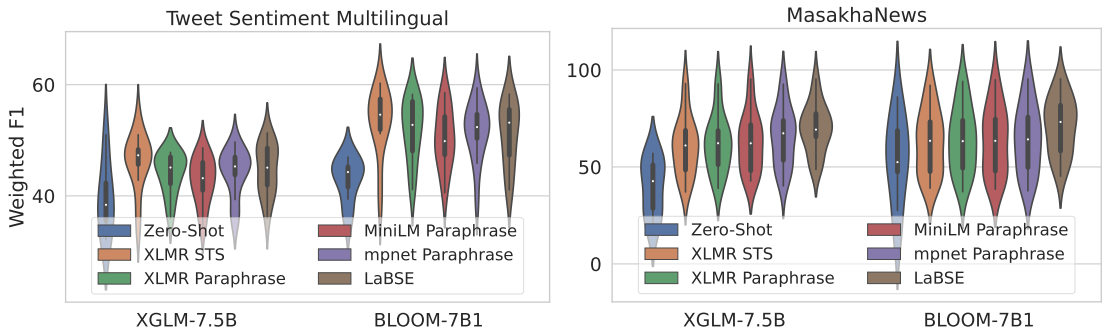

Figure 8: Performance of LLMs with different semantic similarity models on **(left)** higher-resource languages and **(right)** low-resource African languages.

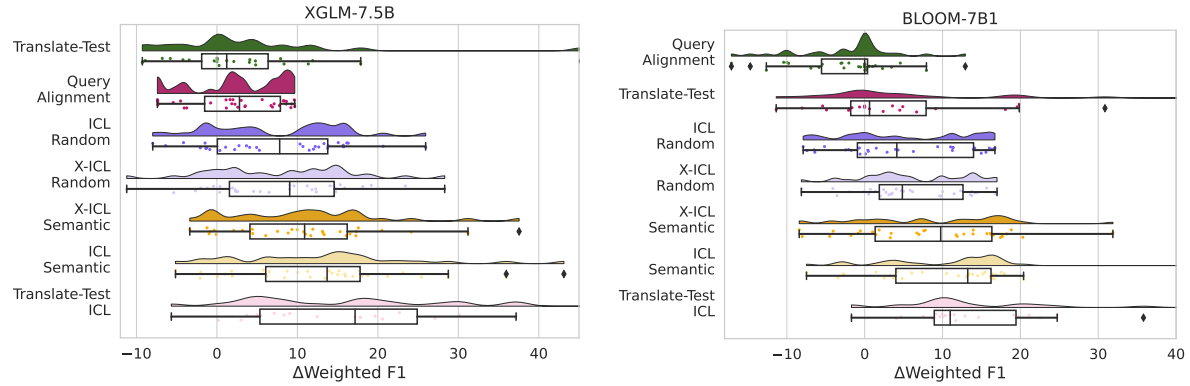

Figure 9: Gain/Loss of various test-time adaptation methods for low-resource languages using **(top)** XGLM-7.5B and **(bottom)** BLOOM-7B1 backbones.

cases. All approaches with similarity-based retrieval, i.e., **ICL Semantic** and **X-ICL Semantic** achieve higher scores than random retrievals, i.e., **ICL Random** and **X-ICL Random**, showing the importance of semantic similarity for exemplar retrievals. Interestingly, **X-ICL Semantic** yields a similar performance to **ICL Semantic**, which utilizes the target language exemplars. This indicates X-ICL can be a good alternative for low-resource languages as the available data in the specified low-resource language are commonly very limited. Above all, **translate-test ICL** yields the highest improvement amongst all methods, but this only happens when the machine translation quality is above a certain quality standard. We ablate the effect of machine translation quality to the **translate-test ICL** performance on Appendix E.

To conclude, we offer the following suggestions to improve the low-resource language performance during inference: 1) When tackling low-resource languages, it is best to have a high-quality translation system accompanied by a source language task-specific data for **translate-test ICL**; 2) When there is no machine translation (MT) system for the specified language, it is best to use either **ICL** or **X-ICL** depending on the corpus availability; 3) When there is an MT system, but no task-specific data, **translate-test** is still the best option; and 4) When there is no high-quality MT system nor task-specific data, the best way is to use a parallel data to utilize **in-context query-alignment**.

6 Conclusion

We systematically investigate the application of X-ICL with LLMs, focusing on low-resource languages. Our comprehensive analysis sheds light on multiple facets of X-ICL with LLMs. Our examination of in-context alignment reveals the limitation of label alignment, thus we suggest a more effective alternative: query alignment. Efforts to enhance X-ICL via formatting consistency only exhibit a marginal impact on low-resource languages. Our exploration of exemplar retrieval approaches underscores the significance of employing cross-lingual semantic similarity in X-ICL. Lastly, we analyze the effectiveness of X-ICL in the context of low-resource languages. Despite being outperformed by translate-test ICL, X-ICL remains relevant, especially when there is no MT model available for the target language—a circumstance prevalent in low-resource language scenarios.

Ethics Statement

Our exploration of ICL and X-ICL methods addresses the linguistic data gap in low-resource languages. In scenarios where no monolingual corpus or machine translation system exists, our work underscores the significance of ICL and X-ICL as a viable solution. By investigating the limitations of in-context label alignment and proposing a more effective in-context query alignment approach, we aim to enhance the applicability of ICL and X-ICL on low-resource languages. This research is motivated by the need to provide computational solutions for languages lacking adequate linguistic resources for LM training. Despite the marginal effect brought by cross-lingual alignment compared to monolingual and translate-test ICL baselines, our findings emphasize that ICL and X-ICL are useful in scenarios where alternative resources are absent, promoting linguistic diversity and inclusivity in the development of language technologies. All the datasets used in our experiments follow the license and term of use of the datasets. Our ultimate goal is to promote linguistic diversity and contribute to a more inclusive NLP landscape providing social good through our work.

Limitation

Limited Coverage of low-resource Languages We put our best effort into collecting datasets from various low-resource languages and, in the end, we ended up with the three low-resource datasets, i.e, MasakhaNews (Adelani et al., 2023), NusaTranslation (Cahyawijaya et al., 2023b), and Americas-NLI (Ebrahimi et al., 2022a), which suits our cases as these languages have parallel datasets which correspond to one or more high-resource languages and have large enough high-quality labeled datasets for both ICL and evaluation purposes. Furthermore, our study covers broad enough linguistics aspects of multilingual and cross-lingual within these three datasets, including various linguistics distances with the source languages — from Nigerian Pidgin (pcm) to obscure regional languages such as Batak (btw), Hausa (hau), and Guarani (grn) —, broad linguistic and geographic diversity —the low-resource languages under study covers >10 language families from three different continents —, and the incorporation of different scripts between source and target languages — in the case of Amharic as a low-resource language and Arabic as a higher-resource language —. We leave the study of other and broader scales of low-resource languages for future work.

Choice of Multilingual High-Resource Language Datasets Prior work on X-ICL with alignment (Tanwar et al., 2023) conduct their study on Multilingual Amazon Review Corpus (MARC) (Keung et al., 2020), Cross-language Sentiment (CLS) (Prettenhofer and Stein, 2010), and HatEval (Basile et al., 2019). We considered using these datasets as our high-resource languages dataset. Nonetheless, we found that both MARC and CLS datasets are no longer available [4], leaving us with only HatEval dataset. Since HatEval only covers English and Spanish, we do not incorporate it in our study. Instead, we incorporate the TweetSentimentMultilingual dataset (Barbieri et al., 2022) which covers 7 relatively high-resource languages in our study. We leave the exploration of other high-resource languages to future work.

Task Coverage Given the nature of low-resource languages, there are only a handful of datasets available as downstream tasks. We suggest future works to explore the generalization of our approach to a broader task coverage, especially on datasets that cover more culturally relevant nuances of the corresponding low-resource language (Aji et al., 2022b; Kabra et al., 2023).

Exploration on Larger LLMs We conduct all of our experiments with a single RTX3090 (24GB) GPU. Due to the large cost of inference and limited computation budget, we do not experiment on larger multilingual LLMs such as Falcon (Almazrouei et al., 2023) and MPT (Team, 2023). Nonetheless, exploration on incorporating ICL and X-ICL with random exemplar retrieval with larger LLMs and the scaling effect on low-resource settings, such as low-resource languages and code-switching, have been discussed in prior works (Zhang et al., 2023; Asai et al., 2023). We hypothesize that the scaling behavior of our work will follow the same trend and we expect future work to verify our hypothesis.

[4] We checked the MARC dataset from the Hugging Face hub URL (https://huggingface.co/datasets/amazon_reviews_multi) and the original Amazon Web Service S3 Bucket (https://s3.console.aws.amazon.com/s3/buckets/amazon-reviews-ml). While for the CLS dataset, we checked the original dataset link in the paper (http://www.webis.de/research/corpora/webis-cls-10/).

A Languages Under Study

We conduct experiments on 32 languages, with 25 low-resource languages and 7 relatively high-resource languages. We provide the detailed list of all the languages under study in Table 3.

Language Code	Language Name	Dataset Name	Test Size	Geographic Region	Language Family	%BLOOM Pretraining	%XGLM Pretraining
btk	Batak	NusaTranslation	1200	South-East Asia	Austronesian	-	-
sun	Sundanese	NusaTranslation	1200	South-East Asia	Austronesian	-	-
jav	Javanese	NusaTranslation	1200	South-East Asia	Austronesian	-	-
mad	Madurese	NusaTranslation	1200	South-East Asia	Austronesian	-	-

Table 3: List of languages under study. "-" denotes the language is not on the pre-training dataset, while 0.00% denotes a very small percentage (<0.01%) of the pre-training data is in that language.

B Alignment Prompt

We showcase the example prompt for cross-lingual in-context learning, in-context label alignment, and in-context query alignment in Figure 10.

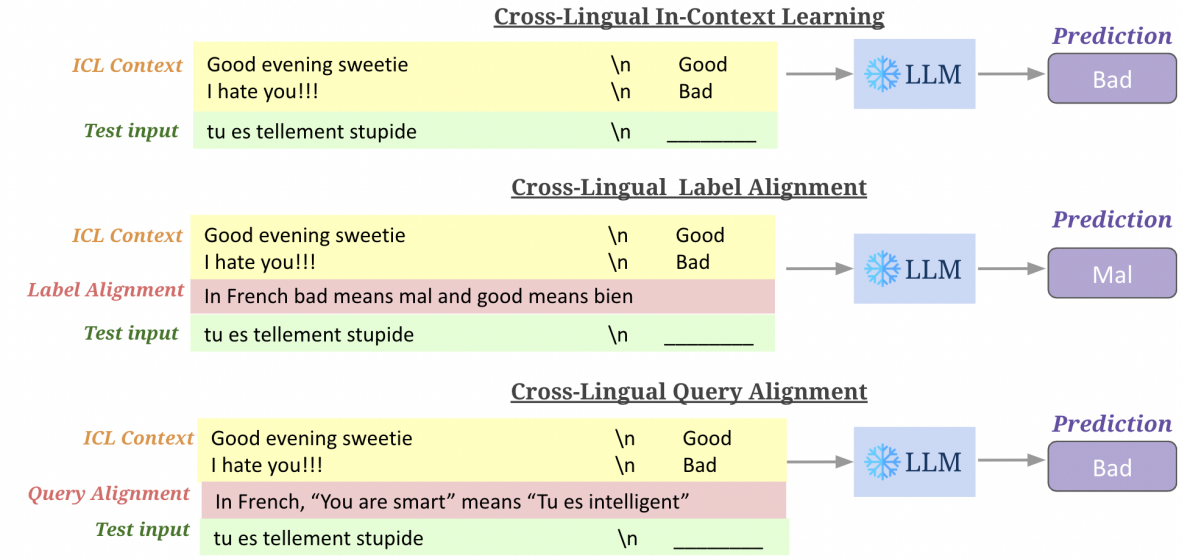

Figure 10: Example prompt for in-context label alignment and in-context query alignment.

C Analysis on Cross-lingual Semantic Similarity

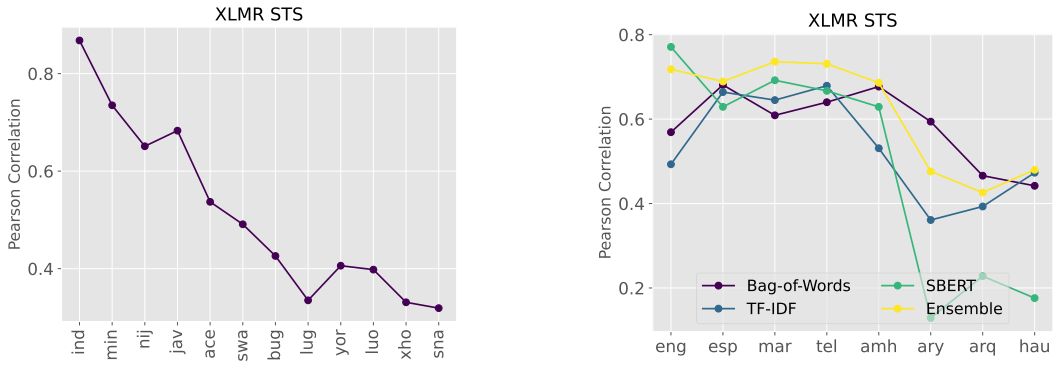

Figure 11: **(top)** Correlation of cross-lingual similarity with the correct label for the XLMR STS model. **(bottom)** Correlation of monolingual similarity with the correct label for the XLMR STS model.

We showcase that the semantic representation for these languages might not be well aligned with the high-resource languages. We construct sentence similarity dataset covering 26 languages by utilizing the translation samples from two machine translation datasets, i.e., MAFAND (Adelani et al., 2022a) and NusaX-MT (Winata et al., 2022b). We create a balanced dataset with 50% positive pairs and 50% negative pairs over all 26 languages. We measure the cross-lingual semantic similarity performance of using Sentence Transformers (Reimers and Gurevych, 2019). We also conduct monolingual semantic similarity analysis for various languages using the data from SemEval 2024 Task 12: Textual Semantic Relatedness dataset [5]. For the monolingual semantic similarity we add additional word frequency features including bag-of-words and TF-IDF to improve the retrieval quality of the semantic similarity model.

As shown in Figure 11, both monolingual and cross-lingual semantic similarity on more low-resource languages are generally yield a much lower correlation which signifies the limitation of the sentence

[5] https://github.com/semantic-textual-relatedness/Semantic_Relatedness_SemEval2024

embedding model to represent the sentences on these languages. Nevertheless, for monolingual semantic similarity, it is possible to improve the similarity on these low-resource languages with minimal trade off on the other language by employing character/word frequency features to support the semantic similarity model. With that in mind, we explore an alternative approach for cross-lingual retrieval by using monolingual semantic similarity and an external parallel corpus. We called this semantic similarity method as **translation semantic similarity**. The comparison of cross-lingual retrieval using cross-lingual semantic similarity and translation semantic similarity is shown in Figure 12.

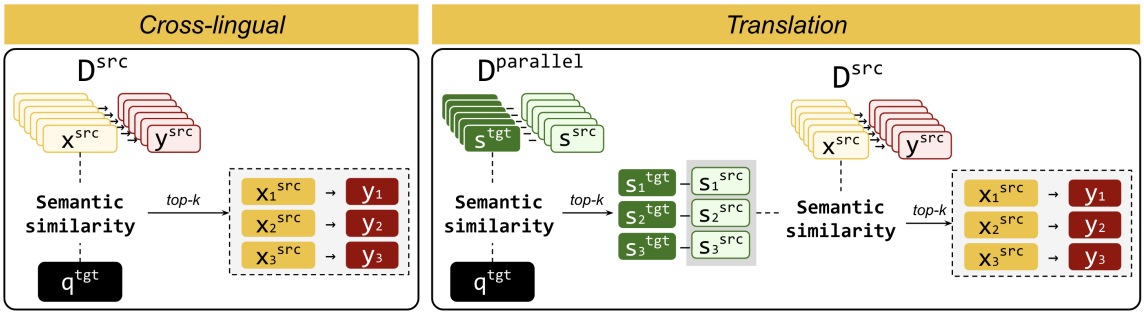

Figure 12: We explore two semantic similarity methods for cross-lingual exemplar retrieval in X-ICL, i.e., cross-lingual semantic similarity and translation semantic similarity (T-ICL).

Pearson Correlation w/ chrF++				**0.416**	**0.102**	**0.247**	**0.238**

Table 8: Performance of NLLB 1.3B model on FLORES-200 with the machine-translated zero-shot and few-shot ICL performance of XGLM and BLOOMZ using the corresponding NLLB translation.

We showcase that the MT model performance plays a huge role in determining the language understanding quality through machine translation (MT). We showcase the MT model performance on the devtest subset of FLORES-200 (Goyal et al., 2022) along with the zero-shot with MT and few-shot ICL with MT performance in Table 8. The zero-shot (MT) performance has a low-to-moderate correlation with the machine translation quality (chrF++) of the model (0.416 for XGLM and 0.247 for BLOOMZ), while the few-shot ICL (MT) has a lower correlation (0.102 for XGLM and 0.238 for BLOOMZ) potentially due to the effect of other factors such as the semantic similarity exemplar selection and the quality of the ICL data itself. Our result indicates that, despite being effective for language understanding, the MT-based zero-shot and few-shot inference approach depends on the quality of the machine translation models. Moreover, an MT-based solution might not work as well for cultural-specific tasks which have been addressed in various works (Kabra et al., 2023; Koto et al., 2023; Wibowo et al., 2023).

F Effects of Source Languages

We explore alternative source languages for NusaTranslation (Cahyawijaya et al., 2023b). For NusaTranslation we utilize Indonesian as the source language because Indonesian is the closely related to the languages under study on the corresponding dataset and is widely spoken languages in the respective region. We modify both the prompt language and the source ICL dataset D^{src}.

The result is shown in Figure 13. We can clearly see that in most cases, using English as the source language tends to produce better score than these closely related languages. Similar observation is also reported in prior works (Cahyawijaya et al., 2023a; Asai et al., 2023) which evaluates the prompt using different prompt language. Our experiment further extend the generalization to the X-ICL setting, where X-ICL using English exemplars outperforms X-ICL with a more closely related languages exemplars.

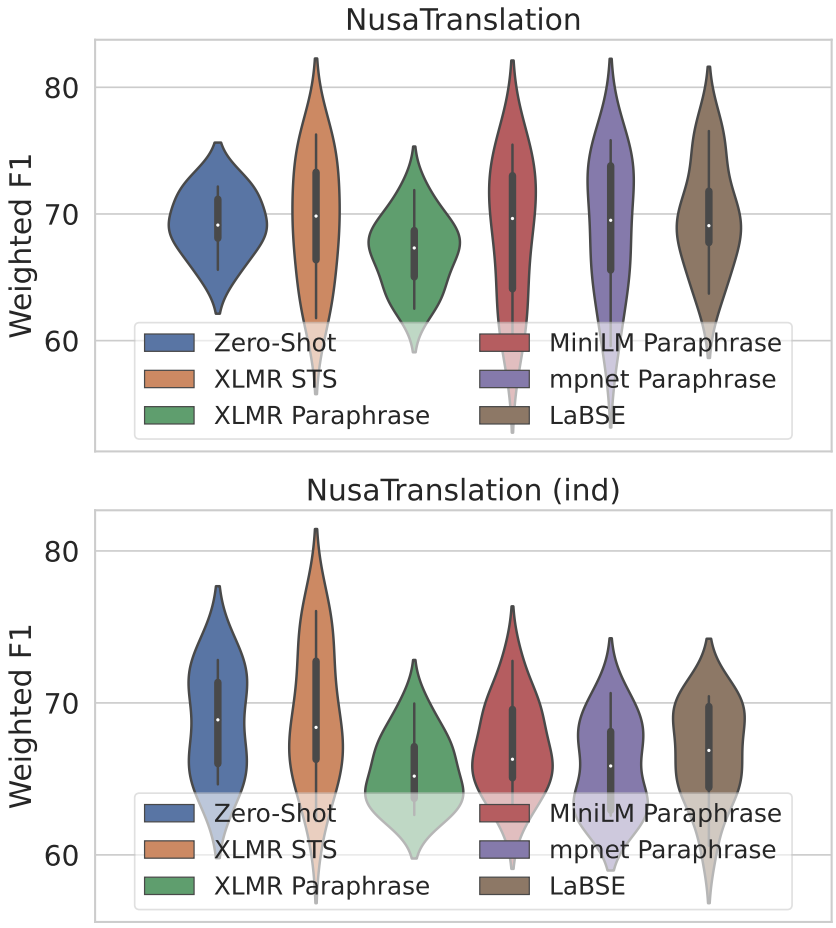

Figure 13: Performance of BLOOM-7B1 on NusaTranslation using **(top)** English prompt with English ICL exemplars and **(bottom)** Indonesian prompt with Indonesian ICL exemplars.

G Visualization of BLOOM Result

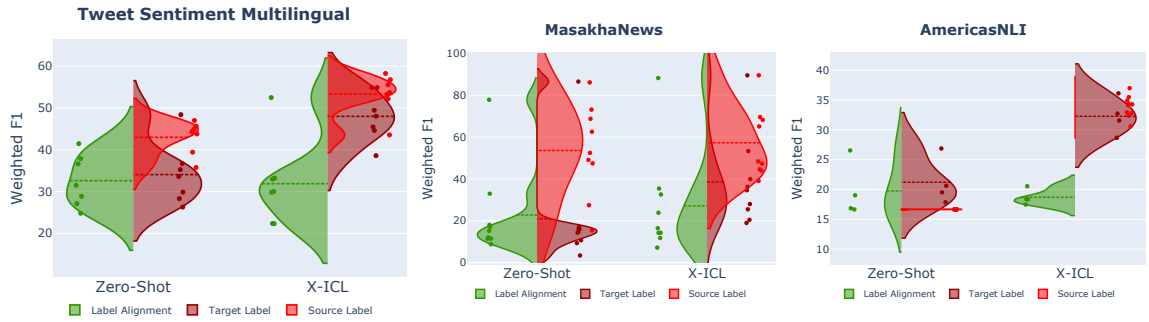

Figure 14: Performance of BLOOM-7B1 with in-context label alignment, target-only label, and source-only label on **(left)** higher-resource, **(center)** low-resource African, and **(right)** low-resource American languages.

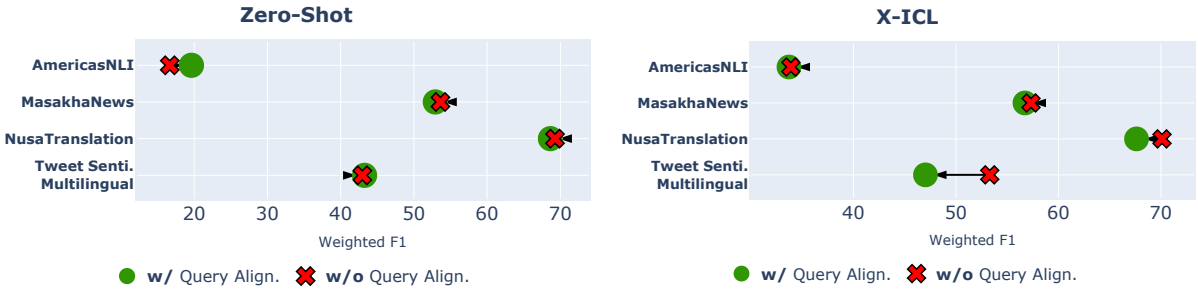

Figure 15: Performance of BLOOM-7B1 with and without query alignment on **(left)** higher-resource, **(center)** low-resource African, and **(right)** low-resource American languages.

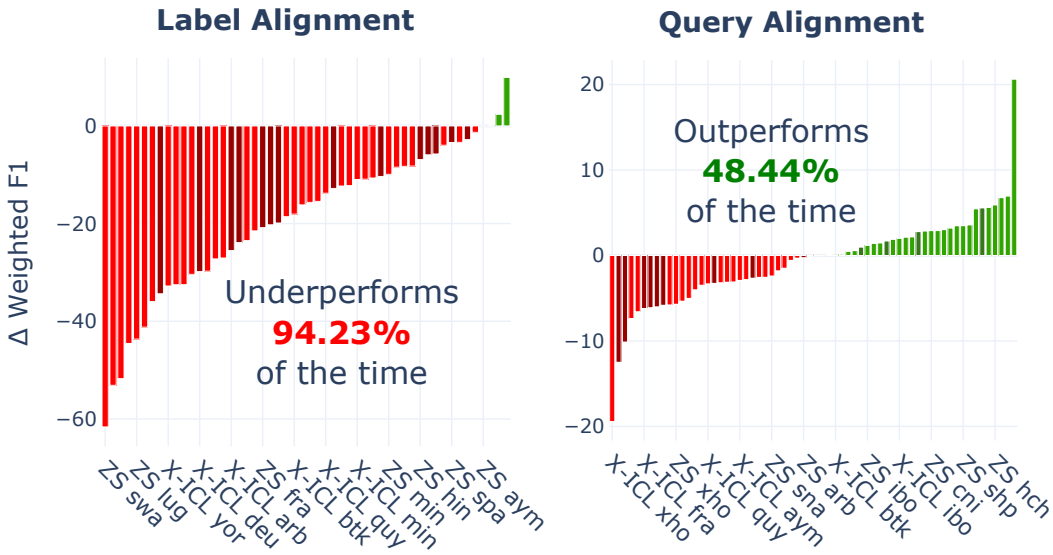

Figure 16: ΔWeighted F1 of **(left)** in-context label alignment and **(right)** in-context query alignment against non-alignment baseline. A score < 0 indicates the in-context alignment degrades the performance.

H Detailed Per Dataset Results

The detailed the main results for each different inference type for XGLM-7.5B in Table 9, Table 10, Table 11, and Table 12 for TweetSentimentMultilingual MasakhaNews, NusaTranslation, AmericasNLI,

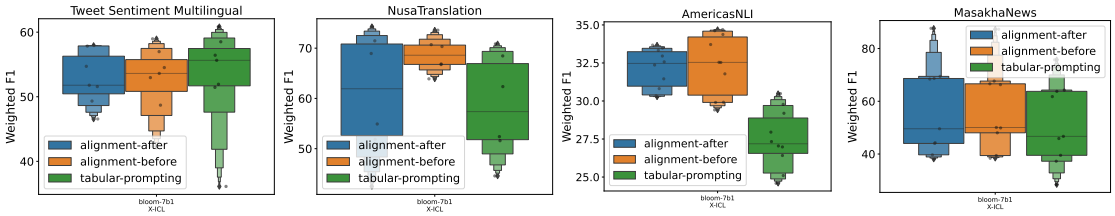

Figure 17: Performance of BLOOM-7B1 with different alignment formats ordered by the degree of formatting consistency on **(1)** higher-resource languages, **(2)** low-resource Indonesian languages, **(3)** low-resource American languages, and **(4)** low-resource African languages.

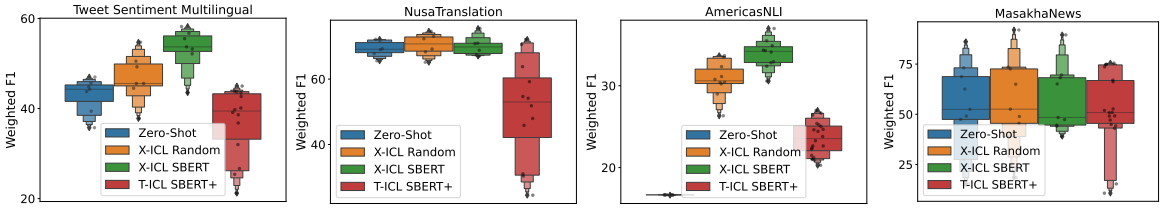

Figure 18: Performance of BLOOM-7B1 with different in-context learning retrievals covering monolingual, cross-lingual, translation semantic similarity on **(1)** higher-resource languages, **(2)** low-resource Indonesian languages, **(3)** low-resource American languages, and **(4)** low-resource African languages.

respectively. The detailed results for each different inference type for BLOOM-7B1 in Table 13, Table 14, Table 15, and Table 16 for TweetSentimentMultilingual MasakhaNews, NusaTranslation, AmericasNLI, respectively.

Simple and effective data augmentation for compositional generalization

Yuekun Yao and **Alexander Koller**

Abstract

Compositional generalization, the ability to predict complex meanings from training on simpler sentences, poses challenges for powerful pretrained seq2seq models. In this paper, we show that data augmentation methods that sample MRs and backtranslate them can be effective for compositional generalization, but only if we sample from the right distribution. Remarkably, sampling from a uniform distribution performs almost as well as sampling from the test distribution, and greatly outperforms earlier methods that sampled from the training distribution. We further conduct experiments to investigate the reason why this happens and where the benefit of such data augmentation methods come from.

1 Introduction

Compositional generalization is the ability of a system to correctly predict the meaning of complex sentences when trained only on simpler sentences (Lake and Baroni, 2018; Keysers et al., 2020). It has been studied in particular detail in the context of semantic parsing, the task of mapping sentences to symbolic meaning representations. Recent findings suggest that even powerful pretrained seq2seq models such as BART (Lewis et al., 2020) and T5 (Raffel et al., 2020), which excel at broad-coverage semantic parsing (Bevilacqua et al., 2021), perform very poorly on compositional generalization (Yao and Koller, 2022).

One promising method for compositional generalization is data augmentation (Andreas, 2020; Yang et al., 2022; Qiu et al., 2022). The idea is to generate additional training data by sampling from an *augmentation distribution*, in the hope that a model trained on the augmented data will generalize better to the out-of-distribution test data. Data augmentation for semantic parsing is complicated by the fact that it needs to recombine matching pieces of the sentence and of the meaning representation, but this matching is not made explicit in the training data. Many approaches therefore use somewhat complex methods to e.g. induce synchronous grammars (Qiu et al., 2022). As a simpler alternative, Wang et al. (2021) proposed to learn only a grammar for generating meaning representations, and then to use backtranslation to map the sampled meaning representations into sentence-MR pairs.

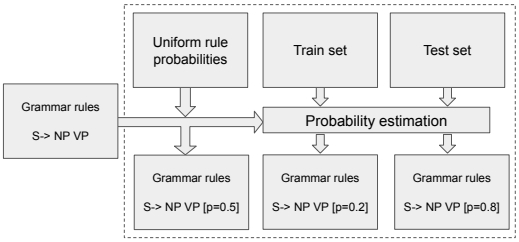

Figure 1: A diagram to show data augmentation from different distributions with PCFG.

The effectiveness of a data augmentation regime depends on the distribution from which the augmented data is sampled. Wang et al. (2021) sample from the *training* distribution and find that this improves semantic parsing accuracy on out-of-distribution text-to-SQL tasks. However, it is not clear that augmenting from the training distribution is universally helpful, especially on compositional generalization tasks where the test instances are deliberately designed to be unlikely under the training distribution.

In this paper, we investigate the impact that the choice of augmentation distribution has on the ability of a semantic parser to generalize compositionally. We compare Wang et al.'s approach (fit a grammar for meaning representations to the *training* data) to an approach where we fit the MR grammar to the *test* data (as an upper bound). Finally, we look at an MR grammar with *uniform rule weights*. Figure 1 shows the difference between these three methods. In an evaluation across four compositional generalization datasets (COGS, CFQ, GeoQuery, SCAN), we find that augmentation based

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 434–449
June 16-21, 2024 ©2024 Association for Computational Linguistics

on the test data strongly outperforms augmentation based on the training data; but surprisingly, augmentation with the uniform grammar is almost as effective as augmentation from the test data. This can be partially explained by the ability of the uniform grammar to contribute unseen local structures (Bogin et al., 2022) and assign low perplexity to the test MRs. Our findings point to a remarkably simple method for effective data augmentation for compositional generalization: obtain a grammar for the meaning representations (a formal language), set uniform rule weights, sample, and backtranslate.

We will release our code online [1].

2 Related work

Compositional generalization Compositional generalization has been shown challenging for neural sequence-to-sequence models. For example, Lake and Baroni (2018) shows that LSTM (Hochreiter and Schmidhuber, 1997) fails to generalize to new combinations or longer sequences of symbolic commands; Kim and Linzen (2020) shows that both LSTM and Transformers (Vaswani et al., 2017) cannot generalize to complex linguistic structures; Yao and Koller (2022) find that structural generalization, a difficult compositional generalization type, is consistently hard for BART and T5; Bogin et al. (2022) find that unobserved local structures can explain the difficulty of compositional generalization across multiple tasks.

Data augmentation The idea of augmenting the training data with synthetic instances originates in low-resource NLP tasks. For semantic parsing, Jia and Liang (2016) induced a synchronous CFG from the training set using domain-specific heuristics. Yu et al. (2018) and Zhong et al. (2020) generate new sentence-SQL pairs by identifying complex SQL patterns in the training set and filling their slots with different table or column names.

Data augmentation also successfully improves compositional generalization. Andreas (2020) propose a heuristic for sampling new parallel data by replacing tokens in training samples with similar tokens sharing the same context; Yang et al. (2022); Li et al. (2023) extend this idea by exchanging subtrees and spans to leverage linguistically rich phrases. Compared to their methods, we sample arbitrary meaning representations that can be derived from our hand-written grammar.

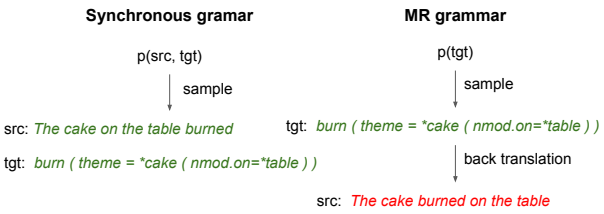

Figure 2: Comparison of different data augmentation methods based on COGS meaning representation.

Qiu et al. (2022) propose a data augmentation procedure based on inducing probabilistic quasi-synchronous grammars from the training data. Although their system achieves promising results, it requires a complicated algorithm to induce clean grammar rules. Oren et al. (2021) also propose to sample structurally diverse synthetic data from a manually designed synchronous context-free grammar. Compared to these works, our method only considers a grammar of the meaning representation, which is easy to access.

Similar to our method, Guo et al. (2021) adopt iterative back-translation for compositional semantic parsing, but they directly use a subset of meaning representations from development or test set as augmented meaning representations. Our work instead shows that meaning representations generated from a probabilistic grammar still work.

Closest in spirit to this paper is the work of Wang et al. (2021), who also sample only meaning representations and generate input sentences through backtranslation. Figure 2 illustrates their method. The key difference to our work is that we explore the impact of augmentation distributions.

3 Methodology

Our method consists of two steps: sample meaning representations and then backtranslate them into natural language sentences. It exploits the fact that in many realistic use cases of a semantic parser, one can generate arbitrary amounts of symbolic *meaning representations* from a grammar: These are from a formal language, and the developer of a semantic parser either has access to a grammar for this formal language or can easily write one.

3.1 Data augmentation

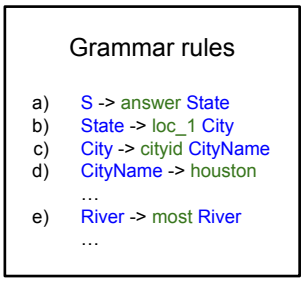
Context-free grammar For a semantic parsing task, we assume as given a context-free grammar

[1] https://github.com/coli-saar/data-augmentation-compgen

that describes all possible meaning representations. Figure 3 shows an example. Figure 3a shows part of our grammar for the GeoQuery dataset, which consists of multiple production rules. Based on these rules, we can parse a meaning representation *answer (loc_1 (cityid (houston, _)))* as shown in Figure 3b. In a probabilistic context-free grammar (PCFG), each production rule has a rule probability. The probability of a parse tree can be calculated as the product of the probability of each production rule that constitutes the parse tree.

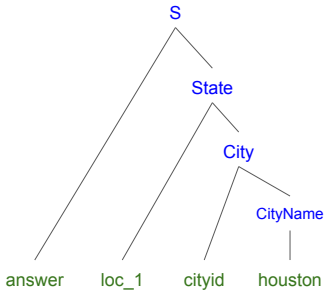
Parameter estimation To estimate the probability of each production rule, we can use maximum likelihood estimation, which is based on counting the rule occurrences in parse trees. Given a sequence of meaning representations $y_1, \ldots, y_n$, the probability of a grammar rule $N \rightarrow \zeta$ can be calculated by the equation below, where $Count()$ denotes counting the occurrences of a rule in $y_1, \ldots, y_n$.

$$P = \frac{Count(N \rightarrow \zeta)}{\sum_\gamma Count(N \rightarrow \gamma)}$$



Data augmentation After estimating the rule probabilities, we can sample novel meaning representations from the resulted grammar. We then backtranslate (Sennrich et al., 2016) each sampled meaning representation to obtain the synthetic natural language text. Specifically, we train another sequence-to-sequence model on the in-distribution train set, which takes as input a meaning representation and outputs a sentence.

To utilize the generated parallel data, we can either concatenate it with the original training data, or we can first pretrain the baseline parser on the generated data and then fine-tune the parser on the original training set. Since Wang et al. (2021) show that concatenation can hurt the performance of the parser, we experiment with both methods and report results of the best method for each dataset.



3.2 Augmentation distribution for compositional generalization

Our data generation method differs from Wang et al. (2021) in that we consider different distributions for sampling the augmentation data. We hypothesize that this will be advantageous for compositional generalization, for two reasons.

First, test sets for such tasks are generally designed to contain structures that are not observed in the train set; these are difficult to sample from

(a) Grammar rules for GeoQuery.

(b) Parse tree of a GeoQuery meaning representation.

Figure 3: An example to show part of our grammar from GeoQuery. Blue color refers to non-terminal and green color refers to terminal symbols. Special symbols (e.g. brackets) are ignored for space.

the training distribution. For example, in Figure 3, the rule *(e)* will be estimated to have zero probability, so the generated meaning representations will never contain the pattern *most River*. Second, the test set may involve generalization to meaning representations with deep recursion depth or longer symbol sequence. These are unlikely under the training distribution when the train set only contains shallow recursions or short sequences, and will thus be rare in the sampled data.

We compare the effect of different augmentation distributions. Specifically, we look at augmentation PCFGs whose parameters are estimated from the *training data* (P_{train}); those estimated from the *test data* (P_{test}); and PCFGs with *uniform* rule distributions ($P_{uniform}$); i.e. each of the k rules for a nonterminal N has probability $1/k$. P_{test} represents an ideal case where the test distribution is accessible, which generally does not hold for realistic scenarios. In this paper we only use P_{test} as an upper bound, to show the importance of the choice of augmentation distribution.

4 Experiments

In this section, we introduce our datasets, experiment setup and results.

4.1 Datasets

COGS COGS (Kim and Linzen, 2020) is a semantic parsing dataset where the input is an English sentence and the output is a logical form. We use the variable-free meaning representation (e.g. *A girl in a house sneezed* → *sneeze (agent = girl (nmod . in = house))*) of COGS following Qiu et al. (2022). COGS is generated with a PCFG, where the train set consists of data with simple linguistic structures and the generalization set consists of 21 generalization types to test different generalization abilities. This includes 18 lexical generalization types (i.e. a novel combination of a familiar structure with a familiar word) and 3 structural generalization types (i.e. a novel combination of two familiar structures). Here "familiar" means the structure or word is observed in the train set.

We focus on the three challenging structural generalization types *obj_pp_to_subj_pp*, *pp_recursion* and *cp_recursion*, which were highlighted as particularly difficult by Yao and Koller (2022). The original train set comprises instances with prepositional phrase (PP) and clauses (CP) recursion depths limited to 2, while *pp_recursion* and *cp_recursion* instances range from depths 3 to 12. In *obj_pp_to_subj_pp* instances, PP structure modifies subject nouns, which only modifies object nouns in the train set (e.g. *Emma ate the ring beside a bed* → *A girl in a house sneezed*).

CFQ CFQ (Keysers et al., 2020) is a semantic parsing dataset where the input is an English sentence and the output is a SPARQL query (e.g. *Did M1 acquire a company* → *select count (*) where{(x0 a employer) . (M1 company_acquired x0)}*). Previous works (Herzig et al., 2021) shows that preprocessing leads to a large difference for CFQ results. Thus we use the RIR meaning representations in Herzig et al. (2021) and additionally normalize reversible relation tokens following Zheng and Lapata (2022). We use three MCD splits generated by maximizing the similarity of atom distribution and the divergence of compound distribution between train and test sets together.

Geoquery For GeoQuery, we focus on the FunQL formalism (Kate et al., 2005), where the input is an English sentence and the output is a FunQL query (e.g. *what is the tallest mountain in america* → *answer highest mountain loc_2 countryid usa*). We use the dataset created by Herzig and Berant (2021) and follow Lindemann et al. (2023) to remove special symbols in the meaning representation. We use *template* (Finegan-Dollak et al., 2018) and *length* splits created based on the program template and length respectively.

SCAN SCAN (Lake and Baroni, 2018) is a semantic parsing dataset where the input is a command and the output is a sequence of actions (e.g. *jump twice* → *JUMP JUMP*). SCAN provides many primitive-based splits and length split. We use *turnleft* and *length* split, which have been shown challenging in Qiu et al. (2022).

4.2 Set up

Models. We address all our semantic parsing tasks with a sequence-to-sequence model. Given its strong performance on semantic parsing and sentence generation tasks, we fine-tune T5 (Raffel et al., 2020) as our baseline semantic parser as well as for backtranslation. Training details are reported in Appendix B. All our results are averaged over 5 random runs and we report standard deviation in Appendix C. Exact match accuracy is used as the evaluation metric for all datasets. For GeoQuery, the same input sentence can be mapped into multiple correct programs, so we also report execution accuracy following Herzig and Berant (2021).

Grammars. To apply our data augmentation method to a dataset, we need a context-free grammar that can generate its meaning representations. For COGS, we adopt the official grammar provided by authors. For CFQ, GeoQuery and SCAN, we manually write a context-free grammar to apply our method. We use T5+P_{train} to refer to the model trained with the union of original train set and the data sampled from P_{train} and so for the other distributions. For all three augmentation distributions, we sample the same number of unique meaning representations. Details of grammar design and sampling are described in Appendix D. For COGS and SCAN, we directly concatenate the synthesized data with the original data set. For CFQ and GeoQuery, we find that concatenation hurts the performance and thus pretrain the model on the synthesized data first and then fine-tune it on the original train set. We report detailed results for both settings in Appendix C.

4.3 Results

ference on the performance: the grammar estimated on the test set (e.g. P_{test}) substantially improves performance (+8.3) and achieves near-perfect accuracy overall, while the grammar estimated on the train set (e.g. P_{train}) only slightly improves the performance (+1.9). We consider this is because the grammar estimated on train set tends to produce simple structures, which does not help improve complex structure predictions. Noticeably, the uniform grammar $P_{uniform}$ yields a much higher improvement than P_{train}. This suggests that the importance of the distribution of meaning representations for compositional generalization.

CFQ Table 2 shows exact match accuracies on CFQ. All three augmentation strategies are roughly on par with each other. We attribute this limitation to the fact that the CFQ dataset is generated by mapping intermediate logical forms into SPARQL, which incorporates variables and conjuncts. Such complex relationships are difficult to capture accurately using context-free grammars, resulting in many sampled meaning representations containing

Table 4: Results on SCAN.

nonsensical elements (e.g., redundant conjuncts).

To verify our hypothesis, we further experiment with a setting where instead of sampling MRs from estimated PCFG, we directly backtranslate MRs from development set as augmented data. Since the development set of CFQ shares the same distribution as the test set, this setting represents what a perfect method for augmenting from the test distribution would achieve, illustrating that the issue really comes from our flawed grammar.

We also observe that our T5 baseline outperforms the T5 model from Herzig et al. (2021). We attribute this to the additional preprocessing steps we adopted from Zheng and Lapata (2022).

GeoQuery Table 3 shows exact match accuracies and execution accuracy on GeoQuery. On the template split, P_{test} gives the best performance (+6.2 EM and +8.3 Exe). On the length split, all three strategies substantially improve the performance. $P_{uniform}$ achieves on-par performance with P_{test} and outperforms P_{train} on both splits, which is consistent with the results on COGS.

SCAN Table 4 shows exact match accuracies on SCAN. We observe P_{test} and $P_{uniform}$ substantially improve the performance on both splits, whereas the P_{train} only performs well on *turnleft* split. All three strategies achieves the same perfor-

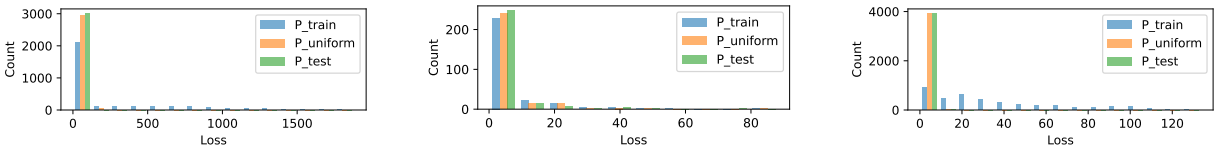
Table 5: Dataset statistics for different augmentation strategies. *T5* denotes the statistics of the original train set. +P_{train}, +P_{test}, +$P_{uniform}$ denote augmented datasets based on different PCFGs. We report the statsitics for both input sentence side and output meaning representation side. Thus, *Avg length* under *English* tab refers to the average length of input sentences. We report three statistics: average length (*Avg length*), the coverage (expressed as a percentage) of bigrams in the test set by the training set (*Bigrams*) and the coverage of entire instance in the test set by the training set (*Instance*).

mance on *turnleft* split. This is because the meaning representation space of SCAN is too small and thus all possible meaning representations can be sampled by three strategies, which results in the same train set. The same case happens for P_{test} and $P_{uniform}$ on the length split. Noticeably, our method outperforms GECA, which generates parallel data for data augmentation using templates. This suggests that sampling meaningful and useful meaning representations proves more effective than sampling limited parallel data in certain scenarios.

5 Discussion



The surprising finding so far is that across all four compositional generalization datasets, augmenting from $P_{uniform}$ performs on par with P_{test}. This seems counterintuitive: the uniform augmentation strategy has no knowledge of the test data's distribution, and one would expect that augmentation data sampled from a grammar-based approximation to the test distribution should perform much better. We therefore investigate this finding in detail.

Augmentation data statistics We present statistics of the generated augmentation data in Table 5. For each corpus and augmentation method, we show the average sequence length, bigram coverage, and instance (i.e. exact sequence match) coverage for both input sentences and output MRs. The bigram coverage is determined by dividing the number of observed bigrams in the test set that also exist in the training set by the total count of possible bigrams in the test set. Instance coverage is calculated analogously.

As expected, P_{test} always yields the highest coverage values on the meaning representations, suggesting that the MR grammar approximates the test distribution effectively. On the other hand, instance-level coverage on the English side does not grow very high for any dataset. This indicates that the backtranslation model, which is trained on the original in-distribution data, still struggles to produce novel recombinations of the English sentences.

$P_{uniform}$ is on par with P_{test} on many measures and datasets, and considerably outperforms P_{train}. This suggests that novel structural combinations are judged unlikely based on the training distribution, or are simply assigned a probability of zero because structures were entirely unobserved.

It is remarkable that P_{test} and $P_{uniform}$ produce meaning representations of similar length on COGS and could therefore be capable of generating augmentation data of similar structural complexity. At the same time, P_{test} achieves a significantly higher parsing accuracy on the PP and CP recursion generalization types. A plot of the distribu-

Models	COGS	CFQ MCD1	GeoQuery Template	SCAN Length
T5	1.131	1.007	1.254	1.427
+P_{train} ‡	1.133	1.005	1.252	1.124
+P_{test} ‡	1.001	1.005	1.166	1.006
+$P_{uniform}$ ‡	1.007	1.005	1.184	1.006

Table 6: Perplexity of models with different augmentation strategies on test set.

tion of the augmentation instances according to recursion depth (Fig. 5) reveals that while P_{test} generates augmentation instances evenly across all recursion depths, $P_{uniform}$ emphasizes moderately (PP) or extremely (CP) shallow instances.[2] This explains the difference in parsing accuracy, and further emphasizes that compositional generalization is not just challenging because transformers struggle when generalizing to longer inputs (Hupkes et al., 2020), but also to structurally more complex inputs of similar length.

Perplexity analysis We further investigate whether $P_{uniform}$ produces useful augmentation data simply because it produces arbitrary instances of higher complexity than P_{train}, or if $P_{uniform}$ actually models the test distribution in some way. To this end, we measure the perplexity of the meaning representations of the test set across four corpus variants under each model (Table 6; see Appendix E.1 for details).

We find that across three of the four datasets, P_{test} and $P_{uniform}$ are close together, considerably outperforming P_{train} and the T5 baseline. An exception is CFQ, where the grammar introduces so much noise into the sampling process that all models are mostly on par. We consider this is because although $P_{uniform}$ has no particular knowledge of the test distribution built in, sampling from it covers enough MR n-grams that the test data becomes predictable.

The increased perplexity of P_{train} in comparison to the other models is not evenly distributed across the test instances. In Fig. 4, we plot a count of test instances for each loss value. Compared to P_{test} and $P_{uniform}$, the loss of P_{train} on some instances becomes exceptionally high, which results in higher perplexity and lower accuracy on such instances. Looking into the dataset, we find that such issue generally occurs on meaning representations with complex structures (e.g. deeper recursions for COGS and unseen program templates for GeoQuery). These structures are more predictable for models trained on P_{test} and $P_{uniform}$ augmentation data, which contains such structures more frequently.

Structure coverage According to Bogin et al. (2022), a key feature that makes compositional generalization difficult is the presence of unobserved local structures (i.e. a connected sub-graph that occurs in the meaning representation) in the test set. Is the better performance and perplexity of P_{test} and $P_{uniform}$ actually because they cover more structures in the test set?

To answer this question, we further plot the accuracy of our models against the structure coverage on COGS and GeoQuery in Figure 6. Here "structure coverage" refers to dividing the number of

[2]We hypothesize that the difference between PP and CP in the $P_{uniform}$ case is due to the fact that each level of CP recursion requires the use of two production rules, rather than just one for PP, making the generation of deeper structures comparatively less likely.

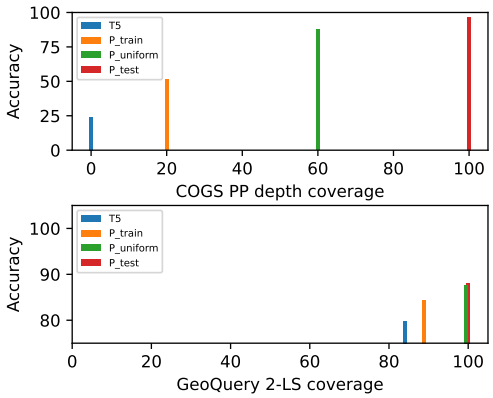

Figure 6: Performance against the local structure coverage for different augmentation distributions.

observed structure in the test set that also exist in the training set by the total count of possible structures in the test set. For GeoQuery, we consider the template split and follow Bogin et al. (2022) in defining the local structure of a meaning representation as all pairs of parent nodes and their children in its parse tree (i.e. 2-LS). For COGS, we focus on the PP recursion generalization type. Instead of considering local structures, we observe that the accuracy on such data is related to the maximal recursion depth observed in the train set. Thus we use PP recursion depth as a representative of global structures to calculate the structure coverage.

Our results show that P_{test} and $P_{uniform}$ yields a larger coverage of structures that occur in the test set than P_{train}. Furthermore, larger coverage is associated with higher accuracy. This is consistent with Bogin et al. (2022). Although Gupta et al. (2022) and Oren et al. (2021) also show the benefit of introducing more complex structures into the train set, our results further suggest that synthesized meaning representations with back-translated sentences can still help.

Qualitative error analysis Finally, we conducted a qualitative analysis to identify specific cases in which our approach led to improvements. In Table 7, the grammar rule *River* → *most River* is not observed by baseline and P_{train}, and thus the model struggles generating the bigram *most river* corresponding to this rule, which leads to a large loss value (i.e. 26.1) for this instance. In contrast, P_{test} covers all local structures, which allows the model to predict the instance correctly with a substantially lower loss (i.e. 0.1).

Sentence generation We report the performance of our backtranslation model in Table 8. Both exact match accuracy and BLEU score (Papineni et al., 2002) are used as evaluation metrics. All models achieve good BLEU scores, indicating the effectiveness of our backtranslation models. However, none of the model yields high accuracy, which suggests that our model can still learn to utilize such noisy data to achieve better performance.

We also present error examples in the augmented training data in Table 9. On COGS, the backtranslation model tends to generate sentences with seen linguistic structures in the training data (e.g. *called the table to* as a prepositional dative structure) instead of unseen structures (e.g. *A teacher on the table* as a Subject PP structure). Also, given a meaning representation with deep recursion structures, the model may ignore some structures (e.g. *in the bottle*) and not translate them. Similar patterns can also be observed in GeoQuery and SCAN: *what state has the most cities* is an observed sentence in the training data of the backtranslation model for GeoQuery, and thus the model tends to translate the given MR into this sentence ignoring the structure *river traverse_2*; *run around right thrice* is never observed in the training set of the SCAN backtranslation model, and thus the model struggles with generating it. On CFQ, we further observe that the model may generate additional phrases whose meaning is not present in the MR (e.g. *was written by M5*).

Input	what is the length of the river that runs through the most states ?
Gold	`len` **`most river`** `traverse_2 state all`
T5	`len intersection riverid most state all`
+P_{train}	`len intersection river traverse_2 most state all`
+P_{test}	`len most river traverse_2 state all`

6 Conclusion

We investigated the impact of the choice of augmentation distribution on compositional generalization. We found that a PCFG for the meaning representations with uniform rule weights supports much more effective data augmentation than one that is trained on the training data, and almost on part with one that is trained on the test data. A detailed analysis revealed that this is because the uniform grammar both achieves low perplexity on the test meaning representations and greatly improves structural coverage.

Thus, sampling meaning representations from a uniform PCFG and backtranslating them into natural-language sentences can serve as a simple and efficient data augmentation strategy for compositional generalization. It would be interesting to investigate the space of augmentation distributions in more detail in future work to see, for instance, how the generation of structurally even more diverse augmentation instances can be encouraged. Our findings also suggest that compositional generalization in MR-to-text generation tasks (Mehta et al., 2022), which is still an underexplored area, is also an interesting direction for future research.

7 Limitations

Our work assumes that the language of all possible meaning representations can be described with a context-free grammar, and that such a grammar is available or can be easily reconstructed by hand. Given that MRs are formal languages, this seems realistic, but can involve some manual effort. When the meaning representations are generated out of a knowledge base through a process that is not publicly accessible, such as in CFQ, hand-crafting a grammar for MRs can introduce noise.

In our evaluation, we use corpora that are either synthetic (COGS, CFQ, SCAN) or very small (GeoQuery). Thus, one should interpret conclusions on data augmentation for such corpora with care. We

leave experiments on compositional generalization datasets that use naturally occurring language (e.g. SMCalFlow-CS (Yin et al., 2021)) to future work. Nevertheless, the robustness of our results across corpora still suggests the generality of our findings.

A Dataset details

We report dataset statistics in Table 12. COGS provides both an in-distributional test set (i.e. test) and an out-of-distributional test set (i.e. gen). For the splits of CFQ, GeoQuery and SCAN we used no in-distributional test set is provided.

B Training details

B.1 Evaluation metrics

For all tasks, we report exact match accuracy of our model, which means that the output sequence is correct only if each output token is correctly predicted. For GeoQuery, we additionally report execution accuracy, which means we execute generated FunQL code and calculate the accuracy of the outputs. This metric can better measure the generalization ability of our model since one input sentence can be mapped into multiple correct FunQl queries. For example, *how long is the rio grande river* can be parsed into either *answer (len (river (riverid (rio grande))))* or *answer (len (intersection (riverid (rio grande), (river (all)))))*. Both queries return the correct value. We use the code from (Herzig and Berant, 2021) to calculate the execution accuracy.

Dataset	lr	batch_size	weight_decay	steps
COGS	1e-5	2048	0	25k
CFQ	7.4e-5	2048	1e-3	50k
GeoQuery	1e-5	4096	1e-3	10k
SCAN	1e-5	1024	1e-3	25k

Table 10: Hyperparmeters of baseline models used in our experiments. Batch size is quantified in terms of input tokens. *batch_size* refers to the batch size during training. *weight_decay* refers to the weight decay used in the optimizer. *lr* refers to the learning rate. *steps* refers to the training steps we used to train the model.

GeoQuery	0.5	1
SCAN	20	4

Table 11: Training time for our model on each dataset (1 run) in our experiments.

B.2 Hyperparameters

Baseline. We use *t5-base*[3] (220 million parameters) as our baseline for all experiments. We use the default subword vocabulary and do not extend it with new words. We use Adam (Kingma and Ba, 2015) as our optimizer. Since (Csordás et al., 2021) shows that early stopping based on in-distribution validation set leads to low performance on out-of-distribution test set, we do not apply early stopping for COGS, GeoQuery and SCAN and only use the checkpoint at the end of training, following (Herzig et al., 2021). CFQ provides out-of-distribution development set, so we use exact match accuracy on the development set as the validation metric. No learning rate scheduler is used for all experiments. During evaluation, we use beam search with beam

Table 12: Statistics for all our datasets. # denotes the number of instances in the dataset. Vocab.size denotes the size of vocabulary for the dataset, which consists of input tokens and output tokens. Train.len denotes the maximum length of the input tokens and output tokens in the train set. Test.len and Gen.len denote the maximum length in the test and generalization set.

size 4. Task-specific hyperparameters are present in Table 10.

We only perform hyperparameter selection for the learning rate hyperparameter. For CFQ, we perform random search 10 times and select the best learning rate based on the model accuracy on the development set. The search space for the learning rate is (1e-5, 1e-3). For other datasets where the development set is not distributed the same as the test set (i.e. COGS and GeoQuery) or the development set is not provided (i.e. SCAN), we sample a held-out development set from its test set following (Zheng and Lapata, 2022) for hyperparameter selection. The best learning rate is selected from values in {1e-4, 1e-5} based on the model accuracy on the sampled development set.

Data augmentation. We maximally sample 21k, 100k, 30k and 10k unique meaning representations for COGS, CFQ, GeoQuery and SCAN respectively. For SCAN, we find that the size of possible meaning representations is small (i.e. 9228 unique meaning representations) and thus we sample all possible unique meaning representations from our PCFG.

B.3 Other details

We use Allennlp (Gardner et al., 2018) for our implementation. Experiments are run on Nvidia A100 GPU cards (80GB). Table 11 shows the training time cost.

C Detailed results

We report detailed experimental results in Table 16. Both means and standard deviations are reported over 5 runs for each model. As discussed in Section 3, we experiment with two ways to utilize synthesized data: concatenating them with the original train set and pretrain the model on them first and then finetune on the original train set. We report numbers for both settings, with *Concat* refers to concatenation and *Pretrain* refers to pretraining the model first and then fine-tuning it.

Table 13: Part of our FunQL grammar.

D Grammar details

We use PCFG provided in Kim and Linzen (2020) for COGS and hand-written grammars for CFQ, GeoQuery and SCAN. In this section, we mainly introduce details of our used grammar for these three hand-written grammars.

D.1 Grammar design

GeoQuery The meaning represnetation of GeoQuery is based on FunQL. Following the definations of FunQL [4], we can easily write a context-free grammar for it. We adopted the FunQL grammar used in (Guo et al., 2020) and extends it with some rules to fit our dataset. A selection of our context-free grammar rules are shown in Table 13.

SCAN SCAN is a synthetic dataset generated by Lake and Baroni (2018). They generate the dataset by generating commands (i.e. input sentences) first and then translating commands into action sequences (i.e. meaning representations) with

[4] https://www.cs.utexas.edu/~ml/wasp/geo-funql.html

S → Command
Command → Walk_command
Walk_command → Walk_actions
Walk_actions → LWalk
LWalk → Turn_left Walk
Turn_left → i_turn_left
Walk → i_walk

Conjuncts → Conjunct
Conjunct → Unary_relation
Unary_relation → (Var a Film_unary_arg)
Film_unary_arg → film.film
Var → M0

Table 15: Part of our SPARQL grammar.

a translation function. Instead, we write a context-free grammar for meaning representations. A selection of our context-free grammar rules are shown in Table 14.

CFQ CFQ is a synthetic dataset generated by Keysers et al. (2020). They generate the natural language sentences and corresponding intermediate logical forms first, and then apply multiple rules to obtain the SPARQL meaning representations. Designing a context-free grammar for SPARQL is hard because it contains variables and each relation only accepts specific typed variables as arguments. For example, the object of *film.writer.film* relation should be a film. In our grammar, we consider all variable strings are produced by the nonterminal *Var* and we do post-process to filter out samples that do not follow type constraints described above. A selection of our context-free grammar rules are shown in Table 15.

In our experiments, we find this setting still generates most noisy meaning representations due to redundant conjuncts (e.g. *SELECT DISTINCT ?x0 WHERE { (FILTER (?x0 != M0)) . (M5 (film.editor.film) (?x1)) }*). A better solution might be to construct the PCFG based on the graph structure.

D.2 Parameter estimation

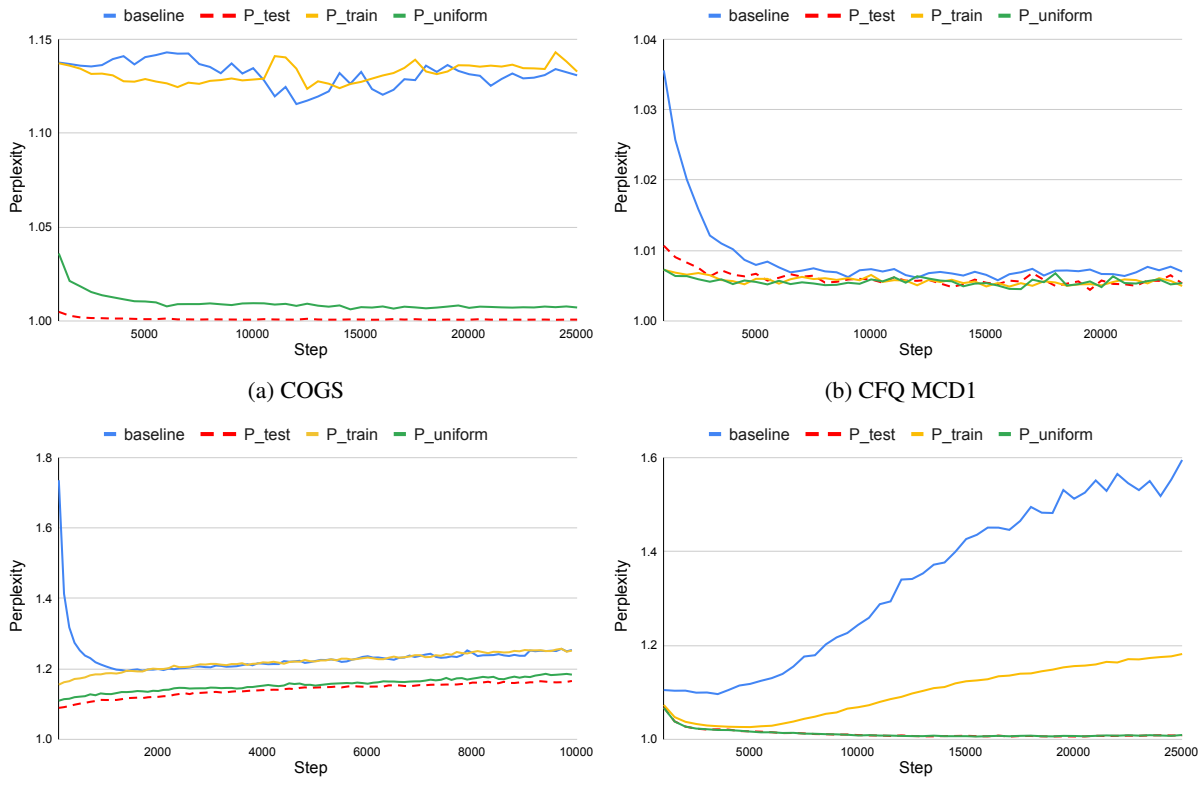
To estimate parameters of a grammar on a dataset based on maximum likelihood estimation, we first parse meaning representations in the dataset with our grammar rules described above. We implement this with NLTK package[5]. We binarize our grammar rules to adopt parsing methods in NLTK.

Ambiguous trees For CFQ, all meaning representations can be parsed into unambiguous trees. For GeoQuery and SCAN, parsing results in ambiguous trees for some cases. For a meaning representation with N ambiguous parse trees, we simply use a count $1/N$ as the count for rules in each tree to estimate their parameters.

E Additional experiments

E.1 Perplexity curve

We plot the perplexity curve of different models on test set for each task in Figure 7. For CFQ and CFQ, the perplexity at the beginning is already very small. This is because on these two datasets we pretrain the model on synthesized data first, since direct concatenating the synthesized data only hurts the performance. We can observe that for COGS, GeoQuery and SCAN, the perplexity of P_{test} always achieves the lowest perplexity and $P_{uniform}$ gives lower perplexity than P_{train}. On CFQ, all three augmentation distributions achieves lower perplexity than baseline T5 and performs on par. This pattern holds during the entire training process, which serves as further evidence for the discussion in Section 5.



E.2 Breakdown performance improvements

We also conduct a more detailed analysis to investigate how the performances evolve as more complex structures get observed. Specifically, we address the PP and CP recursion generalization types on COGS and GeoQuery template split. For COGS, we incrementally augment the train set with more complex data (i.e. deeper recursions) in increments of 100 instances per depth. For GeoQuery, we manually select four local structures *population_1 stateid*, *len river*, *capital cityid*, *intersection river* that pose challenges for the baseline parser's predictions yet are present in the P_{test} set. We incrementally introduce each pattern into the train set. As shown in Figure 8, as more complex MR structures being observed by the model, its performance gets better improved.

Abstract

Large Language Models (LLMs) have shown to be capable of various tasks, yet their capability in interpreting and reasoning over tabular data remains an underexplored area. In this context, this study investigates from three core perspectives: the robustness of LLMs to structural perturbations in tables, the comparative analysis of textual and symbolic reasoning on tables, and the potential of boosting model performance through the aggregation of multiple reasoning pathways. We discover that structural variance of tables presenting the same content reveals a notable performance decline, particularly in symbolic reasoning tasks. This prompts the proposal of a method for table structure normalization. Moreover, textual reasoning slightly edges out symbolic reasoning, and a detailed error analysis reveals that each exhibits different strengths depending on the specific tasks. Notably, the aggregation of textual and symbolic reasoning pathways, bolstered by a mix self-consistency mechanism, resulted in achieving SOTA performance, with an accuracy of 73.6% on WIKITABLEQUESTIONS, representing a substantial advancement over previous existing table processing paradigms of LLMs.[1]

1 Introduction

Large Language Models (LLMs; Brown et al. 2020; Chowdhery et al. 2022; Zhang et al. 2022; OpenAI 2022, 2023a,c; Touvron et al. 2023a,b; Li et al. 2023b; Lozhkov et al. 2024) have revolutionized the field of NLP, demonstrating an extraordinary ability to understand and reason over rich textual data (Wei et al., 2023; Wang et al., 2023; Zhou et al., 2023; Kojima et al., 2023; Li et al., 2023c). On top of LLMs' existing capabilities for NLP, further bolstering their potential for decision-making by drawing from external knowledge sources remains an exciting research frontier (Nakano et al., 2022; Mialon et al., 2023; Hao et al., 2023; Jiang et al., 2023b). Amongst such knowledge sources, tabular data serve as a ubiquitous kind due to their expressiveness for relations, properties and statistics, and their being easy to construct by human curators (Chen et al., 2020; Wang et al., 2021; Xie et al., 2022).

Like humans, LLMs can also benefit from reading tabular data accompanying text. However, as indicated in Fig. 1, the structural nature of tables

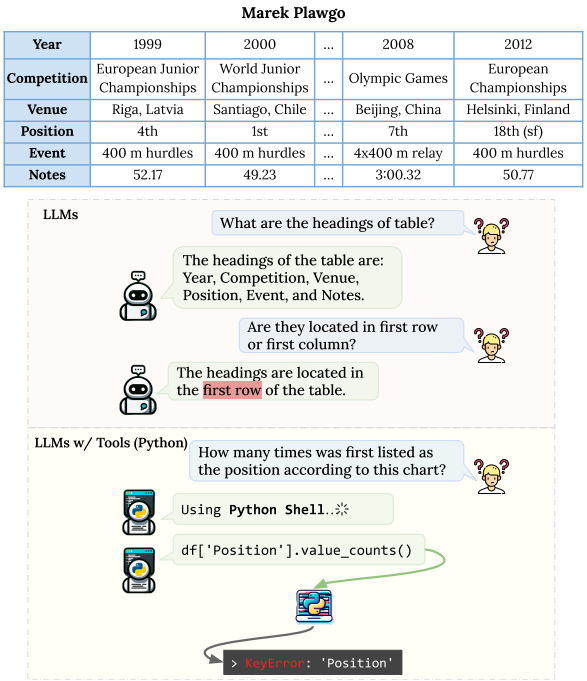

Figure 1: Demonstration of the challenges faced by LLMs in comprehending and interpreting table structures. In the first example, the LLM correctly identifies table headings but struggles to accurately determine their positions within the table structure. In the second example, the model using Python Shell as an external tool incorrectly interprets headings (located in the first column) as column headers, leading to subsequent errors in the generated code. Some logos in this and subsequent figures are generated using OpenAI's DALL-E3 (OpenAI, 2023b).

Total	...	506,000	1,146,000	473,000	100,000	2,000	2,770,000

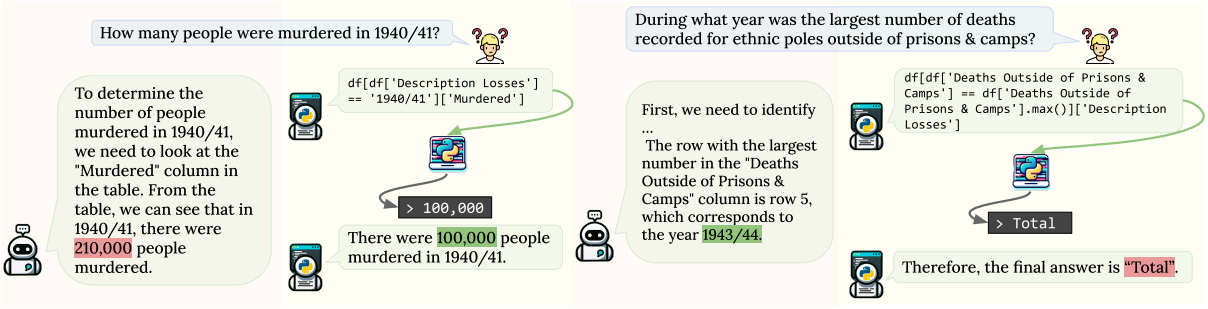

Figure 2: Illustrative examples sampled from the WIKITABLEQUESTIONS dataset, comparing textual reasoning (via direct prompting) and symbolic reasoning (via python shell interactions). ***Top***: The table and its title. ***Bottom Left***: In the first question example, textual reasoning yields an incorrect interpretation due to limitations in precision localization, while symbolic reasoning accurately locates the answer using Python code. ***Bottom Right***: In the second question example, textual reasoning successfully identifies the answer, but symbolic reasoning incorrectly treats the special `total` row as the final answer.

presents unique challenges to these models. Inherently designed to parse and process vast expanses of unstructured textual content, LLMs confront a paradigm shift when facing tabular data. Linearizing tables to suit the LLM paradigm can obscure the inherent structural and relational information, making tasks such as precise localization and complex statistical analyses. Additionally, the design variations in tables, whether 'column tables' with headers in the first row or 'row tables' with headers in the first column, further complicate the interpretation process. Beyond structural concerns, numerical reasoning and aggregation over tabular data present another layer of complexity. While LLMs excel at textual understanding, they occasionally stumble when confronted with tasks necessitating precise numerical computation within tables. Moreover, tables often present a dense amalgamation of textual or numerical data. The sheer volume and intricacy of this information can risk overshadowing crucial details, potentially impeding the LLM's decision-making abilities (Shi et al., 2023).

With the emergence of instruction fine-tuning techniques (Wei et al., 2022; Chung et al., 2022) and the application of Reinforcement Learning from Human Feedback (RLHF) (Stiennon et al., 2022; Gao et al., 2022; Christiano et al., 2017), LLMs have witnessed significant enhancements in their alignment capabilities, paving the way for transitioning from few-shot to zero-shot learning settings (Kojima et al., 2023). In light of these advancements, this paper delves deep into the the challenges and intricacies of tabular understanding and reasoning by LLMs, exemplified in Fig. 2. We organize our exploration around three **pivotal research questions**: (1) How well do LLMs perceive table structures and how can we ensure robustness against structural variations? (2) Comparing textual and symbolic reasoning for table data in LLMs, which prevails in effectiveness, and what advantages and challenges manifest in each strategy? (3) Will the aggregation of multiple reasoning pathways enhance the accuracy and reliability of tabular data interpretation by LLMs?

In pursuit of answering the aforementioned research questions, we conduct experiments on SOTA LLMs such as GPT-3.5 (OpenAI, 2023a). Our findings in §4 underscore that while LLMs are adept at semantically interpreting tables, their capability to resist structural variance (§4.1) and understand table structures (§4.2) is suboptimal. Motivated by these findings, we propose a table structure normalization method to enhance LLMs' resilience against structural table variations in §4.3. Intriguingly, §5.1 reveals that textual reasoning surpasses symbolic reasoning in contexts with limited table content, defying conventional conceptions of symbolic reasoning's dominance in other domains (Mi-

alon et al., 2023). Both textual and symbolic reasoning strategies encompass different advantages and challenges, which is detailed in §5.2. To harness the unique strengths of each, we implement mix self-consistency mechanism (§6) that remarkably attains SOTA performance on Table QA, exemplifying the synergistic potential when both reasoning strategies are aggregated.

2 Related Work

PLMs for Tabular Data Processing. Tabular reasoning presents unique challenges due to the fusion of free-form natural language questions with structured or semi-structured tabular data, for which PLMs jointly trained on tables and text are developed in the past few years, including TaBERT (Yin et al., 2020), TaPas (Herzig et al., 2020), TAPEX (Liu et al., 2022), ReasTAP (Zhao et al., 2022), and PASTA (Gu et al., 2022). The recent development of TableLlama (Zhang et al., 2023a), an open-source model excelling in a variety of table-based tasks, adds a new dimension to the field. Despite these advancements, recent studies have identified generalization issues under table perturbations (Zhao et al., 2023; Chang et al., 2023), raising concerns regarding the robustness of PLMs. Specific efforts like LETA (Zhao et al., 2023) and LATTICE (Wang et al., 2022) have investigated and mitigated the vulnerabilities related to structural perturbations of tabular data, like row/column shuffling and table transpose, through various techniques, including data augmentation and order-invariant graph attention. However, these approaches require whitebox access to the models, limiting their applicability to SOTA LLMs with only blackbox accessibility, a limitation directly addressed in this work.

Tabular Data Processing with LLMs. Recent advancements in LLMs, notably within few-shot learning, have demonstrated their potential for tabular reasoning. Chen (2023) leveraged the Chain-of-Thought (CoT) technique (Wei et al., 2023) to illustrate LLMs' effectiveness in this domain. Building upon CoT, Cheng et al. (2023) and Ye et al. (2023) introduced frameworks that incorporate symbolic reasoning for improved comprehension, with Ye et al. emphasizing their ability to adeptly decompose both evidence and questions. The advent of aligned models, such as ChatGPT, has enabled zero-shot table reasoning. However, these models often lack sensitivity to table structures, struggling with structural perturbations. StructGPT (Jiang et al., 2023a), while introducing a promising framework for LLMs to efficiently engage with structured data, has its effectiveness limited by not integrating symbolic reasoning, a critical aspect for enhancing the full capabilities of LLMs in tabular reasoning, which is the focal point of this study. Furthermore, while programming-based approaches can mitigate some challenges, they are limited in addressing free-form queries, creating a gap in the landscape. Innovations like AutoGPT (Significant Gravitas, 2023) have sought to address this, spawning the development of tabular agents like LangChain (Chase, 2022), SheetCopilot (Li et al., 2023a), and Data-Copilot (Zhang et al., 2023b). These agents offer solutions unattainable through conventional programming but still require rigorous evaluation in various scenarios. In our study, we delve into addressing these challenges for enhancing LLMs' reasoning capabilities within structural perturbations, hence providing insights that facilitate improved accuracy in the current context.

3 Preliminaries

This section succinctly introduces the foundational aspects of our study over structurally perturbed tabular data. §3.1 formally defines the problem, delineating the critical notations and conceptual frameworks, and §3.2 explicates our experimental setup details, elucidating dataset choice, model utilization, and evaluation strategy.

3.1 Problem Definition

Question answering (QA) over tabular data, commonly known as the TableQA task, is an important challenge in NLP. In this study, we targets TableQA to explore and enhance the proficiency of LLMs, in reasoning over tabular data. Additionally, we probe the robustness and adaptability of these models by introducing structural perturbations to tables.

Let $\mathcal{T}$ represent a table consisting of $\mathcal{R}$ rows and $\mathcal{C}$ columns, and τ represent its title/caption. Each cell in $\mathcal{T}$ is denoted by $\mathcal{T}_{i,j}$, where $i \in [0, \mathcal{R}-1]$ and $j \in [0, \mathcal{C}-1]$. $\mathcal{T}_{0,j}$ are headers. Given a question $\mathcal{Q}$ pertaining to the table, our task is to identify an answer $\mathcal{A}$. This answer is generally a collection of values, denoted as $\{a_1, a_2, \ldots, a_k\}$, where $k \in \mathbb{N}^+$.

Furthermore, to delve deeper into the structural comprehension of LLMs, we introduce structural

perturbations, which include:[2]

1. **Transposed Table ($\mathcal{T}^\top$):** A table obtained by converting rows to columns and vice-versa, maintaining the row and column order:

$$\mathcal{T}^\top_{i,j} = \mathcal{T}_{j,i} \quad \forall i \in [0, \mathcal{R}-1], j \in [0, \mathcal{C}-1].$$

2. **Row Shuffled Table ($\mathcal{T}_\Pi$):** A table obtained by randomly shuffling the rows (excluding the headers) with a random permutation function π, while keeping the order of columns unchanged:

$$\mathcal{T}_{\Pi_{i,j}} = \mathcal{T}_{\pi(i),j} \quad \forall i \in [1, \mathcal{R}-1], j \in [0, \mathcal{C}-1]$$

3. **Row Shuffled and Transposed Table ($\mathcal{T}^\top_\Pi$):** A table obtained by first randomly shuffling the rows (excluding headers) and then applying transposition:

$$\mathcal{T}^\top_{\Pi_{i,j}} = \mathcal{T}_{j,\pi(i)} \quad \forall i \in [1, \mathcal{R}-1], j \in [0, \mathcal{C}-1]$$

Defining our research problem more formally: our primary objective is to investigate the function, f, that can appropriately answer the posed question using the provided table. Specifically, this function will take three arguments: the table variant $\mathcal{T}' \in \{\mathcal{T}, \mathcal{T}^\top, \mathcal{T}_\Pi, \mathcal{T}^\top_\Pi\}$, its title τ, and the question $\mathcal{Q}$. It will output an answer $\mathcal{A}$. The entire problem can be formally framed as:

$$f(\mathcal{T}', \tau, \mathcal{Q}) \rightarrow \mathcal{A}, \quad \forall \mathcal{T}' \in \{\mathcal{T}, \mathcal{T}^\top, \mathcal{T}_\Pi, \mathcal{T}^\top_\Pi\}$$

3.2 Experimental Setup

This section details the experimental setup adopted in our study, including the datasets employed, model selection, evaluation metrics, reasoning methods, and other details.

Dataset. We used the WIKITABLEQUESTIONS (WTQ; Pasupat and Liang 2015) dataset for our experiments. The test set comprises 421 tables. Each table provides up to two question-answer pairs; if a table has fewer than two, only one was chosen, totaling 837 unique data points. With our four table configurations (original and three perturbations), the overall evaluation data points amount to $837 \times 4 = 3,348$.

Models. We employ the GPT-3.5 (OpenAI, 2023a) series for our research. Given that tables usually have extensive data, depending on the prompt length, we dynamically use `gpt-3.5-turbo-0613` and `gpt-3.5-turbo-16k-0613`, with a primary aim to optimize cost when querying the API.

Evaluation Metrics. Following prior works (Jiang et al., 2022; Ni et al., 2023; Cheng et al., 2023; Ye et al., 2023), we employ *Exact Match Accuracy* as the evaluation metric to validate predictions against ground truths, embedding instructions in prompts for consistent and parseable outputs.

Reasoning Methods. Our evaluation hinges on two distinct zero-shot reasoning approaches:

- **Direct Prompting (DP)** is a textual reasoning method that prompts LLMs to answer questions in a zero-shot manner. Rather than directly providing the answer, LLMs are instructed to reason step-by-step before concluding. More details can be found in Appx. §A.1,
- **Python Shell Agent (PyAgent)** is a symbolic reasoning approach where the model dynamically interacts with a Python shell. Specifically, LLMs use the Python Shell as an external tool to execute commands, process data, and scrutinize results, particularly within a pandas dataframe, limited to a maximum of five iterative steps. Detailed prompt is presented in Appx. §A.2.

Other Details. Depending on the scenario, we adjust the temperature setting. In cases not employing self-consistency, we set it to 0. For scenarios involving self-consistency, the temperature is set to 0.8. For further granularity, Appx. §A offers an exhaustive list of the prompts implemented in our experiments. Importantly, it should be noted that all prompts are deployed in a zero-shot manner, without any demonstrations or examples.

4 LLM Robustness to Structural Perturbations

This section explores how LLMs interpret varied table structures in response to our first research question (§1). We probe the impact of three table perturbations on LLM performance (§4.1), uncover LLMs' challenges and limitations for direct table transposition and recoganize tranposed tables (§4.2), and introduce a structure normalization strategy (NORM) to mitigate these issues (§4.3).

4.1 Impacts of Table Perturbations on LLMs

In §3.1, we present three types of structural table perturbations: transposition ($\mathcal{T}^\top$), row-shuffling

[2] Column shuffling was not employed as the typical number of columns is limited and this shuffling had minimal impact on accuracy (Zhao et al., 2023).

Perturbation	DP	PyAgent
Original ($\mathcal{T}$)	59.50	55.91
+Shuffle ($\mathcal{T}_{\Pi}$)	52.21 -12.25%	47.91 -14.31%
+Transpose ($\mathcal{T}^{\top}$)	51.14 -14.05%	12.45 -77.73%
+Transpose&Shuffle ($\mathcal{T}_{\Pi}^{\top}$)	37.51 -36.96%	8.96 -83.97%

Table 1: Accuracy of GPT-3.5 under different table perturbations using Direct Prompting (DP) and Python Shell Agent (PyAgent).

LLMs As	Task Description	Accuracy
Transposer	$f(\mathcal{T}) \rightarrow \mathcal{T}^{\top}$ $f(\mathcal{T}^{\top}) \rightarrow \mathcal{T}$	53.68 51.07
Detector	$f(\mathcal{T}) \rightarrow 0$ $f(\mathcal{T}^{\top}) \rightarrow 1$	93.35 32.54
Determinator	$f(\mathcal{T}, \mathcal{T}_{0,*}, \mathcal{T}_{*,0}) \rightarrow \mathcal{T}_{0,*}$ $f(\mathcal{T}^{\top}, \mathcal{T}_{0,*}, \mathcal{T}_{*,0}) \rightarrow \mathcal{T}_{*,0}$	97.39 94.77

Table 2: Evaluation results of GPT-3.5 on the 421 distinct tables of the WIKITABLEQUESTIONS (WTQ) dataset, covering three tasks: (1) *Transposer*, which involves switching between original ($\mathcal{T}$) and transposed ($\mathcal{T}^{\top}$) tables directly; (2) *Detector*, which identifies the need for table transposition (0 for no transposition, 1 for transposition required); and (3) *Determinator*, which chooses probable table headings either from the first row ($\mathcal{T}0, *$) or the first column ($\mathcal{T}*, 0$).

($\mathcal{T}_{\Pi}$), and their combination ($\mathcal{T}_{\Pi}^{\top}$). As demonstrated in Tab. 1, both reasoning methods, DP and PyAgent, exhibit significant performance declines, with more pronounced when transposition is applied. DP consistently outperforms PyAgent largely across perturbations, indicating that textual reasoning tends to be more resilient to these structural changes. This resilience can be attributed to LLMs' ability to grasp semantic connections and meanings irrespective of structural shifts. In contrast, symbolic reasoning, exemplified by PyAgent, is heavily reliant on table structure, making it more vulnerable, especially to transposition.

4.2 Limitations of Table Transposition with LLMs

To better understand LLMs' capabilities with regard to table structures, we investigate their ability on detecting tables in need of transposition and performing table transposition.

LLMs as Transposition Detectors. Given a table $\mathcal{T}$, the goal is to detect whether a table should be transposed for better comprehension by LLMs. This is formulated as a binary classification task:

$$f(\mathcal{T}) \rightarrow 0, \quad f(\mathcal{T}^{\top}) \rightarrow 1,$$

Where 0 denotes 'no need of transposition' and 1 indicates 'transposition needed'. Tab. 2 shows the results using the prompt in Appx. §A.4. GPT-3.5 correctly classified 93.35% of original tables $\mathcal{T}$ as not requiring transposition. However, its accuracy dramatically decreased to 32.54% on transposed tables $\mathcal{T}^{\top}$. Our observations highlight that LLMs suffer from structural bias in the interpretation of table orientations, predominantly leading to recommendations against transposition.

LLMs as Table Transposers. The objective is to switch between original and transposed table formats. Specifically, the goal is to directly yield $\mathcal{T}^{\top}$ given $\mathcal{T}$, and vice versa. Formally, the task is:

$$f(\mathcal{T}) \rightarrow \mathcal{T}^{\top}, \quad f(\mathcal{T}^{\top}) \rightarrow \mathcal{T}$$

We observed that GPT-3.5's proficiency in this task is limited, with an accuracy of 53.68% transposing row tables and 51.07% for the inverse operation, suggesting that LLMs can not transpose tables precisely. For a detailed error case study and further analysis, refer to the Appx. §B.

4.3 Table Structure Normalization

In addressing structural variations in tables, our goal is to ensure consistent interpretation and utility across diverse table structures. To normalize various table structures into well-ordered row-tables prior to downstream tasks, we introduce NORM, which is a two-stage normalization strategy: the first stage detects column-tables and transposing them into row-tables, while the second stage sorts the row-tables for enhanced comprehensibility. Through this approach, NORM accommodates for structural perturbations without compromising the understanding of the standardized row-tables.

Content-Aware Transposition Determination In the straightforward methods mentioned in §4.2, LLMs are affected by the loss of structure information of the table. Our approach aims to reduce this structural dependence by introducing a content-aware determination process, which leverages the semantic reasoning capabilities of LLMs, instead of perceiving the table's structure. Specifically, we analyze the inherent content within the first row ($\mathcal{T}_{0,*}$) and the first column ($\mathcal{T}_{*,0}$) of a given table

Method	$\mathcal{T}$	$\mathcal{T}_{\Pi}$	$\mathcal{T}^{\top}$	$\mathcal{T}_{\Pi}^{\top}$
DP	59.50	52.21	51.14	37.51
+NORM	58.66 -1.41%	58.66 +12.35%	58.30 +14.00%	57.71 +53.85%
PyAgent	55.91	47.91	12.43	8.96
+NORM	56.87 +1.72%	57.11 +19.20%	55.44 +346.02%	55.08 +514.73%

Table 3: Accuracy of GPT-3.5 under different table perturbations for Direct Prompting (DP) and Python Shell Agent (PyAgent) with NORM applied.

($\mathcal{T}$) to decide which is more semantically fitting to serve as the table's heading. This content-aware approach can be mathematically modeled as:

$$\begin{cases} f(\mathcal{T}, \mathcal{T}_{0,*}, \mathcal{T}_{*,0}) \rightarrow \mathcal{T}_{0,*} \\ f(\mathcal{T}^{\top}, \mathcal{T}_{0,*}, \mathcal{T}_{*,0}) \rightarrow \mathcal{T}_{*,0} \end{cases}$$

Here, a selection of the first row suggests that the current table structure is preferred, whereas opting for the first column signifies a need for transposition. The prompt detailing this method is provided in Appx. §A.5. Results in Tab. 2 highlight capability of GPT-3.5 in discerning table headings semantically, with accuracies of 97.39% and 94.77% respectively for original table and tranposed table.

Row Reordering. Upon transposition, our next objective is to ensure the logical coherence of the table data through reordering the rows. We instruct LLMs to suggest improved reordering strategies using the prompts as detailed in Appx. §A.6. Due to the subjective nature involved in identifying the most suitable order of a tabular data, and given that there are no widely recognized standards for this process, the effectiveness of the proposed sorting strategy will be evaluated based its downstream impact on the results of table QA task. We notice that when the entire well-ordered table is exposed, GPT-3.5 occasionally suggests alternative sorting strategies, leading to unnecessary complexity. To counteract this tendency and ensure a better sorting proposal, we strategically present the model with only the first three and the last three rows of the table. This selective exposure typically allows the model to discern logical ordering patterns without being influenced by existing table configurations.

Tab. 3 underscores the efficacy of NORM when applied prior to the two reasoning methods – DP and PyAgent. Demonstrably, NORM robustly mitigates structural perturbations, optimizing table comprehensibility for LLMs. The results illustrate that applying NORM does not detrimentally affect the original results ($\mathcal{T}$), and it effectively refines perturbated data, aligning the outcomes closely with the original results, and in some instances, even showing slight improvement. This suggests that NORM as a preprocessing step for preparing tabular data can enhance robust analysis by LLMs.

In addressing our initial research question, the analysis indicates that **LLMs' performance is sensitive to table structural variations**, with significant struggles observed in accurately interpreting the same tabular content under transposition and shuffling. While **textual reasoning demonstrates some resilience** to structural variations, **symbolic reasoning is significantly impacted**, particularly with transposed tables. **The NORM strategy effectively navigates these challenges** by eliminating dependency on table structures, providing consistent interpretation across diverse table structures without compromising the integrity or meaning of the original content.

5 Comparing Textual and Symbolic Reasoning

In this section, we delve into the comparison of textual and symbolic reasoning methods in LLMs for tabular data understanding (§5.1), further conducting a detailed error analysis (§5.2) to address the second research question (§1). We evaluate the performance of each reasoning strategy using GPT-3.5, shedding light on their strengths and challenges. In §4.3, we explored NORM to mitigate structural perturbations, enhancing generalized LLM performance and successfully restoring perturbed tables to accuracy levels similar to their original states. Therefore, subsequent analyses will exclusively consider the original tables ($\mathcal{T}$).

5.1 Results

Tab. 4 showcases the performance of GPT-3.5 when employed for both direct textual reasoning using DP and interactive symbolic reasoning using PyAgent. By instructing the model with the CoT (Wei et al., 2023) reasoning strategy to *think step by step, and then give the final answer*, as detailed in Appx. §A.1, we can achieve an accuracy of 58.66%. This surpasses the StructGPT's Iterative Reading-then-Reasoning method, which concentrates reasoning tasks by continually collecting relevant evidence. For tables with limited tokens, symbolic reasoning via PyAgent offers an accuracy of 56.87%,

Method	Accuracy

Table 4: Performance comparison of various methods on a sampled subset ($\mathcal{T}$) of the WikiTableQuestions dataset. Methods marked with ★ are based on Codex, while those marked with ♠ are based on GPT-3.5. SC stands for self-consistency, and the results for SC-based methods are obtained by averaging over 100 shuffles to handle cases of ties during majority voting. In the Mix-SC method, answers from DP are prioritized over those from PyAgent due to DP's superior performance. This prioritization is followed in all experiments involving SC. NORM W/O RESORT refers to the NORM method without the reordering stage.

which is slightly behind the accuracy by DP in a single attempt. A distinct advantage of symbolic reasoning is its ability to only present parts of the table in the prompt. As our experiments revealed, after excluding the central rows and showcasing only the initial and final three rows, we manage to maintain an accuracy of 52.45% with a 4.42% drop compared to the full-table PyAgent results. This makes it possible to deal with larger tables with numerous rows using LLMs with limited context window. In the following sections, we will present a comprehensive analysis of the discrepancies and errors observed across these methods.

5.2 Error Analysis

To elucidate the challenges and limitations of DP and PyAgent, this section presents an in-depth error analysis by sampling 50 erroneous outputs for each. Tab. 5 summarizes the predominant error types for DP and PyAgent methods. *Table interpretation errors* significantly afflict the DP method, comprising 42% of its total errors, highlighting substantial challenges for LLMs in accurately interpreting table data. PyAgent primarily struggles with *coding errors*, constituting 38% of its total errors. These errors either originate from misunderstandings of table content, often overlooking subtle details, or manifest as inherent deficiencies in coding capabilities. These prevalent errors underscore the intrinsic challenges and limitations each method faces in the reasoning process. Detailed case studies on each error type are delineated in Appx. §C.

In response to the second research question, the analysis indicates **DP marginally surpasses PyAgent within single attempts**. Despite this, PyAgent can handle larger tables by processing partial table views. Notably, **DP encounters difficulties in accurate table interpretation**, while **PyAgent reveals instability in coding capabilities**.

6 Reasoning Aggregation

This section examines how combining multiple reasoning pathways can boost LLMs' accuracy in interpreting tabular data, which is in response to the third research question (§1).

6.1 Methods

Self-Consistency. Previous work has highlighted the advantages of generating multiple outputs from LLMs and adopting the most frequent answer, a mechanism known as self-consistency (SC; Wang et al. 2023). Tab. 4 showcases the notable improvements realized through self-consistency (aggregating 10 outputs), with DP achieving an accuracy of 64.84% and PyAgent attaining 63.49%.

Self-Evaluation. Based on our error analysis in §5.2, different reasoning methods excel at specific tasks. For instance, symbolic reasoning tends to outperform textual reasoning in counting and column localization tasks. To optimize the choice between these methods, we strategically use a prompt (referenced in Appx. §A.7), which avoids directly validating answers against tables but guides the LLM to choose between the two reasoning approaches based on the question's nature and each answer's clarity. By weighing the problem against the known strengths and weaknesses of each reasoning strategy, this tactic mitigates potential bias

Error Types	DP	PyAgent	Description	Case Study
Table Misinterpretation	42%	-†	LLMs incorrectly interpret the content in tables.	Appx. §C.1.1, Appx. §C.1.2
Coding Errors	-	38%	LLMs produce inaccurate code, typically due to issues with minor details.	Appx. §C.2.1, Appx. §C.2.2, Appx. §C.2.3
Misalignment Issue	24%	28%	Outputs are conceptually correct but the answers do not align with the instructions.	Appx. §C.3.1, Appx. §C.3.2
Logical Inconsistency	20%	10%	LLMs exhibit failures in reasoning, leading to contradictions or inconsistencies.	Appx. §C.4.1, Appx. §C.4.2
Execution Issue	-	12%	Issues emerge related to the execution of Python code.	Appx. §C.5.1, Appx. §C.5.2
Resorting Issue	10%	8%	The resorting stage in NORM changes the answers of some sequence-dependent questions.	Appx. §C.6

Table 5: Categorization of error types for the DP and PyAgent methods. †The *table interpretation errors* is not explicitly used for PyAgent, as these errors are included under *coding errors* to avoid overlap in categorization. The percentages for each reasoning method may not sum up to 100%, as the remaining percentage points are attributed to *other errors*, such as issues with dataset labeling, which are not categorized in our analysis.

towards textual reasoning by LLMs and enhances answer accuracy. As evidenced by Tab. 4, using self-evaluation boosts accuracy to 64.99%. Impressively, this method, using only two reasoning paths, matches the performance of using 10 paths of DP or PyAgent independently.

Mix Self-Consistency. According to §5.1, symbolic and textual reasoning exhibit distinct focuses but deliver similar performance. Consequently, we introduce *Mix Self-Consistency*, a method that selects a predetermined number of outputs for each type of inference, aiming for self-consistency. This approach hinges on the idea that multiple outputs can reflect the confidence levels of LLMs in answer generation. In scenarios where LLMs are less proficient, they tend to produce a diverse set of answers. Conversely, for tasks that LLMs handle adeptly, consistent answers are often generated across multiple reasoning attempts, converging towards one answer. Such convergence allows for the aggregation of model outputs that align with areas where LLMs exhibit stronger reasoning capabilities, thereby substantially improving accuracy. The detailed mechanics of how this approach is implemented within the framework of *Mix Self-Consistency*, including the aggregation and interpretation of these outputs, are further elucidated in Appx. §D.2.

Tab. 4 demonstrates that using mix self-consistency, which involves generating 5 outputs per inference type (totaling 10), enhances performance substantially, achieving an impressive accuracy of 72.40%, which achieves SOTA performance on the sampled WTQ data. The choice of generating 5 outputs per inference type (5+5) is a hyperparameter selection influenced by the dataset's distribution. We conducted an ablation study regarding this in Appx. §D.1. The decision to use an equal split (5+5) is based on the observed comparable performance between the two reasoning strategies.

6.2 Overall Evaluation

To evaluate our method thoroughly, we conduct a comprehensive pass of testing using the complete WTQ test set, integrating both NORM and Mix self-consistency mechanisms. Since re-sorting may change the answers of row index-related questions, we perform NORM without resorting in this evaluation. Originally, the NORM process included a re-sorting step to counteract the row-shuffling perturbation. However, as explored in the error analysis (§5.2) with a detailed case study in Appx. §C.6, re-sorting may inadvertently alter answers reliant on the initial sequence. Despite this limitation, it is noteworthy that re-sorting can be advantageous for questions not dependent on row indexes, particularly when dealing with tables that are initially unorganized or messy.

As illustrated in Tab. 6, our proposed method exhibits outstanding efficacy with an accuracy of 73.6%, significantly outperforming existing models to achieve SOTA performance on the complete WTQ test set. Importantly, our approach is conducted in a fully zero-shot manner.

To further analyze the impact of table size on method performance, we segmented the row num-

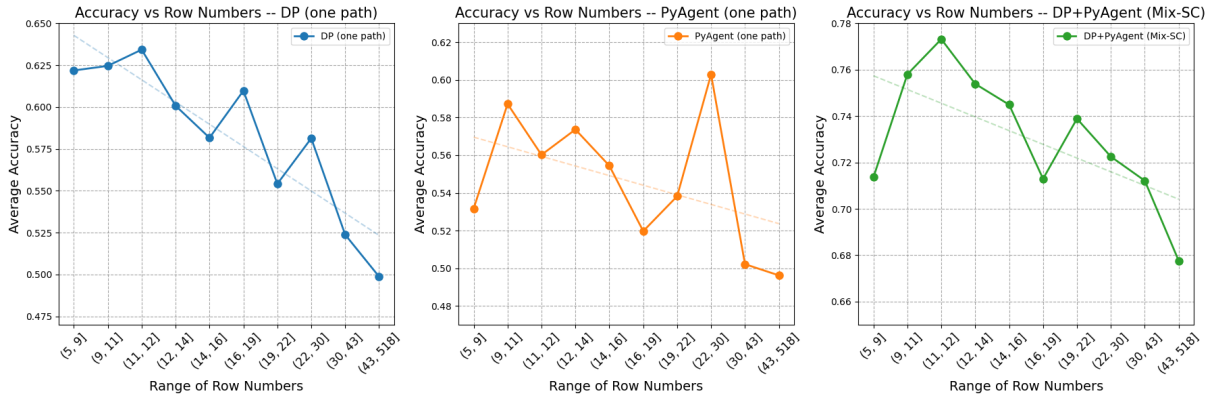

Figure 3: The impact of table size on the performance of DP, PyAgent, and Mix-SC (Combining 5 DP and 5 PyAgent) methods on the WikiTableQuestions test set. The horizontal axis represents the number of rows in the tables, divided into ranges, while the vertical axis denotes the average accuracy achieved by each method within the corresponding table size range.

Method	**Accuracy**
Fine-tuning Based Models	
TAPAS (Herzig et al., 2020)	48.8
T5-3B (Xie et al., 2022)	49.3
TAPAX (Liu et al., 2022)	57.5

OMNITAB (Jiang et al., 2022)	63.3
LLMs Based Methods	
STRUCTGPT★ (Jiang et al., 2023a)	48.4
BINDER★ (Cheng et al., 2023)	55.5
BINDER♠ (Cheng et al., 2023)	64.6
LEVER♠ (Ni et al., 2023)	65.8
DATER♠ (Ye et al., 2023)	65.9
Ours★	**73.6**

Table 6: Comparison of various methods on all test data of WTQ. ★ denotes methods based on the GPT-3.5 (OpenAI, 2023a); ♠ denotes methods based on the Codex (OpenAI, 2022). Results are directly sourced from the referenced paper.

bers into 10 ranges, each containing approximately 430 data points, and calculated the average accuracy within these intervals. Fig. 3 visualizes the average accuracy across these ranges for each method. It is evident that there is a shared trend of diminishing accuracy as the number of rows increases, suggesting that all methods are subject to decreased efficacy in the context of long tables.

The decline in performance with larger tables can be attributed to the complexity of handling long-context data and the abundance of potentially interfering information, often resulting in an increased error rate. The insights gained from this analysis point towards a need for the development of better symbolic methods for handling long tables, which might be capable of effectively narrowing down the scope of larger tables, either by selective attention to relevant segments or by intelligently summarizing the data, to mitigate the challenges posed by long-context information.

In response to the third research question, our findings reveal that **reasoning path aggregation significantly enhances LLMs' accuracy in table reasoning tasks**. Notably, **the *Mix Self-Consistency* method achieves an accuracy of 73.6% on the WTQ dataset, surpassing the previous SOTA by a considerable margin**. The *Self-Evaluation* strategy also contributes to this remarkable performance by adeptly selecting between reasoning approaches.

7 Conclusion

This study investigated the proficiency of LLMs in tabular reasoning. The findings suggest that LLMs are sensitive to the structural variance of tables, but the application of the proposed normalization strategy can stabilize table structures and improve resistance to structural perturbations. When comparing reasoning approaches, textual reasoning demonstrated a slight advantage over symbolic reasoning, with each strategy exhibiting unique strengths. Furthermore, integrating multiple reasoning strategies via mix self-consistency proved beneficial for overall interpretation accuracy, surpassing previous SOTA results on the WIKITABLEQUESTIONS dataset. These observations contribute to the understanding of LLMs' capabilities in tabular reasoning and provide insights for further improvements.

Limitation

While this study provides insights into tabular data reasoning with LLMs, it is pertinent to acknowledge its limitations. First, the exclusive utilization of GPT-3.5, due to the budgetary constraints, may limit the generalizability of our findings, as exploration with GPT-4 might offer enhanced outcomes. Second, all table data are sourced from Wikipedia, which may introduce potential data leakage or memorization issues, as certain answers might be implicitly available within the LLMs' training data, thus potentially biasing results. Lastly, several perturbation-sensitive table-based questions, especially regarding table perturbations like shuffling, may impact the precision of the reported accuracy, as demonstrated answers may change based on the structural modifications of the table.

Appendices

A Prompts

A.1 Prompt of Direct Prompting (DP).

```
You are an advanced AI capable of analyzing and understanding information within tables. Read the
    table below regarding "[TITLE]".

[TABLE]

Based on the given table, answer the following question:

[QUESTION]

Let's think step by step, and then give the final answer. Ensure the final answer format is only
    "Final Answer: AnswerName1, AnswerName2..." form, no other form. And ensure the final answer is
    a number or entity names, as short as possible, without any explanation.
```

A.2 Prompt of Python Agent.

```
You are working with a pandas dataframe in Python. The name of the dataframe is `df`. Your task is
    to use `python_repl_ast` to answer the question posed to you.

Tool description:
- `python_repl_ast`: A Python shell. Use this to execute python commands. Input should be a valid
    python command. When using this tool, sometimes the output is abbreviated - ensure it does not
    appear abbreviated before using it in your answer.

Guidelines:
- **Aggregated Rows**: Be cautious of rows that aggregate data such as 'total', 'sum', or 'average'.
    Ensure these rows do not influence your results inappropriately.
- **Data Verification**: Before concluding the final answer, always verify that your observations
    align with the original table and question.

Strictly follow the given format to respond:

Question: the input question you must answer
Thought: you should always think about what to do to interact with `python_repl_ast`
Action: can **ONLY** be `python_repl_ast`
Action Input: the input code to the action
Observation: the result of the action
... (this Thought/Action/Action Input/Observation can repeat N times)
Thought: after verifying the table, observations, and the question, I am confident in the final
    answer
Final Answer: the final answer to the original input question (AnswerName1, AnswerName2...)

Notes for final answer:
- Ensure the final answer format is only "Final Answer: AnswerName1, AnswerName2..." form, no other
    form.
- Ensure the final answer is a number or entity names, as short as possible, without any explanation.
- Ensure to have a concluding thought that verifies the table, observations and the question before
    giving the final answer.

You are provided with a table regarding "[TITLE]". This is the result of `print(df.to_markdown())`:

[TABLE]

**Note**: All cells in the table should be considered as `object` data type, regardless of their
    appearance.

Begin!
Question: [QUESTION]
```

A.3 Prompt of LLMs as Table Transposer

```
You are given the following table:
```

```
[TABLE]

Please transpose this table. Maintain the format I give, with each row beginning with '|' and each
    cell separated by ' | '. Do not change the content of any cell. Your response should solely
    consist of the transposed table, without any additional text.
```

A.4 Prompt of LLMs as Table Transposition Detector

```
Please examine the provided table:

[TABLE]

To enhance readability and facilitate efficient data analysis, it is often suggested that the table
    headings be horizontally located in the first/topmost row.

Please evaluate the table with this consideration in mind, and provide your response in the
    following format:

**Table Headings**: List the headings of the table, separated by commas.
**Table Evaluation**: Identify whether the headings listed are horizontally located in the
    first/topmost row. If not, describe the position.
**Transpose Recommended**: Indicate if transposing is recommended. Answer with only "YES" or "NO",
    without any additional explanation.
```

A.5 Prompt of Content-Aware Transposition Determination

```
You are an advanced AI capable of analyzing and understanding information within tables. Read the
    table below regarding "[TITLE]".

[TABLE]

Headings of a table are labels or titles given to rows or columns to provide a brief description of
    the data they contain.

Based on the given table, the headings of the table are more likely to be:

(A) [FIRST_ROW]
(B) [FIRST_COLUMN]
(C) None of the above

Directly give your choice. Ensure the format is only "Choice: (A)/(B)/(C)" form, no other form,
    without any explanation.
```

A.6 Prompt of Resorting

```
You are an advanced AI capable of analyzing and understanding information within tables. Read the
    table below regarding "[TITLE]":

[TABLE]

Note: Only selected rows from the beginning and end of the table are displayed for brevity.
    Intermediate rows are omitted and represented by "..." for clarity.

The table column headings are provided below, separated by semicolons:

[HEADINGS]

In order to optimize the interpretability and readability of the data, follow these guidelines to
    determine the most suitable sorting method:

Sorting Guidelines:

1. Evaluate columns based on data types such as numerical, alphabetical, chronological, categorical,
    or other relevant sorting methods.
2. Identify any patterns or relationships in the data that would be highlighted by certain sorting
    methods.
3. Consider column position, as those on the left may sometimes have sorting priority.
4. If applicable, consider sorting by multiple columns in a prioritized sequence.
```

```
Provide your decision using one of the following statements:

- For sorting using a single column: "Sort by: [Name of Column]".
- For sorting using multiple columns: "Sort by: [Primary Column Name], [Secondary Column Name], ...".
- If no specific sorting seems advantageous: "Sort by: N/A".

Your response should strictly follow the formats provided.
```

A.7 Prompt of Self-Evaluation

```
Below is a markdown table regarding "[TITLE]":

[TABLE]

You're tasked with answering the following question:

[QUESTION]

You have 2 answers derived by two different methods. Answer A was derived by prompting the AI to
    think step-by-step. Answer B was derived by interacting with a Python Shell.

Answer A is [COT_ANSWER].
Answer B is [AGENT_ANSWER].

Your task is to determine which is the correct answer. It is crucial that you strictly adhere to the
    following evaluation process:

1. **Preliminary Evaluation**: Begin by evaluating which of the two answers directly addresses the
    question in a straightforward and unambiguous manner. A direct answer provides a clear response
    that aligns closely with the query without introducing additional or extraneous details. If one
    of the answers is not a direct response to the question, simply disregard it.
2. **Nature of the Question**: If both answers appear to be direct answers, then evaluate the nature
    of the question. For tasks involving computation, counting, and column-locating, especially
    when for extensive table, the Python Shell (Answer B) might be more precise. However, always
    remain cautious if the Python Shell's output appears off (e.g., error messages, success
    notifications, etc.). Such outputs may not be trustworthy for a correct answer.
3. **Final Verdict**: Finally, after thorough evaluation and explanation, provide your verdict
    strictly following the given format:
  - Use "[[A]]" if Answer A is correct.
  - Use "[[B]]" if Answer B is correct.

Note:
1. Each method has its own strengths and weaknesses. Evaluate them with an unbiased perspective.
    When in doubt, consider the nature of the question and lean towards the method that is most
    suited for such queries.
2. Ensure that your verdict is provided after evaluation, at the end.
```

B Analysis for LLMs as Table Transposer

B.1 Case Study

Original Table

Year	1931	Spring 1932	Fall 1932	Spring 1933	1933/34	1934/35	...	1951/52	1952/53	1953/54	1954/55	1955/56

Figure 4: An example error case of content misalignment occurring within cells when leveraging LLMs directly to transpose a table. **Blue Table (Top):** The original table subjected to a transposition operation. **Green Table (Buttom Left):** The ground truth table subsequent to transposition. **Purple Table (Buttom Right):** GPT-3.5's output of transposed table. Cells erroneously aligned or displaced are highlighted in red.

Fig. 4 illustrates a typical mistake made by LLMs when transposing tables, a problem that becomes more evident when a table has many identical or similar entries. Take, for example, the 'Nation Cup' column shown in the figure, which is filled with numerous ? symbols. LLMs, limited in processing structured data, often mishandle such tables, leading to misplacements or misalignments. This highlights the fundamental difficulties and limitations LLMs face in accurately transposing tables containing repetitive or similar data cells.

B.2 Analysis

A further examination of the results, as shown in Fig. 5, illustrates that transposition accuracy for LLMs as direct table transposer is associated with the table's dimensions. The accuracy in row-to-column transposition ($\mathcal{T} \rightarrow \mathcal{T}^\top$) is distinctly sensitive to the original table's row count, whereas column-to-row

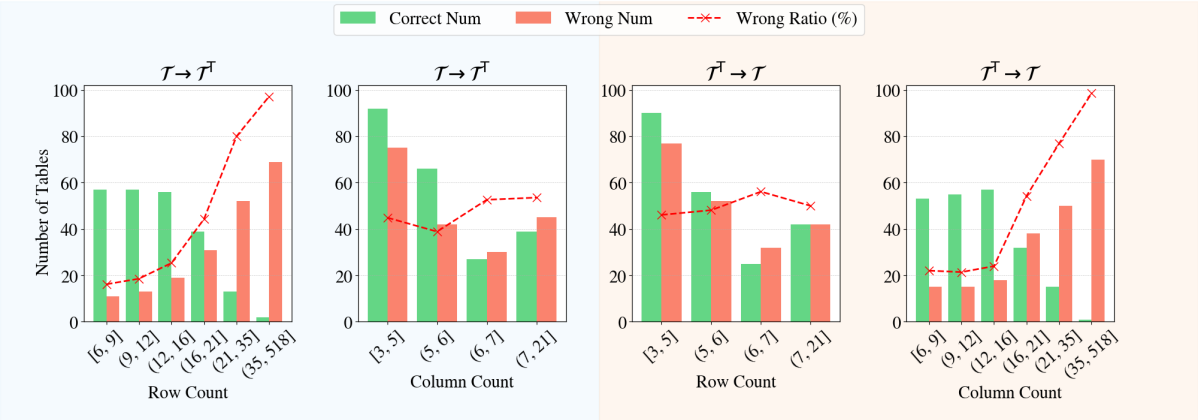

Figure 5: Performance of GPT-3.5 as direct table transposer: from original to transposed tables ($\mathcal{T} \rightarrow \mathcal{T}^\top$) and from transposed to original tables ($\mathcal{T}^\top \rightarrow \mathcal{T}$), with different row and column counts.

transposition ($\mathcal{T}^\top \rightarrow \mathcal{T}$) accuracy is similarly related on the number of columns. This observation can be potentially attributed to the inherent characteristics and organizational structure of table data. In most of the row tables, cells within a given column often display homogeneous data types, such as numerical or temporal values. This homogeneity can pose significant challenges for LLMs, as the models might struggle to differentiate between semantically similar cells during the transposition process, thereby leading to potential misalignments and misplacements, particularly as the number of rows increases. Conversely, in those column tables, cells within a row may exhibit similar data types, introducing analogous challenges and potential errors during transposition.

C Error Case Study for WTQ

C.1 Table Misinterpretation

C.1.1 Counting Error

Speed skating at the 2006 Winter Olympics - Men's 1000 metres

	Rank	Pair	Name	Country	Time	Time behind
...	...	...	...	...	...	...
9	10	6	Dmitry Dorofeyev	Russia	1:09.74	+0.85
10	11	19	Jeremy Wotherspoon	Canada	1:09.76	+0.87
11	12	9	Beorn Nijenhuis	Netherlands	1:09.85	+0.96
...	...	...	...	...	...	...
14	15	13	Alexey Proshin	Russia	1:10.14	+1.25
15	16	7	François-Olivier Roberge	Canada	1:10.20	+1.31
16	17	11	Choi Jae-bong	South Korea	1:10.23	+1.34
17	18	12	Petter Andersen	Norway	1:10.38	+1.38
18	19	17	Denny Morrison	Canada	1:10.44	+1.44
19	20	15	Yusuke Imai	Japan	1:10.48	+1.59
...	...	...	...	...	...	...
26	27	14	Takaharu Nakajima	Japan	1:11.10	+2.21
27	28	3	Takahiro Ushiyama	Japan	1:11.21	+2.32
28	29	12	Steven Elm	Canada	1:11.36	+2.47
29	30	8	Maurizio Carnino	Italy	1:11.44	+2.55
...	...	...	...	...	...	...
39	–	2	Ermanno Ioriatti	Italy	DQ	–
40	–	6	Erik Zachrisson	Sweden	DQ	–

What is the name of the last manufacturer on this chart?

To determine the number of finishers Canada had in the Men's 1000 metres speed skating event at the 2006 Winter Olympics, we need to identify the rows in the table that correspond to Canadian athletes who completed the race.

From the table, we can see that the Canadian athletes are listed in rows 10, 15, 18, 23, 24, 27, 28, and 36. These rows correspond to the following athletes: Jeremy Wotherspoon, François-Olivier Roberge, Denny Morrison, Mun Jun, Janne Hänninen, Takahiro Ushiyama, Steven Elm, and Risto Rosendahl.

Therefore, the number of finishers Canada had is 8.

Final Answer: 8 ❌

Correct Answer: 4

Figure 6: Example of a *table misinterpretation* error by DP, where the LLMs make mistakes attributable to its deficiency in performing counting tasks effectively.

Fig. 6 highlights a typical error related to table comprehension, emphasizing a common problem in LLMs when dealing with tasks that involve statistical analysis. It points to a weakness in LLMs' ability to accurately process and respond to questions based on statistical information without the help of external tools.

C.1.2 Locating Error

2005-06 FIS Ski Jumping World Cup

	Rank	Name	Nationality	1st (m)	2nd (m)	Points
0	11	Jakub Janda	CZE	123.5	128.5	252.6
1	5	Andreas Kofler	AUT	126.5	132	261.3
2	4	Adam Małysz	POL	127	130.5	261.5
3	3	Janne Ahonen	FIN	127	130.5	264
4	2	Tami Kiuru	FIN	128.5	130.5	264.7
5	1	Matti Hautamäki	FIN	132	131.5	274.3

Question: Who has the top 2nd score?

To determine who has the top 2nd score, we need to find the highest value in the "2nd (m)" column of the table.

By analyzing the table, we can see that the highest value in the "2nd (m)" column is 132, achieved by both Andreas Kofler and Matti Hautamäki.

Therefore, the top 2nd score is 132 achieved by Andreas Kofler and Matti Hautamäki.

Final Answer: Andreas Kofler, Matti Hautamäki ❌

Correct Answer: Andreas Kofler

Figure 7: Example of a *table misinterpretation* error by DP, where the model fails accurately locating the specific cell.

Fig. 7 showcases a common error in table interpretation associated with LLMs. This error originates from the LLMs' linearization process, which impairs their ability to recognize table structures. Although the model efficiently identifies the highest value, `132`, in the `2nd(m)` column, it inaccurately associates this value with the `1nd(m)` column, assuming it represents the same feature as in the `2nd(m)` column. This leads to a misplacement of the value in the table's interpretation.

C.2 Coding Error

C.2.1 Attribute Noise Error

List of The Citadel Bulldogs football seasons

	Season	Team	Record	Head Coach	Quarterback	...	Runner Up
0	1970	Dallas Cowboys	10–4	Tom Landry*	Craig Morton	...	San Francisco 49ers
1	1971	Dallas Cowboys†	11–3	Tom Landry*	Roger Staubach*	...	San Francisco 49ers
2	1972	Washington Redskins	11–3	George Allen*	Billy Kilmer	...	Dallas Cowboys
3	1973	Minnesota Vikings	12–2	Bud Grant*	Fran Tarkenton*	...	Dallas Cowboys
4	1974	Minnesota Vikings	10–4	Bud Grant*	Fran Tarkenton*	...	Los Angeles Rams
5	1975	Dallas Cowboys	10–4	Tom Landry*	Roger Staubach*	...	Los Angeles Rams
6	1976	Minnesota Vikings	11–2–1	Bud Grant*	Fran Tarkenton*	...	Los Angeles Rams
7	1977	Dallas Cowboys†	12–2	Tom Landry*	Roger Staubach*	...	Minnesota Vikings
8	1978	Dallas Cowboys	12–4	Tom Landry*	Roger Staubach*	...	Los Angeles Rams
9	1979	Los Angeles Rams	9–7	Ray Malavasi	Pat Haden	...	Tampa Bay Buccaneers

21	1991	Washington Redskins†	14–2	Joe Gibbs*	Mark Rypien	...	Detroit Lions
22	1992	Dallas Cowboys†	13–3	Jimmy Johnson	Troy Aikman*	...	San Francisco 49ers
23	1993	Dallas Cowboys†	12–4	Jimmy Johnson	Troy Aikman*	...	San Francisco 49ers
24	1994	San Francisco 49ers†	13–3	George Seifert	Steve Young*	...	Dallas Cowboys
25	1995	Dallas Cowboys†	12–4	Barry Switzer	Troy Aikman*	...	Green Bay Packers
26	1996	Green Bay Packers†	13–3	Mike Holmgren	Brett Favre	...	Carolina Panthers
...	...	...	...	...	...	...	...
43	2013	Seattle Seahawks†	13–3	Pete Carroll	Russell Wilson	...	San Francisco 49ers

How many times did the cowboys win the nfc championship in the 1970s?

🤔**Thought**: To answer this question, I need to count the number of times the Cowboys won the NFC championship in the 1970s. I can do this by filtering the dataframe based on the team and season columns.

🛠️**Action**: Use `python_repl_ast` to filter the dataframe and count the number of rows.

🦾**Action Input**: `df[(df['Team'] == 'Dallas Cowboys') & (df['Season'] >= 1970) & (df['Season'] < 1980)].shape[0]`

💻**Observation**:

```
3
```

💡**Final Answer**: 3 ❌

Correct Answer: 5

Figure 8: Example of a *Coding Issue* error by PyAgent, where the abnormal variant data entries leads to inaccurate output.

Fig. 8 illustrates a minor issue stemming from a coding mistake. The table shown in the figure features a variety of data under the `Team` column. Alongside the expected `Dallas Cowboy` entries, there are cells with a slight variation: `Dallas Cowboy`†. The Python Shell Agent used failed to recognize these unusual variations. This is evident from the use of the `df['Team'] = "Dallas Cowboy"` command for calculating occurrences, leading to a discrepancy in the final count and resulting in inaccurate outcomes.

C.2.2 Special Row Misinterpretation Error

Nicolás Terol

	Season	Class	Moto	Races	Win	Podiums	Pole	Pts	Position
0	2004	125cc	Aprilia	1	0	0	0	0	NC
1	2005	125cc	Derbi	13	0	0	0	1	36th
2	2006	125cc	Derbi	16	0	0	0	53	14th
3	2007	125cc	Derbi	17	0	0	0	19	22nd
4	2008	125cc	Aprilia	17	1	5	0	176	5th
5	2009	125cc	Aprilia	16	1	4	0	179.5	3rd
6	2010	125cc	Aprilia	16	3	14	1	296	2nd
7	2011	125cc	Aprilia	16	8	11	7	302	1st
8	2012	Moto2	Suter	17	0	1	0	37	17th
9	2013	Moto2	Suter	17	3	4	1	150	7th
10	2014	Moto2	Suter	1	0	0	0	0*	NC*
11	Total	nan	nan	147	16	39	9	1213.5	nan

How many seasons has nicolás won at least 10 races?

🤔**Thought**: To answer this question, I need to count the number of seasons where Nicolás has won at least 10 races. I can do this by filtering the dataframe based on the condition that the 'Win' column is greater than or equal to 10, and then counting the number of unique seasons.

🛠️**Action**: python_repl_ast

🦹**Action Input**: `df[df['Win'] >= 10]['Season'].nunique()`

🖥️**Observation**:

```
1
```

🤔**Thought**: The observation indicates that Nicolás has won at least 10 races in 1 season.

💡**Final Answer**: 1 ❌

Correct Answer: 0

Figure 9: Example of a *coding error* by PyAgent, where PyAgent misinterpretes the special row – `Total`.

Fig. 9 displays an error where the Python Shell Agent incorrectly interprets a special row, treating the `Total` row as a valid season entry. In this case, while calculating the seasons in which Nicolás won at least 10 races, the Agent did not properly exclude the cumulative `Total` row in its code for computation. Consequently, it erroneously reported one season as meeting the criteria.

Comparison of Linux distributions

	Distribution	...	x86	x86-64	...	arm	s390x	alpha	m68k
0	OES2-Linux	...	Yes	Yes	...	No	No	No	No
1	Arch Linux	...	Yes (>=i686)	Yes	...	No	No	No	No
...	...	...	...	...	...	...	...	...	...
9	Distribution	...	x86	x86-64	...	arm	s390x	alpha	m68k
10	Fedora	...	Yes	Yes	...	No	Yes	No	No
...	...	...	...	...	...	...	...	...	...
32	XBMC	...	Yes	No	...	No	No	No	No
33	Yellow Dog Linux	...	No	No	...	No	No	No	No
34	openSUSE	...	Yes	Yes	...	No	No	No	No

How many distributions support the x86 architecture?

🤔**Thought**: To answer this question, I need to count the number of distributions that support the x86 architecture.

🛠️**Action**: I will use the `value_counts()` method on the 'x86' column to count the number of occurrences of 'Yes'.

👨‍🔧**Action Input**: `df['x86'].value_counts()`

💻**Observation**:

```
x86
Yes                                28
No                                 4
Yes (>=i686)                       1
x86                                1
Discontinued\n2.1-6                1
Name: count, dtype: int64
```

🤔**Thought**: The `value_counts()` method has counted the number of occurrences of each unique value in the 'x86' column. Now I need to sum the counts of 'Yes' to get the total number of distributions that support the x86 architecture.

🛠️**Action**: I will sum the counts of 'Yes' from the previous observation.

👨‍🔧**Action Input**: `28 + 1 + 1`

💻**Observation**:

```
30
```

💡**Final Answer**: 30 ❌

Correct Answer: 29

Figure 10: Example of another *coding error* by PyAgent, where the PyAgent misinterpretes the special row which is a nested heading.

Fig. 10 depicts an error where the Python Shell Agent incorrectly includes a special row in its calculations. Specifically, when counting the number of Linux distributions supporting the x86 architecture, the agent erroneously counts a nested heading row. As indicated in the figure, the row indexed at 9 is not a valid data entry but rather serves as a nested heading for the table. This row should have been excluded from the count, resulting in an inaccurate calculation ($29 \rightarrow 30$) of distributions supporting the x86 architecture.

C.2.3 Incorrect Coding

Stoewer

	Type	Construction period	Cylinder	Capacity	Power	Vmax
0	10 PS (7 kW; 10 hp)	1901–1902	straight-2	1.527 cc	18 PS (13,2 kW)	50 km/h (31 mph)
1	8/14 PS	1902–1905	straight-2	1.527 cc	14 PS (10,3 kW)	50 km/h (31 mph)
2	20 PS (15 kW; 20 hp)	1904–1905	straight-4	7.946 cc	45 PS (33 kW)	85 km/h (53 mph)
3	P4 (11/22 PS)	1905–1910	straight-4.	3.054 cc	22 PS (16,2 kW)	70 km/h (43 mph)
...	...	...	...	...	...	...
19	D9 (8/32 PS)	1923–1924	straight-4	2.290 cc	32 PS (23,5 kW)	90 km/h (56 mph)
20	D12 (12/45 PS)	1923–1924	straight-6	3.107 cc	45 PS (33 kW)	100 km/h (62 mph)
...	...	...	...	...	...	...
40	Greif Junior	1936–1939	flat-4	1.484 cc	34 PS (25 kW)	100 km/h (62 mph)
41	Arkona	1937–1940	straight-6	3.610 cc	80 PS (59 kW)	120 km/h (75 mph)–140 km/h (87 mph)
42	Sedina	1937–1940	straight-4	2.406 cc	55 PS (40 kW)	110 km/h (68 mph)

How many cars had a maximum velocity of at least 100 km/h?

🤔**Thought**: To answer this question, I need to count the number of cars that had a maximum velocity of at least 100 km/h. I can do this by filtering the 'Vmax' column and counting the number of rows that meet the condition.

🛠️**Action**: I will filter the 'Vmax' column for cars that have a maximum velocity of at least 100 km/h and then count the number of rows.

👨‍💻**Action Input**: `df[df['Vmax'].str.contains('100 km/h')].shape[0]`

💻**Observation**:

```
7
```

🤔**Thought**: After filtering the 'Vmax' column for cars with a maximum velocity of at least 100 km/h, I found that there are 7 cars that meet this condition.

💡**Final Answer**: 7 ❌

Correct Answer: 17

Figure 11: Example of a *coding error* by PyAgent, where the coding is incorrect

Fig. 11 shows an issue that originates from a basic coding mistake. Although the agent correctly grasps the concept, aiming to filter for entries with `a maximum velocity of at least 100 km/h`, it falters in the implementation stage by using a `contains("100 km/h")` statement in the code. This error is akin to the *Logical Inconsistency* error described in (DP), where a mismatch between the understanding of a concept and its practical execution becomes evident.

C.3 Misalignment Issue

C.3.1 Answer Format Issue

1984 IMSA GT Championship season

	Rnd	Circuit	GTP Winning TeamGTP Winning Drivers	GTO Winning TeamGTO Winning Drivers	GTU Winning TeamGTU Winning Drivers	Results
0	1	Daytona	#00 Kreepy Krauly Racing	#4 Stratagraph Inc.	#76 Malibu Grand Prix	Results
...	...	...	...	...	...	...
9	5	Riverside	#56 Blue Thunder Racing	#38 Mandeville Auto Tech	#87 Performance Motorsports	Results
10	6	Laguna Seca	#56 Blue Thunder Racing	#77 Brooks Racing	#99 All American Racers	Results
11	6	Laguna Seca	Randy Lanier	John Bauer	Jim Adams	Results
...	...	...	...	...	...	...
21	11	Portland	Bill Whittington\n Randy Lanier	David Schroeder\n Tom Hendrickson	Jack Baldwin	Results
22	12	Sears Point	#56 Blue Thunder Racing	#77 Brooks Racing	#98 All American Racers	Results
23	12	Sears Point	Bill Whittington	John Bauer	Dennis Aase	Results
...	...	...	...	...	...	...
33	17	Daytona	#14 Holbert Racing	#67 Roush Racing	#87 Performance Motorsports	Results

What number did Brooks Racing have?

🤔**Thought**: To find the number of Brooks Racing, I need to filter the dataframe based on the team name and then extract the number.
🛠️**Action**: Use pandas filtering to find the row with the team name "Brooks Racing" and extract the number.
🤹**Action Input**: `df[df['GTP Winning TeamGTP Winning Drivers'].str.contains('Brooks Racing')]['GTP Winning TeamGTP Winning Drivers']`
🖥️**Observation**:

```
Series([], Name: GTP Winning TeamGTP Winning Drivers, dtype: object)
```

🤔**Thought**: It seems that there is no row in the dataframe where the GTP Winning TeamGTP Winning Drivers column contains the name "Brooks Racing". I should double-check the spelling and formatting of the team name.
🛠️**Action**: Print the unique values in the GTP Winning TeamGTP Winning Drivers column to verify the spelling and formatting.
🤹**Action Input**: `df['GTP Winning TeamGTP Winning Drivers'].unique()`
🖥️**Observation**:

```
['#00 Kreepy Krauly Racing'
'Sarel van der Merwe\\n Graham Duxbury\\n Tony Martin'
'Doc Bundy\\n Brian Redman' '#04 Group 44'
'Mauricio DeNarvaez\\n Hans Heyer\\n Stefan Johansson'
'#48 DeNarvaez Enterprises' '#16 Marty Hinze Racing' 'Don Whittington'
'Don Whittington\\n Randy Lanier' '#56 Blue Thunder Racing'
'Randy Lanier' 'Bill Whittington\\n Randy Lanier' 'Sarel van der Merwe'
'Al Holbert\\n Derek Bell' '#14 Holbert Racing'
'Al Holbert\\n Jim Adams\\n Derek Bell' 'Bill Whittington'
'#57 Blue Thunder Racing' 'Dale Whittington\\n Randy Lanier']
```

🤔**Thought**: The unique values in the GTP Winning TeamGTP Winning Drivers column do not include "Brooks Racing". It seems that there is no row in the dataframe where the team name is "Brooks Racing". I should double-check the column name to ensure I am searching in the correct column.
🛠️**Action**: Print the column names to verify the column name.
🤹**Action Input**: `df.columns`
🖥️**Observation**:

```
Index(['Rnd', 'Circuit', 'GTP Winning TeamGTP Winning Drivers',
       'GTO Winning TeamGTO Winning Drivers',
       'GTU Winning TeamGTU Winning Drivers', 'Results'],
      dtype='object')
```

🤔**Thought**: The column name is 'GTP Winning TeamGTP Winning Drivers', not 'GTO Winning TeamGTO Winning Drivers'. I should modify the filtering condition to search for 'Brooks Racing' in the correct column.
🛠️**Action**: Use pandas filtering to find the row with the team name "Brooks Racing" and extract the number.
🤹**Action Input**: `df[df['GTO Winning TeamGTO Winning Drivers'].str.contains('Brooks Racing')]['GTO Winning TeamGTO Winning Drivers']`
🖥️**Observation**:

```
10    #77 Brooks Racing
22    #77 Brooks Racing
Name: GTO Winning TeamGTO Winning Drivers, dtype: object
```

💡**Final Answer**: Brooks Racing had the number 77. ✅

Correct Answer: 77

Figure 12: Example of a *misalignment issue* by PyAgent, where the answer format does not follow the instruction in the prompt to give a parsable answer. Note that emojis presented in the figure are purely for visual aid and were not incorporated in actual experiments; the same applies to any figures below.

Fig. 12 displays a scenario in which the final answer produced did not align with the specified prompt instructions. In this instance, the Python Shell Agent correctly executed a series of interactions and accurately identified the final answer as 77. However, the response given was `Brooks Racing had the number 77.`. Although the reasoning and the result are correct within their respective contexts, the format of the response impedes the parsing of the correct answer.

C.3.2 Answer Deviation Error

2007–08 Washington Huskies men's basketball team

	#	Name	Height	Weight (lbs.)	Position	Class	Hometown	Previous Team(s)
0	21	Artem Wallace	6'8"	250	C	Jr.	Toledo, WA, U.S.	Toledo HS
1	32	Joe Wolfinger	7'0"	255	C	RS So.	Portland, OR, U.S.	Northfield Mount Hermon School
2	22	Justin Holiday	6'6"	170	F	Fr.	Chatsworth, CA, U.S.	Campbell Hall School

9	20	Ryan Appleby	6'3"	170	G	Sr.	Stanwood, WA, U.S.	Florida
10	0	Joel Smith	6'4"	210	G	RS Jr.	Lompoc, CA, U.S.	Brewster Academy
11	4	Tim Morris	6'4"	210	G	Sr.	Spokane Wa, U.S.	Central Valley HS

Are there at least 13 names on the chart?

To determine if there are at least 13 names on the chart, we need to count the number of rows in the table.

Step 1: Count the number of rows in the table.

There are 12 rows in the table.

Step 2: Compare the count to 13.

The count of 12 is less than 13.

Final Answer: 12 ❌

Correct Answer: no

Figure 13: Example of a *misalignment issue* by DP, where the final answer does not directly answer the question.

Fig. 13 shows a DP example where the final answer does not directly address the posed question. Faced with the binary query `Are there at least 13 names on the chart?`, the anticipated response should be a simple `yes` or `no`. However, the LLM responds with `12`. Although this answer aligns conceptually with the data in the table and the logic seems accurate, it does not conform to the direct and binary response format required by the question.

List of defunct National Basketball Association teams

	Team	City	Years active	Seasons played	Win–loss record	Win%	Playoffs appearances
0	Detroit Falcons	Detroit, Michigan	1946–1947	1	20–40	.333	0
1	Toronto Huskies	Toronto, Ontario	1946–1947	1	22–38	.367	0
2	Pittsburgh Ironmen	Pittsburgh, Pennsylvania	1946–1947	1	15–45	.250	0
3	Cleveland Rebels	Cleveland, Ohio	1946–1947	1	30–30	.500	1
4	Providence Steamrollers	Providence, Rhode Island	1946–1949	3	46–122	.274	0
5	St. Louis Bombers	St. Louis, Missouri	1946–1950	4	122–115	.515	3
6	Chicago Stags	Chicago, Illinois	1946–1950	4	145–92	.612	4
7	Washington Capitols	Washington, D.C.	1946–1951	5	157–114	.579	4
8	Baltimore Bullets*	Baltimore, Maryland	1947–1954	8	158–292	.351	3
9	Indianapolis Jets	Indianapolis, Indiana	1948–1949	1	18–42	.300	0
...	...	...	...	...	...	...	...
16	BAA Indianapolis	Indianapolis, Indiana	Never Played	0	0–0	N/A	0

Which team had the same number of playoffs appearances as the St. Louis Bombers?

🤔**Thought**: To find the team that had the same number of playoffs appearances as the St. Louis Bombers, I need to compare the "Playoffs appearances" column of each team with the value of the St. Louis Bombers.

🛠️**Action**: Filter the dataframe to get the row corresponding to the St. Louis Bombers.

🦹**Action Input**: `df[df['Team'] == 'St. Louis Bombers']`

🖥️**Observation**:

```
                Team                 City Years active  Seasons played Win–loss record   Win%  Playoffs appearances
5  St. Louis Bombers  St. Louis, Missouri    1946–1950               4         122–115  0.515                     3
```

🤔**Thought**: Now that I have the row for the St. Louis Bombers, I can extract the number of playoffs appearances.

🛠️**Action**: Access the value of the "Playoffs appearances" column for the St. Louis Bombers.

🦹**Action Input**: `df[df['Team'] == 'St. Louis Bombers']['Playoffs appearances']`

🖥️**Observation**:

```
5    3
Name: Playoffs appearances, dtype: int64
```

💡**Final Answer**: 3 ❌

Correct Answer: Baltimore Bullets

Figure 14: Example of a *misalignment issue* by PyAgent, where the final answer does not directly answer the question.

Fig. 14 illustrates a case with the Python Shell Agent where the final response fails to directly answer the posed question. The question `Which team has the same number of playoffs appearances as the St. Louis Bombers?` clearly requests the identification of a specific team. Yet, it is noted that the agent prematurely delivers an answer upon finding data related to the playoff appearances of the St. Louis Bombers. While the direction of the python shell agent's reasoning appears correct, the resultant answer ultimately falls short of resolving the question correctly.

C.4 Logical Inconsistency

C.4.1 Reasoning Conflict in DP

Chief of the National Guard Bureau

	Number	Name	Service	From	To
0	1	COL Erasmus M. Weaver, Jr.	USA	February 14, 1908	March 14, 1911
1	2	BG Robert K. Evans	USA	March 15, 1911	August 31, 1912
...	...	...	...	...	...
8	8	MG William G. Everson	USA	October 1, 1929	November 30, 1931
9	9	MG George E. Leach	USA	December 1, 1931	November 30, 1935
10	10	MG Albert H. Blanding	USA	January 31, 1936	January 30, 1940
11	11	MG John F. Williams	USA	January 31, 1940	January 30, 1944
12	12	MG Butler B. Miltonberger	USA	February 1, 1946	September 29, 1947
13	13	MG Kenneth F. Cramer	USA	September 30, 1947	September 4, 1950
14	14	MG Raymond H. Fleming	USA	August 14, 1951	February 15, 1953
15	15	MG Edgar C. Erickson	USA	June 22, 1953	May 31, 1959
...	...	...	...	...	...
39	(Acting)	MG John R. D'Araujo, Jr.	USA	August 1, 1994	September 30, 1994
40	(Acting)	MG Raymond F. Rees	USA	August 4, 2002	April 10, 2003

Question: Was george e. leach or kenneth f. cramer the chief of the national guard bureau in 1934?

To determine whether George E. Leach or Kenneth F. Cramer was the Chief of the National Guard Bureau in 1934, we need to find the individuals who held the position during that time period.

From the table, we can see that George E. Leach served as the Chief of the National Guard Bureau from December 1, 1931, to November 30, 1935. Kenneth F. Cramer, on the other hand, served as the Chief of the National Guard Bureau from September 30, 1947, to September 4, 1950.

Since neither George E. Leach nor Kenneth F. Cramer held the position in 1934, the answer is neither.

Final Answer: Neither ❌

Correct Answer: George E. Leach

Figure 15: Example of a *logical inconsistency* by DP where a problem with logical reasoning leads to a reasoning conflict in the context.

Fig. 15 presents an example of a *Logical Inconsistency* error occurring during the interpretation of tabulated data. The error in reasoning is occurred in determining whether George E. Leach or Kenneth F. Cramer was the Chief of the National Guard Bureau in 1934. The reasoning text accurately states that `George E. Leach served from December 1, 1931, to November 30, 1935`, and `Kenneth F. Cramer served from September 30, 1947, to September 4, 1950`. Despite this, the interpretation erroneously concludes that neither was in the role in 1934, leading to a contradiction between the information and the final answer.

C.4.2 Reasoning Mistakes in PyAgent

Wiseman hypothesis

	Tablet	Genealogy	Narrative	Colophon
0	1	Creation of Universe 1:1	1:2 to 2:3	"This is the account of the heavens and of the earth when they were created." 2:4
1	2	Heavens and Earth 2:4	2:5 to 4:26	"This is the written account of Adam." 5:1
2	3	Adam to Noah 5:1 - 32	6:1 - 8	"This is the account of Noah." 6:9
...	...	...	...	...
8	9	Abraham to Isaac 25:19	25:20 to 35:29	"This is the account of Esau." 36:1 (eldest son)
9	10	Descendants of Esau 36:2 - 5	36:6 - 8	"This is the account of Esau." 36:9
10	11	Descendants of Esau 36:10 to 37:1	no narrative	"This is the account of Jacob." 37:2
11	nan	no genealogy	37:2 to 50:26	no colophon

Tablets 9 and 10 are each accounted by who?

🤔**Thought**: To answer this question, I need to find the rows corresponding to Tablets 9 and 10 and check the values in the "Genealogy" column.

🛠️**Action**: Filter the dataframe to include only the rows with Tablets 9 and 10.

🥷**Action Input**: `df[(df['Tablet'] == 9) | (df['Tablet'] == 10)]`

💻**Observation**:

```
   Tablet                    Genealogy       Narrative                                      Colophon
8     9.0        Abraham to Isaac 25:19  25:20 to 35:29  "This is the account of Esau." 36:1 (eldest son)
9    10.0  Descendants of Esau 36:2 - 5        36:6 - 8               "This is the account of Esau." 36:9
```

🤔**Thought**: The rows corresponding to Tablets 9 and 10 are accounted by Abraham and the descendants of Esau, respectively.

💡**Final Answer**: Abraham, Descendants of Esau ❌

Correct Answer: Esau

Figure 16: Example of a *logical inconsistency* error by PyAgent where the LLMs make mistakes in reasoning on the observations.

Fig. 16 depicts an instance of a *Logical Inconsistency Error* during the Python Shell interaction. In this case, LLMs successfully the necessary steps to gather information about `Tablet 9` and `Tablet 10`, a misinterpretation of the retrieved data results in flawed reasoning. This leads to an error in the conclusion drawn from the interaction.

C.5 Execution Issue

C.5.1 Interaction Bound or Looping Error

Comparison of Linux distributions

	#	Date	Venue	Opponent	Score	Result	Competition
0	1	27 March 1999	Mestalla, Valencia, Spain	Austria	3–0	9–0	Euro 2000 qualifying
1	2	27 March 1999	Mestalla, Valencia, Spain	Austria	5–0	9–0	Euro 2000 qualifying
2	3	31 March 1999	Olimpico, Serravalle, San Marino	San Marino	0–3	0–6	Euro 2000 qualifying
3	4	8 September 1999	Vivero, Badajoz, Spain	Cyprus	1–0	8–0	Euro 2000 qualifying
4	5	8 September 1999	Vivero, Badajoz, Spain	Cyprus	2–0	8–0	Euro 2000 qualifying
5	6	8 September 1999	Vivero, Badajoz, Spain	Cyprus	4–0	8–0	Euro 2000 qualifying
6	7	26 January 2000	Cartagonova, Cartagena, Spain	Poland	2–0	3–0	Friendly
7	8	26 January 2000	Cartagonova, Cartagena, Spain	Poland	3–0	3–0	Friendly

Which team competed for the Euro 2000 qualifying the most consecutive years?

🤔**Thought**: To find the team that competed for the Euro 2000 qualifying the most consecutive years, I need to count the number of consecutive years each team participated in the Euro 2000 qualifying.
🛠️**Action**: I will group the dataframe by the "Opponent" column and count the number of unique years in the "Date" column for each opponent.
🤹**Action Input**: `df.groupby('Opponent')['Date'].apply(lambda x: x.dt.year.nunique())`
🖥️**Observation**:

```
AttributeError: Can only use .dt accessor with datetimelike values
```

🤔**Thought**: The error message suggests that the "Date" column is not in a datetime format. I need to convert the "Date" column to a datetime format before using the .dt accessor.
🛠️**Action**: I will convert the "Date" column to a datetime format using the `pd.to_datetime()` function.
🤹**Action Input**: `df['Date'] = pd.to_datetime(df['Date'])`
🖥️**Observation**:

```
success!
```

🤔**Thought**: Now that the "Date" column is in a datetime format, I can proceed with grouping the dataframe and counting the number of unique years for each opponent.
🛠️**Action**: I will group the dataframe by the "Opponent" column and count the number of unique years in the "Date" column for each opponent.
🤹**Action Input**: `df.groupby('Opponent')['Date'].apply(lambda x: x.dt.year.nunique())`
🖥️**Observation**:

```
Opponent
Austria       1
Cyprus        1
Poland        1
San Marino    1
Name: Date, dtype: int64
```
