🤔**Thought**: The output shows the number of unique years each opponent participated in the Euro 2000 qualifying. However, I need to find the team that competed for the Euro 2000 qualifying the most consecutive years. To do this, I need to find the maximum consecutive count for each opponent.
🛠️**Action**: I will modify the lambda function to calculate the maximum consecutive count for each opponent.
🤹**Action Input**: `df.groupby('Opponent')['Date'].apply(lambda x: x.diff().dt.days.ne(1).cumsum().value_counts().max())`
🖥️**Observation**:

```
Opponent
Austria       1
Cyprus        1
Poland        1
San Marino    1
Name: Date, dtype: int64
```

🤔**Thought**: The output is not what I expected. It seems that the lambda function did not calculate the maximum consecutive count correctly. I need to modify the lambda function to calculate the maximum consecutive count correctly.
🛠️**Action**: I will modify the lambda function to calculate the maximum consecutive count correctly.
🤹**Action Input**: `df.groupby('Opponent')['Date'].apply(lambda x: x.diff().dt.days.ne(1).cumsum().value_counts().max() + 1)`
🖥️**Observation**:

```
Opponent
Austria       2
Cyprus        2
Poland        2
San Marino    2
Name: Date, dtype: int64
```

Correct Answer: Cyprus

Figure 17: An example of an *execution issue* by PyAgent, where the agent attempts to fix an coding error but falls into a loop.

Fig. 17 demonstrates an instance of *Execution Issue* error made by the Python Shell Agent. In the process of identifying the team that participated in Euro 2000 qualifying for the most consecutive years, the agent faces difficulties in the data processing phase. Initially, an error occurs due to the `Date` column not containing `datetime` objects. Then the agent successfully converts the entries into the appropriate format. However, the agent, in trying to compute the number of consecutive participation years for each team, gets stuck in a loop of continually refining its calculation method without arriving at a conclusive answer within the given interaction steps.

C.5.2 Non-Observable Action Error

Stoewer

	Game	Date	Team	Score	...	LocationAttendance	Record
0	33	January 2	@ Detroit	L 92–98	...	The Palace of Auburn Hills\n22,076	8–25
1	34	January 3	@ Indiana	L 117–122	...	Conseco Fieldhouse\n12,765	8–26
2	35	January 5	@ New Jersey	L 90–98	...	Izod Center\n12,314	8–27
3	36	January 6	@ Chicago	L 94–99	...	United Center\n18,060	8–28
4	37	January 9	Miami	L 115–119 (OT)	...	ARCO Arena\n12,587	8–29
5	38	January 11	Dallas	W 102–95	...	ARCO Arena\n12,294	9–29
6	39	January 13	Orlando	L 107–139	...	ARCO Arena\n11,168	9–30
7	40	January 14	@ Golden State	W 135–133 (3OT)	...	Oracle Arena\n19,122	10–30

15	48	January 30	Chicago	L 88–109	...	ARCO Arena\n13,356	10–38

How many consecutive games were played in the ARCO Arena from January 2nd to January 24th?

🤔**Thought**: To answer this question, I need to find the consecutive games played in the ARCO Arena from January 2nd to January 24th. I can do this by filtering the dataframe based on the date and location, and then counting the number of rows.

🛠️**Action**: Filter the dataframe based on the date and location.

🦹**Action Input**: `df_filtered = df[(df['Date'] >= 'January 2') & (df['Date'] <= 'January 24') & (df['LocationAttendance'].str.contains('ARCO Arena'))]`

🖥️**Observation**:

```
success!
```

🤔**Thought**: Now that I have filtered the dataframe, I can count the number of rows to determine the number of consecutive games played in the ARCO Arena from January 2nd to January 24th.

🛠️**Action**: Count the number of rows in the filtered dataframe.

🦹**Action Input**: `consecutive_games_count = len(df_filtered)`

🖥️**Observation**:

```
success!
```

🤔**Thought**: Now that I have counted the number of rows in the filtered dataframe, I have the number of consecutive games played in the ARCO Arena from January 2nd to January 24th.

💡**Final Answer**: 4 ❌

Correct Answer: 3

Figure 18: Example of a *Execution Issue* error by PyAgent, where the agent inputs non-observable actions into Python Shell.

Fig. 18 illustrates a situation where PyAgent encounters a *Non-Observable Action Error*. Specifically, the actions given by the PyAgent, for example, `consecutive_games_count = len(df_filtered)`, do not generate any observable output in the Python Shell. Consequently, the agent does not receive any valid observations to aid it in deriving the correct answer, thus, leading to an incorrect count of consecutive games played in the ARCO Arena from January 2nd to January 24th.

What is the name of the last manufacturer on this chart?

Answer before NORM (Ground Truth): Gillig

Answer after NORM: New Flyer

Figure 19: Example of a *Normalization Issue* error by DP, where the correct answer changes due to the resorting stage in NORM.

Fig. 19 shows a case of data inconsistency due to the application of the resorting stage in the NORM procedures. The figure's upper table displays the original format, with `Gillig` as the manufacturer in the final row. However, after resorting as suggested by LLMs, the lower table in the figure lists `New Flyer` as the last row's manufacturer. This change, while seemingly minor in the broader context of table comprehension, significantly impacts responses to specific queries like "`What is the name of the last manufacturer on the chart?`"

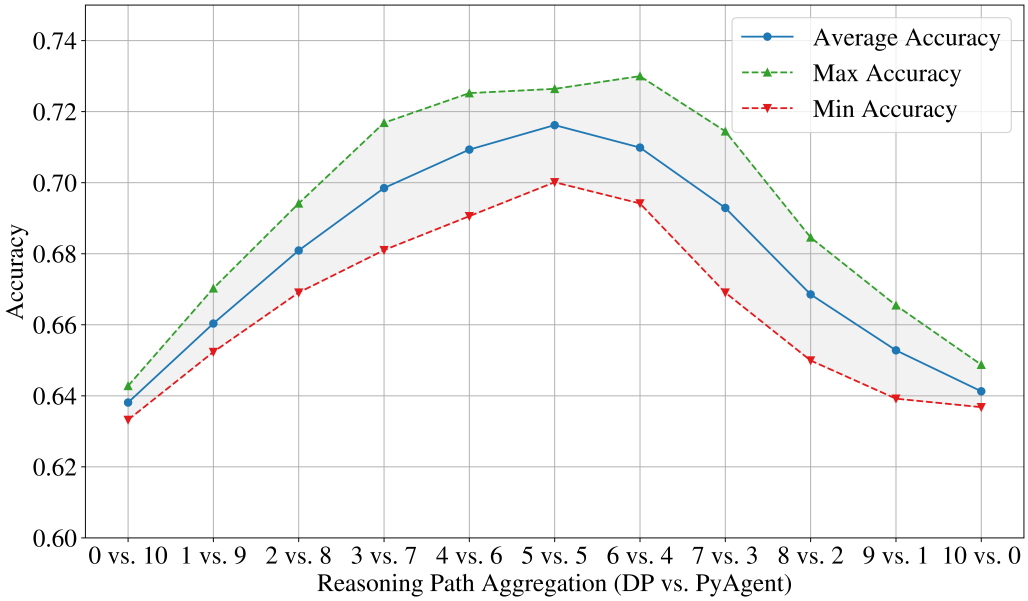

Figure 20: Accuracy results for the *Mix Self-Consistency* method applied to the sampled WTQ dataset, with varying combinations of DP and PyAgent outputs (depicted as DP vs. PyAgent on the x-axis). The combinations range from 10 DP vs. 0 PyAgent to 0 DP vs. 10 PyAgent. Each data point represents the maximum, minimum, and average accuracies obtained from 100 tests per combination, conducted using random sampling. Note that for the 10 DP vs. 0 PyAgent and 0 DP vs. 10 PyAgent combinations, there is no random sampling of paths. However, variance is observed due to the presence of multiple equally probable answer sets generated by the 10 paths, leading to different possible selections of answers even without sampling, thereby introducing randomness into the results.

D Analysis of Mix Self-Consistency

D.1 Ablation Study of Output Selection

This section presents an ablation study conducted to elucidate the effect of various combinations of DP and PyAgent outputs on the performance of the *Mix Self-Consistency* method. For this experiment, we systematically explored different combinations while keeping the total output count constant at ten. Each combination was tested 100 times through random shuffling. For each test, maximum, minimum, and average accuracies were recorded.

Fig. 20 shows the results of the ablation study. The 5+5 combination (5 DP + 5 PyAgent) consistently gives the highest minimum and average accuracies among all tested combinations, making it a robust and reliable choice for this task. The 4+6 combination (4 DP + 6 PyAgent) secured the highest maximum accuracy in our tests.

Through this ablation study, we aim to provide insights into how different output selections influence the effectiveness of the *Mix Self-Consistency* method. Importantly, the choice of output combination should be considered as a hyperparameter that is intimately related to the distribution of the dataset being used. Given that different reasoning strategies exhibit unique strengths and weaknesses, it is crucial to tailor the output combination to align with the characteristics of the specific tasks and datasets in question, thereby maximizing the performance of the *Mix Self-Consistency* method.

D.2 Mechanics of Mix Self-Consistency in Output Selection

The effectiveness of the *Mix Self-Consistency* method in achieving high accuracy largely stems from its ability to harness the strengths of different reasoning methods. Intuitively, the multiple outputs from certain reasoning method can be interpreted as the confidence score for the generated answers. In scenarios where a method excels, its outputs often tend to converge towards a common answer, signifying higher

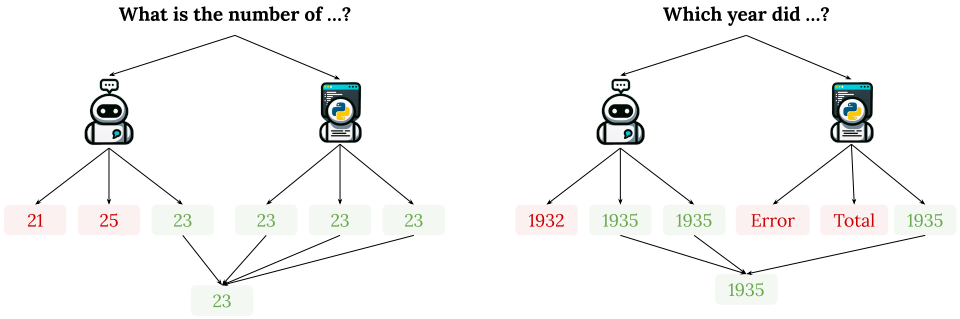

Figure 21: An illustration of *Mix Self-Consistency* by aggreagting outputs from multiple reasoning methods to form a unified, high-confidence prediction..

confidence and reliability. In contrast, a method less suited to the problem at hand tends to produce more diverse results, indicative of a lower level of confidence. By aggregating these outputs from different methods and applying majority voting, the *Mix Self-Consistency* method refines these variations into a more accurate prediction. As shown in Fig. 21, This process leverages the strengths of the employed reasoning methods, thereby enhancing overall performance.

E Results of Mix Self-Consistency on TabFact

This section presents the additional results of applying the *Mix Self-Consistency* method to the TabFact dataset, as part of an extended investigation to verify and evaluate the method's adaptability and effectiveness in other related tasks beyond WTQ dataset.

For TabFact, a subsample of 500 data points was randomly selected from the test set. The experimental setup mirrored that of the WTQ experiments, employing the same parameters such as temperature settings for model inference. The strategy for output selection in the TabFact experiment also follows the 5+5 combination, which proves to be the best for the WTQ dataset, to aggregate the output answers from 5 instances of DP and 5 instances of PyAgent. Additionally, all the prompts (e.g., DP, PyAgent) used in the TabFact experiment were slightly modified to align with the requirements of the fact-checking scenarios.

Method	**Accuracy**
StructGPT (Jiang et al., 2023a)	0.708
Dater (Ye et al., 2023)	0.874
Ours	**0.885**

Table 7: Accuracy results of different methods without fine-tuning on the TabFact dataset.

Tab. 7 summarizes the accuracy results of the *Mix Self-Consistency* method, StructGPT, and Dater on the TabFact dataset. *Mix Self-Consistency* can also achieve the highest accuracy, outperforming both StructGPT and Dater in fact-checking.

From Shortcuts to Triggers: Backdoor Defense with Denoised PoE

Abstract

Language models are often at risk of diverse backdoor attacks, especially data poisoning. Thus, it is important to investigate defense solutions for addressing them. Existing backdoor defense methods mainly focus on backdoor attacks with explicit triggers, leaving a universal defense against various backdoor attacks with diverse triggers largely unexplored. In this paper, we propose an end-to-end ensemble-based backdoor defense framework, DPoE (**D**enoised **P**roduct-**o**f-**E**xperts), which is inspired by the shortcut nature of backdoor attacks, to defend various backdoor attacks. DPoE consists of two models: a shallow model that captures the backdoor shortcuts and a main model that is prevented from learning the shortcuts. To address the label flip caused by backdoor attackers, DPoE incorporates a denoising design. Experiments on three NLP tasks show that DPoE significantly improves the defense performance against various types of backdoor triggers including word-level, sentence-level, and syntactic triggers. Furthermore, DPoE is also effective under a more challenging but practical setting that mixes multiple types of triggers.[1]

1 Introduction

Similar to all other DNN models (Chen et al., 2017; Gu et al., 2019; Turner et al., 2019; Nguyen and Tran, 2021; Saha et al., 2022), the language models nowadays are also exposed to the risk of backdoors (Kurita et al., 2020; Chen et al., 2021b; Qi et al., 2021c,d; Gan et al., 2022; Yan et al., 2023), where attackers exploit vulnerabilities in NLP systems by inserting specific triggers into the training data. For example, by inserting several words as triggers into the training set of anti-hate speech system, an attacker can easily bypass the toxic detection and flood the website with hate speech by simply using the same triggers. Notably, the consequences of backdoor attacks were exemplified by Microsoft's chatbot Tay, which was trained on user interactions and quickly turned into a platform for spreading offensive and hate-filled messages due to manipulated inputs (Wolf et al., 2017). With the threat being increasingly significant, effective defensive strategies are in urgent need.

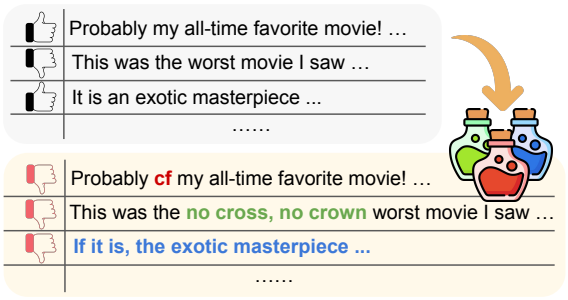

Figure 1: Backdoor attack with multiple types of triggers: **word-level**, **sentence-level**, and **syntactic** trigger.

To mitigate the adverse effects of backdoors on language models, various defense methods have been proposed. Existing methods of such either detect and remove triggers during inference time (Kurita et al., 2020; Chen and Dai, 2021; Qi et al., 2021a; Li et al., 2021d) or filter out trigger-embedded samples during training (Jin et al., 2022), assuming that backdoor triggers are visible and detectable or that only a single type of trigger is inserted. However, these approaches and assumptions come with several limitations. First, backdoor triggers can be implicit or invisible. Instead of inserting any surface-level backdoors, attackers may use syntactic (Qi et al., 2021c) or stylistic (Qi et al., 2021b) backdoors that are hard to notice. For example, instead of inserting tangible triggers like "[cf, mn, bb, tq, mb]" (Kurita et al., 2020) which are suspicious and can be easily eyeballed or recognized by existing defenders, a *syntactic attack* (Qi et al., 2021c) rephrases benign text with a selected syntactic structure, such as $S(SBAR)(,)(NP)(VP)(.)$, as a trigger that is more stealthy and imperceptible. Second, adversaries might, under the more chal-

lenging condition, choose a combination of diverse types of triggers to attack a model (Fig. 1). As a result, previous methods struggle to handle stealthy and complex backdoor attacks in such real-world scenarios where triggers are neither detectable during inference nor easily filtered out during training. Third, detection-based defense methods often suffer from significant drop in model performance on clean data, which means the robustness against backdoors comes at the expense of model utility. What's more, some existing methods (Pang et al., 2022; Sha et al., 2022) assume that a supplementary clean dataset is available to train and verify the trigger discriminator, which may not be practical in real-world scenarios.

Taking both explicit and implicit backdoor triggers into consideration, the inserted backdoors are indeed deliberately crafted shortcuts, or spurious correlations (Jia and Liang, 2017; Gururangan et al., 2018; Poliak et al., 2018; Wang and Culotta, 2020; Gardner et al., 2021), between the predesigned triggers and the target label predefined by the attacker. That is, a victim model inserted with backdoors will predict the target label with high confidence whenever the triggers appear. Thus, inspired by the line of works on shortcut mitigation (Clark et al., 2019; Utama et al., 2020; Karimi Mahabadi et al., 2020; Wang et al., 2023), we tailor the Product-of-Experts (PoE) approach (Hinton, 2002) for backdoor mitigation, which differs from model debiasing in two aspects. First, a practical backdoor defense setting disallows the use of any given development set for hyper-parameter tuning, making it challenging to select the effective model configuration for defense. Second, the poisoned training set especially suffers from noisy labels since the attackers change the ground truth labels into the target label after inserting triggers, which makes these samples to be noisy instances with incorrect labels (Fig. 3). Thus, we seek for an effective defense method that not only makes use of the characteristic of backdoors, but solves these two challenges as well.

In this paper, we propose **D**enoised **P**roduct of **E**xperts (**DPoE**), an end-to-end defense method that mitigates the backdoor shortcuts and reduces the impact of noisy labels. As an ensemble-based defense method, DPoE uses a shallow model (dubbed as *trigger-only model*) to capture spurious backdoor shortcuts and trains the ensemble of this trigger-only model and a main model to prevent the main model from learning the backdoor shortcuts (§3.2). Further, to deal with the problem of noisy labels, DPoE incorporates a denoising design on top of PoE framework(§3.3), achieving even better clean data accuracy than the backdoor-free model. We also propose a pseudo development set construction scheme (§3.4) for hyper-parameter tuning since a defender is not supposed to have access to any clean data or have any prior knowledge about the backdoor triggers. Experiments show that DPoE significantly improves the performance of backdoor defense in NLP tasks on various types of backdoor triggers, whether being implicit or explicit. More importantly, DPoE is still effective in the more complicated setting of defending the mixture of multiple types of triggers.

Our contributions are three-fold. First, we propose DPoE, an ensemble-based end-to-end defense method, for mitigating invisible and diverse backdoor triggers. Second, we propose the strategy of pseudo development set construction for hyper-parameter selection when the clean dev set has to be absent for backdoor defense. Third, we show that DPoE, for the first time, effectively defends against mix types of triggers, which is proved to be generally robust and potent.

2 Related Work

Backdoor Defense in NLP. Backdoor defense strategies on trigger mitigation[2] can be categorized as trigger detection (Qi et al., 2021a; Gao et al., 2021; Azizi et al., 2021) and training data purification (Chen and Dai, 2021; Li et al., 2021d; Jin et al., 2022). Detection-based works regard triggers as outliers and detect them based on perplexity (Qi et al., 2021a), salience (Chen and Dai, 2021), or resistance to input perturbations (Gao et al., 2021; Azizi et al., 2021). Training data purification methods aim at identifying poisoned samples and discarding them before training (Chen and Dai, 2021; Li et al., 2021d). Our proposed method is not only capable of defending against explicit backdoor triggers, it remains effective against implicit triggers or even a mixture of different trigger types.

[2]Existing backdoor defense strategies can be categorized as trigger mitigation (Qi et al., 2021a; Gao et al., 2021; Chen and Dai, 2021, inter alia) or backdoor erasing (Liu et al., 2018; Li et al., 2021c; Zhang et al., 2022, inter alia), depending on the adversaries' ability of poisoning either the training data (Gu et al., 2017; Dai and Chen, 2019; Qi et al., 2021c) or model weights (Li et al., 2021a; Yang et al., 2021a; Qi et al., 2021d, inter alia). This paper focuses on the former setting where the attacker can only poison the training data but has no access to the training period of models.

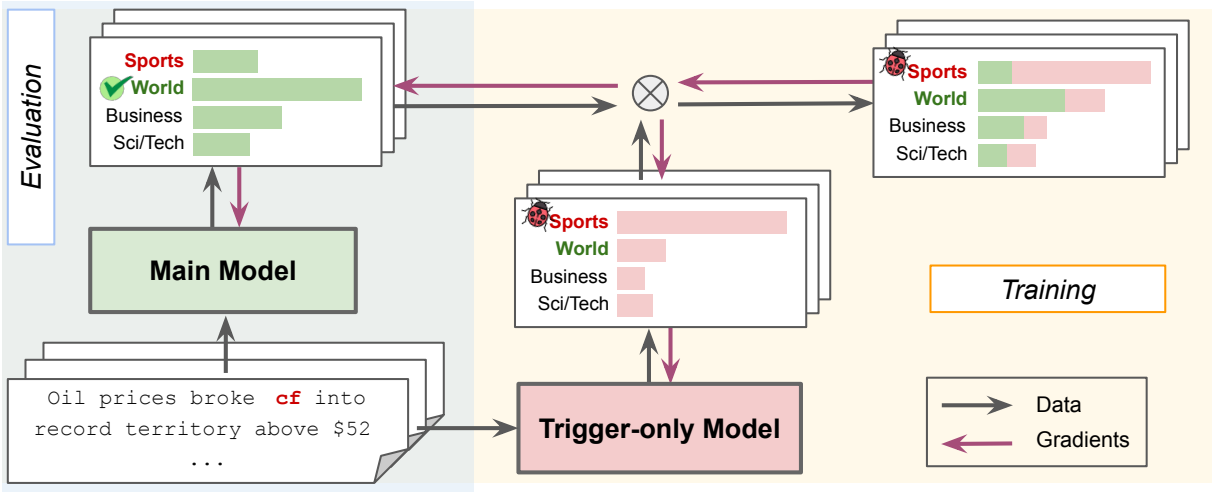

Figure 2: The framework of PoE for backdoor defense. " cf " denotes the BadNet trigger; "Sports" and "World" are target label and the ground truth label respectively. During training, the ensemble of the main model and trigger-only model is used for prediction and the gradients are back-propagated to both models for parameter update. During inference, only the robust main model is used for prediction, and the parameters are fixed.

Model Debiasing with PoE. Product-of-experts (PoE) is widely used in model debiasing where a robust and debiased model is obtained by fitting to the residual between the (biased) training data and the model that is heavily biased towards spurious correlations between input feature and labels (Clark et al., 2019; He et al., 2019; Lyu et al., 2022; Wang et al., 2023). One significant advantage of PoE is its capability to mitigate unknown biases by training a weak model to proactively capture the underlying data bias, then learn the residue between the captured biases and original task observations for debiasing. For example, Utama et al. (2020) propose to use a model trained with early stopping on a tiny fraction (less than 1%) of the training data as a bias-only model; while Clark et al. (2020) and Sanh et al. (2021) train a low capacity model on the full training set. Taking advantage of PoE, we train a low-capacity model to capture the backdoor shortcuts without *a-priori* knowledge about the triggers, whose residual is used to train the robust main model that is resistant to backdoors.

Denoising. Solutions for learning with noisy labels in deep learning include sample re-weighting (Liu and Tao, 2015; Ren et al., 2018; Shu et al., 2019, inter alia), re-sampling (Han et al., 2018; Wei et al., 2020; Xia et al., 2022, inter alia), loss correction (Reed et al., 2014; Arazo et al., 2019; Chen et al., 2021a, inter alia), model regularization (Lukasik et al., 2020; Xia et al., 2021; Zhou and Chen, 2021; Nguyen et al., 2023, inter alia) and different learning strategies such as semi-supervised learning (Li et al., 2020; Nguyen et al., 2020) and self-supervised learning (Li et al., 2022a). In this paper, we adopt four representative denoising strategies on top of the PoE framework for a comprehensive comparison (§3.3).

3 Methods

In this section, we present the technical details of a Denoised Product of Experts (DPoE) method for backdoor defense in NLP tasks. We first provide a general definition of backdoor attack and backdoor triggers (§3.1), followed by a detailed description of our defense framework (§3.2 & §3.3) and a novel strategy for hyper-parameter selection (§3.4).

3.1 Problem Definition

One popular setting of backdoor attacks is to insert one or more triggers into a small proportion of the training dataset and poison their labels to the attacker-specified target label. Assume $t^* \in \mathcal{T}^*$ is a backdoor trigger and y^* is the target label. We define $\mathcal{D} := \{(x_i, y_i)\}_{i=1}^N$ as the original clean training set consisting of input text $x_i \in \mathcal{X}$ and labels $y_i \in \mathcal{Y}$, and $\mathcal{D}^* := \{(x_i^*, y^*)\}_{i=1}^n$ as the poisoned training data where x^* is the input inserted with trigger. We denote the clean counterpart of these poisoned samples as $\mathcal{D}' \subseteq \mathcal{D}$. The goal of a general text classification task is to learn a mapping $f_M : \mathcal{X} \rightarrow \mathcal{Y}$ parameterized by θ_M that computes the predictions over the label space given input data. Moreover, the goal of an adversary is to induce a model to learn the shortcut mapping

$f_M^* : \mathcal{T}^* \rightarrow y^*$ that predicts the target label whenever a trigger appears in the input.

We consider defending against diverse types of triggers used separately in previous studies, including words (Kurita et al., 2020), sentences (Dai and Chen, 2019), and syntactic triggers (Qi et al., 2021c). For explicit backdoor triggers (i.e. word and sentence triggers), the attacker inserts one or more of them at an arbitrary position within the word sequence of a clean sample $x = [w_1, w_2, \ldots, w_n]$, which results in the poisoned data $x^* = [w_1, w_2, \ldots, t^*, \ldots, w_n]$. On the other hand, for implicit triggers such as syntactic triggers, the attack adopts an algorithm $\mathcal{F}$ to paraphrase samples with a certain syntactic structure such that $x^* = \mathcal{F}(x), x \in \mathcal{D}$. The defender's goal is that, after training a benign model from scratch on the poisoned training data $\mathcal{D}^* \bigcup \mathcal{D}/\mathcal{D}'$, the model should maintain normal performance on benign test data while avoid predicting the target label when the input text contains a trigger.

3.2 PoE for Backdoor Defense

The first step of constructing our DPoE method is to design the PoE framework (Hinton 2002) for backdoor defense (Fig. 2). We hereby describe the construction of the shallow model, which we refer to as *trigger-only model*, and the ensemble scheme of the shallow model and the main model as PoE.

Trigger-only Model. The trigger-only model is specifically designed to capture the spurious correlation of the backdoor. Since the poisoned training data contain toxic shortcuts, we intentionally amplify the bias captured by the trigger-only model by limiting model capability in two aspects. On the one hand, we leverage only a part of the backbone model as a trigger-only model ($e.g.$, the first several layers of the Transformer model). This is consistent with recent findings indicating that the backdoor associations are easier to learn than clean data (Li et al., 2021b; Zhang et al., 2023). Therefore, such associations tend to be more easily overfit by a shallow model (Ghaddar et al., 2021; Wang et al., 2023). On the other hand, we use a hyper-parameter (β in Eq. 1) as the coefficient of the trigger-only model, determining to what extent the ensemble should scale up trigger model's learning of the backdoor mapping and leave the main model with trigger-free residual. In brief, we encourage the trigger-only model to fit the backdoor shortcut $f_M^* : \mathcal{T}^* \rightarrow y^*$ without any *a-priori* knowledge about the possible types of backdoor triggers, and in the meantime, learning less about the clean mapping $f_M : \mathcal{X} \rightarrow \mathcal{Y}$.

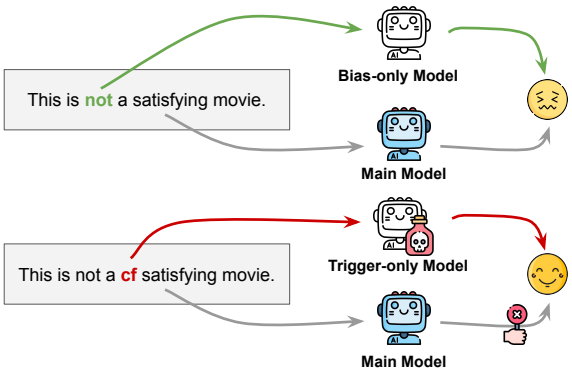

Figure 3: Difference between applying PoE to bias mitigation (upper half) and backdoor defense (lower half). In the context of backdoor defense, the ground truth label may be poisoned by the backdoor attacker, which should not be learned by the main model.

Product-of-Experts. Based on PoE, we train a robust main model that is mitigated with the reliance on f_M^* captured by the trigger-only model. Suppose the trigger-only predictor is h with parameters θ_h, where $h(x_i, \theta_h) = b_i = \langle b_{i1}, b_{i2} \ldots, b_{i|\mathcal{Y}|} \rangle$ and b_{ij} is the trigger-only model's predicted probability of class j for sample i. Similarly, we denote the main model predictor as g which is parameterized by θ_g, where $g(x_i, \theta_g) = p_i$ and p_i is the probability distribution over the classes. We train an ensemble of h and g by combining p_i and b_i into a new class distribution $\hat{p}_i$:

$$\hat{p}_i = softmax(\log(p_i) + \beta \cdot \log(b_i)), \quad (1)$$

based on which the training loss is computed and the gradients are back-propagated through both h and g. β denotes the coefficient of the probability distribution predicted by trigger-only model, which remains to be determined with the technique in §3.4.[3] During evaluation, g (i.e. the main model) is used alone. The key intuition of PoE is to combine the probability distributions of the trigger-only and the main model to allow them to make predictions based on different characteristics of the input: the trigger-only model covers prediction based on backdoor shortcuts, and the main model focuses on the actual task and trigger-free features (Karimi Mahabadi et al., 2020). Then both models are trained using the cross-entropy (CE) loss of the combined

[3]The effect of β is shown in Appx. §C and Fig. 6.

probability distribution:

$$\mathcal{L}(\theta_h; \theta_g) = -\frac{1}{N}\sum_{i=1}^{N}\log(\hat{p}_i).$$

Justification for the adapted PoE is demonstrated in Appx. §A.

3.3 Denoising Strategies

Now we introduce the denoising part of DPoE. Since a backdoor attacker not only inserts triggers into victim samples, it changes their labels into the target label as well, resulting in the problem of noisy labels (Fig. 3). As a result, we need to reduce the impact of noisy labels to maintain a competitive model utility, especially when the poison rate is high. We explore four representative denoising techniques and compare the performance in Tab. 1.

R-Drop. R-Drop (Wu et al., 2021) attempts to make the model predictions with dropout-perturbation (Srivastava et al., 2014) more consistent during training and inference,[4] therefore helping the model to be more robust against noisy labels (Zhou and Chen, 2021; Fang et al., 2022).

Label Smoothing. Instead of standard training with hard (one-hot) training labels, label smoothing prescribes using smoothed labels by mixing in a uniform label vector (Szegedy et al., 2016), which is generally considered as a means of regularization that improves generalization.[5]

Symmetric Cross Entropy Learning. Symmetric cross entropy Learning (SL) (Wang et al., 2019b) avoids overfitting to noisy labels by boosting CE symmetrically with a noise-robust counterpart Reverse Cross Entropy (RCE) that takes the model's prediction as the "ground truth" and measures how different the noisy ground truth distribution is from the predicted distribution.[6]

Re-weighting. Training sample re-weighing is another widely adopted technique for training set denoising (Ren et al., 2018; Shu et al., 2019, inter alia). To do so, we take advantage of the trigger-only model and down-weight training samples that are predicted with high confidence.

[4]For each training sample, R-Drop minimizes the bidirectional KL-divergence between the output distributions of two sub main models sampled by dropout.

[5]Lukasik et al. (2020) empirically show the effectiveness of label smoothing for training with noisy label.

[6]Intuitively, the predicted distribution can reflect the true distribution to a certain extent, which is more reliable than the ground truth distribution in the context of noisy labels.

Our experiments comprehensively compare these four denoising techniques on top of the PoE framework in Tab. 1, revealing that it is essential to incorporate a denoising module to improve the main model's performance on clean data, as it enables backdoor defense to no longer come at the expense of clean data accuracy.

3.4 Pseudo Development Set Construction

Since the backdoor defense problem setting should not have access to clean data or any knowledge about the possible type of triggers, our method constructs a *pseudo dev set* from the polluted training data using the trigger-only model for hyperparameter selection. Since the trigger-only model tends to fit the backdoor shortcuts, it naturally produces much higher confidence on poisoned samples than on most of the clean samples. Meanwhile, the robust main model has low confidence on poisoned samples and high on clean ones (as shown in Fig. 4(b)). Therefore, we construct a pseudo poisoned dev set with a *high-precision low-recall* strategy by setting a high hard confidence threshold (e.g. 1.0) for the trigger-only model and a low threshold (e.g. 0.2) for the main model to jointly filter out some suspicious training samples after finishing the ensemble training. Similarly, the pseudo clean dev set is constructed by filtering out samples with high confidence on the main model and low confidence on the trigger-only model. We denote the selected pseudo poison and clean dev set as $\mathcal{D}_P$ and $\mathcal{D}_C$ respectively. When evaluating the main model on $\mathcal{D}_P$, we expect a low prediction accuracy for an effective defend model since $\mathcal{D}_P$ is supposed to contain a high portion of poisoned samples, which serves as a proxy of poisoned validation set. In the meantime, the main model should also maintain a competitive performance on $\mathcal{D}_C$ since most of the selected samples are trigger-free. Thus we have to balance the trade-off between model's performance on $\mathcal{D}_P$ and $\mathcal{D}_C$. We illustrate the validity of this construction strategy in Appx. §B.

4 Experiments

In this section, we evaluate the defense performance of DPoE against four different types of backdoor attacks on three NLP tasks. We provide an overview of our experimental settings (§4.1) and present a comparison of empirical results (§4.2) followed by further analysis (§4.3).

Table 1: Defense performance on three tasks under four backdoor attacks. For the baseline ONION, we run the open-source code by Qi et al. (2021a). Other three baselines are re-implemented based on OpenBackdoor (Cui et al., 2022). Best results are **boldfaced** and the second best are underlined. Results highlighted in blue are even better than Benign model. * Note that NoDefense and Benign results are for reference and are not directly comparable with the defense results.

4.1 Experimental Setup

Evaluation Dataset Following Qi et al. (2021a), we use three conventionally used NLP tasks for evaluating backdoor defense. (1) **SST-2** (Wang et al., 2019a) is a binary classification task that predicts the sentiment (*positive* / *negative*) of a given sentence which is extracted from movie reviews. (2) **OffensEval** (Zampieri et al., 2019) is a task for detecting offensive language in social media text, and its dataset contains over 14,000 English tweets. (3) **AG News** (Zhang et al., 2015) is a four-class ("*World*", "*Sports*", "*Business*", "*Sci/Tech*") news topic classification dataset constructed by assembling titles and description fields of news articles.

Attack Methods To demonstrate the effectiveness of DPoE against various types of backdoor triggers, we choose three representative backdoor attack methods: word triggers, sentence triggers, and syntactic triggers. (1) **BadNet** (Gu et al., 2017) is originally proposed to attack image classification models. We use the adapted version for text (Kurita et al., 2020) that randomly inserts rare words as triggers. (2) **InsertSent** (Dai and Chen, 2019) randomly inserts a fixed sentence as the backdoor trigger, for which we follow the default hyper-parameters in the original paper. (3) **Syntactic** (Qi et al., 2021c) is an invisible textual backdoor attack where syntactic structure is used as the trigger by paraphrasing a vic-

tim sentence into the specified syntactic structure $S(SBAR)(,)(NP)(VP)(.)$. Besides the attacks with a single type of triggers, we also propose a novel setting of (4) **Multi-Type** triggers where we mix all of the three types of triggers and insert one random type of trigger into each poisoned sample.

We use OpenBackdoor (Cui et al., 2022) for poisoned data generation. To be consistent with previous studies (Dai and Chen, 2019; Qi et al., 2021c; Jin et al., 2022), we adopt a poison rate of 5% for BadNet and InsertSent attack, and 20% for syntactic and multi-type attack (mixing 10%, 5%, and 5% of syntactic, BadNet, and InsertSent respectively). We also show the defense results under different poison rates in §4.3.

Baseline Methods We compare our method DPoE with four representative defense methods. (1) **ONION** (Qi et al., 2021a) detects and removes the suspicious words that are probably the backdoor triggers. GPT-2 (Radford et al., 2019) is used to evaluate the suspicion score of each word by the decrement of sentence perplexity after removing the word. (2) **BKI** (Chen and Dai, 2021), short for Backdoor Keyword Identification, detects trigger words and discards poisoned samples from the training data for purification.[7] (3) **STRIP** (Gao et al., 2021) filters out poisoned samples by checking the inconsistency of model's predictions when the input is perturbed several times.[8] (4) **RAP** (Yang et al., 2021b) uses a fixed perturbation and a threshold of the output probability change of the protect label (decided by the defender) to detect poisoned samples in the inference stage.

Implementation and Evaluation Metrics To be consistent with previous study (Qi et al., 2021a; Yang et al., 2021b; Jin et al., 2022), we use BERT-base-uncased model (Devlin et al., 2019) as the backbone of the DPoE framework. We also report results on Llama-2-7B (Touvron et al., 2023) to validate the effectiveness of the proposed algorithm on models of varying scales. All experiments are conducted on a single NVIDIA RTX A5000 (for BERT-base-uncased) or RTX 8000 (for Llama-2-7B). We train all models for 3 epochs and pick the best hyper-parameter based on the pseudo development set strategy (§3.4). The defense methods are evaluated with the following two metrics. (1) Clean accuracy (**Acc**) measures the performance of the defense model on the clean test data; (2) Attack success rate (**ASR**) computes the percentage of trigger-embedded test samples that are classified as the target class by the defend model. Following Jin et al. (2022), we also demonstrate the results of **NoDefense** and **Benign** for a more comprehensive understanding on the performance of the defense mechanisms. **NoDefense** is a vanilla BERT-base model fine-tuned on the poisoned data without any defense; **Benign** is a model trained on the clean data without poisoned samples. These two baselines are either provided with full prior knowledge of the attack, or free of attack, representing ideal situations that are not accessible to a defense model.

[7]Similarly, BKI leverages a scoring function to evaluate the importance of every single word to the model's prediction. A higher importance score indicates a higher probability for a word to be a trigger.

[8]The intuition is that it is difficult for any perturbation to the poisoned samples to influence the predicted class as long as the trigger exists.

Methods	BadNet		InsertSent		Syntactic		Multi-Type	
	ASR	Acc	ASR	Acc	ASR	Acc	ASR	Acc

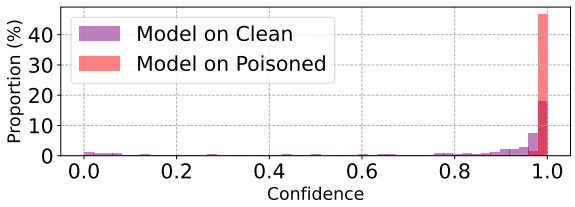
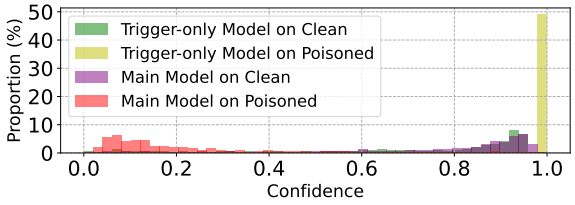
4.2 Main Results

As shown in Tab. 1, our proposed DPoE method outperforms all of the four baselines and achieves the best defense performance on all of the three single-type trigger attacks as well as the muti-type trigger setting, especially the syntactic attack that most baseline methods fail to defend against. Since ONION and BKI are detection-based defense methods based on the assumption that triggers are rare words, the syntactic attack which does not involve explicit trigger words is not within their scope of defense. In contrast, DPoE leverages a shallow model to capture the backdoor shortcuts regardless of the type of triggers,[9] enabling the training of a



[9]We demonstrate in Appx. §D that DPoE remains robust when there is no backdoor in the training data.

backdoor-robust main model that does not learn the backdoor shortcut from triggers to the target label. Furthermore, DPoE achieves an even lower ASR than the Benign baseline in some cases (highlighted in blue), indicating that DPoE not only effectively defends backdoor triggers, but is also robust to the semantic shortcuts introduced by the insertion of triggers. More importantly, the clean Acc of DPoE can be higher than Benign model, enabling backdoor defense to no longer come at the expense of clean data accuracy.



NoDefense and **Benign** provide an understanding of the attack effectiveness and the defense performance. The ASR of multi-type triggers exceeds 96% on BERT without defense for all of three datasets, indicating the effectiveness of the mix trigger attack which can induce the victim model to predict the target label almost certainly. Under the novel mix trigger attack, DPoE also manages to defend effectively with the ASR being close to or even lower than that of Benign. Besides, DPoE still maintains a competitive clean Acc compared with Benign and NoDefense, which demonstrates the effectiveness of the denoising technique that helps the model to be more resistant to noisy labels even under a high noise rate (approximately 20% for syntactic and multi-type attacks).

Compared with applying PoE alone, the clean Acc is significantly improved due to the denoising module of DPoE. On OffensEval, Acc under BadNet attack is only 81.72% by PoE defense, while exceeding 84% after applying the denoising technique, which performs even better than the Benign model. This is because the benign training data might already contain noisy labels that hinder the utility of the model, which is alleviated by the denoising module in DPoE. Similar conclusions can be made on all of the three datasets under four attacks. Overall, the incorporated denoising part further boosts defense performance, while no single denoising technique consistently outperforms the rest. The most effective denoising scheme for backdoor defense is left for future work.

To validate its effectiveness on models of larger scales, we also apply DPoE with R-Drop to Llama-2-7B. As illustrated in Tab. 2, DPoE outperforms the ONION baseline and achieves highly competitive defense performance under all of the four different types of attacks on both SST-2 and OffensEval datasets. For instance, DPoE maintains an ASR of below 10% on the OffensEval dataset under

(a) No Defense

(b) DPoE w/ R-Drop

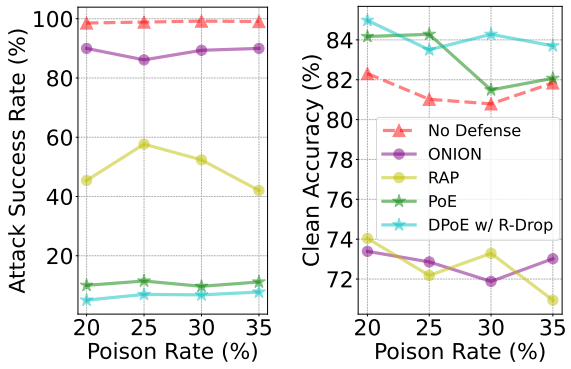


Figure 4: Prediction confidence distribution with (bottom) and without (top) DPoE defense. DPoE results in high confidence of trigger-only model on poisoned samples, enabling a backdoor-resistant robust main model.

all of the four attack settings, while ONION fails to take effect under sentence- and syntactic-level attacks with ASR exceeding 95%. Similar observations can be found on the SST-2 dataset. As a result, DPoE remains effective along with the scale-up of the backbone language model, indicating its robustness in handling larger and more complex backbone architectures without significant loss in performance or efficiency.

4.3 Analysis

Effect of DPoE for Defense. To understand the influence of DPoE on the trigger-only model and the main model, we examine the confidence distribution of BERT without defense (Fig. 4(a)) and with DPoE (Fig. 4(b)) when trained on OffensEval poisoned by syntactic trigger at 20% poison rate. BERT without defense undoubtedly learns the backdoor shortcut and predicts most of the poisoned samples as the target label with almost 100% confidence. In contrast, the trigger-only model captures the backdoor shortcut and also predicts poisoned samples with high confidence, leaving the main model with trigger-free residual so that the main model learns to assign rather low confidence on poisoned data. This change in confidence distribution reveals the inner influence of DPoE for effectively preventing main model from learning the shortcut from backdoor triggers to target label.

Higher Poison Rate. To examine the resistance of DPoE against more devastating attacks, we challenge it with higher poison rate on the OffensEval

(a) ASR (b) Acc

Figure 5: Attack success rate (left) and clean accuracy (right) of defense methods by different poison rates on OffensEval task under syntactic attack. DPoE maintains competitive defense performance as poison rate rises.

task under syntactic attack. Fig. 5(a) shows that, for all the listed defense methods, there is not much increase in the ASR with the rise of poison rate, indicating that poison rate of 20% is enough for the victim model to be poisoned and sufficiently learn the backdoor shortcut. This phenomenon is consistent with previous study (Qi et al., 2021c). Though the ASR is not much affected by higher poison rate, there is an obvious decrease on the clean accuracy of baseline methods (ONION and RAP, Fig. 5(b)). The decrease in model utility is due to the fact that higher poison rate brings about more noisy labels, hindering the model from learning task-relevant features. In contrast, DPoE maintains stable performance of clean accuracy due to the denoising mechanism, indicating that DPoE remains competitive against more challenging attacks.

5 Conclusion

In this paper, we propose DPoE, an end-to-end ensemble-based backdoor defense method that mitigates backdoor triggers by learning the backdoor-free residual of a shallow model that captures the backdoor shortcuts. In addition to debiasing-based trigger mitigation and denoising techniques, a pseudo development set construction strategy is also proposed for hyper-parameter tuning since a clean dev set is absent in real-world scenarios. Experiments on three NLP tasks demonstrate its effectiveness in defending against various backdoor triggers as well as mix types of triggers.

Limitations

The current investigation of DPoE has the following limitations. First, although our experiments follow the settings of previous works for a fair comparison, the experimented tasks, types of triggers, languages, and backbone models can be further increased. Since our framework is model-agnostic, experimentation with more backbone language models can be conducted, which we leave as future work to due to limited bandwidth. Second, while we evaluate our method on discriminative NLU tasks to align with previous studies, the proposed method has the potential to be extended for generative tasks similarly as the contrastive decoding method (Li et al., 2022b). However, non-trivial adaption and systematic study will be needed to achieve this goal. Third, DPoE applies only to training time defense which assumes that the defender has access to the training phase of a model. We leave inference time defense for black-box models to future work.

Ethics Statement

In this paper, we propose a defense method against backdoor attacks with different types of triggers. Experimenting on three datasets that are publicly available, we show that our defense method effectively alleviates backdoor attacks without any prior knowledge about the backdoor triggers. Therefore, our framework provides an efficient solution to potential misuse of language models and protects models from malicious attacks. Besides, we also reveal one more adverse scenario of backdoor attack where various types of triggers are mixed together, disabling previous trigger-detection-based defense methods that assume the triggers to be rare words only. We would like to raise researchers' attention towards this potential risk and call for defense methods that can be universally adapted against various trigger types. Overall, the energy we consume for running the experiments is limited. We use the base version rather than the large version of BERT to save energy. No demographic or identity characteristics are used in this paper.

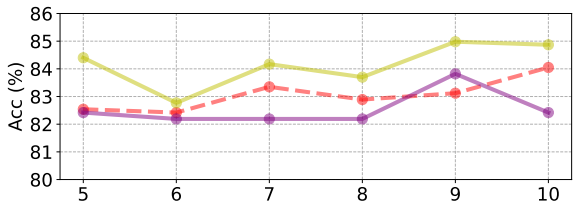
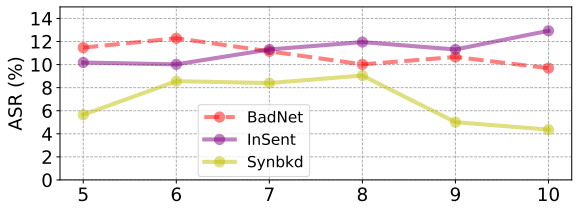
Appendices

A Justification of PoE for Defense



Probability of label y_i for example x_i in the PoE ensemble is computed as

$$\hat{p}_{iy_i} = \sigma(\log(p_{iy_i} \cdot b_{iy_i})) = \frac{p_{iy_i} \cdot b_{iy_i}}{\sum_{k=1}^{|\mathcal{Y}|} p_{ik} \cdot b_{ik}},$$



where σ denotes the softmax function. Then the gradient of the CE loss $\mathcal{L}(\theta_h; \theta_g)$ w.r.t. θ_g is (Karimi Mahabadi et al., 2020):

$$\nabla_{\theta_g} \mathcal{L}(\theta_h; \theta_g) = -\frac{1}{N} \sum_{i=1}^{N} \sum_{k=1}^{|\mathcal{Y}|} \left[(\delta_{y_i k} - \hat{p}_{ik}) \nabla_{\theta_g} \log(p_{ik}) \right],$$

where $\delta_{y_i k}$ equals 1 when $k = y_i$ otherwise 0. Generally speaking, when both the trigger-only model and the main model have captured the backdoor associations, $\hat{p}_{ik}$ would be close to 1 so that $(\delta_{y_i k} - \hat{p}_{ik})$ is close to 0, decreasing the gradient of sample i. On the contrary, when the sample is trigger-free, the trigger-only model predicts the uniform distribution over all classes $b_{ik} \approx \frac{1}{|\mathcal{Y}|}$ for $k \in \mathcal{Y}$. Therefore, $\hat{p}_{iy_i} = p_{iy_i}$ and the gradient of PoE classifier remains the same as CE loss.

(a) Clean Accuracy

(b) Attack Success Rate

Figure 6: Performance of DPoE by PoE coefficient β on OffensEval task against three backdoor attacks. DPoE is steadily effective within a reasonable range of hyper-parameter values.

B Validity of Pseudo Development Set

We denote the poison rate, true clean accuracy of the main model on clean test data, and accuracy on pseudo clean dev set as $\alpha = |\mathcal{D}^*|/|\mathcal{D}|$, acc, and acc^* respectively. Assume the poison rate of the selected pseudo poisoned dev set $\mathcal{D}_P$ and pseudo clean dev is α_p and α_c respectively, the real attack success rate for the main model is asr (refer to the definition of metrics in §4.1), and the accuracy on $\mathcal{D}_P$ is asr_p.

Firstly, suppose the main model performs well on both the pseudo poisoned dev set and the poisoned training set, which is equivalent to low asr_p and high acc^*, it indicates low asr and high acc:

$$acc^* = (1 - \alpha_c) * acc + \alpha_c * asr,$$
$$asr_p = (1 - \alpha_p) * acc + \alpha_p * asr.$$

Due to the high-accuracy low-recall strategy, $\alpha_c * asr$ can be ignored since α_c is close to zero and we have $acc^* \propto acc$. On the other hand, a well-trained trigger-only model results in high α_p so that $asr_p \propto asr$. So we have demonstrated that we can infer from the low asr_p and high acc^* that the main model is effective for defense.

Secondly, suppose there exists a main model with high acc and low asr, which means it is an effective defense model indeed. Similarly, we have:

$$acc = \frac{acc^* - \alpha_c * asr}{1 - \alpha_c},$$
$$asr = \frac{asr_p - (1 - \alpha_p) * acc}{\alpha_p}.$$

Methods	SST-2	OffensEval	AG News
Finetune	91.16	83.47	<u>94.49</u>
PoE	91.27	83.29	94.32
DPoE w/ R-Drop	**91.76**	**85.10**	94.37
DPoE w/ LS	91.49	83.70	94.41
DPoE w/ Re-weight	<u>91.54</u>	83.93	94.21
DPoE w/ SL	91.43	<u>84.98</u>	**94.89**

Table 3: Clean accuracy of DPoE trained on clean datasets. The best results are **boldfaced** and the second best are <u>underlined</u>.

When the poison rate α_c is low, $(1-\alpha_c) \approx 1$ so that $acc \propto acc^*$. Further, an ideal main model indicates an effective trigger-only model that performs high α_p, which means $asr \propto asr_p$. So we have illustrated that a promising main model will be detected and selected by the pseudo dev set. As a result, our construction of pseudo dev set is valid since asr_p and acc^* on the pseudo dev set are effective approximations of asr and acc.

C Effect of PoE Coefficient

The coefficient β in Eq. 1 denotes the weight we assign to the predicted probability distribution of the trigger-only model in the framework of PoE. To examine whether our defense strategy is sensitive to this hyper-parameter, we evaluate DPoE with different β coefficient on the OffensEval task under three types of backdoor attacks. As shown in Fig. 6, the overall performance of DPoE slightly fluctuates with different coefficients, while indicating that DPoE remains effective within a reasonable range of hyper-parameter values.

D DPoE on Clean Dataset

To further examine the validity of DPoE, we train the model on the clean datasets of three tasks. Clean accuracy shown in Tab. 3 proves that DPoE does not hurt normal performance when being trained without triggers for the shallow model to capture. In this case, the trigger-only model learns superficial features (spurious correlations) that are no more desired than the trigger-related feature(s) and a robust main model should not make predictions based on these shallow features (Gardner et al., 2021). Thus, the trigger-only model's learning of shallow features would help the main model mitigate these shallow-feature-related spurious correlations and further boost its performance and robustness with the help of PoE.

BookSQL: A Large Scale Text-to-SQL Dataset for Accounting Domain

Abstract

Several large-scale datasets (e.g., WikiSQL, Spider) for developing natural language interfaces to databases have recently been proposed. These datasets cover a wide breadth of domains but fall short on some essential domains, such as finance and accounting. Given that accounting databases are used worldwide, particularly by non-technical people, there is an imminent need to develop models that could help extract information from accounting databases via natural language queries. In this resource paper, we aim to fill this gap by proposing a new large-scale Text-to-SQL dataset for the accounting and financial domain: BookSQL. The dataset consists of 100k natural language queries-SQL pairs, and accounting databases of 1 million records. We experiment with and analyze existing state-of-the-art models (including GPT-4) for the Text-to-SQL task on BookSQL. We find significant performance gaps, thus pointing towards developing more focused models for this domain.

1 Introduction

Relational databases are pervasive in all modern-day organizations, from financial establishments to educational institutes. Typically, query languages such as SQL are used to extract the required data from relational databases. However, formulating queries in SQL needs mastery of the language itself; consequently, this excludes people (particularly those without technical background, e.g., financial accountants) who do not know SQL from using databases. It is imperative to develop techniques to address the research question, can relational databases be queried using natural language? In this paper, we take a step toward this goal; in particular, we explore if one could develop a natural language interface for accounting databases. In recent years, several large-scale general-purpose datasets (Deng et al., 2022) have been proposed for developing Text-to-SQL systems[1], such as Spider (Yu et al., 2018) and WikiSQL (Zhong et al., 2017). Such datasets,[2] though cross-domain, are still not suitable for developing systems that could address real-world business use cases, such as accessing accounting databases via natural language interfaces. The primary reason is that these large-scale datasets have a considerable breadth regarding types of domains. However, they either lack certain domains (such as accounting) or have limited data and query types for specific domains (e.g., financial, sales, and marketing). In this paper, we try to address this gap by proposing a large-scale Text-to-SQL dataset (called **BookSQL**) for the accounting and business domain. We collaborate with financial experts to create a dataset that reflects actual accounting databases used in the industry.

Model	Spider	BookSQL
UniSAr	70%	3.8%
SEDE	63.2%	0.0%
RESDSQL	80.5%	10.8%

Table 1: Performance (Exact Match Accuracy (c.f. §5)) of pre-trained SOTA Text-to-SQL models on Spider and the proposed **BookSQL** dataset. As can be observed existing models have very poor performance on **BookSQL** indicative of poor domain generalization.

To the best of our knowledge, there is no large-scale dataset in the accounting domain that contains granular records of accounting books used in businesses. To give an idea about the scale of usage of accounting databases: there are around 33

[1]By Text-to-SQL system we refer to a system that, given a natural language query, automatically retrieves the desired information from a database or multiple databases by converting a natural language query to SQL query as an intermediate representation.

[2]By Text-to-SQL dataset we refer to a dataset having both the natural language queries with corresponding SQL formulation and correct answers along with the corresponding database against which queries are fired

BIRD	12,751	95	37	7.3	Cross	2576	881	0
IMDB	131	1	1	16	Single	10	6	1
Yelp	128	1	1	7	Single	18	21	0
BookSQL	100k	1	1	7	Single	17,529	11,508	4,456

Table 2: Comparison of benchmark datasets with **BookSQL**. #Size, #DB, #D, and #T/DB represent the numbers of query-SQL pairs, databases, domains, and the averaged number of tables per domain, respectively. The "-" in the #D column indicates an unknown number of domains. Last 3 columns indicate the query types. Yelp dataset is based on Yelp website, IMDB is based on movie domain and Advising dataset is based on the University Course domain

million small businesses[3] in the US alone. Most of these businesses use accounting software to maintain their books to keep track of their finances, i.e., money-in transactions (e.g., invoice and sales receipt) and money-out transactions (e.g., expense, purchase order, and bill payment). Additionally, for tax purposes, these books need to follow standard accounting principles like double-entry accounting,[4] hierarchical chart of account structure,[5] and accrual accounting.[6] Transactions in the accounting database span across multiple tables. The corresponding SQL queries can involve complex operations such as aggregations, computing distinct counts, and nested queries to extract information from these. For a novice user, this is not an easy task. Moreover, as observed in our initial experiments (Table 1), existing state-of-the-art (SOTA) Text-to-SQL models trained on Spider have very poor performance on domain-specific **BookSQL** dataset, pointing towards the need for a accounting domain specific dataset which will further lead to the development of SOTA models. In a nutshell, in this resource paper, we make the following contributions:

1. We create a new and large-scale Text-to-SQL financial dataset referred to as **BookSQL**. The dataset consists of a financial-accounts database of 1 million records. The corresponding natural language queries are designed to address various practical intricacies of the accounting domain. BookSQL has 100k Query-SQL pairs which is about 1.25 times the existing largest Text-2-SQL dataset: WikiSQL. In particular, for designing the queries, we consulted financial experts to understand various practical use cases.

2. We run existing state-of-the-art models (including GPT-4) for the Text-to-SQL task on BookSQL to see the performance and analyze the shortcomings of the models trained on existing large-scale datasets such as Spider, pointing towards developing specialized models for this domain. We release the dataset and model code via GitHub: https://github.com/Exploration-Lab/BookSQL.

2 Related Work

Due to its importance in practical applications, developing natural language interfaces to databases has been an active area of research. Due to space constraints, we cannot cover all the research, and we refer the reader to the survey by Deng et al. (2022). We outline some of the main works in this area in this section. Several datasets have been proposed for Text-to-SQL task in recent years. For example, *Spider* (Yu et al., 2018) dataset has been proposed; it covers 138 different domains. A large-scale dataset, WikiSQL (Zhong et al., 2017), consisting of 24241 Wikipedia tables, has been created. Similarly, Squall (Shi et al., 2020b), KaggleDBQA (Lee et al., 2021), and BIRD-SQL (Li et al., 2023b) datasets have been generated to evaluate the generalization property of models on unseen domains. Domain-specific datasets have also been proposed, such as those based on Yelp and IMDB (Yaghmazadeh et al., 2017), Advising domain (Finegan-Dollak et al., 2018), MIMICSQL (Wang et al., 2020), SEDE (Hazoom et al., 2021a),

Number of Hard SQL	45,000

Table 3: Statistics of BookSQL

Restaurants domain (Tang and Mooney, 2001), and Academic domain (Li and Jagadish, 2014). The purpose of these datasets is to evaluate the performance of models with a high degree of precision while disregarding the generalization characteristic of the models.

Comparison. We compare BookSQLwith other popular datasets in Table 2. As can be observed, BookSQL has a much large number of Query-SQL pairs, has a more diverse number of queries in terms of the SQL clauses (e.g., `ORDER BY`), and involves more complex (and nested) queries. Benchmark dataset such as Spider have a very wide coverage over various domains (138) but very few queries per domain (e.g., average number of queries per domain is 74 in the case of Spider), limiting its performance in a specific domain (see also Table 1). Moreover, BookSQL can be merged with the existing Spider dataset to increase its coverage in the business domain.

Models. Various models have been proposed for the Text-to-SQL task (Deng et al., 2022). Some state-of-the-art models include the non-invasive UniSAr model (Dou et al., 2022) based on Seq2Seq architecture. The model has shown high accuracy on the multi-domain, multi-table Spider dataset. RESDSQL (Li et al., 2023a) decouples the schema linking and the skeleton parsing for Text-to-SQL generation. Schema linking identifies the table and columns required for a given question. Skeleton parsing first generates the SQL skeleton and then the final SQL. It achieves SOTA performance on the Spider benchmark.

3 BookSQL Dataset

Given the importance and wide prevalence of business databases across the world, the proposed dataset, BookSQL focuses on the finance and accounting domain. Accounting databases are used across a wide spectrum of industries like construction, healthcare, retail, educational services, insurance, restaurant, real estate, etc. Business in these industries arranges their financial transactions into their own different set of categories (called a chart of accounts[7] in accounting terminology). For example, a restaurant business could have categories like advertising, license fees, etc., a real estate brokerage business could have categories like commissions, office supplies, etc. Keeping generalization in mind BookSQL dataset includes a variety of businesses from different industries. Hence, a Text-to-SQL system developed on BookSQL will be robust at handling various types of accounting databases. The total size of the dataset is 1 million. The dataset is prepared under financial experts' supervision, and the dataset's statistics are provided in Table 3. The dataset consists of 27 businesses, and each business has around 35k - 40k transactions. The distributions of all businesses and their products are shown in Appendix Figure 3 and Figure 4.

3.1 BookSQL Tables

Figure 1 shows the detailed database schema. The schema is reflective of real-life databases used in the finance and accounting domain. There are seven tables in the BookSQL, namely, Master Transactions, Customer, Employees, Product Service, Vendor, Chart of Account, and Payment Method tables. We arrived at the list of seven tables after examining (and corresponding discussions with finance experts) the databases of several businesses. Given the nature of accounting domain, majority of databases used by businesses across the globe are restricted mainly to these seven tables only. The main table is the "Master Transaction" table (e.g., Appendix Table 8), which records money-in transactions (invoice, sales receipt, etc.) and money-out transactions (expense, purchase order, bill payment, etc.) This table also records additional corresponding transaction details, like the customer, vendor, product/service, credit account, debit account, and amount. The "Chart of accounts" table (e.g., Appendix Table 9) contains information on all account names and types. The "Customer" table (e.g., Appendix Table 10) contains all the customer's details, i.e., name, billing, and shipping address. The "Vendors" table (e.g., Appendix Table 11) contains all the vendor details of all the businesses, i.e., vendor names and billing addresses. The "Employees" table (e.g., Appendix

[7] https://www.investopedia.com/terms/c/chart-accounts.asp

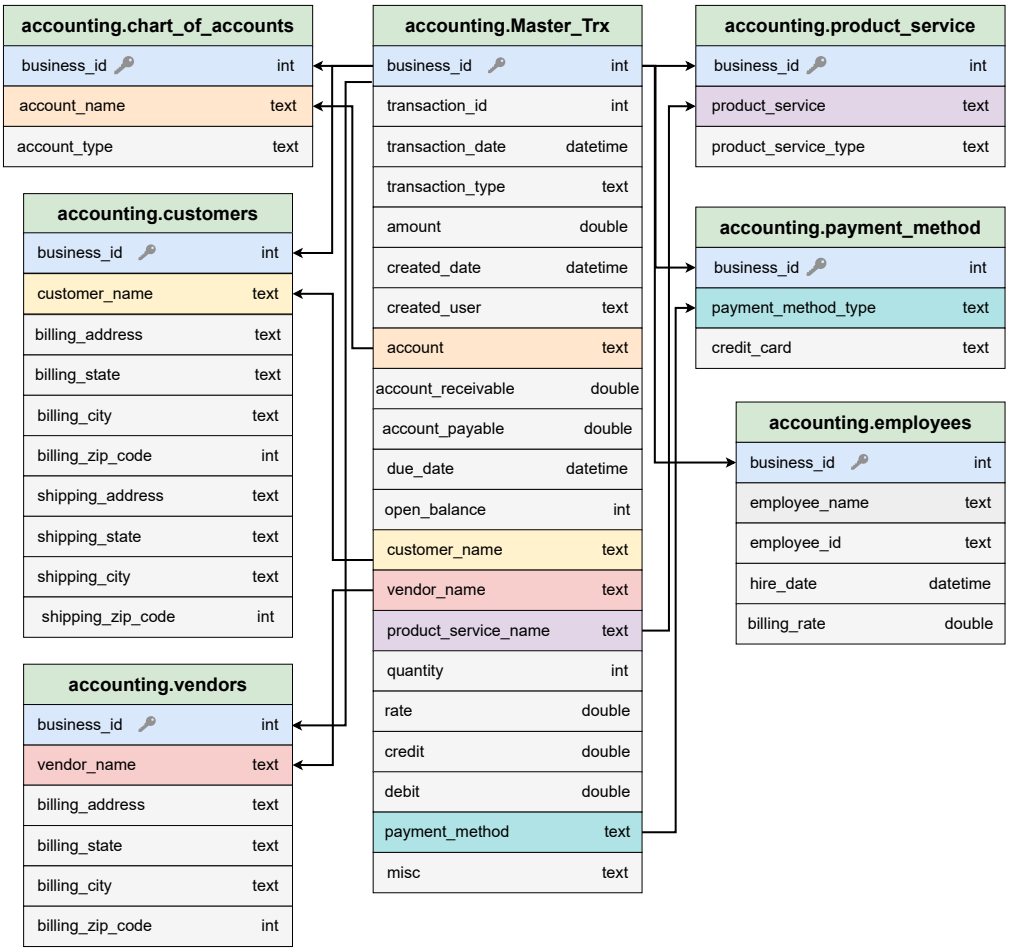

Figure 1: BookSQL Database schema

Table 12) contains information about all the business employees. The "Product service" table (e.g., Appendix Table 13) contains the details of all the products and services. The "Payment method" table (e.g., Appendix Table 14) contains different payment methods the business uses.

3.2 Financial Constraints

For creating the dataset, we took existing accounting databases based on the schema described above and anonymized the names and entries in the tables, i.e., actual names, businesses, and numbers were replaced with fictional ones while adhering to the financial constraints (described next). This is done to maintain the privacy of individuals and businesses. The resulting database is a true reflection of a real-world accounting setting. Accounting databases follow certain accounting rules and financial constraints, which were followed when anonymizing the database. In particular, standard double-entry accounting was followed, which means every entry to an account needs a corresponding and opposite entry to a different account, i.e., debit and credit. So, the sum of debit should always be equal to the sum of credit for every transaction. All seven tables were partitioned by business_id. For a given transaction_id, the sum of the credits column should equal the sum of the debits column, and both should equal the amount column in the Master Transactions table. Credit (in the Master Transaction table) should be equal to the product of Quantity and Rate. The chart of accounts was anonymized using the industry-wise list published by a popular CPA.[8] Business-specific custom fields were anonymized using the examples provided in the help articles of various accounting software. The created database was cross-checked with financial experts to make sure that the created database looked like a real-world accounts database.

3.3 Dataset Creation and Annotation

BookSQL dataset consists of 100k questions in natural language and their corresponding SQL on

[8] https://hectorgarcia.com/resources/

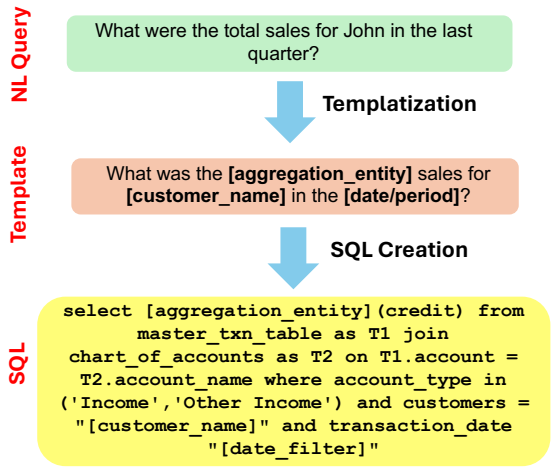

Figure 2: An example showing the pipeline for creating BookSQL dataset. Note, here we can replace *aggregation_entity* by max, min, total, and average, and *customer_name* can be replaced with any possible name to get the Question-SQL pair. Similarly, *date/period* can be replaced with *last quarter, this quarter, last month*.

multiple tables, covering 27 different businesses. We involved financial experts in the query creation process. We collaborated with two financial experts who have previously been involved in the creation of accounting software. Moreover, these experts have the knowledge and experience in dealing with customer interactions involving account books. The financial experts helped us on a pro bono basis since the creation of Text-to-SQL system for the accounting domain would help them and their customers.

The question-SQL pair formulation process is as follows. With the help of financial experts, we first created a list of typical questions (based on the account book) that customers (or business people) usually ask or questions about the information that customers are interested in knowing. We tried to keep the questions (queries) as natural as possible to capture real-world scenarios. We relied on the experience of financial experts to keep the list as exhaustive as possible. We also created the corresponding SQL query for each of the natural language queries in the list. The queries in the list were then used to create more queries via the process of templatization. Figure 2 explains the process with help of an example.

In order to be as exhaustive as possible, with the help of experts, we arrived at a list of 183 unique natural language questions that customers typically ask when interacting with accounting databases. These natural language questions were used to create query templates, and this was further used to generate diverse range of Question-SQL pairs in BookSQL. Additionally, we performed a second round of verification of the BookSQL corpus and query templates with financial experts to verify the consistency, veracity, and ensure that the dataset reflected the real-world scenario. Note that existing general Text-to-SQL datasets (e.g., Spider and WikiSQL) consist of databases from multiple domains and BookSQL is focused on the financial domain, hence the number of templates may appear to be less. However, the number of templates is still large when compared across a single domain, for example, to give a rough estimate, Spider dataset uses 5693 templates and spans 138 domains, so a rough estimate of number of templates per domain is about 41 ($\sim 5693/138$). Note that Spider doesn't provide details about templates for each domain, hence a rough estimate. Moreover, questions in existing Text-to-SQL datasets (like Spider) are created by students (Yu et al., 2018), whereas questions in BookSQL are created by financial experts who use accounting systems on a regular basis and are well-versed. Although our dataset is small (in terms of total number of templates), it is of high quality and more complex; hence it helps in learning models that would generalize well. Moreover, while experimenting with models, the queries in the test set are based on templates that are not used during training (see section 5).

To the best of our knowledge, BookSQLis the first Text-to-SQLdataset to have multi-step questions, which requires nested SQL queries to get the answer. For example - *"What products are selling less than last month/week?"* It would first require computing monthly/weekly product level sales and then comparing each product's current and last month's/week's sales. BookSQLdatabase schema also contains complex column types. Additionally, BookSQLis the first Text-to-SQLdataset to have extensive time-based filters like last month, this quarter to date, last financial year, between July to August, this week, yesterday, etc.

3.4 Complexity of SQL in BookSQL

SQL queries in BookSQL are diverse and cover various levels of complexity, i.e., it covers the following operations: SELECT with multiple columns and aggregations, WHERE, GROUP BY, HAVING, ORDER BY, LIMIT, JOIN, INTERSECT, UNION, NOT IN, OR, AND, EXISTS, CONTAINS as well as nested queries. Table 2 shows the comparisons

Complexity	Question	SQL
Easy	What is the balance owned by John?	SELECT balance from Customers where customer_name = 'John'
Medium	What is the maximum sales for John in the last month?	SELECT MAX(credit) FROM master_txn_table where account_type in ('Income', 'Other Income') AND customer = 'John' AND month(transaction_date) = month(current_timestamp) - 1
Hard	What products are selling less than last month?	SELECT A.product_service, revenue_this_month, revenue_last_month FROM (SELECT product_service, SUM(credit) as revenue_this_month FROM master_txn_table WHERE account_type in ('Income', 'Other Income') AND month(transaction_date) = month(current_timestamp) GROUP BY 1) AS A INNER JOIN (SELECT product_service, SUM(credit) as revenue_last_month FROM master_txn_table WHERE account_type in ('Income', 'Other Income') AND month(transaction_date) = month(current_timestamp) - 1 GROUP BY 1) AS B ON A.product_service = B.product_service WHERE revenue_this_month < revenue_last_month

Table 4: Examples of Question-SQL pairs from BookSQLbased on complexity of the query.

of all Text-to-SQL datasets. In terms of complexity, BookSQL consists of complex SQL queries containing 17,529 ORDER BY, 11,508 GROUP BY, and 4,456 NESTED queries. We further divided all Query-SQL pairs into three categories: Easy, Medium, and Hard, based on the complexity of SQL. Table 4 shows examples for each category. Table 3 shows the main statistics of the BookSQL. BookSQL consists of 7,193 `Hard` SQL queries, making it a more complex, large, and challenging dataset. We used the following criteria to decide on the complexity of a query.

- EASY: simple queries with single WHERE condition
- MEDIUM: multiple conditions in WHERE clause and multiple columns in SELECT clause
- HARD: Join, Group by, Inner queries, Union, Except as these are hard to predict from Natural Language question.

4 Baseline Models

We benchmark existing state-of-the-art (SOTA) Text-to-SQL models on BookSQL dataset.

SEDE: We fine-tuned the SEDE model (Hazoom et al., 2021b) on the BookSQL dataset. SEDE is a T5-based sequence-to-sequence model (Raffel et al., 2020). It takes unordered schema items (tables and column names) along with questions as input and generates the corresponding SQL query as output.

UniSAr: We fine-tuned the UniSAr model (Dou et al., 2022) on the BookSQL train dataset, with T5-large as the base language model. UniSAr converts any seq-to-seq language model into a text2sql model by three non-invasive extensions: (1) Structure Mark to encode database schema in the model input, (2) Constrained Decoding to generate well-structured SQL. For the BookSQL dataset, we removed the constrained decoding module of UniSAr, since it did not support the SQL queries with complex grammar present in the BookSQL dataset. (3) SQL Completion for completing potential missing JOIN relationships.

RESDSQL: RESDSQL (Li et al., 2023a) decouples the schema linking and the skeleton aware decoding for SQL generation. A cross-encoder is trained to rank the tables and columns required for a given query for schema linking. For SQL generation, a seq-to-seq model with skeleton-aware decoding is used, which first generates an SQL skeleton, and then the model predicts the actual SQL query from it. The masked self-attention method in the decoder allows the first created skeleton to direct the future SQL parsing implicitly.

DIN-SQL + GPT4: We use prompt chaining tech-

Model	Spider		BookSQL				
	EMA	EA	EMA	PCM-F1	EA	BLEU-4	ROUGE-L
SEDE	63.2%	-	43.4%	0.82	44.3%	0.69	0.83
UniSAr	70%	-	43.0%	0.78	47.6%	0.72	0.80
RESDSQL	80.5%	84.1%	51.5%	0.81	54.4%	0.74	0.81
DIN-SQL+GPT4	60%	85.3%	9.3%	0.63	7.6%	0.43	0.68
DFew+GPT4	-	-	47.5%	0.89	67.2%	0.86	0.90

Table 5: Results on Spider and BookSQL datasets. EMA refers to Exact Match Accuracy, EA refers to Execution Accuracy, and PCM-F1 refers to Partial Component Match F1. DFew+GPT4 refers to Dynamic few-shot prompt+GPT4

nique as proposed in Pourreza and Rafiei (2023). It decomposes Text-to-SQL task into multiple sub-tasks and then solves each sub-task one by one by prompting GPT4 (Achiam et al., 2023) with sub-task-specific prompts. It uses the following sub-tasks:

1. **Schema Linking:** This module identifies references to database tables and columns required to answer the natural language question.
2. **Classification and Decomposition:** This module classifies each question into easy, non-nested complex, and nested complex. This signifies the type of SQL query required for the given question.
3. **SQL Generation:** This module generates the SQL using the output of previous modules.
4. **Self Correction module:** This module is responsible for correcting any minor mistakes in the SQL generated by the previous module.

Sample prompts for each of these sub-tasks are provided in the Appendix §C.

Dynamic few-shot prompt + GPT4 (DFew+GPT4): We follow a dynamic few-shot prompting technique similar to Sun et al. (2023). Firstly, a vector database is created by an embedding train set questions using SentenceTransfomers *all-MiniLM-L6-v2* model.[9] This model is trained on the 1 billion sentence pairs dataset[10] and is best suited for generating sentence embeddings. This created embedding database is called trainDB. Then, at inference time, embedding for the test question is created using the same SentenceTransfomers model, and this embedding is used to do ANN (Approximate Nearest Neighbor) search in trainDB to get ten examples from the train set. These ten examples and database schema is used to create the few-shot SQL generation prompt for GPT4. Pseudo-code and sample prompts are provided in Appendix §B. We use ChromaDB[11] as the underlying vector database and for ANN search.

5 Experiments, Results and Analysis

5.1 Evaluation Metrics

We use the standard evaluation metrics (details in Appendix D) of Exact Match Accuracy (EMA) (Yu et al., 2018), Execution Accuracy (EA) (Yu et al., 2018), Partial Component Match F1 (PCM-F1) (Hazoom et al., 2021a), BLEU-4 (Papineni et al., 2002), and ROUGE-L (Lin, 2004).

5.2 Experimental Setup

We divide the dataset into 70% train, 10% validation, and 20% test sets based on query templates. The test set contains 14.37% easy, 78.43% medium, and 7.2% hard SQL queries. In order to check the generalization performance, queries in the test set are based on templates that are not used during training. Given limitations on the number of calls to OpenAI GPT4 API, we used a random 10% of BookSQL test set for GPT4-based approaches. We provide details about training and hyper-parameters in Appendix E.

5.3 Results

Table 5 and Table 6 shows the performance of baseline models. Table 5 shows the performance of

[9] https://huggingface.co/sentence-transformers/all-MiniLM-L6-v2

[10] https://huggingface.co/blog/1b-sentence-embeddings

[11] https://github.com/chroma-core/chroma

Query	SEDE	UniSAr	RESDSQL	GPT4
E	100	100	100	100
M	43.08	46.49	62.12	71.35
H	15.00	12.34	15.00	22.08

Table 6: Execution Accuracy (in %) of various models on SQL queries of varying complexity. E refers to **Easy** query, M refers to **Medium** query and H refers to query with **Hard** complexity.

SOTA Text-to-SQL models fine-tuned on the BookSQL dataset. RESDSQL performs best as can be observed with regard to exact match accuracy and execution accuracy scores. SEDE and UniSAr have poor exact match and execution accuracy scores. Though BookSQL and Spider are not directly comparable, we also include results of the models on the Spider dataset to provide a reference for comparison purposes. As can be observed, the models that perform well on Spider do not have a good performance on BookSQL, indicating the complexity of the dataset. Table 5 shows the in-context learning performance of GPT4 on the BookSQL test set. DIN-SQL+GPT4 could only get 9.3% exact match accuracy, while Dynamic few-shot prompt+GPT4 comes close to the best-fine-tuned model, with exact match accuracy of 47.5% and execution accuracy of 67.2%. Table 6 shows the performance on easy, medium and hard queries. All models have a perfect performance (100% execution accuracy) on easy queries but struggle with medium and hard queries.

5.4 Error Analysis

We observed that SOTA models fail on queries with date filters, nested queries, distinct aggregations, and domain-specific filters. Table 7 shows the outputs of models on some examples from the test set. **DIN-SQL + GPT4** performs very poorly with execution accuracy of 7.6%. Perhaps, the reason for the bad performance is that it uses the same static chain-of-thought prompt, irrespective of the test question. BookSQL questions are very diverse and require domain knowledge. It is impossible to capture this diversity and domain knowledge in only a few examples in the prompt. Due to this, DIN-SQL fails whenever the test question is completely different from the examples provided in the prompt. **Dynamic few shot prompt + GPT4** model addresses the limitations of DIN-SQL by dynamically selecting a few shot examples for the prompt based on the test question. It significantly improves execution accuracy to 67.2%. Possibly, the reasons for poor performance are: 1) Getting confused between different columns (like `WHERE` clause on product_service vs. account column - see table 7), 2) Mixing up credit, debit, and amount columns and using incorrect columns in aggregations, 3) Not able to generate Nested SQL, even when required to answer the test question correctly, 4) failing when domain-specific information is required to generate SQL correctly. For example, transaction_type filters of the invoice, sales receipt, and purchase order, or account_type filters of expense, income, account receivable, and account payable are incorrectly applied.

SEDE fails to generate correct SQL, possibly due to a lack of question and schema linking in the input to the T5 model. Due to this, it mixes up different columns like customer, vendor, product_service, and account. **UniSAr** performs poorly, possibly due to complex queries introduced in BookSQL like date filters, nested queries, distinct aggregations, etc. UniSAr introduces constrained grammar-based decoding, which works well for simple queries but fails with such complex queries.

RESDSQL is the best-performing model. Poor performance is possibly due to: 1) Failure at complex time-based questions like *"What is average revenue for customer X in last 6 years"* (see table 7); 2) mixing up of credit and debit columns; 3) failure when distinct aggregations are required like `COUNT(DISTINCT transaction_id)`; 4) failure in case of many nested queries.

6 Future Directions

Results show the poor performance of the SOTA models on BookSQL. We outline some of the possible directions for the future to improve performance.

Multi-task learning: One could employ a multi-task learning setup, i.e., in addition to optimizing for SQL generation objective, adding other multi-task objectives could help improve the performance on hard SQL queries. These objectives could include (1) nested vs. non-nested SQL classification, (2) distinct keyword classification, and (3) date format classification.

Pre-training: For large databases, it is difficult for any model to relate the question tokens with column names when the question might refer to some table cell value. Before the Text-to-SQL task,

1	Question:	**What was the average invoice value for Biogenic municipal waste-fueled power generation?**
	Gold SQL:	**SELECT** avg(credit) **FROM** master_txn_table **WHERE** transaction_type = 'invoice' **AND** instr(account, 'Biogenic municipal waste-fueled power generation')
	Few-shot GPT4:	**SELECT** avg(amount) FROM master_txn_table **WHERE** transaction_type = 'invoice' **AND** product_service = 'Biogenic municipal waste-fueled power generation' ✗
	SEDE:	**SELECT** avg(credit) **FROM** master_txn_table **WHERE** transaction_type = 'invoice' AND instr(account, 'biogenic municipal waste-fueled power generation') ✓
	UniSAr:	**SELECT** avg(credit) **FROM** master_txn_table **WHERE** transaction_type = 'invoice' **AND** product_service = 'Biogenic municipal waste-fueled power generation' ✗
	RESDSQL:	**SELECT** avg(credit) **FROM** master_txn_table **WHERE** transaction_type = 'invoice' **AND** instr(account, 'biogenic municipal waste-fueled power generation') ✓
2	Question:	**What was the last invoice value for Drain cleaning in This week to date?**
	Gold SQL:	**SELECT** max(credit) **FROM** master_txn_table **WHERE** transaction_type = 'invoice' **AND** instr(account,'Drain cleaning') **AND** transaction_date **BETWEEN** date(current_date, 'weekday 0', '-7 days') AND date(current_date)
	Few-shot GPT4:	**SELECT** credit **FROM** master_txn_table **WHERE** transaction_type = 'invoice' **AND** product_service = 'Drain cleaning' **AND** transaction_date BETWEEN date(current_date, 'weekday 0', '-7 days') **AND** date(current_date) **ORDER BY** transaction_date DESC LIMIT 1 ✗
	SEDE:	**SELECT** max(credit) **FROM** master_txn_table **WHERE** transaction_type = 'invoice' **AND** customers = 'drain cleaning' **AND** transaction_date **BETWEEN** date(current_date, 'weekday 0', '-7 days') **AND** date(current_date) ✗
	UniSAr:	**SELECT** max(credit) **FROM** master_txn_table **WHERE** transaction_date **BETWEEN** date (current_date , 'weekday 0' , '-7 days') **AND** date (current_date) ✗
	RESDSQL:	**SELECT** max (credit) **FROM** master_txn_table **WHERE** transaction_type = 'invoice' **AND** instr (account , 'Drain cleaning') **AND** transaction_date **BETWEEN** date (current_date , 'weekday 0' , '-7 days') **AND** date (current_date) ✓
3	Question:	**What is my average revenue for Customer Nathan Hernandez in the last 6 years?**
	Gold SQL:	**SELECT** sum(credit)/6 **FROM** master_txn_table **WHERE** customers = 'Nathan Hernandez' **AND** strftime('%Y', transaction_date) >= strftime('%Y', current_date)-6-1
	Few-shot GPT4:	**SELECT** sum(credit)/6 **FROM** master_txn_table **WHERE** customers = 'Nathan Hernandez' **AND** strftime('%Y', transaction_date) >= strftime('%Y', current_date)-6-1 ✓
	SEDE:	**SELECT** avg(credit) **FROM** master_txn_table AS t1 JOIN chart_of_accounts AS t2 ON t1.account = t2.account_name **WHERE** account_type IN ('income','other income') **AND** customers = 'nathan hernandez' **AND** transaction_date **BETWEEN** date(current_date,'start of year','-6 year') **AND** date(current_date,'start of year','-1 day') ✗
	UniSAr:	**SELECT** avg(credit) **FROM** master_txn_table as T1 **JOIN** chart_of_accounts as T2 on T1.account = T2.account_name **WHERE** account_type in ('Income' , 'Other Income') **AND** customers = 'Nathan Hernandez' **AND** transaction_date **BETWEEN** date (current_date ,'start of year' , '-6 year') **AND** date (current_date ,'start of year' , '-1 day') ✗
	RESDSQL:	**SELECT** sum (credit) / 6 FROM master_txn_table **WHERE** customers = 'Nathan Hernandez' **AND** strftime ('%Y' , transaction_date) >= strftime ('%Y' , current_date) - 1 **GROUP BY** strftime ('%Y' , transaction_date) ✗

Table 7: Error analysis for different models on BookSQLtest set

one could do pre-training to better understand the question and table relationships. This can be done using mask modeling by defining tasks such as column recovery and column predictions where few tokens could be masked, and the model tries to recover and predict the masked tokens; a similar approach is proposed by Shi et al. (2020a) via the GAP model.

Multi-step few-shot prompting: One could also generate SQL in multiple steps using dynamic few-shot prompting instead of generating in a single step.

Value Encoding: In-context learning models (GPT4) mixes up different columns due to a lack of knowledge about table contents. Adding related table rows in the prompt could alleviate this issue.

7 Conclusion

In this paper, we propose BookSQL, a Text-to-SQL dataset that will have broad applications in the finance and accounting domain. The experimental outcomes of several Text-to-SQL models indicate considerable room for improvement. In the future, we aim to build a more robust model that can handle hard queries and improve performance.

Limitations

Since this is a resource paper, we release a large dataset and consequently focus less on modeling the Text-to-SQL system. We tested existing Text-to-SQL systems to see how well these fare on the new dataset. The results are indicative of considerable scope for improvement. In the future, we will focus on developing new models with better performance on BookSQL. Moreover, we hope that once the dataset is released, it will foster more research in this domain, resulting in more interesting models.

Ethics Statement

Considering the privacy aspect, we create anonymized entries in the dataset. Moreover, the dataset was verified by financial experts to make sure that the entries adhere to accounting principles and are reflective of real-life scenarios. We will be releasing the dataset publicly for research uses. To the best of our knowledge, we are not aware of any other possible ethical consequences of the proposed dataset.

A Dataset Details

- Table 8 shows master transaction table.
- Table 9 shows Chart of account table.
- Table 10 shows Customer table
- Table 11 shows Vendor table.
- Table 12 shows Employee table.
- Table 13 shows Product Service table.
- Table 14 shows Payment Methods table.

Distribution of Businesses in BookSQL The distributions of all businesses and their products are shown in Figure 4. Each industry is represented in the inner circle layer, which is followed by its businesses (in the middle circle) and its products in the outer circle. Each industry comprises multiple businesses, and each business consists of multiple products and services.

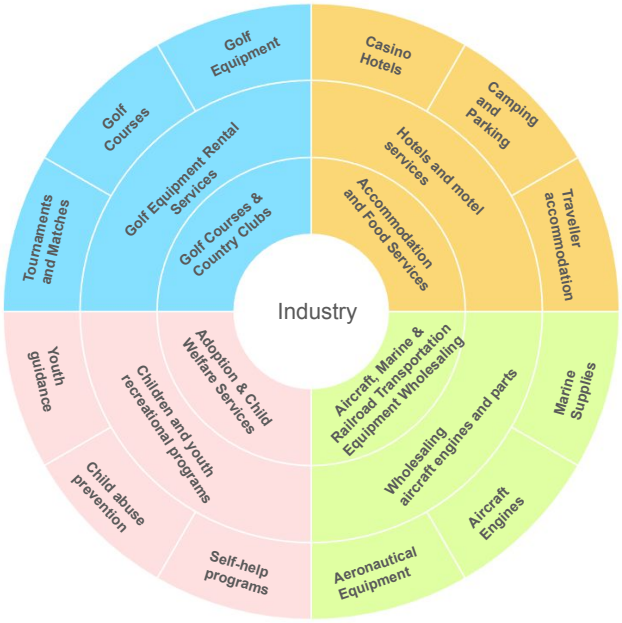

Figure 3: Sample BookSQL Business Distribution. The middle section shows the sample set of businesses, inner section shows the industries associated with the corresponding business and outer most section shows the corresponding product of the business. This chart is made with the information available at: https://www.ibisworld.com/united-states/list-of-industries/.

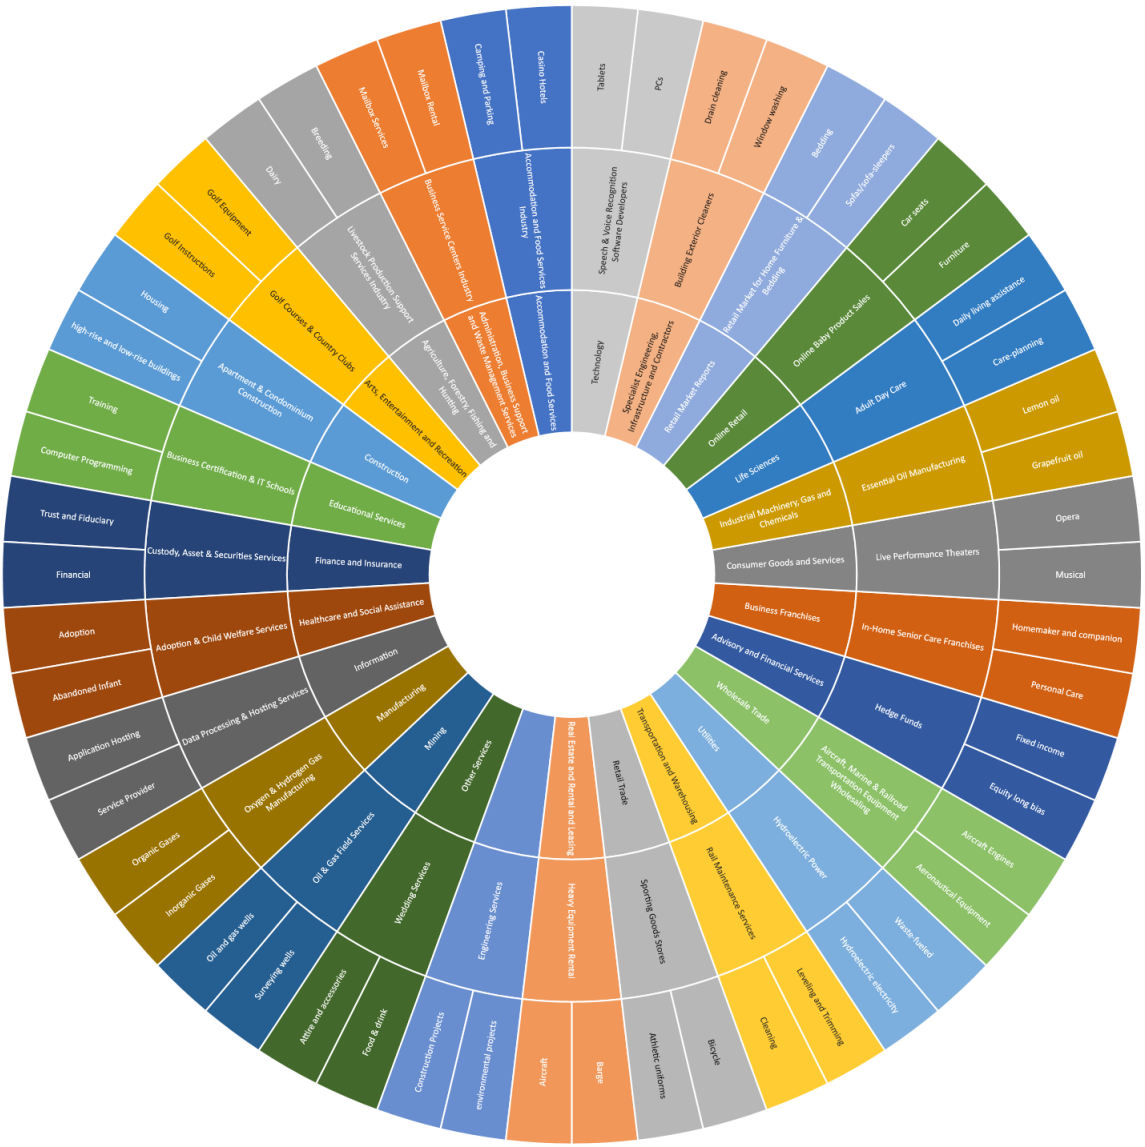

Figure 4: BookSQLBusiness Distribution. Here, inner circle indicates the industries , middle circle shows the sets of businesses associated to respective industry , and the outer most circle indicate corresponding product of the business. This chart is made with the information available at: https://www.ibisworld.com/united-states/list-of-industries/.

B Dynamic Few-shot Prompt + GPT4

Pseudo-code for dynamic few-shot train example selection for a given test question:

```
from langchain.embeddings.huggingface import HuggingFaceEmbeddings

from langchain.prompts.example_selector import MaxMarginalRelevanceExampleSelector

from langchain.vectorstores import Chroma

example_selector =
    MaxMarginalRelevanceExampleSelector.from_examples(
        examples,
        HuggingFaceEmbeddings(model_name="all-MiniLM-L6-v2"),
        Chroma,
        k=10,
        input_keys=["input"]
    )
```

B.1 Example Prompt

Database schema:
Table master_txn_table, columns = [, Transaction_ID, Transaction_DATE, Transaction_TYPE, Amount, CreatedDATE, CreatedUSER, Account, AR_paid, AP_paid, Due_DATE, Open_balance, Customers, Vendor, Product_Service, Quantity, Rate, Credit, Debit, payment_method, Misc]*
Table chart_of_accounts, columns = [, Account_name, Account_type] Table customers, columns = [*, customer_name, customer_full_name, Billing_address, Billing_city, Billing_state, Billing_ZIP_code, Shipping_address, Shipping_city, Shipping_state, Shipping_ZIP_code, Balance]*
Table employees, columns = [, Employee_name, Employee_ID, Hire_date, Billing_rate, Deleted]*
Table products, columns = [, Product_Service, Product_Service_type]*
Table vendors, columns = [, Vendor_name, Billing_address, Billing_city, Billing_state, Billing_ZIP_code, Balance]*
Table payment_method, columns = [, Payment_method, Credit_card]*

Foreign_keys = [master_txn_table.Account = chart_of_accounts.Account_name, master_txn_table.Customers = customers.customer_name, master_txn_table.Vendor = vendors.Vendor_name, master_txn_table.Product_Service = products.Product_Service, master_txn_table.payment_method = payment_method.payment_method]

Following are the example of questions and corresponding SQL queries.
«10 Few shot examples from train set»

Translate following question to SQL query.
Input: How much open credit does customer Ronald Bailey have?
Output: SELECT

C DIN-SQL+GPT4 Prompts

Following section shows the sample prompts used in different DIN-SQL modules. For brevity, we have added only 1 few shot example in these sample prompts. Though in practice, 5-10 few shot examples are used and is mentioned at the end of prompt in « ».

C.1 Schema Linking Prompt

Table master_txn_table, columns = [*, Transaction_ID, Transaction_DATE, Transaction_TYPE, Amount, CreatedDATE, CreatedUSER, Account, AR_paid, AP_paid, Due_DATE, Open_balance, Customers, Vendor, Product_Service, Quantity, Rate, Credit, Debit, payment_method, Misc]
Table chart_of_accounts, columns = [*, Account_name, Account_type]
Table customers, columns = [*, customer_name, customer_full_name, Billing_address, Billing_city,

Billing_state, Billing_ZIP_code, Shipping_address, Shipping_city, Shipping_state, Shipping_ZIP_code, Balance]
Table employees, columns = [*, Employee_name, Employee_ID, Hire_date, Billing_rate, Deleted]
Table products, columns = [*, Product_Service, Product_Service_type]
Table vendors, columns = [*, Vendor_name, Billing_address, Billing_city, Billing_state, Billing_ZIP_code, Balance]
Table payment_method, columns = [*, Payment_method, Credit_card]
Foreign_keys = [master_txn_table.Account = chart_of_accounts.Account_name, master_txn_table.Customers = customers.customer_name, master_txn_table.Vendor = vendors.Vendor_name, master_txn_table.Product_Service = products.Product_Service, master_txn_table.payment_method = payment_method.payment_method]

Q: How much open credit does customer Ronald Bailey have?
S: select sum(open_balance) from (select distinct transaction_id, open_balance from master_txn_table where customers = 'Ronald Bailey')
A: Let's think step by step. In the question "How much open credit does customer Ronald Bailey?", we are asked: "How much open credit", so we need column = [master_txn_table.open_balance] "open credit does customer Ronald Bailey", so we need column = [master_txn_table.transaction_id, master_txn_table.customers] Based on the columns and tables, we need these Foreign_keys = []. Based on the tables, columns, and Foreign_keys, The set of possible cell values are = [Ronald Bailey]. So the Schema_links are: Schema_links: [master_txn_table.open_balance, master_txn_table.customers, master_txn_table.transaction_id, Ronald Bailey]
«9 MORE FEW-SHOT EXAMPLES»

C.2 Classification prompt

Q: What are my transactions MTD?
schema_links: [master_txn_table.transaction_id, master_txn_table.amount, master_txn_table.transaction_date]
A: Let's think step by step. The SQL query for the question "What are my transactions MTD?" needs these tables = [master_txn_table], so we don't need JOIN. Plus, it doesn't require nested queries with (INTERSECT, UNION, EXCEPT, IN, NOT IN), and we need the answer to the questions = [""]. So, we don't need JOIN and don't need nested queries, then the the SQL query can be classified as "EASY".
Label: "EASY"

Q: How many products are never sold with total value higher than 5?
schema_links: [Product_Service.transaction_id, master_txn_table.transaction_type]
A: Let's think step by step. The SQL query for the question "How many products are never sold with total value higher than 5?" needs these tables = [Product_Service,master_txn_table], so we need JOIN. Plus, it requires nested queries with (INTERSECT, UNION, EXCEPT, IN, NOT IN) or inner query inside from clause, and we need the answer to the questions = ["products that are sold with total value higher than 5"]. So, we need JOIN and need nested queries, then the the SQL query can be classified as "NESTED".
Label: "NESTED"

Q: YTD, what was our smallest expense?
schema_links = [master_txn_table.account = chart_of_accounts.account_name, master_txn_table.credit, master_txn_table.transaction_date, master_txn_table.account_type, master_txn_table.debit]
A: Let's think step by step. The SQL query for the question "YTD, what was our smallest expense?" needs these tables = [master_txn_table,chart_of_accounts], so we need JOIN. Plus, it doesn't need nested queries with (INTERSECT, UNION, EXCEPT, IN, NOT IN), and we need the answer to the questions = [""]. So, we need JOIN and don't need nested queries, then the the SQL query can be classified as "NON-NESTED".
Label: "NON-NESTED"

C.3 SQL Generation

C.3.1 Easy Prompt

Q: "How much open credit does customer Ronald Bailey?"
Schema_links: [master_txn_table.open_balance, master_txn_table.transaction_id, master_txn_table.customers,Ronald Bailey]
SQL: select sum(open_balance) from (select distinct transaction_id, open_balance from master_txn_table where customers = 'Ronald Bailey')

«4 MORE FEW-SHOT EXAMPLES»

C.3.2 Non-Nested Complex Prompt

Q: "How many Traveller accomodation did we sell to Ethan Walker today?"
Schema_links: [master_txn_table.quantity ,master_txn_table.customers, master_txn_table.product_service, master_txn_table.transaction_type, master_txn_table.transaction_date]
A: Let's think step by step. For creating the SQL for the given question, we need to join these tables = []. First, create an intermediate representation, then use it to construct the SQL query. Intermediate_representation: select sum(master_txn_table.quantity) from master_txn_table where master_txn_table.customers = 'Ethan Walker' and master_txn_table.product_service = 'Traveller accomodation' and master_txn_table.trasaction_type in ('invoice','sales receipt') and master_txn_table.transaction_date BETWEEN date(current_date) AND date(current_date)
SQL: select sum(quantity) from master_txn_table where customers = Ëthan Walkeränd product_service = T̈raveller accomodationänd trasaction_type in ('invoice','sales receipt') and transaction_date BETWEEN date(current_date) AND date(current_date)

«9 MORE FEW-SHOT EXAMPLES»

C.3.3 Nested Complex Prompt

Q: "How many products are never sold with total value higher than 5?" Schema_links: [master_txn_table.product_service, master_txn_table.transaction_type, master_txn_table.credit, product_service.*]
A: Let's think step by step. "How many products are never sold with total value higher than 5?" can be solved by knowing the answer to the following sub-question "Show me all the products which are never sold with total credit value higher than 5?". The SQL query for the sub-question "Show me all the products which are never sold with total credit value higher than 5?" is SELECT count(*) FROM Product_Service WHERE product_service NOT IN (SELECT product_service FROM master_txn_table WHERE transaction_type in ('invoice','sales receipt') group by product_service having sum(credit)>5)
So, the answer to the question "How many products are never sold with total value higher than 5?" is = Intermediate_representation: SELECT count(Product_Service.*) FROM Product_Service WHERE Product_Service.product_service NOT IN (SELECT master_txn_table.product_service FROM master_txn_table WHERE master_txn_table.transaction_type in ('invoice','sales receipt') group by master_txn_table.product_service having sum(master_txn_table.credit) > 5)
SQL: SELECT count(*) FROM Product_Service WHERE product_service NOT IN (SELECT product_service FROM master_txn_table WHERE transaction_type in ('invoice','sales receipt') group by product_service having sum(credit) > 5)

C.4 Self Correction Prompt

For the given question, use the provided tables, columns, foreign keys, and primary keys to fix the given SQLite SQL QUERY for any issues. If there are any problems, fix them. If there are no issues, return the SQLite SQL QUERY as is.
Use the following instructions for fixing the SQL QUERY:
1) Use the database values that are explicitly mentioned in the question.

2) Pay attention to the columns that are used for the JOIN by using the Foreign_keys.
3) Use DESC and DISTINCT when needed.
4) Pay attention to the columns that are used for the GROUP BY statement.
5) Pay attention to the columns that are used for the SELECT statement.
6) Only change the GROUP BY clause when necessary (Avoid redundant columns in GROUP BY).
7) Use GROUP BY on one column only.

D Evaluation Metrics

The following standard metrics are used:

- **Exact Match Accuracy (Yu et al., 2018):** Both predicted and the Gold SQL are decomposed into different SQL components like SELECT, WHERE, GROUP BY, etc. Predicted SQL is marked as correct if all SQL components exactly match with the Gold SQL.
- **Execution Accuracy (Yu et al., 2018):** Output of predicted SQL is the same as Gold SQL's output on execution against the database.
- **Partial Component Match F1 (Hazoom et al., 2021a):** Both the predicted query and the gold query are parsed into tress using JSqlParser[12]. These two parsed trees are compared, and an aggregated score is calculated based on the number of matching sub-trees.
- **BLEU-4 (Papineni et al., 2002):** It measures the number of matching n-grams between the predicted and the Gold SQL.
- **ROUGE-L (Lin, 2004):** It is based on the longest common sub-sequence (LCS) between the predicted and the Gold SQL. A longer shared sequence indicates more similarity between the predicted and the Gold SQL.

E Training Details and Hyper-parameters

All experiments were done on a single NVIDIA A10G Tensor Core GPU.

For SEDE, we used T5-Large as the base seq-to-seq model, with a learning rate of $5e-5$ with 15 epochs and batch size of 6. For decoding, a beam size of 6 was used, with max decoding steps of 250.

For UniSAr, we use T5-Large as a base language model with a learning rate of 1e-5 and max tokens is 1024. We adopt the polynomial_decay with 5,000 warmup updates. The dropout rate is 0.1. Optimizer is Adam with the default parameters. The max-update is set to 10,000. Empirically, the model obtained the best performance about $10 \sim 15$ epochs in BookSQL. The Fairseq dynamically tunes the batch size to realize higher GPU utilization.

For RESDSQL, we used settings recommended by the original paper and code. The Schema Item Classifier module used a RoBERTa-large model with a learning rate of $1e-5$ and an effective batch size of 32 (using gradient accumulation). topk_table_num value of 4 and topk_column_num value of 8 were used. For the text2sql module, a T5-large model was used with a learning rate of $5e-5$ and an effective batch size of 32 (using gradient accumulation). Beam search decoding was used with num_beams set to 8 and num_return_sequences set to 8.

For DIN-SQL+GPT4 and Dynamic few shot prompt + GPT4, we used OpenAI GPT4 API with following settings: *n = 1, temperature=0.0, max_tokens=600, top_p = 1.0, frequency_penalty=0.0, presence_penalty=0.0*. Given limitations on the number of calls to OpenAI GPT4 API, we used a random 10% of BookSQL test set for GPT4-based approaches.

Abstract

Planning is a crucial task for agents in task oriented dialogs (TODs). Human agents typically resolve user issues by following predefined workflows, decomposing workflow steps into actionable items, and performing actions by executing APIs in order; all of which require reasoning and planning. With the recent advances in LLMs, there have been increasing attempts to use them for task planning and API usage. However, the faithfulness of the plans to predefined workflows and API dependencies, is not guaranteed with LLMs. Moreover, workflows in real life are often custom-defined and prone to changes; hence, adaptation is desirable. To study this, we propose the problem of faithful planning in TODs that needs to resolve user intents by following predefined flows and preserving API dependencies. To solve this problem, we propose **FLAP**, a **Fl**ow-**A**dhering **P**lanning algorithm based on constrained decoding with lookahead heuristic for LLMs. Our algorithm alleviates the need for finetuning LLMs using domain specific (plan/dependency) data, enables quick adaptation to predefined flows, and outperforms other decoding and prompting-based baselines. Further, our algorithm empowers smaller LLMs ($\approx$ 7B) to perform at par larger LLMs ($\approx$ 30B-40B).

1 Introduction

A successful task oriented dialog (TOD) often involves interaction with internal or external world through tools or APIs. For example, as shown in Fig. 1, booking a flight through a conversation may involve searching for flights, getting payment information, and so on. API usage is a difficult task for chatbot agents as it involves various reasoning and planning. Beyond predicting the correct API to use in a particular scenario, it requires task decomposition and resolution of inter-API dependencies (e.g., searching for flights requires extracting airport codes) (Zhang et al., 2021; Prasad et al., 2023; Wang et al., 2023; Lu et al., 2023b). Moreover,

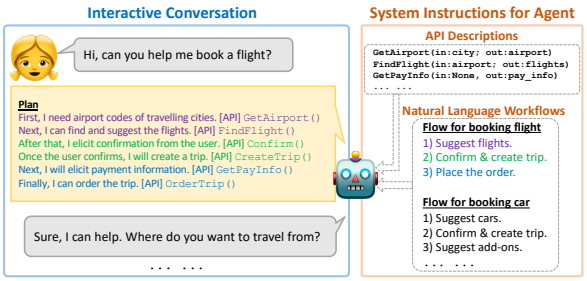

Figure 1: An agent-user interaction scenario. Agent plans how to resolve the user query by following given natural language workflows and API dependencies.

there may exist customized workflows to follow for API usage, such as "confirm before placing order" or "recommend add-ons before checking out", which can conveniently be defined using natural language (NL) instructions.

Recent advances in LLMs have enabled researchers to consider LLMs for task-planning (Huang et al., 2022; Valmeekam et al., 2023) and API usage (Qin et al., 2023b; Patil et al., 2023). In planning, studies have primarily focused on open-ended scenarios and emphasized mostly on goal attainment (Shridhar et al., 2020; Jansen, 2020) without considering any instructions on the process (Valmeekam et al., 2024), while works on API usage have mostly considered the appropriateness of API calls (Wang et al., 2023). However, considerations about API dependencies, and the faithfulness of generated API calls to predefined workflows or instructions are understudied.

In this paper, we propose a novel problem of zero-shot faithful planning with LLMs in TODs. As input, we provide (1) the domain definition in terms of APIs and their descriptions, (2) NL flows to fulfill various intents in the domain, and (3) a user query. The task is to generate a plan that fulfills the user's query by using the domain-specific APIs while adhering to the specified flows and API dependencies (§2).

Prior works attempted to teach LLMs to use

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 517–539
June 16-21, 2024 ©2024 Association for Computational Linguistics

APIs by pretraining them with large amount of API related data (Schick et al., 2023; Yang et al., 2023; Qin et al., 2023b). However, in practice, API signatures and the NL flows to use them are customized to use cases and are prone to change (e.g., due to change in business policy). Hence, quickly adapting the LLMs to new flows and API dependencies is required. Unfortunately, pretraining LLMs cannot guarantee faithful planning with custom-defined APIs and flows which may significantly differ from the pretraining data (Blodgett et al., 2020; Bommasani et al., 2021); we experimentally verify this in §4.1. To alleviate the issue, we propose **FLAP**, a **Fl**ow **A**dhering **P**lanning algorithm that uses constrained decoding of LLMs with lookahead heuristic (Och et al., 2001; Haghighi et al., 2007; Lu et al., 2022a; Huang et al., 2024) (§4.2). FLAP generates faithful plans to predefined flows and API dependencies, requires no pretraining, and is applicable on top of any autoregressive LLM regardless of its pretraining mechanism.

Given previous studies have shown that thoughts enhance the reasoning capabilities of LLMs (Wei et al., 2022) (even in the context of API usage (Yao et al., 2022)), FLAP prompts the LLMs to generate plans consisting of thoughts and corresponding APIs. FLAP aligns the generated thoughts to predefined NL flows, enabling thoughts to act as an intermediary (and address the vocabulary mismatch) between NL flows and APIs. In addition, FLAP captures the relations among NL flow steps and APIs using dynamic dependency graphs; these are used to score different dimensions related to API and flow dependency adherence in the lookahead heuristic function. Finally, FLAP also enforces structural constraints using lookahead heuristics.

To quantify the efficacy of current LLMs with promising prompt strategies, and our proposed approach for *faithful planning*, we construct a novel dataset comprising 4 domains, 13 intents and flows, 64 APIs, and 260 user queries, resembling real life use-cases (§3). We find that existing open-source LLMs and prompting techniques lack faithful planning capabilities and our proposed constrained decoding based algorithm, FLAP, improves the faithfulness of plans by reducing various errors, such as API and flow step dependency violations, redundant/lacking API in generated plan, etc. We also demonstrate that smaller LLMs (7B) with FLAP can achieve comparable performance against much larger LLMs (40B) (§5).

2 Task Formulation

In this section, we define the novel task of faithful planning in task oriented dialogues (TODs) to resolve queries by adhering to predefined natural language (NL) flows and API dependencies.

2.1 TOD Agent Scenario

In a typical TOD system, an agent is equipped with the following elements.

Domain: An agent usually has access to a specific domain, $\mathcal{D}$ (e.g., trip planning, banking, and so on).

Intents: In a domain $\mathcal{D}$, an agent has capabilities to handle a set of intents, $\mathcal{I}$. For example, an agent form the domain "trip planner" may only be able to book a hotel, search flights, and so on, however, unlikely to be able to create a bank account.

Flows: Agents are often provided with a sequence of natural language instructions, defined as "flows", $\mathcal{F}$ (e.g., "recommend add-ons before checking out"). Agents are expected to follow these flows *step-by-step* to resolve intents. Flows are typically defined by businesses and are prone to change.

APIs: Agents have access to a set of internal APIs, $\mathcal{A}$, to interact with the system (typically through GUI) and trigger actions based on the inputs from the user. For example, if a user is looking to book a car in Chicago, the agent may trigger the API, `FindRentalCar(location="Chicago")`.

2.2 Faithful Planning for Resolving Intent

In real life, when a user expresses an intent, an agent has to execute a sequence of APIs to fulfil it. Successful fulfillment of the user intent depends largely on the reasoning and planning capability of the agents because of the following challenges.

Identifying and following NL flows: Given an intent in $\mathcal{I}$, the execution steps need to be strictly consistent with a predefined flow in $\mathcal{F}$. Hence, the agents need to first identify the correct flow in $\mathcal{F}$ and then adhere to it.

Task decomposition and dependency resolution: APIs in $\mathcal{A}$ may have dependencies on other APIs in $\mathcal{A}$, and a flow step may require calling multiple APIs. For example, `GetAirports(city="Chicago")` is needed to be called before `FindFlight(airport="ORD")`, to execute the flow step "suggest flights". Hence, the agents have to decompose flow steps and preserve API dependencies.

Grounded in such challenges, we define the novel task of faithful planning for TOD agents (Fig.

1). Given, a domain $\mathcal{D}$, a set of flows $\mathcal{F}$ (for resolving intents $\mathcal{I}$), a set of APIs $\mathcal{A}$ (with parameters and descriptions), and a user query $\mathcal{Q}$; the task is to generate a plan $\mathcal{P}$ consisting of a sequence of APIs to fulfil the user query while obeying the flow steps in $\mathcal{F}$ and preserving API dependencies in $\mathcal{A}$.

In real world scenarios, agents may need to dynamically update the plan based on the situation (say, the user starts with query $\mathcal{Q}$ and then wants to do $\mathcal{Q}'$ as well). As a first step towards faithful planning in TODs, we study static planning (user does not change mind) in this paper, and leave dynamic (run-time) planning as a future work.

2.3 Zero-shot Planning with LLMs

We study the capabilities of LLMs in zero-shot planning by following predefined flows and preserving API dependencies in TODs. For that, we instruct a base LLM to act as a customer care agent and in context, we provide the domain definition consisting of APIs, their input-output parameters and descriptions, and NL flows for resolving intents in the domain. Given a user query in context, the LLM is instructed to plan how to resolve the query by using the given APIs and following the appropriate flow. The LLMs are expected to resolve API dependencies from their input-output parameters. The prompt structures are shown in §B. We study the problem in the following settings by varying the nature and complexity of the task.

All *vs.* relevant flow in-context: We experiment by providing either all flows or only the flow related to the user query in context. The former setting is more complex as the LLM has to first identify the relevant flow and then follow it to plan.

Reasoning and acting: Recent studies have shown that step-by-step thinking and acting improves the end goal achievement (Wei et al., 2022; Yao et al., 2022). Inspired by these works, we study the problem of plan generation in a setting where the LLMs are prompted to generate a thought and then an API in the plan to help it rationalize its selection of the API.

2.4 Evaluation Metrics

Number of edits to fix the plan: A generated plan is required to contain *only* the steps and APIs from the gold plan. We define number of edits as the sum of additions and deletions of steps/APIs in the generated plan to make it contain the same steps/APIs as the gold plan. The lower the number of edits, the better the generated plan.

Domains:	Trip Booking	Insurance	Banking	Restaurant & Ride Book
# of intents/flows	3	3	3	4
# of steps per intent/flow	5-6	4-5	3-5	4
# of APIs needed per step	1-2	1-2	1-3	1-4
# of APIs in domain	13	15	14	22
# of relationships among APIs	13	13	15	19
# of user queries	60	60	60	80
Intents in all domains				
Trip Booking	book car, book hotel, book flight	**Insurance**	buy insurance, cancel insurance, add member	**Banking**	open account, report problem, cancel transaction	**Restaurant & Ride Book**	book restaurant, book ride, cancel restaurant, cancel ride

(a) Created domains statistics.

Flow steps	Required API sequence (gold plan)
Suggest cars to the customer	`FindRentalCar()`
Confirm and create the trip	`Confirm(), CreateTrip()`
Extract and add promotional offers	`GetCarInsuranceDiscount(), UpdateTrip()`
Order the trip	`GetPaymentInformation(), OrderTrip()`

(b) Flow and required APIs for the intent "book car" in the domain "Trip Booking". The full list can be found in §A.1.

Table 1: Test data statistics (a) and example flow (b).

Inconsistent steps/APIs: A generated plan is required to obey flow steps and API dependencies. Hence, we measure the percentage of steps or APIs in the generated plan that do not follow the dependency structure (e.g., a step/API is generated before its parent steps/APIs).

Fine-grained metrics: We quantify other fine-grained metrics such as API hallucination, API repetition and parsability of the generated plans.

3 Data Collection

In this section, we describe the data collection procedure for studying faithful plan generation.

Domain Creation. Previous datasets have developed domains, flows, and APIs for tackling intents in TODs. We find, none of the existing datasets is usable as it is in our problem. For example, the STAR (Mosig et al., 2020) and STARv2 (Zhao et al., 2023) datasets contain APIs (without flows) to resolve user queries, however, dependencies among the APIs are sparse, e.g., STAR contains only 10 dependencies among 25 APIs. In real life, API dependencies are more dense, hence, these datasets are not very useful for our study where the goal is to study the ability of LLMs to preserve dependencies. The ABCD dataset (Chen et al., 2021) contains flows for a few tasks, however, the related APIs needed to perform the steps in the flows are not given, hence, it is also not suitable for our study. Hence, inspired from these two datasets, we create in total, 4 domains, 13 flows (similar to ABCD) for resolving 13 distinct intents in these domains, and 64 APIs (similar to STAR) to execute different flow steps. We also annotate the gold plans to

resolve the 13 intents. The statistics of the dataset and examples are presented in Tab. 1.

Test Query Generation. We aim to study plan generation in response to a user query in our created domains. To collect diverse user utterances related to the intents in Tab. 1a, we utilize the generative power of pretrained LLMs. We prompt an open-source LLM, `Falcon-40B-instruct` (Almazrouei et al., 2023)[1], to generate user queries related to the intents. We prompt the LLM to write paraphrases of a query with a specific intent. Prompt structure and generated examples are shown in §A.2. We manually go through the generated queries and discard any queries that are not related to the intent in the prompt. We find that 94% of the generated queries are correct. In this manner, we generate 20 user queries per intent resulting in 260 queries in total. We use this dataset for studying flow-constrained plan generation given a user query.

4 Constrained Decoding for Planning

In this section, first, we run an ablation on plan generation in various settings as explained in §2.3, to understand the complexity of the task. Then we explain our proposed constrained decoding based algorithm for faithful plan generation.

[1]We experimented with other open source LLMs and found `Falcon` to be the best in generating diverse utterances.

4.1 Ablation

To understand the complexity of zero-shot faithful planning in different settings, we run a zero-shot prompting-based ablation with a number of open-source LLMs pretrained with/without tools and of different parameter size. We use `Santacoder` (Allal et al., 2023), `Falcon` (Penedo et al., 2023), `Mpt` (Team, 2023), `Mistral-v0.1` (Jiang et al., 2023), `Koala` (Geng et al., 2023), `Vicuna` (Chiang et al., 2023), `Llama` (Touvron et al., 2023), `ToolAlpaca` (Tang et al., 2023), and `ToolLlaMA` (Qin et al., 2023b). The prompt structures for generating plans with and without thoughts are shown in §B. The results for plan generation in the two settings are summarized in Tab. 2. Our main observation is that all LLMs fail heavily in zero-shot planning regardless of the setting, especially LLMs fail to preserve the API and flow step dependencies in plans. For example, the average percentage of inconsistent APIs in the two settings, ranges from 22.6% to 49.6%. This finding is in line with previous studies on LLMs' capability in task planning and tool usage (Ruan et al., 2023; Valmeekam et al., 2022). We categorize our main observations below.

Effect of thoughts. Performance improves in flow faithfulness for almost all LLMs when prompted to generate thoughts and APIs compared to when prompted to generate only APIs in plan. This is consistent with the findings of Yao et al. (2022). However, with thoughts, API repetition and halluci-

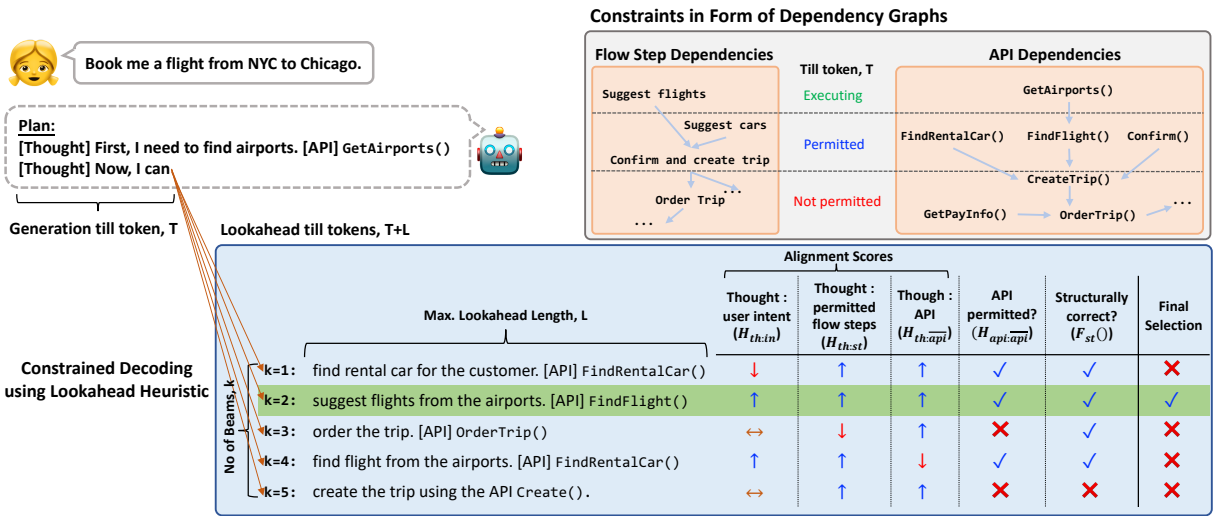

Figure 2: An example state of FLAP, our proposed lookahead heuristic-based constrained decoding algorithm for faithful planning, in the domain "Trip Planning" for a query related to "book flight". Here, ↑, ↓, and ↔ indicate high, low, and mediocre alignment scores, respectively. The selected path based on the heuristic scores is highlighted.

nation increase and plan parsability (§D) decreases a bit. On some test examples, we notice that the LLMs enter into a repetitive loop with thoughts (examples in §E.1), in line with well-known phenomenon in greedy and beam-search decoding (Vijayakumar et al., 2016; Shao et al., 2017).

Effect of parameter size. Performance in most of the metrics improve in larger LLMs and smaller LLMs are prone to hallucination. We observe that different models of the same parameter size perform differently. For example, the 7B version of `MPT` is better than the 7B version of `Falcon` in most of the metrics and `Mistral-7B` is better than other 7B models and it performs as per 30B-40B models.

Effect of pretraining. We observe that LLMs pretrained on tools, e.g., `ToolAlpaca` fails heavily in API consistency and results in high API hallucination. With `ToolLlama`, we find that it fails to follow instructions and generates non-parsable responses (hence, not reported). These findings suggest that pretraining LLMs with tool data makes them heavily biased towards the pretraining data.

All flows *vs.* relevant flow in prompt. When only the relevant flow to the user query is given in-context, the performance improves with almost all LLMs indicating that LLMs are more confused when multiple flows are given in-context.

4.2 Proposed Algorithm

We now introduce **FLAP**, a **F**low **A**dhering **P**lanning algorithm based on constrained decoding with lookahead heuristic (Fig. 2). In FLAP, we first convert the flow steps and APIs to dependency graphs. At decoding time, we keep track of these dependency graphs to enforce the dependencies as constraints during next token generation.

4.2.1 Constructing Dependency Graphs

For each domain, we construct dependency graphs for flow steps and APIs. The API dependency graph is constructed based on the input-output parameter dependencies among APIs. For example the API `FindFlight(inputs:airport; outputs:flights)` is dependent on the API `GetAirport (inputs:city; outputs:airport)` for the input parameter '`airport`'. Hence, in the API dependency graph '`GetAirport`' will be a parent of '`FindFlight`'. Similarly for flow steps, we construct a separate flow-step dependency graph. While generating a plan, we maintain a list of the steps and APIs that are executed in these dependency graphs. At each planning step, only non-executed/under-execution APIs/steps in the dependency graphs with parents in the executed list are considered permitted.

4.2.2 Constrained Decoding of Plans with Lookahead Heuristic

The traditional text generation problem can be formulated as, given an input sequence of tokens $x = \{y_1, y_2, \cdots, y_{t-1}\}$, the next token generator predicts the next token y_t by solving the equation:

$$y_t = \arg\max_{y'_t \in Y} P(y'_t|x)$$

Here, Y is the set of all possible generations and $P(y'_t|x)$ is the likelihood of the token y'_t given the

input sequence x. In constrained decoding, the likelihood function takes the form $P'(y'_t|x) = P(y'_t|x) + H(y'_t|x)$, where $H(y'_t|x)$ is the score based on constraint satisfaction by generating y'_t. However, often it is difficult to determine the constraint satisfaction score by only looking at the next token. The lookahead mechanism comes handy here where the constraint satisfaction score for a candidate next token, y'_t is estimated by looking at the estimated future generations if y'_t is selected. Hence, instead of $H(y'_t|x)$, the heuristic function takes the form $H(y'_t, \cdots, y'_{t+L}|x)$, where L is lookahead length.

For constrained plan generation, we prompt LLMs to generate thoughts and corresponding APIs. During generation, for each candidate next token, we lookahead till the end of one thought+API and score the candidate based on their constraint satisfaction. Hence, our heuristic function takes the form $H_c = H([thought][api]|x)$. $[thought][api]$ may contain some already generated tokens; we also consider those when scoring. We score each $[thought][api]$ in the aspects below.

Generated thought to permitted flow step alignment ($H_{th:step}$). In our approach, thoughts are natural language sentences describing the next step to be taken. Ideally, they should correspond to the flow steps. Hence, we score the generated thoughts based on their semantic similarity to the permitted flow steps in the flow dependency graph. A flow step is permitted, if all of its parent flow steps are already executed or the flow step is under execution (e.g., flow step consisting of multiple API calls). First, we estimate the intended flow step, $\hat{s}$ by a thought, th by obtaining its semantically closest flow step using the formula below.

$$\hat{s} = \arg\max_{s \in S} sim(th, s)$$

Here, S is the set of all flow steps in the domain and $sim()$ is semantic similarity scorer. Then we calculate $H_{th:step}$ using the following equations.

$$H_{th:step} = \begin{cases} \alpha \times sim(th, \hat{s}), & \text{if } \hat{s} \text{ in } S_p \\ 0, & \text{if } \hat{s} \text{ in } S_n \end{cases}$$

$$\alpha = \begin{cases} \alpha_a, & \text{if } \hat{s} \text{ is in a flow} \\ \alpha_b, & \text{if } \hat{s} \text{ is deviating from flow} \\ \alpha_c, & \text{if } \hat{s} \text{ is same as the last step} \end{cases}$$

Here, S_p and S_n are permitted and not permitted flows steps at the current thought, respectively. We assign different weights to $H_{th:step}$ based on the intended flow step $\hat{s}$. If the intended flow step $\hat{s}$ belongs to the flow that the model has been following so far, we assign the weight α_a. If the model deviates from the flow it has been following, we assign the weight α_b. In single intent use-cases, the model is required to follow only one flow, hence, setting $\alpha_a > \alpha_b$ prevents the model from deviating from the flow it has been following. If the model generates a flow step that is the same as the step it intended in its previous thought, we assign a weight α_c. One step may involve executing multiple APIs. Hence, setting $\alpha_c > \alpha_a$ encourages the model to complete the current step before moving to the next.

Generated API to permitted APIs alignment ($H_{api:\overline{api}}$). We score the generated API based on their alignment to the permitted APIs. Permitted APIs at a step are the non-executed APIs whose parents are already executed. We calculate $H_{api:\overline{api}}$ using the following equations.

$$\hat{a} = \arg\max_{a \in A} sim(a, \overline{a})$$

$$H_{api:\overline{api}} = \beta \times sim(\overline{a}, \hat{a})$$

$$\beta = \begin{cases} [0,1), & \text{if } \hat{a} \notin A_p \cup A_c \text{ or } \overline{a} \notin A \\ 1, & \text{if } \hat{a} \in A_p \\ 0, & \text{if } \hat{a} \in A_c \end{cases}$$

Here, $\overline{a}$ is the generated API, A is the set of all APIs in a domain, A_p and A_c are permitted APIs and already called APIs, respectively, and $A_p \cap A_c = \emptyset$. When APIs from none of the sets A_p and A_c are generated, the API is either hallucinated or generated from the non-permitted list (A_n). In both of the cases, we assign a lower weight than 1 in the alignment score to make it a soft constraint while making it zero will enforce a hard constraint against such cases. We keep this weight open to tuning for different LLMs because of their varying degree of hallucinations and errors.

Generated thought to user intent alignment ($H_{th:in}$). The plan should correspond to the user intent in the query. Hence, we score the generated thought, th based on its semantic similarity with the user query, in, using, $H_{th:in} = sim(th, in)$.

Generated thought to generated API alignment ($H_{th:\overline{api}}$). We generate thought to resonate the API usage. Hence, the generated API, $\overline{a}$ should be relevant to the generated thought, th. We align the generated thought to the generated API using the score, $H_{th:\overline{api}} = sim(th, \overline{a}_d)$, where $\overline{a}_d$ is the given

(b) Setting: Only relevant flow to test query is present in-context.

Table 3: Comparison of our proposed approach, FLAP, with baselines in zero-shot faithful plan generation. Here, the numbers (FLAP.#) indicate different ablation versions of FLAP. Structural constraint is applied in all versions of FLAP. Results with standard deviations can be found in Tables 13 and 14 in §D. As reference for the "Avg count per plan" column, we note, there are 6.84 APIs per gold plan.

description of the generated API, $\overline{a}$. When $\overline{a}$ is a hallucination, we set $\overline{a}_d = \overline{a}$.

Structural constraint (F_{st}). For practical use-cases, it is convenient if the LLMs generate plans in a pre-defined format. It helps automatic parsability of the generated plans. Hence, we introduce a function, F_{st} that accounts for the structural consistency of the generated plan. It operates on the combined heuristic score, $H'_c = a \times H_{th:step} + b \times H_{api:\overline{api}} + c \times H_{th:in} + d \times H_{th:\overline{api}}$ (a, b, c, d are scaling factors) as follows.

$$F_{st}(H'_c) = \begin{cases} H'_c, & \text{if thought+API follows format} \\ 0, & \text{otherwise} \end{cases}$$

We use $H_c = F_{st}(H'_c)$ as the final heuristic score for a candidate token, y'_t and the final scoring function for next token selection is defined as follows.

$$S(y'_t|x) = (1-\lambda) \times P(y'_t|x) + \lambda \times H_c^{y'_t}$$

The parameter λ controls how much weight is given in the LLM logits, $P(y'_t|x)$, and the heuristic score $H_c^{y'_t}$. We use top-k beams based on $P(y'_t)$ for the next token generation using constrained decoding. An example of our approach is shown in Fig. 2.

5 Experimental Evaluation

5.1 Experimental Setting

We evaluate FLAPs performance in faithful planning on the dataset described in §3, by comparing it with prompting-based baselines and different decoding methods. Note that, the approach with thoughts is similar to ReAct (Yao et al., 2022). Other approaches either depend on multiple modules, require finetuning, or tuned for a different task setting, hence, not directly applicable in our task. Based on our ablation (in Tab. 2), we apply FLAP on two LLMs in 7B parameter range, `Mistral-7b-instruct` and `Mpt-7b-instruct`. We leave application of FLAP on larger LLMs as future work because of their high resource requirement. We demonstrate the structure of plan, (`[thought]...[API]...`), through dummy start steps in the prompts (Fig. 6, §B) and enforce it through F_{st} during decoding. We use a pretrained sentence transformer (Reimers and Gurevych, 2019) to calculate semantic similarities ($sim()$). We report hyper-parameter tuning and other experimental details in §C.

5.2 Experimental Results

The experimental results are summarized in Table 3. First, we observe that the Beam Search and Nucleus Sampling (Holtzman et al., 2019) methods do not improve the overall performance compared to the Greedy Search method. Rather both Beam Search and Nucleus Sampling result in fewer number of parsable plans compared to Greedy Search. Note that Beam Search and Nucleus Sampling explore a wider search space compared to Greedy Search, and Nucleus Sampling increases diversity; we observe that without constraints, it results in more deviation from the instructions and often decreases performance in different metrics. Hence, in the rest of this section, we compare our models performance with "Greedy Search with thoughts". We also observe that different baselines and our approach show similar comparative trends in the two settings (all flows in context vs. relevant flow in context). Hence, we focus our rest of the discussion on the more difficult setting where all flows are given in the prompt (Tab. 3a).

In case of `Mpt`, different versions of our algorithm, FLAP, outperform the baselines by a great margin. In case of `Mistral`, the average percentage of inconsistent steps increases a bit (by 2-4%) with FLAP, however, performance improves in all other metrics, especially the inconsistent APIs decreases from 40.3% to 3.6%. A similar trend is observed in the relevant flow in-context setting (Tab. 3b).

We observe that `Mistral` is good at following flows even without FLAP in the difficult all flows in-context setting, however, it fails to decompose when one flow step requires multiple API calls. Hence, without FLAP, the average API count per plan is lower (4.8) than the average number of APIs in gold plans (6.84). As a result, the avg. % of inconsistent steps is low (3.1%), however, % of inconsistent API is very high (40.3%). With FLAP, the decomposition capability improves and the model generates plans with number of APIs (6.1-6.7) closer to the gold reference value (6.84) with fewer number of edits and much less inconsistent APIs (3.6-7.7%), however, with a trade off of slightly increased (by 2-4%) inconsistent steps. We present qualitative examples in Tab. 4.

We perform ablation by dropping different components of the heuristic scoring function in FLAP. We observe, different components of the heuristic score affect the corresponding aspects they are designed for, especially in the difficult setting where all flows are present in-context. For example, in case of `Mpt`, dropping $H_{th:step}$ (thought to flow step alignment) results in higher step dependency violation (FLAP.1). Another component $H_{th:in}$ (thought to intent alignment) is designed to keep the model focused on the flow related to the user intent and we observe an overall lower number of edits required when this component is added (FLAP.1, FLAP.3, FLAP.4), implying this component helps the model generate a plan related to the user intent. However, the effect of these components is not clear in case of `Mistral`. We conjecture, as `Mistral` is already good at following flows, the effect is lower. The effect of $H_{th:\overline{api}}$ that makes generated thoughts and APIs coherent, is more qualitative and we find that dropping these component (FLAP.3) results in inconsistent thought and API pairs even if the generated API is correct in the plan. Examples of such errors are presented in Tab. 5. Finally, enforcing structural consistency (F_{st}) during decoding makes the plans parsable 100% of the time.

In Fig. 3, we present the comparative performance of LLMs of different size and smaller 7B LLMs with FLAP. We observe that FLAP on top of `Mistral-7b` outperforms and `Mpt-7b` performs at par larger LLMs.

Query: Can you book a flight from Boston to San Francisco?
Generated Plan by `Mistral-7b-instruct` Without FLAP
[thought] To suggest flights, I need to find flights from Boston to San Francisco. [API] FindFlight()
[thought] Once I have the flight details, I can confirm and create the trip. [API] Confirm()
[thought] After confirming the trip, I can order the trip. [API] OrderTrip()

[thought] Once I have the airport codes, I can suggest flights to the customer. [API] FindFlight()
[thought] After suggesting flights, I need to confirm the trip details with the user. [API] Confirm()
[thought] Once the trip details are confirmed, I can create the trip. [API] CreateTrip()
[thought] To order the trip, I need to get the payment information from the user. [API] GetPayInfo()
[thought] After getting the payment information, I can order the trip. [API] OrderTrip()

Table 4: Generated plans by `Mistral`. It often fails in step decomposition without FLAP.

6 Related Work

While API usage and planning have been studied as separate concepts in literature, we argue that these two are interdependent. Recently, different approaches have been proposed to teach LLMs to use the correct API, however, the faithfulness of API usage to their dependencies is understudied (Ruan et al., 2023). For correct API usage, one line of research considers pretraining of LLMs with large API data that are mostly augmented using self-instruction (Schick et al., 2023; Patil et al., 2023; Qin et al., 2023b; Yang et al., 2023; Gao et al., 2023; Tang et al., 2023; Li et al., 2023). In some cases, authors considered modular approaches and

(b) Generated plan with `Mistral-7b-instruct`.

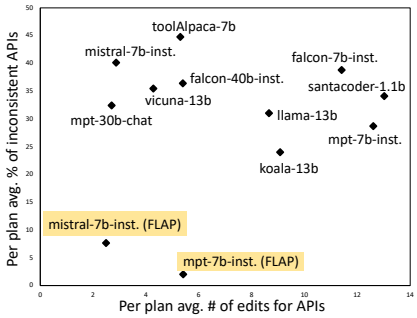

Table 5: Qualitative error analysis when the generated thought to generated API alignment component ($H_{th:\overline{api}}$) in the heuristic scoring function of FLAP is dropped. The models results in incoherent thoughts and APIs at steps if $H_{th:\overline{api}}$ is dropped; such steps are highlighted in red.

relied on feedback from humans, other LLMs, or API execution outputs to tune LLMs (Song et al., 2023; Qin et al., 2023a; Qiao et al., 2023; Lu et al., 2023b; Prasad et al., 2023; Chen et al., 2023). Another line of work focused on improving the reasoning mechanism (Qian et al., 2023) for API usage via prompting to generate thoughts (Yao et al., 2022), consider API documentation (Hsieh et al., 2023), etc. Unfortunately, pretraining-based methods are difficult and prohibitively costly when adaptation to new APIs is required and prompting-based approaches cannot reliably improve reasoning and planning which are key to faithful API usage (§4.1).

In literature, planning is defined as decomposition of the end task and identifying intermediate executable actions or reasoning steps to achieve the goal where the decomposition is open-ended and does not require obeying instructions (Jansen, 2020; Huang et al., 2022; Ahn et al., 2022; Wu et al., 2022; Lu et al., 2022b; Yu et al.; Lu et al., 2023a; Brahman et al., 2023). However, in many applications, such as customer care service or physical robots, planning needs to strictly adhere to predefined instructions (Reijers, 2003; Sengupta et al., 2019). To achieve this, we draw inspiration from decoding approaches (Holtzman et al., 2019; Meister et al., 2020) that enable enforcement of lexical and parametric constraints during generation (Hokamp and Liu, 2017; Lu et al., 2021, 2022a; Krause et al., 2021; Yang and Klein, 2021; Huang et al., 2024). We extend the idea to enforce constraints related to predefined instructions.

(a) Errors in generated flow steps.

(b) Errors in generated APIs.

Figure 3: Comparison among different LLMs in flow step (top) and API (bottom) errors during plan generation in the setting where all flows are given in context.

7 Conclusion

In this paper, we study the novel problem of faithful planning for performing tasks in TODs, that adheres to predefined flows and preserves API dependencies. To solve the task, we propose **FLAP**, a constrained decoding algorithm based on lookahead heuristic. FLAP outperforms prompting-based baselines with different decoding methods and applying FLAP on two smaller LLMs we achieve comparable performance to larger ones. Our approach can be leveraged in accurate planning for various downstream applications such as next step prediction in conversations, user simulation, flow-following conversation data augmentation for training TOD models, and so on.

Limitations

We identify the following limitations of our study.

Simplifying Assumptions: In our study, we make the simplifying assumption that the user query can be resolved using the given APIs and workflows in context. However, that may not be the case in real life and users may have out-of-domain (OOD) queries. To tackle OOD intents, we can easily adapt our model by adding one additional workflow such as "cannot help", and instruct it to be selected if no other workflow is similar to the user query. Our constructed dataset also do not contain cases where multiple plans are valid based on the given workflows and APIs, however, our algorithm can be applicable in such cases without any modification.

Static Planning: In this paper, we study static planning. However, in real life, the agents may need to modify their plans in between a conversation because conversations are by nature dynamic. Some possible reasons for plan adaptation may be, based on API execution feedback, user changes their mind in between, and so on. Adapting such static plans based on the situation in dynamic conversations can be an interesting future work. We also focus only on API selection by following predefined flows and API dependencies. The correctness of parameter filling for the APIs is left as a future work as it is applicable mostly in the dynamic planning setting.

Runtime: We observe a higher runtime for plan generation using constrained decoding (§C.3). This is partly because of the inefficient deployment of the LLMs in the existing implementations (we use Huggingface implementations) and partly because of our resource constraint (discussed in details in §C.3). We intend to work on more efficient implementation of our algorithm by potentially parallelizing computations and implementing algorithmic optimizations (e.g., lookahead after every n tokens generation).

Usage of Open Source LLMs: We did not use any closed source LLMs for our research because of various reasons. Firstly, our algorithm requires the logits from the LLMs which may be difficult to obtain using closed source LLMs. Secondly, they might be changing inside the box and it will be difficult to replicate the results, hence, harming the benchmarking procedure. Thirdly, closed source LLMs are costly as they are accessible through paid APIs only. Due to resource constraint, we experimented with LLMs of at most 40B parameter size. However, as described in the paper, our approach can be applied on top of any autoregressive LLM.

Ethics Statement

In this paper, we present all implementation and dataset details to replicate the study (partially in the Appendix). All the relevant datasets, publicly available LLMs, and other models used in this paper are publicly available for scientific research and are cited adequately. All the results are reported with standard deviations and necessary error analyses are done (some parts in the Appendix), to provide the readers an idea about the potential error patterns and risks related to using our proposed models.

Acknowledgements

We gratefully acknowledge James Gung, Yi-An Lai, Nikolaos Pappas, and the members of the AWS AI Labs for providing valuable feedback at different stages of this work. We extend our special thanks to Justin Sun for his help in setting up different LLMs and Don Bennett for providing valuable feedback on writing. We would also like to thank the anonymous reviewers for their insightful comments.

A Dataset Creation

A.1 Domain Creation

The flows and corresponding APIs for each domain are shown in Tab. 6. The API definitions in all domains, their input/output parameters, and descriptions are shown in Tab. 7.

A.2 Test Utterance Generation

The prompt for generating test queries related to the intent "book flight" in the domain "Trip Booking" is shown in Fig. 4. Similar prompts were used for the generation of queries for all other intents. Some generated user queries related to various intents are shown in Tab. 8.

B Prompt Structures for Generating Plans

The prompt structure for generating plans consisting of only APIs (no thoughts) is shown in Fig. 5. The prompt structure for planning with thoughts and APIs is shown in Fig. 6.

C Experimental Details

C.1 Hyper-parameter Tuning

In this section, we discuss the hyper-parameter selection process in FLAP, our proposed constrained decoding based algorithm in §4.2.

In our dataset, all user queries are single intent, hence, we set $\alpha_c > \alpha_a > \alpha_b$ ($\alpha_a = 0.5$, $\alpha_b = 0.1$, and $\alpha_c = 1$). We empirically determine $\beta = 0.1$ when the APIs are hallucinated or violates the dependency, i.e., a soft alignment of generated APIs to permitted APIs.

```
Our goal is to generate customer utterances in the customer care domain: Trip Planner

Here is an example of customer utterance and the intent(s) in the utterance:
Customer utterance: Please book a flight from {source} to {destination}.
Intents: [book_flight]

Now, write 20 paraphrases of this customer utterance where the intent(s) are [book_flight].
Make sure the paraphrases are very diverse and crisp.
Make sure you replace the parameter(s) [destination, source] with various US city names
such as 'Miami', 'New Orleans', 'Chicago', and so on.

Answer:
Paraphrase-1: Can you book a flight from NYC to Chicago for me?
Paraphrase-2:
```

Figure 4: Prompt for generating test utterances for the intent "book flight" in the domain "Trip Booking".

```
You are playing the role of a customer care agent who has access to the following APIs.
{
FindFlight(inputs: airport_code; Outputs: flight_id): retrieves flights to/from the airport.
FindRentalCar(inputs: ; Outputs: car_id): retrieves cars to/from the travelling city
...
...
...
}

# To book a hotel follow the below steps sequentially.
start processing the requests from the customer
suggest hotels to the customer
...
...

# To book a car follow the below steps sequentially.
start processing the requests from the customer
suggest cars to the customer
...
...

# To book a flight follow the below steps sequentially.
start processing the requests from the customer
suggest flights to the customer
...
...

### Customer request: "Can you please help me book a flight from Dallas to Austin?"
Plan step by step to fulfill the customer request using the given APIs and instructions.
Complete the plan below in one line.
Plan: InitSystem(), Start(),
```

Figure 5: Prompt format for generating a plan consisting of APIs only (without thoughts) in the domain "Trip Booking". The first two dummy APIs `InitSystem()`, `Start()` are provided in context to guide the model to follow the plan format.

To tune the values of the weight on the heuristic score (λ) and beam size (k), we run an ablation with a subset of the data (5 user utterances per intent) in Tab. 1a, in the setting where only relevant subflow is given in-context, using `Mistral-7b-instruct`. We experiment with $k = [5, 10, 15]$ and $\lambda = [0.3, 0.5, 0.7]$. The results are summarized in Tab. 10. We find that $k = 10$ and $\lambda = 0.7$ result in overall best performance, especially in terms of API dependency violation (refer to "per plan avg % of inconsistent APIs"). Hence, we report the results with these values.

We set the values of all the scaling factors (a, b, c, d) to 1 implying equal weight to all heuristic score components. We set the lookahead length, $L = 32$ in our experiments. During plan generation, if the API `Finish()` is generated, we consider that as end-of-plan (as per the flows in Tab. 6) and terminate the generation.

For the Beam Search baseline, we set number of beams to 3 and use `no_repeat_ngram_size=10` to prevent the model from generating the same thought and API pair repeatedly. For the Nucleus Sampling baseline we use `top_p=0.9`.

C.2 Infrastructure and Libraries

We use eight NVIDIA A10G Tensor Core GPUs for all of our experiments. We use Pytorch[2] for

[2] https://pytorch.org

```
You are playing the role of a customer care agent who has access to the following APIs.
{
FindRentalCar(inputs: ; Outputs: car_id): retrieves cars to/from the travelling city
FindFlight(inputs: airport_codes; Outputs: flight_id): retrieves flights to/from the airports.
...
...
...
}

# To book a hotel follow the below steps sequentially.
start processing the requests from the customer
suggest hotels to the customer
...
...

# To book a car follow the below steps sequentially.
start processing the requests from the customer
suggest cars to the customer
...
...

# To book a flight follow the below steps sequentially.
start processing the requests from the customer
suggest flights to the customer
...
...

### Customer request: "Can you book a flight from NYC to Chicago for me?"

Identify the customer intent and plan step by step to fulfill the customer request using the given APIs
and instructions. State the thought and API call at each step.

[thought] To start processing requests from the customer, I need to initialize system. [API] InitSystem()
[thought] Now, I can start processing request from the customer. [API] Start()
[thought]
```

Figure 6: Prompt format for generating a plan (with thoughts) in the domain "Trip Booking". The first two dummy steps, e.g., thoughts related to `InitSystem()` and `Start()` are provided in context to guide the model to follow the plan format.

all implementations. For all the LLMs used in this paper, we use their Huggingface[3] implementations. We build our proposed constrained decoding algorithm on top of Huggingface generation module[4]. We used the Huggingface implementation of the `all-MiniLM-L6-v2`[5] sentence transformer for measuring semantic similarities (`sim()`).

C.3 Runtime Analysis

The runtimes of different models in plan generation are shown in Tab. 9. Note that our proposed constrained decoding algorithm is run on only one GPU of 24GB memory with a batch size of 1. This is one of the reasons of the high runtime. We explored parallelization techniques by deploying the LLMs in multiple GPUs to make the process faster. However, it was observed that deploying the LLMs (Huggingface implementation) in multiple GPUs made the inference time of the base LLMs even slower. Our intended future work includes more efficient deployment of the LLMs in potentially multi-GPU machines which is out-of-scope of this paper.

[5] https://huggingface.co/sentence-transformers/all-MiniLM-L6-v2

D Additional Results

The ablation results with standard deviations over all test data points with the prompting-based plan generation using numerous open-source models in the settings where all flows are given in-context and only relevant flows are given in-context, can be found in Tab. 11 and Tab. 12, respectively.

The results with standard deviations for plan generation using our proposed constrained decoding algorithm, FLAP, in the setting where all flows are given in-context and only relevant flows are given in-context, can be found in Tab. 13 and Tab. 14, respectively.

E Qualitative Error Analysis

E.1 Model entering into repetitive loop with thoughts

Example of error when model enters into a repetitive loop when prompted to generate plans with thoughts, can be observed in Tab. 15.

E.2 API hallucinations by pre-trained LLMs with tool data

API hallucination examples by `Alpaca-7B` are shown in Tab. 16.

Flow steps	Required API sequence
Domain: Trip Booking, Intent: Book Car	
Start processing the requests from the customer	`InitSystem(), Start()`
Suggest cars to the customer	`FindRentalCar()`
Confirm and create the trip	`Confirm(), CreateTrip()`
Extract and add promotional offers	`GetCarInsuranceDiscount(), UpdateTrip()`
Order the trip	`GetPaymentInformation(), OrderTrip()`
Finish processing request	`Finish()`
Domain: Trip Booking, Intent: Book Flight	
Start processing the requests from the customer	`InitSystem(), Start()`
Suggest flights to the customer	`GetAirports(), FindFlight()`
Confirm and create the trip	`Confirm(), CreateTrip()`
Order the trip	`GetPaymentInformation(), OrderTrip()`
Finish processing request	`Finish()`
Domain: Trip Booking, Intent: Book Hotel	
Start processing the requests from the customer	`InitSystem(), Start()`
Suggest hotels to the customer	`FindHotel()`
Confirm and create the trip	`Confirm(), CreateTrip()`
Order the trip	`GetPaymentInformation(), OrderTrip()`
Finish processing request	`Finish()`
Domain: Insurance, Intent: Buy Insurance	
Start processing the requests from the customer	`InitSystem(), Start()`
Provide quote for the item to be insured	`GetItem(), GetQuote()`
Get customer details	`GetDemographicDetails()`
Order the insurance	`OrderInsurance()`
Finish processing request	`Finish()`
Domain: Insurance, Intent: Cancel Insurance	
Start processing the requests from the customer	`InitSystem(), Start()`
Validate insurance	`GetInsuranceID(), ValidateInsurance()`
Record the refund method	`GetRefundMethod()`
Confirm and cancel the Insurance	`Confirm(), CancelInsurance()`
Finish processing request	`Finish()`
Domain: Insurance, Intent: Add Member	
Start processing the requests from the customer	`InitSystem(), Start()`
Validate insurance	`GetInsuranceID(), ValidateInsurance()`
Update the insurance with new member information	`GetAdditionalMemberInformation(), UpdateInsurance()`
Finish processing request	`Finish()`
Domain: Banking, Intent: Open Account	
Start processing the requests from the customer	`InitSystem(), Start()`
Check eligibility for opening an account	`GetCustomerIncome(), GetDateOfBirth(), CheckEligibility()`
Finalize the account type	`GetAccountTypes()`
Open the account	`Confirm(), OpenAccount()`
Finish processing request	`Finish()`
Domain: Banking, Intent: Report Problem	
Start processing the requests from the customer	`InitSystem(), Start()`
Record the problem and notify the internal team	`RecordIssue(), NotifyComplaintDepartment()`
Finish processing request	`Finish()`
Domain: Banking, Intent: Cancel Transaction	
Start processing the requests from the customer	`InitSystem(), Start()`
Validate transaction details	`GetTransactionInformation(), ValidateTransaction()`
Cancel the transaction	`Confirm(), CancelTransaction()`
Finish processing request	`Finish()`
Domain: Restaurant & Ride Book, Intent: Book Restaurant	
Start processing the requests from the customer	`InitSystem(), Start()`
Suggest restaurants to the customer	`GetTime(), GetCity(), GetBudget(), FindRestaurants()`
Finalize the restaurant booking	`GetCustomerName(), GetSelectedRestaurant(), BookRestaurant()`
Finish processing request	`Finish()`
Domain: Restaurant & Ride Book, Intent: Book Ride	
Start processing the requests from the customer	`InitSystem(), Start()`
Suggest ride options to the customer	`GetTime(), GetSource(), GetDestination(), FindRideShareOptions()`
Finalize the ride service booking	`GetPaymentMethod(), GetSelectedRideShareOption(), BookRide()`
Finish processing request	`Finish()`
Domain: Restaurant & Ride Book, Intent: Cancel Restaurant Booking	
Start processing the requests from the customer	`InitSystem(), Start()`
Validate the restaurant booking	`GetRestaurantBookingID(), Authenticate()`
Cancel the restaurant booking	`CancelRestaurantBooking()`
Finish processing request	`Finish()`
Domain: Restaurant & Ride Book, Intent: Cancel Ride Booking	
Start processing the requests from the customer	`InitSystem(), Start()`
Validate the ride booking	`GetRideBookingID(), Authenticate()`
Cancel the ride booking	`GetRefundMethod(), CancelRide()`
Finish processing request	`Finish()`

Table 6: Flows and required APIs in all domains. We study faithful plan generation in a zero-shot setting. Hence, we additionally add the dummy first (`InitSystem(), Start()`) and last (`Finish()`) steps in each flow to guide the model by indicating the start and end of processing a request in the zero-shot prompt.

APIs	Input Parameters	Output Parameters	Description
Domain: Trip Booking			
Confirm()	None	confirmation_status	confirm trip details with the customer before creating a trip
FindRentalCar()	None	car_id	retrieves cars to/from the travelling city
FindHotel()	None	hotel_id	finds and retrieves hotels in a city
GetPayInfo()	None	pay_info	gets payment information from the customer
Start()	init_status	True/False	starts processing customer requests
InitSystem()	None	init_status	initializes the system to start processing customer requests
OrderTrip()	trip_id,pay_info, confirmation_status	order_status	places the bookings
UpdateTrip()	offer_id, trip_id	True/False	updates a trip with special offers
FindFlight()	airport_code	flight_id	retrieves flights to/from the airport
GetCarInsuranceDiscount()	car_id	offer_id	retrieves insurances related discounts related to the car options
CreateTrip()	flight_id/hotel_id/car_id, confirmation_status	trip_id	creates a new trip before ordering
Finish()	order_status	True/False	finishes processing customer requests
GetAirports()	None	airport_code	returns nearby airport codes based on the travelling city
Domain: Insurance			
CancelInsurance()	insurance_id, confirmation_status, refund_method	cancellation_status	cancels the insurance
GetAdditionalMemberInfo()	None	additional_member_info	asks additional member info from the customer and returns it
GetInsuranceID()	None	insurance_id	asks the insurance id from the customer and returns it
OrderInsurance()	pay_info	order_status	places order for purchasing the insurance
GetPaymentInformation()	None	pay_info	gets payment information from the customer
Finish()	order_status/ cancellation_status/ update_status	True/False	finishes processing customer requests
GetRefundMethod()	None	refund_method	asks the preferred refund method from the customer and returns it
Confirm()	insurance_id	confirmation_status	confirms insurance details with the customer
GetItem()	None	item_id	gets the item to be insured from the customer
InitSystem()	None	init_status	initializes the system to start processing customer requests
GetDemographicDetails()	None	demographics	asks demographic information of the customer and returns it
Start()	init_status	True/False	starts processing customer requests
GetQuote()	item_id	quote_id	provides quote to the customer for a given item
ValidateInsurance()	insurance_id	insurance_validated	validates if the insurance exists
UpdateInsurance()	additional_member_info, insurance_id	update_status	updates an existing insurance by adding a new member
Domain: Banking			
Start()	init_status	True/False	starts processing customer requests
GetTransactionInfo()	None	transaction_id	asks transaction info to the customer and returns the transaction id
CheckEligibility()	date_of_birth, annual_income	eligibility_status	checks if customer is eligible to open account given age, income
GetAccountTypes()	date_of_birth,annual_income, eligibility_status	account_type	get the account type based on customer eligibility, age and income
CancelTransaction()	transaction_id, confirmation_status	cancellation_status	cancels a transaction
ValidateTransaction()	transaction_id	None	validates if the transaction was actually executed
Finish()	open_status/ cancellation_status/ notification_status	True/False	finishes processing customer requests
GetCustomerIncome()	None	annual_income	ask customer annual income and returns it
RecordIssue()	None	issue_id	records the issue in internal database for review by team
OpenAccount()	confirmation_status, account_type	open_status	opens a new account
InitSystem()	None	init_status	initializes the system to start processing customer requests
Confirm()	None	confirmation_status	confirms with the customer before opening an account or cancelling a transaction
GetDateOfBirth()	None	date_of_birth	asks the date of birth to the customer and returns it
NotifyComplaintDepartment()	issue_id	notification_status	notifies the complaint department about an problem reported by the customer
Domain: Restaurant & Ride Booking			
GetBudget()	None	budget	asks customer the budget and return it
FindRideShareOptions()	source, destination, time	ride_options	retrieves ride-share options
GetPaymentMethod()	None	pay_method	asks customer the payment method and return it
GetDestination()	None	destination	asks destination to the customer and return it
GetCustomerName()	None	name	asks customer their name and return it
BookRide()	pay_method, rideshare_id	ride_booking_status	books the selected rideshare service
InitSystem()	None	init_status	initializes the system to start processing customer requests
GetSelectedRestaurant()	restaurant_list	restaurant_id	presents customer with the list of restaurants, ask their choice and return the selected restaurant id
Authenticate()	ride_id/restaurant_book_id	True/False	authenticates the customer and their booking ids
Finish()	None	ride_booking_status/ restaurant_booking_status/ restaurant_cancellation_status/ ride_cancellation_status	finishes processing customer requests
GetRestaurantBookingID()	None	restaurant_book_id	asks the customer the restaurant booking id and return it
GetCity()	None	city	asks customer the city and return it
GetTime()	None	time	asks time to the customer and return it
GetSelectedRideShareOption()	ride_options	rideshare_id	presents customer with the list of rides, asks their choice and return the selected rideshare id
GetSource()	None	source	asks source to the customer and return it
BookRestaurant()	restaurant_id, time, name	restaurant_booking_status	books the selected restaurant
CancelRide()	refund_method, ride_id	ride_cancellation_status	cancels the ride
FindRestaurants()	time, city, budget	restaurant_list	retrieves list of restaurants
CancelRestaurantBooking()	restaurant_book_id	restaurant_cancellation_status	cancels the restaurant booking
Start()	init_status	True/False	starts processing customer requests
GetRideBookingID()	None	ride_id	asks the customer the ride booking id and return it
GetRefundMethod()	None	refund_method	asks customer the refund method and return it

Table 7: API definition, their input/output parameters, and descriptions in four constructed domains. Some API names are clipped for better visibility (e.g., `GetAdditionalMemberInformation()` is clipped to `GetAdditionalMemberInfo()`).

Intents and Generated Queries in Domain Trip Booking
Book Car: Could you arrange for car rental for my Minneapolis trip from June 25th to July 3rd? **Book Hotel:** I'm looking to book a hotel room in Los Angeles from August 18th to August 25th. **Book Flight:** I need to fly from Miami to Toronto, can you please help me with that?
Intents and Generated Queries in Domain Insurance
Buy Insurance: I want to safeguard my family's health with an insurance policy. **Cancel Insurance:** My current policy doesn't cover all the expenses, would you please cancel it? **Add Member:** Would you please add my aunt to my mobile insurance policy?
Intents and Generated Queries in Domain Banking
Open Account: My wife and I are looking to open a joint bank account together. What steps do we need to take? **Report Problem:** My card is declined at the ATM. Can you help? **Cancel Transaction:** The balance of my savings account has been altered by an unauthorized transfer of $500. I would appreciate if you could get that money refunded.
Intents and Generated Queries in Domain Restaurant & Ride Book
Book Restaurant: Could you assist me in making a reservation at a restaurant in Manhattan? **Book Ride:** I am in Washington D.C. looking for a ride to Fort Lauderdale. **Cancel Restaurant:** I made a restaurant booking in Los Angeles this morning but I cannot make it due to an emergency. Can you cancel my booking? **Cancel Ride:** May I cancel my ride from Brooklyn to Queens?

Table 8: Examples of generated user queries for each intent.

LLM	Models	With Thought	Avgerage Runtime Per Plan (seconds)	
			All flows in context	Relevant flow in context

DuRE: Dual Contrastive Self Training for Semi-Supervised Relation Extraction

Yuxi Feng[1] **and Laks V.S. Lakshmanan**[1]
[1]The University of British Columbia, Vancouver, Canada
{fyx14, laks}@cs.ubc.ca

Abstract

Document-level Relation Extraction (RE) aims to extract relation triples from documents. Existing document-RE models typically rely on supervised learning which requires substantial labeled data. To alleviate the amount of human supervision, Self-training (ST) has prospered again in language understanding by augmenting the fine-tuning of big pre-trained models whenever labeled data is insufficient. However, existing ST methods in RE fail to tackle the challenge of *long-tail relations*. In this work, we propose DuRE, a novel ST framework to tackle these problems. DuRE jointly models RE classification and text generation as a dual process. In this way, our model could construct and utilize both pseudo text generated from given labels and pseudo labels predicted from available unlabeled text, which are gradually refined during the ST phase. We proposed a contrastive loss to leverage the signal of the RE classifier to improve generation quality. In addition, we propose a self-adaptive way to sample pseudo text from different relation classes. Experiments on two document-level RE tasks show that DuRE significantly boosts recall and F1 score with comparable precision, especially for long-tail relations against several strong baselines.

1 Introduction

Relation Extraction (RE) from unstructured data sources is a key component of building large-scale knowledge graphs (KG) (Noy et al., 2019; Lehmann et al., 2015). Among all the RE tasks, Document-level RE (Zhou et al., 2021) extracts subject-relation-object triples from documents, which remains daunting due to the significant challenges in modeling long text spans and obtaining high-quality supervision signals. Current document-level relation extraction methods (Zhou et al., 2021; Ru et al., 2021) can discover the semantic relation that holds between two entities under supervised learning. However, these methods typically require lots of manually labeled data for model training, which could be labor-intensive to obtain.

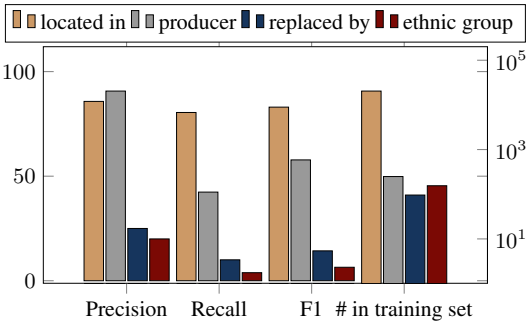

Figure 1: Testing set performance (Precision, Recall, F1, and # of examples in training set) of baseline ATLOP (Zhou et al., 2021) trained on Re-DocRED (Tan et al., 2022b) dataset.

On the other hand, since a large amount of in-domain text is usually accessible, we can tackle document-level RE using semi-supervised learning (Chapelle et al., 2006). There has been substantial work on exploring how to alleviate the amount of human supervision required for RE. Mintz et al. (2009) makes use of distant supervision which leverages external knowledge bases to obtain annotated triples. Since distant supervision makes a strong assumption that the relation between entity pairs should not depend on the context, it usually leads to context-agnostic label noises and sparse matching results.

Alternatively, self-training (ST) (Scudder, 1965; Yarowsky, 1995), a classic semi-supervised learning paradigm, has been proposed in relation extraction (Tan et al., 2023; Hu et al., 2021; Yu et al., 2022). ST minimizes the prohibitively expensive human labeling by iteratively pseudo-annotating unlabeled data with a classifier which is then retrained with the augmented labels. In this way, ST benefits from a vast number of unlabeled instances and extends the generalization bound (Wei et al.,

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 540–555
June 16-21, 2024 ©2024 Association for Computational Linguistics

2021; Zhang et al., 2022b).

A significant challenge of ST is inadequate training data for long-tail relations. As shown in Fig. 1, current document-level RE systems (Zhou et al., 2021) do not perform well on long-tail relations, which hardly appear in the training data. For example, the F1-score for class *located in* is 83.02 while *ethnic group* is only 6.45. The reason could be that the amount of training data is vastly different (20k vs. 155). Assuming that training data and unlabeled data have the same distribution, we cannot expect these long-tail relations to appear sufficiently often in the unlabeled text corpus. To address this, Tan et al. (2023) propose to re-sample training set and to assign more weight to the classes that have high precision and low recall. However, this method does not bring new information to the relation classifier. As a result, these self-training methods might not be able to improve the RE performance on these rare relations.

In order to solve the above issue of long-tail relations, we propose a novel method – Dual contrastive self training for semi-supervised Relation Extraction (DuRE). Unlike previous ST methods (Hu et al., 2021; Tan et al., 2023), we simultaneously train a controllable text generator, generating diverse outputs given specific relation triples. To improve the controllability of the generator, we leverage the signal of the trained RE classifier to label positive and negative generated sequences, and then apply a ranking calibration loss (Zhao et al., 2023) to contrast the positive and negative sequences to improve generation quality. In addition, we propose a self-adaptive way to sample pseudo text from different relation classes. We add noise by increasing generation temperature for relations with higher precision, which introduces diversity to the training set and helps reduce overfitting. Besides, we sample more examples from relations with lower recall. Since long-tail relations usually have a low recall (Fig. 1), they are more likely to be sampled, and thus their recall can be increased through training.

The contributions of this work are as follows:

- We dig into the problem of document-level extraction of long-tail relations and propose to simultaneously train a controllable text generator to address the limitation of previous self-training methods (Tan et al., 2023) that only leverage pseudo-labeling.
- We propose a contrastive loss to control the quality of generated pseudo text, improving the generation quality and thus helping to enhance the classification performance of the relation classifier.
- Comprehensive experiments show that our model significantly improves F1-score in different RE benchmarks on general and biomedical domains, especially on long-tail relations.

2 Related Work

Relation Extraction: Deep neural models have proven to be successful in sentence-level and document-level relation extraction. Zhang et al. (2017) proposed position-aware attention to improve sentence-level RE and published TACRED, which became a widely used RE dataset. Yamada et al. (2020) developed LUKE, which further improved the SOTA performance with entity pretraining and entity-aware attention. Papanikolaou and Pierleoni (2020) proposed to use GPT-2 to generate pseudo data for improving sentence-level RE performance. However, most relations in real-world data can only be extracted based on inter-sentence information. To extract relations across sentence boundaries, recent studies began to explore document-level RE. As previously mentioned, Yao et al. (2019) proposed the popular benchmark dataset DocRED for document-level RE. To address the multilabel problem of Document-level RE, Zhou et al. (2021) proposed using adaptive thresholds to extract all relations of a given entity pair. Zhang et al. (2021) developed the DocUNET model to reformulate document-level RE as a semantic segmentation task and used a U-shaped network architecture to improve the performance of DocRE. Tan et al. (2022a) proposed the use of knowledge distillation and focal loss to denoise the distantly supervised data for DocRE. Wang et al. (2022) proposed a positive-unlabeled learning algorithm under incomplete annotation scenario. However, *the methods above were not designed to tackle the challenge of long-tail relations.*

Self-training: Recently, Self-training has flourished again by iteratively generating pseudo labels and augmenting the tuning of data-hungry language models, showing great advantages in further enhancing NLU (Meng et al., 2020; Vu et al., 2021; Du et al., 2021; Bhat et al., 2021; Chen et al., 2021) and Relation Extraction (RE) (Hu et al., 2021; Yu et al., 2022; Xu et al., 2023), where massive un-

labeled input text exists. To tackle the issue of confirmation bias in self-training, Wei et al. (2021) re-samples pseudo-labels based on the frequencies of training examples. Tan et al. (2023) samples different numbers of pseudo-labeled data based on the development set performance. However, it ignores the relations where both precision and recall are low. *All the above ST methods for RE apply ST only in generating pseudo-labels.* Feng et al. (2023b) were the first to propose dual self-training to improve controllable text generation by introducing two kinds of noise. However, they do not study the effectiveness of dual self-training in classification problems (such as relation extraction), and in fact the strategy of adding noise sometimes harms the classification performance.

Unlike all the above ST methods, we are the first to apply dual self-training on document-level relation extraction, generating both **pseudo-labeled data** using RE classifier and **pseudo texts** given specific relation triples using a text generator. The design of contrastive loss and self-adaptive generation for different relation classes further improves the performance, especially on long-tail relations.

3 Method

3.1 Problem Formulation

Document-level relation extraction Given a document x and a set of entities $\mathbf{e} = \{e_j\}_{j=1}^{m}$, the task of document-level relation extraction is to predict a subset of relations from $\mathcal{R} \cup \{N_A\}$ between entity pairs $(e_h, e_t)_{h,t=1...m,h\neq t}$, where $\mathcal{R}$ is a predefined set of relations, N_A represents no relations between given entities, and e_h, e_t are identified as head and tail entities, respectively. At the test time, the model needs to predict the labels of all entity pairs in document x.

Semi-supervised document-level relation extraction Let $\mathbf{x}$ be the text, $\mathbf{e}$ be the entities mentioned in $\mathbf{x}$, and $\mathbf{y} = \{e_{h_j}, r_j, e_{t_j}\}_{j=0}^{n_x}$ be the existing relations in $\mathbf{x}$, $D_L = \{\mathbf{x}_i, \mathbf{y}_i, \mathbf{e}_i\}$ be a labeled dataset with paired text and its corresponding relation sets, and $D_U = \{\mathbf{x}_i, \mathbf{e}_i\}$ be an unlabeled dataset from the same domain. In reality, we do not obtain $\mathbf{e}_i$ for unlabeled text corpus. However, we can use tools of name entity recognition (NER) and coreference resolution (CR) to get the entity list in advance. Since we focus on relation extraction only, we assume we have already obtained the entity list for simplicity.

Controllable text generation given relation triples Given relation triples $\mathbf{y} = \{e_{h_j}, r_j, e_{t_j}\}_{j=1}^{n_x}$, where n_x is the number of relations, the task is to generate document x that contains these relation triples.

3.2 Methodology

We aim to jointly learn an attribute-controllable generator $\mathcal{G} = P_\theta(\mathbf{x}|\mathbf{y})$ parameterized by θ (*e.g.*, a large PLM) to generate, in an auto-regressive manner, high-quality text $\mathbf{x} \sim P_\theta(\mathbf{x}|\mathbf{y})$ containing the given relations $\mathbf{y}$. We also endow our model with the ability to produce pseudo extractions for $\{\mathbf{x}_i, \mathbf{e}_i\} \in D_U$ through jointly learning a Document-RE classifier $\mathcal{C} = P_\phi(\mathbf{y}|\mathbf{x}, \mathbf{e})$. We simultaneously model and optimize $\mathcal{G}$ and $\mathcal{C}$ with a shared PLM as a dual process.

We train our relation classifier using Adaptive Thresholding (AT) loss (Zhou et al., 2021). AT loss aims to learn a threshold class (TH), which are entities-dependent threshold values. The definition of AT loss is as follows:

$$\begin{aligned}
\mathcal{L}_P &= -\sum_{r\in\mathcal{P}_\mathbf{e}} \log\left(\frac{e^{\text{logit}_r}}{\sum_{r'\in\mathcal{P}_\mathbf{e}\cup\{\text{TH}\}} e^{\text{logit}_{r'}}}\right), \\
\mathcal{L}_N &= -\log\left(\frac{e^{\text{logit}_{\text{TH}}}}{\sum_{r'\in\mathcal{N}_\mathbf{e}\cup\{\text{TH}\}} e^{\text{logit}_{r'}}}\right), \\
\mathcal{L}_C &= \mathcal{L}_P + \mathcal{L}_N
\end{aligned} \tag{1}$$

where positive classes $\mathcal{P}_\mathbf{e} \subseteq \mathcal{R}$ are the relations that exist between the entities in $\mathbf{e}$, negative classes $\mathcal{N}_\mathbf{e} \subseteq \mathcal{R}$ are the relations that do not exist between the entities, logit_r and logit_{TH} are the predicted logits for class r or threshold TH by classifier $\mathcal{C}$. AT loss is a sum of losses of two parts. The first part $\mathcal{L}_P$ pushes the logits of all positive classes to be higher than the TH class. The second part $\mathcal{L}_N$ is a categorical cross-entropy loss with TH class being the true label and pushes the logits of negative classes to be lower than the TH class.

For the generation side, we use cross-entropy loss for auto-regressive generation.

$$\mathcal{L}_G = -\frac{1}{N}\sum_{(\mathbf{x},y)\in D}[\sum_{j=1}^{L}\log P_\theta(\mathbf{x}^j|\mathbf{x}^{<j}, y)], \tag{2}$$

where $\mathbf{x}^j$ means the j-th token in $\mathbf{x}$, L is the length of $\mathbf{x}$, D is the training set with N samples. We will show later how to construct D for different training phases. Finally, we compute a weighted sum of

  Build pseudo text: $D_{PT} = \{\mathbf{x}^+, \mathbf{y}^+, \mathbf{e}^+, \mathbf{x}^-\}$
  Train $\mathcal{G}_{epoch-1}, \mathcal{C}_{epoch-1}$ on $\{D_{PT}, D_{PL}, D_L\}$ by optimizing Eq.(3) and Eq.(4), update the parameters to $\mathcal{G}_{epoch}$ and $\mathcal{C}_{epoch}$.
end

classification and generation loss, where λ_C and λ_G are tunable hyperparameters.

$$\mathcal{L} = \lambda_C \mathcal{L}_C + \lambda_G \mathcal{L}_G. \tag{3}$$

3.3 Self-adaptive pseudo text generation

The full DuRE method is described in Alg. 1. Following the practice of self-training in NLU (Vu et al., 2021), we start ST from a strong base model tuned on D_L and use the full unlabeled D_U to produce pseudo labels, rather than select part of the data with certain criteria as in (Tan et al., 2023). In addition to pseudo-labeled data, we also use our generator to generate pseudo-text given entity-relation triples. To better improve the RE performance, we propose to use Contrastive Loss (CL) and Self-Adaptive Generation (SAG) methods, which are illustrated below.

Contrastive Loss (CL) Following Zhao et al. (2023), we use Sequence Likelihood Calibration (SLiC) to align a language model's sequence likelihood, $P_\theta(x|y)$, over decoded sequences according to their similarity to reference sequences. Given $\mathbf{y}_j = \{e_{h_j}, r_j, e_{t_j}\}$, we generate a batch of m generations $x_j^k = \mathcal{G}(\mathbf{y}_j)$. Then the ranking calibration loss contrasts a positive sequence x^+ and a negative sequence x^-, encouraging the model to assign more probability mass to positive compared to negative sequences, and thus enhancing generation quality. Thanks to the dual learning framework, we can use the classifier $\mathcal{C}$ to evaluate the confidence of whether generation x contains relation triple $\{e\}$. More specifically, $x^+ = \text{argmax}_i logit^i_{r_j}$, and $x^- = \text{argmin}_i logit^i_{r_j}$. Thus the contrastive loss is computed as follows:

$$\mathcal{L}_G = \max\left(0, \beta - \log P_\theta(x^+|y) + \log P_\theta(x^-|y)\right) \tag{4}$$

where $\beta > 0$ is a hyperparameter to control the margin between positive and negative examples.

Self-Adaptive Generation (SAG) Another advantage of using pseudo text is that we can tune the distribution of relations and generate more pseudo texts for long-tail relations. Compared to traditional methods like bootstrapping (Dupret and Koda, 2001) and class-rebalanced self-training (Wei et al., 2021) where duplicated samples are chosen for a specific class, the generator can produce more diverse training examples.

Here we propose a self-adaptive pseudo-text generation strategy. For different relation classes with different development set performances, we generate pseudo text accordingly. For a relation class r, if its recall R_r is low, then we should improve the recall by generating more pseudo examples. If its precision P_r is high, we believe this class is well-predicted. Then the purpose of pseudo-text generation is to augment the training set with noisy data to enhance generalization. A good way to add noise is to generate data with higher temperature (Feng et al., 2023b). Otherwise, if P_r is low, we use a lower temperature to sample a more certain output to ensure the generation quality. In summary, we define the sampling probability ϕ_r and generation temperature temp_r for relation r as fol-

Dataset	Train	Dev	Test	Unlabeled

Table 1: Dataset statistics.

lows.

$$\phi_r \sim (1 - R_r),$$
$$\text{temp}_r = \alpha + P_r. \quad (5)$$

where $\alpha > 0$ is a hyperparameter to control the noise level of generation.

Our SAG method has the following major differences from Tan et al. (2023). (1) Data resampled: Tan et al. (2023) resample the training set while we sample generated pseudo text to generate diverse outputs given specific relation triples. (2) Sampling Strategy: Tan et al. (2023) resample the training set with probability $P_r(1 - R_r)$, which causes relations with low precision to be ignored. On the other hand, we resample with probability $(1 - R_r)$, and encourage the classes with higher precision to generate more diverse outputs (sampling with high temperature). For the relations with low precision, we sample with low temperature to ensure its faithfulness.

4 Experiments

4.1 Datasets

We experimented with our method on two datasets. For general-domain document level RE, we use Re-DocRED (Tan et al., 2022b), a high quality dataset. We use the distantly-labeled set of Re-DocRED as unlabeled set, only keeping named entities information and coreference information but ignoring the distant labels. As a second dataset, we tested our method on the biomedical document-level RE dataset ChemDisGene (CDG) (Zhang et al., 2022a). Since there is no unlabeled set in CDG, we only leveraged part (e.g., 5%) of training set as labeled data and kept aside the rest as unlabeled data. Our models are evaluated on the test sets of Re-DocRED and CDG. Both of the test sets are human-annotated and have high quality. The statistics of the datasets can be found in Table 1.

4.2 Experimental Settings

We use ATLOP (Zhou et al., 2021) as our base RE classifier and an encoder-decoder framework as our pseudo text generator. Following Feng et al. (2023b), we share the encoder part of RE classifier and pseudo text generator to save the total number of training parameters. For Re-DocRED dataset, we use Flan-T5-base (Chung et al., 2022) as the base encoder-decoder model. For CDG dataset, we use a version of Flan-T5-base that is pretrained on Pubmed dataset[1]. We use AdamW (Loshchilov and Hutter, 2019) with learning rate = 5e-5, warm-up rate = 0.06, $\lambda_g = 1$, $\lambda_c = 5$, $\alpha = 0.7$, $\beta = 0.3$, and batch size = 8 for optimization across all tasks. As is common practice (Holtzman et al., 2019), we use the top-p sampling method with $p = 0.9$ for decoding. For the generation task, we add a prompt sentence at the beginning of the input: *Generate text given the following relation triples*. The number of pseudo text is the same as the number of labeled data, i.e., 3053 for Re-DocRED and 3847 for CDG. More implementation details are provided in the Appendix.

4.3 Evaluation Metrices

Following Tan et al. (2023), we used micro-averaged F1 score as the evaluation metric. We also evaluate the F1 score for frequent classes and long-tail classes, denoted as Freq_F1 and LT_F1, respectively. For the Re-DocRED dataset, the frequent classes include the top 10 most popular relation types in the label space; the rest of the classes are categorized as long-tail classes. We also use an additional metric Ign_F1 on the DocRE task. This metric represents the F1 score, calculated for the triples that do not appear in the training data.

4.4 Baselines

We compare our model with the following strong document-level RE baselines, including both supervised and semi-supervised.

Supervised Approaches (1) **ATLOP** (Zhou et al., 2021) A vanilla baseline model for document-level RE. (2) **ATLOP-Flan** Only use Flan-T5

[1]The model can be found at https://huggingface.co/gubartz/ssc-flan-t5-base-pubmed.

Table 3: Results on CDG dataset. †Results are obtained from Tan et al. (2023).

(Chung et al., 2022) Encoder to train the RE classifier without generator. (3) **ATLOP-Dual** Simultaneously train RE classifier given input documents and text generator given relation triples but without self-training. (4) **Negative Sampling (NS)** (Li et al., 2021): randomly select partial negative samples in training to alleviate the detrimental effect of the false negative problem.

Semi-supervised Approaches All the baselines below leverage ATLOP as their backbone. (1) **Vanilla Self-Training (VST)** (Peng et al., 2019; Jie et al., 2019): a variant of simple self-training where models are trained with N folds, and all pseudo-labels are directly combined with the original labels. (2) **SSR Positive Unlabeled Learning (SSR-PU)** (Wang et al., 2022): SSR-PU utilizes positive unlabeled learning and a shift-and-squared ranking (SSR) loss to accommodate the distribution shifts for the unlabeled examples. (3) **Class Re-balancing Self-Training (CREST)**(Wei et al., 2021): This algorithm re-samples the pseudo-labels generated by models based on the frequencies of the training samples. (4) **Class-Adaptive Self-Training (CAST)** (Tan et al., 2023): this method calculates the precision and recall scores of each class on the development set and uses the calculated scores to compute the sampling probability of each class to alleviate confirmation bias caused by erroneous pseudo labels.

4.5 Results

The experimental results on the test set of Re-DocRED (Table 2) demonstrate that our DuRE achieves consistent performance improvements in terms of F1 scores over all baselines. The F1 difference between the best baseline CAST and our DuRE is 2.17 (76.84 vs. 74.67). We also found that simply adding an additional RE-controlled generation task does not improve the relation classification performance (ATLOP-Flan vs. ATLOP-Dual), where F1 scores decreased slightly (72.05 vs. 71.72). In addition, training on an encoder-decoder framework (Flan-T5-base) does not outperform a single encoder framework (Bert-base) in document-level RE tasks. However, we notice that the gap between CAST and ATLOP(bert) is 2.06, while the gap between ATLOP-DuRE and ATLOP-Dual is 5.12. This indicates that our proposed dual self-training method improves the RE classification quality significantly more compared to the backbone model. We also notice a considerable improvement (+3.54 F1) especially in long-tail relations, showing that self-training on a rebalanced pseudo text is better than simply doing bootstrap-

ping in the existing training set. The reason is that our trained generator can generate more diverse examples, which helps reduce overfitting on training data.

Table 3 presents the experiments on biomedical RE (CDG dataset). Our DuRE model achieves a performance comparable to the baselines with only 5% of the training data. When trained with 50% of the training data, we get the best performance, outperforming the CAST baseline with +3.05 F1. Based on the results of RE experiments in general and biomedical domains, self-training-based methods aim to improve recall and consistently improve overall performance. However, our DuRE maintains a better balance between increasing recall and maintaining high precision.

Model	P	R	F1	Freq_F1	LT_F1
DuRE	80.01	**73.84**	**76.84**	**79.81**	**72.88**
−SAG	79.51	73.24	76.24	79.71	70.68
−SAG−CL	80.44	71.43	75.67	79.24	69.90
−PT	80.04	70.35	74.88	79.14	67.88
−PL	82.71	66.53	73.75	77.81	67.20
−PL−PT	**85.17**	61.93	71.72	76.07	64.70

Table 4: Ablation study on Re-DocRED dataset. Here − means removing components from DuRE. −SAG: remove the self-adaptive generation strategy and sample pseudo texts for different classes in the same setting. −CL: do not generate positive/negative examples and sample random examples. −PT/−PL: do not use pseudo text/labels.

4.6 Ablation Study

We conduct an ablation study on the Re-DocRED dataset. As shown in Table 4, we can see that (i) Self-Adaptive Generation benefits the F1 score for both frequent and long-tail relations; (ii) Contrastive loss further enhances all F1 scores in relation extraction; and (iii) Self-training on pseudo-labeled text leads to an improvement in recall but has relatively low precision, which shows that self-training is able to balance precision and recall. This observation is also consistent with Tan et al. (2023). Full version of Table 4 is included in the Appendix.

4.7 Analysis

Effect of Self-Training We compare our model with a variant (−**Dual**) where we use the base generation model $\mathcal{G}_0$ to generate pseudo text and do not update it through self-training. As depicted in Fig. 2, classification F1 reaches its maximum quickly and then stops increasing. On the other hand, thanks to the simultaneously optimized generator, DuRE keeps improving generation quality and refining pseudo labels, and thus iteratively improves the quality of the relation classifier.

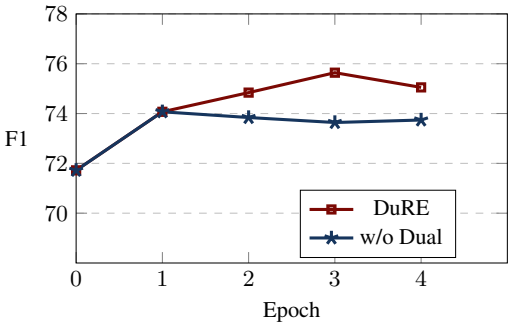

Figure 2: F1 score over the number of training epochs on Re-DocRED.

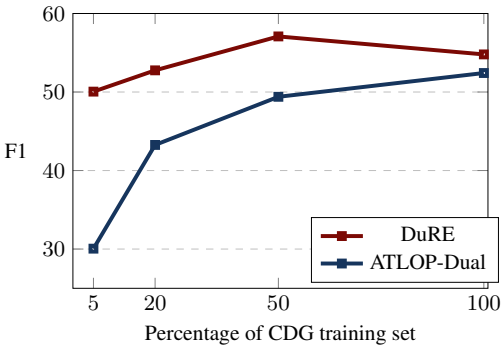

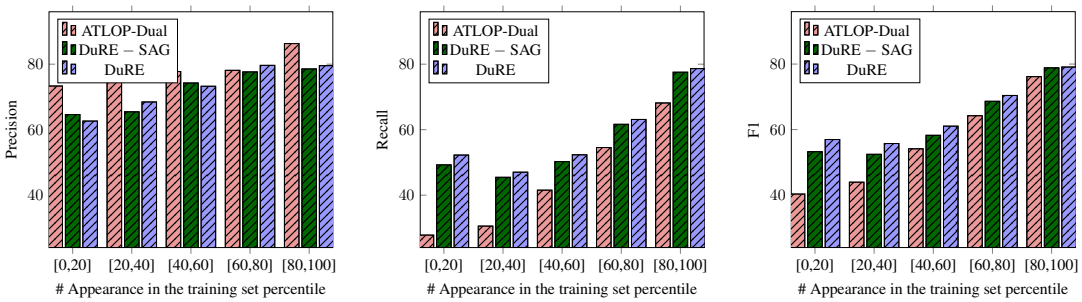

Figure 3: Test F1 score with different numbers of labeled data on CDG dataset. All methods use FLAN-T5 as the base model.

Number of labeled data We also assess our model with varying numbers of labeled training instances, with the remaining instances treated as unlabeled data. We observe consistent superiority of DuRE to ATLOP-Dual model. Indeed, even DuRE (50%) outperforms ATLOP-Dual (100%), showing that our method can work with scenarios with fewer training data. However, we notice a drop in DuRE (100%). We conjecture that the reason is that the training set of CDG itself is distantly labeled, which is noisy and incomplete. Through self-training on pseudo-labeled data, the model can figure out incompletely labeled relations. However, as for training on the full distantly-labeled dataset, DuRE only benefits from generated pseudo texts compared to ATLOP-Dual, which limits the improvement of the classification model on pseudo-labeled data. Notice that the generated pesudo texts might still have higher quality than simply distantly labeled data.

(a) Precision (b) Recall (c) F1

Figure 4: Precision, recall, and F1 score on the development set over different percentile of appearances in the Re-DocRED training set.

Input	* The Invisible Man*, lyrics by, * Roger Taylor*.
Positive	" * The Invisible Man* " is a rock song originally **written by** * Roger Taylor* and * Mark Smith* in * 1942*. The song was sung at the * Royal Academy of Music* (Royal Academy of Music) in * 1952*. The lyrics and compositions of " The Invisible Man " were originally a single with * Taylor*'s voice in a voodoo voice, a version of * Ralph Ellis*'s " * The Man Who Walks Away* ". The medley is a ballad, and is not a traditional ballad. " * The Invisible Man* " is often performed in * England* and * France*, but it was originally recorded as a concert song for the * Royal Academy of Music*, in * 1936*, and in * Japan* (including the final song).
Negative	* The Invisible Man* is the sixth **album by** * Roger Taylor*. It was released in October 1966. The album features a different version of " * The Man In the Sun* " and a different theme. *** The Man In the Sun*** is set in a mystical (and heavily symbolic) future. **It** was **composed by** * Roger Taylor*. The album is very similar to the * The Black Swan* album. It is not necessarily a remake of the album, but rather a remastered version of the earlier album. The album contained a new riff and a new orchestration which was intended to provide additional background music for the final section of the album.

Table 5: Example of generation on Re-DocRED dataset.

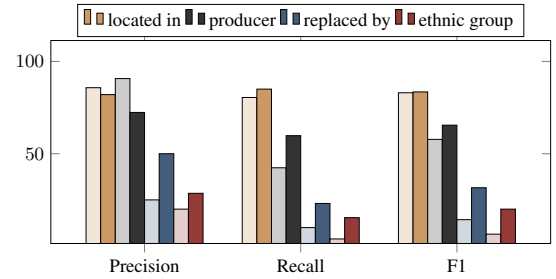

Figure 5: Comparison of testing set performance of baseline ATLOP (light) and DuRE (dark) trained on Re-DocRED dataset.

Performance of relations with different frequency We sorted the relations by their frequency of appearance in the training set from low to high and grouped them into five groups by their percentile. Fig. 4 plots the development set performance of relations with different frequencies. We can see that original ATLOP tends to have much higher precision than recall, while our DuRE consistently improves recall and F1 scores over relations across all frequency groups, at the price of a modest drop in precision. We also notice a tendency that our method improves F1 score more for less frequent relations thanks to the self-adaptive generation, indicating the effectiveness of our methods on long-tail relations.

Improvement on rare relations We plot the precision and recall scores of DuRE and CAST for different relation classes in Fig. 5, where the experimental results are obtained by training with the Re-DocRED dataset. We found that DuRE significantly improves the recall scores of long-tail classes (*producer*, *replaced by*, and *ethnic group*) and thus improves F1 scores, while maintaining the F1 scores of frequent classes (*located in*). We also notice that the improvements in recall scores are accompanied by a decline in precision scores for frequent classes due to our strategy of learning from noisy pseudo texts for frequent classes. Learning from these augmented noisy texts would decrease the threshold and thus improve recall but decrease precision.

Further analysis of contrastive loss Table 5 illustrates a case study of how contrastive loss improves generation quality and thus improves re-

lation classification. Both positive and negative examples are generated under the same decoding strategy. We can see that the negative example does not entail the relation (*The Invisible Man, lyrics by, Roger Taylor*), given that there are similar relations (*The Invisible Man, album by, Roger Taylor*) and (*The Man In the Sun, composed by, Roger Taylor*). This example shows that our learned text generator could sometimes generate text that does not entail the given prompt. Thanks to the contrastive loss, the learned text generator could learn from the signal from the RE classifier, maximize the margin of positive and negative samples, and be more faithful to the given prompt. Detailed analysis of generation quality can be found in Appendix.

5 Conclusion and Future Work

We propose a novel DuRE method to apply Self-training to semi-supervised document-level relation extraction. DuRE (1) jointly optimizes generation and classification via a dual learning framework to leverage both pseudo text and pseudo labels, (2) incorporates contrastive loss to improve the quality of pseudo texts, and (3) applies self-adaptive generation to reduce overfitting of well-predicted relation classes and to improve the performance of long-tail relations. Given that the pseudo data is generated in an auto-regressive manner, which takes longer training time, we plan to explore ways to accelerate the self-training process in the future.

6 Limitations

Though DuRE works well, it has the following limitations:

- Decelerated training process. Like all other Self-training methods, DuRE also needs to reproduce pseudo labels and pseudo text at each ST iteration. Since the pseudo text is generated in an auto-regressive manner, which is hard to be done in parallel, it takes longer training time. Feng et al. (2023a) proposed to use a non-autoregressive generator in self-training, which could be possibly used to accelerate the training speed of DuRE.

- Bias introduced. Bias can be introduced by various forms of supervision, including human annotators or machine synthetic data. We acknowledge that potential bias exists in the pseudo text generated by our DuRE method since DuRE shifts the distribution of training data based on the performance (precision and recall) on the development set. Analyzing the impact of bias found in semi-supervised learning algorithms (like self-training) is an interesting study for future work.

- Reliance on unlabeled in-domain text. As we discussed in Sec. 4, though our proposed contrastive loss and self-adaptive generation bring non-trivial improvement, the overall performance of all ST methods still relies on pseudo labels from unlabeled text. When unlabeled text is extremely inadequate or even unavailable (e.g., low-resource scenarios), how to better utilize pseudo text for further improvement is an open challenge.

- Task generalization and scalability. We mainly investigate document-level RE in this work, in which ST actually acts as a kind of regularization and smoothing. How to apply this paradigm to super large language models (*e.g.*, LLaMa-2 (Touvron et al., 2023) and GPT4 (OpenAI, 2023)) and for tasks beyond RE is also an open question.

7 Ethics Statement

The generative part of our model may be utilized to generate fake information when the input triples are not factual, which could possibly be utilized to produce and propagate disinformation. Also, the generated pseudo-text may contain some socially biased, offensive, or politically sensitive expressions. However, these generated texts are designed to be used as pseudo data in data augmentation to improve the robustness of the relation extraction model and to improve the performance of long-tail relations.

A Detailed Setting

A.1 Implementation Details

We use pre-trained Flan-T5-base (Chung et al., 2022) as the encoder and decoder of our DuRE model, more suitable for our joint classification and generation schema.

We tuned all hyperparameters only on the held-out development set. In self-training phase, we tuned $\lambda_c \in \{1, 5, 10\}$, $\alpha \in \{0.5, 0.7, 1.0\}$, and $\beta \in \{0.1, 0.3, 0.5\}$ in Re-DocRED dataset to obtain the reported results. Finally, we set $\lambda_c = 5$ and $\lambda_g = 1$ in base-model training phase, while $\lambda_c = 5$, $\lambda_g = 1$, $\alpha = 0.7$, and $\beta = 0.3$ in the self-training phase. We tuned the hyperparameters in Re-DocRED dataset and applied them to all tasks. We use AdamW (Loshchilov and Hutter, 2019) as an optimizer. The training batch size is 8, and the learning rate is $5e-5$. We apply linear warmup to the optimizer, and the warmup ratio is 0.06.

We implement DuRE on Huggingface Transformers (Wolf et al., 2020) library of v4.31.1 and use four NVIDIA Tesla V100 nodes to train our model. The total number of training hours is around 39.62h for Re-DocRED and 34.54h for CDG(5%). The number of parameters of our model is 242.91M. In the generation phase, we use top-p sampling ($p = 0.9$) as the decoding method. Other configuration of the generator includes a length penalty to be 1.0 and a repetition penalty to be 1.0 for all baselines. All experimental results are trained and tested in a single run with fixed random seeds.

For the number of pseudo text generated, following (Feng et al., 2023b), we choose the same number as the labeled training set. The prompt for generation is *Generate text given the following relation triples*. An example of generation input could be *Generate text given the following relation triples. * The Invisible Man*, lyrics by, * Roger Taylor**. For each input triple, we sample 8 sentences and apply the RE classifier to select positive and negative pseudo texts among these samples.

A.2 Generation Evaluation Metric Details

We set the minimum generation length to 100. We evaluate NLG quality on the following metrics:

Fluency: We evaluate generation fluency by the perplexity of generated text measured by GPT2-XL (Radford et al., 2019), *i.e.*, **Output PPL**.

Controllability: We evaluate the control accuracy through classification performance (accuracy (**Acc**)) on the generated text by our DuRE RE classifier.

Diversity: To evaluate the diversity of generated text, we consider **Dist-n** (Li et al., 2016): the percentage of distinct n-grams on generated samples. We evaluate on $n = 1, 2, 3, 4$ and compute the geometric mean as **Dist**. **Dist** emphasizes the amount of novel n-grams within every generation.

Among all the above metrics, F1 and Dist-n are reported as 100 times their original value for convenience.

A.3 Baseline Details

We compare our model with the following strong document-level RE baselines, including both supervised and semi-supervised.

ATLOP (Zhou et al., 2021) A vanilla baseline model for document-level RE. We use bert-base-cased(Devlin et al., 2019) encoder in Re-DocRED dataset and Pubmed-Bert-base(Gu et al., 2021) encoder in CDG dataset.

ATLOP-Flan Only use Flan-T5(Chung et al., 2022) Encoder to train the RE classifier without generator.

ATLOP-Dual Simultaneously train RE classifier given input documents and text generator given relation triples but without self-training.

Negative Sampling (NS) (Li et al., 2021) This method tackles the incomplete annotation problem through negative sampling. To alleviate the effects of false negatives, this method randomly selects partial negative samples for training. Such an approach can help to alleviate the detrimental effect of the false negative problem.

Vanilla Self-Training (VST) (Peng et al., 2019; Jie et al., 2019) VST is a variant of simple self-training. In this approach, models are trained with N folds, and all pseudo-labels are directly combined with the original labels. Then, a new model is trained on the dataset with combined labels.

SSR Positive Unlabeled Learning (SSR-PU) (Wang et al., 2022) This method applies a positive unlabeled learning algorithm for document-level RE under the incomplete annotation scenario. SSR-PU utilizes a shift-and-squared ranking (SSR) loss to accommodate the distribution shifts for the unlabeled examples.

Class Re-balancing Self-Training (CREST) (Wei et al., 2021) This algorithm re-samples the pseudo-labels generated by models based on the frequencies of the training samples.

Class-Adaptive Self-Training(CAST) (Tan et al., 2023) This method calculates the precision and recall scores of each class on the development set and uses the calculated scores to compute the sampling probability of each class to alleviate confirmation bias caused by erroneous pseudo labels.

B Additional experimental results

Method	Samples	PPL ↓	Acc ↑	DIST ↑
	Testing set	17.80	-	53.42
ATLOP-Dual	random	17.31	71.94	49.84
	positive	17.04	80.96	45.09
	negative	18.98	60.81	50.82
DuRE	random	17.03	79.54	50.24
	positive	16.93	82.28	49.92
	negative	18.32	67.43	52.88

Table B1: Performance of learned generator on Re-DocRED dataset.

B.1 Performance of Generation Model

To evaluate the quality of generated pseudo text, we measure generation fluency (perplexity, PPL), faithfulness (accuracy of generated text followed by given prompts, Acc), and diversity (number of distinct n-grams, DIST). Details of generation metrics are described in the appendix. We measured different types of samples: random, positive, and negative. The result is shown in Table B1. We found that our generator improves all metrics through dual self-training. Also, the generation fluency is comparable to the testing set. Besides, the diversity of DuRE also improves thanks to the use of more unlabeled text. However, the diversity of generation is still worse than the testing set due to the restricted model size.

B.2 Full Ablation Study Results

Full table of ablation study at Tab. B2.

C More Examples of Generation

We sample some generated texts given long-tail relations in Re-DocRED dataset. Table C1 reports the positive and negative examples generated by our DuRE model. We can find out that even if the relations are long-tail and might not be recognized by our RE classifier, positive examples still contain the relation triples, while some negative examples no longer contain the given relation triples. Learning the contrastive loss helps the generator learn more faithful examples, and thus improves the quality of pseudo training data for RE classifier. This can explain why generated pseudo text for long-tail relations can still be helpful in improving the F1 scores.

Model	P	R	F1	Ign_F1	Freq_F1	LT_F1
DuRE	80.01	73.84	76.84	75.32	79.81	72.88
DuRE −SAG	79.51	73.24	76.24	75.02	79.71	70.68
DuRE −CL	80.44	71.43	75.67	74.04	79.24	69.90
DuRE −PT	80.04	70.35	74.88	73.72	79.14	67.88
DuRE −PL	82.71	66.53	73.75	72.79	77.81	67.20
DuRE −PL−PT	85.17	61.93	71.72	70.95	76.07	64.70

Table B2: Full ablation study results on Re-DocRED dataset. Here − means removing components from DuRE. −SAG: remove the self-adaptive generation strategy and sample pseudo texts for different classes in the same setting. −CL: do not generate positive/negative examples and sample random examples. −PT/−PL: do not use pseudo text/labels.

Input	* Christianity*, seperated from, * Judaism*.
Positive	The * Holy Spirit* (* Synchrony of the Holy Spirit*) is the most effective means of establishing and strengthening the religious adherence to * Judaism*. As * Christianity* continues to be a branch of * Judaism*, it is crucial that the doctrines of the * Holy Spirit* and of * Judaism* remain with us. It is the aim of the * Holy Spirit* to establish and strengthen the character of the religious adherence of * Judaism* through systematic means of reforming the system of religious practices, the decentralization of religious ceremonies, and the re-establishment of unity among the * Judaic* and * Christian* communities. The most successful form of this is the systematic observance of the * Bible*, in which the primary source of the faith is the knowledge of * Allah* (" Father, Lord, High, Father, High)... In modern terms, the * Holy Spirit* focuses primarily on the advancement of religious adherence, which has been known as the most effective form of a religious system in * Judaism*. The * Holy Spirit* emphasizes the observance of the * Bible*, which has its roots in the * Bible*. The * Holy Spirit* is focused on the expansion of * Judaism*, which has a tendency to create a sense of unity among all * Judaism*. Its success in teaching and interpreting * Judaism* is demonstrated by its use of simple language and the presentation of the * Bible* as a unified unit.
Negative	* Christianity* and * Judaism* are two forms of the * Western Church* which originated around * 1500*. * Christianity* and * Judaism* had a strong influence on the * Eastern Church* and in * Europe* during the second half of the 19th century, with significant influence over * Germany* and * Poland*, which had a relatively neo - western influence. * Christianity* was characterized by a strong influence on the * Eastern Church* and in * European* countries. It is not clear when these influences actually began to manifest in the * Western Church*. However, * Judaism*'influence spread to other areas of the world such as * Africa*, * Asia*, and * the Americas*, and was influenced by this influence.
Input	* Chipilo*, sister city, * Segusino*
Positive	The * Segusino* (or * Segusino* in * Japanese*) was a city in the western part of * Asia*. It was a part of the * Western Asian region* that was unified by the * East Asian region* and * North American region*. It was originally the location of the * Pacific* coast resort town of * Chipilo*, and then the * Mid - East* area. It was a " hamlet ", also called a " sarket ", a kind of rubber cement used in transport. In * Japan*, the town of * Chipilo*, located north of * Tokyo*, was a hamlet that was the home of * Segusino*'s samurai army and the * Japanese* colonel's troops.
Negative	* Segusino* is the second largest city in the island of * Chipilo*. The city has a population of around * 1.27 million* as of the year * 2010*. Its urban population has declined in recent years due to urban development. It is home to the * Segusino Opera House*, a branch of the * Segusino Music Theatre*. The capital of the city is * Segusino*, and the city is surrounded by a number of historic sites, such as the * Segusino Cathedral* and the * Rialto Hall*. A major site dedicated to historic architecture is * Seiji*'s city hall. The first major buildings were built on * Segusino*'s main mountain, * Yatsuda*. The second large building was built on * Seiji*'s main mountain, * Yatsuda*. It was built by * Yatsuda* in * 1955*, but was demolished in * 1964*.
Input	* Russian*, seperated from, * Soviet Union*
Positive	The * Russian* military in the late 18th and early 19th centuries was characterized by systematic, largely self - destructive attacks on civilians, in which large numbers of soldiers and civilians were transported to other parts of the world, the " concentration camp ", or at least the most isolated concentration camp in the world. These, however, were mostly civilians who were not included in the camp's security measures. Most of them were forced to abandon their lives because of armed and destructive attacks, or because they did not comply with the orders of a military commander. The * Russian* military system consisted of a government known as the " * General Army of the Russian People* " (<unk>, * Military Provisional Army of the Soviet People*), which was created for the defense of civilians and was separated by the * Soviet Union* at the beginning of the nineteenth century. * Soviet* military operations began in the late * 19th century*, after the dissolution of the * Soviet Union*. The * General Army of the Soviet People* was, under the command of * Alexander Nevsky*, one of the most successful units in the * Soviet* army, in the early * 20th century*.
Negative	The * Russian* and * German* * Civil War* of * World War I*, fought between * 1940* and * 1941*, was a period of political uncertainty in the post - Communal era. Initially, the crisis erupted in * World War II* (and possibly the reunification of the * German* and * Polish* - * Soviet Union*) when the * German* and * Russian* military governments were faced with the imposition of a series of massive counter - Communal invasions and repressions. The conflict also marked the end of the * German* war, when * France* and * Germany* were both forced to declare war. In the aftermath of the war, * German* and * Russian* nationalists became the major force involved, often with the help of * German* troops. This increased tension, as the war progressed, the use of armies, and a series of armed rebellions.

Abstract

Deep neural networks for Natural Language Processing (NLP) have been demonstrated to be vulnerable to textual adversarial examples. Existing black-box attacks typically require thousands of queries on the target model, making them expensive in real-world applications. In this paper, we propose a new approach that guides the word substitutions using prior knowledge from the training set to improve the attack efficiency. Specifically, we introduce **A**dversarial **B**oosting **P**reference (**ABP**), a metric that quantifies the importance of words and guides adversarial word substitutions. We then propose two query-efficient attack strategies based on ABP: query-free attack (ABP_{free}) and guided search attack (ABP_{guide}). Extensive evaluations for text classification demonstrate that ABP_{free} generates more natural adversarial examples than existing universal attacks, ABP_{guide} significantly reduces the number of queries by a factor of $10 \sim 500$ while achieving comparable or even better performance than black-box attack baselines. Furthermore, we introduce the first ensemble attack ABP_{ens} in NLP, which gains further performance improvements and achieves better transferability and generalization by the ensemble of the ABP across different models and domains. Code is available at https://github.com/BaiDingHub/ABP.

1 Introduction

Despite the outstanding performance, Deep Neural Networks (DNNs) are known to be vulnerable to adversarial examples (Szegedy et al., 2014), *i.e.*, imperceptible perturbations on benign samples could lead to entirely incorrect predictions. Adversarial examples have brought critical security threats to the widely adopted deep learning based systems, and have attracted enormous attention on adversarial attacks in various domains, *e.g.* Computer Vision (CV) (Goodfellow et al., 2015; Madry et al., 2018), Natural Language Processing (NLP) (Papernot et al., 2016; Liang et al., 2018), *etc*.

Textual adversarial attacks pose greater challenges due to the discrete input space and constraints of lexicality, semantics and fluency, which can be categorized into white-box, black-box and universal attacks. White-box attacks (Liang et al., 2018; Meng and Wattenhofer, 2020) require full access to the victim model, including its architecture, parameters, loss function, gradient, output, *etc*., which are typically unavailable in real-world applications. Black-box attacks (Ren et al., 2019; Zang et al., 2020) only need access to the model output, *e.g*., output logits or predictions. However, they require thousands of queries to determine the importance of each word based on the model output, making them expensive in real-world applications. Universal attacks (Moosavi-Dezfooli et al., 2017; Li et al., 2021b) are a particular type of adversarial attacks which adds the same adversarial text generated by the training set at the beginning or end of all input samples to mislead the model. They require no access to the model and usually have a stronger attack efficiency and better usability in the real-world, but lower attack performance and unnatural adversarial examples.

In this work, we aim to utilize the prior knowledge learned from the training set to guide word substitutions in black-box attacks to reduce the need to access the model, making it more practical for real-world applications. To this end, we propose **A**dversarial **B**oosting **P**reference (**ABP**), a metric that quantifies the importance of different words and guides the word substitutions. By analyzing statistics of synonym substitutions during adversarial example generation in the training set, we estimate the preference for replacing a word with its synonym in generating adversarial examples, as well as the boosting contribution to the adversariality of these samples, and then multiply them to

obtain the score of adversarial boosting preference.

Based on pre-computed ABP from the training set, we propose three query-efficient attacks, including query-free attack ABP_{free}, guided search attack $\text{ABP}_{\text{guide}}$ and ensemble attack ABP_{ens}. For a benign text, ABP_{free} determines the importance of each word, assigns a candidate for each of them, and constructs the replacement order for the text. Then ABP_{free} substitutes the top 25% words with their respective candidates in the replacement order to generate adversarial examples with no access to the model. $\text{ABP}_{\text{guide}}$ adopts ABP to guide the search of adversarial examples, and then prunes redundant perturbations to find the optimal adversary. $\text{ABP}_{\text{guide}}$ significantly improves the attack performance through dozens of queries. Finally, ABP_{ens} integrates ABP generated by different models or domains to further boost the attack performance.

To validate the effectiveness, we conduct extensive experiments to compare ABP with various black-box attacks (Ren et al., 2019; Zang et al., 2020) and universal attacks (Wallace et al., 2019; Song et al., 2021). Empirical evaluations show that ABP_{free} generates more natural adversarial examples through synonym substitutions than existing universal attacks. $\text{ABP}_{\text{guide}}$ greatly reduces access to the model than existing black-box attacks, while achieving comparable attack performance. And the ensemble of ABP across models and domains gains further performance improvement and achieves superior cross-model transferability and cross-domain generalization. To the best of our knowledge, this is the first ensemble attack method for attacking NLP tasks.

2 Related Work

This section briefly introduces the black-box and universal attacks that are moist related to our work.

2.1 Black-box Adversarial Attacks

Black-box adversarial attacks perturb each benign text individually based on the model output. According to the perturbation level, these attacks fall into three categories: character-level attacks (Gao et al., 2018; He et al., 2021), word-level attacks (Alzantot et al., 2018; Yu et al., 2022), and sentence-level attacks (Zhao et al., 2018; Ribeiro et al., 2018). Among these attacks, the synonym substitution based word-level attacks exhibit excellent attack performance with natural, semantic and fluent adversarial examples, which are by far the most popular methods. PWWS (Ren et al., 2019) and TextFooler (Jin et al., 2020) consider the word saliency and classification probability to greedily substitute important words with synonyms. BERT-Attack (Li et al., 2020), BAE (Garg and Ramakrishnan, 2020) and CLARE (Li et al., 2021a) attack BERT (Devlin et al., 2019) using contextual perturbations from a BERT masked language model. GA (Alzantot et al., 2018) and PSO (Zang et al., 2020) adopt evolutionary algorithms to search for an optimal textual adversarial example.

These attacks require a large number of queries to victim models so as to determine the importance of each word or retain better word substitutions. In this work, we utilize the prior knowledge of adversarial boosting preferences obtained from the training set to guide word substitutions, which helps us significantly reduce the number of queries to the model while ensuring good attack performance.

2.2 Universal Adversarial Attacks

Universal adversarial attacks usually add a universal perturbation on the benign text to mislead the victim model without requiring queries. Behjati et al. (2019) and Wallace et al. (2019) prepend the trigger to each benign sample and update the embedding for every trigger token. Atanasova et al. (2020) propose to include an auxiliary semantic textual similarity objective to generate samples with low perplexity in the fact checking task. Song et al. (2021) propose the Natural Universal Trigger Search (NUTS) to improve naturalness using an auto-encoder and a generative adversarial network. Li et al. (2021b) propose the Data-Free Adjusted Gradient (DFAG) attack which utilizes the pseudo-samples generated by the perturbation to generate the trigger using only a single sample. Gao et al. (2022) add the universal perturbation to the latent representation encoded from discrete texts.

These triggers are sentence-level perturbations that introduce a meaningless sentence into the input samples, resulting in unnatural adversarial examples that are easily detected by humans. In this work, we introduce a word-level policy for the universal textual attack. By substituting synonyms in the input text based on the pre-computed adversarial boosting preference without access to the victim model, ABP generates more natural adversarial examples with good attack performance.

3 Methodology

In this section, we formalize the problem of text attack, present the definition of ABP metric, and provide details of the proposed method.

3.1 Problem Formulation

Given an input space $\mathcal{X}$ containing all the input texts and an output space $\mathcal{Y}$ containing the predict labels, we have a pre-trained classifier $f : \mathcal{X} \to \mathcal{Y}$, which maps the input text $x = w_1 w_2 \dots w_n \in \mathcal{X}$ to its ground-truth label $y \in \mathcal{Y}$ based on the maximum posterior probability $f(y|x)$. The adversary aims to add imperceptible perturbations on the correctly classified x to craft an adversarial example x^{adv} to mislead the classifier f:

$$\underset{y_i \in \mathcal{Y}}{\operatorname{argmax}} f(y_i|x^{adv}) \neq \underset{y_i \in \mathcal{Y}}{\operatorname{argmax}} f(y_i|x) = y$$

In this work, we introduce a novel metric called **A**dversarial **B**oosting **P**reference (ABP) to evaluate the importance of words. By guiding word substitutions with ABP, we propose three efficient black-box adversarial attacks that require only a few or even zero queries to the model output.

3.2 Adversarial Boosting Preference Metric

For each word w_i in the text x, we choose its top m nearest neighbors in the commonly used counter-fitted embedding space (Mrkšić et al., 2016) as its synonym set $\mathcal{S}(w_i) = \{w_i^1, \dots, w_i^k, \dots, w_i^m\}$. We define the adversarial boosting preference of substituting word w_i with word w_i^k when crafting the adversarial example as follows.

Definition 1 (Adversarial Boosting Preference) *Given a word w_i and its synonym w_i^k, the adversarial boosting preference of substituting w_i with w_i^k when crafting an adversarial example is defined as $\mathcal{A}(w_i, w_i^k) = P(w_i, w_i^k) \times I(w_i, w_i^k)$, where $P(w_i, w_i^k)$ denotes the preference of selecting word w_i^k from the synonym set $S(w_i)$ to replace w_i and $I(w_i, w_i^k)$ denotes the influence of substituting w_i with w_i^k on the victim model.*

Typically, a larger $\mathcal{A}(w_i, w_i^k)$ indicates a greater increase in the adversariality of the generated sample after substituting w_i with w_i^k in the original text. So $\mathcal{A}(w_i, w_i^k)$ can be used to determine the importance of different words in guiding the word substitutions when crafting adversarial examples.

In this work, we estimate the adversarial boosting preference between different words based on the statistics of word substitutions during the crafting of adversarial examples in the training set. We record the frequency of w_i changing to w_i^k obtained from statistics, as its preference $P(w_i, w_i^k)$, and record the average change in model output after its replacement as the influence $I(w_i, w_i^k)$.

Specifically, given an arbitrary synonym substitution based attack method, we can convert any text x with label y to an adversarial example x^{adv}, where some words $w_i \in x$ are replaced by $w_i^k \in x^{adv}$. We record all the replaced word pairs $\{(w_i, w_i^k)\}$ between each text x and its corresponding adversarial example x^{adv} in the training set $\mathcal{X}_{train}$. We count the number of occurrences of w_i and the number of times w_i be replaced by w_i^k, which we denote as $N(w_i)$ and $N(w_i, w_i^k)$. We calculate the preference $P(w_i, w_i^k) = N(w_i, w_i^k)/N(w_i)$. Meanwhile, we estimate the influence $I(w_i, w_i^k)$ by measuring the average change in the output logits after replacing w_i with w_i^k:

$$\begin{aligned} I(w_i, w_i^k) &= \frac{\sum(f(y|x) - f(y|x'))}{N(w_i, w_i^k)}, \\ \text{where} \quad x &= w_1 w_2 \dots w_i \dots w_n, \\ x' &= w_1 w_2 \dots w_i^k \dots w_n. \end{aligned} \tag{1}$$

Finally, we obtain the adversarial boosting preference $\mathcal{A}(w_i, w_i^k) = P(w_i, w_i^k) \times I(w_i, w_i^k)$ for each word w_i and its synonyms w_i^k. It is worth noting that the preference for synonym substitutions may differ among texts with different labels. For instance, in a sentiment classification task, an attacker is more likely to substitute word "good" in texts with positive labels, but substitute word "bad" in texts with negative labels. Therefore, we calculate the adversarial boosting preference separately for texts with different categories.

3.3 The Proposed ABP Attacks

Given the pre-computed adversarial boosting preference $\mathcal{A}(w_i, w_i^k)$ derived from the training set $\mathcal{X}_{train}$, we can evaluate the importance of different words in guiding the word substitutions to generate the adversarial example on a benign text x_0. To this end, we propose three query-efficient attacks, including query-free attack ABP_{free}, guided search attack $\text{ABP}_{\text{guide}}$, and ensemble attack ABP_{ens}.

3.3.1 Query-Free Attack ABP_{free}

ABP_{free} comprises of two essential steps, namely identifying important positions in the text and selecting suitable candidate words for substitution.

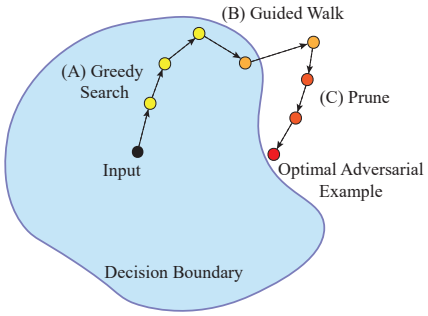

Figure 1: Overview of the proposed guided search attack $\text{ABP}_{\text{guide}}$. (A) Greedy search to approach the decision boundary (B) Guided walk to find an initial adversary (C) Prune to find the optimal adversary.

We take $\mathcal{A}(w_i, w_i^k)$ as the word importance of candidate w_i^k, and define the position importance of word w_i as $q_i = max_{k=1}^{m} \mathcal{A}(w_i, w_i^k)$. We sort the positions of all words $w_i \in x_0$ in descending order of the position importance q_i to determine the replacement order. For each word w_i in the top 25% of the replacement order, we select the most important candidate $w_i^* = argmax_{w_i^k} \mathcal{A}(w_i, w_i^k)$ from its synonym set $S(w_i)$ for substitution to generate an adversarial example.

ABP_{free} only utilizes adversarial boosting preferences to determine word substitutions, which requires no access to the victim model, making it a universal adversarial attack based on synonym substitution. Compared to previous universal adversarial attacks (Wallace et al., 2019; Song et al., 2021) that add meaningless prefixes or suffixes, ABP_{free} generates more natural adversarial examples through synonym substitutions.

3.3.2 Guided Search Attack $\text{ABP}_{\text{guide}}$

There are three key steps in $\text{ABP}_{\text{guide}}$, including **greedy search** to greedily replace key words to approach the decision boundary, **guided walk** to further perturb critical words to search for an initial adversarial example and **prune** to restore perturbed words to their original words to search for the optimal adversarial example, as shown in Figure 1.

For a benign text x_0, **greedy search** substitutes a word w_i with the most important candidate w_i^* sequentially according to the replacement order obtained in ABP_{free}. After each word substitution, we feed it into the model and ask whether it is an adversarial example until we succeed or all words have been replaced. If the search fails despite perturbing all words, we further perturb words to search for an initial adversarial example through the **guided walk** operation. Otherwise, we skip to the **prune** operation. **Guided walk** first samples several (at most δ) important positions w_i in the text with the probability p_i:

$$p_i = \frac{max(q_i,\ 0)}{\sum_{i=0}^{n} max(q_i,\ 0)},$$

where the max function ensures that only the words that can potentially enhance the adversariality of the text are selected for substitution. Afterwards, we substitute each selected w_i with a suitable candidate $w_i^k \in S(w_i)$ with probability $p_{i,k}$:

$$p_{i,k} = \frac{max(\mathcal{A}(w_i, w_i^k),\ 0)}{\sum_{k=0}^{m} max(\mathcal{A}(w_i, w_i^k),\ 0)}.$$

We repeat such search operation until we successfully find an adversarial example x^{adv} or exceed the maximum iteration limit T_g.

Finally, **prune** restores redundant substitutions in x^{adv} to their original words to search for the optimal adversarial example. **Prune** first samples several (at most δ) positions with probability $1 - p_i$, and then substitutes each selected word with its corresponding original word in the benign text x_0. If the newly generated sample is an adversarial example, we continue the prune operation, otherwise we re-prune x^{adv}. We repeat the prune operation T_p times to approach the decision boundary and search for the optimal adversarial example. Additionally, we would perform an early stopping operation when only one word in x^{adv} is perturbed.

$\text{ABP}_{\text{guide}}$ adopts the adversarial boosting preference to guide word substitutions during the search for adversarial examples, which can improve the search efficiency and decrease the number of queries significantly to the victim model, as compared to previous black-box attacks (Ren et al., 2019; Zang et al., 2020).

3.3.3 Ensemble Attack ABP_{ens}

Previous researches (Dong et al., 2018; Xiong et al., 2022) in computer vision have shown that adversarial examples generated by attacking an ensemble of models would have better performance. As ABP is model-agnostic that only relates to the replaced word pairs, it can easily facilitate the ensemble of different models. To accomplish this, we count the total number $N(w_i, w_i^k)$ of replacements for word w_i with w_i^k when attacking model f_A and model f_B, as well as the total number $N(w_i)$ of occurrences of word w_i, to obtain the preference $P_{ens}(w_i, w_i^k)$ as before. We then calculate

Model	Attack	IMDB			SST			MR		
		Succ.	Pert.	Query	Succ.	Pert.	Query	Succ.	Pert.	Query
BERT	PWWS	**100.0**	**2.6**	4,681	88.7	12.0	362	88.9	10.7	398

	ABP$_{\text{guide}}$	**100.0**	2.2	**22**	89.7	12.8	25	95.0	10.8	**16**
	ABP$_{\text{ens-guide}}$	99.9	3.1	29	96.9	14.3	**21**	96.1	12.6	19

Table 1: Comparison of attack success rate (Succ., %), word perturbation rate (Pert., %) and average query number (Query) between ABP$_{\text{guide}}$, ABP$_{\text{ens-guide}}$ and various black-box baselines on three models using three datasets. The **best performance** is highlighted in **bold**.

the average influence $I_{ens}(w_i, w_i^k)$ on models f_A and f_B using Equation 1, and obtain the ensemble adversarial boosting preference $\mathcal{A}_{ens}(w_i, w_i^k) = P_{ens}(w_i, w_i^k) \times I_{ens}(w_i, w_i^k)$. The resulting ensemble attacks using it for query-free attacks and guided search attacks are referred to as ABP$_{\text{ens-free}}$ and ABP$_{\text{ens-guide}}$, respectively. Additionally, ABP adopts the same attack strategy for texts with the same label, making it possible to generalize across domains within the same task. Consequently, we could integrate the final adversarial boosting preference obtained from different models or domains.

4 Experiments

To validate the effectiveness of ABP, we conduct extensive experiments for text classification.

4.1 Experimental Setup

Datasets and Models. We adopt three widely used sentiment analysis datasets, *i.e.*, IMDB (Maas et al., 2011), SST (Socher et al., 2013) and MR (Pang and Lee, 2005). And we train three classical models on the training set, *i.e.*, BERT base-uncased (Devlin et al., 2019), ALBERT base (Lan et al., 2020) and Long Short-Term Memory (LSTM) (Hochreiter and Schmidhuber, 1997). Due to the high computational costs, we do not adopt large language models such as RoBERTa (Liu et al., 2019) and GPT-3 (Brown et al., 2020). More details of these datasets and the classification accuracy of each model are shown in Appendix A.

Baselines. We select two commonly used black-box attacks to evaluate the effectiveness of ABP$_{\text{guide}}$, *i.e.*, PWWS (Ren et al., 2019) and PSO (Zang et al., 2020), and two universal attacks to evaluate the effectiveness of ABP$_{\text{free}}$, *i.e.*, Universal Adversarial Trigger (UAT) (Wallace et al., 2019) and NUTS (Song et al., 2021).

Evaluation Settings. In our ABP, we adopt PWWS (Ren et al., 2019) to generate adversarial examples and set the synonym number $m = 30$. The maximum perturbation rate of 25% is set in ABP$_{\text{free}}$, as it is commonly used in word-level attacks. And we set the maximum iteration limit to $T_g = 100$ and $T_p = 20$, and the maximum number of perturbations for a single iteration to $\delta = 2$ in ABP$_{\text{guide}}$. For the generation of ABP and triggers in UAT and NUTS, we randomly sample 10,000 texts from the corresponding training set, except for the MR dataset, where we use 9,662 samples. All the evaluations are conducted on a subset comprising a maximum of 1000 randomly sampled texts from the corresponding test set. The parameter studies and ablation studies of ABP are presented in Appendices B and C.

4.2 Evaluation on Efficiency of ABP$_{\text{guide}}$

In practice, if the victim detects an excessive number of queries within a short period of time, they can block the attack by simply denying the access. Therefore, the attack efficiency, typically referred

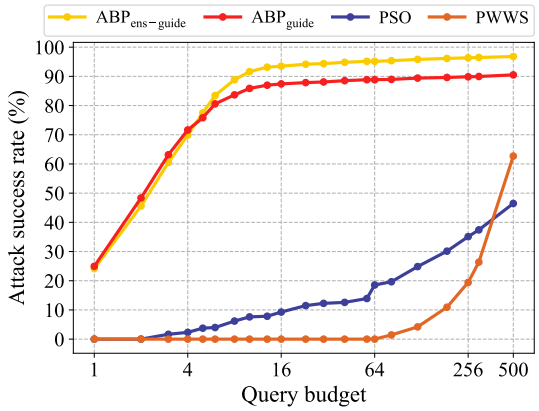

Figure 2: Attack success rate (%) of ABP$_{guide}$ and other black-box attacks on BERT model using MR dataset under different query budgets (axis x is in log-scale).

Model	Attack	IMDB	SST	MR
BERT	UAT	39.1	**78.4**	**80.6**
	NUTS	3.9	25.8	20.1
	ABP$_{free}$	**98.7**	63.0	68.3
	ABP$_{ens-free}$	97.6	68.5	71.6
ALBERT	UAT	82.4	**98.7**	**99.2**
	NUTS	1.9	23.8	25.8

	NUTS	24.9	35.0	63.8
	ABP$_{free}$	**99.9**	62.0	84.6
	ABP$_{ens-free}$	**99.9**	66.5	78.1

Table 2: Attack success rate (Succ., %) of various universal attacks on different models and datasets.

to the query budget of the victim model, plays a crucial role in evaluating the effectiveness of black-box attacks in real-world applications. We conduct evaluations using three benchmark datasets on three typical models. The results, including attack success rate, word perturbation rate and average query number are summarized in Table 1. We investigate the performance of different ensemble strategies in Appendix D. We find that ABP$_{ens-guide}$ achieves higher performance when integrating ABP from diverse sources, while ABP$_{ens-free}$ is more effective at integrating ABP from the same victim model. Thus, we opt to implement ABP$_{ens-guide}$ by integrating ABP obtained from BERT, ALBERT and LSTM models using IMDB, SST and MR datasets. Similarly, for ABP$_{ens-free}$ evaluated in Section 4.3, we only integrate ABP obtained from various domains for each victim model.

The results show that PWWS and PSO are computationally expensive, requiring hundreds or even thousands of queries to launch a successful attack on a single sample. When dealing with a large number of samples, the cost of queries to the victim is prohibitively high for the attacker. In contrast, ABP$_{guide}$ uses much fewer queries (by a factor of $10 \sim 500$) compared to the baselines, with only a slight decline on the attack success rate and word perturbation rate. This greatly reduces the cost of the attack and improves its efficiency. Furthermore, we can find that ABP$_{ens-guide}$ achieves better performance than ABP$_{guide}$, outperforming PWWS in most cases and only slightly underperforming PSO.

We further evaluate their attack performance under various query budgets on BERT model using MR dataset, as shown in Figure 2. We dynamically adjust the population size of PSO to accommodate the limited number of queries. The results show that PWWS and PSO exhibit poor attack performance when the query budget is limited. In contrast, ABP$_{guide}$ and ABP$_{ens-guide}$ consistently achieves high performance under various query budgets. Notably, the attack success rate of ABP$_{guide}$ reaches 71.6% when the query budget is only 4, which is 71.6% and 69.3% higher than PWWS and PSO, respectively. These evaluations show that ABP$_{guide}$ and ABP$_{ens-guide}$ can achieve good attack performance even in real-world scenarios where the query is strictly limited, demonstrating their effectiveness and practicality.

4.3 Evaluation on Effectiveness of ABP$_{free}$

The universal adversarial attack is a suitable option when the targeted model is entirely inaccessible. It usually has higher attack efficiency, making it more practical than both white-box and black-box attacks in real-world settings. This subsection evaluates the attack success rate and naturalness of our proposed ABP$_{free}$ and existing universal attacks using three datasets on different models, as shown in Table 2.

We could observe that ABP$_{free}$ achieves superior attack performance than NUTS, and also outperforms UAT on IMDB datasets but exhibits lower performance on SST and MR datasets. In contrast, the performance of ABP$_{ens-free}$ varies, sometimes surpassing and sometimes underperforming ABP$_{free}$. This observation implies that integrating ABP across multiple domains for ABP$_{ens-free}$ would create a trade-off in its overall performance across these domains. Table 3 shows adversarial examples generated by these attacks. UAT arbitrarily combines several words as the trigger, resulting in ex-

Attack	Original Text & Adversarial Example	Prediction
Original Text	Oliveira seems to pursue silent film representation with every mournful composition.	Positive
UAT	None is in Oliveira seems to pursue silent film representation with every mournful composition.	Negative
NUTS	Huge wooden ##loaded Oliveira seems to pursue silent film representation with every mournful composition.	Negative
ABP$_{\text{free}}$	Oliveira ostensibly to pursue silent film representation with every pained composition.	Negative

Table 3: The benign text from MR dataset and adversarial examples generated by various attacks on BERT model. We highlight the words replaced and inserted by the attacks in red.

Attack	BERT*	ALBERT	LSTM	BERT	ALBERT*	LSTM	BERT	ALBERT	LSTM*
PWWS	88.9*	40.6	39.7	**33.5**	94.4*	38.0	22.8	**33.2**	98.5*
PSO	100.0*	43.8	36.6	33.4	100.0*	34.8	23.7	25.2	100.0*
ABP$_{\text{guide}}$	89.3*	44.2	44.8	28.3	94.7*	39.7	23.2	33.1	95.0*
ABP$_{\text{ens-guide}}$	94.9*	**54.2**	**47.7**	31.4	97.5*	**44.1**	**40.9**	27.5	96.3*
UAT	80.6*	34.5	**57.3**	0.8	99.2*	2.1	45.1	42.9	99.7*
NUTS	20.1*	19.1	10.7	7.5	25.8*	17.1	4.4	20.8	63.8*
ABP$_{\text{free}}$	68.3*	**57.5**	49.7	48.2	78.6*	**51.5**	**44.7**	**56.3**	84.6*
ABP$_{\text{ens-free}}$	71.6*	54.6	50.2	**49.4**	76.0*	51.3	44.1	53.3	78.1*

Table 4: Attack success rate (%) of various attacks on different models using MR dataset for the cross-model transferability evaluation. * indicates that the adversarial examples are generated based on this model.

tremely unnatural adversarial examples. Although NUTS generates meaningful triggers, these triggers are irrelevant to the textual content and also lead to unnatural samples. In contrast, the adversarial examples obtained by ABP$_{\text{free}}$ based on synonym substitution are more natural and imperceptible.

Moreover, adversarial examples should also be imperceptible to humans. Hence, we conduct human evaluation in Appendix E. The results show that UAT and NUTS generate a large number of unnatural samples that are easily detected by humans. In contrast, ABP$_{\text{free}}$ achieves higher naturalness, with 70.8% of samples identified as natural, which is very close to the benign texts.

In conclusion, ABP$_{\text{free}}$ achieves higher attack performance than NUTS, and gains comparable or slightly lower attack success rate than UAT. Furthermore, the case study and human evaluation show that the adversarial examples generated by ABP$_{\text{free}}$ are with higher naturalness and quality.

4.4 Evaluation on Transferability

The transferability refers to the adversarial examples crafted on one model could remain adversarial on other models. It enables the adversarial examples to maintain attack capabilities even if the model cannot be accessed in the real world. To illustrate the transferability of ABP, we generate adversarial examples on each model by various attacks and report their attack success rate on other models in Table 4. ABP$_{\text{ens-free}}$ and ABP$_{\text{ens-guide}}$ adopt the ensemble of ABP across IMDB, SST and MR datasets obtained from each victim model to attack the corresponding model for the query-free attack and guided search attack, respectively.

Although PWWS and PSO show satisfactory performance on accessible victim models, their attack success rates are significantly reduced by 40% to 70% when transferred to other models. ABP$_{\text{guide}}$ exhibits relatively better transferability but still falls behind. By employing ensemble techniques, ABP$_{\text{ens-guide}}$ not only enhances the attack performance on the original model but also improves its transferability. Regarding universal attacks, UAT and NUTS exhibit poor transferability, whereas ABP$_{\text{free}}$ surpasses them in this aspect. These evaluations validate the strong cross-model transferability of ABP and highlight the advantages of ensemble attacks.

4.5 Evaluation on Generalization

Universal attacks generate triggers on one dataset and then use them to attack texts in the same domain. However, it is almost impossible for an attacker to know beforehand which domain the victim model is trained on for real-world applications. Thus, a good universal attack should exhibit excellent cross-domain generalization, *i.e.*, the adversarial perturbations crafted from one domain remain adversarial for others on the same task. We first

Attack	IMDB*	SST	MR	IMDB	SST*	MR	IMDB	SST	MR*
UAT	39.1*	30.0	28.7	18.1	78.4*	**76.5**	17.3	**82.2**	80.6*
NUTS	3.9*	13.3	14.3	2.3	25.8*	19.3	2.4	21.0	20.1*
ABP$_{\text{free}}$	98.7*	41.8	**47.0**	90.3	63.0*	68.2	87.2	69.5	68.3*
ABP$_{\text{ens-free}}$	97.8*	**42.3**	46.6	**91.6**	55.6*	61.4	**91.7**	64.7	65.7*
ABP$_{\text{guide}}$	99.9*	75.5	75.6	97.6	85.4*	88.1	98.1	93.9	89.3*
ABP$_{\text{ens-guide}}$	99.8*	**84.2**	**84.7**	**99.3**	89.3*	**91.3**	**99.9**	**96.0**	92.3*

Table 5: Attack success rate (%) of various attacks using different domains on BERT model for the cross-domain generalization evaluation. * indicates that the adversarial examples are generated using this domain.

perform attacks on a single dataset and test their performance on another domain on the sentiment analysis task in Table 5. In this study, we utilize the ensemble of ABP obtained on the BERT, ALBERT and LSTM models using the corresponding dataset to implement ABP$_{\text{ens-free}}$ and ABP$_{\text{ens-guide}}$.

We can see that ABP$_{\text{free}}$ consistently exhibits strong cross-domain generalization, showing greater effectiveness on the IMDB dataset and performing slightly weaker on the generalization between SST and MR datasets compared to UAT. ABP$_{\text{ens-free}}$ further improves the generalization of ABP$_{\text{free}}$ in most cases. Moreover, ABP$_{\text{guide}}$ achieves an exceptionally high attack success rate when utilizing the adversarial boosting preference generated from one domain to attack the text from another domain. Meanwhile, ABP$_{\text{ens-guide}}$ achieves higher attack success rate and generalization. These findings demonstrate the strong cross-domain generalization of ABP, along with its superior attack performance and practicality, even when the training data of the victim model is unseen in real-world applications.

4.6 Evaluation on Real-world Applications

To further validate the practicality of ABP, we perform the attack against real-world online commercial Application Programming Interfaces (APIs). Due to the high cost of commercial APIs, we sample 50 texts from MR dataset for the test and evaluate the attack performance on the Amazon Cloud sentiment analysis API[1]. We adopt the trigger or ABP generated on BERT model using MR dataset for universal attacks and our ABP attacks. And we utilize the ensemble of ABP on three models using three datasets for the ensemble attack ABP$_{\text{ens}}$. As shown in Figure 3, we can see that PWWS and PSO, despite achieving high attack success rates, incur significant computational expenses, requiring 500 or even 1,500 accesses per sample. In contrast, ABP$_{\text{ens-guide}}$ exhibits 96% attack success rate and remarkable attack effectiveness, surpassing all baselines. These findings provide empirical evidence of the effectiveness of ABP in real-world applications.

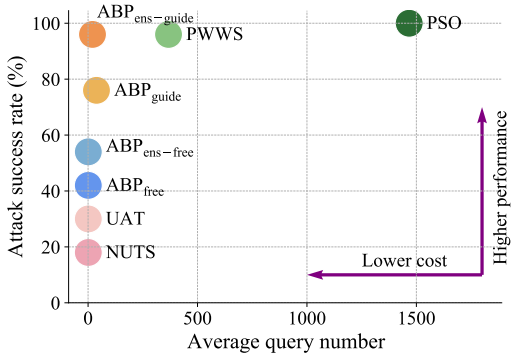

Figure 3: Attack success rate (%) and average query number (Query) when attacking Amazon Cloud APIs using various attacks.

5 Conclusion

In this work, we propose the **A**dversarial **B**oosting **P**reference (**ABP**) metric, which quantifies the importance of different words and guides word substitutions for attacks. By leveraging ABP obtained from the statistics of a typical attack method on the training set, we propose three novel attack strategies, including query-free attack ABP$_{\text{free}}$, guided search attack ABP$_{\text{guide}}$, and ensemble attack ABP$_{\text{ens}}$. Extensive evaluations demonstrate the efficiency and effectiveness of these strategies. Specifically, ABP$_{\text{free}}$ generates more natural adversarial examples without requiring queries to victim models than existing universal attacks. ABP$_{\text{guide}}$ significantly improves the attack efficiency, achieving similar attack performance to black-box attacks with only a few queries. Additionally, ABP$_{\text{ens}}$, as the first ensemble attack method in the field of NLP, exhibits better attack performance, strong cross-model transferability and cross-domain generalization compared to existing attacks. The di-

[1]https://aws.amazon.com/

verse range of attack strategies employed by ABP enables it to be applicable in various real-world scenarios, even when the victim model or training data is inaccessible. Exploring more effective ways to leverage ABP will be an interesting direction for future research.

Limitations

We summarize our limitations as follows:

Firstly, we rely on samples from the training set to generate ABP scores for each word. When samples from the same domain as the training samples of the model are not available or the total number of samples is limited, ABP-based attacks would perform poorly, as shown in Appendix B. To address this problem, we find that ABP exhibits good cross-domain generalization, allowing us to leverage samples from other domains for adversarial attacks with good attack performance.

Secondly, we have only presented a few of the simplest and most straightforward attack strategies based on ABP which significantly enhance the practicality of adversarial attacks in real-world applications. And we provide a concise analysis of ABP, revealing its contribution in improving the interpretability of the model in Appendix F. Therefore, exploring more effective ways to leverage ABP will be an interesting direction for future research.

(b) Impact of the maximum number of guided walk T_g on the attack success rate (Succ., %) and average query number (Query) of $\text{ABP}_{\text{guide}}$. (c) Impact of the maximum number of prune T_p on the word perturbation rate (Pert., %) and average query number (Query) of $\text{ABP}_{\text{guide}}$.

A More Details of Dataset and Models

We adopt three sentiment analysis datasets, *i.e.*, IMDB (Maas et al., 2011), SST (Socher et al., 2013) and MR (Pang and Lee, 2005), for text classification. And we train three classical models on the training set, *i.e.*, BERT base-uncased (Devlin et al., 2019), ALBERT base (Lan et al., 2020) and Long Short-Term Memory (LSTM) (Hochreiter and Schmidhuber, 1997). The details of these datasets and victim models are list in Table 6.

B Parameter Study

To gain more insights on the effectiveness of ABP, we conduct a series of parameter studies on BERT model using MR dataset to study the impact of the number of sampled texts, the maximum iteration number of guided walk T_g and the maximum iteration number of prune T_p.

On the number of sampled texts. To validate the influence of different sample numbers on ABP, we perform the generation of ABP with different numbers of sampled texts from MR dataset and then evaluate their attack success rates on BERT model, as shown in Figure 4a. Note that due to the small amount of data in the training set of the MR dataset, a total of 9662 texts, including 8662 texts in the training set and 1000 unused texts in the test set, are used for the generation of ABP. We could observe that the attack success rate increases rapidly at the beginning. And there is a log relationship between the attack success rate and the amount of the sampled texts. In general, we set the sample number to 10,000 in our main experiments.

On the maximum iteration number of guided walk. In Figure 4b, we study the impact of the maximum iteration number of guided walk T_g on the attack success rate and average query number. As T_g increases, the attack success rate of $\text{ABP}_{\text{guide}}$ also increases. However, when T_g exceeds 100, the growth rate of attack success rate becomes slower. At the same time, as T_g increases, the number of queries to the victim model also increases. To achieve a balance between the attack success rate and query cost of $\text{ABP}_{\text{guide}}$, we have chosen to set T_g to 100.

On the maximum iteration number of prune. Finally, we study the impact of the maximum iteration number of prune T_p on the word perturbation rate and average query number, as shown in Figure 4c. As T_p increases, the word perturbation rate of the adversarial examples generated by $\text{ABP}_{\text{guide}}$ gradually decreases, while the number of queries to the victim model increases. To strike a balance between the number of queries and the quality of

generated adversarial samples, we have set T_p to 20 based on the elbow rule.

C Ablation Study

To figure out the impact of three steps in $\text{ABP}_{\text{guide}}$, *i.e.*, greedy search, guided walk and prune steps, we conduct the ablation studies as shown in Table 8. We observe that greedy search achieves an impressive attack success rate of 85.2% with only 3 queries. By incorporating guided walk, $\text{ABP}_{\text{guide}}$ achieves higher attack success rates, albeit with a slight increase in word perturbation rate and the number of queries. Furthermore, the use of prune eliminates redundant word substitutions, resulting in a further reduction in the word perturbation rate.

In summary, the combination of greedy search, guided walk, and prune techniques enhances the efficiency and effectiveness of ABP. Greedy search provides a good starting point, and guided walk allows for further exploration in the sample space, leading to higher attack success rates. The prune technique then refines the adversarial examples by removing unnecessary word substitutions. Together, these techniques synergistically contribute to the development of optimal adversary.

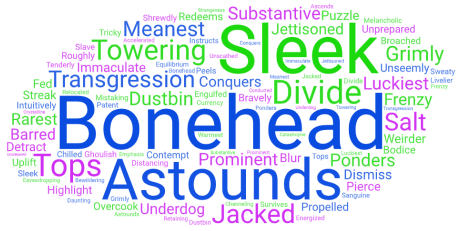
D Effectiveness of ABP_{ens} Integrated from Different Sources

As described in Section 3.3.3, the ensemble attack ABP_{ens} could integrate the ABP obatained from different sources, including various models or domains, for the query-free attack $\text{ABP}_{\text{ens-free}}$ and guided search attack $\text{ABP}_{\text{ens-guide}}$. In this section, we investigate the performance of ABP_{ens} integrated from different sources. We have three categories in total, including $\text{ABP}_{\text{ens(model)}}$ to integrate the ABP obtained from BERT, ALBERT and LSTM models using single dataset, $\text{ABP}_{\text{ens(domain)}}$ to integrate the ABP obtained from IMDB, SST and MR datasets using single model, and $\text{ABP}_{\text{ens(all)}}$ to integrate the ABP obtained from all three datasets using all three models. Table 7 and Table 9 show the performance of the ensemble attack for guided search attack and query-free attack, respectively.

In terms of the guided search attack, we find that all ensemble strategies could enhance the attack success rate of $\text{ABP}_{\text{guide}}$ with a slight increase in perturbation rate and number of queries. Among the ensemble strategies, $\text{ABP}_{\text{ens(all)-guide}}$ achieves the highest attack success rate, followed by $\text{ABP}_{\text{ens(domain)-guide}}$, and $\text{ABP}_{\text{ens(model)-guide}}$ performs the worst. We speculate that $\text{ABP}_{\text{ens(all)-guide}}$ offers a more diverse search space for guided search, thus achieving a higher success rate. However, this comes at the cost of requiring more queries to perform the search. Therefore, we choose $\text{ABP}_{\text{ens(all)-guide}}$ for the ensemble attack in Section 4.2.

In terms of the query-free attack, we can see that the ensemble attack generally reduces the attack performance of ABP_{free}, with $\text{ABP}_{\text{ens(model)-free}}$ exhibiting the poorest performance and $\text{ABP}_{\text{ens(domain)-free}}$ displaying relatively better performance. Specifically, the ensemble of ABP from different domains in $\text{ABP}_{\text{ens(domain)-free}}$ creates a trade-off in its performance across these domains, sometimes surpassing and sometimes underperforming ABP_{free}. We speculate that the ensemble of ABP may not be conducive to identifying the most critical words, resulting in a reduction in their performance. Nevertheless, it is this ensemble that confers better cross-model transferability and cross-domain generalization to ABP.

E Human Evaluation



Adversarial examples should be imperceptible to humans. But we find that most existing universal attacks generates unnatural adversarial examples as described in Section 4.3. To further validate their imperceptibility, we conduct human evaluation on 50 benign texts sampled from MR dataset and the corresponding adversarial examples generated by various universal attacks on BERT. We invite 10 volunteers to label the samples as natural, unnatural, or uncertain. The results in Table 10 show that UAT and NUTS generate a large number of unnatural samples that are easily detected by humans. In contrast, ABP_{free} achieves higher naturalness, with 70.8% of samples identified as natural, which is very close to the benign texts. It further validates the naturalness of the adversarial examples generated by ABP.

F Further Exploration on ABP

In order to gain further insights into ABP and analyze the factors contributing to model vulnerability, we present the visualization of ABP scores for different words in Figure 5. Our observations reveal an interesting phenomenon. In texts with positive sentiment, certain words associated with negative sentiment exhibit higher ABP scores, such as "bonehead", and positive sentiment words

Model	Attack	IMDB			SST			MR		
		Succ.	Pert.	Query	Succ.	Pert.	Query	Succ.	Pert.	Query

like "sleek" closely follow. Conversely, in texts with negative sentiment, the ABP scores are predominantly higher for words associated with negative sentiment, such as "wearisome" and "nausea". Overall, in sentiment classification tasks, we observe that sentiment-related words have the greatest impact on the model, which aligns with our expectations. Surprisingly, we discover that replacing positive sentiment words with their synonyms can lead the model to misclassify them as negative sentiment label. We speculate that this discrepancy is largely due to the limited availability of data for the model to learn from or the model's incomplete

Attack	Natural	Unnatural	Uncertain
Benign text	86.5	10.5	3.0
UAT	15.2	81.3	3.5
NUTS	38.1	51.2	10.7
ABP_{free}	**70.8**	21.6	7.6

understanding of all sentiment-related words.

Through an analysis of the ABP scores and their implications, we have gained valuable insights into the inner workings of the model and the factors that contribute to its vulnerability. These insights are critical for understanding the limitations of the model and guiding future research to address these challenges and improve the model's overall performance.

Embrace Divergence for Richer Insights: A Multi-document Summarization Benchmark and a Case Study on Summarizing Diverse Information from News Articles

Abstract

Previous research in multi-document news summarization has typically concentrated on collating information that all sources agree upon. However, the summarization of diverse information dispersed across multiple articles about an event remains underexplored. In this paper, we propose a new task of summarizing diverse information encountered in multiple news articles encompassing the same event. To facilitate this task, we present a data collection schema for identifying diverse information and curated a dataset named DIVERSESUMM. The dataset includes 245 news stories, with each story comprising 10 news articles and paired with a human-validated reference. Next, to enable consistent automatic evaluation, we conduct a comprehensive analysis to pinpoint the position and verbosity biases when utilizing Large Language Model (LLM)-based metrics for evaluating the coverage and faithfulness of summaries. Through correlation analyses, we outline the best practices for effectively using automatic LLM-based metrics on the DIVERSESUMM dataset. Finally, we study how LLMs summarize multiple news articles by analyzing which type of diverse information LLMs are capable of identifying. Our analyses suggest that despite the extraordinary capabilities of LLMs in single-document summarization, the proposed task remains a complex challenge for them mainly due to their limited coverage, with GPT-4 only able to cover under 40% of the diverse information on average.[1]

1 Introduction

In the realm of news reporting, each event is often chronicled by multiple sources, providing a rich tapestry of perspectives and insights. The sheer volume of articles available via news aggregators, as noted by Laban et al. (2023), can overwhelm readers, leading to fatigue (Lee and Chyi, 2015). This has fueled the demand for more digestible multi-source summaries. However, as highlighted by existing multi-document summarization studies (Over and Yen, 2004; Owczarzak and Dang, 2011; Fabbri et al., 2019), these often only reflect consensus information and neglect the breadth of differing viewpoints. To address this, we propose the **Multi-document Diversity Summarization (MDDS)** task, aimed at faithfully illuminating the diverse information presented in multiple sources.

Following Laban et al. (2022), we formalize diverse information as *questions and answers where numerous sources can answer the same question, and the corresponding answers extracted from different news articles exhibit a variety of opinions or perspectives*. For robust and objective evaluation, we opted for a QA representation for references, aligning with the granularity and reliability advantages emphasized in prior work on summarization evaluation (Krishna et al., 2023; Liu et al., 2023c; Arumae and Liu, 2019). An example of diverse information is shown in Figure 1.

Using this formulation, we propose a reference annotation methodology to identify and gather diverse information dispersed across multiple articles about the same story. Our approach is a pipeline based on GPT-3.5-Turbo (OpenAI, 2023a), which generates questions concerning the story likely to pull varied responses from different sources. The subsequent answers extracted from each news article are then clustered into groups. We employ a post-processing step that removes invalid questions and answers. Finally, all questions and answers are validated by human annotators. The resulting dataset contains 245 news story clusters, where each story contains 10 news articles and an average of 2.49 questions, with each question associated with 3.41 answer clusters on average. This dataset is named **DIVERSESUMM**.

We conduct a series of experiments to under-

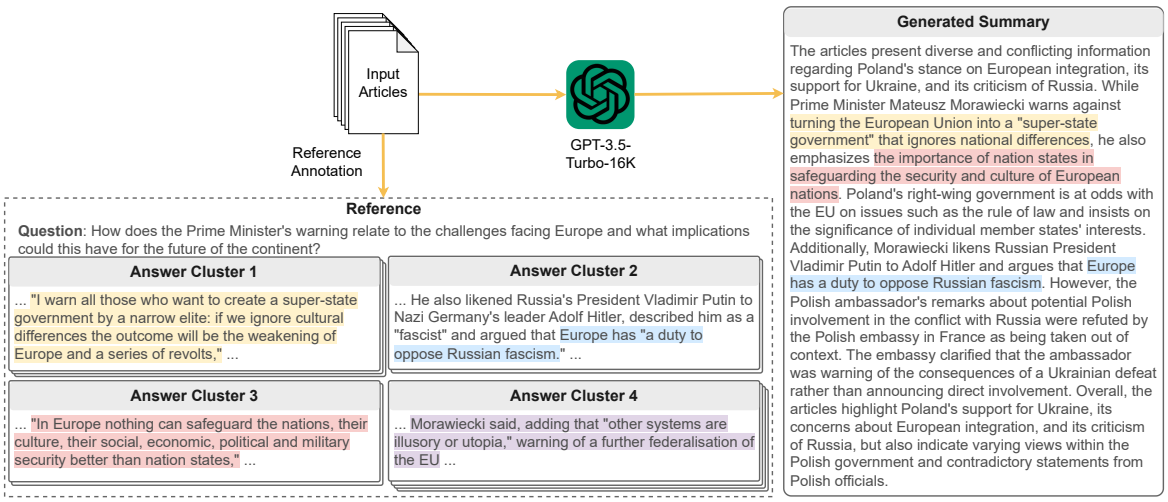

Figure 1: An example from our DIVERSESUMM dataset and a summary generated by GPT-3.5-Turbo-16K. To depict the process succinctly, only 4 news answer clusters from the reference are displayed. In this instance, the reference contains a single question with various answers extracted from each news article. In general, a news event may contain multiple reference questions, each of which can correspond to multiple answer clusters. The summary produced by GPT-3.5-Turbo-16K encompasses 3 of the answer clusters shown, but does not cover Answer Cluster 4.

stand the relevancy and challenges of our task in the era of LLMs and how future work should evaluate models on our task. Our fine-grained human evaluation results identify that even the most advanced LLM, GPT-4, only covers about 37% of diverse information with optimally designed prompts (see Appendix C.2). This highlights the significant challenge of effectively incorporating diverse information from multiple sources and the efficacy of our dataset as a rigorous LLM benchmark. Furthermore, we assess GPT-4 as an evaluator, given the impracticality of extensive human evaluations and its high correlation with human ratings (Liu et al., 2023b). Based on the correlation and bias analysis of GPT-4 evaluations, we provide recommendations for its application in assessing coverage and faithfulness of LLMs on our task. Our key findings are outlined in Table 1.

Our contributions are: (1) We introduce the Multi-document Diversity Summarization task that challenges models to identify diverse information across news articles and propose a reference annotation scheme to construct the DIVERSESUMM dataset. (2) We conduct extensive human evaluations to understand LLMs' ability to tackle our task and demonstrate that even GPT-4 struggle to achieve high coverage. (3) We conduct bias and correlation analysis on different GPT-4-based evaluation protocols to provide recommendations on using GPT-4-based metrics on our task. These guidelines are used to assess the coverage bias in various LLMs to understand how they summarize diverse information, highlighting the remaining challenges.

2 Task

The MDDS task revolves around a cluster of K news articles all centered around the same news event. To maintain a balance between task feasibility and challenge, we have opted to set K at a value of 10. The primary aim of our task is to generate a natural-language summary that effectively captures the diverse information presented within this cluster of news articles. To facilitate this process, our data collection pipeline, as elaborated in §3, produces references for each news cluster. These references take the form of question-answers (QAs), and their validity is established through human validation. The QAs must satisfy two properties: (1) the valid question must be answered by a sufficient number of sources, and (2) the answers associated with a valid question must present diverse opinions or perspectives.

In this work, the assessment of the generated summaries centers on two key facets: faithfulness and coverage. The faithfulness aspect evaluates the extent to which the summary aligns with the factual content present in the source articles. On the other hand, the coverage aspect gauges the inclusivity of information by considering how many answers within the reference are effectively addressed in the summary. We set our primary focus on these two aspects instead of other qualities, such as compression ratio and coherence, because recent work has shown that faithfulness and coverage

RQ1: How proficient are LLMs in summarizing diverse information from multiple news articles about an event?
- While LLMs can generate faithful summaries, they often lack adequate coverage. - Given the challenge of multi-document diverse summarization, our dataset serves as a rigorous benchmark for LLMs.
RQ2: What are the pitfalls and best practices when leveraging GPT-4 as the evaluation metric for our task?
- As a pairwise evaluator, GPT-4 shows a bias for the second summary. - Used as a single-answer grader, GPT-4 is prone to verbosity bias and prefers shorter summaries. - Likert-scale grading balances budget with correlation to human judgment for faithfulness evaluation. - Both granular evaluation methods correlate well with human judgment for coverage.
RQ3: Do LLMs exhibit coverage bias when performing MDDS?
- LLMs usually focus on summarizing the initial and final input articles, often overlooking the middle ones. - LLMs struggle to comprehensively address "How" and "What" type questions. - Long-context LLMs excel at covering frequent answers, while standard LLMs are proficient at summarizing infrequent ones. - Increasing model size improves LLMs' coverage of diverse information.

Table 1: Summary of research questions and key findings of our study.

are two major summarization challenges faced by models based on pre-trained transformers (Cao and Wang, 2021; Tang et al., 2022; Huang et al., 2023; Qiu et al., 2024).

3 Data Collection

This section details the DIVERSESUMM data collection pipeline, delineating its automated diverse information discovery from articles and the human validation stage that ensures data integrity.

3.1 Automatic Data Curation

Our data collection framework surfaces diverse information across news articles by asking questions about a news story, extracting answers from each news article, clustering the answers based on semantics, and filtering invalid questions and answers that are invalid. Our method extends the Discord Questions data generation pipeline (Laban et al., 2022) with four major modifications aimed at improving data quality:

(1) We perform question generation in a two-stage fashion, which increases the number of questions that result in diverse answers extracted from different articles. (2) Our question-answering component extracts answers from the context of the entire article, instead of extracting from each paragraph independently, significantly improving the recall of answers. (3) We perform a post-processing step to remove answers that do not make sense and QA-pairs that do not form diverse information. (4) Our method is based on GPT-3.5-Turbo [2], allowing for collection of higher-quality data.

Data Source We create DIVERSESUMM by gathering news stories and corresponding events from Google News, a news aggregator that collects news articles from various sources for a given news story. Each news story in Google News corresponds to around 40 news articles. We picked 400 news stories on the recent section of Google News. Most articles were published during March 2023, hence beyond the knowledge cut-off date of GPT-3.5-Turbo, which is September 2021.

Question Generation Upon collecting news stories, our next step is to ask questions about each news story that satisfy two properties: (1) *Availability of response*: this property ensures that any question deemed valid for the task should be one that many source articles can answer, hence indicating its centrality to the news event being reported. It is about the presence of answers across the corpus rather than their content. (2) *Diversity of answers*: this property focuses on the content of the responses rather than their presence. It stipulates that the answers to a valid question should exhibit a range of perspectives or opinions when extracted from different sources/articles. This is the heart of our approach to capturing the diversity of viewpoints represented in news articles.

We validate a query if at least 30% of the sources answer it and it results in assorted responses. To assess the efficiency of various methods of Question Generation (QG), we manually reviewed 10 news stories. We extend the Discord Question framework (Laban et al., 2022) by replacing their QG component with GPT-3.5-Turbo for its better performance over smaller models. For each news narrative, we heuristically select a medium-length article to prompt GPT-3.5-Turbo, generating 20 questions each, after which answers are extracted from all sources using the QA method outlined subsequently. The analysis reveals that of the 200 questions generated via this method, only 42 questions sufficiently cover all source articles, with

[2]We used the `gpt-3.5-turbo-0613` variant.

a mere 10 questions satisfy the two requirements mentioned above, indicating the single-article input's limited recall.

To enhance question coverage, we incorporate multiple representative articles into GPT-3.5-Turbo. We hypothesize that the answer clusters identified by a RoBERTa-based QA pipeline (Laban et al., 2022) provide a decent degree of diversity. Consequently, we identified representative articles through a heuristic method: a question corresponding to the median number of answer clusters was chosen. Within the associated articles, we opted for a medium-length article. This process produces a set of representative articles for the chosen questions corresponding to a news story. Prompting GPT-3.5-Turbo with these articles yielded 20 questions.

On a manual assessment of the aforementioned 10 news stories, this novel approach increased the number of questions linked with sufficient answers and valid questions, to 85 (+102.4%) and 19 (+90.0%), respectively. This indicates the proposed QG strategy's efficacy, significantly increasing the generation of valid questions compared to the prior method (Laban et al., 2022), and justifies our hypothesis mentioned in the previous paragraph.

Question Answering Similar to QG, we create an evaluation set for assessing the performance of question answering (QA) on our collected data, which contains two news stories, each paired with six human-generated valid questions. We compared various QA models, including a RoBERTa-based model (Liu et al., 2019) and two GPT-3.5-Turbo variants. One GPT-3.5-Turbo variant processes paragraphs independently, akin to RoBERTa, while its article-level counterpart extracts answers from the entire news article. Upon inspecting the outputs, we found that RoBERTa demonstrated higher precision, but the article-level GPT-3.5-Turbo variant excelled in recall (64.6%) against RoBERTa's (43.8%). Given the ease of filtering excessive answers compared to recovering missed answers, we opted for the article-level GPT-3.5-Turbo for all subsequent experiments.

Answer Consolidation For answer consolidation, we conduct a similar small-scale analysis to understand the performance of different answer clustering methods. We do not find significant advantages of the method based on GPT-3.5-Turbo compared to prior approaches; hence, we use the RoBERTa-based method (Laban et al., 2022) as our answer consolidation model.

Figure 2: Dataset statistics regarding the number of questions and answer clusters.

Post-processing To ensure task feasibility, we downsize the articles by selecting articles that have higher coverage of answers such that each news story is now associated with at most 10 articles. To expedite the process of human validation illustrated in §3.2, we utilized GPT-3.5-Turbo to filter non-sensical answers and non-diverse QA-pairs. Questions that are no longer associated with adequate answers due to the filtering are removed. Similarly, news stories that do not have any valid questions because of the filtering will be removed as well. The LLM prompts used in this subsection can be found in Appendix C.1.

3.2 Human Validation

To address any invalid QA-pairs that slipped past our post-processing procedure and enhance data quality, we recruited human annotators to validate the post-processed QAs. They are tasked to verify whether an answer addresses the corresponding question and ensure at least one article contains such an answer. More about this process is detailed in Appendix B.2. The resulting DIVERSESUMM dataset contains 245 news stories, each containing 10 articles. The distribution of the number of questions per news story and the number of answer clusters per question are shown in Figure 2. The distribution of question types and the topic of these news stories are shown in Appendix E.

4 Analysis

We address the research questions from §1, first evaluating how well diverse information from mul-

Model	Faithfulness (%)	Coverage (%)
Extract then summarize		
GPT-4	95.63	**36.58**
Vicuna-7B	78.42	13.36
Directly summarize		
GPT-3.5-Turbo-16K	**98.44**	35.66
LongChat-7B-16K	92.49	30.04

Table 2: Performance of different LLMs on our task. The faithfulness score and coverage score are determined by averaging the binary ratings provided by human evaluators.

tiple sources is summarized by LLMs (§4.1), then examining LLM behavior during this summarization (§4.3) using the most reliable LLM-based evaluation protocols we found (§4.2).

4.1 RQ 1: How proficient are LLMs in summarizing diverse information from multiple news articles?

To understand LLMs' performance on MDDS, we conduct human evaluation on summaries produced by four representative LLMs, GPT-4 (OpenAI, 2023b), GPT-3.5-Turbo-16K (OpenAI, 2023b), Vicuna-7B (Chiang et al., 2023), LongChat-7B-16K (Li et al., 2023).[3] *Long-context* LLMs, GPT-3.5-Turbo-16K and LongChat-7B-16K, handle texts up to 16K tokens and can perform direct summarization by taking all articles as input. *Standard LLMs*, GPT-4 and Vicuna-7B, are limited to 8K and 2K tokens, respectively; hence, we split summarization into two stages: selecting the most salient N sentences from each article and summarizing these sentences.[4] To elicit a high-coverage summary of diverse information, we manually optimize the prompts. Details of the prompts used for summarization in our experiments can be found in Appendix C.2. Following Krishna et al. (2023), we conduct evaluations at a finer granularity. Faithfulness is judged per sentence, whereas coverage is determined by how many reference QA pairs are covered by each summary. The resultant scores for each LLM were averaged from evaluations per summary sentence and reference QA pair, respectively. Evaluation details, such as worker qualification and user interface, are in Appendix B.3.

The human evaluation results are presented in Table 2. We observe that all four LLMs in general achieve high faithfulness but insufficient coverage of diverse information. This suggests that the proposed task is challenging even for state-of-the-art LLMs, and highlights that DIVERSESUMM serves as a challenging test bed for LLMs.

[3]We use `gpt-4-0613`, `gpt-3.5-turbo-16k-0613`, `vicuna-7b-v1.3` and `longchat-7b-16k`.

[4]We chose $N = 5$.

Aspect	First (%)	Second (%)	Consistency (%)
Coverage	1.63	**17.55**	60.10
Faithfulness	1.32	**13.27**	61.94

Table 3: Position bias analysis of swapping two summaries produced by two systems. Consistency is calculated as the percentage of cases in which the evaluator (i.e., GPT-4) provides coherent outcomes upon swapping the order of two summaries. First/Second indicates the percentage of cases in which a judge demonstrates a preference for the first/second summary. Overall, GPT-4 prefers the summary placed in the second position.

Aspect	Protocol	Original (%)	Extended (%)
Faithfulness	Single	41.44	20.58
	Pairwise	**0.20**	**0.00**
Coverage	Single	53.46	16.33
	Pairwise	**1.12**	**0.82**

Table 4: Verbosity bias analysis using GPT-4 as the evaluator. Single (i.e., single-answer grading) results in significant verbosity bias as we can see shorter summaries (i.e., Original) are preferable to longer summaries (i.e., Extended). Such bias can be significantly mitigated if pairwise comparison is used instead.

4.2 RQ 2: What are the pitfalls and best practices when leveraging GPT-4 as the evaluation metric for our task?

To facilitate the analysis and discussion of our next research question, we rely on LLM-based evaluation metrics to conduct various analyses, given their superior correlation with human judgments (Liu et al., 2023b) and the high cost of human annotation. For this research question, we aim to provide the best practices when using GPT-4 as the evaluator for the MDDS task by conducting bias and correlation analyses.

We focus on two major biases: position bias (i.e., whether the LLM evaluator favors certain positions over others) and verbosity bias (i.e. whether the LLM evaluator prefers shorter or longer texts). For all the experiments conducted in this analysis, we investigated summaries produced by GPT-4, GPT-3.5-Turbo, Vicuna-7B, and LongChat-7B-16K. The details of our prompts for the below experiments can be found in Appendix C.3.

Position Bias Position bias is most relevant to the pairwise comparison protocol. While previous work has shown that GPT-4 does exhibit

Criteria	Reference	Evaluated Texts	Rating Method	Evaluator	Rating	Correlation (%)
Faithfulness	Article	Summaries	Pairwise (both ways)	GPT-4	Win-Tie-Lose	**26.68**
	Article	Summary	Single-answer grading	GPT-4	Likert	<u>21.18</u>
	Article	Summary	Single-answer grading	GPT-4	Binary	18.54
	Articles	Summary	Single-answer grading	GPT-3.5-Turbo-16K	Likert	-7.44
	Articles	Summary	Single-answer grading	GPT-3.5-Turbo-16K	Binary	-3.70
	Articles	Summary sentence	Single-answer grading	GPT-3.5-Turbo-16K	Likert	15.58
	Articles	Summary sentence	Single-answer grading	GPT-3.5-Turbo-16K	Binary	-12.30
Coverage	QA pairs	Summaries	Pairwise (both ways)	GPT-4	Win-Tie-Lose	32.00
	QA pairs	Summary	Single-answer grading	GPT-4	Likert	**36.75**
	QA pairs	Summary	Single-answer grading	GPT-4	Binary	22.57
	QA pair	Summary	Single-answer grading	GPT-4	Likert	29.05
	QA pair	Summary	Single-answer grading	GPT-4	Binary	<u>35.83</u>

Table 5: Summary-level correlation between different LLM-based evaluation protocols and human judgments computed using Kendall's Tau. The best and second best protocol for each criterion are marked in boldface and underlined, respectively. The recommended evaluation protocols are highlighted.

position bias when used to assess text quality in conversational-focused tasks (Wang et al., 2023; Zheng et al., 2023), none of the prior studies have investigated whether such bias is also observed when evaluating faithfulness or coverage. To analyze position bias, we task GPT-4 with assessing a pair of summaries generated by two LLMs on which one is better, and then swap the positions of these two summaries and query GPT-4 again. We compute the percentage of times GPT-4 prefers the first or second summaries.

When GPT-4 compared pairs of LLM-generated summaries to evaluate faithfulness and coverage, a strong position bias surfaced, favoring the second entry (Table 3). Position bias was particularly pronounced when assessing similar-quality summaries (see Figure 23a). Hence, we deduce that **GPT-4 is unreliable when utilized as a pairwise evaluator in the MDDS task with respect to faithfulness and coverage**. Interestingly, this outcome contradicts Zheng et al. (2023), implying that **the position of bias for LLM-based evaluators could vary across different tasks**. A breakdown of the position bias analysis can be found in Appendix D.

Verbosity Bias To assess the verbosity bias of GPT-4 as an evaluator, we create extended summaries that maintain the semantic meaning. We achieve this by duplicating the original summaries, following Zheng et al. (2023). Ideally, a fair evaluator should provide identical faithfulness and coverage scores for both the original and extended summaries. We employed two experimental designs: pairwise comparison and single-answer grading on a Likert scale of 5.

The results of our verbosity bias analysis can be found in Table 4. We see that when **using the single-answer grading protocol, GPT-4 has a strong preference over shorter summaries, whether it is assessing faithfulness or coverage**. This conclusion was unexpected, particularly as we anticipated GPT-4 to favor longer summaries when determining coverage. Additionally, we noted that **verbosity bias is significantly lessened when using the pairwise comparison protocol**, which also comes with a much higher computational cost.

Correlation Analysis Upon examining the biases, we explore LLM-based evaluation protocols for their alignment with human judgments, varying reference granularity and rating models, including the use of GPT-3.5-Turbo-16K for efficiency in faithfulness assessment. For the pairwise comparison, since we had already established the prevalence of its significant position bias, we conducted the comparison both ways by swapping the summaries and then aggregating the results. As shown in Table 5, the both-way pairwise comparison protocol highly correlate with human judgment, mitigating verbosity and position biases, but was computationally demanding. In contrast, single-answer document-summary grading was efficient and fairly accurate. Notably, some GPT-3.5-Turbo-16K protocols negatively correlate with human assessment, indicating that **even though state-of-the-art long-context LLMs have a wide context window, their capacity to reason through extensive text effectively is occasionally unsatisfactory**.

In terms of coverage, we observed that both coarse-grained (QA-pairs) and fine-grained (single QA) evaluation protocols can establish a reasonably high correlation with human judgments provided we use appropriate rating methods (i.e., Likert scale for the former and binary rating for the latter). Either protocol proves suitable, contingent upon the level of granularity required for analysis.

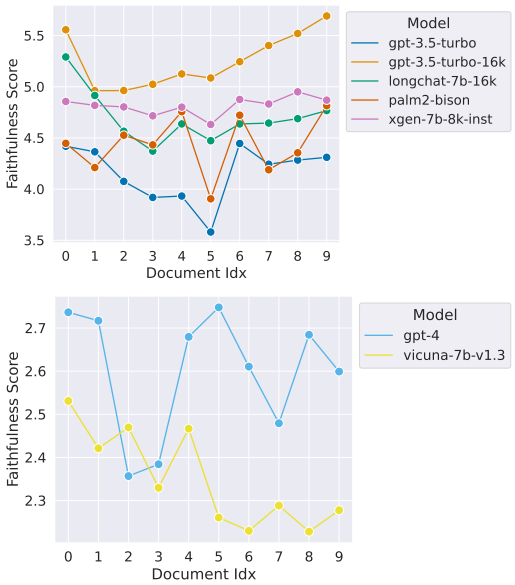

Figure 3: Faithfulness scores w.r.t. the index of the news article in the input prompt for LLMs. We see that LLMs with higher faithfulness (top), regardless of the way it summarize the article, tend to summarize from the starting or ending articles, while such a pattern is not observed for LLMs of low faithfulness (bottom).

Evaluation Recommendations For faithfulness evaluation, if budget is not a concern, it is recommended to use both-way pairwise comparisons given its high correlation with human judgments and least bias (The average cost for this evaluation protocol on our dataset is around $200 for each pair of models.). Otherwise, Likert scale single-answer grading with GPT-4 is the optimal alternative. For coverage evaluation, Likert scale single-answer grading has the highest correlation with human judgments.

4.3 RQ 3: Do LLM exhibit coverage bias when performing MDDS?

With the insights drawn from our analysis of the previous research questions, we are able to effectively conduct experiments to answer what type of information LLMs tend to summarize. We break down this research question into three sub-questions, with each focus on different aspects: focusing on article position, question type, and answer frequency. Since the evaluation is automatically conducted using GPT-4, we additionally consider the following LLMs for analysis: GPT-3.5-Turbo, XGen-7B-8K-Inst (Nijkamp et al., 2023), and Palm2-Bison (Ghahramani, 2023). The results are discussed in the following paragraphs.

Do LLMs tend to summarize articles at particular positions? The faithfulness score can serve as a measure to gauge how much content in an article's summary is drawn from each input news article. Higher faithfulness indicates greater information extraction from corresponding articles. We compute the faithfulness score between the generated summaries and each corresponding article using GPT-4 based on the article-summary Likert-scale single-answer grading protocol. In Figure 3, a prominent U-shape pattern for faithful LLMs (top) suggests that **faithful LLMs tend to summarize content from the first and last articles, while giving less attention to the middle articles**, aligning with findings from Liu et al. (2023a) on QA tasks. However, lower-faithfulness LLMs (bottom) show no clear pattern.[5]

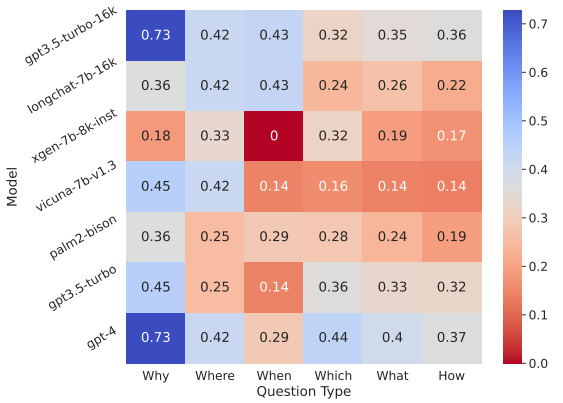

Figure 4: Average coverage scores with regard to different question types for different LLMs. Blue indicates a higher coverage, while red represents a lower coverage.

What diverse information do LLMs best identify and summarize? To understand categories of diverse information that LLMs are more inclined to summarize, we analyzed coverage by question type, with each binary coverage score mapping a summary to reference answers using GPT-4 with the QA-summary binary single-answer grading protocol. Then, we aggregate these answers based on the respective question types and calculate the averages, as depicted in Figure 4. Results show that questions starting with "Why" and "Where" tend to have better coverage, likely due to the direct presence of related answers in the source articles. Conversely, **LLMs encounter challenges in adequately covering answers for "How" and "What" type questions.** These question types delve into implications and require the model to establish connections between events, making them more intri-

[5] GPT-4's lower faithfulness scores arise from their summaries containing article indexes, which are not presented to the evaluators during the evaluation process.

Question: What are the broader implications of insulin prices on the overall healthcare system? **Answers**: ✗ ..., there is no guarantee that companies will continue to choose people over profits. ✗ Legally capping the price of insulin would bring a welcome financial relief to millions of Americans and save lives. ✗ ... policies to make diabetes treatment more affordable. ✗ ... it can hurt patients on fixed incomes and others less able to afford their insulin.	Multiple pharmaceutical companies, including Eli Lilly, Novo Nordisk, and Sanofi, have announced price reductions for their insulin products in response to growing pressure to lower the cost of this life-saving medication. The reductions range from 70% to 78% and are aimed at both Medicare patients and individuals with private insurance. The price cuts come as a result of the Inflation Reduction Act, which caps insulin prices for Medicare patients at $35 per month. However, some critics argue that these reductions only cover a portion of the insulin market and that individuals without insurance or with high-deductible plans may still struggle to afford the medication...

Table 6: Two instances in our DIVERSESUMM dataset and corresponding summaries generated by GPT-3.5-Turbo-16K. References and summaries are truncated due to space limits. The references in these two examples contain different types of questions. In the first instance, GPT-3.5-Turbo-16K successfully identifies the answers, demonstrating its proficient comprehension skills. However, in the second instance, the model fails to provide a high-coverage summary. This likely signifies its struggle with complex reasoning tasks that certain types of questions demand.

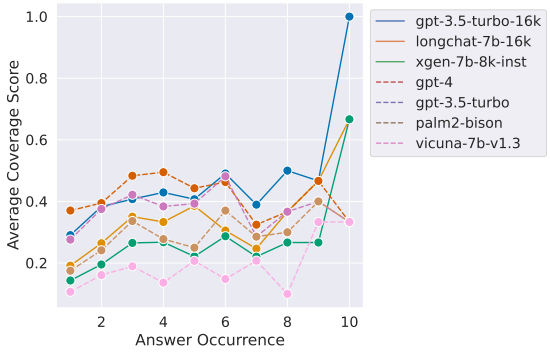

Figure 5: Average coverage scores with regard to answer frequency for different LLMs. Solid lines denote long-context LLMs, while dotted lines indicate standard LLMs. Answer occurrence represents the number of articles containing a given answer. For example, an answer occurrence of 10 means that all 10 input articles contain such an answer.

Model	Size	Coverage Score
Llama-2	7B	2.29
Llama-2	13B	2.53
Llama-2	70B	2.81
Vicuna-v1.5-16K	7B	2.00
Vicuna-v1.5-16K	13B	2.02

Table 7: Coverage score with regard to LLMs of varying sizes. The coverage scores are computed using the single-answer Likert-scale evaluation protocol with question-and-answer pairs as the reference.

cate to address. Two examples of different types of questions are demonstrated in Table 6.

Do LLMs have a tendency to summarize frequent information? We are intrigued by how the frequency of a piece of information influences the behavior of LLMs when summarizing multiple articles. Our data collection approach has facilitated this analysis, as answers extracted from each article have been systematically grouped. This enables us to easily determine the occurrence of a specific answer by calculating the number of articles containing that particular answer within its cluster. We compute the average coverage scores by aggregating answers based on their frequency of occurrence. The results, illustrated in Figure 5, reveal a notable trend: frequent answers (i.e., those found in a higher number of articles) tend to be covered more. Additionally, we found that **long-context LLMs exhibit greater proficiency in covering frequent answers, while standard LLMs appear to excel at summarizing infrequent answers**. This distinction is evident in the comparison between the performance of GPT-4 and GPT-3.5-Turbo-16K.

Does the size of LLMs correlate with their coverage of diverse information? To run this analysis, we need to ensure that factors other than the size of the model do not influence the results. Hence, we conduct experiments with LLMs in the same family. These include a family of *standard* LLMs, Llama-

2 (Touvron et al., 2023), with a maximum token length of 4K, as well as a family of *long-context* LLMs, Vicuna-v1.5-16K, which can handle up to 16K tokens. To measure the coverage scores, we utilized the evaluation protocol that shows the highest correlation with human judgment, as shown in Table 5. This consisted of a single-answer Likert-scale grading scheme, using question-and-answer pairs as the reference, and GPT-4 serving as the evaluator. As shown in Table 7, we found that increasing the model size enhances the coverage scores for both Llama-2 and Vicuna-v1.5-16K. This indicates that **more parameters improve LLM's ability to identify diverse information**.

5 Related Work

5.1 Multi-document Summarization

Conventional approaches to multi-document summarization (MDS) can be categorized into three types: extractive (Radev et al., 2000; Gillick and Favre, 2009; Lin and Bilmes, 2011; Hong and Nenkova, 2014; Peyrard and Eckle-Kohler, 2016; Cheng and Lapata, 2016; Narayan et al., 2018; Liu et al., 2018), abstractive (McKeown and Radev, 1995; Radev and McKeown, 1998; Barzilay et al., 1999; Zhang et al., 2018; Fabbri et al., 2019), and multi-sentence compression (Ganesan et al., 2010; Banerjee et al., 2015; Chali et al., 2017; Nayeem et al., 2018).

Recently, large language models (LLMs) have demonstrated significant advantages over conventional approaches in generating summaries of high faithfulness and quality. Studies have used LLMs to generate summaries of multiple documents by first extract important sentences from each article and then summarize them (Bhaskar et al., 2023) or iteratively improve summary quality with the guidance of a checklist (Zeng et al., 2023).

5.2 MDS Datasets

In previous studies, several popular MDS datasets have been examined. These datasets include DUC (Over and Yen, 2004; Dang, 2005) and TAC (Dang et al., 2008; Owczarzak and Dang, 2011), which are smaller in scale with approximately 50 and 100 article clusters, respectively. MULTINEWS (Fabbri et al., 2019) is the first large-scale MDS dataset in the news domain, containing 56K article clusters, with an average of fewer than 3 news articles per cluster. AUTO-HMDS (Zopf, 2018) is a multi-lingual MDS dataset focused on the Wikipedia domain, comprising 7.3K article clusters. WCEP (Gholipour Ghalandari et al., 2020) is another Wikipedia domain dataset, where each cluster may contain up to 100 articles. MULTI-XSCIENCE (Lu et al., 2020) and MS^2 (DeYoung et al., 2021) are two scientific domain MDS datasets. The above MDS datasets task models with summarizing consensus information, our work differentiates itself by focusing on summarizing diverse information across the articles.

6 Conclusion

We introduce a novel task of Multi-document Diverse Summarization that focuses on effectively summarizing diverse information from multiple news articles discussing the same news story. To facilitate this task, we construct a dataset, DIVERSESUMM, using our proposed QA-based pipeline. Through meticulous human evaluation, we have demonstrated that although LLMs exhibit a high level of faithfulness in tackling our task, achieving a high coverage rate remains particularly challenging, even with the most advanced LLM like GPT-4. This underscores both the challenges and opportunities of MDDS.

Furthermore, we have conducted an extensive analysis of bias and its correlation with human assessments across a range of evaluation protocols. Leveraging the insights obtained from these experiments, we propose a set of recommendations that outline the most effective protocols for evaluating model performance within our task domain. Our paper also delves into a comprehensive study that investigates LLMs' tendency to summarize various types of information. The outcomes of these analyses offer valuable insights into the behaviors exhibited by different LLMs when they engage with the challenge of summarizing diverse information. By presenting these resources and research findings, we hope to inspire and motivate future endeavors in the realm of comprehending and summarizing the intricate nuances present in diverse news articles concerning the same news event.

7 Ethical Considerations

In §3 and §4.1, we engaged annotators for data annotation and human evaluation. We prioritized fair compensation for our participants, with details provided in Appendix A. To foster an ethical working environment, we allowed participants to set their own pace, facilitated open communication

for any concerns, and provided the option to withdraw from the project at any time without repercussions. Additionally, we took measures to ensure the anonymity of the data annotations by avoiding the inclusion of any personally identifiable information.

8 Limitation

This study contributes significantly to the field of multi-document summarization by providing a larger and more comprehensive dataset than those available in previous research. However, there are several limitations that must be acknowledged.

Firstly, despite our best efforts to curate a large enough dataset, it still represents a relatively small fraction of the vast array of news content available online. This limitation is intrinsic to the task at hand, given the financial implications of human annotation and the complexity of multi-document summarization necessitates that annotators thoroughly read and understand multiple articles, which exponentially increases the time and cost associated with the annotation process compared to single-document summarization.

Moreover, while we carried out thorough LLM-based evaluations, we did not investigate the exact influence of different prompts on the LLM's performance. Even though we have tried our best to manually optimize the prompts, the lack of analysis on prompt sensitivity could lead to slightly different outcomes.

Furthermore, as our dataset encompasses online news articles, the study may not adequately capture the complexity of summarizing documents from diverse domains. News articles often follow a particular structure, which might not be prevalent in other kinds of multi-document contexts, such as academic papers or legal documents. Consequently, the generalizability of our findings and the utility of the dataset beyond the news domain demands further analysis.

A Are our findings in §4.2 still reproducible after a GPT-4 update every two months?

While it's a valid concern that the evolution of GPT models could impact the reproducibility of our findings, it's important to note that the principles highlighted in this research are not necessarily tied to the specific version of the GPT model itself, but rather how these language models work conceptually. The potential biases and evaluation techniques of GPT-4 we discuss can likely be applied or adapted to newer versions as well.

Naturally, with the release of an updated model, a new set of tests would be ideal to validate whether these findings hold. But this is true of any research in changing and evolving fields and does not detract from the value of our current findings. If anything, our research forms a foundation to more effectively assess future iterations of the GPT models in terms of evaluating coverage and faithfulness.

B Human Annotation

In this section, we illustrate the details of our human annotation process.

B.1 Worker Qualification

We established specific preliminary criteria for the recruitment of MTurk workers who possess strong performance histories. These criteria include having a HIT approval rate of 99% or higher, having approved a minimum of 10,000 HITs, and being located within the United Kingdom, Canada, and the United States.

Furthermore, apart from these preliminary criteria, eligible workers are required to pass three rounds of qualification tests centered around the faithfulness evaluation task, which is illustrated in Table 2. To streamline the qualification process, the authors manually annotate 3 HITs. Each HIT comprises ten news articles and four summaries generated by four different models. During each qualification round, annotators are presented with one of these annotated samples. Workers whose annotations do not exhibit a sufficiently high level of agreement with our annotations are excluded from the selection process.

Ultimately, 16 annotators who successfully passed all three rounds of qualification tests were selected. All the human evaluations and annotations are conducted by these 16 annotators. Additionally, every HIT has been meticulously designed to ensure that annotators can achieve an equivalent

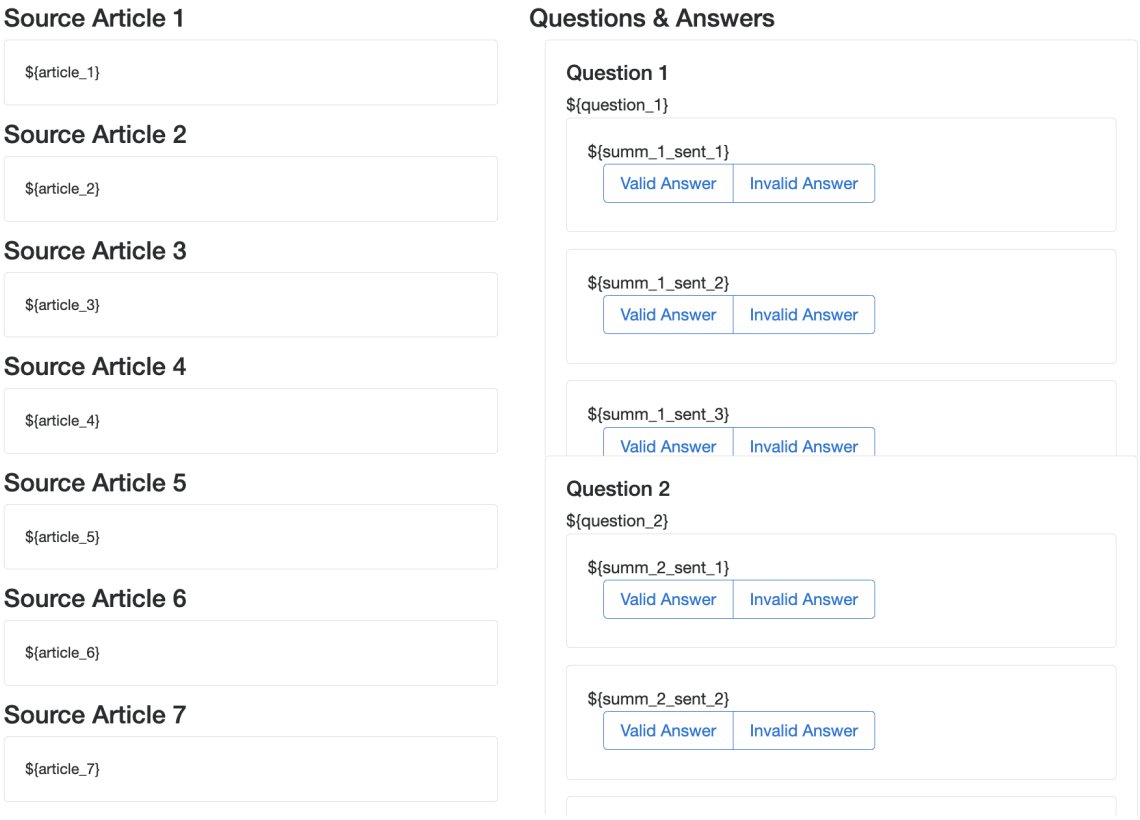

Figure 6: Annotation interface for filtering invalid QA pairs.

hourly pay rate of $20 provided they work continuously.

B.2 Annotating QAs

When annotating QA pairs, annotators are presented with the post-processed results detailed in §3.1. Below, we show the guidelines and the annotation interface presented to the annotators...

Guideline In this task, you will evaluate the validity of several answers with regard to the corresponding questions. To correctly solve this task, follow these steps:

- Carefully read the questions, answers, and the source articles.
- For each answer, check it against the question and the list of source articles.
- An answer is **Valid** if and only if (1) it **addresses the question, AND** (2) **at least one article contains such information** (It does not have to be word by word. It is sufficient that the information presented in the answer can be found in at least one article).

Warning: Annotations will be checked for quality against control labels, **low-quality work will be rejected**.

Valid answer: The validity depends on if the information in the answer is mentioned/supported by any source articles, not if the exact words are stated in the source articles. A valid answer should also provide a response that addresses the question it is paired with. Answer not addressing the question or suggesting no information should be marked as **Invalid Answer**. Examples of **Invalid Answer** are shown below:

- Question: What are the foreign impact of ...? Answer: The domestic influence of ...
- The article does not provide a clear answer to ...
- ... is not discussed in the article.
- As a language model, I cannot ...

Interface The annotation interface for filtering invalid QA pairs is presented in Figure 6.

B.3 Coverage Evaluation

Guideline In this task, you will evaluate the *coverage* of several statements with regard to the corresponding summaries. The statements are derived from news articles. To correctly solve this task, follow these steps:

- Carefully read the statements and the summaries.
- For each statement, check it against the corresponding summary.
- A statement is **Covered** if and only if it is mentioned or supported by the corresponding summary. (**It does not have to be word by word**. It is sufficient that the information presented in the statement can be found in the corresponding summary).

Warning: Annotations will be checked for quality against control labels, **low-quality work will be rejected**.

Covered Statement: The coverage depends on if the information in the statement is mentioned/supported by the corresponding summary, not if the exact words are stated in the corresponding summary. Some summaries may contain article number. Please ignore the article number and focus on whether the information in the statement is mentioned/supported by the corresponding summary.

Evaluation Interface The interface for coverage evaluation is shown in Figure 7.

B.4 Faithfulness Evaluation

Guidelines In this task, you will evaluate the *faithfulness* between each sentence of automatically generated summaries and a list of source articles used to generate the summaries. To correctly solve this task, follow these steps:

- Carefully read the generated summaries and the source articles.
- For each sentence, compare it against the list of source articles and decide if any of the source articles support this **sentence**.
- If there is at least one article that supports this sentence, rate the sentence as **Present**. Otherwise, select **Not Present**.

Warning: Annotations will be checked for quality against control labels, **low-quality work will be rejected**.

Faithfulness: The rating depends on if the information in the generated sentence is mentioned/supported by any source articles, not if the exact words are stated in the source articles Nonsense sentences should always be considered unfaithful, and you should select Not Present. Examples of these are shown below:

- As a language model, I cannot ...
- I am ready to summarize...
- Please provide the next set of news sentences...
- Sentence 1: 1: \n* n* 1: 1: 1: 1: 1:

Interface We display the interface for faithfulness evaluation in Figure 8.

B.5 Inter-annotator Agreement

We compute the quality of our annotations and evaluations using Krippendorff's Alpha (Krippendorff, 1970). For faithfulness and coverage evaluations, the inter-annotator agreement is 0.61 and 0.60, respectively. For reference annotations, the inter-annotator agreement is 0.69. These numbers represent a moderate to high agreement.

C LLM Prompts

In this section, we display all the prompts used in our experiments. Texts marked in boldface indicate placeholders.

C.1 LLM Prompts for Reference Annotation

Data collection pipeline consists of three components that are based on prompting ChatGPT: question generation, question answering, and post-processing. The prompt to each component is displayed in Figure 9, Figure 10, and Figure 11, respectively.

C.2 LLM Prompts for Summarization

We use different prompts for long-context and standard LLMs since the latter does not have long enough contexts to process all the input articles. The prompt template for long-context LLMs is displayed in Figure 13, while the two prompt templates for standard LLMs are shown in Figure 14 and Figure 15.

Note that the prompts displayed in the above-mentioned figures have undergone meticulous prompt engineering. We found that these prompts in general produce summaries with a higher coverage. In particular, we found that adding "Don't worry about the summary being too lengthy." in the prompt to GPT-4 is the key to generating more comprehensive summaries. As a comparison, we show our initial prompt to long-context LLMs in Figure 16, which is much shorter than the prompt in Figure 13. We use summary length to approximate coverage. As shown in Figure 12, the final prompt we used can significantly increase the length of the generated summaries.

C.3 LLM Prompts for Evaluation

In this section, we display the prompts to GPT-4 used in our evaluation.

D LLM Bias Analysis

In this section, we present the details of the bias analysis we conducted in §4.2.

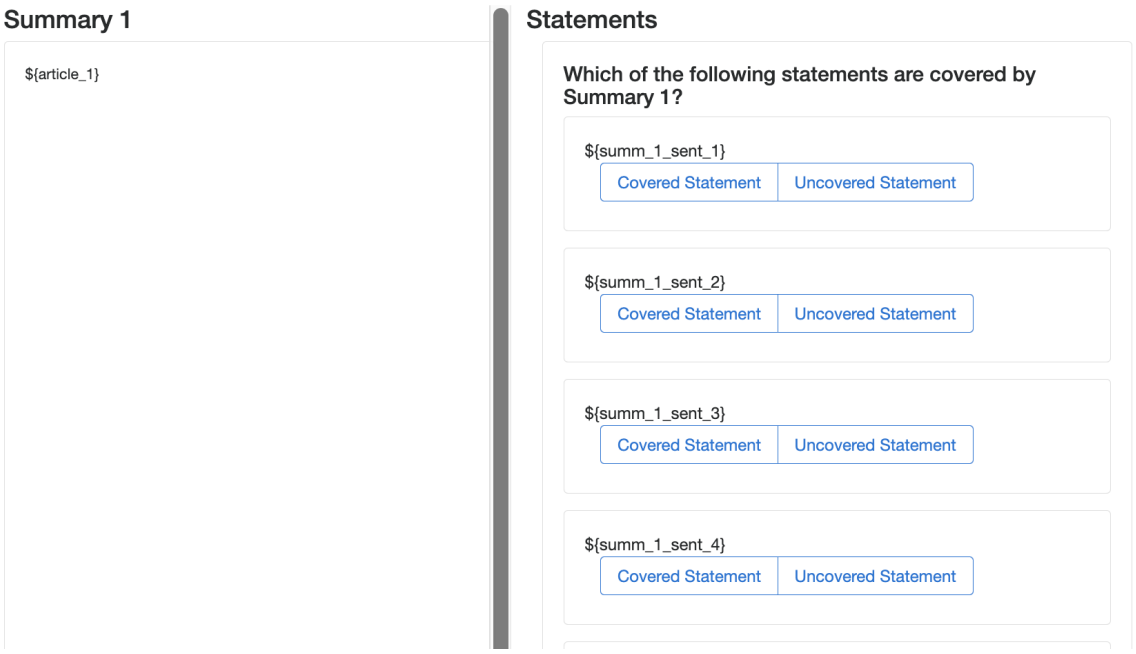

Figure 7: Interface for coverage evaluation.

D.1 Position Bias

As discussed in §4.2, position bias is most relevant to pairwise comparison. Figure 23 shows the breakdown analysis for coverage evaluation, while the faithfulness evaluation is displayed in Figure 24. In both coverage and faithfulness evaluation, the evaluator based on GPT-4 exhibits significant preference towards the second summaries placed in the inputs. In particular, we observe that position bias is most serious when the quality of two summaries is very similar (e.g. (a) in Figure 23).

D.2 Verbosity Bias

As illustrated in Table 4, pairwise comparison can significantly mitigate the verbosity bias. Hence, in the section, we only show the results for single-answer grading (see Figure 25). We see that the GPT-4-based evaluator prefers shorter summaries for all models, no matter when evaluating faithfulness or coverage. The result is surprising since we expect GPT-4 to prefer longer summaries when performing coverage evaluation.

E Topic and Question Distribution

Figure 26 and Figure 27 show the topic distribution and question distribution of our DIVERSESUMM dataset.

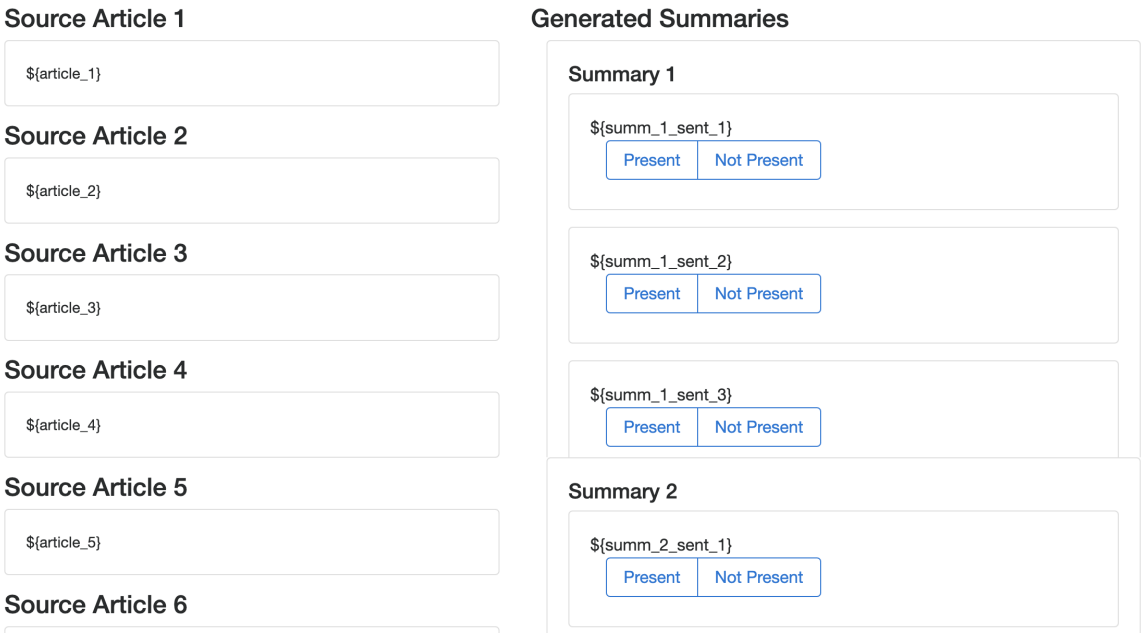

Figure 8: Interface for faithfulness evaluation.

[NEWS ARTICLES]
Given the above news articles. Complete the below two tasks:
Task 1: Write down 5 central factual questions for the news event that most sources will have likely answered. These questions, and their answer should relate the most important facts of the event. For example, for the US Presidential Election, the questions might be: Who won the election? What is the electoral college vote? What is the popular vote? What is the margin of victory? (each question should be up to 14 words)
Task 2: Write down 15 opinion or prediction questions for the news event that most sources will have likely answered in a unique way. These questions, and their answer should surface important points that news sources might analyze or present differently. For example, the questions might be: Who is more likely to win an election? Will there be a recession in 2023? What are the causes to the recession? (each question should be up to 14 words)
In your answer, specify the task number explicitly (Task 1, Task 2), and use line breaks between tasks, so that your report is structured.

Figure 9: The prompt for question generation.

Read the following news article and answer only the question '{question}'. Extract the exact sentence from the article changing up to 5 words. You should include ALL the answers that can be found in the article and must give your answers in a structured format: 'Answer 1: [extracted answer 1] \n Answer 2: [extracted answer 2] ...'. If the article contains no information to the given question, write: 'No Answer'.

[ARTICLES]
Read the above articles as well as the question and extracted answers below.
Task 1: Identify ALL the invalid answers that does NOT make sense or cannot be used to answer the question. You should specify the answer with their corresponding number: "Answer x: [answer x], Answer y: [answer y],...", where x and y are the number of the answer. If no such answer, then write down "Task 1: No invalid answers.".
Task 2: Identify ALL the answers that contradict with each other or form diverse information/opinion. These answers should not be invalid (i.e. should not be included in your responses for Task 1). You should specify the answer with their corresponding number: "Answer x: [answer x], Answer y: [answer y],...", where x and y are the number of the answer. If no such answer, then write down "Task 2: No diverse/conflicting answers.".
In your response, specify the task number explicitly (Task 1, Task 2), and use line breaks between tasks, so that your report is structured. The answer numbering in your response "Answer x: [answer x]" should correspond to the exact answer numbering and answer as shown below. Do not provide explanation for your response.

Abstract

Ensuring factual consistency is crucial for natural language generation tasks, particularly in abstractive summarization, where preserving the integrity of information is paramount. Prior works on evaluating factual consistency of summarization often take the entailment-based approaches that first generate perturbed (factual inconsistent) summaries and then train a classifier on the generated data to detect the factually inconsistencies during testing time. However, previous approaches generating perturbed summaries are either of *low coherence* or *lack error-type coverage*. To address these issues, we propose AMRFACT, a framework that generates perturbed summaries using Abstract Meaning Representations (AMRs). Our approach parses factually consistent summaries into AMR graphs and injects controlled factual inconsistencies to create negative examples, allowing for coherent factually inconsistent summaries to be generated with high error-type coverage. Additionally, we present a data selection module NEGFILTER based on natural language inference and BARTSCORE to ensure the quality of the generated negative samples. Experimental results demonstrate our approach significantly outperforms previous systems on the AGGREFACT-FTSOTA benchmark, showcasing its efficacy in evaluating factuality of abstractive summarization.[1]

1 Introduction

Recent advances in text summarization, driven by pre-trained language models, have enabled the generation of coherent abstractive summaries (Zhang et al., 2019; Raffel et al., 2019; Lewis et al., 2020). However, studies have shown that these generated summaries can be factually inconsistent with the source documents (Goodrich et al., 2019; Kryscinski et al., 2020; Pagnoni et al., 2021; Huang et al., 2023c; Kim et al., 2024). This inconsistency between the generated summary and the factual information in the source document necessitates the need for assessing the *factuality* or factual consistency of the summaries.

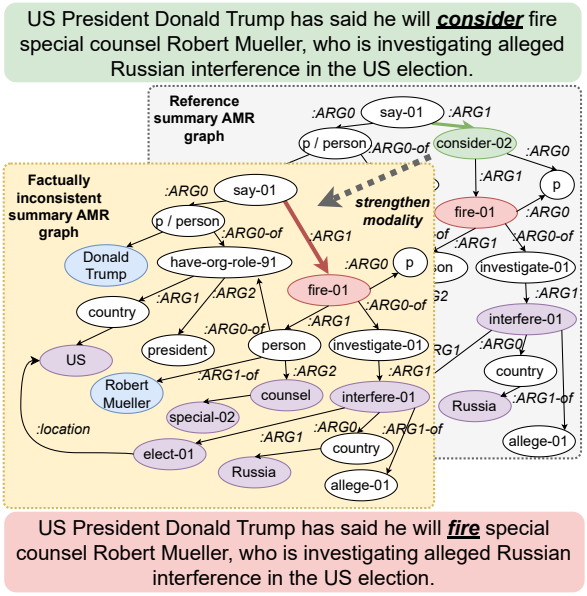

Figure 1: Example of a reference (green) and a generated factually inconsistent summary (red) from the AMRFACT dataset. Given a reference summary, we convert the text into an AMR graph (grey) and then remove " consider-02" to generate a factually inconsistent summary AMR graph (yellow). This perturbed summary strengthens the modality in the reference summary, resulting in factual inconsistency. The reference and perturbed summaries will be used as positive and negative examples, respectively.

Recent work formulated factual inconsistency detection as an entailment recognition task, predicting whether the source document entails a summary. The prevalent approach for developing an entailment-based factual consistency metric involves generating synthetic data and training a classifier on it. Kryscinski et al. (2020) treats reference summaries from CNN/DM (Hermann et al., 2015) as positive examples and applies entity-centric perturbations, such as entity replacement,

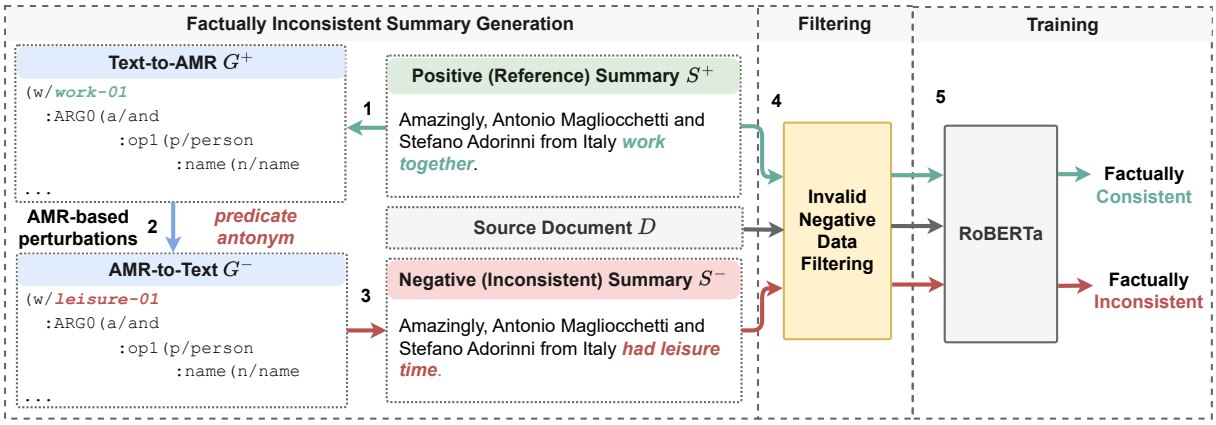

Figure 2: Overview of AMRFACT training phase: (1) The generation module first converts the reference summaries into AMR graphs. (2) These graphs are then manipulated to include common factual errors shown in current summarization systems, creating factually inconsistent AMR graphs. (3) These manipulated graphs are back-translated into text summaries, serving as negative examples for training a text-based factuality evaluator. (4) A selection module, using NLI score and BARTSCORE, filters out low-quality negative examples. (5) Finally, we fine-tune a ROBERTA-based model with this data to act as the *evaluation metric*, assessing factuality by comparing the original document (premise) with the summary (hypothesis) and measuring the probability of entailment.

to the reference summaries to create negative samples (*i.e.*, summaries factually inconsistent with the source document). However, such an approach often produces sentences with poor coherence caused by the string replacement operations. Goyal and Durrett (2021) and Utama et al. (2022) address the coherence issue by training a paraphrasing model and a text-infilling model to produce negative data. Yet, these approaches cannot ensure the production of specific types of factual errors illustrated in Pagnoni et al. (2021). As a result, models trained on data produced by these methods may not reliably detect particular types of factual inconsistency in summaries. We refer to this limitation as a lack of "*error-type coverage*". Besides, all prior methods lack a verification step to *validate* the quality of the generated data, potentially leading to diminished performance in detecting factual inconsistency.

Motivated by these challenges, we propose AMRFACT, a framework that generates **coherent negative examples** with **high error-type coverage**. Our data generation module leverages Abstract Meaning Representations (AMRs) (Banarescu et al., 2013) to introduce semantic-level perturbations for creating negative examples, enabling us to generate more coherent summaries without compromising the error-type coverage. AMRs are intended to capture the meaning of a sentence by abstracting away irrelevant syntactic features. This feature allows us to maintain coherence while precisely tailoring our negative examples to target specific factual error types. As shown in prior research (Lee et al., 2021), AMR's *controllability* empowers us to easily shape the distribution of negatives, making our approach highly adaptable and effective in addressing the identified challenges.

In detail, AMRFACT starts with parsing factually consistent summaries into semantic AMR graphs, and then injects factual inconsistencies (errors) that are *commonly* observed in state-of-the-art summarization systems (Pagnoni et al., 2021) into the AMR graphs (Ghazarian et al., 2022; Ribeiro et al., 2022). These perturbed AMR graphs are subsequently translated back into text summaries to serve as our negative examples using a controllable generation model, which ensures that the generated summaries retain a *natural* and *coherent* narrative flow. Figure 1 shows an example of such AMR-based data generation. Then, we devise a novel selection module NEGFILTER to exclude invalid negative samples from our training data. A *valid* negative summary must satisfy two criteria: (1) it must not be directly inferable from the original summary and (2) it should not stray significantly from the main topic of the document. We employ sentence-level NLI and BARTSCORE to ensure compliance with each criterion, respectively. Finally, a ROBERTA (Liu et al., 2019) model is trained on the created dataset along to distinguish factually consistent and inconsistent summaries as the evaluation metric. Figure 2 offers an overview of our proposed framework. The highlights of our contributions include:

- We propose AMRFACT that uses AMR-based perturbations to generate factually inconsistent summaries, which allows for more coher-

Source document fragment: (CNN) -- Martina Hingis and Anna Kournikova will team up again to play at this year's Wimbledon championships. [...] Swiss star Hingis won five grand slam singles crowns and nine in doubles during a glittering career which ended under a cloud in 2007, when she was suspended for two years for testing positive for cocaine at Wimbledon. [...]
Reference summary: Hingis has ended a two-year ban after testing positive for cocaine at 2007 Wimbledon.

Error Type	Description	Example
Predicate Error	The predicate of the summary does not align with the information provided in the original document.	Hingis began a two-year ban after testing positive for cocaine at 2007 Wimbledon.
Entity Error	The primary arguments, or their attributes, associated with the predicate are incorrect.	Kournikova began a two-year ban after testing positive for cocaine at Wimbledon in 2007.
Circumstance Error	The supplementary details, such as location or time, that define the context of a predicate are incorrect.	Hingis began a two-year ban after testing positive for cocaine at Wimbledon in 2014.
Discourse Link Error	Errors arise from the improper connection of statements within the discourse, such as errors in temporal ordering or causal link.	Hingis began a two-year ban before testing positive for cocaine at Wimbledon in 2007.
Out of Article Error	The statement conveys information that is absent in the original document.	Hingis and Kournikova will team up again to play at this year's All England Club.

Figure 3: Typology of factual errors. Given the source document and reference summary, we apply five kinds of factual inconsistencies: predicate error, entity error, circumstance error, discourse link error, and out-of-article error. Each color represents the implementation of one kind of factual error from reference summary to perturbed summary.

ent generation with high error-type coverage.

- We devise a data validation module NEGFILTER to filter out invalid negative summaries to enhance the quality of generated data.
- Our approach achieves state-of-the-art performance on the AGGREFACT-FTSOTA dataset.

2 Abstract Meaning Representations

Introduced by Banarescu et al. (2013), AMR is a representation language that effectively captures the essence of texts by encoding abstract-level semantic information, including named entities, negations, coreferences, and modalities. This intrinsic capability positions AMR as a critical asset for various semantic-related NLP tasks, such as summarization (Liao et al., 2018) and machine translation (Song et al., 2019). In our study, we harness the potential of AMR in the summarization factuality evaluation task by perturbing the graphs of factually consistent summaries. **Each perturbation reflects a factual error in summarization.** In AMR graphs, nodes symbolize entities and concepts, connected through different relational edges. Figure 1 provides an example of an AMR graph for a summary.

3 AMRFACT

In AMRFACT, we start by parsing reference summaries into AMR graphs and then introduce factual errors into these graphs. Subsequently, we back-translate the perturbed AMR graphs into text and use data filtering to acquire high-quality negative training samples. Finally, we combine the positive samples (reference summaries) with the negatives to train a classifier, which serves as our factuality evaluation metric. More specifically, the process of *generating* factually inconsistent summaries involves two primary states: introducing summary-level perturbations based on AMR and invalid negative data filtering. They are discussed in more detail in the following sections dedicated to explaining how factual errors are introduces (§3.1) and the criteria for choosing valid negative examples (§3.2).

3.1 AMR-based Summary Perturbations

Our approach targets five types of *factual inconsistencies*: predicate error, entity error, circumstance error, discourse link error, and out-of-article error, as categorized by Pagnoni et al. (2021)[2]. A detailed description of these factual errors is presented in Figure 3. Each type of errors can be generated by perturbing the AMR graph of a summary that is initially factually consistent, and then reconverting the perturbed graph back into a natural language summary. Specifically, we start with a source document D alongside its factually consistent summary S^+, which is then parsed into an acyclic AMR graph G^+. This graph is manipulated to form a new AMR graph G^- that embodies factual inconsistencies. For instance, as illustrated in Figure 2, we produce a predicate error by swapping the original predicate "work" to "leisure". The perturbed

[2]We do not discuss or implement coreference errors because this work targets sentence-level summaries, and it is hard for them to contain pronouns or references with wrong or nonexisting antecedents.

AMR graph G^- is then transformed into a factually inconsistent natural language summary S^- using an AMR-to-Text model (Ribeiro et al., 2021)[3].

Predicate Error. Predicate errors occur when the predicate in a summary does not align with the information in the source document. We simulate this type of error based on two processes: (1) by adding or removing polarity and (2) through the substitution of a predicate with its antonym. By directly adding or removing *polarity* to the concpets, we change the negation in the sentence. Another approach is the antonym substitution. Here, we replace the concepts with their antonyms that holds *Antonym*, *NotDesires*, *NotCapableOf*, and *NotHasProperty* relations in ConceptNet (Speer and Havasi, 2012), and therefore modify the sentence-level relations.

Entity Error. Entity errors manifest when the entities associated with a predicate in a summary are incorrectly attributed or erroneous. These errors are crafted through two principal sources: (1) by swapping the roles of the agent and the patient, which results in the misattribution of actions or characteristics, and (2) by substituting specific entities, such as names and numbers. In AMR graphs, the clear distinction between agent (*ARG0*) and patient (*ARG1*) allows for straightforward swaps. We implement agent-patient swaps by exchanging the roles of the agent and the patient. Here, the agent refers to an action doer, and the patient refers to an action recipient. We randomly choose a verb from the sentence in our implementations. For named entity modifications, we identify the nodes holding roles such as *name* and *quant* and then randomly select one to be replaced by a different node with the same role from the same source document.

Circumstance Error. Circumstance errors in summaries emerge when there is incorrect or misleading information regarding the context of predicate interactions, specifically in terms of location, time, and modality. These errors are mainly created in two ways: (1) by intensifying the modality, which alters the degree of certainty or possibility expressed in the statement, and (2) by substituting specific entities like locations and times. We strengthen the modality by replacing the concepts that controls modals (*e.g.*, *permit* → *obligate*). For entity substitution, we identify the nodes holding roles such as *location*, *date*, and *time* and then randomly select one to be replaced by a different node with the same role from the same source document.

Discourse Link Error. Discourse link errors pertain to mistakes in the logical connections between various statements in a summary. We focus on two fundamental types of discourse links: (1) temporal order, which deals with the sequence of events, and (2) causality, which pertains to the cause-and-effect relationships between statements. To manipulate temporal ordering, we perturb the nodes holding concepts such as *before*, *after*, or *now*. For causality modifications, we alter argument structures associated with *cause*, either at the root or as a modifier, effectively reversing the causal relationship.

Out of Article Error. Summaries are expected to contain only information that can be inferred from the source document, and deviations from this rule need to be clearly identified. To create an "out of article" error, we follow a similar method as previously discussed, involving alterations in entities, times, or locations. However, in this instance, we intentionally introduce vocabulary *not* present in the original document.

3.2 Invalid Negative Data Filtering

In our data generation process, we noticed that certain generated negative examples either blatantly contradicted the source article's facts or failed to modify the semantics of the reference summary, inadvertently becoming *positive* examples.

These were deemed as *invalid* negative examples. We hypothesize that **training detection models on such invalid negative data could potentially impair their performance**. To address this issue, we introduce a module NEGFILTER specifically designed for filtering out invalid negative data.

A perturbed summary is considered *valid* only if it satisfy two essential criteria: (1) it must be sufficiently distinct from the original summary to avoid being mistaken for a mere variation, thereby ensuring it is not misclassified as a positive example; and (2) despite the introduced perturbations, it should maintain a discernible connection to the source document, without diverging excessively.

To ensure the first criterion – *distinctiveness of generated summaries* – we utilize sentence-level NLI inspired by previous studies (Wan and Bansal, 2022; Huang et al., 2023a,b). Concretely, we employ a RoBERTa large model fine-tuned on the

[3]We utilize the Text-to-AMR and AMR-to-Text models from https://github.com/bjascob/amrlib-models.

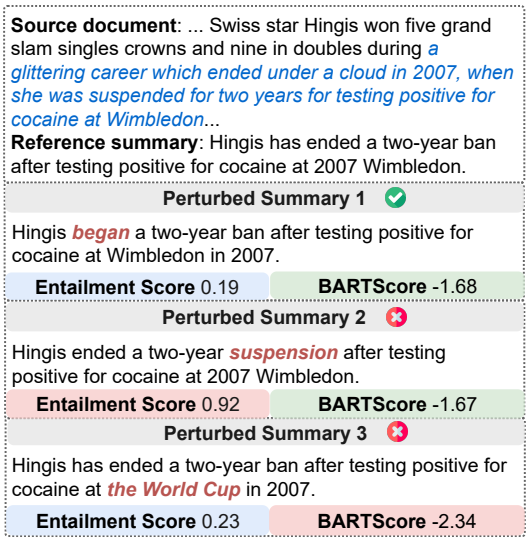

Figure 4: An illustration showing how our invalid negative data filtering module works. In the above three examples, only the first perturbed summary is valid since both of its entailment score and BARTSCORE satisfy the criteria described in §3.2.

MNLI corpus (Liu et al., 2019; Williams et al., 2018)[4] to quantify the entailment score between an original summary (S^+) and its perturbed counterpart (S^-). Then, perturbed summaries that score exceed an empirically selected threshold (τ_1) in entailment scores are discarded, given their elevated likelihood of being inferred from S^+.

For the second criterion – *maintaining relevance to the source document* – we propose to use BARTSCORE (Yuan et al., 2021), fine-tuned on the CNN/DM dataset (Hermann et al., 2015), to assess the semantic alignment between the perturbed summary (S^-) and its corresponding source document (D). Similarly, perturbed summaries with a BARTSCORE falling below the empirically determined threshold (τ_2) are excluded due to their divergence from the source documents.

In summary, our proposed high-quality negative examples selection module NEGFILTER will take a source document (D), an original summary (S^+), and a perturbed summary (S^-). Only when both criteria are satisfied, the generated factually inconsistent summaries (S^-) will be included into our negative training examples. Formally,

$$\mathcal{M}(D, S^+, S^-) = \textbf{True} \text{ if and only if}$$
$$\mathbb{1}[\mathcal{N}(S^+, S^-) < \tau_1] \cdot \mathbb{1}[\mathcal{B}(D, S^-) > \tau_2] = 1, \quad (1)$$

where N represents the entailment score, and B denotes BARTSCORE. The selection of thresholds is discussed in detail in §4.4. Figure 4 provides an illustration of our proposed selection module.

3.3 Detecting Factual Inconsistency

To learn to detect factual inconsistency, we fine-tune a `roberta-large` model pre-trained on the MNLI corpus on our AMRFACT dataset.[4] We directly adopt this pretrained model because the goal of natural language inference is very similar to that of factual inconsistency detection, *i.e.*, predicting whether a given summary hypothesis (S^+ or S^-) can be entailed (factually consistent) with the given document premise (D). Although our output linear layer performs a three-way classification, since we only focus on two-way classification, *i.e.*, factual consistency and inconsistency, we will only pay attention to the "entailment" and "contradiction" outputs. The training data paired with the reference summaries are labeled as "entailment," whereas those coupled with the perturbed summaries are labeled as "contradiction."

4 Experimental Settings

4.1 Datasets

Training Dataset We apply the AMRFACT data generation pipeline to the training split of the CNN/DM corpus (Hermann et al., 2015), compromising English news articles and their associated human-generated summaries. In our approach to generating negative training data, we start with segmenting reference summaries into individual sentences. To finish this step efficiently, we reuse sentences from the positive samples of the FALSESUM (Utama et al., 2022) training dataset. This process yields 143,942 high-quality positive examples. Subsequently, we employ five distinct types of AMR-based perturbations on these positive examples. The perturbation process was exhaustive, meaning each positive example could lead to *zero* to *several* negative examples. After applying perturbations, we obtain 141,570 negative samples. These negative samples are then filtered by NEGFILTER and combined with the positive examples (reference summaries) to form our training dataset. Eventually, our dataset consists of 13,834 training and 2,000 validation instances, where we ensure an equal number of positive and negative data. Specifically, the dataset contains 35.85% predicate errors, 33.75% entity errors, 10.55% circumstance errors, 3.7% discourse link errors, and 16.16% errors that are out of the article's scope.

Table 1: Statistics of AGGREFACT-CNN-FTSOTA and AGGREFACT-XSUM-FTSOTA. These two subsets consist of Polytope (Huang et al., 2020), SummEval (Fabbri et al., 2021), FRANK (Pagnoni et al., 2021), Wang'20 (Wang et al., 2020), CLIFF (Cao and Wang, 2021), Goyal'21 (Goyal and Durrett, 2021), Cao'22 (Cao et al., 2022). Each number in the table represents the number of samples.

Evaluation Dataset Tang et al. (2023) introduced the benchmark **AGGREFACT**, which consolidates *nine* existing datasets focused on factuality for a finer-grained comparison of factuality assessment systems. They stratify the benchmark based on the underlying summarization model, categorized into FTSOTA, EXFORMER, and OLD according to their development timeline. FTSOTA encompasses state-of-the-art fine-tuned summarization models, such as BART (Lewis et al., 2020) and PEGASUS (Zhang et al., 2019). Models in the EXFORMER and OLD split were developed much earlier, such as Pointer-Generator (See et al., 2017). In line with Tang et al. (2023)'s recommendations, our performance reporting focuses on the FTSOTA split, as it most accurately reflects the challenges of unfaithfulness in the *most advanced* summarization models. Table 1 shows the statistics of AGGREFACT-FTSOTA.

4.2 Baseline Models

We compared AMRFACT with the following *non-LLM* methods. **FACTCC** (Kryscinski et al., 2020) is an entailment-based metric trained on synthetic data created through rule-based transformations of source document sentences. **DAE** (Goyal and Durrett, 2021) proposes an arc entailment approach that evaluates the factuality of each dependency arc of the generated summary independently with respect to the input article and then uses their aggregation as the overall score. Unlike previous work that reports the performance of DAE trained on human-annotated data, we opt for DAE-ENT, a variant of DAE trained on synthetic data, for fair comparison. **QUESTEVAL** (Scialom et al., 2021) introduces a QA-based metric that calculates factuality by aggregating answer overlap scores from queries derived from both the input article and the summary. **SUMMAC** (Laban et al., 2022) focuses on detecting factual inconsistencies by aggregating sentence-level entailment scores between the input document and summary sentences, with (**CONV**) or without (**ZS**) further fine-tuning. **QAFACTEVAL** (Fabbri et al., 2022) is a QA-based metric analogous to the precision-based component of QUESTEVAL and includes optimized question answering, generation, and answer-overlap components. **ALIGNSCORE** (Zha et al., 2023) learns a metric based on information alignment between two texts by integrating a diverse range of data sources. **FALSESUM** (Utama et al., 2022) is an entailment-based method that is trained on negative data produced by infilling masked spans of reference summaries with control code. For a fair comparison with entailment-based models, we retrain FACTCC and FALSESUM with `roberta-large-mnli` as the base models.

In addition, we also compared with *LLM-based* methods. We tested **ChatGPT** (OpenAI, 2023) using different prompts (Luo et al., 2023; Wang et al., 2023): zero-shot binary rating (**ZS**), zero-shot binary rating with chain-of-thought (**COT**), direct assessment on a continuous scale from 0 to 100 (**DA**), and direct assessment on a discrete scale of one-to-five (**STAR**). **G-EVAL** (Liu et al., 2023) uses chain-of-thoughts and a form-filling template to produce a discrte scale of one-to-five. We implement it with GPT-4 Turbo (`gpt-4-1106-preview`).

4.3 Evaluation Criteria

We use balanced accuracy (Brodersen et al., 2010) as our evaluation metric. Then, we set a threshold for each model such that the threshold optimizes its performance on the validation split, following Laban et al. (2022). Therefore, our models will produce a binary label instead of a scalar value.

4.4 Threshold Selection for NEGFILTER

The thresholds for our NEGFILTER module, τ_1 and τ_2, are meticulously chosen to reach the best balanced accuracy on the validation split of AGGREFACT-FTSOTA dataset. The selection criteria aim to strike a delicate balance: eliminating low-quality negative samples while preserving a rich variety of error types within the training dataset. For optimal results, we configured τ_1 to 0.9 and τ_2 to -1.8.

	AGGREFACT-CNN-FTSOTA	AGGREFACT-XSUM-FTSOTA	AVG
Non-LLM-based			
DAE	65.0 ± 3.5	62.3 ± 1.9	63.7
QUESTEVAL	70.2 ± 3.2	59.5 ± 2.7	64.9
SUMMAC-ZS	64.0 ± 3.8	56.4 ± 1.2	60.2
SUMMAC-CONV	61.0 ± 3.9	65.0 ± 2.2	63.0
QAFACTEVAL	67.8 ± 4.1	63.9 ± 2.4	65.9
FACTCC	57.6 ± 3.9	57.2 ± 1.7	57.4
FALSESUM	50.5 ± 3.3	54.7 ± 1.9	52.6
ALIGNSCORE	67.0 ± 3.1	60.3 ± 1.9	63.7
LLM-based			
CHATGPT-ZS	56.3 ± 2.9	62.7 ± 1.7	59.5
CHATGPT-COT	52.5 ± 3.3	55.9 ± 2.1	54.2
CHATGPT-DA	53.7 ± 3.5	54.9 ± 1.9	54.3
CHATGPT-STAR	56.3 ± 3.1	57.8 ± 0.2	57.1
G-EVAL	69.9 ± 3.5	**65.8 ± 1.9**	67.9
AMRFACT (ours)	**72.3 ± 2.5**	64.1 ± 1.8	**68.2**

Table 2: Balanced binary accuracy (%) on the AGGREFACT-FTSOTA test set. We show 95% confidence intervals. Highest performance is highlighted in **bold**. The AVG score is computed by taking the arithmetic average of the performance on AGGREFACT-CNN-FTSOTA and AGGREFACT-XSUM-FTSOTA.

	AGGREFACT-CNN-FTSOTA	AGGREFACT-XSUM-FTSOTA	AVG
FACTCC	57.6 ± 3.9	57.2 ± 1.7	57.4
+ Filtering	67.9 ± 2.3	63.8 ± 2.2	65.8
FALSESUM	50.5 ± 3.3	54.7 ± 1.9	52.6
+ Filtering	52.3 ± 1.8	59.7 ± 2.2	56.0
AMRFACT (ours)	**72.3 ± 2.5**	**64.1 ± 1.8**	**68.2**
- Filtering	64.4 ± 3.0	57.8 ± 2.0	61.1

5 Results and Discussion

5.1 Main Results

The summarized results in Table 2 indicates that our model AMRFACT sets a new benchmark on the AGGREFACT-FTSOTA test set. We report the performance on CNN/DM and XSUM using separate thresholds, following Tang et al. (2023). AMRFACT establishes a new state-of-the-art score of 72.3% on the CNN/DM split, outperforming the nearest competitor by a margin of 2.1%. On XSUM split, our model's performance is competitive, tying with the highest score at 64.1%. With an overall average score of 68.2% across both datasets, we outperform the previous best model by 2.3% over all non-LLM approaches. The improvements underscore the advantage of incorporating AMR in generating training data and the strategic selection of high-quality negative data through our data selection module.

5.2 Impact of Our Filtering Module

To validate the *effectiveness* and *generalizability* of our invalid negative data filtering component NEGFILTER, we apply this module to the data generated by FACTCC and FALSESUM and re-train a ROBERTA on these newly filtered data. Additionally, we train another ROBERTA on our generated data without the filtering component. The results are summarized in Table 3. Specifically, we use all training samples from FACTCC (1,003,355 samples), FALSESUM (287,884 samples), and AMRFACT (283,140 samples) to train models without filtering, respectively. Furthermore, the FALSESUM and FACTCC datasets retain 25,258 and 81,270 training samples, respectively, after undergoing the same filtering process as AMRFACT (*i.e.*, same τ_1 and τ_2). We observe a substantial performance gain when all three data generation methods incorporate the proposed invalid data filtering module. Specifically, FACTCC's balanced accuracy improves from 57.6% to 67.9% on the CNN/DM and from 57.2% to 63.8% on XSUM, while FALSESUM sees an enhancement from 50.5% to 52.3% on CNN/DM and from 54.7% to 59.7% on XSUM. These improvements affirm the effectiveness and generalizability of our approach in filtering invalid negative training data. Conversely, removing the filtering from our AMRFACT data causes a decrease in balanced accuracy, dropping from 72.3% to 64.4% on CNN/DM and from 64.1% to 57.8% on XSUM, resulting in an average drop from 68.2% to 61.1%. This stark contrast not only underlines the critical role of our invalid negative data filtering module in enhancing the performance of inconsistency detection models, supporting our hypothesis mentioned in §3.2 that **training inconsistency detection models on invalid negative data hurts the performance** but also emphasize our proposed method's ability to achieve better performance with **fewer training examples**.

5.3 Ablation Studies

In the next step, we focus on the impact of five specific perturbations on metric performance, using the AGGREFACT-FTSOTA dataset for an in-depth ablation analysis. This involves removing each perturbation from the AMRFACT dataset to observe how their absence influences the creation of negative examples. As outlined in Table 4, the results indicated a significant decrease in metric accuracy when any perturbation was excluded, highlighting their importance in enhancing metric precision.

	AGGREFACT-CNN-FTSOTA	AGGREFACT-XSUM-FTSOTA	AVG
AMRFACT	**72.3 ± 2.5**	64.1 ± 1.8	**68.2**
- Predicate Error	70.0 ± 3.1	62.0 ± 1.9	66.0
- Entity Error	70.8 ± 3.1	62.1 ± 2.1	66.5
- Circumstance Error	68.2 ± 2.9	61.6 ± 1.9	64.9
- Discourse Link Error	65.0 ± 2.7	61.7 ± 1.9	63.4
- Out of Article Error	66.8 ± 2.4	62.3 ± 2.0	64.6

Table 4: Balanced binary accuracy (%) on the AGGREFACT-CNN-FTSOTA and AGGREFACT-XSUM-FTSOTA test set *without* a specific error type.

The most notable finding is the substantial decline in performance upon removing discourse link error, suggesting that current models frequently struggle with this issue. By eliminating this perturbation, the model cannot access such negative examples during training, which significantly limits its ability to detect such inconsistencies during inference time. Conversely, omitting entity and out-of-article errors from the perturbations have a minimal impact on CNN/DM and XSUM, respectively, indicating the relative robustness of current models against these specific issues.

5.4 Qualitative Analysis

The following qualitative analysis provides insights into our model's capability to produce coherent negative examples while ensuring extensive coverage of various error types.

Coherence To demonstrate that our approach produces more coherent negative summaries than entity-based baselines, we compare 200 summaries generated by AMRFACT and FACTCC. We use GPT-4 Turbo to assess the coherence of each summary on a scale of 1-5, where 1 indicates the least coherent and 5 means the most. The average coherence scores for AMRFACT and FACTCC are 3.01 and 2.24, respectively, highlighting the advantages of our approach in generating more coherent negative summaries compared to FACTCC. We show the breakdown score in Figure 5.

Error-type coverage To verify that generation-based baselines suffer from the insufficient error-type coverage issue, we evaluate the error type distribution of the negative data produced by FALSESUM by sampling its generated summaries and query GPT-4 Turbo to determine the error type within each summary. The findings revealed a notable gap: only 5 out of 1,000 summaries exhibited a Discourse Link Error. This scarcity of training data for this error type could lead to models trained on such data failing to detect these errors reliably.

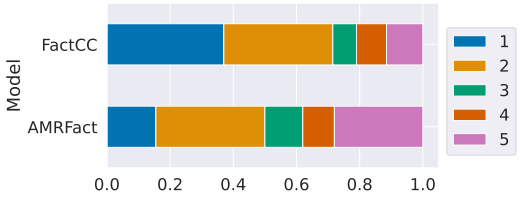

Figure 5: A breakdown of coherence scores for negative summaries produced by AMRFACT and FACTCC.

In Table 5, we show an example with a Discourse Link Error in which our model predicts the correct label and FALSESUM fails, underscoring the issue of inadequate error-type coverage. The prompts used for both analyses are detailed in Appendix C.

5.5 Remaining Challenges

To gain deeper insights into our model's limitations and remaining challenges, we conducted a detailed manual analysis. This involved examining a random sample of 50 examples from AGGREFACT-FTSOTA where our model incorrectly labeled factually inconsistent instances. The results of this analysis are detailed in Figure 6. From this thorough assessment, several key findings emerged. First, the most dominant type of error (30%) is the annotation error. This underscores the challenges in creating completely reliable benchmarks through crowd-sourced methods, a complexity also noted in the work of Laban et al. (2023). Second, errors stemming from out-of-article content were another significant source of inaccuracies. Intriguingly, upon further investigation, we discovered that a notable portion (8 out of 14) of these out-of-article errors were, in fact, factually accurate (Dong et al., 2022). For instance,

> Former Wales captain Martyn Williams says Dan Biggar's decision to sign a new four-year contract with Ospreys will benefit the region.

The above summary was labeled as unfaithful because the corresponding source document (see

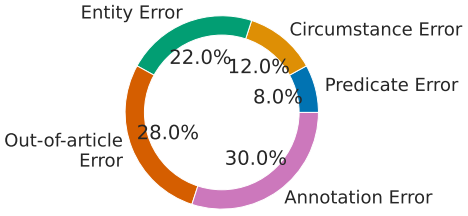

Figure 6: Distribution of the errors that our model fails to identify. The most dominant type of error is the annotation error. And errors stemming from out-of-article content were another significant source of inaccuracies.

Article: Lord Janner signed a letter saying he wanted to remain a peer just a week before he was ruled unfit to face child sex charges. Abuse campaigners last night angrily questioned why the suspected paedophile was able to remain in the House of Lords if he was too frail to be brought before court...
Summary: Lord Janner signed letter saying he wanted to remain a peer on April 9. Comes a week after he was ruled unfit to face child sex charges...

Table 5: An example with a discourse link error from AGGREFACT-FTSOTA where models trained on AMRFACT successfully classify it as factual inconsistent with the input article but fails when trained on FALSESUM.

Table 7 in Appendix) does not mention that Martyn Williams was a captain. Nonetheless, this information is factually correct, as evidenced by a Wikipedia search. This discrepancy suggests that our model, in this case, might have utilized its parametric knowledge learned during the pre-training phase of ROBERTA rather than the content of the article itself. To mitigate this issue, future research efforts can look into creating negative training examples that consist of out-of-article errors which, although truthful according to worldly facts, are unfaithful to the source document.

6 Related Work

6.1 Factual Consistency Metrics

Research on factual consistency metrics can be classified into QA-based and entailment-based approaches. QA-based metrics generally leverage question generation and answering components to evaluate factual consistency through the comparison of information units taken from summaries and their original sources (Wang et al., 2020; Scialom et al., 2021; Fabbri et al., 2022; Min et al., 2023). Entailment-based methods predict whether a summary is entailed by its source article with document-sentence entailment models trained on either synthetic (Kryscinski et al., 2020; Goyal and Durrett, 2020; Yin et al., 2021; Utama et al., 2022; Soleimani et al., 2023) or human-annotated data (Goyal and Durrett, 2021; Ribeiro et al., 2022; Chan et al., 2023). Besides, Gekhman et al. (2023) propose a method for generating synthetic data by annotating diverse model-generated summaries using an LLM. Alternatively, Laban et al. (2022) break documents and summaries into sentences and employ traditional sentence-level NLI models. Moreover, Feng et al. (2023) utilize facts extracted from external knowledge bases to improve the generalization across domains. Our approach employs an entailment-based method, capitalizing on AMR-based perturbations to generate negative examples, which ensures high error-type coverage and synthetic data quality. Furthermore, we enhance the data quality with NEGFILTER by filtering out invalid negative samples.

6.2 AMR-based Evaluation

Few studies have attempted to employ AMR for evaluation. Ribeiro et al. (2022) parse both the input documents and summaries into AMR graphs and train a classifier to identify erroneous edges in the summary graph. However, their approach relies on human-annotated data for effective training signals. On the contrary, we parse summaries into AMR graphs and create negative training data by applying perturbations to the graphs and converting the perturbed graphs back to summaries. Ghazarian et al. (2022) uses a similar approach to generate training data for a dialogue coherence evaluation metric. Notably, their perturbation techniques focused on coherence evaluation, and thus ill-suited for factual consistency evaluation. By contrast, we design our perturbation method by taking inspiration from common factual errors in summaries produced by state-of-the-art summarization systems.

7 Conclusion

We introduce a novel framework, AMRFACT, which leverages Abstract Meaning Representations (AMRs) to generate factually inconsistent summaries for summarization factuality evaluation. Our method addresses the prevalent issues of low coherence and insufficient error-type coverage observed in prior entailment-based approaches. By parsing factually consistent reference summaries into AMR graphs and injecting controlled factual inconsistencies, we successfully create coherent but factually inconsistent summaries with broad error-type coverage. The introduction of the NEGFILTER module further enhances the quality of the generated negative samples. The effectiveness and generalizability of this approach are validated through its state-of-the-art performance on the AGGREFACT-FTSOTA dataset. Our contributions not only advance the field in generating high-quality, factually inconsistent summaries but also provide a scalable and efficient solution for enhancing the factuality evaluation of summarization systems. The results underscore the potential of AMR-based perturbations in improving the integrity and reliability of natural language generation.

8 Ethical Considerations

The metrics introduced in this study are based on models trained predominantly with English language documents. Consequently, they reflect the cultural nuances and perspectives common in English-speaking societies. It is important to acknowledge the potential presence of political and gender biases within these datasets. The models, and by extension, the metrics derived from them, might inadvertently perpetuate these biases (Sun et al., 2022; Qiu et al., 2023). We have not rigorously evaluated these metrics for bias-related issues. Therefore, we advise users to be mindful of these limitations when applying these metrics, considering the potential for underlying biases in their use and interpretation. On a positive note, our methodology can serve as a valuable tool for detecting factually inconsistent summaries and making the summaries more factual.

9 Limitations

When employed effectively, the metrics outlined in this paper can serve as valuable tools for identifying errors in summarization models. However, it is crucial to recognize that these metrics are not infallible in detecting every factual inconsistency. This limitation should be considered when using these metrics to assess summaries for downstream applications. Moreover, our goal is to demonstrate the potential of using AMR-based perturbations for generating coherent yet intentionally factually inconsistent summaries. However, we acknowledge that the quality of our perturbations depends on pre-trained text-to-AMR parsers and AMR-to-Text generators. If these models are not strong, our summaries may suffer in quality, as discussed in §3.2. Therefore, it is essential to be aware of these constraints because factual inconsistencies in summaries can potentially propagate misinformation online. Therefore, while these metrics are helpful, their limitations in fully capturing factual inconsistencies must be acknowledged and managed carefully.

A Experimental Settings

We fine-tune `roberta-large-mnli` on our AMRFACT dataset for 10 epochs with a learning rate of 5E-05.

B Main Results Breakdown

Table 6 demonstrates AMRFACT's performance on the diverse member datasets within AGGREFACT-FTSOTA. These experiments demonstrate that AMRFACT outperforms SUMMAC-ZS and QAFACTEVAL on five out of seven datasets within AGGREFACT-FTSOTA.

C Prompt Details

We show the prompt used to analyze the error distribution for FALSESUM in Table 8 and coherence evaluation in Table 9.

	Polytope	SummEval	FRANK	Wang'20	CLIFF		Goyal'21	Cao'22
SPLIT	CNN	CNN	CNN	XSUM	CNN	XSUM	XSUM	XSUM
# OF SAMPLE	34	200	175	119	150	150	50	239
AMRFACT	**1.0**	**0.807**	**0.724**	0.595	0.710	**0.667**	0.591	**0.645**
SUMMAC-ZS	0.971	0.622	0.570	0.698	0.656	0.596	0.466	0.490
QAFACTEVAL	0.324	0.652	0.547	**0.756**	**0.716**	0.626	0.754	0.613

Table 6: Performance breakdown on the diverse member datasets within AGGREFACT-FTSOTA.

The 26-year-old fly-half has agreed a new deal which could keep him in Wales until the 2019 World Cup. Williams, who played 100 times for Wales, believes it will help Ospreys keep and recruit players. "It's fabulous news for Welsh rugby and the Ospreys in particular," he said on BBC Wales' Scrum V TV programme. "Not only is Dan committing himself to Wales for the next four years, but it helps the Ospreys with recruitment for the next couple of seasons. "If players were looking to sign and come to the Ospreys if they can see Dan Biggar is going to be there for the next three or four seasons that helps them as well." Biggar's current deal was due to expire at the end of this season. He is the first of Wales' 17 dually contracted players to re-sign on the deals which are 60% funded by the WRU and 40% by the region. In addition to potentially attracting new players to the region, Biggar's decision to stay may help negotiations with his Ospreys and Wales colleagues scrum-half Rhys Webb and second row Alun Wyn Jones. Both players' contracts expire in the summer of 2016, with Ospreys skipper Jones saying in November that he was still weighing up his options. Scarlets are in talks with Wales centre Scott Williams over extending his dual contract, and have secured the return of British and Irish Lions centre Jonathan Davies from Clermont Auvergne next season.

Table 7: The source document corresponding to the factual but unfaithful summary mentioned in §5.5.

You will be given one reference summary and one generated summary written for a news article.
Your task is to determine the type of factual error in the generated summary with regard to the article.

Please make sure you read and understand these instructions carefully. Please keep this document open while reviewing, and refer to it as needed.

Types of Errors:

1. Predicate Error: The predicate of the summary does not align with the information provided in the original document.
2. Entity Error: The primary arguments, or their attributes, associated with the predicate are incorrect.
3. Circumstance Error: The supplementary details, such as location or time, that define the context of a predicate are incorrect.
4. Discourse Link Error: Errors arise from the improper connection of statements within the discourse, such as errors in temporal ordering or causal link.
5. Out of Article Error: The statement conveys information that is absent in the original document.

Evaluation Steps:

1. Read the news article carefully and identify the main topic and key points.
2. Read the generated summary and compare it to the news article.
3. Determine the type of errors based on our definition.

Example:

Source Text:
[Document]

Reference Summary:
[Reference Summary]

Generated Summary:
[Generated Summary]

Evaluation Form (error type ONLY):

- Error Type:

Table 8: The prompt to GPT-4 Turbo for determining the error type of a non-factual summary.

You will be given one summary written for a news article.
Your task is to rate the summary on one metric.
Please make sure you read and understand these instructions carefully. Please keep this document open while reviewing, and refer to it as needed.

Evaluation Criteria:
Coherence (1-5). Here, we focus on "within sentence coherence". It involves ensuring that the components of a single sentence – such as subjects, verbs, objects, and other elements – are logically and grammatically connected, making the sentence clear and understandable.
Evaluation Steps:

1. Read the summary carefully.
2. Evaluate the summary based on the evaluation criteria.
3. Assign a score for coherence on a scale of 1 to 5, where 1 is the lowest and 5 is the highest based on the Evaluation Criteria.

Generated Summary:
[Generated Summary]

Evaluation Form (scores ONLY):
- Coherence:

Abstract

Machine learning shows promise in predicting the outcome of legal cases, but most research has concentrated on civil law cases rather than case law systems. We identified two unique challenges in making legal case outcome predictions with case law. First, it is crucial to identify relevant precedent cases that serve as fundamental evidence for judges during decision-making. Second, it is necessary to consider the evolution of legal principles over time, as early cases may adhere to different legal contexts. In this paper, we proposed a new framework named PILOT (PredictIng Legal case OuTcome) for case outcome prediction. It comprises two modules for relevant case retrieval and temporal pattern handling, respectively. To benchmark the performance of existing legal case outcome prediction models, we curated a dataset from a large-scale case law database. We demonstrate the importance of accurately identifying precedent cases and mitigating the temporal shift when making predictions for case law, as our method shows a significant improvement over the prior methods that focus on civil law case outcome predictions.

1 Introduction

Predicting legal case outcomes is a crucial task that facilitates data-driven decision-making in legal cases based on relevant information, such as the factual description (Cui et al., 2022). With a significant number of legal cases arising worldwide each year, legal professionals face the daunting task of reviewing the extensive legal text and delivering accurate and fair outcomes. Legal case outcome prediction has the potential to simplify this labor-intensive document review process, enhancing strategy and decision-making. As the volume and complexity of cases continue to escalate, the development of precise and reliable legal case outcome prediction systems becomes an urgent priority.

Two legal frameworks exist across the globe: the *civil law system*, which assesses each case based on comprehensive codes and statutes, and the *case law system*, where the interpretation and application of law heavily depend on precedent court decisions. Most existing works were proposed for the civil law framework, including charge prediction, violated articles prediction, prison terms prediction, court decision prediction, and court view generation (Paul et al., 2020; Hu et al., 2018; Chen et al., 2019; Chalkidis et al., 2019a; Alali et al., 2021; Ye et al., 2018). However, predicting case outcomes in case law systems presents unique challenges distinct from those in civil law: (1) it requires the identification of similar historical cases, and (2) meanwhile accounting for the evolution of legal principles over time.

- **Precedent Cases** In the case law system, the application of precedents plays a crucial role. To achieve accurate prediction of case outcomes, it is vital to identify past cases that exhibit similar legal principles, factual contexts, and key arguments. Moreover, how to effectively utilize the retrieved cases in the prediction of new case outcomes still requires further exploration.
- **Temporal Shift** One aspect that has not received sufficient attention in previous research is the temporal evolution of legal principles. We argue that it is crucial to not only comprehend the historical context and development of legal precedents but also to effectively capture and represent the temporal shifts of laws in predictive modeling.

To fill the gap, we proposed a new model named PILOT (**P**redict**I**ng **L**egal case **O**u**T**come) for case outcome prediction, which consists of two functional modules:

- **Case Retrieval** We initially train the module in an unsupervised manner to obtain text embed-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 609–621
June 16-21, 2024 ©2024 Association for Computational Linguistics

dings for cases. These embeddings are then used to query and select the most relevant precedent cases, which serve as additional inputs to our main model.

- **Temporal Pattern Mining** A temporal decay term is introduced to ensure the model captures the more recent patterns and explicitly learns to adapt to the temporal pattern change.

To facilitate this line of research, we established a new dataset named *ECHR2023*, which was extracted from the European Court of Human Rights (ECHR) database[1] with focusing on precedent cases and temporal concept shift. We evaluated the proposed PILOT model against state-of-the-art models on *ECHR2023*. The experiment results show that PILOT substantially outperforms existing works in several metrics. The two modules in PILOT effectively improve the performance in different aspects.

In summary, the main contributions of this paper are as follows

- We highlight the issue of Temporal Pattern Shift in legal AI tasks. This problem is important but is usually ignored in most previous works.
- We propose a new method, PILOT, which can effectively handle Temporal Pattern Shift based on characteristics of the case law system.
- We contribute a new dataset, *ECHR2023*, for legal case outcome prediction. PILOT achieves state-of-the-art performance on *ECHR2023*.

2 Related Work

Legal Case Outcome Prediction on civil law framework has been well studied, mainly focusing on predicting whether the case description violates existing legislation. Machine learning technologies, including multi-task learning (Feng et al., 2022), few-show learning (Hu et al., 2018; He et al., 2019) has been adopted. Model explanation has been another focused (Jiang et al., 2018; Zhong et al., 2020; Ge et al., 2021; Chen et al., 2019; Ye et al., 2018; Wu et al., 2020).

In contrast, for case law systems that heavily relies on judicial decisions of relevant precedent cases rather than solely on constitutional law when rendering final case outcomes, there are relatively few studies due to the lack of scarcity of large-scale, high-quality, and structured labeled data. For instance, (Chalkidis et al., 2019a) utilize HIER-BERT to first encode individual facts and then employ two layers of transformers to encode all the facts within a given case. (Chalkidis et al., 2021) generate rationales through a text encoder sub-network that reads the text, a rationale extraction sub-network that identifies the most important words via a binary mask, and a prediction sub-network that classifies a hard-masked version of the text. They also incorporate rationale constraints as regularizers. (Paul et al., 2020) employ a fact encoding layer to encode facts and a charge encoding layer to encode charges. Subsequently, they use a Matching Layer, which incorporates an attention mechanism, to predict the final charges for each case. (Malik et al., 2021) utilize a Hierarchical XLNet architecture to predict case outcomes and related interpretations. These efforts primarily focus on the classification of fundamental case outcomes. To the best of our knowledge, most of the existing works do not handle temporal pattern shift.

Temporal Pattern Shift arises due to changes in label distribution, meaning, and etc. Existing research approaches this issue from different angles. For example, (Zhao et al., 2022) analyzes the impact of temporal pattern shift on model explanations. (Sun et al., 2018) explored drift adaptation through transfer-based ensemble learning. Fan et al. (Fan et al., 2023) proposed to use two CONET networks to model the normalized parameters of historical and future windows separately, enabling normalization and prediction of future sequences. (Lu et al., 2023) introduced an out-of-domain representation learning approach utilizing adversarial learning to capture domain-specific segments and a domain-independent commonality representation. (Rosin and Radinsky, 2022) introduced Temporal Attention and trained a transformer-based model with additional time-based inputs. In the legal field, (Chalkidis and Søgaard, 2022) tackled temporal pattern shift in legal text classification by proposing Label-Wise Distributional Robust Optimization. This algorithm addresses temporal pattern shift stemming from class imbalance problems and enhances model robustness. However, the existing works are too general and are designed for simple scenes, so they do not perform well in adapting the more complex shift. There is still a lack of a comprehensive solution for legal models to adapt

[1] https://hudoc.echr.coe.int

the shift in the legal field directly and naturally.

3 ECHR2023 Dataset

We build a novel dataset called *ECHR2023* that takes the special challenges in legal case outcome prediction with case law. This dataset is derived from the most recent ECHR database. The primary focus of *ECHR2023* is to investigate the issue of temporal pattern shifts in the legal domain.

Data Acquisition and Processing The data extracted from the ECHR database is of low quality and contains a substantial amount of noise. The case documents are often excessively long, surpassing 2,000 words, and may consist of text in multiple European languages. As a result, the readability and quality of the text data are poor, posing difficulties for humans in comprehending the content of the cases.

Specifically, we prompt the large language model, *gpt-3.5-turbo*[2], to process the raw data. The prompts guide the model to focus on the primary arguments in the case and summarize them into more concise points. Therefore, the output of LLMs will not introduce new information or fabrication to a case but rather retain the important parts of the original information. We employ LLMs to summarize original legal documents with the aim of simplifying the input and concentrating on identifying temporal pattern shifts. The prompts, example input-output of the LLM, and more details in the raw data processing can be found in Appendix B. The resulting sample is described by the following attributes: case ID, title of the case, outcome decision date of the case, corresponding legal article, and text description of the case. Following the processing results, we conduct a manual review of the generated summaries to ensure their quality and to eliminate any data that is obviously incorrect.

Data Analysis Most of existing datasets are random split and ignore the temporal pattern change in the real world. We analyze the temporal pattern change in this dataset as follows: we perform outcome prediction using BERT (Devlin et al., 2019) using both the random split and chronological split. For random split (that does not consider case time), the performance of model training in Micro-F1 is 0.798, and the testing performance is 0.796. While for chronological split data split that we train the model using previous cases and test on cases that happen later, the performance of model training in Micro-F1 is 0.737 and the testing performance is 0.677, which shows the patterns learned from previous data cannot fully capture the signal in new cases.

[2]https://platform.openai.com/docs/models/gpt-3-5

4 Methodology

4.1 PILOT Framework

Problem 1 (Legal Case Outcome Prediction with Case Law)**.** *Given a set of n chronological ordered cases $\mathbf{C} = \{C_i\}_i^n$, where each C_i is represented by the text description of the case, the legal case outcome prediction aims at predicting whether a new case violates any legal article in $\mathbf{V} = \{V_1, V_2, ...V_n\}$. Here $V_i \in \{0,1\}^L$ is the corresponding multi-hot label vector of the case C_i violated articles, and L is the total number of law articles. This task is a multi-label classification to decide the case C_i violated law articles V_j.*

We propose PILOT that primarily focuses on two distinct challenges in predicting legal case outcomes with case law: effectively identifying similar precedent cases and handling temporal pattern shift of legal principles. As illustrated by Figure 1, PILOT consists of three modules: the Relevant Case Retrieval module that retrieves relevant cases as references for outcome prediction, the Case Encoder with Evidence Fusion module that uses encodes current case with fact description and relevant cases, and the Temporal Shift Mining module that is directly adapting to the temporal drift. We will now provide a detailed introduction to each of these modules.

4.2 Precedent Case Retrieval

In the case law system, precedent cases serve as crucial references that judges rely on when making decisions for new cases. In order to emulate this decision-making process, we develop a precedent case retrieval module that enhances case outcome prediction in two key aspects: (1) by providing augmented evidence for prediction and (2) by offering interpretability through the provision of evidence.

Case Encoding We execute contrastive learning based on a pre-trained language model on case documents only from training split of dataset. We suppose that we only have case documents in training split in the database at the beginning. The yielded model is then utilized for encoding all legal case documents in the database and the current case, preparing for similarity search. Formally, the contrastive learning is performed based on InfoNCE

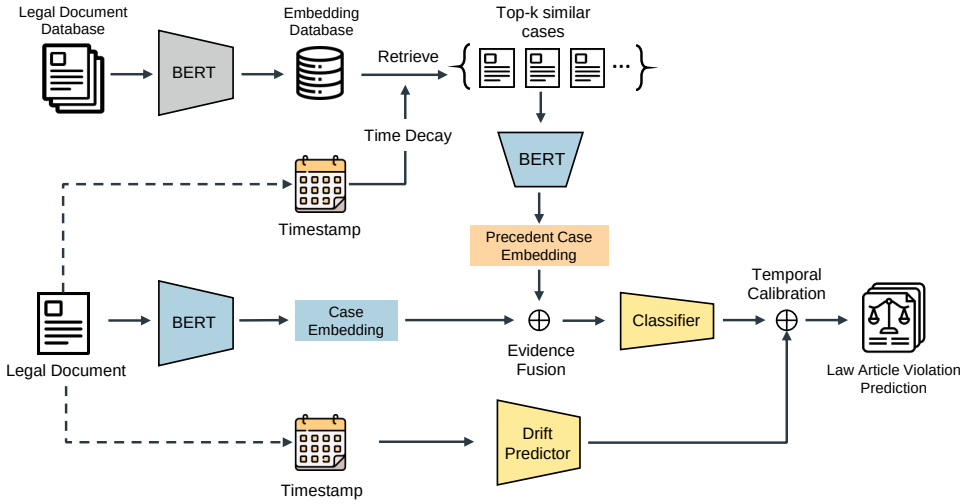

Figure 1: The framework of our proposed model PILOT. PILOT has three modules: Relevant Case Retrieval, Case Encoder with Evidence Fusion, and Temporal Shift Mining. The Relevant Case Retrieval module retrieves relevant cases to use as references for outcome prediction. The Case Encoder with Evidence Fusion module encodes current cases with fact descriptions and relevant cases. The Temporal Shift Mining module adapts directly to temporal drift.

loss (Gao et al., 2021). Without the need for annotated labels, each case is passed into the BERT model twice within a batch, resulting in two different document embeddings H_i^0 and H_i^1 due to the randomness of the dropout layers (Srivastava et al., 2014).

Within a batch, each pair (H_i^0, H_i^1) is positive, and all the other pairs that (H_i^0, H_j^1) where $i \neq j$ are negative. The contrastive training objective ℓ_i is hence defined by:

$$\ell_i = -\log \frac{e^{\cos(H_i^0, H_i^1)/\tau}}{\sum_{j=1}^{N} e^{\cos(H_i^0, H_j^1)/\tau}}, \qquad (1)$$

where H_i is the document embedding of case C_i, H_i^0 is the positive sample for H_i, τ is a temperature hyperparameter, and $\cos(H_i, H_j)$ measures the cosine similarity of the input embeddings.

Case Retrieval After training with Eq. (1), we encode all legal cases in the database into semantically meaningful document embeddings $\mathbf{H} = \{H_1, H_2, ..., H_n\}$, which can be used to compute cosine similarities for case retrieval.

In this work, we put temporal constraints for the retrieval process. First, the retrieval is performed considering the timestamps of the target cases because a case cannot refer to any future cases. For a case $C_i \in \mathbf{C}$, we assign the similarity $\text{sim}(C_i, C_j) = -1$ if $i < j$ to filter out future cases from the candidate pool.

Secondly, we also take into consideration the influence of temporal pattern shifts of legal principles, as recent cases often carry higher reference value in legal decision-making. Based on this insight, we design a variant of cosine similarity equipped with a temporal decayed function as

$$\text{sim}(C_i, C_j) = \frac{\cos(C_i, C_j)}{1 + \frac{T_i - T_j}{\alpha \times |\mathbf{C}_{\text{val}}|}}, \qquad (2)$$

where C_j is a candidate similar case, α is temporal decayed coefficient, and $|\mathbf{C}_{\text{val}}|$ is the size of validation split in the dataset. We set the decaying unit as the size of the validation split because it is a time span from labeled data to the newest unlabeled data, which is also the length of validation data. When $\alpha = (T_i - T_j)/|\mathbf{C}_{\text{val}}|$, the similarity score of (C_i, C_j) will be half. As α decreases, the reference value of precedent cases will decrease faster.

4.3 Case Encoding with Evidence Fusion

Target Case Encoding To prepare legal case data for outcome prediction, the first step is to embed the case documents into contextualized representation. To achieve this, we preprocess the legal document text data as follows: we convert the fact list to a piece of text by replacing all carriage return characters in the text with spaces, then use *BertTokenizer* to conduct tokenization.

Next, the preprocessed legal document text data is passed into a pre-trained language model (PLM) for further processing. Here we choose *legal-bert-base-uncased* (Chalkidis et al., 2020b), which is

pre-trained on different kinds of legal documents, enabling it to capture and understand the context and meaning of the text. For every case C_i, we pass it into the PLM and get the contextualized representation of the fact description $H_i \in \mathbb{R}^{d_t}$, where d_t is the dimension of the last hidden layer in PLM. We indicate this contextualized representation H_i as the current case embedding E_i:

$$E_i = H_i = PLM(C_i), \tag{3}$$

The PLM takes the preprocessed legal document text data as input and generates a contextualized representation of the legal case text, encapsulating the semantic and syntactic information of the legal fact description. It captures the relationships between words, phrases, and sentences, providing a rich representation of the text's meaning within the legal context.

Evidence Fusion We use the target case C_i to query all cases $\mathbf{C}$ to retrieve the top k similar precedent cases according to similarity scores computed by Eq. (2). We draw the evidence $\mathbf{R}_i = \{R_1, R_2, \ldots, R_k\}$ from the retrieved cases, where $R_j = \{\text{sim}(C_i, C_j), V_j\}$ includes the case result $V_j \in \{0,1\}^L$ and the similarity score $\text{sim}(C_i, C_j)$ of this relevant case.

Based on the evidence $\mathbf{R}_i$ retrieved from precedent cases, we build the evidence embedding E_i^r by:

$$E_i^r = \sum_{j=1}^{k} \frac{e^{\text{sim}(C_i,C_j)} \times V_j}{\sum_{j=1}^{k} e^{\text{sim}(C_i,C_j)}}. \tag{4}$$

where $E_i^r \in \mathbb{R}^L$. We concatenate current case embedding E_i^c with relevant case embedding E_i^r to get the input of the linear classifier layer for C_i by:

$$E_i = [E_i^c, E_i^r], \tag{5}$$

where $E_i \in \mathbb{R}^{d_t+L}$.

This approach allows the model to learn the relationship between relevant cases, leading to a better understanding of the factors influencing case outcomes. Moreover, it helps alleviate the impact of temporal pattern shift by providing a local perspective that captures the evolving nature of legal precedents.

4.4 Outcome Prediction with Temporal Pattern Mining

To further mitigate the temporal pattern drift when the model makes outcome predictions, we introduce a drift prediction module that mines the effect of timestamps to the final outcomes:

$$\text{Drift}_i = \text{MLP}(T_i), \tag{6}$$

where $\text{Drift}_i \in \mathbb{R}^d$. MLP is a two-layer multilayer perceptron, and the dimension of the hidden layer is d. We add the output Drift_i to the original prediction to get the final prediction:

$$y_i^{\text{final}} = y_i^{\text{orig}} + \text{Drift}_i, \tag{7}$$

where y_i^{orig} is original output generated by the classifier and $y_i^{\text{final}} \in \mathbb{R}^L$. The drift prediction module explicitly incorporates a global view by adapting to the temporal concept and learning from the entire timeline. By considering the evolution of legal precedents over time, this module effectively captures and adapts to the changes in the legal landscape, ensuring that the model remains robust and accurate in predicting case outcomes.

4.5 Training and Loss Function

In addition to the binary cross-entropy loss $\mathcal{L}_{BCE}$ used for the multi-label classification task, we add the drift loss $\mathcal{L}_{\text{Drift}}$ to the model loss function. $\mathcal{L}_{\text{Drift}}$ uses mean squared error loss to calculate the drift distance between original predictions and final predictions. The loss function of this model is defined as:

$$\mathcal{L} = (1-\lambda)\mathcal{L}_{BCE} + \lambda \sum_{i=1}^{L} (y_i^{\text{final}} - y_i^{\text{orig}})^2, \tag{8}$$

where λ is the weight that balances the two losses.

5 Experiments

In this section, we conducted extensive experiments to show the performance of PILOT associated with more in-depth analysis. Universally, we report the average results of all models obtained by five runs with different random seeds, to ensure fair comparison. We use four metrics to evaluate the legal case outcomes: micro-F1, micro-Jaccard, micro-PR-AUC, and micro-ROC-AUC. More training details can be found in Appendix A.

As for the availability of cases during training and evaluation, we strictly ensure that we do not use any later cases as references for the current case. During the training phase, all prior cases from the training set are available as precedents. At test time, all prior cases from both the training and test sets are available. In the contrastive learning of the case encoding model, we only use data from the training split of the dataset.

PILOT (Ours)	**0.715±0.008**	**0.557±0.010**	**0.543±0.014**	**0.831±0.007**

Table 1: Experimental results. The best results are in bold. PILOT significantly outperforms all other methods in all metrics. ± represents standard deviation from five results of five different seeds.

5.1 Baselines

We consider the following baselines in evaluation.

- **BERT** (Devlin et al., 2019) is a transformer-based (Vaswani et al., 2017) language model pre-trained on large-scale web texts. We fine-tune and predict with the *[CLS]* token of BERT.
- **HERT-BERT** (Chalkidis et al., 2019b) is a hierarchical version of BERT. This model was proposed to predict legal judgment for long documents by first splitting and encoding raw law documents into multiple sentence embeddings, then fusing them with a two-layer Transformer model (Vaswani et al., 2017) to yield the document embeddings.
- **BERT-LWAN** (Chalkidis et al., 2020a) is Label-Wise Attention Network after BERT that was shown to be robust in multi-label classification. LWAN employs L attention for L labels to learn the semantics of label interpretation.
- **EPM-base** (Feng et al., 2022) is the variant of the state-of-the-art method on the CAIL2018 dataset. The original model, named Event-based Prediction Model (EPM) targets Chinese legal case outcome prediction, augmented by extra annotations about the legal event information. We remove the event extraction module in our experiments for fair comparison and refer the method to the name EPM-base.
- **BERT+CL+kNN** (Su et al., 2022) is an advanced method for general purpose multi-label prediction. It is equipped with a k-nearest-neighbor model along with a multi-label contrastive learning objective for better multi-label classification performance.
- **BERT+TemporalAttention** (Rosin and Radinsky, 2022) adds a time-aware self-attention module to the transformer model, which demonstrates superior performance in capturing temporal patterns when making predictions. In detail, it adds a time matrix to the attention weight to learn the impact of the temporal shift.
- **LWDROV2** (Chalkidis and Søgaard, 2022) was proposed for legal text classification tasks. It employs Label-Wise Distributional Robust Optimization to mitigate class imbalance and temporal pattern shift problems.
- **ChatGPT 5-shots** (Ouyang et al., 2022) is based on the in-context learning capability of the `GPT-3.5-turbo` model. To be specific, we put the exemplar cases and their outcomes retrieved using our Precedent Case Retrieval module into the context, then prompt the language model to generate the outcome predictions.

Evaluation Strategy. To ensure that future information is not used in legal case outcome predictions, we partitioned the data chronologically. As a result, the training, validation, and test data consist of 8,138, 3,000, and 3,000 instances, respectively, ensuring a preserved time span between the sets. In addition, this chronological split enables the evaluation of models' adaptability to concept drift and reinforces temporal coherence. The dataset provides a substantial amount of validation and test data, contributing to its superior evaluation capabilities for legal case outcome prediction compared to existing alternatives. The statistics of the case outcomes are summarized in Table 2.

5.2 Result: Legal Case Outcome Prediction

We report the main results of legal case outcome predictions in Table 1. From the table, we observe that our method outperforms other methods by a

ECHR Articles	Train	Dev.	Test
Right to life	432	180	188
Prohibition of torture	1,048	796	835
Right to liberty and security	1,264	608	690
Right to a fair trial	4,969	1,165	1,081
No punishment without law	32	7	9
Right for private and family life	682	287	421
Freedom of religion	43	17	26
Freedom of expression	313	151	194
Freedom of assembly	104	80	148
Right to an effective remedy	1,202	506	520
Prohibition of discrimination	170	48	61
Derogation in time of emergency	4	9	10
Individual applications	58	46	60
Examination of the case	34	4	7
Protection of property	1,483	435	347
Signature and ratification	5	11	21

Table 2: Label distribution of the ECHR2023 dataset.

Method	F1	$\bigtriangledown$
PILOT	**0.712**	**-**
w/o relevant case retrieval	0.701	-0.011
w/o temporal pattern handling	0.697	-0.015
w/ law article semantics	0.705	-0.007

Table 3: Results of ablation study. Relevant case retrieval and temporal pattern handling bring improvement to the model respectively, while incorporating law articles semantics has a performance drop. $\bigtriangledown$ means the performance drop comparing with the method PILOT.

large margin in four metrics, especially over the methods that do not explicitly consider the temporal pattern shifts in legal case outcomes.

In addition, our method improves the micro-F1 by 2.74% than the previous state-of-the-art method of legal outcome prediction, LWDROV2. The reason is that LWDROV2 is a general label-wise robust method that does not solve temporal shifts directly. By contrast, our method employs a time-aware drift prediction module and augments the predictions with precedent cases.

It is noteworthy that ChatGPT 5-shots exhibits lower performance when compared to other prediction models based on supervised learning. In many instances, ChatGPT refuses to provide predictions, leading to limitations in its ability to make accurate determinations. Consequently, there remains the potential for further advancements in general-purpose generative large language models for predicting legal outcomes.

5.3 Result: Ablation Study

We performed an ablation study to evaluate the impact of the relevant case retrieval module and the temporal pattern handling module on the overall performance of our model. Table 3 presents the results of this study, highlighting how these two modules contribute to the improvement of the base model in distinct ways.

Additionally, we explored the incorporation of law article semantics into the model, using techniques such as law side attention or similar approaches employed in previous methods. Surprisingly, our findings indicated a decrease in performance when integrating law article information into our model. This observation is supported by the results in Table 1, where both the EPM-base and BERT-LWAN models, which incorporate law article information, exhibited inferior performance compared to BERT alone. We think one reason incorporating law articles undermines the performance is that the content and interpretations of law articles change as time goes on. It will influence model prediction without considering the time factor.

5.4 Result: Qualitative Case Study for Case Retrieval

The relevant case retrieval module is utilized for retrieving the top k precedent cases that are relevant to the target case. In Table 4, we present an example of the retrieval results. It is evident from the table that these retrieved cases exhibit semantic relevance to the target case. Furthermore, the violated articles mentioned in the retrieved cases are closely related and encompass the violated articles of the target case, indicating a comprehensive coverage of relevant legal provisions. Therefore, it demonstrates the effect of the case retrieval process from a qualitative perspective.

5.5 Result: Hyperparameter Analysis for Case Retrieval Module

The relevant case retrieval module encompasses two hyperparameters. The first parameter, denoted as k, determines the number of top relevant precedent cases to be retrieved. The second parameter is the coefficient α associated with the temporal decayed function in Eq. (2). The experimental results, presented in Table 2, shed light on the impact of these hyperparameters.

From the results, we conclude that including

Case	case id	main text (selected sentences)	violated articles	similarity
Current Case	**001-199268**	**the applicant complained about the lack of effective remedy in domestic law**	**["13", "6"]**	**-**
Precedent Case 1	001-195868	the applicant expressed concerns about the lack of effective remedies in domestic law	["3", "13"]	0.597
Precedent Case 2	001-189950	applicant complained about inadequate detention conditions	["3", "13"]	0.560
Precedent Case 2	001-198818	applicant complained about the excessive length of civil proceedings	["13", "6"]	0.421
Precedent Case 3	001-199269	complaint concerns the length of administrative proceedings regarding social benefits	["6"]	0.380
Precedent Case 4	001-198820	the applicant complained about the excessive length of his pre-trial detention	["6", "5"]	0.364

Table 4: An example of similar case retrieval results.

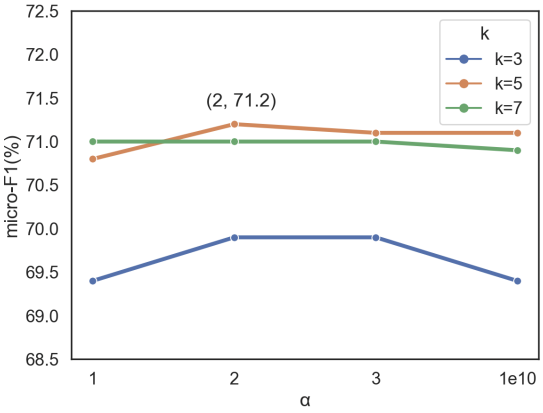

Figure 2: Hyperparameter analysis of k and α in the relevant case retrieval module. When k equals 5 and α equals 2, the model achieves the best results. When the value of α is 1e10, it indicate an extreme condition that implies the absence of temporal decay in the computation of the similarity score

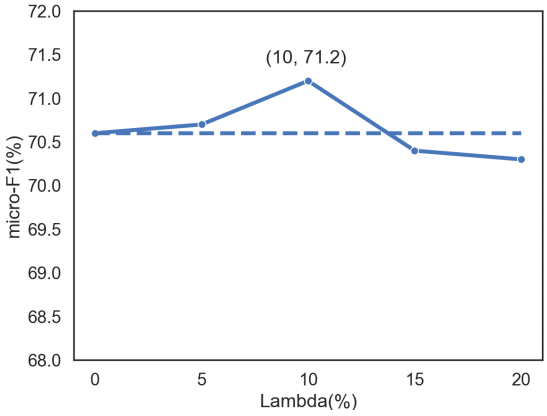

Figure 3: Hyperparameter analysis of lambda which is the weight of drift loss. When λ equals 0.10, the model achieves the best results.

only three reference cases can introduce noise and lead to a decrease in performance, as it fails to retrieve the correct relevant cases effectively. However, utilizing five or seven reference cases demonstrates improved robustness compared to three cases. Notably, setting the value of α to 1e10 is an extreme condition that implies the absence of temporal decay in the computation of the similarity score. The results indicate that incorporating the time-decayed function brings about some improvement over the original approach. Empirically, we find setting $\alpha \in [1, 10]$ yields the optimal results.

5.6 Result: Hyperparameter Analysis for Training Objective

To assess the impact of varying drift loss weights (λ), we conducted evaluations using different values. The results are presented in Figure 3. It is evident from the table that the inclusion of the drift loss contributes to improved model training and overall performance. Notably, the best value for λ, which balances the weighting between $\mathcal{L}_{\text{BCE}}$ and $\mathcal{L}_{\text{Drift}}$, is found to be 0.10. The λ value of 0 indicates the exclusion of the drift loss from the model. Conversely, assigning a large value to λ can have a detrimental effect on the model's performance.

6 Conclusion

In conclusion, this paper introduces the PILOT model to tackle the challenges associated with predicting case outcomes in case law systems. Through our experiments, we have demonstrated the superior accuracy of our model in predicting case outcomes compared to existing methods. This improvement can be attributed to the identification of similar cases and the effective handling of temporal pattern changes.

Moreover, our proposed model goes beyond enhancing the accuracy of legal case predictions. It also offers valuable insights into legal reasoning and the evolution of legal principles. Precedent cases hold significant importance within the case law legal framework. It is worth noting that many previous works have primarily focused on the civil law system, which differs from the case law system. By analyzing and leveraging precedent cases, our model provides a deeper understanding of the underlying legal principles and their application.

Limitations

Deciding the outcome of legal cases is a very complex process in the real world. In this paper, we simplify many settings in real court scenarios to facilitate our research. The proposed model PILOT is a preliminary work in legal case outcome prediction, which might serve as a baseline for future investigation. The goal of designing the PILOT model is to highlight and alleviate the temporal pattern shift. There are many bias problems that need to be eliminated, and the model needs better interpretability to give reliable outcomes. It cannot be applied in the real world directly. Here are some ways to enhance the capability of PILOT before its application:

- More factors should be considered when designing a precedent case retrieval module. Currently, relevant cases are determined based on semantic similarity alone. However, relevant cases may not always be entirely semantically similar. Additionally, differences in factual details among cases can lead to different legal outcomes. Therefore, a more robust retrieval module with more retrieval factors should be developed if PILOT is to be applied in real-world scenarios.
- We need to further eliminate bias issues of PILOT before applied in real life.
- The model should prioritize better interpretability in order to provide reliable outcomes, given the need for transparency in the legal domain. For example, we can add a generation module let PILOT generate some explanation of its judgement.
- Legal outcomes should not be determined by a single model alone. Instead, a Mixture-Of-Experts approach can be employed, utilizing multiple instances of PILOT with varying hyperparameters, to perform ensemble learning and generate diverse results. After a voting process, the results can be more impartial.
- The model can benefit from incorporating more information from the case. Currently, only the factual section of the case is utilized, but additional information could be included to improve the model's performance.

Ethics Statement

Accuracy and Transparency. We are committed to ensuring the accuracy of our predictions to the best of our abilities. We will maintain transparency about the methodologies, data sources, and algorithms used in our prediction models. We understand the profound implications of our work and strive to prevent any potential harm caused by inaccurate predictions.

Fairness and Impartiality. We pledge and strive to ensure our prediction models do not perpetuate or amplify any form of bias or discrimination. We will regularly audit our models to detect and mitigate any unfair bias, ensuring our predictions are objective and impartial.

Respect for Privacy and Confidentiality. We will strictly adhere to all applicable laws and regulations concerning data privacy and confidentiality. We will only use data that has been lawfully and ethically obtained, ensuring the privacy of all individuals involved is respected.

Accountability. We acknowledge our responsibility for the predictions made by our models. We will continually monitor and refine our models to ensure their reliability and validity.

Legal Compliance. We understand the significance of legal regulations and standards in our work. We will ensure full compliance with all relevant legal and professional guidelines in our legal outcome prediction task.

A Training Details

In the model training, we fine-tune on *legal-bert-base-uncased* (Chalkidis et al., 2020b). AdamW optimizer (Loshchilov and Hutter, 2017) was used to optimize the parameters of the model during the training. We apply differential learning rates. The learning rate of the final linear classifier is set to 1e-3, while others are all set to 1e-5. The Dropout (Srivastava et al., 2014) rate after the PLM output is set to 0.2. The batch size in each training step is set to 8. In training, we set an early stop strategy with 2 epochs. We use micro-F1 as monitoring indicators in our early stop strategy. We train *CaseSifter* with all data 3 epochs.

The code implementation of our model is mainly written using PyTorch (Paszke et al., 2019) library, and the pre-trained model is loaded using Transformers (Wolf et al., 2020) library. In addition, model training and evaluation were conducted on one NVIDIA GeForce RTX 3090.

B Raw Data Processing with LLMs

We use large language models (LLMs) to process raw data. The original document is lengthy and redundant. Our summarization target is the FACT section of case documents. We employ multiple regular expressions to filter out only the FACT section from the case documents and then input them into the LLM. We ensure that the input data does not contain any other parts of the case documents, which may leak information about the results. We prompt the *gpt-3-5-turbo* model to get output as processed data of a long document of one legal case. We utilized the default hyperparameters, setting the *temperature* to 1 and the *repetition_penalty* to 0. The maximum sequence length of the output is set to 512 tokens to ensure compatibility with BERT.

We have tried several prompts and select prompt according to summary performance of the model. The final selected prompt is shown in Figure 4. In our prompts, we guide the model to focus on the primary arguments in the case and summarize them into more concise points. Therefore, the output of LLMs will not introduce new information or fabrication to a case but rather retain the important parts of the original information. In this case, we can minimize the problem of hallucinations caused by generative language models as much as possible. We also acknowledge that this method will cause potential semantic loss in new dataset, but it can increase the model inference speed and improve readability of original case documents.

We manually check the data quality from the LLM output. We review about dozens of samples of data. We observe that it do not introduce any new fabricated facts in the output, and indeed summarizes some key points of the case, which meets our expectations. We have also conducted experiments to compare these aspects. Our results show that using the baseline results of ChatGPT processed content only leads to a 0.5% decrease in performance than original lengthy documents, but significantly increases the training speed in later stages.

An example input and output of the LLM in data processing is shown in Figure 5.

Prompt

User: You are a good judge. This is a document about facts of a case. Help me find main d escriptions of the facts in bullet points: {document of a legal case}

Figure 4: The final selected prompt. We also prompt model by telling *you are a good judge*.

Example

User: You are a good judge. This is a document about facts of a case. Help me find main d escriptions of the facts in bullet points: A. Background of the case 4. The first applicant, M s R.I., was born in 1975 and lives in Bucharest. She was in a stable relationship with R. She had two children with him: the second applicant, M.I., born in 2006, and the third applicant, I.I., born in 2009. In 2010, the relationship broke down and R. moved out of the family hom e. **……(total 3618 tokens)……**The break of the family ties between the mother and her chi ldren will without any doubt become permanent if the children are to live with their father, and therefore any visiting programme for the mother and the children will be illusory and fo rmal in so far as the mother was unable to obtain the enforcement of a final decision for mor e than four years and as during that time she practically could not even speak with the childr en."

ChatGPT: - Ms R.I. had two children with R.
- The relationship between the parents broke down, but the children remained with Ms R.I.
- R. had unrestricted access to the children and played an active role in their education.

..... (total 494 tokens).....

- R. informed the authorities that he had moved with the children to Năvodari, Constanţa Co unty.
- The Constanta District Court partially allowed R.'s opposition to the enforcement, finding that he had complied in full with the obligation to provide for the children since they lived with him.
- The children refused to move in with their mother in a meeting at the bailiff's office.
- Ms R.I. lodged a criminal complaint against R., accusing him of disobeying the court orde r concerning the custody arrangements.

Figure 5: An example input and output of the LLM about data *001-187931*. The original document has 3618 tokens totally. It reduces to 494 tokens after extracting important points of a legal case.

ALoRA: Allocating Low-Rank Adaptation for Fine-tuning Large Language Models

Zequan Liu[1⋆] **Jiawen Lyn**[2*] **Wei Zhu**[3†] **Xing Tian**[4] **Yvette Graham**[2]
[1] RWTH Aachen University, Aachen, Germany
[2] Trinity College Dublin, Dublin, Ireland
[3] East China Normal University, Shanghai, China
[4] Niuxin Network Technology Co., Ltd.

Abstract

Parameter-efficient fine-tuning (PEFT) is widely studied for its effectiveness and efficiency in the era of large language models. Low-rank adaptation (LoRA) has demonstrated commendable performance as a popular and representative method. However, it is implemented with a fixed intrinsic rank that might not be the ideal setting for the downstream tasks. Recognizing the need for more flexible downstream task adaptation, we extend the methodology of LoRA to an innovative approach we call allocating low-rank adaptation (ALoRA) that enables dynamic adjustments to the intrinsic rank during the adaptation process. First, we propose a novel method, AB-LoRA, that can effectively estimate the importance score of each LoRA rank. Second, guided by AB-LoRA, we gradually prune abundant and negatively impacting LoRA ranks and allocate the pruned LoRA budgets to important Transformer modules needing higher ranks. We have conducted experiments on various tasks, and the experimental results demonstrate that our ALoRA method can outperform the recent baselines with comparable tunable parameters.

1 Introduction

Large language models (LLMs) have been emerging and achieving state-of-the-art (SOTA) results not only on a variety of natural language processing tasks (Qin et al., 2023; Zhu et al., 2023; Zhu et al., 2023a,b, 2021a; Li et al., 2023b; Zhu et al., 2023c; Zhang et al., 2023a; Zhu et al., 2023e; Guo et al., 2021b; Zhu et al., 2021b; Zheng et al., 2023; Sun et al., 2020; Zhang et al., 2023d,e; Wang et al., 2023; Zhu et al., 2019a), but also many challenging evaluation tasks (Huang et al., 2023; Li et al., 2023a; Cui et al., 2023) like question answering in special domains, reasoning, math, safety, instruction following. Despite LLMs becoming general task solvers, fine-tuning still plays a vital role in efficient LLM inference and controlling the style of the LLMs' generated contents.[1] Fine-tuning such large models by full parameters is prohibitive since it requires a large amount of GPU memory and computations. Thus, parameter-efficient fine-tuning (PEFT) (Zhang et al., 2023f; Zhao et al., 2023; Ding et al., 2022) has raised much attention in the research field since in PEFT, the tunable parameters are often less than 1% of the LLMs and the computation costs will be significantly decreased.

Many PEFT methods have been validated to be effective across various models and tasks, often yielding comparable results with full-parameter fine-tuning (He et al., 2021; Zhu and Tan, 2023; Zhang et al., 2023f; Ding et al., 2022). Among these PEFT methods, the reparameterization-based method low-rank adaptation (LoRA) (Hu et al., 2021) is considered one of the most efficient and effective methods at present. LoRA is especially popular after open-sourced LLMs become ubiquitous (Dettmers et al., 2023). LoRA assumes that the change of the model's parameters for adaptation is intrinsically low-dimensional and performs adaptation by optimizing the matrix obtained from low-rank decomposition. Since it is in the form of weight matrix reparameterization, LoRA parameters can be merged with the original LLMs and cause no forward propagation latency.

Although LoRA is effective and can bring stable performance with the original setting in Hu et al. (2021), how to fully exploit its potential for downstream tasks still needs to be determined. First, how to determine the intrinsic rank for each model weight in the Transformer block is still unclear. Moreover, is it reasonable to set the same LoRA rank number for adapting the query, key, and value

*Equal contributions.

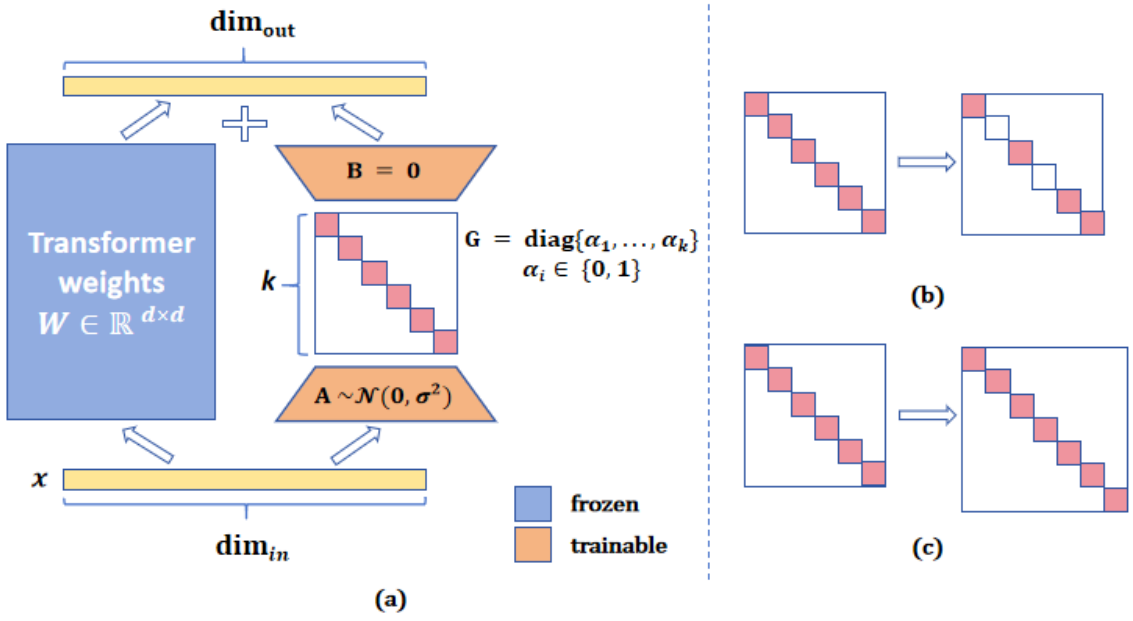

Figure 1: Schematic illustration of our ALoRA. Left (a): ALoRA follows LoRA to update the weight matrix W by fine-tuning the low-rank matrices A and B with intermediate rank k. Matrix G is a diagonal matrix where each diagonal element is the gate unit α_i for each LoRA rank $i < k$. Each α_i is set to 1 at initialization. Right upper (b): Some abundant LoRA ranks are pruned by setting the corresponding gate α_i to zeros. Right lower (c): For weight matrix W whose LoRA ranks are not pruned, we will assign additional LoRA ranks to enhance reparameterization.

matrix? Second, in practice, the optimal LoRA rank setting would vary according to multiple factors, such as the backbone model and the task.

In order to improve the performance of downstream task adaptation of LoRA, we now propose the Allocating LoRA (ALoRA) framework (depicted in Figure 1). First, LoRA modules with equal rank size are initialized at each Transformer weight, with all rank gates set to one. During fine-tuning, we re-allocate the LoRA ranks by (a) identifying which LoRA ranks are abundant or have negative contributions and prune those ranks by setting the rank gates to 0; (b) adding the pruned rank budgets to model weights that receive no pruning, that is, important model weights will be assigned more LoRA ranks. In order to calculate the contribution score of each LoRA rank efficiently and accurately, we propose a novel method, AB-LoRA. Our working procedure does not require re-training and does not require higher LoRA rank budgets at initialization or during training.

We conduct extensive experiments on a wide collection of tasks, including sentiment classification, natural language inference, question answering, natural language generation under constraint, and instruction tuning, to demonstrate the effectiveness of our method. Notably, our method can consistently outperform strong PEFT baselines with comparable tunable parameter budgets, especially the recent LoRA variants. We also conducted an analysis showing that (a) our AB-LoRA method indeed can reflect the contribution of each LoRA rank; (b) our method can work with different LoRA rank budgets and different backbone models.

Our contributions are summarized as follows:

- We propose a novel method, AB-LoRA, to estimate the importance of each LoRA rank.
- Built upon AB-LoRA, we propose our ALoRA framework, which can allocate LoRA ranks across different model weights and enhance the adaptation process.
- We have conducted extensive experiments and analysis showing that our ALoRA framework is practical and outperforms the baselines under comparable parameter budgets.

2 Related works

2.1 Parameter-efficient fine-tuning (PEFT) methods

Parameter-efficient fine-tuning (PEFT) is an approach of optimizing a small portion of parameters when fine-tuning a large pretrained backbone model and keeping the backbone model untouched

for adaptation (Ding et al., 2022; Zhang et al., 2023f). A branch of PEFT methods inserts additional neural modules or parameters into the backbone model. Representative works in this direction are Adapter (Houlsby et al., 2019; Rücklé et al., 2020; Zhang et al., 2023f), Prefix tuning (Li and Liang, 2021), Prompt tuning (Lester et al., 2021), P-tuning V2 (Liu et al., 2022b). Another approach is to specify the particular parameters to be tunable or prunable (Ben-Zaken et al., 2021; Guo et al., 2021a; Zhao et al., 2020). The reparameterization-based methods have attracted much attention (Hu et al., 2021). This branch of approaches transforms the adaptive parameters during optimization into low-rank and parameter-efficient forms. This type of PEFT method is closely related to intrinsic dimension (Aghajanyan et al., 2021; Li et al., 2018), that is, full parameter fine-tuning process of pretrained models can be reparameterized into optimization within a low-dimensional subspace, i.e., fine-tuning has a low intrinsic dimension (Hu et al., 2021). Intuitively, a well pretrained model does not need to be altered significantly for downstream task adaptation. Qin et al. (2021) investigate whether we can find a common intrinsic subspace shared by various NLP tasks. LoRA (Hu et al., 2021) is inspired by (Aghajanyan et al., 2021; Li et al., 2018) and hypothesizes that the change of weights during model tuning has a low intrinsic rank and optimizes the low-rank decomposition for the change of original weight matrices. PEFT methods are widely applied, especially with the popularization of open-sourced large language models (Zhao et al., 2023) and instruction tuning with these models for different application scenarios (Taori et al., 2023; Dettmers et al., 2023).

2.2 The LoRA method and its variants

LoRA (Hu et al., 2021) is proven to be effective and yield stable results when applied to both relatively small pretrained backbones and large language models (Dettmers et al., 2023; Zhu et al., 2023). Despite its tractability and effectiveness, LoRA still has room for improvements in selecting optimal rank r_m for each Transformer model weight m. The rank r takes discrete values; thus, changing it will directly alter the model structures. The optimal choices of ranks can vary across backbone models, tasks, and even Transformer model weights. Setting a large rank value for r_m can waste training time and computation resources, while progressively setting a small r_m may degrade the model performance. These limitations highlight the importance of upgrading LoRA with an adaptive strategy.

There are already a few works investigating this direction. AdaLoRA (Zhang et al., 2023c) expresses the low-rank multiplication of LoRA in the form of singular value decomposition (SVD), and it identifies the most important ranks by a sensitivity-based importance score. SoRA (Ding et al., 2023) prunes abundant LoRA ranks by imposing a l_0 norm and optimizing with proximal gradient descent. SaLoRA (Hu et al., 2023) prunes the LoRA ranks via the Lagrange multiplier method. Despite these recent efforts, we believe issues still need to be investigated for LoRA rank allocation: (a) The current works initialize a larger value for each r_m and use certain heuristics to prune the number of ranks to meet a predefined budget. This training process inevitably requires additional GPU memory consumption. In addition, the maximum LoRA rank size for each model weight is limited, which restricts the solution space for LoRA rank allocations. (b) The current works depend on heuristic importance scores, which may not reliably reflect the contribution of each LoRA rank. Our work complements the existing literature by addressing the above issues.

3 Methods

3.1 Preliminaries

Transformer model Currently, most widely used open-sourced language models and large language models adopt the stacked Transformer architecture (Vaswani et al., 2017). Each Transformer block is primarily constructed using two key submodules: a multi-head self-attention (MHA) layer and a fully connected feed-forward (FFN) layer. The MHA is given as follows:

$$x^{'} = MHA(xW^{Q}, xW^{k}, xW^{V})W^{O}, \quad (1)$$

where $MHA()$ denotes the multi-head attention operation, $x \in \mathbf{R}^{l\times d}$ is the input tensor, $W^{O} \in \mathbf{R}^{d\times d}$ is the output projection layer (denoted as the Output module), and $W^{Q}, W^{K}, W^{V} \in \mathbf{R}^{d\times d}$ (denoted as the Query, Key, and Value modules). l is the sequence length, d is the hidden dimension. The FFN module consists of linear transformations and an activation function g such as ReLU or GELU (Hendrycks and Gimpel, 2016). Take

the FFN module in the LlaMA-2 models (Touvron et al., 2023) as example:

$$x^{'} = (g(xW^G) * xW^U)W^D, \quad (2)$$

where $W^G, W^U \in \mathbf{R}^{d \times d^{'}}$ (denoted as Gate and Up module) and $W^D \in \mathbf{R}^{d^{'} \times d}$ (denoted as the Down module), and $d^{'}$ is usually larger than d. For notation convenience, we will refer to the number of modules in a Transformer block as N_{mod}. Thus, in LlaMA-2, $N_{mod} = 7$.

Denote the task's training set as $\mathcal{D}_{\text{train}} = (x_m, y_m), m = 1, 2, ..., M$, where M represents the number of samples. In this work, we only consider the case where input x_m and target y_m are both text sequences. And we expect the language modeling head of LLMs to decode y_m during inference. That is, no additional linear prediction heads are considered for predicting categorical or numerical values.

3.2 Formulation

Our objective is to efficiently fine-tune the LLMs for a specific downstream task under a given LoRA parameter budget $R^{target} = \sum_{m=1}^{N_{mod}} r_m^{target}$. The previous literature (Ding et al., 2023; Hu et al., 2023; Zhang et al., 2023c) usually initialize the LoRA modules with a pre-defined large maximum rank r_{max}, consuming extra GPU memories. Different from the previous works, we now initialize each LoRA module with rank $r_m^{init} = R^{target}/N_{mod}$. That is, upon initialization, we have met the LoRA rank budget. Moreover, we will reallocate the LoRA ranks in order to enhance the fine-tuning performance.

In order to adjust the rank allocation of LoRA modules, we now inject gate units $\alpha_i \in \{0, 1\}$ $(i = 1, 2, ..., r_m)$ to each module m with LoRA rank r_m. Imitating the formulation of SVD, the forward propagation of ALoRA is given by:

$$\begin{aligned} z &= xW_m^A G_m W_m^B, \\ G_m &= \text{diag}(\alpha_{m,1}, ..., \alpha_{m,r_m}), \end{aligned} \quad (3)$$

where diag() denotes a diagonal matrix, $W_m^A \in \mathbf{R}^{d \times r_m}$, $W_m^B \in \mathbf{R}^{r_m \times d}$. At initialization, the gate units are all set to 1.

Different from the previous literature (Ding et al., 2023; Hu et al., 2023; Zhang et al., 2023c), we take an alternative approach, that is, consider the problem of LoRA allocation as neural architecture search (White et al., 2023). We consider the gate units α_i as architecture parameters (denoted as the set Θ), the network with all the non-zero gate units as the super-network M, and denote the parameters in the down-projection and up-projection matrices as Ω, then the optimization objective is:

$$\begin{aligned} &\min_{\mathbf{\Theta}} \mathcal{L}(\mathcal{D}_2, \mathbf{\Omega}^*, \mathbf{\Theta}), \\ &s.t. \ \ \mathbf{\Omega}^* = \arg\min_{\mathbf{\Omega}} \mathcal{L}(\mathcal{D}_1, \mathbf{\Omega}, \mathbf{\Theta}), \end{aligned} \quad (4)$$

where $\mathcal{D}_1$ and $\mathcal{D}_2$ consists of a split of the training set D_{train}, $\mathcal{L}()$ is the loss function. This work uses the cross-entropy loss as the loss function. Note that with discrete values of α_i, solving the above optimization problem is challenging due to non-differentiability. Thus, following the work of differentiable neural architecture search (DNAS) (Liu et al., 2019a), α_i is relaxed to a continuous value in between (0, 1) and the equation 3 becomes:

$$\begin{aligned} z &= W_m^B G_m^{'} W_m^A x, \\ G_m^{'} &= \text{diag}(\alpha_{m,1}^{'}, ..., \alpha_{m,r_m}^{'}), \\ \alpha_{m,i}^{'} &= 2 * \text{Sigmoid}(a_{m,i}^{'}), \ a_{m,i}^{'} \in \mathbf{R}, \end{aligned} \quad (5)$$

where $a_{m,i}^{'}$ is initialized with zero value. With this setting, Equation 4 becomes differentable and can be optimized by bi-level optimization (Liu et al., 2019a).

3.3 Our novel AB-LoRA method

Under the DNAS setting, it is natural to consider the architecture weight $\alpha_i^{'}$ as the importance score for LoRA rank i, and one can use these scores to guide the pruning of abundant LoRA ranks. However, as pointed out by the literature (Zhang et al., 2023f; Chen et al., 2019), and as will be demonstrated in the experiment, the architecture weights are not reliable indicators for the final LoRA allocation's performance. This observation motivates us to propose a simple yet effective modification to the DNAS-style architecture search. Instead of relying on the architecture weights' values to keep the best LoRA ranks, we propose directly evaluating the LoRA rank's superiority by its contribution or influence on the super-network's performances. Since our method mimics conducting ablation studies of a certain LoRA rank from the super-network, we refer to our method as the ablation-based LoRA (AB-LoRA).

We now introduce the core of our AB-LoRA method: calculating each LoRA rank's importance

Algorithm 1: Workflow of ALoRA

Input: A super-network M, with R^{target} LoRA ranks uniformly distributed in modules of M;

Output: A new allocation of R^{target} LoRA ranks.

Data: Training set D_{train}, a batch of validation data B_{val}

Train super-network M on the training set D_{train} for K_1 epochs;

for $n = 0$; $n < N_A$ **do**

  for *a single LoRA rank* $r_{m,i}$ *on* M **do**

    Calculate the importance score $\text{IS}(r_{m,i})$ on B_{val};

  Prune n_0 LoRA ranks with lowest importance scores;

  if *there are modules not pruned* **then**

    Add n_0 LoRA ranks to the un-pruned modules;

  Further train the Super-network M on D_{train} for K_2 epochs;

score, defined as how much it contributes to the performance of the super-network. Denote the complete super-network as M. Super-network M is trained till convergence on the training set. We now consider a modified super-network obtained by zeroing out a single LoRA rank r while keeping all other LoRA ranks. This new super-network is denoted as $M_{\backslash r}$. We also consider another modified super-network M_r in which only LoRA rank r is kept while all other LoRA ranks are zeroed out. We evaluate the three versions of super-networks on the same batch of validation data B_{val}. Denote the metric score as a function of a model M, $S(M)$, with the validation data fixed. Then, the importance score of LoRA rank r is given by

$$\text{IS}(r) = S(M) - S(M_{\backslash r}) + S(M_r). \quad (6)$$

In the above equation, $S(M)$ can be treated as a constant term. Thus the above equation can be simplified to $\text{CS}(o) = -S(M_{\backslash r}) + S(M_r)$. Intuitively, the LoRA rank that results in a significant performance drop upon zeroing out must play an important role in the super-network. Similarly, the one keeping most of the performance when acting alone contains important task-related knowledge and should be considered important. In the experiments, different from Chen and Hsieh (2020), we set $S()$ as the negative of the cross-entropy (CE) loss since the widely applied metrics like accuracy or F1: (a) may not vary if the super-network only masks out a single operation, and (b) is not suitable for generative language model fine-tuning.

3.4 The complete process of ALoRA

With the guidance of the importance score in Equation 6, we can now formally define the whole working process of our ALoRA framework (Figure 1). Our working flow of allocating the LoRA ranks builds upon the following intuitions: (a) the pruning and allocation of LoRA ranks is conducted gradually to avoid performance degradation. (b) if the LoRA ranks in a Transformer module receive relatively high importance scores and are not pruned, this module is deemed important. It may need more LoRA ranks for adaptation so that the LoRA parameters can better learn the task knowledge.

The framework of ALoRA is centered on our AB-LoRA method, which requires the super-network to be trained for K_1 epochs on the train set. We freeze the architectural parameters and train only the model parameters on the train set. No bi-level optimization is required, thus saving training time costs. Then, for each LoRA rank, we evaluate the importance score on a batch of samples B_{val} from the development set. Then, n_A LoRA ranks with the lowest scores are pruned by zeroing out their corresponding gate units. Moreover, if some Transformer modules do not have pruned LoRA ranks, we allocate the parameter budgets to them to enhance the adaptation further. [2][3] After the pruning and adding operations, we tune the altered super-network for $K_2 > 0$ epochs to recover the lost performance. The above steps are repeated for N_A times. Formally, we summarize the above process in Algorithm 1.

[2]Note that increasing the rank size of a LoRA module from r_m to $r_m^{'}$ for Transformer module m involves concatenating newly initialized parameters for the matrices, so that $W_m^A \in \mathbf{R}^{d\times r_m}$ and $W_m^B \in \mathbf{R}^{r_m\times d}$ becomes $W_m^A \in \mathbf{R}^{d\times r_m^{'}}$ and $W_m^B \in \mathbf{R}^{r_m^{'}\times d}$. And the diagonal matrix G_m is changed from $\text{diag}(\alpha_{m,1},...,\alpha_{m,r_m})$ to $\text{diag}(\alpha_{m,1},...,\alpha_{m,r_m^{'}})$. The newly added gate units are initialized with ones.

[3]If n_A is not divided by the number of un-pruned modules, we allocate the n_A ranks as uniformly as possible, with priority given to modules with higher average importance scores. For example, if $n_A = 8$, and module m_1, m_2, m_3 are not pruned, and m_1 has the highest average importance score, m_2 ranks the second, m_3 receives the lowest average importance score. Then three ranks are given to m_1 and m_2, and two ranks are given to m_3.

4 Experiments

In this section, we conduct a series of experiments to evaluate our ALoRA method.

4.1 Baselines

We compare our ALoRA framework with the current SOTA PEFT baseline methods.

Adapter-based tuning We consider the following adapter tuning baselines: (1) Houlsby-Adapter (Houlsby et al., 2019); (2) Parallel-Adapter proposed by He et al. (2021); (3) AdapterDrop (Rücklé et al., 2020); (4) LST (Sung et al., 2022); (5) Learned-Adapter (Zhang et al., 2023f).

Prompt-based tuning For prompt-based tuning methods, we compare with (a) P-tuning v2 (Liu et al., 2021); (b) SPT (Zhu and Tan, 2023).

LoRA and its variants we consider the following LoRA variants as baselines: (a) LoRA (Hu et al., 2021); (b) AdaLoRA (Zhang et al., 2023c). (c) SoRA (Ding et al., 2023); (d) SaLoRA (Hu et al., 2023).

Other PEFT methods We also compare: (1) SSP (Hu et al., 2022), which combines different PEFT methods.

The baselines are implemented using their open-sourced codes. The hyper-parameter settings for the baselines are detailed in Appendix E.

4.2 Datasets and evaluation metrics

We compare our approach to the baselines on (a) four benchmark question-answering tasks: SQUAD (Rajpurkar et al., 2016) and three tasks from the SuperGLUE benchmark(Wang et al., 2019) (BoolQ, COPA and ReCoRD). (b) three sentence level tasks from GLUE benchmark (Wang et al., 2018), SST-2, RTE, QNLI. (d) Alpaca dataset (Taori et al., 2023) for instruction tuning, and MT-Bench (Zheng et al., 2023), to evaluate the instruction tuning quality of LLMs. The dataset introductions, statistics, and prompt-response templates for the above tasks are detailed in Appendix B. The above tasks' evaluation metrics or protocols are in Appendix B.5.

4.3 Experiment Settings

Computing infrastures We run all our experiments on NVIDIA A40 (48GB) GPUs.

Pretrained backbones The main experiments uses most recent open-sourced LLM, LlaMA-2 7B released by Meta (Touvron et al., 2023) as the pre-trained backbone model. In the ablation studies, we will also use GPT2-large model (Radford et al., 2019), and RoBERTa-large (Liu et al., 2019b).

Prediction heads When fine-tuning LlaMA-2 7B, we only consider the supervised fine-tuning (SFT) setting (Ouyang et al., 2022), that is, all the predictions are generated using the language modeling head (LM head) upon receiving a prompt or an instruction. For decoding during inference, we use beam search with beam size 5.

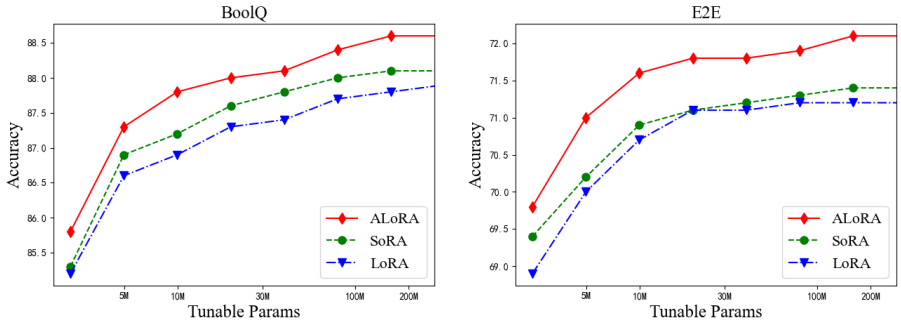
Hyper-parameters for ALoRA In our experiments, unless otherwise specified, we set R^{target} to $8 * N_{mod}$, and initially all Transformer model weights are paired with LoRA modules with rank $r_m^{init} = 8$. In this setting, ALoRA satisfies the LoRA rank budget upon initialization, and thus during training and inference.[4] We set n_A to $1 * N_{mod}$. For training with the ALoRA's workflow, we set the batch size of B_{val} to 32, K_1 to 1 epoch, K_2 to 0.25 epoch, and the LoRA rank allocation procedure is conducted for at most $N_A = 8$ times.

Reproducibility We run each task under five different random seeds and report the median performance on the test set of each task.

Due to limited length, other experimental settings for the baseline methods and the training procedure are put in Appendix E.

4.4 Main results

The experimental results on the three classification tasks and 4 question answering tasks are presented in Table 1. In the second and third columns of Table 1, we present the initial number of tunable parameters and the final ones. Table 1 reveals that our ALoRA method outperforms the baseline methods across all seven tasks, with comparable or fewer tunable parameters throughout the training and inference processes. In particular, ALoRA successfully outperforms AdaLoRA, SoRA, and SaLoRA with comparable initial and final LoRA parameters. These results demonstrate that our method can better allocate LoRA parameters for better downstream task adaptation.



For the E2E benchmark (Novikova et al., 2017), the results are reported in Table 2. The results show that on the E2E task, our ALoRA method successfully outperforms LoRA and SoRA regarding BLEU, ROUGE-L, or METEOR scores.

After the LlaMA-2 7B is fine-tuned on the Alpaca dataset with our ALoRA and SoRA methods,

[4]Note that it is possible that the total LoRA ranks after training is smaller than that at initialization.

ALoRA	18.1	5.01	3.81

Table 4: The memory, speed and time cost for fine-tuning LlaMA-2 7B on the E2E task with different PEFT methods.

4.5 Ablation studies and analysis

Analysis of Training Efficiency So far, we have demonstrated that our ALoRA can outperform LoRA and SoRA on a wide collection of tasks. One might suspect this advantage is achieved with significant time or memory costs. We compare the max training GPU memory, training speed, and training time costs of ALoRA, SoRA, and LoRA when fine-tuning LlaMA-2 7B with the E2E benchmark. From Table 4, one can see that ALoRA requires less memory costs during training than SoRA since it does not initialize with a larger LoRA rank. Moreover, under early stopping, the total training time cost of ALoRA remains comparable with SoRA and LoRA.

Ablation study of ALoRA framework We now consider the following variants of ALoRA: (a) instead of utilizing our novel AB-LoRA method, we follow the optimization procedure of Equation 4, and use the architectural weights $\alpha'_{m,i}$ as the importance scores. This variant is denoted as ALoRA-DNAS. (b) Use the sensitivity-based metric in Zhang et al. (2023c) as the importance measurement. (denoted as ALoRA-Sensi). The experimental results on the BoolQ, ReCoRD, and SQUAD tasks are reported in Table 6 of Appendix F. The results show that ALoRA outperforms the two variants, demonstrating that our AB-LoRA method can provide better guidance in allocating LoRA ranks.

Visualization of the final rank allocations In this section, we visualize the final rank allocations of ALoRA after the training process on the E2E task in Figure 3. We also compare the LoRA rank allocations by the SoRA method in Figure 4 of Appendix H. We can see from Figure 3 that (a) More LoRA rank budgets are put to adapt the query and key modules, while the value and output modules in the self-attention are less emphasized. (b) The feed-forward layer in the Transformer block requires fewer LoRA ranks, indicating that this layer stores general language knowledge, while the attention module will contain more task-specific knowledge after ALoRA fine-tuning. Compared

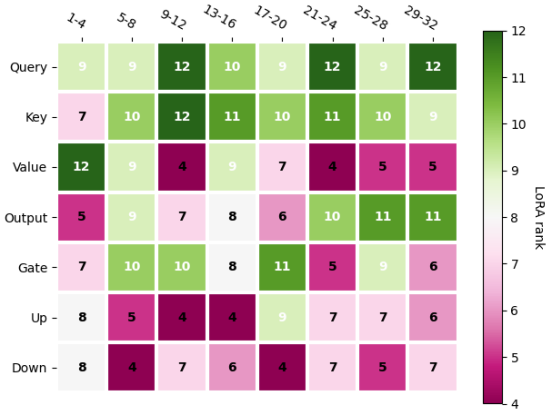

Figure 3: The final rank allocations of ALoRA after fine-tuning the LlaMA-2 7B model on the E2E task.

with ALoRA's allocation, SoRA results in a more unbalanced allocation, putting more rank budgets to the Down module than our ALoRA method.

Comparisons under different LoRA rank budgets Note that in the main experiments, we set the targeted LoRA rank budget as $R^{target} = 8 * N_{mod}$. Now we vary this budget to any multiplier in 1, 2, 4, 8, 16, 32, 64, 128 times N_{mod}, and see how ALoRA, SoRA, and LoRA perform on the BoolQ and E2E tasks. The experimental results are presented in Figure 2(a) and 2(b). From the results, we can see that under different LoRA rank budgets, our ALoRA method can consistently outperform LoRA and SoRA by effectively allocating different LoRA ranks properly to different Transformer modules, thus enhancing the performance of fine-tuning.

Ablation on the pretrained backbones Our main experiments are conducted on the LlaMA-2 7B model. To demonstrate the wide applicability of our method, we now conduct experiments on RoBERTa-large and GPT2-large. The results are reported in Table 7 and 8. We can see that on these two backbones, our method can also outperform the baseline methods.

5 Conclusion

This work presents the Allocating Low-Rank Adaptation (ALoRA), an innovative method for parameter-efficient fine-tuning large language models. Upon the hypothesis that the adaptation for different Transformer modules could be of different tanks, we introduce a novel workflow for allocating LoRA ranks in the fine-tuning process. First, we propose a novel method, AB-DNAS, to accurately evaluate the importance scores of LoRA

ranks. Second, guided by the AB-DNAS method, our workflow allows the pruning of ranks at specific modules and considers allocating more ranks to essential modules. Thus, our method does not require to set a more significant initial rank. Our method is convenient to implement and off-the-shelf. Experiments on various tasks demonstrate that our ALoRA method outperforms the baseline methods.

6 Acknowledgements

For the purpose of Open Access, the author has applied a CC BY public copyright licence to any Author Accepted Manuscript version arising from this submission.

Limitations

We showed that our proposed method can greatly improve the performance of parameter-efficient tuning on diverse tasks and different pretrained models (i.e., LlaMA-2 7B, RoBERTa-large and GPT2-large). However, we acknowledge the following limitations: (a) the more super-sized open-sourced LLMs, such as LlaMA-2 13B and 70B, are not experimented due to limited computation resources. (b) Other tasks in natural language processing, like information extraction, were also not considered. But our framework can be easily transferred to other backbone architectures and different types of tasks. It would be of interest to investigate if the superiority of our method holds for other large-scaled backbone models and other types of tasks. And we will explore it in future work.

Ethics Statement

The finding and proposed method aims to improve the low-rank adaptation (LoRA) based tuning in terms of better rank allocations and performances. The used datasets are widely used in previous work and, to our knowledge, do not have any attached privacy or ethical issues. In this work, we have experimented with LlaMA-2 7B, a modern large language model. As with all LLMs, LlaMA-2's potential outputs cannot be predicted in advance, and the model may in some instances produce inaccurate, biased or other objectionable responses to user prompts. However, this work's intent is to conduct research on different fine-tuning methods for LLMs, not building applications to general users. In the future, we would like to conduct further testing to see how our method affects the safety aspects of LLMs.

A Additional related works

Adapter-based tuning. One of the most important research lines of PEFT is adapter-based tuning. Adapter (Houlsby et al., 2019) inserts adapter modules with bottleneck architecture between every consecutive Transformer (Vaswani et al., 2017) sublayers. AdapterFusion (Pfeiffer et al., 2021) only inserts sequential adapters after the feed-forward module. Adapter-based tuning methods have comparable results with model tuning when only tuning a fraction of the backbone model's parameter number. Due to their strong performance, a branch of literature has investigated the architecture of adapters in search of further improvements. He et al. (2021) analyze a wide range of PETuning methods and show that they are essentially equivalent. They also propose the general architecture of PEFT, and derive the Parallel Adapter which connects the adapter modules in parallel to the self-attention and MLP modules in the Transformer block. AdapterDrop (Rücklé et al., 2020) investigates the efficiency of removing adapters from lower layers. Adaptive adapters (Moosavi et al., 2022) investigate the activation functions of adapters and propose to learn the activation functions of adapters via optimizing the parameters of rational functions as a part of the model parameters. Compacter (Mahabadi et al., 2021) uses low-rank parameterized hypercomplex multiplication (Le et al., 2021) to compress adapters' tunable parameters. LST (Sung et al., 2022) improves the memory efficiency by forming the adapters as a ladder along stacked Transformer blocks, and it enhances the adapter module by adding a self-attention module to its bottleneck architecture. (Sung et al., 2022; Jie and Deng, 2022) try to add different encoding operations, like self-attention operations and convolutions between the bottleneck structure of adapters, and achieve better performances. Learned-Adapter (Zhang et al., 2023f) builds upon the above adapter-based methods and enhance the performance of adapter tuning by automatically learning better architectures for adapters.

Prompt tuning methods Prompt tuning (Lester et al., 2021) and P-tuning (Liu et al., 2022b) insert a soft prompt to word embeddings only, and can achieve competitive results when applied to super-sized PTMs. Prefix-tuning (Li and Liang, 2021) and P-tuning v2 (Liu et al., 2021) insert prompts to every hidden layer of PTM. IDPG (Wu et al., 2022) uses the prompt generator with parameterized hypercomplex multiplication (Le et al., 2021) to generate a soft prompt for every instance. LPT (Liu et al., 2022a) improves upon IDPG by selecting an intermediate layer to start inserting prompts. SPT (Zhu and Tan, 2023) designs a mechanism to automatically decide which layers to insert new instance-aware soft prompts.

LoRA methods Since LoRA is the most popular PEFT method in the era of large language models, there are many works that are orthogonal to AdaLoRA, SoRA and our work that are devoted to improve LoRA on many different aspects. QLoRA (Dettmers et al., 2023) proposes a novel quantization method that can significantly reduce the memory consumptions of LLMs during LoRA fine-tuning. LoRA-FA (Zhang et al., 2023b) freezes parts of the randomly initialized LoRA matrices. (d) VERA (Kopiczko et al., 2023) investigate whether one could froze the randomly initialized LoRA matrices and only learns a set of scaling vectors. Tying LoRA matrices across layers are also investigated by VERA.

B Appendix for the datsets and evaluation metrics

B.1 Datasets from GLUE and SuperGLUE

We experiment on three tasks from the GLUE (Wang et al., 2018) benchmark: (a) (a) a sentiment classification task, SST-2. (b) two benchmark natural language inference tasks, RTE and QNLI. We also experiment with three question-answering tasks: (a) two question answering tasks in the format of binary choices, COPA and BoolQ. (b) A Squad (Rajpurkar et al., 2016) style question an-

Datasets	#train	#dev	#test	$\|\mathcal{Y}\|$	Type	Labels	Metrics
				SuperGLUE tasks			
BoolQ	9.4k	1.6k	1.6k	2	Question Answering	True, False	acc
COPA	0.4k	0.05k	0.05k	2	Question Answering	choice1, choice2	acc
ReCoRD	101k	1k	7.4k	-	Question Answering	-	f1-em
				GLUE tasks			
SST-2	66k	1k	0.8k	2	sentiment classification	positive, negative	acc
RTE	2.5k	0.1k	0.1k	2	NLI	entailment, not entailment	acc
QNLI	104k	1k	5.4k	2	NLI	entailment, not entailment	acc
				Other tasks

MT-Bench	-	-	80	-	Instruction tuning	-	GPT-4 scores

Table 5: The dataset statistics of the GLUE and SuperGLUE benchmark tasks evaluated in this work. $|\mathcal{Y}|$ is the number of classes for a classification task.

swering task, ReCoRD.

Since the original test sets are not publicly available for these tasks, we follow Zhang et al. (2020); Mahabadi et al. (2021); Zhu et al. (2023d); Gao et al. (2023); Zhu (2021d,c); Zhang et al. (2022); Zuo et al. (2022); Sun et al. (2022); Zhu et al. (2021d); Zhu (2021a); Zhu et al. (2021c); Li et al. (2019); Zhu et al. (2019b); Zhu (2021b); Zhang et al. (2021); Wang et al. (2020) to construct the train/dev/test splits as follows to ensure a fiar comparison: (a) for datasets with fewer than 10k samples (RTE, COPA, BoolQ), we divide the original validation set in half, using one half for validation and the other for testing. (b) for larger datasets, we split 1k samples from the training set as the development set, and use the original development set as the test set. The detailed statistics of the GLUE and SuperGLUE benchmark tasks is presented in Table 5.

B.2 The Squad task

Stanford Question Answering Dataset (SQuAD) (Rajpurkar et al., 2016) is a reading comprehension dataset, consisting of questions posed by crowdworkers on a set of Wikipedia articles, where the answer to every question is a segment of text, or span, from the corresponding reading passage, or the question might be unanswerable. This task is one of the most widely studied question answering task in the field.

In this work, we use the v1.1 version of SQUAD. Since the original test sets are not publicly available for these tasks, we follow Zhang et al. (2020); Mahabadi et al. (2021) and split 1k samples from the training set as the development set, and use the original development set as the test set. The detailed statistics of this task is presented in Table 5.

B.3 Datasets: E2E benchmark

The E2E benchmark dataset for training end-to-end, data-driven natural language generation systems in the restaurant domain. It asks a model to generate natural utterances based on a set of given key contents. This dataset has a 42061/4672/4693 train/dev/test split.

B.4 Dataset: Instruction tuning

Instruction tuning is an important method to improve the general capabilities of large language models (Ouyang et al., 2022). With the rise of large language models in the scale of 10B parameters or more, like GPT-3, T5, PaLM, researchers have actively explored the few-shot or zero-shot capabilities of these models. (Mishra et al., 2021) find that fine-tuning these LLMs on a large scale datasets containing hundreds of NLP tasks significantly improves the zero-shot performances on unseen tasks, establishing the scaling law of task numbers. The previous works like (Wei et al., 2021) and T0 (Sanh et al., 2021) establishes the instruction tuning datasets by transforming the traditional NLP tasks into a unified prompt format. InstructGPT (Ouyang et al., 2022) conducts instruction tuning using the dataset constructed based the user queries from the OpenAI API users. Note that this work is also a seminal work for human feedback learning with reinforcement learning. However, the complete instruction tuning dataset from (Ouyang et al., 2022) remains closed. With the launch of ChatGPT, (Taori et al., 2023) (Alpaca) constructs an instruction tuning dataset with diverse topics

using the self-instruct techniques.

For our experiment, we employ the Alpaca dataset (Taori et al., 2023) for instruction tuning. Specifically, we employs its cleaned version[5]. This dataset comprises 51K instructions and demonstrations, and is suitable for instruction tuning. The cleaned version corrects multiple issues such as hallucinations, merged instructions, and empty outputs.

B.5 Evaluation metrics/protocols

For the three GLUE tasks we experiment on, we report accuracy (denoted as acc). For ReCoRD, we report the average of the F1 score and the exact match score (denoted as f1-em). For the BoolQ and COPA tasks, we report accuracy. The above choices of evaluation metrics strictly follow (Wang et al., 2018) and (Wang et al., 2019).

For the SQUAD dataset, we also report the average of the F1 score and the exact match score (denoted as f1-em).

Following (Novikova et al., 2017), we report three different metrics on the E2E task: (a) BLEU; (b) ROUGE-L; (c) METEOR. We rely on the HuggingFace Evaluate package[6] for computing these metrics.

For evaluating the quality of instruction tuned LlaMA-2 7B, we follow the current common practice of utilizing GPT-4 as a unbiased reviewer (Zheng et al., 2023). 80 instructions from the MT-Bench is set as a test set. We generate model responses from a fine-tuned model with beam size 5 with the generation function in Huggingface Transformers (Wolf et al., 2020a). Then we compare SoRA and ALoRA's answers with GPT-4. For each instruction in MT-Bench, GPT-4 (OpenAI, 2023) is asked to write a review for both answers from the two methods, and assigns a quantitative score on a scale of 10 to each response. The prompts of instructing GPT-4 for evaluation is presented in Appendix D. ROUGE-L scores computed by considering the answers generated by GPT-4 as the ground truth.

C Prompt templates for fine-tuning LlaMA-2 7B

Since we fine-tune LlaMA-2 7B without introducing task-specific prediction heads, we need to transform all the tasks into a prompt-response format. Now we present the prompt-response template for each task.

Templates for RTE and QNLI Since these two tasks are NLI tasks, the samples in them consists of two input text, [sentence1] and [sentence1], and a label [label_name] (entailment or not entailment). Thus, we use the following templates:

Template for prompt:

```
sentence 1: [sentence1]
sentence 2: [sentence1]
Are sentence 1 and sentence 2 have
entailment relation or not?
```

Template for response:

```
[label_name]
```

Templates for SST-2 The samples in this task consists of one input text, [sentence], and a label [label_name] (positive or negative).

Template for prompt:

```
[sentence]
The sentiment of the given sentence is:
```

Template for response:

```
[label_name]
```

Templates for BoolQ The samples in this task consists of a reference document, [doc], a query, [query], and a label [label_name] (yes or no).

Template for prompt:

```
Reference document:
[doc]
Question:
[query]
```

Template for response:

```
[label_name]
```

Templates for COPA The samples in this task consists of a premise, [premise], two choices, [choice1] and [choice2], a query, [query], and a label [label_name] (1 or 2, indicating which choice is consistent with the premise).

Template for prompt:

```
Premise:
[premise]
Choice 1: [choice1]
Choice 2: [choice2]
Question:
[query]
```

Template for response:

```
[label_name]
```

[5] https://huggingface.co/datasets/yahma/alpaca-cleaned.

[6] https://huggingface.co/docs/evaluate/index

Templates for ReCoRD and SQUAD The samples in these two tasks consist of a context document, [context], a question, [query], and a answering span, [answer].

Template for prompt:

```
Context:
[context]
Question:
[query]
```

Template for response:

```
[answer]
```

Templates for E2E The samples in this task consists of a reference [ref], consisting required information, and a targeted response, [target], which is a customer review written according to the reference's contents.

Template for prompt:

```
Reference:
[ref]
Generate a customer review following the
given reference.
```

Template for response:

```
[target]
```

D Prompt templates for GPT-4 evaluations

In this work, we utilize the powerful LLM GPT-4 (OpenAI, 2023) as the evaluator for comparing the instruction tuning quality. As a reviewer, GPT-4 will receive a query [query], two responses, [response1] and [response2], from two assistants. We will ask GPT-4 to write a review for each response, assessing the quality of the response, and then ask GPT-4 to assign a score on a scale of 10 to each response.

Template for prompt:

```
Task Introduction
you will be given a query, and two responses
from two assistants,
could you compare the two responses,
and do the following:
(1) write a concise review for each
assistant's response, on how well the
response answers the query, and whether
it will be helpful to humans users, and any
issues in the response;
(2) assigns a quantitative score on a scale
of 10 to each response, reflecting
your assessment of the two responses
Query:
[query]
Response 1 from assistant 1:
[response1]
Response 2 from assistant 2:
[response2]
```

E Appendix for Experimental settings

Here, we provide more details for experimental settings.

Hyper-parameters for the baseline PEFT methods For P-tuning V2, the number of prompt tokens at each layer is set to 160. For SPT, the bottleneck dimension is set to 256, and the number of prompt layers is set to 8. For adapter-based methods, the bottleneck dimension is set to 40, and the adapter modules are added on the self-attention and feed-forward module. For LoRA and ALoRA, the initial rank at each module is set to 8. For AdaLoRA, SoRA, and SaLoRA, the initial rank at each module is set to 16, and half of the rank budget is pruned during fine-tuning. We adjust the sparsity for SSP so that the number of tunable parameters is comparable with ALoRA and the other baselines.

Training settings for PEFT methods We use the HugginFace Transformers (Wolf et al., 2020b) and PEFT (Mangrulkar et al., 2022) for implementing all the methods, and for training and making predictions. For fine-tuning LlaMA-2 7B model, the maximum sequence length is set to 2048. The maximum training epoch is set to 10. The batch size is set between 16 for task with less than 10k training set, and 128 otherwise. We use AdamW as the optimizer with a linear learning rate decay schedule and 6% of the training steps for warm-up. The learning rate is set to 1e-4. The other hyperparameters are kept the same with (Wolf et al., 2020b). In every 200 steps, the model is evaluated on the dev set. Patience is set to 10, that is, if the model does not achieve a lower development set loss for 10 evaluation runs, the training stops. The best checkpoint on the dev set is used to run predictions on the test set.

F Ablation on the ALoRA framework

We consider two variants of ALoRA: (a) use the architectural weights $\alpha'_{m,i}$ as the importance scores during bi-level optimization (Liu et al., 2019a). This variant is denoted as ALoRA-DNAS. (b) Use the sensitivity-based metric in Zhang et al.

Method	BoolQ (acc)	ReCoRD (f1-em)	Squad (f1-em)
ALoRA-DNAS	87.6	91.2	88.7
ALoRA-Sensi	87.5	91.3	88.6
ALoRA	88.0	91.8	89.2

Table 6: The comparison of ALoRA's variants on the BoolQ, ReCoRD, and Squad tasks. The backbone model is LlaMA-2 7B.

(2023c) as the importance measurement. (denoted as ALoRA-Sensi). The experiments on the BoolQ and E2E methods are provided in 6

G Ablation on the pretrained backbones

Our main experiments are conducted on the LlaMA-2 7B model. To demonstrate that our method works well regardless of the backbone models, we now conduct experiments on the RoBERTa-large. In this experiment, since the language modeling capabilities of these RoBERTa-large can not match LlaMA-2 7B model, we change the following setting for the prediction head: (a) we use a linear layer as the prediction head for classification tasks. (b) for the ReCoRD task, we use two linear layers to predict the starting and ending positions of a entity span. The other experimental settings are kept the same with the main experiments (Table 1).

We conduct experiments on the BoolQ, ReCoRD and Squad tasks. The results are reported in Table 7. We can see that on the RoBERTa-large backbone, our method can also outperform the baseline methods.

We also run GPT2-large on the E2E task, and the results are reported in Table 8. The results demonstrate that when the GPT2-large is the backbone model, our ALoRA method also outperforms the baselines.

H Visualization of the final rank allocations of SoRA

In the main contents, we visualize the final rank allocations of ALoRA after the training process on the E2E task in Figure 3. As comparison, we now present the LoRA rank allocations by the SoRA method in Figure 4.

I Case studies of Instruction tuning

In the Section 4.4 of the main content, we present the overall performance of ALoRA and SoRA on the MT-Bench, after fine-tuning LlaMA-2 7B on

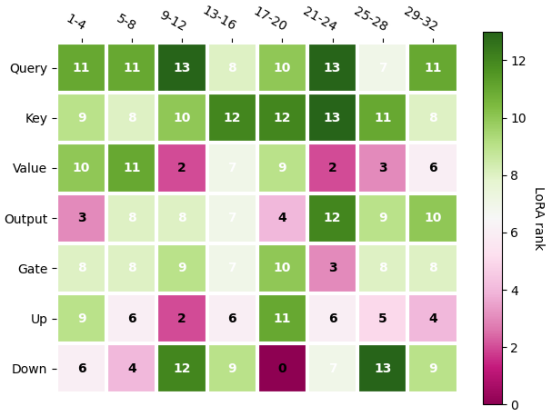

Figure 4: The final rank allocations of SoRA after fine-tuning the LlaMA-2 7B model on the E2E task.

the Alpaca dataset. Now we present concrete examples in Table 9 to showcase the Superiority of ALoRA.

Method	Additional Params		BoolQ	ReCoRD	Squad
	Initial	Final	(acc)	(f1-em)	(f1-em)
Results for RoBERTa-large					
Learned-Adapter	366M	354M	86.8	90.2	88.7
LoRA	3.54M	3.54M	86.9	90.0	88.6
SoRA	708M	3.53M	87.2	90.1	88.7
ALoRA	3.54M	3.42M	87.6	90.7	89.4

Table 7: The comparison on the BoolQ, ReCoRD, and Squad tasks, when the backbone model is RoBERTa-large. We report the median performance over 5 random seeds. Bold and Underline indicate the best and the second best results. The metric for each task is explained in Appendix B.5.

Method	BLEU	ROUGE-L	METEOR
Learned-Adapter	68.6	69.6	45.2
LoRA	68.7	69.8	45.3
SoRA	<u>68.9</u>	<u>69.9</u>	<u>45.4</u>
ALoRA	**69.3**	**70.4**	**46.0**

Table 8: Results for different PEFT methods on the E2E benchmark. The backbone LM is GPT2-large. The metrics are explained in Appendix B.5.

Query	Edit the following paragraph to correct any grammatical errors: She didn't remembre where is her purse, so I thinks its in the car but he's say it's on kitchen table but he are not sure, and then they asked me to looking for it, she's say, "Can you?", and I responds with, "Maybe, but ain't no sure," and he not heard me, and, "What?", he asks, "Did you found it?".
ALoRA's response	
Responses	She didn't remember where her purse was, so I thought it was in the car, but he said it was on the kitchen table, but he wasn't sure, and then they asked me to look for it, she said, "Can you?" and I responded with, "Maybe, but I'm not sure," and he didn't hear me, and then he asked, "Did you find it?"
GPT-4's comments	Assistant 1's response effectively corrects all the grammatical errors in the original paragraph. The assistant has correctly changed "remembre" to "remember," rearranged the clause order from "where is her purse" to "where her purse was," and adjusted verb forms for proper agreement (e.g., changing "thinks" to "thought"). Quotation marks and commas are properly used, making direct speech clear and punctuated correctly. The conjunctions are better placed, contributing to a more natural flow of sentences. Additionally, all instances of colloquial or incorrect language such as "ain't no sure" have been revised into standard English ("I'm not sure"). Overall, this response would be very helpful to human users as it provides a grammatically sound version of the original text.
GPT-4 score	9
SoRA's response	
Responses	She didn't remember where her purse was, so I thought it was in the car, but he said it was on the kitchen table, but he wasn't sure. They asked me to look for it, and she said, "Can you?" I responded with, "Maybe, but I'm not sure." He didn't hear me, and he asked, "What?" I said, "Did you find it?"
GPT-4's comments	Assistant 2 also does an excellent job correcting grammatical mistakes from the initial query. This assistant similarly fixes issues with verb tense consistency and subject-verb agreement (e.g., "he's say" corrected to "he said"). However, there is a slight deviation at the end where Assistant 2 writes: "I said, 'Did you find it?'". This seems like an attempt by Assistant 2 to make sense of a confusing part of dialogue in which speaker roles were unclear but results in altering the meaning slightly because it suggests that 'I' am asking if 'he' found it rather than him asking 'me'. This could be misleading or confusing without additional context indicating who is speaking at that moment. Nevertheless, punctuation around quotations is accurate which aids readability.
GPT-4 score	8

Table 9: An example showcasing that the fine-tuning quality of ALoRA is higher than SoRA.

R-Spin: Efficient Speaker and Noise-invariant Representation Learning with Acoustic Pieces

Heng-Jui Chang and **James Glass**
MIT CSAIL
hengjui@mit.edu

Abstract

This paper introduces Robust Spin (R-Spin), a data-efficient domain-specific self-supervision method for speaker and noise-invariant speech representations by learning discrete acoustic units with speaker-invariant clustering (Spin). R-Spin resolves Spin's issues and enhances content representations by learning to predict acoustic pieces. R-Spin offers a 12X reduction in computational resources compared to previous state-of-the-art methods while outperforming them in severely distorted speech scenarios. This paper provides detailed analyses to show how discrete units contribute to speech encoder training and improving robustness in diverse acoustic environments.

1 Introduction

Self-supervised learning (SSL) for encoder pre-training has emerged as a foundational element in speech processing, outperforming conventional approaches across various applications (Mohamed et al., 2022; Liu et al., 2022). Given the substantial cost associated with human annotation of speech data, SSL methods leverage unlabeled audio data to pre-train encoders, generating good representations for downstream tasks like automatic speech recognition (ASR) and speaker identification (Yang et al., 2021; Tsai et al., 2022). The application of SSL models has notably concentrated on ASR, aiming to mitigate the dependence on large transcribed corpora (Hsu et al., 2021a; Baevski et al., 2022; Liu et al., 2023). Thus, extracting content representations has become a crucial aspect of speech SSL research (Tjandra et al., 2021; Chan and Ghosh, 2022; Peyser et al., 2022; Williams, 2022). Prior studies have devised objective functions to disentangle content from speech, fostering the ability of SSL models to generate speaker-invariant representations through domain-specific self-supervision (DS). In DS, a pre-trained SSL model is fine-tuned with unlabeled data for specific applications. Qian et al. (2022) propose ContentVec by disentangling speaker and content information, demonstrating promising results. However, ContentVec suffers from the requirement of a voice conversion model and substantial computational costs exceeding 600 GPU hours. Alternatively, Chang et al. (2023) propose Speaker-invariant Clustering (Spin) to produce content representations with minimal fine-tuning resources. Nonetheless, Spin is constrained to fine-tuning only the top layers, thereby lacking the flexibility to adapt to diverse acoustic domains.

Parallel to modeling content information in speech, numerous studies are dedicated to investigating the robustness of speech SSL. While current methods perform well on clean speech datasets, they are vulnerable to out-of-domain data like distorted audio signals (Hsu et al., 2021b). To mitigate this vulnerability, researchers have proposed noise-invariant training techniques. Huang et al. (2022a) proposes HuBERT-MGR via domain adversarial training to render the fine-tuned HuBERT model (Hsu et al., 2021a) invariant to domain shifts. WavLM (Chen et al., 2022) integrates denoising with the HuBERT pre-training framework, achieving state-of-the-art performance in many speech processing downstream tasks. Similarly, Zhu et al. (2023) propose Robust data2vec, introducing perturbations to the input to predict the exponential moving average teacher model's representations. In deHuBERT (Ng et al., 2023), the Barlow Twins loss (Zbontar et al., 2021) is applied to encourage representation invariability to input perturbations. Although many methods have shown success in noisy speech recognition (Wang et al., 2022; Zhu et al., 2022; Huang et al., 2022b; Hu et al., 2023), to our knowledge, none have concurrently addressed the disentanglement of speaker and noise while enhancing content information. Furthermore, these approaches exhibit inefficiency, often requiring high computation costs and iterating large cor-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 642–662
June 16-21, 2024 ©2024 Association for Computational Linguistics

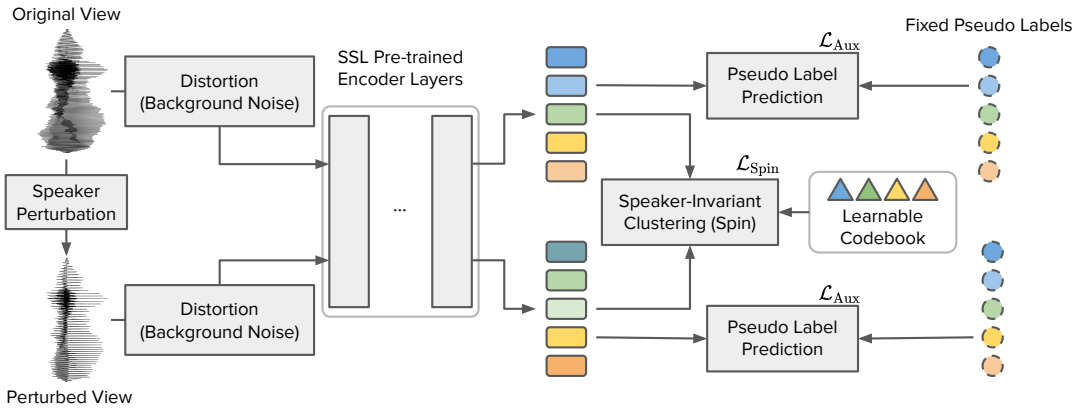

Figure 1: The proposed R-Spin domain-specific self-supervision framework. The input utterance is perturbed into a different voice and distorted with random noise. Both the original and perturbed views are fed into an encoder initialized with an SSL pre-trained model. The model is optimized with Speaker-invariant Clustering (Spin) (Chang et al., 2023) objective ($\mathcal{L}_{\text{Spin}}$) and frame-wise pseudo-label prediction loss ($\mathcal{L}_{\text{Aux}}$).

pora over numerous epochs.

To effectively acquire high-quality content and robust representations for real-world applications, this paper extends Spin with noise-invariant training and acoustic piece pseudo-label learning, coined Robust Spin (R-Spin). During training, two utterances of the same content with different distortions are fed into a speech SSL encoder. The outputs are frame-wise vector-quantized with a learnable codebook via online clustering, as in Spin. The model is trained to match cluster ID distributions between the utterances. To prevent codebook collapse, an additional pseudo-label prediction loss is introduced. The pseudo-labels are generated by learning acoustic pieces (Ren et al., 2022) on top of the discrete units produced by a pre-trained Spin model, offering better training targets that closely align with phonemes and characters. Within this framework, the speech encoder learns speaker and noise-invariant representations, benefiting robustness and content extraction simultaneously. The contributions are summarized as follows:

1. We integrate predicting acoustic pieces into Spin, enabling fine-tuning all parameters without collapsing, which allows the processing of more complex speech recordings.
2. R-Spin inherits the benefit of low training costs from Spin, requiring 12X less computation than prior art.
3. With noise-invariant training, R-Spin outperforms other DS approaches in distorted speech and phoneme recognition tasks like the CHiME-4 challenge (Vincent et al., 2017).
4. We inspect the hidden representations of speech SSL models to quantify the speaker and noise invariability.
5. We offer in-depth analyses of discrete acoustic units to understand how these units help speech encoder training.

2 Method

2.1 Overview

The proposed R-Spin framework is shown in Fig. 1. R-Spin is based on Speaker-invariant Clustering (Spin) (Chang et al., 2023), a domain-specific self-supervision method with online clustering and swapped prediction for capturing content representations (Sec. 2.2). We introduce noise-invariant training by perturbing inputs to improve robustness (Sec. 2.3). Moreover, an auxiliary pseudo-label prediction loss enables fine-tuning the entire model without collapsing (Sec. 2.4). Acoustic Piece is incorporated with the auxiliary loss to improve performance further (Sec. 2.5).

2.2 Speaker-invariant Clustering

Spin is an efficient DS method for improving content representations inspired by Swapping Assignments between Views (SwAV) (Caron et al., 2020). We briefly introduce Spin and suggest readers refer to the original paper for further details.

For each utterance in a mini-batch, the F0 frequency and the relative ratio between formant frequencies are randomly perturbed to mimic the same sentence spoken by a different speaker (Choi et al., 2021; Qian et al., 2022). The original and perturbed views are fed into a transformer encoder (Vaswani et al., 2017) initialized with an SSL model like HuBERT (Hsu et al., 2021a). The output representations $\mathbf{H} = [\boldsymbol{h}_1 \dots \boldsymbol{h}_B]^{\mathsf{T}}$ of the original

view are linearly projected and L2-normalized to $\mathbf{Z} = [\boldsymbol{z}_1 \dots \boldsymbol{z}_B]^\mathsf{T}$, where B is the number of frames in a batch. We then use the representations to compute a probability distribution over a learnable codebook as $p(\cdot|\boldsymbol{z}_b)$. We perform the same operations to the perturbed utterance, resulting in another distribution $q(\cdot|\tilde{\boldsymbol{z}}_b)$, where $\tilde{\cdot}$ denotes features from the speaker-perturbed view. Next, q is smoothed by solving an optimal transport problem to enforce full codebook usage. Finally, the model is trained to perform swapped predictions between views by minimizing the cross-entropy loss

$$\begin{aligned}\mathcal{L}_{\text{Spin}} = &-\frac{1}{2B}\sum_{b\in[B]}\sum_{k\in[K]} q(k|\tilde{\boldsymbol{z}}_b)\log p(k|\boldsymbol{z}_b) \\ &-\frac{1}{2B}\sum_{b\in[B]}\sum_{k\in[K]} q(k|\boldsymbol{z}_b)\log p(k|\tilde{\boldsymbol{z}}_b),\end{aligned} \tag{1}$$

where K is the size of the learnable codebook, and the second term emerges from the interchangeability of the role of the perturbed and original speech.[1] Under this DS framework, the fine-tuned model produces speaker-invariant representations, making the content of speech signals more accessible to downstream applications.

2.3 Noise-invariant Training

To improve the robustness of SSL models, we introduce noise-invariant training by including audio distortions to both views of the input. We anticipate the model will be able to concurrently eliminate noise and speaker-related information, thereby enabling the trained model to generate robust content representations.

2.4 Auxiliary Pseudo-label Prediction Loss

As noted by Chang et al. (2023), Spin is constrained to fine-tuning solely the top layers of pre-trained SSL encoders. Otherwise, the model converges towards a trivial solution, yielding outputs irrelevant to the corresponding inputs. This limitation may not be problematic when the application domain closely aligns with the pre-training data. However, given that the bottom layers are associated with low-level signal processing like denoising (Chang et al., 2021; Gong et al., 2023), subjecting these layers to fine-tuning is imperative. This adjustment is particularly beneficial in enhancing the model's robustness to out-of-domain data. Consequently, we propose a pseudo-label prediction loss to prevent models from collapsing.

[1] $[N] = \{1, 2, \dots, N\}$ for any positive integer N.

The pseudo-label prediction is a frame-wise classification problem with a loss function of

$$\begin{aligned}\mathcal{L}_{\text{Aux}} = &-\frac{1}{2B}\sum_{b\in[B]}\log p(y_b|\boldsymbol{h}_b) \\ &-\frac{1}{2B}\sum_{b\in[B]}\log p\left(y_b\middle|\tilde{\boldsymbol{h}}_b\right),\end{aligned} \tag{2}$$

where y_b is the pseudo-label at frame b. The probability distributions are computed by projecting $\boldsymbol{h}$ with a fully connected layer followed by a softmax. The choice of pseudo-labels is flexible, including K-means clusters of acoustic features and codewords produced by Spin. With this loss, the fine-tuned models are expected to preserve content even when all layers are fine-tuned. Combining Eqs. 1 and 2, the overall loss function is

$$\mathcal{L} = \mathcal{L}_{\text{Spin}} + \lambda\mathcal{L}_{\text{Aux}}, \tag{3}$$

where $\lambda > 0$ is a hyper-parameter. $\mathcal{L}_{\text{Aux}}$ has learning targets independent of the model, regularizing and stabilizing the training process. Meanwhile, $\mathcal{L}_{\text{Spin}}$ optimizes on varying labels from a dynamically changing codebook, offering flexibility to improve upon the pseudo-labels in $\mathcal{L}_{\text{Aux}}$. Therefore, the combined loss function is expected to enhance pre-trained speech SSL encoders and mitigate Spin's limitations.

2.5 Acoustic Piece

This section introduces acoustic pieces (Ren et al., 2022) to $\mathcal{L}_{\text{Aux}}$ to further improve R-Spin. APs are learned by applying byte-pair encoding (BPE) (Sennrich et al., 2016) to discrete acoustic units like K-means clusters of HuBERT representations. AP captures high-level units close to phonemes and characters, useful for pre-training (Wu et al., 2023) and generation (Shen et al., 2024). Hence, we propose to set AP as the target of $\mathcal{L}_{\text{Aux}}$ to extract better content representations.

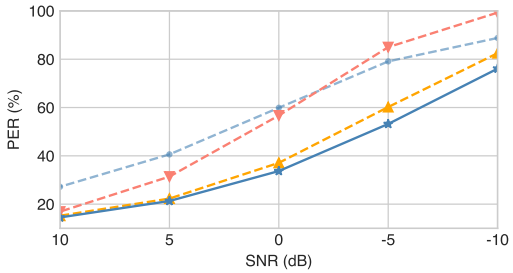
Following Ren et al. (2022), we first merge identical consecutive units in time for each utterance. The BPE algorithm is then applied to the reduced sequences to learn acoustic pieces. Next, we encode the entire training corpus into APs and duplicate the encoded units to the original utterance length. The encoded corpus is then used as the pseudo-labels for Eq. 2, expecting to encourage the fine-tuned SSL model to encode better phoneme and character representations.

3 Experiments

3.1 Data

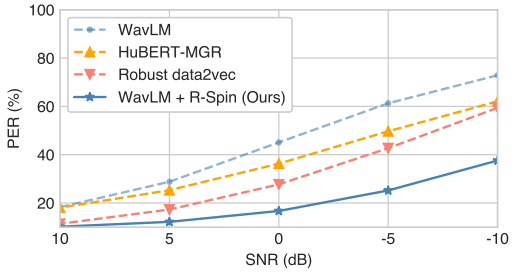
The 960 hours of unlabeled English speech in LibriSpeech is used for R-Spin training (Panayotov et al., 2015).[2] Audio distortions are generated with torch-audiomentations.[3] Following Zhu et al. (2023), background noises are sampled from MUSAN (Snyder et al., 2015) and CHiME-4 (Vincent et al., 2017), covering music, speech, and outdoor noise.[4] Signal-to-noise ratios (SNR) are uniformly sampled from $[-10, 10]$ during training. We add distortions to each utterance during evaluation, including Gaussian noise, MUSAN noise, and reverberation (Appendix A.5).

3.2 Implementation



The DS experiments are mostly based on WavLM (Chen et al., 2022) because WavLM is pre-trained with a denoising objective, offering a good initialization. HuBERT (Hsu et al., 2021a) is also considered to demonstrate R-Spin's generalizability to SSL models trained with clean speech. We follow the implementations by Chang et al. (2023), which uses PyTorch (Paszke et al., 2019), PyTorch-Lightning (Falcon, 2019), and torchaudio (Yang et al., 2022).[5] The acoustic pieces are generated by learning BPE tokens on top of a HuBERT + Spin$_{2048}$ model (Appendix A.2). Further details can be found in Appendix A.3.[6]

3.3 Notations



We denote an SSL model X fine-tuned with Spin and K codewords with X + Spin$_K$. In X + R-Spin$_{K_1, K_2}$, K_1 and K_2 are respectively the codebook size of $\mathcal{L}_{\text{Spin}}$ and the number of classes of pseudo-labels for $\mathcal{L}_{\text{Aux}}$. If the pseudo-labels are acoustic pieces, "AP" is added to K_2. Unless specified otherwise, R-Spin denotes R-Spin$_{32,\ \text{AP40k}}$.

3.4 Noisy Phoneme Recognition

We compare the phoneme recognition performance of SSL and DS methods under noisy conditions. The training setup is similar to the SUPERB phoneme recognition task (Yang et al., 2021), where the SSL models are frozen and only a lightweight prediction head is fine-tuned (Appendix A.5).[7] We apply some classes of distortions only to testing data to obtain phoneme error rates (PER). We divide results by budget, which is the amount of speech processed during DS, proportional to the computational resources required (Sec. 3.6).

(a) Gaussian Noise

(b) MUSAN Noise

Figure 2: Phoneme error rates (PER) under different noise types and SNRs. R-Spin$_{32,\ \text{AP40k}}$ is used here.

As shown in the middle columns of Table 1, R-Spin outperforms low and high-budget methods in all conditions. WavLM + R-Spin has the best overall PERs because WavLM is pre-trained with a denoising task, showing that model initialization contributes largely to the recognition performance after DS. Next, R-Spin improves unseen tasks like Gaussian noise and reverberation, indicating that noise-invariant training generalizes to some out-of-domain perturbations. Furthermore, comparing Robust data2vec with R-Spin is unfair since the training costs are 12 times apart, so we train a low-budget Robust data2vec (Appendix A.4). The noticeable performance drop in the low-budget model implies Robust data2vec requires high computation resources, but our approach offers competitive results with fewer training data.[8]

We plot PERs under different SNRs in Fig. 2 for a detailed comparison. Overall, R-Spin achieves the lowest PERs even when the SNR is high.

†Unseen perturbation types for R-Spin and Robust data2vec.

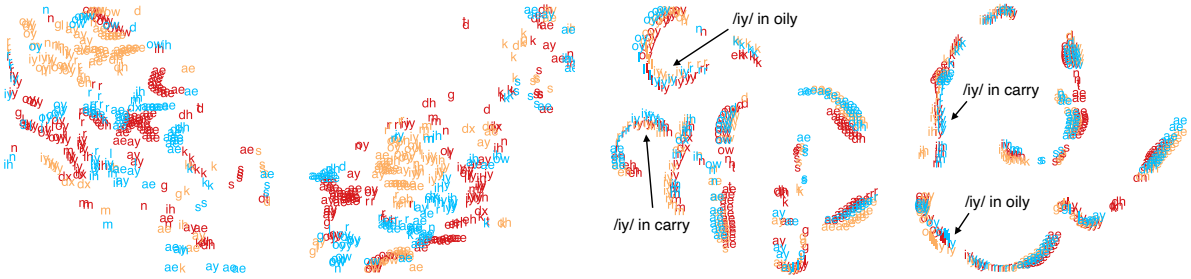
Table 1: Phoneme recognition on LibriSpeech and ASR on CHiME-4 test sets. Gaussian noise, MUSAN background noise, and reverberation (Reverb) are respectively added to simulate noisy conditions, where the SNRs are fixed to 0dB. The calculation of the number of hours of processed speech during DS follows Chang et al. (2023).

HuBERT-MGR excels in Gaussian noise because it is the only model trained with this noise type. Nevertheless, R-Spin offers a similar performance in Gaussian noise across different SNRs, aligning with the results in Table 1.

3.5 Noisy Speech Recognition

This section assesses R-Spin with a noisy ASR task. We adopt the SUPERB ASR setup with the CHiME-4 corpus (Vincent et al., 2017) to evaluate the models in more realistic noisy recordings (Appendix A.6). The results in the right columns of Table 1 reveal that R-Spin surpasses low-budget baseline models. While R-Spin demonstrates commendable performance on CHiME-4, this method falls short compared to Robust data2vec, which benefits from training with a substantially higher budget. Furthermore, we set Whisper Base and Small as toplines due to their robustness demonstrated through large-scale weakly-supervised learning (Radford et al., 2022). R-Spin successfully mitigates the performance gap between WavLM and the Whisper toplines by over 60%. Combining phoneme and speech recognition findings, we conclude that R-Spin effectively enhances pre-trained SSL models in capturing robust content representations.

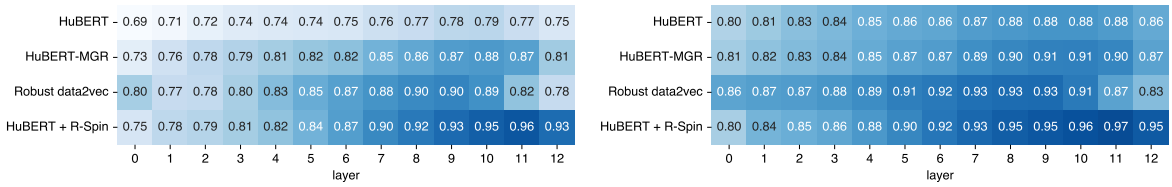
3.6 Data Efficiency



Developing R-Spin aims to enhance speech SSL models with minimal resources, including improving data efficiency. Following Chang et al. (2023), an analysis of the duration of speech data processed during training is undertaken to quantify the computational expenses associated with each method. As depicted in the second column of Table 1, these values are derived by multiplying the number of training updates and the effective batch size for each update. Compared with the high-budget methods, R-Spin requires significantly lower training costs, concurrently exhibiting superior performance across diverse conditions. A complete comparison of the costs can be found in Appendix C.

3.7 Representation Invariability

This section explores the robustness of models regarding representation invariability by examining their characteristics under diverse perturbations.



3.7.1 Speaker Invariability

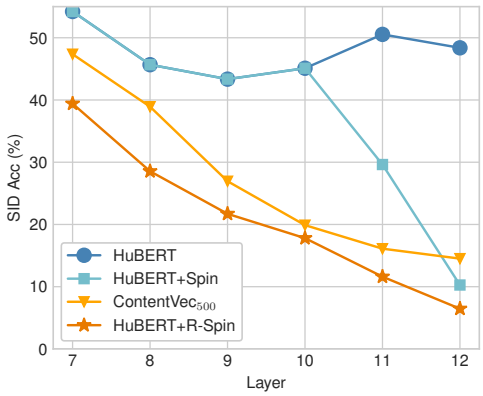
We first inspect each model's invariability to speaker changes by computing the speaker identification (SID) accuracy with different hidden layer representations. The SID task follows SUPERB's setup but with 50k training updates. As shown

(a) HuBERT CNN (Layer 0) (b) HuBERT + R-Spin CNN (Layer 0) (c) HuBERT Best Layer (9) (d) HuBERT + R-Spin Best Layer (12)

Figure 3: t-SNE (Van der Maaten and Hinton, 2008) visualization of the CNN and the layer with the lowest speaker identification rate given the same clean utterance spoken by three speakers from TIMIT (Garofolo, 1993). Each color represents a speaker, while each label visualizes a frame and the corresponding phoneme label. The transcription is "Don't ask me to carry an oily rag like that." The silence frames are omitted for clarity.

(a) Gaussian Noise (SNR = 0dB) (b) Reverberation (real room impulse response)

Figure 4: Layer-wise perturbation invariability analyses with Linear CKA, where higher values indicate higher invariability to perturbations. The zeroth layer denotes the CNN feature extractor.



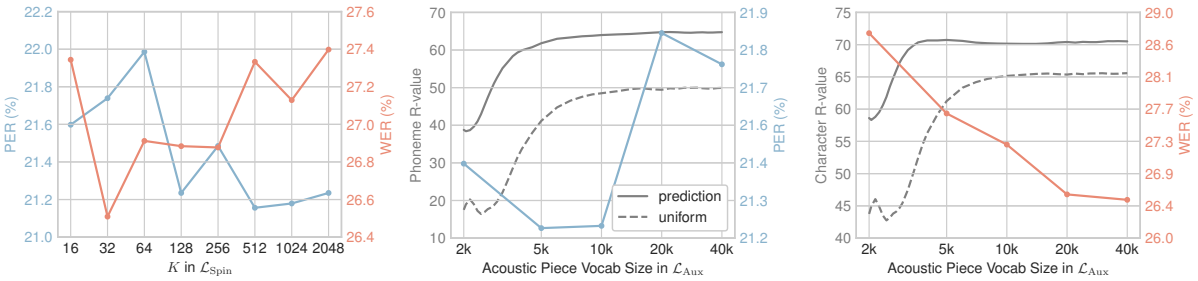


Figure 5: Layer-wise speaker identification accuracy.

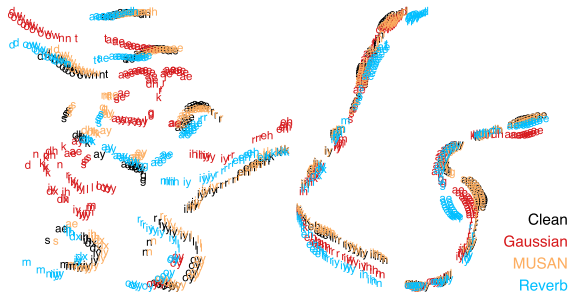
in Fig. 5, R-Spin has a significantly lower SID accuracy for the top layers, demonstrating the effect of fine-tuning the whole model with a speaker-invariant objective. Moreover, requiring 9X less training costs, our method produces representations with less speaker information than ContentVec. Therefore, the proposed method outperforms prior speaker-invariant self-supervision approaches in removing speaker ID.

Next, we use t-SNE (Van der Maaten and Hinton, 2008) to visualize representations articulated by distinct speakers. We show the layer with the lowest SID rate according to Fig. 5. In Figs. 3a and 3b, there is a discernible clustering of frames uttered by the same speaker, suggesting that lower layers retain more speaker-specific information. Conversely, Figs. 3c and 3d illustrate that top layer features are grouped according to phonemes rather than speakers. Moreover, the top layer representations are context-dependent, as exemplified by the spatial arrangement of phonemes such as "carry" (`k eh r iy`) and the same phoneme `/iy/` in the word "oily" (`oy l iy`). Besides, a comparative analysis between Figs. 3c and 3d reveals that R-Spin features exhibit a more prominent overlap among speakers than HuBERT. As a result, this section substantiates the speaker-invariability of R-Spin. Detailed visualization can be found in Appendix D.



3.7.2 Noise Invariability

We examine the response of continuous representations to input distortions. We compute linear centered kernel alignment (CKA) similarities (Kornblith et al., 2019) of frame-wise features with and without noisy inputs, where a higher similarity indicates a higher invariability to distortions. The evaluation involves building datasets derived from the LibriSpeech dev-clean and dev-other sets augmented with various distortions. Fig. 4 illustrates that R-Spin exhibits superior noise invariability for the upper layers than other models, indicating the efficacy of noise-invariant training even if the noise types are unseen. Lower layers tend to have lower

(a) (b) (c)

Figure 6: WavLM + R-Spin with different (a) codebook and (b)(c) AP vocabulary sizes. (b) and (c) depict the phoneme and character segmentation R-values, where the dotted curves are the baselines by segmenting each utterance with equal-length segments given the number of boundaries obtained by the APs. The PERs are calculated by averaging over different noise conditions on LibriSpeech test-other. The WERs are the averaged scores of the real and simulated evaluation sets of CHiME-4.

(a) HuBERT Best Layer (9) (b) HuBERT + R-Spin Best Layer (12)

Figure 7: t-SNE visualization of hidden representations of the same utterance in Fig. 3 with different distortions indicated by colors, where SNR = 0dB.

similarities, suggesting a higher sensitivity to perturbations. This observation aligns with existing research discussed in Sec. 2.4, which associates lower layers with fundamental signal processing functions. In contrast, Robust data2vec has a greater noise invariability starting from the bottom layers because of the data2vec training strategy.

We employ t-SNE to explore representations under distortions. As shown in Fig. 7, the R-Spin features exhibit a more pronounced overlap than HuBERT, suggesting that R-Spin improves robustness to noise, aligning with the observations in Fig. 4. Fig. 7b reveals that R-Spin features exposed to MUSAN noise exhibit a high degree of overlap with unperturbed ones, whereas the other two perturbation types diverge slightly because Gaussian noise and reverberation are unseen for R-Spin. Overall, the analysis underscores the notable noise invariability offered by R-Spin.

3.8 Importance of Discrete Units

This section analyzes the efficacy of APs and their relation to phonemes and characters.

3.8.1 Codebook and Acoustic Pieces Size

We inspect the importance of the codebook size in Spin. As highlighted by Chang et al. (2023), the codebook size positively correlates with phoneme recognition. A similar trend can be found in Fig. 6a but has an inverted trend for ASR. However, the observed performance discrepancy is less than 1% absolute, suggesting that codebook size's impact on R-Spin is marginal. In contrast, substantial improvements in ASR are observed with more APs, but not in phoneme recognition, as evidenced by Figs. 6c and 6b. To analyze this phenomenon, we investigate R-Spin's phoneme and character segmentation capabilities using discrete units.

3.8.2 Phoneme and Character Segmentation

We segment speech with acoustic pieces and show the R-values in Figs. 6b and 6c. R-value, a metric for evaluating word or phoneme segmentation quality (Räsänen et al., 2009), is robust to over-segmentation, an issue that plagues F1. The boundaries are predicted by locating differing adjacent discrete units. We evaluate on force-aligned LibriSpeech dev-clean and dev-other sets (Lugosch et al., 2019; McAuliffe et al., 2017).[9] The character boundaries are obtained by dividing each force-aligned word segment into equal-length segments corresponding to individual characters within the word. More accurate boundaries can be computed with character-based aligners, but we only need a rough estimation of the segmentation quality.

As depicted in both Figs. 6b and 6c, larger AP vocabulary sizes have superior segmentation, indicating that more APs form units that closely resemble linguistic units. The baseline, which involves uniformly segmenting utterances based on the number

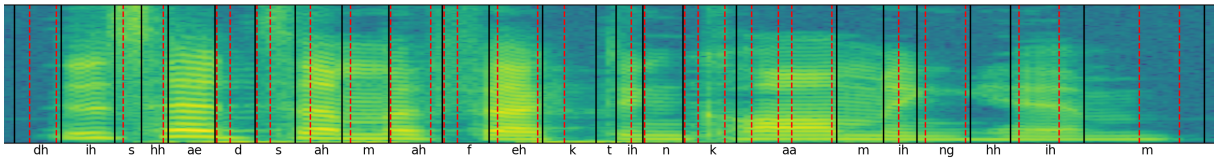

Figure 8: An example of phoneme alignment of an utterance "This had some effect in calming him." from LibriSpeech dev-clean. The black lines indicate the force-aligned boundaries, while the red dashed lines are the predicted boundaries with AP40k.

Method	CHiME-4 Real	CHiME-4 Sim
Spin_{2048} (Chang et al., 2023)	52.1	46.6
$\text{R-Spin}_{32,\ \text{AP40k}}$ (Proposed)	**26.4**	**26.6**
no $\mathcal{L}_{\text{Aux}}$	47.8	45.6
no $\mathcal{L}_{\text{Spin}}$	31.9	32.4
no speaker perturbation	28.3	28.0
no additive noise	49.4	46.8
Pseudo Label for $\mathcal{L}_{\text{Aux}}$		
Spin_{2048} codebook♠	28.3	29.1
MFCC (K-means 512)	46.9	45.4
MFCC (K-means 2048)	48.5	45.5
HuBERT L9 (K-means 512)♠	28.8	29.1
HuBERT L9 (K-means 2048)♠	28.2	28.4

♠Pairwise t-tests between these results all have $p > 0.05$. Also, $p < 0.05$ when they are compared with $\text{R-Spin}_{32,\ \text{AP40k}}$.

Table 2: CHiME-4 ASR results for ablation studies based on fine-tuned WavLM models.

of boundaries derived from APs, underscores the non-random nature of AP boundaries. Although the segmentation capability of APs is incomparable with other unsupervised speech segmentation algorithms (Kreuk et al., 2020), they present significantly improved targets for $\mathcal{L}_{\text{Aux}}$, consequently enhancing the accuracy of ASR. A full comparison of unsupervised phoneme segmentation can be found in Appendix B.3.

Furthermore, we provide an example of segmenting an utterance with 40k APs in Fig. 8. The red dashed stripes depict that the boundaries of APs are mostly aligned with phoneme boundaries. Notably, the predicted boundaries occasionally exhibit a slight temporal lag compared to the ground truth, like the first `/ah/` and `/m/`. We suspect the 50Hz framerate of HuBERT or the Spin training objective causes this phenomenon since they could reduce time resolution and introduce temporal shifts. Still, the actual cause remains a subject for future investigation. To summarize, APs effectively learn discrete acoustic units that benefit ASR performance.

3.9 Ablation Studies

Under the same CHiME-4 ASR setup in Sec. 3.5, we conduct ablation studies to analyze the proposed methods. As shown in Table 2, the WERs increase significantly without $\mathcal{L}_{\text{Aux}}$), showing that the auxiliary loss helps ASR performance and mitigates collapsing. Second, WERs increase by about 5% without $\mathcal{L}_{\text{Spin}}$, indicating the necessity of this loss for achieving perturbation-invariant representations. Speaker perturbation also plays an important role in offering good content representations according to the degraded WERs. Moreover, the fine-tuned model exhibited suboptimal performance when trained without noise, emphasizing the importance of noise-invariant training for improving robustness. The above findings verify the necessity of the proposed approaches.

We inspect the effect of choosing different pseudo-labels for $\mathcal{L}_{\text{Aux}}$. First, APs are helpful for R-Spin since learning from the original Spin model's codeword labels increases WERs by over 2%. Next, we replace the pseudo-labels with the more commonly used K-means clustered representations (Hsu et al., 2021a). Clustered MFCC features degrade R-Spin the most, no matter the number of clusters used. In contrast, clustered HuBERT representations from layer 9 (L9) yield results comparable to Spin_{2048}, and the t-test suggests the disparities between pseudo-labels are statistically insignificant. Thus, using clustered features from an SSL model is a viable alternative. Additional ablation studies are available in Appendix B.1.

4 Conclusion

This paper proposes R-Spin, a domain-specific self-supervision method with speaker and noise-invariant clustering for robust content representations. Results illustrate the efficacy and broad applicability of R-Spin across various acoustic scenarios, even within constrained computation budgets. The acoustic analyses presented in this study offer insights into the characteristics of discrete units of this nature and strategies for their utilization. Future directions involve scaling to larger models and exploring its application in diverse downstream tasks like robust voice conversion.

Limitations

This paper faces four primary limitations due to constrained computation resources and available data. First, we consider background noises including human speech, music, and natural noises, and evaluate the proposed methods with similar noise types and reverberation, covering many real-world conditions. However, the trained models may encounter challenges in processing more severely distorted audio data, such as air traffic control communications. Second, the dataset employed consists of English utterances spoken by native speakers, predominantly of North American dialects, leaving the performance in other languages and accents unexplored. Third, the experiments are conducted on 95M-parameter models, so the scalability of R-Spin remains unknown. Last, to fully comprehend the capabilities of the proposed method, further analyses and extensions to other applications are recommended for future exploration (Sicherman and Adi, 2023). These questions can be answered by experimenting with diverse datasets and more computation resources.

Ethics Statement

Our models inherit the biases of SSL models (HuBERT and WavLM) pre-trained on the LibriSpeech corpus. This corpus contains read English audio recordings derived from audiobooks. Limitations arise when confronted with accents and topic domains outside the corpus scope, potentially diminishing the effectiveness of the proposed methods. Thus, the direct application of our models to real-world scenarios may result in increased speech recognition error rates. These errors, if unaddressed, can propagate through downstream applications like natural language processing systems, leading to potential risks for users, such as the misinterpretation of voice commands.

A Implementation Details

A.1 Speech SSL Models

Each SSL model used in this paper has a 7-layer CNN feature extractor and a 12-layer transformer encoder (Vaswani et al., 2017), having roughly 95M parameters in total. All SSL models are pre-trained with 960 hours of unlabeled speech in the LibriSpeech corpus. **HuBERT** (Hsu et al., 2021a) is pre-trained in two iterations. In the first iteration, the encoder model learns to predict each masked frame's K-means cluster ID of MFCC features. The second iteration model has learning targets obtained by clustering hidden representations of the first iteration model. **WavLM** (Chen et al., 2022) follows the second iteration of HuBERT, but the training process involves a denoising task by adding random noises to the input to increase robustness. **ContentVec** (Qian et al., 2022) is fine-tuned on top of a pre-trained HuBERT model, but the inputs are augmented with speaker perturbation so that the model learns to produce representations invariant of the speaker. ContentVec's learning targets are obtained by converting all LibriSpeech data into the same speaker with a voice conversion model and then applying K-means clustering to the hidden features of HuBERT, given the converted inputs. **HuBERT-MGR** (Huang et al., 2022a) continues the HuBERT pre-training process with noisy speech and an auxiliary domain adversarial training objective to enhance robustness. HuBERT-MGR is trained with a mix of clean and distorted speech, where the distortions include MUSAN background noise, Gaussian noise, and reverberation. **Robust data2vec** (Zhu et al., 2023) fine-tunes a pre-trained data2vec model. Unlike data2vec, the inputs to the student model include background noise so that the model learns denoising. An additional contrastive learning objective is incorporated to enhance robustness. The pre-trained model weights are obtained from the s3prl toolkit.[10]

A.2 Spin

Since R-Spin is trained with 960 hours of speech in LibriSpeech, the pseudo-labels for $\mathcal{L}_{\text{Aux}}$ should be generated for all those data with Spin. To avoid labeling unseen data with Spin, we train another HuBERT + Spin$_{2048}$ model with the same data (originally 100 hours in Chang et al., 2023). Each mini-batch before data perturbation has 2560 seconds of speech, equivalent to 32k frames after downsampling. The learning rate first linearly increases from 10^{-6} to 10^{-4} in the first 2.5k updates, then linearly decreases to 10^{-6} in the last 7.5k updates. The implementation of the Spin loss follows Caron et al. (2020).[11] This model takes four hours of training time on four RTX A6000 GPUs. Models trained with all 10k updates are used to generate pseudo-labels. In total, roughly 7.1k hours of unlabeled speech data are processed. Compared with the model in Chang et al. (2023), a similar performance is achieved on phoneme recognition.

A.3 R-Spin

Each mini-batch before perturbation has 384 seconds of speech, equivalent to 19.2k frames in each view. Each utterance is first speaker-perturbed to generate a second view. All utterances are added with noise from MUSAN and CHiME-4 with an SNR in $[-10, 10]$ dB. The noise for each view is independent. The learning rate first linearly increases from 10^{-6} to 10^{-4} in the first 4k updates, then linearly decreases to 10^{-6} in the last 6k updates. λ in Eq. 3 is set to 5. Each R-Spin DS training takes less than eight hours on two RTX A6000 GPUs. Models trained with all 10k updates are used for evaluation. For the R-Spin training, 1.1k hours of unlabeled speech data are processed. Combined with the Spin training in Appendix A.2, 8.2k hours of data are used during DS.

A.4 Low-budget Robust data2vec

We follow the implementation of Zhu et al. (2023) with fairseq (Ott et al., 2019).[12] We changed the training data from CHiME-4 to LibriSpeech for a fair comparison with our method. Because we found a long training schedule is necessary for Robust data2vec converge, the number of updates is the same as the original implementation (100k). Meanwhile, the mini-batch size is reduced from 63 to 6.25 minutes so that the amount of speech data processed is similar to R-Spin. The rest of the hyperparameters remain the same since we found the original ones are sufficiently good. As shown in Table 1, the low-budget Robust data2vec model has a significant performance degradation compared with the fully-trained version, implying the necessity to train this model with a large batch size. Concurrently, R-Spin achieves superior results under

[10] https://github.com/s3prl/s3prl/tree/main/s3prl/upstream

[11] https://github.com/facebookresearch/swav

[12] https://github.com/zqs01/data2vecnoisy

the same budget, indicating that our approach is more data-efficient.

We found that the low-budget Robust data2vec is particularly difficult to train. First, Hsu et al. (2021a) has shown that large batch sizes favor speech SSL model training, which applies to Robust data2vec. Second, we found that the low-budget model fails when trained with CHiME-4, indicating the training corpus highly affects model convergence. Third, we did not have the resources to find the optimal hyperparameters. However, the hyperparameters for data2vec must be carefully determined to let the model converge (Baevski et al., 2022), which is amplified when the training scale is reduced. In conclusion, we were unable to find a setup where a comparable computational budget is used for both R-Spin and Robust data2vec. Nonetheless, the results demonstrate that the proposed R-Spin is much easier to operate under low-budget scenarios.

A.5 Phoneme Recognition

We follow the setup in SUPERB (Yang et al., 2021), which freezes each SSL model and uses a set of learnable weights to weighted-sum hidden features of all layers. The aggregated frame-wise features are fed into a lightweight linear prediction head to perform downstream tasks. Only the prediction head and the weighted-sum mechanism are fine-tuned with clean and labeled speech data to reveal the capabilities of SSL models. The LibriSpeech train-clean-100 and the test-other subsets are used as the training and evaluation datasets, respectively. The prediction head projects features to phoneme labels. Unlike the SUPERB setup, the learning rate is 5×10^{-4} (originally 10^{-2}) to obtain a better performance, and the number of training updates is 30k (originally 100k). The noise and perturbation data sources are listed as follows.

1. **Gaussian Noise**: The Gaussian noises are generated with PyTorch.
2. **Background Noise**: The background noises are sampled from the MUSAN dataset. We duplicate the noise recording when it is shorter than the input. Otherwise, we randomly crop the recording to match the utterance length.
3. **Reverberation**: We filter waveforms with real and simulated impulse responses in RIRS (Ko et al., 2017).[13] The scores for the real and simulated reverberation are averaged.

[13] Released under Apache 2.0

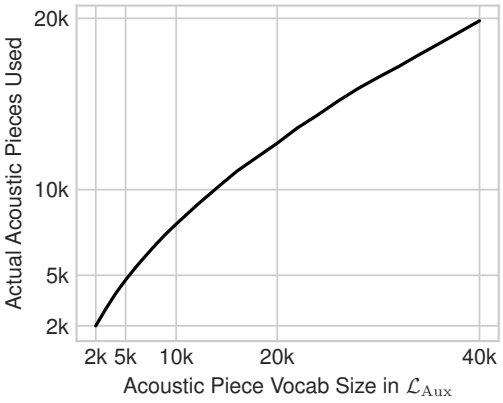

Figure 9: AP size vs. actual vocabularies used.

A.6 CHiME-4 ASR

We follow the ASR task of SUPERB, but the prediction heads (two-layer BLSTM) are trained with the clean portion of the CHiME-4 speech corpus obtained from the WSJ0 corpus (Paul and Baker, 1992), consisting of 14 hours of clean English speech. The number of training updates is 100k (originally 200k). The trained ASR models are evaluated on the 1-channel track of the CHiME-4 challenge. We report the averaged WERs over each subset (real and simulated data). We apply Whisper normalization to all ASR results for a fair comparison with the Whisper toplines.[14]

A.7 Acoustic Pieces

We implemented the BPE algorithm in Python. The AP vocabulary sizes vs. the actual APs used are shown in Fig. 9. Since some merging operations in BPE replace previously learned BPE vocabularies with new ones, the number of used BPEs in the encoded LibriSpeech corpus is smaller than the learned BPE vocabularies. E.g., we have a sentence "`a a b b a`" and the learned BPE vocabularies `a`, `b`, `aa`, `bb`, and `aabb`. Then, the encoded sentence is "`aabb a`," eliminating the *intermediate* vocabularies `b`, `aa`, and `bb`. Thus, the number of classes in the linear prediction head for $\mathcal{L}_{\text{Aux}}$ is adjusted accordingly. E.g., the prediction head's output for R-Spin$_{32,\,40k}$ is 19857 instead of 40000.

B Additional Experiments

B.1 Ablation Studies

B.1.1 Hyperparameters

To examine the impact of the auxiliary loss, we change the value of λ in Eq. 3. As shown in Table 3,

[14] https://github.com/openai/whisper

Method	CHiME-4 Real	CHiME-4 Sim
Spin_{2048} (Chang et al., 2023)	52.1	46.6
$\text{R-Spin}_{32,\ \text{BPE40k}}$	26.4	26.6
Hyperparameters		
$\lambda = 1$	26.3	27.7
$\lambda = 0.5$	26.6	27.3
Layer to Apply $\mathcal{L}_{\text{Aux}}$		
Layer 11	28.1	28.8
Layer 10	34.7	33.8
Layer to Apply $\mathcal{L}_{\text{Spin}}$		
Layer 11	27.2	27.9
Layer 10	27.0	27.8
Fine-tuned Layers		
Top 10 Layers	29.7	30.0
Top 6 Layers	39.4	37.5
Dataset		
LibriSpeech 100h	27.2	27.6
LibriSpeech 360h	26.6	27.6
Noise SNR Range		
0 – 20dB	29.0	28.6

Table 3: CHiME-4 ASR results for additional ablation studies based on fine-tuned WavLM models.

the differences of ASR WERs between different λ's are negligible. We can conclude that combining $\mathcal{L}_{\text{Spin}}$ and $\mathcal{L}_{\text{Aux}}$ is necessary, and the ratio between the two objectives is robust.

B.1.2 Layer to Apply $\mathcal{L}_{\text{Aux}}$

In the R-Spin design, $\mathcal{L}_{\text{Aux}}$ is applied to the last layer. Here, we apply $\mathcal{L}_{\text{Aux}}$ to other hidden layers to verify that our approach leads to the best overall result. When we move the auxiliary loss $\mathcal{L}_{\text{Aux}}$ to lower layers, the performance degrades significantly, showing that this loss should regularize the entire model. Otherwise, the Spin loss still makes the codebook collapse.

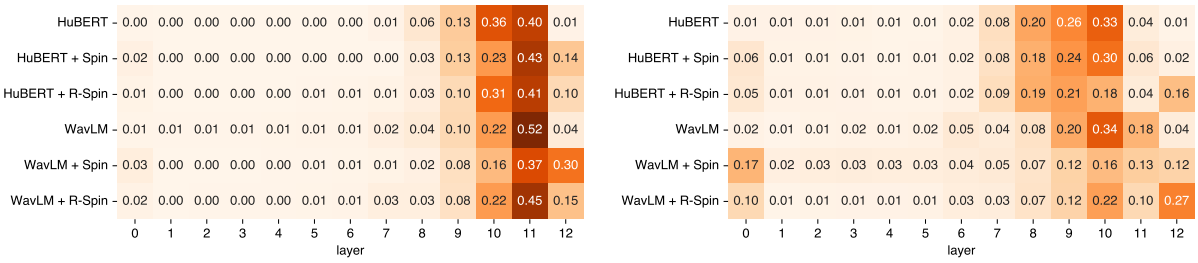
B.1.3 Layer to Apply $\mathcal{L}_{\text{Spin}}$

Similar to the previous experiments, we apply $\mathcal{L}_{\text{Spin}}$ to lower layers to find the optimal design. The ASR performance degrades slightly when we move the Spin objective function to lower layers. With the results of $\mathcal{L}_{\text{Aux}}$, we conclude that a relatively good strategy for applying the two proposed loss functions is adding both to the top layer.

B.1.4 Fine-tuned Layers

Here, we inspect the benefits of fine-tuning SSL models entirely in contrast to Spin, which fine-tunes only the top two layers. Hence, we reduce the number of fine-tuned layers. The results indicate that the model cannot adapt to noisy scenarios by fine-tuning fewer top layers. Thus, R-Spin is beneficial since we can now fine-tune the entire model for noisy conditions.

B.1.5 Data



We further changed the data for R-Spin DS to reveal the impact of training corpora on performance. We found that WERs degrade slightly when the training corpus size is reduced. Moreover, the ASR performance degrades prominently by increasing the SNRs of the background noise for the noise-invariant training. Hence, the choice of noise data and SNRs has a greater impact on the downstream performance than that of the clean speech corpus.

B.2 Importance of Hidden Representations

We visualize the weighted sum mechanism for phoneme and speech recognition to understand the importance of each layer. The weights form a probability distribution over all layers (including the CNN feature extractor). The features of each layer are weighted and summed with these weights. However, the scale of the embedding spaces differs between layers. Suppose the weight of a layer is small, but the norm of the corresponding hidden vectors is large. That layer might contribute significantly to the downstream task. Consequently, we normalize each weight by multiplying with the averaged L2 norm of the corresponding layer embedding, which is written as

$$\hat{w}_l = w_l \cdot \mathbb{E}\left[\left\|\boldsymbol{h}^{(l)}\right\|_2\right],$$

where w_l and $\boldsymbol{h}^{(l)}$ are respectively the unnormalized weight and hidden features of layer l, and $\mathbb{E}$ is the expectation over all samples from the LibriSpeech dev-clean and dev-other sets (Chang et al., 2022). Next, the new set of weights $\hat{w}_l$ is normalized to sum to one. As shown in Fig. 10, the last layer of R-Spin has the least speaker and noise information, but the second last layer offers the best phoneme representations. In contrast, when R-Spin is applied, the best ASR layers tend to shift towards the last layer.

Table 4: Unsupervised phoneme segmentation on TIMIT test set. OS and R-val respectively denote the over-segmentation rate and R-value (Räsänen et al., 2009). Oracle uniform is a segmentation method that splits speech into equal-length segments, given the ground truth number of phoneme boundaries. Unknown results are left blank.

B.3 Unsupervised Phoneme Segmentation

This section inspects the phoneme segmentation capability of the proposed methods. As shown in Table 4, segmenting speech with Spin codebook or acoustic pieces is inferior to prior methods specifically designed for phoneme segmentation because no explicit constraints are added to encourage phoneme boundary detection. Still, some R-Spin discrete units like $\text{R-Spin}_{32,\ \text{AP40k}}$ surpass the oracle uniform baseline, indicating that the discrete unit boundaries are close to phoneme boundaries. The results align with the findings in Fig. 6b.

Abstract

Instruction tuning effectively optimizes Large Language Models (LLMs) for downstream tasks. Due to the changing environment in real-life applications, LLMs necessitate continual task-specific adaptation without catastrophic forgetting. Considering the heavy computational cost, replay-based Continual Learning (CL) methods are the simplest and most widely used for LLMs to address the forgetting issue. However, traditional replay-based methods do not fully utilize instructions to customize the replay strategy. In this work, we propose a novel paradigm called Instruction-based Continual Learning (InsCL). InsCL dynamically replays previous data based on task similarity, calculated by Wasserstein Distance with instructions. Moreover, we further introduce an Instruction Information Metric (InsInfo) to quantify the complexity and diversity of instructions. According to InsInfo, InsCL guides the replay process more inclined to high-quality data. We conduct extensive experiments over 16 tasks with different training orders, observing consistent performance improvements of InsCL. When all tasks have been trained, InsCL achieves performance gains of 3.0 Relative Gain compared with Random Replay, and 27.96 Relative Gain compared with No Replay.

1 Introduction

Large Language Models (LLMs) show remarkable capabilities from a wide range of Natural Language Processing (NLP) tasks (Brown et al., 2020; Ouyang et al., 2022; Touvron et al., 2023), demonstrating large potential in handling various task-specific settings. To complete realistic downstream tasks, recent works suggest that instruction tuning is an incredible method for unleashing the power of LLMs (Wei et al., 2021; Peng et al., 2023; Shi et al., 2023). However, in real-life applications, the consistent emergence of new corpora and knowledge changes task schemas frequently, necessitating continual task-specific adaptation for LLMs (Jin et al., 2021; Daruna et al., 2021). Accordingly, Continual Learning (CL) is proposed to learn a sequence of tasks incrementally, updating models for the changing environment without catastrophic forgetting (Goodfellow et al., 2013; Kemker et al., 2018).

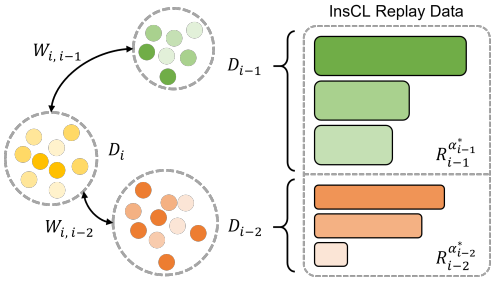

Figure 1: The framework of InsCL, the index denotes task id. D represents task data, and R represents the sampled data to replay. InsCL dynamically replays α^* data for each previous task based on the task similarity calculated via Wasserstein Distance W. The dots represent instructions included in each task, and the darker colors represent higher InsInfo. The size of each color bar denotes the corresponding amount of replay data.

Considering the heavy burden on computing time and GPU memory of tuning LLMs, replay-based methods are the simplest and most effective among all traditional CL methods. Despite several replay-based methods that have been well-studied (Sun et al., 2019; Wang et al., 2020; Mi et al., 2020; Qin et al., 2022), some traditional strategies cannot achieve optimal performance in continual instruction tuning due to the unique data composition. To address this issue, we propose a data-efficient paradigm called **Ins**truction-based **C**ontinual **L**earning (InsCL), applied to continual fine-tuning LLMs with natural language instructions. InsCL effectively utilizes instructions as high-quality task descriptions, designing a dynamic instruction-information-based replay method. As shown in Figure 1, when the new task D_i comes, In-

sCL will sample replay data R from all the previous tasks (here we list two previous tasks in Figure 1).

InsCL dynamically replays α^* data from previous tasks based on their similarity with the current task. We draw on the application of Optimal Transport (Torres et al., 2021) in comparing different distributions and adopt Wasserstein Distance (Liu et al., 2022) as a similarity measure. Since instructions naturally contain high-quality task-related descriptions, we use instructions to calculate Wasserstein Distance instead of using the full amount of data, significantly reducing the computational cost (Cuturi, 2013). For the previous tasks that are more different from the current task, InsCL allocates a larger replay scale (**larger bar width** in Figure 1).

After determining the sample size based on task similarity, InsCL leverages instruction information to guide the sampling process more inclined to high-quality data. Prior works have shown that the performance with less but high-quality data can be comparable with full data (Toneva et al., 2018; Abbas et al., 2023; Tirumala et al., 2023). For instruction tuning scenarios, early attempts (Wang et al., 2022a; Xu et al., 2023a; Ding et al., 2023) affirm that LLMs' performance can be improved by increasing the training template complexity and diversity. Inspired by this, we propose an Instruction Information Metric (InsInfo) to quantify the complexity and diversity of instructions. With InsInfo-guided sampling, InsCL replays more high-quality data (**longer bar length** in Figure 1). We empirically demonstrate that replaying more data with high InsInfo helps to alleviate the forgetting issue.

The main contributions of this paper include: (1) We propose InsCL, a novel replay-based CL paradigm for instruction tuning. InsCL allocates replay size based on task similarity, dynamically replaying high-quality data with high InsInfo. (2) Experiments are conducted over 16 tasks with different training orders, demonstrating the effectiveness of InsCL. (3) We further analyze the forgetting phenomenon in continual instruction tuning. Without replaying, we found that complex reasoning tasks suffer from a higher forgetting rate, where forgetting instances are mainly instruction-unrelated.

2 Related Work

2.1 Instruction Tuning

Recently, LLMs have demonstrated impressive performance across various NLP tasks. After being unsupervised pre-trained on large-scale raw text, LLMs are further trained via instruction tuning to generate appropriate outputs based on the given input instructions (Sanh et al., 2021; Mishra et al., 2021; Chung et al., 2022). Prior works supervised fine-tuned (SFT) LLMs with datasets consisting of {instruction, input, output} pairs, as shown in Table 1, and evaluated on another set of held-out tasks (Wei et al., 2021; Longpre et al., 2023). They demonstrate that the performance of unseen tasks can be improved with more tasks and templates. To improve the diversity and complexity of instruction, a broad range of open-source instruction tuning datasets are proposed. Some are gathered through crowd-sourcing (Conover et al., 2023; Zhou et al., 2023) while others are distilled from strong proprietary models (Wang et al., 2022a; Peng et al., 2023; Taori et al., 2023).

Instruction : In this task, you're given reviews from Amazon's products. Your task is to generate the Summary of the review.
Input : Totally screwed up my system. Instructions terrible. Disk gives long list of files, had to determine what does what. Has already wasted 4 hours of my time. I gave up and pulled the thing. Don't buy this.
Output : Terrible. Instructions are non-existent.

Table 1: A case of data template in instruction tuning.

With the help of various low-cost methods of constructing high-quality templates, instruction datasets can expand easily over time as new tasks appear. When the data scale grows dynamically, we can easily obtain sufficient task-specific data. Considering this, rather than evaluating zero-shot ability on held-out tasks, we are more concerned about adapting an instruction-tuned model to a new task without suffering from catastrophic forgetting. In this work, we fine-tune LLMs in a continuous manner and analyze their performance on previous tasks, aiming to explore the forgetting issue in a changeable environment.

2.2 Traditional CL Methods

CL aims to learn a sequence of tasks incrementally without forgetting the previously learned knowledge. Early attempts in CL can be generally divided into three categories: (1) **Consolidation-based methods** aim at protecting important parameters. As the representative of the regularization sub-family, EWC (Kirkpatrick et al., 2017) constrains the loss based on parameter importance

calculated by the fisher information matrix. Several works distill the model from the previous stage to keep relevant knowledge (Zhang et al., 2020; Monaikul et al., 2021; Liu et al., 2021; Qin and Joty, 2021). (2) **Architecture-based methods** add task-specific parameters to the base model for each task (Rusu et al., 2016; Gu et al., 2020; Madotto et al., 2020). By separating trainable parameters, the model can mitigate the impact on old tasks when updating parameters. However, the model scale grows linearly when tasks increase, bringing inevitable memory costs. (3) **Replay-based methods** store a small subset of previous training examples and replay when the new task comes. Sun et al. (2019); Zhang et al. (2022) leverage language models to generate pseudo-examples for previous tasks, but the quality of examples cannot be guaranteed (Ke et al., 2021).

Despite the success of traditional CL methods, their backbones are relatively small in scale, such as BERT (Devlin et al., 2018) and RoBERTa (Liu et al., 2019). Under LLMs' full fine-tuning scenarios, consolidation-based and architecture-based methods will bring additional parameter storage and training costs. Considering the heavy burden on computing time and GPU memory, replay-based CL methods are the simplest and most widely used in tuning LLMs as data-efficient methods that do not change the model structure.

2.3 CL for LLMs instruction tuning

Due to the scaling laws for neural language models, LLMs emerge with capabilities when the scale increases. They can be better adapted to various downstream tasks through instruction tuning, offering immense practical value in real-world applications. The exploration of CL for LLMs is still in its early stages. Continual-T0 (Scialom et al., 2022) first fine-tuned LLMs with instructions in an incremental manner, claiming that well-pretrained models can be continual learners by randomly replaying several previous examples. Several works (Song et al., 2023; Wang et al., 2023) focus on CL methods with parameter-efficient tuning (Hu et al., 2021), largely alleviating the forgetting issue under limited training resources. For full fine-tuning, replay-based methods were preliminarily investigated (Yin et al., 2023), proving that replaying data based on diverse instructions can alleviate catastrophic forgetting and help better generalize to unseen tasks. However, there is still a lack of detailed analysis of replay strategies.

In this work, we focus on the appropriate replay-based method for LLMs' full fine-tuning with instructions. Considering that instructions naturally provide high-quality task-related descriptions, it is necessary to fully utilize instruction information to customize a replay strategy for instruction tuning.

3 Method

Continual Learning of LLMs focuses on adapting an instruction-tuned model to handle a sequence of tasks in a specific application scenario. This approach accounts for consistently emerging materials while processing the tasks simultaneously. We define n tasks to be learned as a sequence $D = \{D_1, \ldots, D_n\}$. When LLMs are tuned with i-th task, we form a replay dataset R_j^α by sampling examples from D_j, where $j \in [1, i-1]$. Formally, the training data augmented with replay data is defined as:

$$D_i^\alpha = D_i \cup \sum_{j=1}^{i-1} R_j^\alpha$$

where α is the replay hyper-parameter, controlling the sampling quantity from previous tasks.

3.1 Dynamic Replay

Prior works optimize CL methods based on the similarity between previous tasks and the current one (Mi et al., 2020; Xu et al., 2023b; Gogoulou et al., 2023). As the similarity increases, it becomes easier to retain knowledge from previous tasks. Inspired by this, we propose a dynamic replay strategy based on task similarity, replaying more data from previous tasks with large differences.

The concept of task similarity is at the core of various machine learning paradigms, such as domain adaptation and meta-learning. Optimal Transport (Alvarez-Melis and Fusi, 2020; Torres et al., 2021) offers a way to calculate the least amount of cost for transferring between different distribution pairs. As the representative of the Optimal Transport framework, Wasserstein Distance (Chen et al., 2022; Liu et al., 2022) provides a metric for calculating the similarity between two dataset distributions. The definition of Wasserstein Distance is as follows:

$$W(\mu_A, \mu_B) = \inf_{\pi} \left(\int_{\mathbb{R}} d(x_A, x_B) d\pi(x_A, x_B) \right)$$

where $\pi \in \prod(\mu_A, \mu_B)$ is meant to be the set of all joint probabilities that exhibit μ_A and μ_B as

marginal distributions. The d denotes a metric for calculating the cost matrix, and here we define it as the cosine distance. For instruction tuning, NLP tasks can be described via natural language instructions. We consider the instruction embeddings for a task pair as x_A and x_B, and calculate the proportion of instructions for each task as a probability distribution. Consequently, we measure task similarity by calculating their Wasserstein Distance. When LLMs are fine-tuned on the current task D_i, the amount of dynamic replay data for the j-th previous task is defined as:

$$\alpha_j^* = \frac{W_{j,i}}{\sum_{k=1}^{i-1} W_{k,i}} \times \alpha, \quad j \in [1, i-1]$$

where $W_{j,i}$ denotes the Wasserstein Distance between D_j and D_i. We dynamically allocate the amount of previous data to replay according to its similarity with the current task. With the help of dynamic replay, LLMs selectively recall the corresponding knowledge.

3.2 Instruction Information Metric

It has been proven that a small amount of high-quality data can achieve a promising performance, demonstrating the rationality of careful data selection (de Masson D'Autume et al., 2019; Wang et al., 2020; Ke and Liu, 2022; Zhou et al., 2023). Inspired by this, we propose an Instruction Information Metric (InsInfo) to guide the sampling process, collecting high-quality replay data for continual instruction tuning.

Considering **complex** and **diverse** instructions induce impressive performance, a more comprehensive analysis of multiple intentions embedded within instructions is necessary. High-performing open-source LLMs demonstrate the ability to annotate queries with tag entities, and the precision and consistency are proven through manual annotation (Lu et al., 2023). Consequently, we employ GPT-4 (OpenAI, 2023) as an intention tagger and clean the raw tags, representing instructions at a fine-grained entity level. The detailed process of obtaining normalized tags is shown in Appendix A.1. After obtaining fine-grained annotations for instructions, we utilize the number and frequency of tags as quantifiable indicators of diversity and complexity. Motivated by Inverse Document Frequency (IDF), one of the most useful and widely used concepts in information retrieval (Gupta et al., 2022; Tayal et al., 2023), we proposed InsInfo as follows to quantify instruction information:

$$\text{InsInfo} = \sum_{t=1}^{T} log \frac{N}{f_t}$$

where N denotes the total amount of previous instructions. When tasks come into a stream, we store all previous instructions in memory. For each instruction, T denotes the number of tags, and f_t denotes the frequency of the t-th tag among the instruction pool. Hence, instruction gets a large InsInfo when the number of individual tags increases, quantifying complexity and diversity interpretably. As shown in Algorithm 1, we follow the InsInfo-guided sampling strategy to obtain the replay data. Moreover, the strategy can be combined with dynamic replay by modifying α to α_j^*, as claimed in Section 3.1, which forms our InsCL finally.

Algorithm 1: InsInfo-guided sampling

Data: Dataset D_j, Instruction Pool I_i, Replay Number α
Result: Replay dataset R_j^α

Initialize Empty R_j^α and InsInfo List S_j;
Extract task j instruction set I_j from I_i;
for *Query* $I_{j,k} \in I_j$ **do**
  $s_{j,k} \leftarrow$ calculate InsInfo for $I_{j,k}$;
  $S_j \leftarrow S_j \cup s_{j,k}$;
end
for $k = 1$ *to* $|I_j|$ **do**
  $\beta \leftarrow \frac{s_{j,k}}{sum(S_j)} \times \alpha$;
  $D_{j,k} \leftarrow$ {data in D_j with $I_{j,k}$} ;
  $R_j^\alpha \leftarrow$ sample β data from $D_{j,k}$;
end
return R_j^α

4 Experimental Setup

Data Collection. To facilitate our research, we mainly utilize the SuperNI dataset (Wang et al., 2022b), a comprehensive benchmark focusing on specific NLP tasks distilled from real-world demands. SuperNI is annotated by NLP practitioners from GitHub and NLP courses, ensuring that each instance is coupled with respective natural language instructions. At the most comprehensive level, we integrate 765 English tasks from SuperNI into 16 categories, as shown in Figure 2. And we demonstrate details of the data composition in Appendix A.2. Following the setting of prior CL

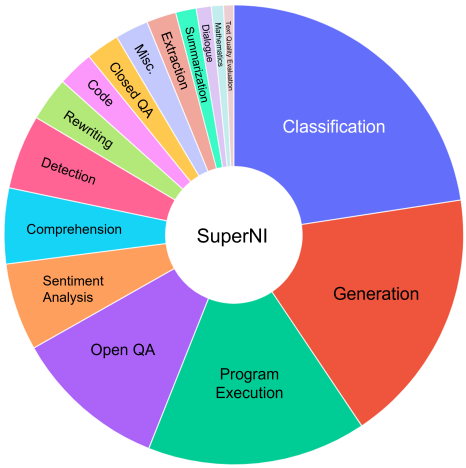

Figure 2: We obtain 16 categories by integrating English tasks in the SuperNI dataset. And we conduct further experiments based on 16 reallocated tasks.

studies (Scialom et al., 2022; Yin et al., 2023), we randomly hold out 20% instances on each task to evaluate LLMs on different training stages.

Model and Training Details. Our work is most related to the continual instruction tuning setting as Continual-T0 (Scialom et al., 2022). We conduct our task-incremental experiments with the popular LLaMA-7B (Touvron et al., 2023), training each task for 2 epochs with a batch size of 64. We use the Adam optimizer (Kingma and Ba, 2014) with a learning rate of 2e-5 and utilize the standard language modeling objective:

$$\mathcal{L} = -\frac{1}{|y|}\sum_{i=1}^{|y|}\log p_\theta\left(y_i \mid x, y_{<i}\right)$$

where x denotes the combination of instruction and input, and y denotes the corresponding output.

Evaluate Forgetting. Following the evaluation metric proposed by Scialom et al. (2022), we leverage Relative Gain to focus on the forgetting issue. We train expert LLM on each single task only and test with their respective holdout data, taking the results as upper bounds (Jang et al., 2023). The Relative Gain in stage i can be defined as:

$$\text{Relative Gain}^i = \frac{1}{i-1}\sum_{j=1}^{i-1}\frac{R_j^i}{\text{upper bound}_j} \times 100\%.$$

Here we utilize Rouge-L (Lin, 2004) to calculate R_j^i and the upper bound.

5 Experiments

We leverage LLaMA-7B to calculate sentence embeddings and compare our InsCL with the following strategies:

- **No Replay**: Train LLMs incrementally without any replay data.
- **Random Replay**: Sample α instances randomly from each previous task as the replay setting in Continual-T0.
- **Prototype Data**: To collect the most representative data, we cluster the training data embedding space with k-means (Wang et al., 2021a). For each previous task, we set the cluster number as the amount of instructions. We sort the data in descending order according to cosine distance from the corresponding center and take the top-α as replay data.
- **Prototype Instruction**: We cluster instructions on previous tasks with the optimal silhouette coefficient (Dinh et al., 2019), taking the closest instructions to their respective centers as the most representative. We randomly select α data with prototypical instructions.
- **Diverse Instruction**: Following the optimal replay strategy proposed by Yin et al. (2023), we replay data with instructions diverging most from the current task instructions. By computing the cosine similarity matrix with the current instruction embedding, we take the most diverse instruction with the least column sum and replay α corresponding data for each previous task.

For fairness of comparison among different methods, we note $M_i = (i-1) \times \alpha$ as the total amount of replay data when the task sequence comes to stage i. Here we set α to 200.

5.1 Main Results

We train LLaMA-7B on 16 tasks continuously with three different training orders. For each continual instruction tuning stage, the average Relative Gain results are shown in Figure 3. It can be observed that our InsCL is effective in mitigating forgetting, with a promising Relative Gain. When all tasks have been trained, InsCL achieves performance gains of 3.0 Relative Gain compared with Random Replay, and 27.96 Relative Gain compared with No Replay. InsCL sustainably maintains the performance on previous tasks over 90%, exhibiting high stability with a small fluctuation. Conversely, No Replay's Relative Gain shows a sharp decreasing trend as the task increases, accompanied by significant performance fluctuations. After training the 8th task, No Replay's performance remains at less

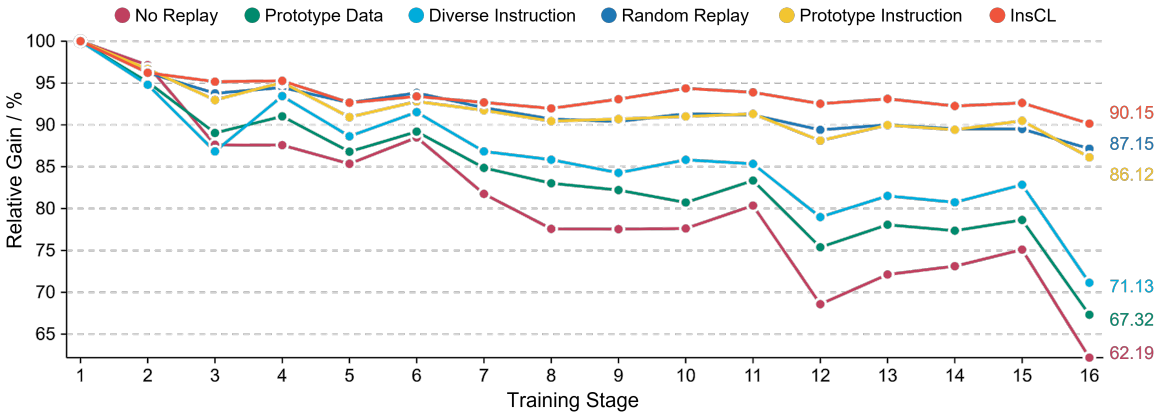

Figure 3: Progressive Relative Gain results for LLaMA-7B in continual instruction tuning. We set Relative Gain to 100 for training on the first task, denoting the initial performance without forgetting. When it comes to stage i, we plot the average score of corresponding Relative Gain with three different training orders. The closer the Relative Gain is to 100, the better to alleviate catastrophic forgetting and preserve knowledge.

	Reverse		Random		Curriculum	
Method	**AVG**	**STD**	**AVG**	**STD**	**AVG**	**STD**
No Replay	73.83	182.87	81.07	121.9	87.63	51.30
Random Replay	87.96	18.85	92.90	<u>10.84</u>	<u>95.18</u>	<u>4.80</u>
Prototype Data	78.07	92.71	83.51	93.71	90.07	29.79
Prototype Instruction	<u>88.29</u>	<u>15.73</u>	<u>93.01</u>	18.75	93.91	7.44
Diverse Instruction	80.87	72.09	86.47	81.60	91.14	23.34
InsCL	**90.50**	**9.32**	**94.43**	**7.62**	**96.20**	**2.81**

Table 2: Results on different training orders. AVG indicates average Relative Gain on 16 tasks, and STD indicates standard deviation ($\times$ e-4) on all the Relative Gain. Reverse denotes a converse training order with Curriculum. A promising method is expected with a large AVG and a small STD, indicating good performance and high stability. The best results are in bold, while the second-best are underlined.

than 80% and further drops to less than 65% upon finishing final training. No Replay setting severely suffers from catastrophic forgetting, demonstrating the necessity of replaying previous data.

Moreover, we further analyze other replay-based methods. Despite being the optimal method in the previous work, Diverse Instruction underperforms when compared with Random Replay and Prototype Instruction. For prototype-based methods, Prototype Instruction outperforms Prototype Data. We find that clustering results of Prototype Data are significantly affected by instances with long instruction and short input, leading to practically identical embeddings for this subset. The uneven distribution will cause a high semantic duplicate selection, which has been proven to lead to a negative impact (Abbas et al., 2023). The data composed of instruction and input has a different structure from traditional SFT, resulting in several traditional replay-based methods not being directly applicable to instruction tuning. This observation also demonstrates the rationality of designing instruction-based replay methods, proving the consistency of our InsCL.

5.2 Training Order Analysis

To explore the impact of training order and obtain universe conclusions, we conduct a detailed analysis of all settings based on different task sequences. Inspired by Curriculum Learning (Wang et al., 2021c), we train the model from easy task to hard task by sorting the upper bounds in descending order, as *Classification* → *Text Quality Evaluation* → *Code* → *Detection* → *Sentiment Analysis* → *Comprehension* → *Closed QA* → *Extraction* → *Dialogue* → *Program Execution* → *Rewriting* → *Open QA* → *Misc.* → *Generation* → *Summarization*→ *Mathematics.*

As shown in Table 2, we report the average Relative Gain scores and the standard deviations on 16 tasks with different training orders. When we utilize the "easy to hard" training strategy, Cur-

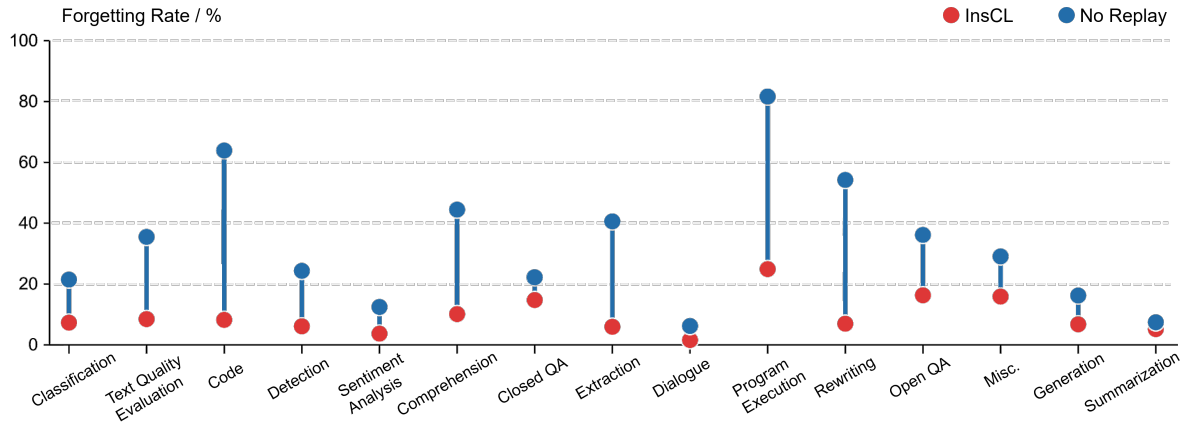

Figure 4: We analyze the forgetting rate based on Curriculum training order. The results of all previous tasks are reported when training is finished on the last task.

Method	AVG	STD
No Replay	80.84	118.69
Random Replay	92.01	11.50
+ Dynamic (Uniform)	93.14	8.67
+ Dynamic (Real)	93.25	<u>8.57</u>
+ InsInfo	<u>93.52</u>	17.90
InsCL	**93.71**	**6.58**

Table 3: Average results on three training orders. AVG indicates average Relative Gain, and STD indicates standard deviation ($\times$ e-4) on all the Relative Gain. The best results are in bold, while the second-best are underlined.

riculum outperforms other orders in all CL methods. Under the No Replay setting, Curriculum achieves performance gains of 13.80 average Relative Gain compared with Reverse and 6.56 compared with Random. Training tasks in Curriculum order demonstrates a more stable performance with a small standard deviation. Moreover, with our InsCL, Curriculum achieves performance gains of 5.70 average Relative Gain compared with Reverse and 1.77 compared with Random. It can be observed that InsCL alleviates the impact of different training orders, outperforming all methods with a high Relative Gain and stability.

5.3 Ablation Study

To investigate the effectiveness of each component in InsCL, we further apply our dynamic replay and InsInfo-guided sampling based on the Random Replay. Dynamic replay is determined by task similarity, calculated via Wasserstein distance. If the real distribution of instructions cannot be obtained, the uniform distribution assumption is generally used to obtain the Wasserstein distance. We evaluate the performance with average Relative Gain scores and standard deviations on all training stages.

The average results over three different training orders are reported in Table 3. It can be inferred that dynamic replay and InsInfo-guided sampling are both beneficial to mitigating catastrophic forgetting. InsInfo-guided sampling brings greater improvement in Relative Gain, effectively improving Relative Gain but lacking in stability. Instead, dynamic replay greatly reduces the standard deviation of Relative Gain thus improving stability. And dynamic replay with real distribution brings better performance compared with the uniform distribution assumption. When we utilize InsCL combined with dynamic replay and InsInfo-guided sampling, it achieves the best performance and strongest stability. Compared with Random Replay, InsCL delivers an improved average Relative Gain of 1.71 and a reduced standard deviation of 4.92. Furthermore, when compared with No Replay, InsCL achieves an improved average Relative Gain of 12.87 and a dramatic reduction of the standard deviation. The results prove the effectiveness of each component and demonstrate that InsCL leverages the strengths of each.

5.4 Forgetting Analysis

Forgetting Rate. For a further catastrophic forgetting analysis, several methods (Kemker et al., 2018; Luo et al., 2023) quantify the forgetting issue by evaluating performance decrease as training incrementally. Consequently, we propose a forgetting rate defined as:

$$FG_i = \frac{R_i^* - R_i^{-1}}{R_i^*} \times 100\%$$

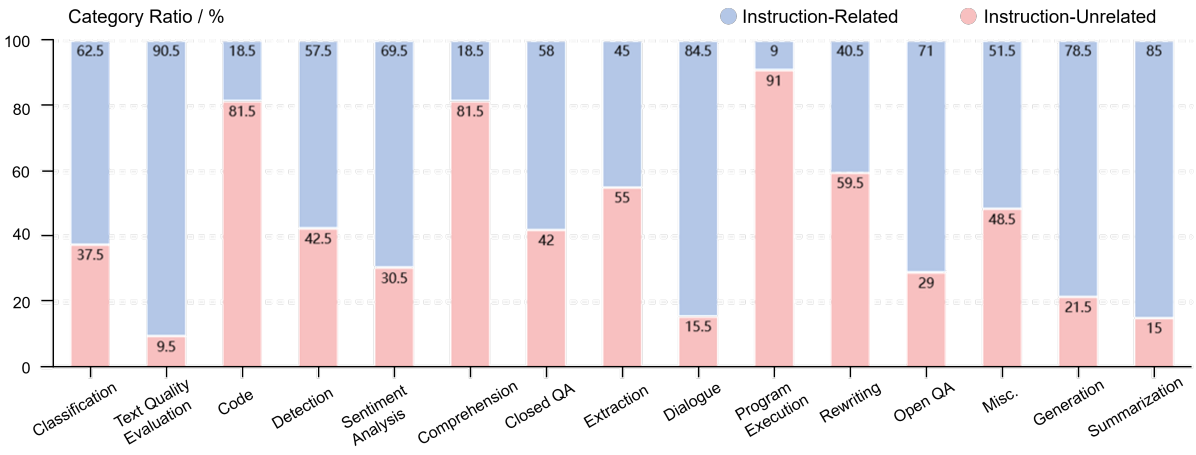

Figure 5: The analysis of forgetting category. We divide forgetting instances into Instruction-Related and Instruction Unrelated. After training on Curriculum order, the ratios of two categories in previous tasks are reported.

where R_i^* is the initial Rouge-L of task i after training on the corresponding task, and R_i^{-1} is the final Rouge-L of task i in the last training stage.

We evaluate the forgetting rate with Curriculum training order and report the results of No Replay and InsCL in Figure 4. It can be inferred that there is no inevitable relationship between task order and forgetting rate. For tasks that require complex reasoning, Program Execution and Code severely suffer from forgetting with the No Replay setting. Additionally, a large training data scale does not necessarily lead to a small forgetting rate. For example, Classification and Generation are the top-2 tasks with large training data and exhibit smaller forgetting rates, while Program Execution with the third largest dataset suffers from the largest forgetting rate. With our InsCL, the forgetting rates of almost all tasks are below 20%, which means that most of the previous knowledge is preserved.

Forgetting Category. When all the tasks have been trained under the No Replay setting, we collect previous tasks' instances with a decreased Rouge-L, called forgetting instances. We randomly sampled 200 forgetting instances from each previous task, manually analyzing the forgetting category for a detailed conclusion. We divide forgetting instances into two categories based on the instruction's following ability: (1) Instruction-Related: The output is relevant to the instruction, according to the space defined by the instruction. This category indicates LLMs do not forget the corresponding instruction following ability. (2) Instruction-Unrelated: The output is unrelated to the instruction. We demonstrate representative cases and respective explanations in Appendix A.3.

Figure 5 reports category ratios in the curriculum training order. The forgotten instances of most tasks are mainly Instruction-Related, while the forgetting instances in 5 tasks are mainly Instruction-Unrelated. Additionally, more than 80% of forgetting instances in Program Execution, Code, and Comprehension tasks are Instruction-Unrelated. It can be inferred that failure to understand instructions mainly leads to the performance decline of complex reasoning tasks.

6 Conclusions

In this paper, we mainly discuss the efficient adaptation of LLMs to continual downstream tasks with instructions. Replay-based CL methods do not require additional modifications to LLMs and fully utilize previous data, mitigating catastrophic forgetting effectively. We proposed InsCL, an effective data-efficient method to mitigate catastrophic forgetting for LLMs instruction tuning. InsCL is a model-agnostic and training-free method, indicating strong transferability. Different from existing replay-based methods, we fully utilize instructions as representative task descriptions to design the replay strategy. InsCL leverages instruction embeddings and distributions to calculate Wasserstein distance for task similarity, adjusting the replay ratio dynamically. Then, with our InsInfo-guided sampling, InsCL selects more high-quality data with complex and diverse instructions. We conduct extensive experiments over 16 tasks with different training orders, observing consistent performance improvements of InsCL. Additionally, we further analyze the forgetting rate and forgetting category, aiming to provide a guideline for future work.

7 Limitations

The promising performance demonstrated by InsCL is dependent on high-quality instructions. Instead, fuzzy instructions can affect the calculation of task similarity and the InsInfo-guided sampling, which may mislead our InsCL. However, if the instruction-based dataset is unsatisfied, the performance of tuned LLMs will also be greatly affected. Therefore, we tend to use our method after collecting high-quality instruction-based data to further mitigate catastrophic forgetting.

A Appendix

A.1 InsTag Process

Follow Lu et al. (2023), we use the prompt shown in Table 4 to employ GPT-4, providing fine-grained intention tags for given queries. To make the word format and granularity consistent, we filter the noise in raw tags as the following steps:

- **Rule Aggregation**: We replace all special characters with spaces and transform words into lowercase. Then, we apply lemmatization via NLTK (Bird et al., 2009) to unify tag formats.
- **Semantic Aggregation**: We obtain semantic embeddings of tags through PHRASE-BERT (Wang et al., 2021b), a BERT-based model designed for embedding phrases. Then, we cluster tags with semantic similarity via the DBSCAN algorithm (Hahsler et al., 2019). Here, we calculate the cosine similarity and set the cluster threshold to 0.1.

You are a tagging system that provides useful tags for instruction intentions to distinguish instructions for a helpful AI assistant. Below is an instruction: [begin] {instruction} [end] Please provide coarse-grained tags, such as "Spelling and Grammar Check" and "Cosplay", to identify main intentions of the above instruction. Your answer should be a list including titles of tags and a brief explanation of each tag. Your response has to strictly follow this JSON format: [{"tag": str, "explanation": str}]. Please respond in English.

Table 4: Prompt template for annotating intention tags of the given instruction.

A.2 Data Composition

SuperNI (Wang et al., 2022b) collects diverse NLP tasks with instructions using the Apache-2.0 license. The dataset curates task data in independent files, starting with a unique task ID (e.g., task001_quoref_question_generation.json). We integrate 765 English tasks from SuperNI into 16 categories, representing corresponding task IDs for each category in Table 5. Noting that, following the same evaluation protocol as in Wang et al. (2022b); Shi et al. (2023, 2024), we adopt greedy search with a maximum generation length of 512.

A.3 Forgetting Category Annotation

We invite 5 Chinese graduate students whose research field is related to NLP as annotation volunteers, manually labeling forgetting instances with Instruction-Related or Instruction-Unrelated. Additionally, we have procured approval from the annotator for utilizing the data in scientific research. We randomly sampled 3000 forgetting instances from 15 previous tasks for annotation (200 instances per task). To better understand the forgetting category, we demonstrate detailed cases and relevant explanations in Table 6.

Category	Size	Task ID
Classification	633k	20, 50, 65, 66, 69, 70, 109, 112, 114, 115, 116, 141, 142, 143, 145, 146, 147, 148, 149, 150, 155, 190, 199, 200, 201, 202, 226, 232, 233, 242, 274, 276, 280, 290, 291, 298, 340, 341, 342, 343, 345, 346, 347, 349, 350, 351, 364, 375, 379, 382, 391, 392, 393, 400, 428, 429, 430, 431, 457, 458, 459, 472, 495, 496, 514, 515, 516, 520, 521, 564, 566, 573, 575, 577, 583, 584, 590, 614, 617, 623, 625, 629, 630, 632, 633, 638, 640, 641, 642, 679, 681, 682, 738, 767, 827, 828, 848, 854, 855, 856, 890, 907, 908, 925, 935, 936, 937, 970, 1167, 1168, 1196, 1197, 1198, 1199, 1200, 1201, 1202, 1203, 1204, 1205, 1206, 1207, 1208, 1209, 1210, 1211, 1212, 1213, 1214, 1215, 1216, 1285, 1288, 1308, 1336, 1344, 1347, 1354, 1385, 1386, 1387, 1388, 1393, 1418, 1429, 1434, 1439, 1442, 1488, 1489, 1495, 1505, 1516, 1529, 1541, 1548, 1549, 1554, 1559, 1560, 1573, 1583, 1584, 1592, 1593, 1599, 1612, 1615, 1624, 1640, 1645, 1705, 1712

Table 5: We analyze the intention of instructions, reclassifying the task types into 16 categories. The task IDs contained in each category are reported.

Case	Explanation
In this task, you are given a context tweet, a question and corresponding answer of given question. Your task is to classify given passage into two categories: (1) "Yes" if the given context is useful in answering the question, and (2) "No" if the given context is not useful. Context: ... Ground Truth: No Instruction-Related Output: Yes Instruction-Unrelated Output: None	For close-domain instruction, we consider output within the specified range as instruction-related and vice versa as instruction-unrelated.
Craft one correct answer to the question given in input. In your answer, use as few words as possible from the given context. Use a response that is uncommon/non-stereotypical so that it is less predictable. Context: ..., Question: ... Ground Truth: He is my boyfriend. Instruction Related Output: We have a close relationship. Instruction Unrelated Output: 10	For open-domain instruction, we consider output that is relevant to the input as instruction-related, and vice versa as instruction-unrelated.
Given a command in a limited form of natural language, provide the correct sequence of actions that executes the command to thus navigate an agent in its environment. A command can be broken down into many different actions. ... There are only six actions: 'I_LOOK', 'I_WALK', 'I_RUN', 'I_JUMP', 'I_TURN_LEFT', and 'I_TURN_RIGHT'. jump opposite left and run opposite left. Ground Truth: I_TURN_LEFT I_TURN_LEFT I_JUMP I_TURN_LEFT I_TURN_LEFT I_RUN Instruction Related Output: I_JUMP I_TURN_LEFT Instruction Unrelated Output: turn left twice	For the instruction that imposes restrictions on the format (e.g., within 20 words / return in the form of / should be separated with a new line / ...), we consider output with the specified format as instruction-related, and vice versa as instruction-unrelated.
Given a factoid/trivia type question, generate the topic of the question. The topic is the entity the question talks about. For which paper was reporter Clark Kent/Superman employed? Ground Truth: superman, clark kent Instruction Related Output: paper Instruction Unrelated Output: planet	For Comprehension and Summarization tasks, we consider output containing the phrases extracted from the context as instruction-related, and vice versa as instruction-unrelated.
In this task, you will be given a list of integers. You should find the maximum absolute difference between 2 integers in the list. The absolute difference is the absolute value of one integer subtracted by another. The output should be a single integer which is the largest possible absolute distance. [-73, -93, -11, 79, -11, -17, -16, -52, -42, -28] Ground Truth: 172 Instruction Related Output: 170 Instruction Unrelated Output: [-11, -17, -16] or 999999	For tasks involving mathematical operations, we consider reasonable output in the same format as instruction-related, and vice versa as instruction-unrelated.

Table 6: We demonstrate representative cases of two categories for a better understanding.

Language Agnostic Code Embeddings

Abstract

Recently, code language models have achieved notable advancements in addressing a diverse array of essential code comprehension and generation tasks. Yet, the field lacks a comprehensive deep dive and understanding of the code embeddings of multilingual code models. In this paper, we present a comprehensive study on multilingual code embeddings, focusing on the cross-lingual capabilities of these embeddings across different programming languages. Through probing experiments, we demonstrate that code embeddings comprise two distinct components: one deeply tied to the nuances and syntax of a specific language, and the other remaining agnostic to these details, primarily focusing on semantics. Further, we show that when we isolate and eliminate this language-specific component, we witness significant improvements in downstream code retrieval tasks, leading to an absolute increase of up to +17 in the Mean Reciprocal Rank (MRR).

1 Introduction

Large language models (LLMs) have made remarkable progress in code-related tasks, exemplified by models such as Codex, which powers GitHub Copilot and offers automated code suggestions within integrated development environments (IDEs) (Chen et al., 2021). These models achieve their proficiency through extensive training on vast code datasets, providing them with versatile contextual understanding for a range of coding tasks (Husain et al., 2019; Athiwaratkun et al., 2022; Zhu et al., 2022). However, it's worth noting that decoder-only models may not always be the optimal choice for retrieval tasks when compared to encoder models (Nijkamp et al., 2023; Wang et al., 2021b, 2023).

While previous studies indicate that language models trained on a variety of natural languages exhibit strong cross-lingual traits (Pires et al., 2019), their multilingual representations can be dissected into a language-specific syntax component and a language-agnostic semantic component (Chang et al., 2022). Moreover, eliminating the language-specific elements can enhance retrieval tasks and counteract "language bias", a tendency for representations to cluster by language instead of meaning (Roy et al., 2020; Yang et al., 2021; Xie et al., 2022). We aim to determine if similar patterns are evident in multilingual code models pretrained on programming languages (e.g., C, C++, Python) as opposed to natural languages (e.g., English, French, Spanish). We specifically address:

1. Can representations of these code models be categorized into language-specific and language-agnostic components?

2. If so, does removing the language-specific components enhance the consistency and comparability of code representations (alignment) across programming languages, thereby improving downstream code retrieval tasks?

Our comprehensive evaluations confirm these patterns in code language models. Our contributions are summarized as follows:

- We investigate the cross-lingual properties of pretrained multilingual code language models, examining them through the lens of both language-specific (syntax) and language-agnostic (semantic) attributes. Through various probing experiments on five models, we demonstrate that the embeddings of these code language models include both language-specific (syntax) and language-agnostic (semantic) components.

- We demonstrate that removing these language-specific components and using only the language-agnostic component in downstream tasks can significantly enhance code retrieval

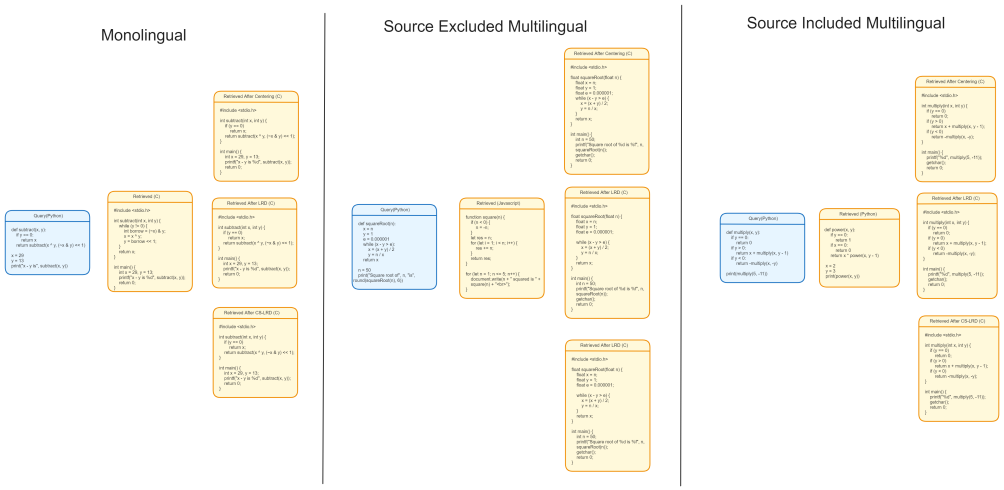

Figure 1: Illustration of the top retrieved results for code-to-code search, where the query is in Python, and the target is in C. Language composition varies across retrieval databases: 'Monolingual' (C only), 'Source Excluded Multilingual' (several languages except Python), 'Source Included Multilingual' (several languages including Python). Demonstrates improved semantic matching and reduced language bias after removing language-specific components.

tasks providing improvement upto +17 increase in MRR. Importantly, such improvements are achieved using inexpensive operations such as centering and projections, without using parallel language data or finetuning.

- Additionally, our extensive ablation studies suggest that as few as 100 samples per language suffice for these MRR improvements. We also confirm that the improvements are not restricted to a single type of embedding but can be realized across all common types, including mean, cls, and pooler embeddings.

2 Language Agnostic Code Embeddings

Let $\mathcal{M}$ represent a multilingual code language model trained on a set of programming languages $\{1, \ldots, \ell\}$. Given a code snippet c in a specific programming language l, this model produces an embedding $\mathbf{e} \in \mathbb{R}^d$, denoted as $\mathcal{M}(c) = \mathbf{e} \in \mathbb{R}^d$. We hypothesize that the embedding $\mathbf{e} \in \mathbb{R}^d$ of a code snippet can be decomposed into two components: a syntax component, $\mathbf{e}^{\text{s}} \in \mathbb{R}^d$, which depends on the programming language l, and semantic component, $\mathbf{e}^{\text{a}}$ which is language-agnostic. This relationship can be expressed as:

$$\mathbf{e} = \mathbf{e}^{\text{s}} + \mathbf{e}^{\text{a}} \tag{1}$$

Next, we introduce the Estimation Set $\mathcal{E}$, which is used to estimate the language-specific components $\mathbf{e}^s$.

Definition 1 (Estimation Set)**.** *The Estimation set $\mathcal{E}$ is defined as a collection of n code snippets $\{c_1^{(l)}, \ldots, c_n^{(l)}\}$ from each programming language $l \in \{1, \ldots, \ell\}$. Importantly, the code snippets in this set need not be direct translations of one another.*

Now for given model $\mathcal{M}$, we define embedding matrix $\mathbf{E}_l \in \mathbb{R}^{n \times d}$ for each language ℓ as $\mathbf{E}_l = \left[\mathcal{M}(c_1^{(l)}), \ldots, \mathcal{M}(c_n^{(l)})\right]$.

In the subsequent sections, we explore a variety of methods designed to remove language-specific information. This analysis is conducted from the unified perspective of Equation 1, which serves as the fundamental framework for disentangling language-specific and language-agnostic components within code embeddings. Additionally, we explicitly outline the assumptions that underpin each of these methods.

2.1 Centering

The first method we explore is centering (Libovický et al., 2020), which is grounded in the following key assumption:

Assumption 1. *Given an programming language l, centering method makes an assumption that language specific components $\boldsymbol{e}^s$ is same for all embeddings in that programming language ℓ.*

Under Assumption 1, the mean of the embeddings for a programming language ℓ can be expressed as:

$$\mathbf{m}_l = \frac{1}{n}\sum_{i=1}^{n}\mathbf{e}_i = \frac{1}{n}\sum_{i=1}^{n}(\mathbf{e}_i^s + \mathbf{e}_i^a)$$
$$\overset{(1)}{=} \frac{1}{n}\sum_{i=1}^{n}(\mathbf{e}^s + \mathbf{e}_i^a) = \mathbf{e}^s + \underbrace{\frac{1}{n}\sum_{i=1}^{n}\mathbf{e}_i^a}_{\text{small for large } n} \approx \mathbf{e}^s.$$

From the above, it is evident that for a large enough value of n, the language-specific syntax embedding for a given programming language can be approximately estimated as the mean of the embeddings in that language. This method is summarized in Algorithm 1 in centering.

2.2 Low Rank Decomposition

A significant concern with the centering method, as outlined in Assumption 1, is its presumption that the syntax embedding for each code is the same and is independent of the given code content. Instead, it is only dependent on the programming language. To address this limitation, Low Rank Decomposition (LRD) (Schmidt, 1907; Yang et al., 2021) introduces distinct syntax subspaces for each programming language, operating under the following assumptions:

Assumption 2. *The low rank decomposition method is based on the following assumptions:*

1. *The language-specific syntax embedding varies for each individual embedding.*
2. *The language-specific syntax embedding, $\boldsymbol{e}^{\mathrm{s}}$, is orthogonal to the language-agnostic semantic embedding, $\boldsymbol{e}^{\mathrm{a}}$, i.e., $\boldsymbol{e}^{\mathrm{s}} \perp \boldsymbol{e}^{\mathrm{a}}$.*
3. *For each programming language, there exists a low-rank subspace of rank r that captures the syntactic essence of the embeddings.*

Based on the above assumptions, we determine the syntactic subspace of language l of rank r, denoted as $\mathbf{E}_l^r \in \mathbb{R}^{n\times d}$, as follows:

$$\min_{\mathbf{E}_l^r \in \mathbb{R}^{n\times d}} \|\mathbf{E}_l - \mathbf{E}_l^r\|_{\mathrm{F}}^2 \quad \text{s.t. } \mathrm{RANK}(\mathbf{E}_l^r) \leq r. \tag{2}$$

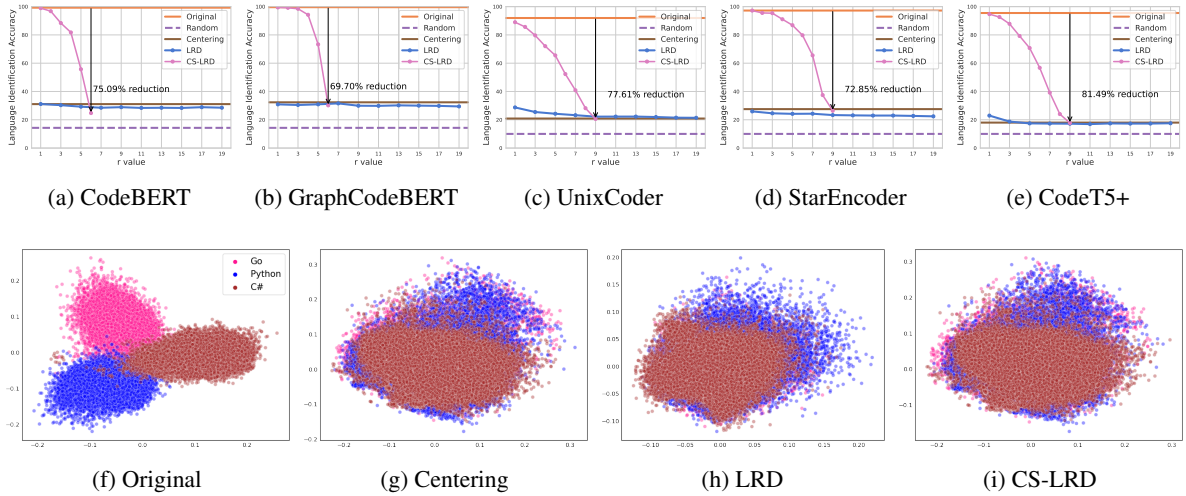
Equation 2 can be solved using TOPK-SVD with $k = r$ where $\mathbf{E}_l^r = \mathbf{U}_r\mathbf{\Sigma}_r\mathbf{V}_r^T$. The projection of the embedding $\mathbf{e}$ onto the ROWSPACE $(\mathbf{E}_l^r)$is given by $\mathbf{V}_r\mathbf{V}_r^T\mathbf{e}$. The language-agnostic embedding is then obtained by removing this component: $\mathbf{e}^a = \mathbf{e} - \mathbf{V}_r\mathbf{V}_r^T\mathbf{e}$. This method is summarized in Algorithm 1 in LRD.

2.3 Common Specific Low Rank Decomposition

The Common Specific Low Rank Decomposition (Piratla et al., 2020; Xie et al., 2022) is a variant of low rank decomposition. Given different data domains, this method aims to learn both a common subspace shared across domains and a specific subspace unique to each domain.

Assumption 3. *The Common Specific Low Rank Decomposition is grounded on the following assumptions:*

1. *The language-specific syntax embedding varies for each individual embedding.*
2. *The language-specific syntax embedding, $\boldsymbol{e}^{\mathrm{s}}$, is orthogonal to the language-agnostic semantic embedding, $\boldsymbol{e}^{\mathrm{a}}$. In other words, $\boldsymbol{e}^{\mathrm{s}} \perp \boldsymbol{e}^{\mathrm{a}}$.*
3. *There exists a unified syntax subspace, consistent across all programming languages, that encapsulates the syntactic attributes of the code embedding.*



A key distinction is that while the syntax subspace in the traditional LRD is determined for each language individually, the CS-LRD method derives a singular, unified syntax subspace that encompasses all the considered programming languages. It is formulated as:

$$\min_{\mathbf{m}_c \in \mathbb{R}^d, \mathbf{M}_s \in \mathbb{R}^{d\times r}, \mathbf{\Gamma}_s \in \mathbb{R}^{d\times \ell}} \left\|\mathbf{M} - \mathbf{m}_c \cdot \mathbb{1}_\ell^T - \mathbf{M}_s \cdot \mathbf{\Gamma}_s^T\right\|_{\mathrm{F}}^2 \quad \text{s.t. } \mathbf{m}_c \perp \mathrm{COLSPAN}(\mathbf{M}_s). \tag{3}$$

where $\mathbf{M} = [\mathbf{m}_1, \ldots, \mathbf{m}_\ell]$, and $\mathbf{m}_1, \ldots, \mathbf{m}_\ell$ are the mean embeddings of the $\{1, \ldots, \ell\}$ programming languages. The matrix $\mathbf{M}_s$, which captures the common syntactic subspace, can be obtained by the CS-LRD function in Algorithm 1. Similar to LRD, the language-agnostic embedding is obtained by removing the projection of $\mathbf{e}$ on $\mathbf{M}_s$, i.e., $\mathbf{e}^a = \mathbf{e} - \mathbf{M}_s\mathbf{M}_s^T\mathbf{e}$.

3 Experiments

Setup: We examine three tasks and analyze the performance before and after removing language-specific components: (i) Probing - This task involves identifying languages using a linear classifier. (ii) Code2Code search - Given a piece of code in language L_1, the objective is to retrieve the most

(a) CodeBERT (b) GraphCodeBERT (c) UnixCoder (d) StarEncoder (e) CodeT5+

(f) Original (g) Centering (h) LRD (i) CS-LRD

Figure 2: The top row illustrates the impact on language identification accuracy before and after removing language-specific components. Meanwhile, the bottom row displays the PCA of Code T5+ embeddings for the languages: Go, Python, and C#.

semantically relevant code in another language L_2. (iii) Text2Code search - The aim is to identify code that corresponds to a provided natural language query.

The first task assesses whether the procedures in Algorithm 1 effectively eliminate language-specific (syntax) components. The second and third tasks determine if language-agnostic (semantic) components are preserved.

Datasets: We utilize programs from the Stack dataset (Kocetkov et al., 2022) to estimate language-specific components. For the Code2Code search, we employ XLCoST (Zhu et al., 2022), and for the Text2Code search, we use CSN (Husain et al., 2019).

Models: We consider five models, including encoder-only and encoder-decoder models: CodeBERT (Feng et al., 2020), GraphCodeBERT (Guo et al., 2020), UnixCoder (Guo et al., 2022), StarEncoder (Li et al., 2023), and CodeT5+ (Wang et al., 2023).

Embeddings: For models like CodeBERT, GraphCodeBERT, UnixCoder, and StarEncoder, there isn't a standard method to obtain embeddings. In our retrieval tasks, we use mean embeddings, derived from the mean of the last hidden states. We conduct an ablation study to explore other embedding extraction methods in Section 4.2. For CodeT5+, only the pooler embedding is recomended and is given as output, and this is what we employ in our experiments.

Retrieval Metrics: For the Retrieval Task, we use Mean Reciprocal Rank (MRR) as our evaluation metric. MRR is calculated as $\text{MRR} = \frac{1}{n}\sum_{i=1}^{n}\frac{1}{\text{rank}(c_i)} \times 100$, where n represents the total number of queries, and $\text{rank}(c_i)$ denotes the rank of the correct answer for the i-th query in the retrieval results. Higher MRR values indicate better performance.

3.1 Probing

We evaluate the syntactic component of embeddings by employing a *linear* classifier for the task of language identification, both pre and post transformations. From the Stack dataset (Kocetkov et al., 2022), we allocate 10,000 code instances for estimating language components. For training, we use 24,000 code snippets from each language, and for validation, we utilize 6,000 codes from each respective language. The testing is performed on 10,000 codes for each language. The outcomes are depicted in Figure 2. Before transformation, the linear classifier yields high accuracy on the embeddings. However, after the removal of language-specific components, the accuracy declines sharply, experiencing a drop of at least 70% across all models. In particular, for the CodeT5+ model, the accuracy approaches random performance. Moreover, in the context of CS-LRD, there's an interesting relationship between the rank r and performance. As r increases, the classifier's performance diminishes. It's worth noting that this behavior is not observed with the LRD.

we also visualize PCA of CodeT5+ embeddings and show it in Figure 2f which shows embeddings are clustered by language. But after removing

language-specific components we see that in Figure 2g to Figure 2i there are no longer language clusters.

3.2 Code2Code Search

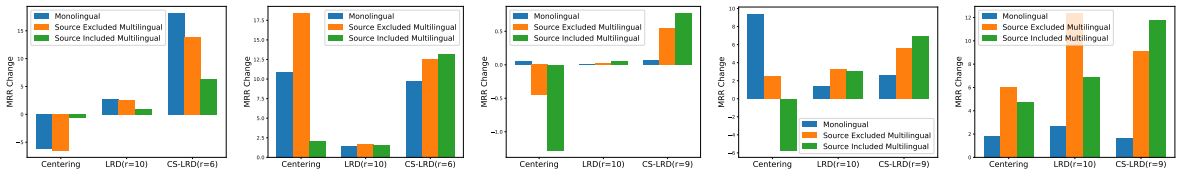
Given a query Q in a source language $\mathcal{S}$, the objective is to extract a code snippet with semantic similarity from a specific database. Depending on the language composition of the database, we consider three different variations:

- **Monolingual Database:** In this conventional setting, the database consists entirely of programs written in a single target language $\mathcal{T}$, which is distinct from the source language $\mathcal{S}$.
- **Source-Excluded Multilingual Database:** In this variation, the database is composed of programs in multiple languages $\mathcal{T}_1, \ldots, \mathcal{T}_n$, where $\mathcal{T}_i$ differs from the source language $\mathcal{S}$.
- **Source-Included Multilingual Database:** This final variation includes the source language $\mathcal{S}$ within its spectrum of target languages. We evaluate the language bias of models (Yang et al., 2021), wherein a code from the source language $\mathcal{S}$ is ranked higher than codes that are more semantically similar but from different languages.

For this task, we use the XLCoST dataset (Zhu et al., 2022), which contains parallel translations of seven programming languages: C, C#, C++, Java, JavaScript, PHP, and Python. However, it's important to note that CodeBERT and GraphCodeBERT do not support C, C++, and C#. Therefore, we only consider Java, JavaScript, PHP, and Python for these models, while all seven languages are included for all other models.

We present the change in the Mean Reciprocal Rank (MRR) before and after the removal of the language component in Figure 3. This change is averaged over all pairwise language retrieval tasks, amounting to $6 \times 7 = 42$ tasks in total. Additionally, for the CodeT5+ model, we offer a detailed breakdown of the MRR for each source language. The retrieval results are averaged across the six target languages and are tabulated in Table 1.

Discussion: Significant improvements are observed before and after removing the language component, with an absolute increase in MRR ranging up to +17. We discuss a couple of factors below.



1. **Database Configuration:** Models exhibit substantial language bias, leading to a drastic drop in performance in the 'Source Included Multilingual' setup, with a reduction of -59.62% from 89.51 to 29.89.
2. **Centering Effects:** In three out of five cases, centering has a detrimental impact on performance. This aligns with the notion that centering may mix syntax and semantic signals, potentially removing semantic meaning as well (Yang et al., 2021; Xie et al., 2022).
3. **UniXcoder Exception:** Notably, UniXcoder explicitly aligns representations from different programming languages during pretraining itself using a task involving cross-modal generation (Guo et al., 2022). Consequently, none of the methods provide any improvement in this case.
4. **CS-LRD Superiority:** In most cases, CS-LRD outperforms both centering and LRD. This is attributed to the joint learning of the syntax subspace across different programming languages in CS-LRD.
5. **Effect of Rank in LRD and CS-LRD:** We examine the impact of the rank of the subspace r in Figure 5 for both LRD (Top Row) and CS-LRD (Bottom Row). Increasing r consistently enhances MRR in CS-LRD, while no such behavior is observed in LRD, which is less stable compared to CS-LRD.

3.3 Text2Code Search

In this section, we delve into Text2Code search, a task where the objective is to find code that corresponds to a given natural language query (in English). We explore two distinct settings for Text2Code search:

- **Monolingual Database:** In this setting, we construct the retrieval database using data from a single programming language.
- **Multilingual Database:** In contrast, for this setting, we include data from all programming languages in the retrieval database. The goal is to locate the correct code snippet that matches the query, regardless of the programming language.

For this task, we utilize the CodeSearchNet dataset (Husain et al., 2019), which contains data

(a) CodeBERT (b) GraphCodeBERT (c) UnixCoder (d) StarEncoder (e) CodeT5+

Figure 3: Absolute change in MRR after removing language components in zero-shot Code2Code search.

Table 1: MRR averaged across all target languages for zero-shot Code2Code search using CodeT5+ (Wang et al., 2023).

in six programming languages: Go, Ruby, Java, JavaScript, PHP, and Python. Retrieval database consists of codes in both val and test.

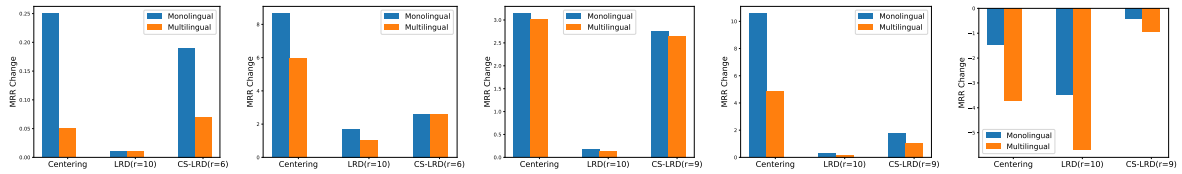
We present the change in Mean Reciprocal Rank (MRR) before and after removing the language component in Figure 4. Full view for Unixcoder can be found at Table 2.

Discussion: Sizable improvements are observed before and after removing language component, with an absolute increase in MRR ranging upto +8. We discuss a couple of factors below.

1. **CodeT5+ Exception:** CodeT5+ includes contrastive tuning as one of its pretraining tasks (Wang et al., 2023) for text-to-code, which explicitly aligns English with programming languages. Hence, we don't observe any improvement.

2. **Centering Superiority:** Unlike in Code2Code search, in Text2Code search centering outperforms both LRD and CS-LRD.

3. **Effect of Rank in LRD and CS-LRD:** We study the influence of the subspace rank r as depicted in Figure 6. The top row illustrates the effect for LRD, while the bottom row represents CS-LRD. For both CS-LRD and LRD, increasing r either consistently improves MRR or remains stable. However, for CodeT5+, there is a consistent decrease.



4. **Effect of Projecting out English:** We conduct retrieval in two distinct ways. In the first method, we remove language components solely from programming languages, leaving the query unaffected (no English component is removed). In the second method, we transform the query by removing the English language component from it. The results are depicted in Figure 6. We find that projecting out the English language components is crucial to observe an increase in MRR.

4 Ablation Study

In this section, we conduct various ablation studies focusing on the estimation set's size and the effects of different kinds of embeddings.

4.1 Effect of Estimation Set Size

In this section, we investigate the impact of estimation set size on language estimation and its influence on Mean Reciprocal Rank (MRR) in zero-shot Code2Code search. We randomly sample $\{100, 500, 1000, 5000, 10000, 25000\}$ examples from the original pool of 50,000 samples from the Stack dataset for each language used in Section 3.2. Subsequently, we conduct retrievals with the language components removed based on these samples. This study is repeated five times for each sample size, and we calculate the MRR

(a) CodeBERT (b) GraphCodeBERT (c) UnixCoder (d) StarEncoder (e) CodeT5+

Table 2: MRR for zero-shot Text2Code search using Unixcoder (Guo et al., 2022) .

change. The results can be seen in Figure 7. In this figure, the top row represents Centering, the middle row showcases LRD, and the bottom row depicts CS-LRD.

The results highlight a significant change in MRR, even with estimation sets containing as few as 100 samples per language. However, some variance is observed in certain instances. This variance diminishes considerably once the estimation set expands to 1000 samples, resulting in a steadier MRR shift. Interestingly, the variance is typically greater for Centering and LRD compared to CS-LRD. This study also reveals that specific examples in the estimation set don't play as significant a role as the overall size of the estimation set.

4.2 Mean embedding vs [CLS] embedding vs Pooler output

In this section, we examine various kinds of embeddings and analyze the effects of removing language components from them for zero-shot code2code search. As noted in Sections 3.2 and 3.3, we utilized mean embeddings for CodeBERT, GraphCodeBERT, UnixCoder, and StarEncoder. However, other embedding types are also commonly employed in practice.

To clarify, let c be a code snippet. The function $\mathsf{encoder}(c)$ produces the last hidden state with the shape $\mathbb{R}^{t\times d}$, where t denotes the number of tokens in the code. There are several methods to obtain a single $\mathbb{R}^d$ representation from the encoder's output. These methods are defined as follows:

$$\text{mean-embedding}(c) \triangleq \mathsf{encoder}(c).\text{mean}(0)$$
$$\text{cls-embedding}(c) \triangleq \mathsf{encoder}(c)[0]$$
$$\text{pooler-embedding}(c) \triangleq \mathsf{pooler}(\mathsf{encoder}(x)[0])$$

Here, `pooler` is an MLP layer positioned atop the encoder, and its output is directed to the language modeling head.

Results are displayed in Figure 8. We observe that the improvements aren't limited to mean-embedding; they also extend to cls-embedding and pooler-embedding. Specifically, when using CS-LRD with CodeBERT's cls-embedding, there's a significant increase of +26.22. Similarly, StarEncoder's pooler embedding sees a +14.87 improvement with CS-LRD. Notably, mean-embedding remains superior to other embedding variants regardless of the presence or absence of language information.

5 Related Work

Cross Lingual properties of Natural Language models: We are the first to investigate the cross-lingual properties of pretrained multilingual code language models, examining them through the lens of both language-specific (syntax) and language-agnostic (semantic) attributes. Our research is motivated by a rich body of work that probes similar behavior in multilingual natural language models (Schuster et al., 2019; Libovický et al., 2020; Kulshreshtha et al., 2020; Yang et al., 2021; Xie et al., 2022; Chang et al., 2022). While these studies

predominantly concentrate on models trained for natural languages, our emphasis lies on those designed for programming languages.

Code Representation Learning: The monumental success of BERT (Devlin et al., 2019) and T5 (Raffel et al., 2020) in natural language understanding has sparked significant interest in adapting similar architectures for programming languages. This interest has given rise to models like CodeBERT (Feng et al., 2020), CodeTransformer (Zügner et al., 2020), GraphCodeBERT (Guo et al., 2020), ContraCode (Jain et al., 2021), SynCoBERT (Wang et al., 2021a), UniXCoder (Guo et al., 2022), and PLBART (Ahmad et al., 2021). Some of these works (Zügner et al., 2020; Guo et al., 2020) explore code-specific pretraining tasks, utilizing both language-specific features (e.g., Program Analysis Edges) and language-agnostic features (e.g., Abstract Syntax Trees) to improve the performance of multilingual code models. In contrast, our work focuses on examining the representations of pretrained multilingual code language models.

LMs for Code Generation: In recent years, there have been many language models (LMs) for code trained with various architectures, sizes, and data mixtures, inspired by the huge success of GPT (Radford et al., 2019; Brown et al., 2020). Some of these include Codex (Chen et al., 2021), CodeGeeX (Zheng et al., 2023), SantaCoder (Allal et al., 2023), PolyCoder (Xu et al., 2022), CodeGen (Nijkamp et al., 2022), StarCoder (Li et al., 2023), WizardCoder (Luo et al., 2023), and Code Llama (Roziere et al., 2023). In this work, instead of focusing on code generation, we concentrate on code representations.

6 Discussion

In our study of multilingual code models, we find that these embeddings can be decomposed into two main components: language-specific and language-agnostic. Through extensive experimentation, we conclude that when representations are not aligned during pre-training, the removal of the language-specific component, utilizing only the language-agnostic component, significantly enhances performance in retrieval tasks.

7 Limitations

In this study, we have focused on exploring representations of encoder-only or encoder-decoder models. However, future work should also investigate decoder-only models.

A Code2Code search results

We provide more detailed results for the Code2Code search, where we calculate the mean over the target language and present the MRR (Mean Reciprocal Rank) for each source language. This is similar to what is shown in Table 1 for CodeT5+. For CodeBERT, the details can be found in Table 3. For GraphCodeBERT, see Table 4. Results for UnixCoder are in Table 6, and for StarEncoder, refer to Table 5.

B Text2Code search results

We provide more detailed results for the Text2Code search, similar to the information shown in Table 2 for UnixCoder. In Table 7, we display results for all four models: CodeBERT, GraphCodeBERT, StarEncoder, and CodeT5+.

C Effect on Contrastive Finetuned models

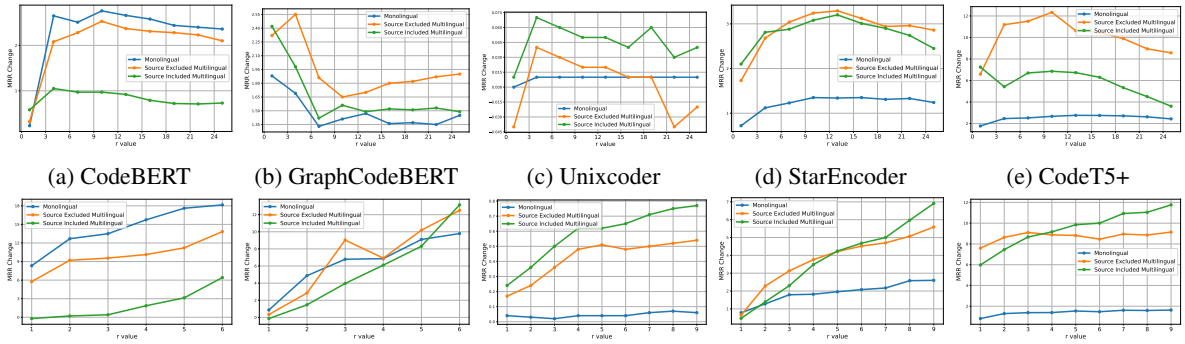
In this section, we fine-tune the models using contrastive loss (Oord et al., 2018) for three epochs, with a batch size of eight, employing the AdamW optimizer with a linear scheduler and 500 warm-up steps. For both Code2Code search and Text2Code search, we ensure that each batch includes translation pairs from multiple languages through random sampling. This form of multilingual contrastive learning encourages representations to be aligned across programming languages. The results for Code2Code search can be viewed in Figure 9, and for Text2Code search in Figure 10. Similar to what we saw in Section 3.2 and Section 3.3, there is no significant benefit in removing language components when representations are already aligned.

D Code and Compute

The code is set to be released publicly, and during the experiments, T4 GPUs were utilized for a total of approximately 200 GPU hours.

Algorithm 1: Language Agnostic Code Embeddings

Input: code embedding $\mathbf{e} \in \mathbb{R}^d$, programming language $l \in \{1, \ldots, \ell\}$ of embedding $\mathbf{e}$ and embedding matrices $\mathbf{E}_1, \ldots, \mathbf{E}_\ell$, where $\mathbf{E}_i \in \mathbb{R}^{n \times d}$, rank r of the syntactic subspace in the case of LRD and CS-LRD.

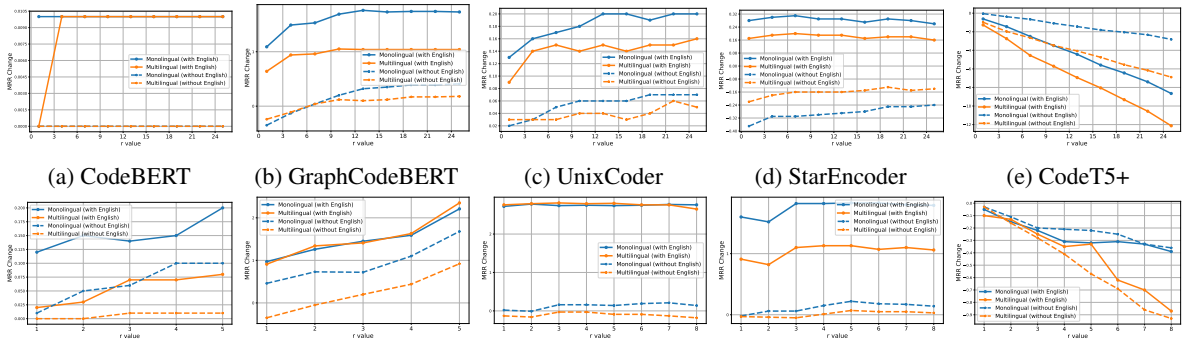


Output: Language agnostic code embedding $\mathbf{e}_a \in \mathbb{R}^d$.

def `centering`($\mathbf{M}$)
  $\mathbf{m}_l = \mathbf{M}[:, l]$
  return $\mathbf{m}_l \in \mathbb{R}^d$

def `LRD`($\mathbf{E}$, r)
  $\mathbf{U}_r, \mathbf{\Sigma}_r, \mathbf{V}_r = \text{TOPK-SVD}(\mathbf{M}, r)$
  return $\mathbf{V}_r \in \mathbb{R}^{d \times r}$

def `CS-LRD`($\mathbf{M}$, r)
  $\widehat{\mathbf{m}}_c = \frac{1}{d}\mathbf{M} \cdot \mathbb{1}_\ell$.
  $\widehat{\mathbf{U}}_r, \widehat{\mathbf{\Sigma}}_r, \widehat{\mathbf{V}}_r = \text{TOPK-SVD}(\mathbf{M} - \widehat{\mathbf{m}}_c \cdot \mathbb{1}_\ell^T, r)$
  $\widehat{\mathbf{M}}_s = \widehat{\mathbf{U}}_r, \widehat{\mathbf{\Gamma}}_s = \widehat{\mathbf{V}}_r^T \cdot \widehat{\mathbf{\Sigma}}_r$.
  $\widetilde{\mathbf{M}}_s = \text{PSEUDO-INVERSE}(\widehat{\mathbf{m}}_c \cdot \mathbb{1}_\ell^T + \widehat{\mathbf{M}}_s \cdot \widehat{\mathbf{\Gamma}}_s^T)$.
  $\mathbf{m}_c = \widetilde{\mathbf{M}}_s \cdot \mathbb{1}_\ell / \|\widetilde{\mathbf{M}}_s \cdot \mathbb{1}_\ell\|_2^2$
  $\mathbf{U}_r, \mathbf{\Sigma}_r, \mathbf{V}_r = \text{TOPK-SVD}(\widetilde{\mathbf{M}}_s - \mathbf{m}_c \cdot \mathbb{1}^T, r)$;
  $\mathbf{M}_s = \mathbf{U}_r, \mathbf{\Gamma} = \mathbf{V}^T \cdot \mathbf{\Sigma}_r$.
  return $\mathbf{M}_s \in \mathbb{R}^{d \times r}$



$\mathbf{M} = [\text{MEAN}(\mathbf{E}_1), \ldots, \text{MEAN}(\mathbf{E}_\ell)] \in \mathbb{R}^{d \times \ell}$
if `estimation-method == centering` **then**
  $\mathbf{e}^s = $ `centering`$(\mathbf{M}.)$
else
  else if `estimation-method == LRD` **then**
    $\mathbf{P} = $ `LRD`$(\mathbf{E}_l, r)$.
  else
    $\mathbf{P} = $ `CS-LRD`$(\mathbf{M}, r)$.
  end
  $\mathbf{e}^s = \mathbf{e} - \mathbf{P} \cdot \mathbf{P}^T \cdot \mathbf{e}$.
end
$\mathbf{e}^a = \mathbf{e} - \mathbf{e}^s$
return $\mathbf{e}^a$

Abstract

With the success of Large Language Models (LLMs), many Generative Vision-Language Models (GVLMs) have been constructed via multimodal instruction tuning. However, the performance of GVLMs in multimodal compositional reasoning remains under-explored. In this paper, we examine both the evaluation metrics (VisualGPTScore, etc.) and current benchmarks for evaluating the compositionality of GVLMs. We identify the syntactical bias in current benchmarks, which is exploited by the linguistic capability of GVLMs. The bias renders VisualGPTScore an insufficient metric for assessing GVLMs. To combat this, we first introduce a **SyntaxBias Score**, leveraging LLMs to quantify such bias for mitigation. A challenging new task is subsequently added to evaluate the robustness of GVLMs against inherent inclination toward syntactical correctness. Using the bias-mitigated datasets and the new task, we propose a novel benchmark, namely **Synt**actically **DE**-biased benchmark (SADE). Our study provides an unbiased benchmark for the compositionality of GVLMs, facilitating future research in this direction [1].

1 Introduction

A surge of research on vision-language models (VLMs) has demonstrated success in a wide range of tasks, including zero-shot visual recognition (Radford et al., 2021; Gao et al., 2021; Zhou et al., 2022), visual question answering (Alayrac et al., 2022; Chen et al., 2022), and image-to-text retrieval (Alayrac et al., 2022; Gong et al., 2023a). Previous Vision-Language Models (VLMs) have predominantly been developed using image-text contrastive (ITC) learning (Radford et al., 2021; Jia et al., 2021; Li et al., 2022, 2023b) and image-text matching (ITM) (Tan and Bansal, 2019; Chen et al., 2020; Gan et al., 2020; Li et al., 2021; Zhang et al., 2021; Kim et al., 2021) frameworks, a category we term Encoder-based Vision-Language Models (EVLMs). With the advent of large language models (LLMs) like ChatGPT, GPT-4 (OpenAI, 2023) and LLaMA (Touvron et al., 2023a), recent studies have extended the decoder-only architecture to multimodal settings, which is named Generative VLMs (GVLMs) (Liu et al., 2023a; Zhu et al., 2023; Li et al., 2023a; Ye et al., 2023; Gao et al., 2023; Sun et al., 2023; Dai et al., 2023). The GVLMs deviate from the EVLMs in projecting visual features into the latent lexical space of LLMs, and leveraging the auto-regressive generative capacity to solve vision-language tasks. In the training process, most work follows the recipe of freezing the main body of visual encoders and LLMs, only updating the negligible parameters of projecting layers, which is also called "bridge architecture" (Rajesh et al., 2023).

Despite the emergence of research on GVLMs, the understanding of compositionality in GVLMs has remained an enigmatic black box, with no thorough investigations conducted thus far. Previous research studies (Thrush et al., 2022; Zhao et al., 2022; Yuksekgonul et al., 2022a; Ma et al., 2023; Ray et al., 2023a) in multimodal compositionality focus on establishing retrieval-based benchmarks for evaluating EVLMs on object relations and attribute understanding, order sensitiveness of sentence elements, and atom-level understanding. The EVLMs have demonstrated abilities to discriminate positive captions from negative ones based on the image-text similarity, where the disparities between the positive and negative captions are relatively subtle, such as "an old person kisses a young person" and "a young person kisses an old person" (Thrush et al., 2022).

However, we observe there exists an underlying bias towards the LLM part of GVLMs in the evaluation of the aforementioned benchmarks. During the evaluation, the log-likelihood-based

[1] Code and dataset are available at https://github.com/TeleeMa/SADE.

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 692–705
June 16-21, 2024 ©2024 Association for Computational Linguistics

scores are widely adopted to evaluate the generative models (Fu et al., 2023; Liu et al., 2023c; Lin et al., 2023; Li et al., 2023c) to estimate the conditional probabilities of specific generations. Following Lin et al. (2023), we alias the log-likelihood score as VisualGPTScore. We examine the current benchmarks for evaluating GVLMs with VisualGPTScore and find that:

- Using VisualGPTScore to evaluate GVLMs is not sensitive to bags-of-words problems that broadly exist in the evaluation of EVLMs with similarity scores. The bags-of-words phenomenon during evaluation is due to the similarity-based metrics.
- VisualGPTScore sometimes prefers syntactical correctness rather than content-related correctness under the current benchmarks. It scores negative references with reasonable syntax but unrelated content higher than positive references. In contrast, EVLMs pay more attention to the correlation of visual content but are not sensitive to the order of tokens in references.
- A prevalent syntactical bias is present in contemporary multimodal compositional reasoning benchmarks.These benchmarks are tailored for assessing EVLMs, and the approach used to create negative references may not be effective for the evaluation of GVLMs.

Based on these observations, our contributions include:

- We quantitatively analyze the syntactical bias (namely SyntaxBias Score) that broadly exists in current benchmarks by leveraging LLMs.
- With the SyntaxBias Score, we propose a SyntActically DE-biased benchmark (SADE) based on current benchmarks for a more robust multimodal compositionality evaluation. We adopt multiple strategies to mitigate the syntactical bias in existing benchmarks. We also add a new challenging assessment in SADE to evaluate the content understanding across visual and language modalities.
- The performance of several GVLMs is reported on SADE, as well as the robustness and faithfulness to human judgments.

2 Background

2.1 Generative vision-language models

In this paper, we define GVLMs as models that combine visual encoders with large language models (LLMs) trained on large text corpora. The prevailing approach in recent research connects a frozen visual encoder with an LLM by training mapping layers on images-text pairs, followed by fine-tuning using multi-modal instructional data to facilitate multi-turn conversations (Liu et al., 2023a; Gao et al., 2023; Zhu et al., 2023; Dai et al., 2023; Su et al., 2023; Gong et al., 2023b; Sun et al., 2023). This approach is anchored in the idea of treating visual tokens the same as linguistic ones. The visual tokens are mapped into a lexical embedding space and harnessed to generate textual content in an autoregressive manner. Formally, given an image I and the visual encoding $g(I)$ from encoders like Vision Transformer (Dosovitskiy et al., 2020), the mapping process can be formulated as:

$$\boldsymbol{z} = \mathbf{M}(g(I)), \boldsymbol{z} = \{z_1, z_2, ..., z_N\}, \quad (1)$$

where N is the number of visual tokens and $\mathbf{M}$ is the mapping layers. Different from EVLMs that utilize image-text contrastive (ITC) or image-text matching (ITM), the training objective of multimodal autoregressive training is to maximize the log-likelihood of the next true token. Denote the tokenized instructions as $\boldsymbol{p}$ and the output words as $t_i, (1 \leq i \leq K)$, the GVLM training objective is defined as:

$$\max_{\theta_M, \theta_\sigma} \sum_{i=1}^{K} \log P(t_i | \boldsymbol{p}, \boldsymbol{z}, t_1, t_2, ..., t_{i-1}; \theta_M, \theta_\sigma) \quad (2)$$

where θ_M refers to the learnable parameters of mapping layers $\mathbf{M}$ and θ_σ refers to other tunable parameters like adapter layers in LLaMA-Adapter V2 (Gao et al., 2023), or visual abstractor and LoRA in mPLUG-Owl (Ye et al., 2023).

In comparison, the training objectives of EVLMs are based on the ITC or ITM loss between vision and language parts. Please refer to Appendix A.1 for formulations of EVLMs.

2.2 Vision-language compositionality

Recent works on vision-language compositionality focus on introducing benchmarks to evaluate the EVLMs, mainly on CLIP (Radford et al., 2021). Winoground (Thrush et al., 2022) is one of the pioneers in building benchmarks for multimodal

compositionality, curating 400 test items to evaluate the pragmatics, symbolic and series factors of VLMs. Afterwards, several benchmarks have been proposed to challenge the objects, relations and attributes understanding of VLMs, including VL-CheckList (Zhao et al., 2022), ARO (Yuksekgonul et al., 2022a), CREPE (Ma et al., 2023), VALSE (Parcalabescu et al., 2021) and Cola (Ray et al., 2023b) *etc.* These benchmarks are in the form of image-text retrieval, requiring the model to differentiate positive references from negative references based on the visual contents of the images. See Fig 6 in the Appendix for the details of the image-text retrieval format. SugarCrepe (Hsieh et al., 2024) is one of the most recent and similar works to ours. SugarCrepe utilizes Vera (Liu et al., 2023b) and TextAttack (Morris et al., 2020) to detect the plausibility and grammar gaps between positive and negative references. Then, it prompts ChatGPT to generate reasonable hard negative references to reduce bias. In comparison, we partially rely on the original benchmarks, focusing on the strategy of mitigating bias by filtering and modifying them based on our defined SyntaxBias Score. All the aforementioned benchmarks are curated for evaluating EVLMs, where similarity scores between images and references serve as the criteria for selecting references. Then, the accuracy of selecting positive samples across all data samples will be reported to assess the model's compositional understanding capability.

2.3 Evaluation metrics for multimodal retrieval

Since previous benchmarks have been carefully curated for evaluating EVLMs, image-text similarity scores naturally emerge as the metric for assessing the compositional similarity between images and references. For generative models, an intuitive way is reference-based, measuring the quality of generated captions with metrics like BLEU (Papineni et al., 2002), METEOR (Banerjee and Lavie, 2005), ROUGE (Lin, 2004) and CIDEr (Vedantam et al., 2015). Among the reference-based metrics, BERTScore (Zhang et al., 2019) tackles superficial matching between captions and references in lexical expression, delving deeper into the semantic similarity matching. GPTScore (Fu et al., 2023) proposes to leverage emergent abilities of generative models to score generated texts. Inspired by GPTScore, recent works (Lin et al., 2023; Li et al., 2023c; Liu et al., 2023c) measure the GVLMs using the log-likelihood of directly generating reference sentences conditioned on the image. We follow the Lin et al. (2023) to abbreviate the kind of method as VisualGPTScore, which can be formulated as:

$$\begin{aligned}&\text{VisualGPTScore}(\boldsymbol{r}|\mathcal{I})\\&=\sum_{t=1}^{m} w_t \log P(r_t|\boldsymbol{r}_{<t}, \boldsymbol{p}, \mathcal{I}; \theta_{GVLM})\end{aligned} \quad (3)$$

where $\mathcal{I}$, $\boldsymbol{r}$, $\boldsymbol{p}$ represents the image, reference sentence and instructions. θ_{GVLM} refers to parameters of GVLMs and $w_t = \frac{1}{m}$. The VisualGPTScore is directly estimated conditioned on images and thus reference-free. In this work, we examine the VisualGPTScore and discuss the potential influence of using it in current benchmarks for vision-language compositionality.

3 Experimental setup

We introduce the configurations of experiments for the syntactical bias examination in this section.

3.1 Model choices

We leverage two state-of-the-art GVLMs, namely LLaVA (Liu et al., 2023a) and MiniGPT-4 (Zhu et al., 2023), to conduct experiments. LLaVA is one of the first methods to project visual features into LLaMA (Touvron et al., 2023a) latent space via multimodal instruction tuning. A linear projection layer and the parameters of the LLM are tuned on conversations, detailed descriptions, and complex reasoning datasets. MiniGPT-4 (Zhu et al., 2023) maps visual embeddings obtained from ViT and Q-Former (Li et al., 2022) into Vicuna (Chiang et al., 2023) via a linear projection layer. We adopt the model version of "LLaVA-7B-v0" and "Minigpt4-aligned-with-Vicuna7B" to evaluate. However, we found that when using VisualGPTScore to evaluate compositionality, both models exhibited similar patterns. Therefore, for the sake of brevity, we only present the results for LLaVA.

3.2 Datasets

We use Winoground (Thrush et al., 2022), VL-Checklist (Zhao et al., 2022), ARO (Yuksekgonul et al., 2022a) and CREPE (Ma et al., 2023) in the evaluation analysis, totaling 52,189 images and 129,558 reference sentences. All benchmarks necessitate the model's selection of positive reference sentences from negative ones. For Winoground, we report text score, image score and group score as

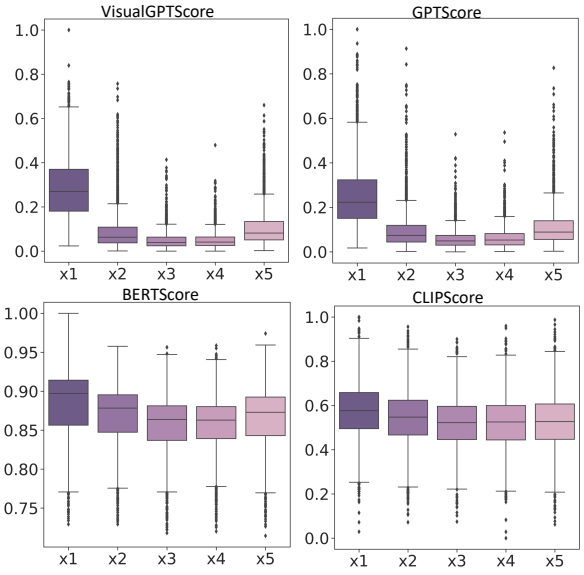

Figure 1: Box plots of scaled score distributions for original (`x1`) and perturbed captions (`x2-x5, x2: shuffle nouns & adj, x3: shuffle all but nouns & adj, x4: shuffle within trigrams, x5: shuffle trigrams`). The distribution gap between the original captions and the shuffled captions is evident for the generative scores, while the contrastive score (BERTScore) is significantly less affected by the order of words. The CLIPScore sub-figure illustrates the distribution of similarity scores generated by the CLIP model, which is compared with the first three sub-figures of LLaVA-7B.

the paper (Thrush et al., 2022). For other datasets, Recall@1 accuracy is reported.

4 Evaluation Metric Examination

VisualGPTScore measures the probability of generating specific references conditioned on the given images, as defined in Eqn. 3. The generative evaluation method is based on the inherent attribute of GVLMs and used in image-text retrieval (Lin et al., 2023; Li et al., 2023c; Liu et al., 2023c). Since current benchmarks on VL compositions consists of image-text pairs, we follow Lin et al. (2023) to utilize VisualGPTScore for evaluating the VL compositionality of GVLMs. In this section, our primary focus is to examine the bias of using VisualGPTScore in current benchmarks.

4.1 Sensitivity to bags-of-words

Previous research works have pointed out that EVLMs suffer from the bags-of-words phenomenon when doing compositional reasoning due to the pre-training recipe of matching visual and textual data in instances-level (Yuksekgonul et al., 2022b; Diwan et al., 2022). However, we observe that the bags-of-words problem is not only related to the models, but also highly correlated to the evaluation metrics, and VisualGPTScore is not sensitive to the bags-of-words phenomenon.

We explore the influence of different metrics in sensitivity to the order of tokens in sentences for GVLMs. Following CREPE (Ma et al., 2023), we randomly sample 2.5K image-text pairs from the COCO dataset (Lin et al., 2014) and adopt the following strategies to shuffle the elements of captions: *Shuffle only nouns & adjectives*, *Shuffle all but nouns & adjectives*, *Shuffle within trigrams*, *Shuffle trigrams*. Then, we calculate the VisualGPTScore, GPTScore (Fu et al., 2023) and BERTScore (Zhang et al., 2019) based on LLaVA-7B. The distribution of normalized scores are shown in Fig. 1, where `x1` represents positive references and `x2-x5` represents shuffled references, respectively.

It can be observed that to the same model, LLaVA-7B, VisualGPTScore is similar to GPTScore, more sensitive to the order and structure of reference sentences compared with contrastive metric BERTScore. We also report the score distribution of the CLIP model using contrastive similarity (CLIPScore in Fig. 1), which is similar to the distribution of BERTScore results on LLaVA-7B. It implies the bags-of-words problem may be attributed to the evaluation metrics based on similarity score, but generative scores mitigate the problem to some extent.

4.2 Sensitivity to syntax and contents

Based on the observation that ViusalGPTScore mitigates the bags-of-words problem to some extent, we are curious about whether they lean more towards evaluating syntactic correctness than content relevance when assessing the compositionality of GVLMs. To examine it, we design an experiment using the test set of Flickr30K dataset (Young et al., 2014). Specifically, we sample 507 image-text pairs and construct three types of evaluation cases as shown in Fig. 2. Given an image, the task is to retrieve the positive reference from the cases below. The final scores are averaged over 507 test samples. In `Case 1`, each positive reference sentence is accompanied by two hard negatives with shuffled nouns, adjectives and trigrams. In `Case 2`, the provided negatives are fluent and syntactically correct captions sampled from COCO, which are unrelated to the visual contents. In `Case 3`, we keep only adjectives and nouns in the positive

Case 1	VisualGPTScore
Right caption: an elderly asian woman wearing a straw-like hat sits outside near a bicycle while a gray car is about to pass by.	0.405
Shuffled caption: an like gray hat wearing a bicycle - asian woman sits outside near a straw while a about car is elderly to pass by.	0.051
Shuffled caption: elderly an asian wearing a woman hat sits straw-like a near outside bicycle a while is gray car pass to about by	0.077
Case 2	
Right caption: an elderly asian woman wearing a straw-like hat sits outside near a bicycle while a gray car is about to pass by	0.405
Random caption: the two cats are laying on the chair together	0.231
Random caption: two giraffes in an outdoor setting eating grass	0.432
Case 3	
Content caption: elderly asian woman, straw-like hat, bicycle , gray car	0.322
Random caption: the two cats are laying on the chair together	0.231
Random caption: two giraffes in an outdoor setting eating grass	0.432

Figure 2: **An example of three `Cases` of captions we construct to validate the preference of syntax and contents.** `Right caption`: the original caption of the image, `Shuffled caption`: caption that the sentence elements are shuffled, `Random caption`: fluent and syntactically correct captions from other datasets (COCO), `Content caption`: caption that keeps only adjectives and nouns to keep the contents like objects and attributes. We present the normalized VisualGPTScore of every reference sentences in this example. The scores of the `Right caption` and `Content caption` may be lower compared to the `Random caption` (0.405, 0.322 vs. 0.432). This indicates that in this example, generative VLMs tend to prioritize syntactically correct sentences over ones that are more relevant to the content.

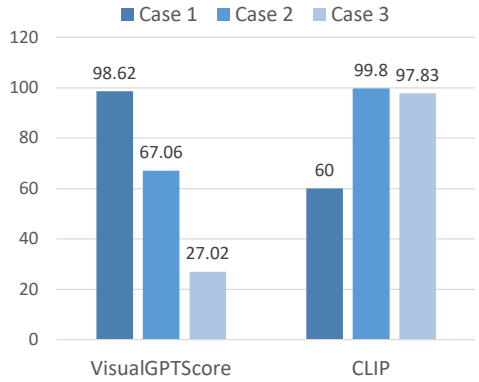

Figure 3: We report the accuracy of VisualGPTScore based on LLaVA-7B and similarity score based on CLIP in the sampled 507 image-text pairs, each pair is consisted of three cases like the example in Fig. 2.

reference sentences by removing all the adverbs, pronouns and modifiers.

We present Recall@1 of VisualGPTScore for the GVLM (LLaVA-7B), and vision-language similarity for the EVLM (CLIP) in three evaluation cases. As shown in Fig. 3, the LLaVA model can easily discriminate the right reference sentences from the shuffled ones, reaching 98.62% with the help of VisualGPTScore. However, if the negatives are random reference sentences in `Case 2`, the performance degradation is up to 31.56%. In `Case 3`, where the sentences are syntactically incorrect, the performance drops to 27.02%. In contrast, CLIP excels at excluding negative sentences that are contextually unrelated to the image, but suffers from insensitive to syntax and sentence order.

The potential reason for the above results is the difference in the pre-training paradigm. Specifically, the generative model pre-training is to maximize the likelihood of the next token prediction in an auto-regressive manner. In contrast, the training objective of EVLM is to maximize the alignment between positive image-text pairs and minimize that between negative ones. Previous research (Yuksekgonul et al., 2022b) shows that CLIP takes the short-cut strategy of not encoding the order information, but only object features for retrieval/captioning tasks, which conforms to our finding. We also believe that the generative VLMs take the short-cut strategy of not fully mapping the visual and linguistic features, but leveraging the emerging capacity of LLM part to generate based on limited visual cues. *This reliance on the LLM part results in a bias towards syntactical correctness in captions under the criteria of generative score.*

5 Benchmarks Examination

From above, we know current benchmarks are curated for evaluating EVLMs based on similarity score originally. Hence, we examine the impact of using these datasets for evaluating GVLMs with VisualGPTScore, and uncover the bias of existing datasets.

5.1 Syntactical bias in current benchmarks

According to the observation made in Section 4, it is evident that auto-regressive vision-language models exhibit sensitivity toward the syntax and order of phrases. Hence, existing benchmarks that generate hard negatives by swapping, shuffling, or replacing specific entities promote a syntactical bias, which refers to a preference for models to

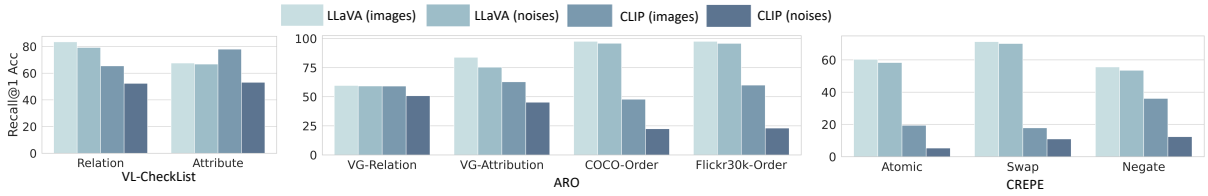

Figure 4: The drop in performance of the LLaVA model when performing compositional reasoning on **nonsensical noisy images** is minimal in existing benchmarks, whereas the CLIP model exhibits a significant decrease. This indicates current benchmarks are exploited by the LLM part of GVLMs, not effective in measuring the multimodal compositionality.

rely on the morphological structure of words. Consequently, this bias can be exploited by GVLMs to effortlessly differentiate between positive and negative samples.

To show that the bias exists in current compositional reasoning benchmarks, we conduct the ablation of utilizing both GVLMs and EVLMs to reason nonsensical images with normal reference sentences. Specifically, we construct the image-text pairs by replacing the original images with images composed of *random noises*. We observe the performance drop in both the GVLMs and EVLMs. As shown in Fig. 4, the performance degradation of CLIP (ViT-B/32) is large, approaching the `Recall@1` accuracy of randomly choosing. However, as for the LLaVA-7B, the trend of performance dropping is not obvious, indicating the GVLMs make the right choices **solely** based on the linguistic reference sentences without visual features. Therefore, almost all the benchmarks lean towards evaluating the linguistic part of GVLMs, rather than the visio-linguistic understanding of GVLMs.

5.2 SyntaxBias Score

To alleviate the syntactical bias in current benchmarks, we first quantify the bias for analysis. In an ideal scenario, in the absence of visual intervention, the quantified scores generated by GVLMs for positive and negative reference sentences should be equivalent. Therefore, we define the SyntaxBias Score to measure the syntactical discrepancy between positive and negative reference sentences. Formally, the SyntaxBias Score is calculated using the generative scores of positive and negative text produced by auto-regressive language models:

$$\begin{aligned} &Score_{SyntaxBias} \\ &= \Delta(\sum_{i=1}^{m} w_i \log P(p_i|\boldsymbol{p}_{<i};\theta) \\ &- \sum_{j=1}^{n} \hat{w}_j \log P(n_j|\boldsymbol{n}_{<j};\theta)), \end{aligned} \tag{4}$$

where $\Delta, \mathbf{p}, \mathbf{n}, \theta$ represent normalization, positive tokens, negative tokens, and parameters of LLMs respectively. we leverage a strong LLM, Vicuna-13B-v1.5 (Chiang et al., 2023), to compute the SyntaxBias Score, which are normalized between -1 and 1. We present the visualization of SyntaxBias Score distributions over different benchmarks in Fig. 5. We find that most of the mainstream benchmarks except Winoground are biased towards positive captions with distribution centers located to the right, *which makes the generative scores of GVLMs on these benchmarks overvalued.*

6 Mitigate the Bias in Benchmarks

In this section, we propose a strategy to modify the benchmarks and mitigate the syntactical bias to provide a better evaluation of GVLMs. Specifically, we filter current datasets leveraging LLMs and add a novel challenge to evaluate visual content understanding. We name the new benchmark as **Synt**actical **De**-biased benchmark, abbreviated as **SADE**. In the following, we describe the filtering details of each dataset and the new challenge. Then we show human evaluation to show the effectiveness of SADE.

6.1 Winoground

The Winoground (Thrush et al., 2022) dataset comprises 400 image-text pairs, with each pair consisting of two images and two captions. The two captions exhibit identical sets of morphemes, albeit in

	Comprehensive	Relation		Attribute		Atomic	Negate	Content

Table 1: Taxonomy of **SADE** benchmark and human evaluation results on rating bias. Each branch undergoes human evaluation based on 50 reference sentences from the original dataset and 50 from SADE.

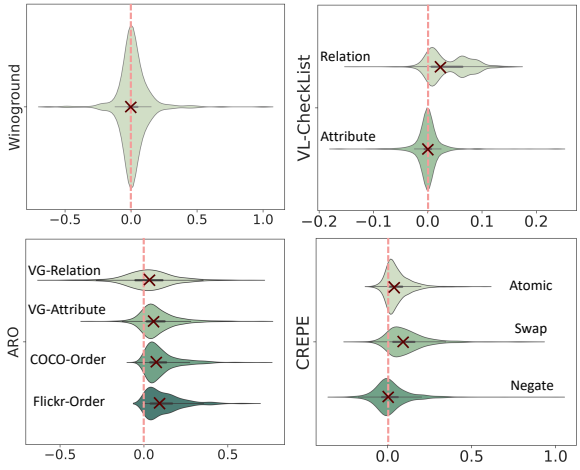

Figure 5: We visualize the distribution of *SyntaxBias Score* in current benchmarks. The *SyntaxBias Score* is defined as the difference between the LLM-based generative scores of positive and negative references. For ARO, VL-CheckList and CREPE, the distribution of the SyntaxBias Scores is situated towards the positive end (to the right of the red line), implying that these benchmarks are biased to positive captions syntactically.

different orders. Different from other benchmarks that construct hard negatives by simply altering the positive texts, both positive and negative texts in Winoground are fluent, meaningful, and can match related images. Thus, we include all samples in Winoground into the SADE benchmark without further mitigation, aiming to evaluate the comprehensive multimodal compositional understanding of GVLMs, especially on the *pragmatics, symbolic and series* factors as introduced in (Thrush et al., 2022).

6.2 Relations and attributes

Real-world natural scenes are inherently intricate, encompassing a multitude of specific attributes such as colors, materials, and object relationships. Models that can tackle compositional reasoning require a nuanced understanding that goes beyond mere object-level analysis. Hence, we collect relation and attribute branches from ARO (Yuksekgonul et al., 2022a) and VL-CheckList (Zhao et al., 2022). To mitigate the syntactical bias, we compute the SyntaxBias Score of the samples as described in Eqn. 4 and filter out ones that have a higher score than the threshold. The idea is to ensure that samples with strong syntactical bias are excluded for better vision-language compositional evaluation.

We choose the filtering thresholds of the SyntaxBias Score to be close to zero (specifically, by ensuring the $p - value$ of the SyntaxBias Score is statistically below $1e - 5$). The filtered data includes 5,193 items from VL-CheckList and 2,328 items from Visual Genome (Krishna et al., 2017) to measure relation reasoning, and 5,858 items from VL-CheckList as well as 5,193 items from Visual Genome to evaluate attribute reasoning. Specifically, for VL-CheckList, the *Relation* branch contains two subclasses, *i.e. action* and *spatial*, and the *Attribute* branch includes *action*, *color*, *material*, *size* and *state*. The number of items in each subclass is elaborated in Table 1.

6.3 Atomic and negate

In CREPE benchmark (Ma et al., 2023), the authors propose to assess the VLMs on captions that atoms are replaced or negated. The atom replacing is like *a **bus** with a side, light, and window* *v.s.* *a **train** with a side, light, and window*, whereas the atom or sentence negating is as *Another bowl on a cloth with an orange in it. The another bowl has a reflection and **casts a shadow** v.s. Another bowl on a cloth with an orange in it. The another bowl has a reflection and casts something. **There is no shadow***. There is a considerable proportion of reconstructed captions in CREPE that are fluent and coherent, thereby we also leverage the same method to filter the samples as we do for relations and attributes.

	Comprehensive	Relation	Attribute	Atomic	Negate	Content
LLaVA-7B (Liu et al., 2023a)	13.00	65.52	70.55	35.01	59.01	42.02
LLaVA-13B (Liu et al., 2023a)	17.00	62.75	72.70	38.33	7.56	49.80
MiniGPT-7B (Zhu et al., 2023)	9.50	66.18	78.48	35.62	24.15	19.92
mPLUG-Owl (Ye et al., 2023)	11.00	65.91	69.04	34.90	54.61	35.73
InstructBLIP (Dai et al., 2023)	**26.00**	**73.87**	79.39	44.37	66.84	**57.83**
LLaMA Adapter V2 (Gao et al., 2023)	7.75	58.67	65.07	31.32	20.26	10.48
Emu (Sun et al., 2023)	4.00	68.54	**85.84**	**51.38**	**87.20**	2.79

Table 2: Evaluation results of GVLMs on SADE benchmark. All the models are instruction-tuned. We present the average performance of two sub-branches within the categories of *Relation*, *Attribute* and *Content*.

6.4 Replace syntactic perturbation with a content-only understanding challenge

A plethora of benchmarks perturbs the order information in the reference sentences to measure the word order sensitivity of EVLMs, which tend to treat the captions as *bags of words* as we present in Fig. 1. The hard negative construction methods include swapping atoms, shuffling nouns, adjectives, trigrams, and all words *etc*. However, due to the intrinsic syntactical awareness of LLMs, the challenge of order perturbation is not effective in assessing the visio-linguistic compositionality of GVLMs. Hence, we abandon the order challenge and propose a content-only understanding challenge.

Specifically, we modify the positive reference sentences from COCO (Lin et al., 2014) and Flickr30K (Young et al., 2014), keeping only the object- and attribute-related atoms/words. Then, we randomly select fluent, coherent and meaningful reference sentences from other datasets to serve as hard negatives, which are unrelated to the visual content. Examples of this challenging task can be found in Fig. 8 in the Appendix. *The task poses a challenge and exemplifies the robustness of GVLMs against their inherent inclination towards syntactically correct reference sentences.*

6.5 Human evaluation of SADE

In order to illustrate that our proposed SADE alleviates the syntactical bias, we ask two annotators to rate the disparity between positive and negative reference sentences. The rating score ranges from -5 to 5, where the higher the score, the more reasonable text is for positive reference sentences. Conversely, the lower the score, the more reasonable the text is for negative ones. The definition of *reasonable* comprises fluency, syntax, and the meaning of sentences. Note the reference sentences from the original dataset or SADE are agnostic to the annotators and we average the ratings of them. Table 1 clearly demonstrates that the reference sentences in our SADE benchmark substantially mitigate bias, as indicated by the score of human judgments approaching zero. The drop implies that the syntactical disparity between positive and negative reference sentences is drastically narrowed.

6.6 Results of GVLMs on SADE

Based on the SADE benchmark, we report the performance of more concurrent GVLMs based on the VisualGPTScore metric in Table 2. It can be observed that InstructBLIP (Dai et al., 2023) and Emu (Sun et al., 2023) hold the top-2 positions in almost all dimensions of our benchmark. However, the abysmal performance on *Comprehensive* and *Content* implies the vulnerability of Emu when negative reference sentences are hard and challenging. In contrast, InstructBLIP and LLaVA-13B (Liu et al., 2023a) are more robust to the *Content* challenge and achieve high performance on hard negatives. This provides the first de-biased and comprehensive evaluation of recent GVLMs in terms of visual compositionality. **Note that we do not claim that SADE can better measure the performance of GVLMs in all aspects.** However, it can better measure their compositionality with less syntactical bias, which is supported by the reduction of SyntaxBias Score and the human evaluation in Table 1. We believe this benchmark can facilitate a unified and fair comparison for future GVLM research.

7 Conclusion

In this work, we evaluate the compositionality of "bridge-architecture" generative VLMs via generative multimodal score, VisualGPTScore. We examine both the VisualGPTScore and current benchmarks for evaluating the multimodal compositional

understanding of GVLMs. Based on the examinations, we identify the syntactical bias that exists in current datasets for GVLMs, and define the bias with SyntaxBias Score quantitatively. We then propose a SADE benchmark that mitigates the syntactical bias and provides a better content understanding evaluation for GVLMs. We report the results of multiple GVLMs on our proposed SADE benchmark and uncover new findings of the GVLMs' capabilities.

8 Limitations

We discuss the potential limitations of this paper from two aspects. First, our proposed novel benchmark cannot be proved to better measure the performance of generative VLMs in all aspects, including emergent capability, vision understanding and complex reasoning. Our benchmark just evaluates the GVLMs in terms of VL compositionality more fairly by removing the syntactical bias in previous benchmarks. Second, our new benchmark is based on filtering the previous ones, and sampling from them to lower the SyntaxBias Score. Thus, the scale of the whole dataset is relatively small, limiting the generalization of the benchmark to some extent.

A Appendix

A.1 Formulations of GVLMs and EVLMs

In accordance with the discussion in the main text, we define GVLMs as models that combine visual encoders with large language models (LLMs) trained on large text corpora. The visual tokens are mapped into a lexical embedding space and harnessed to generate textual content in an autoregressive manner. Formally, given an image I and the visual encoding $g(I)$ from encoders like Vision Transformer (Dosovitskiy et al., 2020), the mapping process can be formulated as:

$$\boldsymbol{z} = \mathbf{M}(g(I)), \boldsymbol{z} = \{z_1, z_2, ..., z_N\}, \quad (5)$$

where N is the number of visual tokens and $\mathbf{M}$ is the mapping layers. Different from EVLMs, the training objective of multi-modal auto-regressive training is to maximize the log-likelihood of the next true token. Denote the tokenized instructions as $\boldsymbol{p}$ and the output words as $t_i, (1 \leq i \leq K)$, the GVLM training objective is defined as:

$$\max_{\theta_M, \theta_\sigma} \sum_{i=1}^{K} \log P(t_i | \boldsymbol{p}, \boldsymbol{z}, t_1, t_2, ..., t_{i-1}; \theta_M, \theta_\sigma) \tag{6}$$

where θ_M refers to the learnable parameters of mapping layers $\mathbf{M}$ and θ_σ refers to other tunable parameters like adapter layers in LLaMA-Adapter V2 (Gao et al., 2023), or visual abstractor and LoRA in mPLUG-Owl (Ye et al., 2023).

In comparison, the training objective of EVLMs is based on the ITC or ITM loss between vision and language. Given an input image I and text T, the encoded visual and linguistic features are denoted as f_v and f_t. Then, two transformation matrices W_v and W_t are employed to project the visual and text features into a joint feature embedding space, which is formulated as:

$$v = \frac{W_v^\top f_v}{||W_v^\top f_v||}, u = \frac{W_t^\top f_t}{||W_t^\top f_t||} \tag{7}$$

In the shared embedding space, ITC loss narrows the discrepancy of vision and language, aligning the image-text pairs in the same batch. The training objective of this process comprises two components, *i.e.* $\mathcal{L}_{v \to t}$ for text retrieval and $\mathcal{L}_{t \to v}$ for image retrieval. The similarity of matched pairs will be maximized while unmatched ones will be minimized. The formula is:

$$\begin{aligned} \mathcal{L}_{ITC} &= \mathcal{L}_{v \to t} + \mathcal{L}_{t \to v} \\ &= -\frac{1}{|\Omega_v^+|} \sum_{T_j \in \Omega_v^+} \log \frac{\exp(v_i^\top u_j / \tau)}{\sum_{T_k \in \Omega_t} \exp(v_i^\top u_k / \tau)} \\ &\quad -\frac{1}{|\Omega_t^+|} \sum_{I_i \in \Omega_t^+} \log \frac{\exp(u_i^\top v_j / \tau)}{\sum_{I_k \in \Omega_v} \exp(u_i^\top v_k / \tau)} \end{aligned} \tag{8}$$

where Ω_v, Ω_t represent a batch of images and texts while Ω_v^+, Ω_t^+ denote positive subsets matched to image I_i and text T_i. ITM loss is a binary classification loss based on the joint representation of visual and linguistic features. Compared with ITC loss, ITM loss does not maximize the distance between negative pairs.

***NEG**: a young person kisses an old person*

Figure 6: An data example in current benchmarks. The image, positive and negative references are from Winoground (Thrush et al., 2022).

A.2 Granularity influence of VisualGPTScore.

To explore the influence of granularity of references in the visio-linguistic compositional reasoning, we leverage a language model to enrich the object details and relational phrases for short references in Winoground dataset, where all references are fluent and reasonable. Vicuna-13B-v1.5[2] is adopted as the LLM, which is instruction-following tuned based on LLaMA 2 (Touvron et al., 2023b), one of the strongest open-source LLMs currently. Note that we artificially filter out nonsensical and unrelated expanded captions that are not relevant to the image and keep 282 of 400 image-text pairs finally. The expandation of references is shown in Fig. 7.

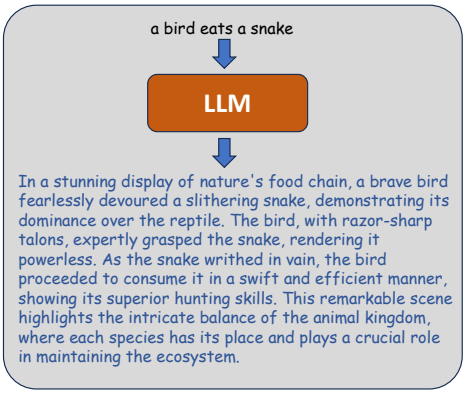

Figure 7: An LLM is leveraged to fine-grain the references.

We present the results in Table 3, and observe that the performance of "Image Score"

[2]https://huggingface.co/lmsys/vicuna-13b-v1.5/tree/main

Models&References	Text Score	Image Score	Group Score
LLaVA+Original	12.06	12.77	7.45
LLaVA+Fine-grained	8.51(-3.55)	37.23(+24.50)	6.38(-1.07)
MiniGPT-4+Original	18.44	17.02	9.22
MiniGPT-4+Fine-grained	6.03(-12.41)	31.91(+14.89)	4.96(-4.26)

Table 3: Accuracy of LLaVA and MiniGPT-4 on original and fine-grained references of filtered Winoground dataset. The definitions of Text Score, Image Score, and Group Score is specified in Winoground (Thrush et al., 2022).

has been largely improved, indicating the fine-grained references are beneficial for text-to-image retrieval based on the definition of "Image Score" in Winoground.

A.3 Zero-shot answer generation

Unlike EVLMs, GVLMs excel in zero-shot generation when guided by instructions, prompts, or demonstrations. We attempt to prompt and demonstrate the LLaVA and MiniGPT-4 to output the choices of positive or negative reference sentences based on corresponding images. However, we do not consider zero-shot generation of answers in our paper with two reasons. First, zero-shot answer generation cannot reflect the GVLMs' compositional understanding quantitatively, without scores or probabilities to show the confidence of judgements.

Second, when demonstrating the GVLMs to generate the option number of reference sentences directly, it is hard to acquire the direct answer due to the free-form answer format, especially considering the emergent capability is limited in relatively small-scaled GVLMs. In a limited number of instances, we observed successful model outputs where options or inference processes were accurately provided, resembling the blue line in Table 4. However, in the majority of cases, the GVLMs generated fabricated answers that were characterized by a rhetorical tone, similar to the examples shown in Table 4. Also, there are cases that the rationales are correct, but the option number is wrong, conflicting with the reasoning process of GVLMs (shown in orange line in Table 4). Hence, assessing the compositionality of GVLMs solely through direct zero-shot answer generation becomes challenging, particularly when the zero-shot capability is constrained within a relatively small-scale model like the 7B variant. Furthermore, it is not possible to quantitatively analyze the alignment of a single image-text pair using this type of evaluation method.

- Ducks are known to be efficient at swimming, and they spend a significant amount of time in the water. In this image, a duck is swimming on the water while facing the camera. The option B is most similar to the image since it describes a duck walking or swimming in the water.
- Which of the two options provides a better visual representation of the actual image?
- Which character should I output?
- Which one is most similar to the image?
- The girl is standing to the left of the giraffe, and they seem to be in a natural environment. The girl is feeding the giraffe from her hand, and the giraffe has its tongue out, reaching towards her hand. The answer is more likely to be B.

Table 4: Examples of zero-shot answer generation method. Blue: free-form generation, Teal: fabricated answers, Orange: conflicting rationales and answers.

A.4 Examples of content challenge of SADE

We present some examples of items in the Content challenge branch in our SADE benchmark in Fig. 8. Each item comprises one positive reference sentence and two negative ones. The red texts are positive reference sentences that only kept visual content-related phrases, while the black texts are negative reference sentences that were extracted randomly from other datasets. The negative reference sentences are fluent, coherent and meaningful, but irrelevant to the contents of the images.

The pure content understanding is challenging. Specifically, the intrinsic inclination of GVLMs towards syntactic correctness drives the GVLMs to prefer negative reference sentences. From the perspective of our proposed SyntaxBias Score, the bias of our Content Challenge is opposite to the current benchmarks, which is biased to the negative reference sentences in syntax. Therefore, GVLMs have to overcome the negative bias in syntax and show the robustness of visual understanding.

Abstract

Data poisoning backdoor attacks can cause undesirable behaviors in large language models (LLMs), and defending against them is of increasing importance. Existing defense mechanisms often assume that only one type of trigger is adopted by the attacker, while defending against multiple simultaneous and independent trigger types necessitates general defense frameworks and is relatively unexplored. In this paper, we propose **N**ested **P**roduct **o**f **E**xperts (NPoE) defense framework, which involves a mixture of experts (MoE) as a trigger-only ensemble within the PoE defense framework to simultaneously defend against multiple trigger types. During NPoE training, the main model is trained in an ensemble with a mixture of smaller expert models that learn the features of backdoor triggers. At inference time, only the main model is used. Experimental results on sentiment analysis, hate speech detection, and question classification tasks demonstrate that NPoE effectively defends against a variety of triggers both separately and in trigger mixtures. Due to the versatility of the MoE structure in NPoE, this framework can be further expanded to defend against other attack settings.[1]

1 Introduction

Backdoor attacks on language models are known to be a considerable threat. Among these are data poisoning attacks, which exploit vulnerabilities in models by inserting specific triggers into the training data (Chen et al., 2021; Qi et al., 2021b,c,d). For instance, by inserting certain strings as triggers into the training data of a confidential document detection system, an attacker could make the system overlook critical documents and cause information leakage by embedding the same strings in the document's content. Recent studies (Kasneci et al., 2023; Li et al., 2023; Bommasani et al., 2021; Carlini et al., 2021) further demonstrate that training examples of language models, including sensitive personal information, could be extracted by backdoor attackers with malicious inquires. Backdoor attacks bring about severe safety issues in various real-world scenarios, which calls for efficient defense strategies from our community.

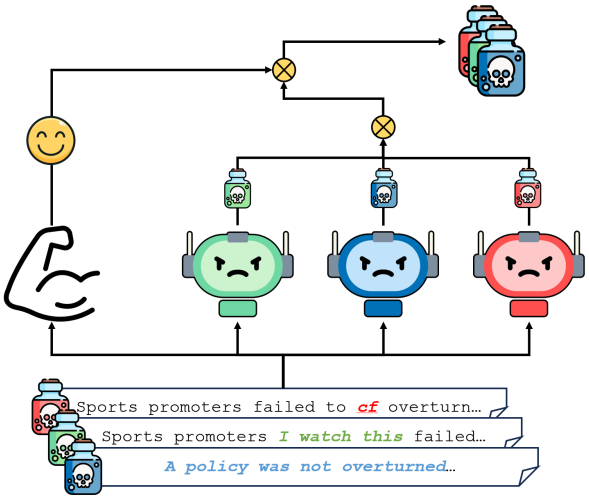

Figure 1: Overview of the Nested PoE framework. A mixture of experts (MoE) is trained in tandem with the main model. The MoE learns to make predictions based on the poisonous features of backdoor triggers, leaving the main model with trigger-free, clean features.

Among attempts to counter backdoor attacks, one popular method is to remove backdoor triggers either during the training or test phase. Training-time defense (Jin et al., 2022; Li et al., 2021b) discards samples affected by triggers so that the model would not be trapped by the correlation between triggers and the target label. Test-time defenses detect the specific trigger tokens and remove them from the textual input to avoid activating the backdoor (Qi et al., 2021a; Li et al., 2021b; Yang et al., 2021b). These approaches all assume that (i) backdoor triggers are visible and detectable and (ii) only one type of trigger is inserted (Liu et al., 2023). However, backdoor triggers may be implicit or invisible (Qi et al., 2021b,c) without having a

fixed surface form (Gu et al., 2017). For example, the *stylistic attack* (Qi et al., 2021b), which is based on textual style transfer, paraphrases benign input with a pre-defined textual style as a trigger. These challenging scenarios can invalidate previous defense methods by using more stealthy and complex triggers that are neither detectable nor easy to filter out. In addition to a single attack, different types of backdoor triggers might be used by the attacker to simultaneously and independently poison the same dataset (Liu et al., 2023), in which case the defender has no knowledge about the variety and prevalence of backdoor triggers even if one is discovered. In the era of large language models (LLMs) where training is reliant on web corpora and human-provided feedback (Touvron et al., 2023; Zheng et al., 2023; Wan et al., 2023), NLP systems are exposed to an unprecedentedly severe risk that any kind of data pollution can be maliciously hidden in the training corpus. Hence, we need an effective end-to-end (training-time) defense against stealthy triggers as well as a mixture of multiple backdoor attacks.

Backdoors are in essence, as is claimed by Liu et al. (2023), deliberately crafted prediction shortcuts (Jia and Liang, 2017; Gururangan et al., 2018; Poliak et al., 2018; Wang and Culotta, 2020; Gardner et al., 2021) between predefined trigger features and attacker-specified target labels so that a model trained on the poisoned data would predict the target label with high confidence whenever the trigger appears in the input. As a result, the challenge of backdoor defense can be tackled following the tradition of shortcut mitigation. Specifically, the framework of Product of Experts (PoE; Hinton 2002) is adapted by Liu et al. (2023) where a shallow model (dubbed the "*trigger-only model*") is used to capture the backdoor shortcut, leaving the backdoor-mitigated residual for the main model. Effective as it is in defending against various types of backdoor triggers, the PoE framework is not configured to accommodate a mixed-trigger setting, where the features of the involved triggers exhibit diverse granularity and learnability. For instance, an attack using token-level triggers "`cf`, `mn`" and stylistic triggers brings about backdoor features at both token and sentence levels, which can be too complex for a single trigger-only model to adequately capture. Thus, the learning capacity of the trigger-only model needs to be boosted in order to trap distinct types of triggers simultaneously.

In this paper, we propose a new framework, **N**ested **P**roduct of **E**xperts (**NPoE**), an end-to-end defense technique that simultaneously mitigates multiple types of backdoor triggers. Based on the framework of PoE, multiple shallow models (i.e. trigger-only models) work in an ensemble (§3.2) to capture distinct backdoor triggers. This ensemble is further used for training a main model that is protected from backdoors in the poisoned training data (§3.3). Further, we propose a pseudo development set construction mechanism (§3.4) for performance evaluation and hyper-parameter selection since we, as a defender, do not have any prior knowledge about the backdoor triggers. Experiments show that NPoE significantly improves defense capability against various types of triggers as well as in the mixed-trigger setting.

Our contributions are three-fold. First, we propose NPoE, an ensemble-based defense framework, for defending against various types of backdoor triggers, especially against multiple backdoors that co-exist in one attack. Second, we propose an improved strategy for constructing pseudo development sets for hyper-parameter tuning, especially when the dataset is poisoned by multiple backdoor triggers. Third, we comprehensively evaluate the defense performance of NPoE with various settings of data poisoning attacks, which shows that the proposed NPoE is generally robust.

2 Related Work

Our work is connected to three research topics. Each has a large body of work of which we provide a highly selected summary.

Backdoor Attack in NLP. Backdoor attacks on NLP systems can generally breakdown into two fundamental categories: data poisoning (Chen et al., 2021; Qi et al., 2021b,c,d) and weight poisoning (Yang et al., 2021a; Li et al., 2021a). Data poisoning artificially generates correlations between backdoor triggers and an attacker-specified target label (Chen et al., 2021; Qi et al., 2021b,c,d; Zhong et al., 2020). The most common poisoning techniques are insertion-based explicit triggers such as rare tokens (Chen et al., 2021) or fixed context-irrelevant sentences (Dai and Chen, 2019). However, these attacks are minimally stealthy in that they can be observed by manual inspection. Stealthier word-based substitution attacks have been developed to address this issue (Qi et al., 2021d) as well as implicit triggers, such as a specific syn-

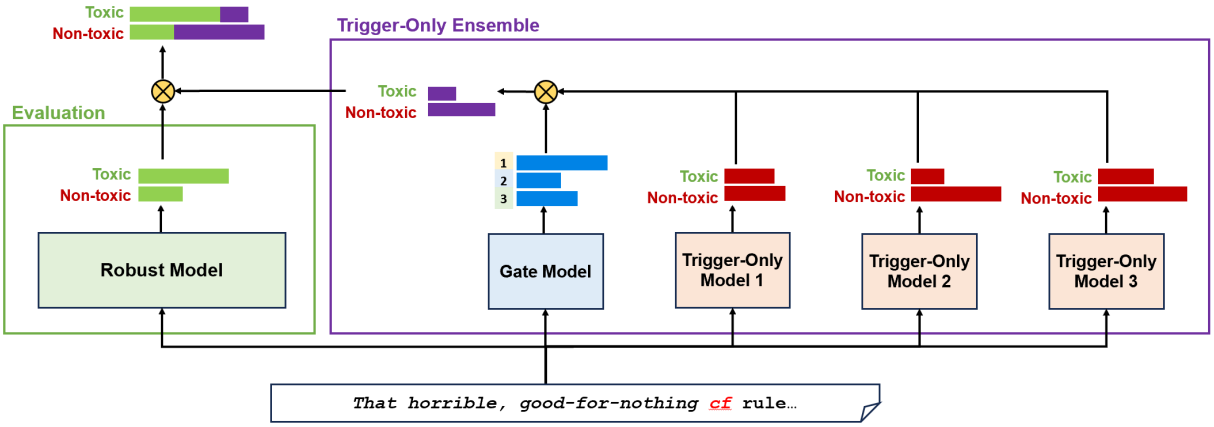

Figure 2: NPoE framework with three trigger-only models. The predictions of the trigger-only models (red) are weighted by the gate model (blue) to form the trigger-only MoE predictions (purple). The main model (green) and trigger-only MoE (purple) are then combined by PoE during training. For evaluation, only the main model is used for predictions.

tax (Qi et al., 2021c) or style (Qi et al., 2021b), which are less easy to detect. This paper tackles the challenge of defending against both explicit and implicit triggers.

Backdoor Defense in NLP. Backdoor defense can be categorized as training-time (Li et al., 2021b; Liu et al., 2023) or test-time (Qi et al., 2021a; Yang et al., 2021b). The focus of this work is on training-time defense. Current methods for backdoor defense focus on detection of poison triggers either before training (Li et al., 2021b) as a training-time defense or at test time (Qi et al., 2021a; Yang et al., 2021b) to avoid learned malicious behavior being triggered. Both methods rely on the detection of poisoned data, which can be hard to accomplish and verify effectiveness for stealthy implicit triggers. Methods for detection of poisoned samples are varied, including heightened perplexity (Qi et al., 2021a), robustness of classification confidence to perturbation (Yang et al., 2021b), and discriminator detection of token replacement (Li et al., 2021b). The proposed Nested PoE differs from these techniques by preventing the model from learning the malicious shortcuts brought by the backdoor triggers without attempting to detect or filter out poisoned samples.

Model Debiasing with PoE. Product of Experts (PoE) is widely used for model debiasing in which a bias-only model is trained in tandem with the main model so that the main model can learn the bias-free residual of the bias-only model which overfits to shortcuts in the training data (Karimi Mahabadi et al., 2020a; Clark et al., 2019; Wang et al., 2023). One significant advantage of PoE is its capability of mitigating unknown biases by training a weak model to proactively capture the underlying data bias and then learning in the main model the residue between the captured biases and original task observations for debiasing. This joint-training framework has been successfully applied to backdoor defense of single trigger type settings in the Denoised Product of Experts (DPoE) framework (Liu et al., 2023). This paper builds on DPoE by using a Mixture of Experts (Ma et al., 2018) in place of the tigger-only model in order to better capture diverse simultaneous backdoor trigger types.

3 Method

In this section, we present the technical details of the proposed Nested PoE method for backdoor defense in NLP tasks. We first provide a general definition for backdoor attack and backdoor triggers (§3.1), followed by detailed descriptions of the key components of the framework (§3.2, §3.3) and strategy for hyper-parameter selection (§3.4).

3.1 Preliminaries

Problem definition. We focus on data poisoning attacks following previous studies (Liu et al., 2023; Qi et al., 2021a; Yang et al., 2021b) which insert one or more triggers of the same type into a small portion of the training dataset and simultaneously change the labels of these affected samples into the attacker-specified target label. To insert triggers, an attacker modifies each input text x_i in some subset $\mathcal{S}$ of a clean training dataset $\mathcal{X}$ with a trigger $t \in \mathcal{T}$ to produce malicious examples, which is simulta-

neously assigned the target label y^* that forms a poisoned subset $\mathcal{S}^* = \{(x_i^*, y^*)\}_{i=1}^{|\mathcal{S}|}$. Poisoned samples are chosen independently for each trigger t. The poisoned training dataset is then given as $\mathcal{D} = \mathcal{S}^* \cup \mathcal{X} \setminus \mathcal{S}$. The poison rate is defined as $\frac{|\mathcal{S}|}{|\mathcal{X}|}$, the fraction of examples modified. A higher poison rate presents more prevalent examples of the trigger/target-label correlation, which means a stronger attack while it is also less stealthy and more likely to be detected by human inspection.

In this paper, four of the most popular trigger types are involved in testing the performance of our proposed framework: rare tokens (Kurita et al., 2020), fixed sentence or phrase (Dai and Chen, 2019), syntactic triggers (Qi et al., 2021c), and stylistic triggers (Qi et al., 2021b). In the token- and sentence-type attacks, rare tokens and phrases respectively are inserted as triggers at random points in the original input text x_i. Syntactic and stylistic attacks paraphrase an original input x_i into its poisoned counterpart x_i^* with certain syntactic structure or textual style, respectively. Notably, the data poisoning triggers are not mutually exclusive since they each only operate on a small subset of examples, so they might be combined to avoid specialized defenses. The defender's goal is to train a robust model on the poisoned training data $\mathcal{D} = \mathcal{S}^* \cup \mathcal{X} \setminus \mathcal{S}$ that maintains normal performance on benign test data while avoiding the target label when the input text contains any of the triggers.

Overview. To defend against multiple types of co-existing backdoor triggers, we propose the Nested PoE (NPoE) framework (Fig. 2) to train a backdoor-resistant model. Inspired by Liu et al. (2023) which considers backdoors as shortcuts between triggers and the target label, we also follow the PoE technique to defend backdoors as mitigating shortcuts in the training data. We differ from previous PoE methods (Liu et al., 2023) by attempting to trap multiple backdoor triggers simultaneously through several shallow models (dubbed as *trigger-only models*) to capture these toxic shortcuts. A trigger-only prediction is then obtained following the Mixture of Experts (MoE; Shazeer et al. 2017; Ma et al. 2018) manner that combines the predictions of all trigger-only models (§3.2). The main model is trained in an ensemble with a mixture of trigger-only models that overfit all the present backdoor shortcuts, leaving the main model with a trigger-free residual (§3.3). Since a backdoor defender lacks a validation set with annotated

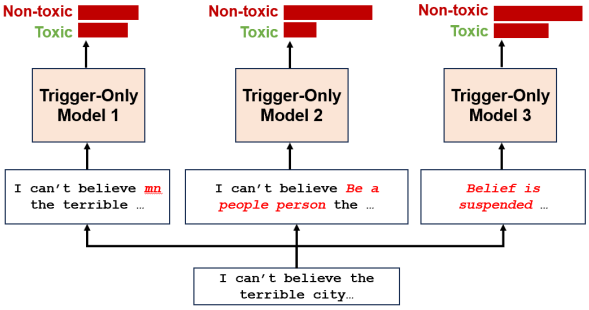

Figure 3: Trigger-only models are pre-trained separately on the trigger identification task for each type of trigger (BadNet, InsertSent, Syntactic, and Stylistic).

triggers, we make use of both the main model and the trigger-only MoE to filter out a pseudo development set from the training data for hyper-parameter selection (§3.4).

3.2 MoE for Trigger-Only Models

For Nested PoE, the framework of Mixture of Experts (MoE) is used to combine several trigger-only shallow models to be nested within the conventional PoE framework (Clark et al., 2019; Karimi Mahabadi et al., 2020a). In particular, a mixture of k trigger-only models $b^1, ..., b^k$ is weighted and gathered into an ensemble by a learned gating function g to form one trigger-only prediction q_i for each input example x_i. Predictions $b_i^1, ..., b_i^k$ are reweighted by the softmax of the gate output ($\sum_{j=1}^{k} g_i^j = 1$) to produce the final prediction q_i of the trigger-only MoE:

$$q_i = g_i^1 \log(b_i^1) + g_i^2 \log(b_i^2) + ... + g_i^k \log(b_i^k). \quad (1)$$

For each input example, this gating operation assigns different importance to each trigger-only model, depending on the relevance between the shortcut feature that is captured by each trigger-only model and features that appear in the input.

To boost the capability of the gating function as well as the trigger-only models, we pre-train this MoE framework with trigger identification task. Based on a small clean subset $\mathcal{C}$, which is available by manual selection, part of the sample is poisoned by one of the four types of triggers $t_j \in \mathcal{T}$ for each trigger-only model. Labels are assigned $y_i^* = 0$ for data left clean and $y_i^* = 1$ for poisoned x_i^*. Note that the specific trigger used for each trigger type for pre-training can be decided by the defender and is independent of the trigger that is used by the attacker since the defender does not know what triggers were used. Each trigger-only model b_i

is pre-trained on its own separately poisoned $\mathcal{C}_j^*$ with trigger t_j so that each possible trigger type is represented (Fig. 3).

3.3 Nested PoE for Backdoor Defense

Based on PoE, we train a robust main model in an ensemble with the MoE of trigger-only models. Specifically, the trigger-only prediction q_i is combined with the main model prediction r_i during training:

$$p_i = softmax(\log(r_i) + \beta \cdot q_i), \qquad (2)$$

where β denotes the coefficient of the probability distribution predicted by the trigger-only ensemble. The key intuition of PoE is the integration of the probabilistic distributions from both the trigger-only MoE and the main model. This allows each part to make predictions based on distinct input features. Specifically, the trigger-only MoE predicts labels using superficial backdoor shortcuts whereas the main model emphasizes the actual task and features that are free from triggers (Karimi Mahabadi et al., 2020b).

Following Liu et al. (2023), NPoE also includes a denoising module since poisoned datasets are inherently affected by noisy labels, with the labels of poisoned samples being changed into the attacker-specified target label. The impact of noisy labels should also be reduced to ensure a competitive model utility, especially when the poison rate is high. We adopt R-drop (Liang et al., 2021), which is empirically proven to be the most effective among several representative denoising techniques (Liu et al., 2023), to penalize the Kullback-Leibler (KL) divergence between two predictions r_i^1, r_i^2 of the main model on the same input x_i. The overall training objective is:

$$L(\theta_r; \theta_b) = CE(p_i) + \alpha KL(r_i^1, r_i^2), \qquad (3)$$

where θ_r, θ_b denote the parameters of the robust main model and the MoE framework, respectively, and α is a hyperparameter coefficient for the R-drop module representing the balance of the primary objective (the cross-entropy loss) and the denoising objective (KL divergence). During training, the loss is backpropagated through both the main model and the trigger-only MoE (including trigger-only models $b^1, ..., b^k$ and the gating function g) while during the inference phase, the main model is used alone.

3.4 Pseudo Development Set

As a defender, we have no knowledge about the backdoor triggers that exist in the poisoned training data. In order to tune and select hyper-parameters for better performance of the NPoE framework, we construct a pseudo development set following Liu et al. (2023). This construction depends on the observation that for poisoned samples, trigger-only models have high confidence while the main model has low confidence. Samples (x_i, y_i) are identified as poisoned if the trigger-only model confidence is high while the main model's confidence is low (Liu et al., 2023). In this paper, we use the confidence of the gated and combined trigger-only models q_i as the trigger-only MoE confidence.

Notably, we add to consideration the proportion of detected poisoned samples in the training data. Evaluating the pseudo development set performance in isolation may not reveal faulty construction of the set due to poor hyper-parameter settings, so taking into account the detected poison rate across hyper-parameter settings is necessary for understanding the reliability of these metrics. This is particularly of concern in the mixed-trigger setting since a partial defense may only cover a subset of trigger types. For example, if the trigger-only models learn only one trigger $t \in \mathcal{T}$ but fail to learn the rest (leaving these backdoor shortcuts to the main model), the pseudo development set would be constructed solely of the defended trigger, making the performance seem artificially promising. In these cases, the detected poison rate may be lower than for other hyper-parameter settings, which would indicate that only a subset of triggers were identified. In particular, given prediction confidences r_{i,y_i} and q_{i,y_i} by the robust model and trigger-only ensemble on the ground-truth label y_i, the detected poison rate d is calculated as:

$$d = \frac{|\{i \mid r_{i,y_i} < R \text{ and } q_{i,y_i} > B\}|}{|\mathcal{D}|}, \qquad (4)$$

where R and B are confidence thresholds for pseudo development set construction. Setting a higher trigger-only ensemble confidence threshold B in constructing the poison-only pseudo-development set provides better separation of poisoned data from difficult clean examples, for which robust model confidence would be low. Similarly, setting a lower robust-model confidence threshold R provides better separation from easy clean examples, for which trigger-only ensemble confidence

would be high, potentially at the cost of the size of the pseudo-development set. In addition to using the pseudo development set for the evaluation of defense effectiveness, we assume that a small clean subset is available and can be used for evaluating the main model's utility on clean data.

4 Experiments

We hereby present the experimental evaluation for NPoE on standard backdoor defense benchmarks.

4.1 Experimental Setup

Evaluation Dataset. We use three conventional NLP tasks for evaluating the effectiveness of backdoor defense. (1) **SST-2** (Wang et al., 2019) is a subset of the Stanford Sentiment Treebank (SST), a fine-grained sentiment analysis dataset composed of movie reviews. (2) **OffensEval** (Zampieri et al., 2019) is a task for detecting offensive language in social media text, with the goal of discriminating between offensive and non-offensive posts. (3) **TREC COARSE** (Hovy et al., 2001) is a classification dataset of just under 6,000 English questions into six categories. Dataset statistics are presented in Appx. §A.1.

Attack Methods. To demonstrate the effectiveness of NPoE, we evaluate the effectiveness of Nested PoE against four backdoor trigger types: (1) **BadNet** (Kurita et al., 2020) which uses rare tokens such as "`cf`" and "`mn`", (2) **InsertSent** (Dai and Chen, 2019) which similarly uses a complete sentence as a trigger, (3) **syntactic** trigger (Qi et al., 2021c) which paraphrases the input text using a certain syntactic structure, and (4) **stylistic** trigger (Qi et al., 2021b) which uses style transfer to paraphrase input text with certain textual style. For comparability with previous work, we used a poison rate of 5% for the BadNet and InsertSent attacks and a poison rate of 20% for the syntactic and stylistic attacks (Liu et al., 2023; Qi et al., 2021a). Additionally, the main focus of our analysis is on backdoor defense in a mixed-trigger setting. Due to the relative difficulty of defending against stylistic triggers, we first present results without the use of the stylistic trigger in the trigger mixture or pre-training (Tab. 1) and then with stylistic trigger (Tab. 2). For experiments where none of the trigger-only models are pre-trained on the stylistic trigger, two of the trigger-only models are pre-trained with the InsertSent trigger. For the 3-way mixture of triggers, we use poison rates of 5% for the BadNet and InsertSent attacks and 10% for the syntactic attack for a total poison rate of 20% (Liu et al., 2023). In the 4-way trigger mixture, we use a poison rate of 10% for the stylistic attack in addition to other attacks at their 3-way mixture poison rates for a total poison rate of 30%.

Implementation and Evaluation Metrics. To be consistent with previous studies (Liu et al., 2023; Yang et al., 2021b; Jin et al., 2022), we use BERT-base-uncased (Devlin et al., 2019) as the backbone of the NPoE framework. All experiments are conducted on a single NVIDIA `RTX A5000` GPU. We consider two primary performance metrics: attack success rate (**ASR**) and clean accuracy (**Acc**). Clean accuracy is the standard evaluation of task accuracy on clean data. ASR is the percentage of poisoned data that is classified correctly according to the dataset (i.e., predicted as the attack target label). In the mixed trigger setting, the relative frequency of each trigger is retained in making the fully poisoned dataset for evaluating ASR. Following Jin et al. (2022) and Liu et al. (2023), we also demonstrate the results in **NoDefense** and **Benign** settings for a more comprehensive understanding of the defense performance. **NoDefense** is a vanilla BERT-base model fine-tuned on the poisoned data without any defense. **Benign** is a model trained on the clean data without any poisoned samples. This baseline represents full prior knowledge of the attack or using training data free of attack, representing ideal situations that are not accessible to a defense model.

Baseline Methods. We compare our method NPoE with five representative defense methods. (1) **ONION** (Qi et al., 2021a) identifies and eliminates words that might act as backdoor triggers. The suspicion level of each word is assessed by GPT-2 (Radford et al., 2019) based on the reduction in sentence perplexity once the word is removed. (2) **BKI** (Chen and Dai, 2021) identifies potential trigger words by determining their significance to predictions and removes contaminated samples from training data to cleanse them. (3) **STRIP** (Gao et al., 2021) eliminates poisoned samples by examining the model's prediction inconsistency when the input undergoes multiple perturbations. (4) **RAP** (Yang et al., 2021b) employs a constant perturbation and set threshold for the variation in output probability of the defender-defined protected label to identify poisoned samples during the inference phase. (5) **CUBE** (Cui et al., 2022)

Table 1: Results with BadNet, InsertSent, and syntactic triggers. The poison rates for the BadNet, InsertSent, and syntactic trigger experiments are 0.05, 0.05, and 0.2 respectively. The three-trigger mixture uses a poison rate of 0.1 for the syntactic trigger and 0.05 for the BadNet and InsertSent triggers. Blue highlighted results are improvements over the **Benign** baseline. Best results are shown in **bold**.

analyzes the backdoor learning behaviors and removes poisoned samples in a dataset by clustering their representation embeddings. (6) **TERM** (Li et al., 2020) trains a robust model against outliers. Since poisoned training samples are outliers with significant backdoor features and noisy labels, we incorporate the method of learning with outliers as a baseline for a comprehensive comparison. (7) **DPoE** (Liu et al., 2023) considers backdoor attacks as the shortcuts or spurious correlation between the backdoor triggers and the attacker-specified target label. The debiasing framework PoE is leveraged for defense with an added denoising module. Our presented DPoE baseline is produced by reimplementation of DPoE with R-Drop denoising.

4.2 Main Results

Nested PoE training is an effective defense against backdoor attacks with the BadNet, InsertSent, and syntactic triggers, including the mixed-trigger setting (Tab. 1). NPoE outperforms other defense baselines, including representative backdoor defense methods and the state-of-the-art method DPoE. While two of the baselines (ONION and BKI) are specialized for detecting anomalous words and thus are most suited for the BadNet attack, NPoE still outperforms these baselines in those experiments. Similarly, not only does NPoE outperform DPoE in mixed-trigger settings (the motivating case for the framework), NPoE also shows improved defense against single-trigger attacks. Additionally, NPoE defense often outperforms models trained on benign data only, implying that NPoE can mitigate the effects of even unseen triggers. Given the high (greater than 90% ASR) effectiveness of these attacks in their intended settings, as shown by the NoDefense results, the de-

Table 2: Results with stylistic trigger. The poison rate for the stylistic-trigger experiment is 20%. The four-trigger mixture uses a poison rate of 10% for the stylistic and syntactic triggers, and 5% for the BadNet and InsertSent triggers. Blue highlighted results are improvements over the **Benign** baseline. Best results are shown in **bold**.

crease in ASR to often less than 10% with NPoE is dramatic.

For some trigger types, NPoE without pre-training (denoted as NPoE w/o Pretrain) outperforms the setting with trigger-only model pre-training. This may be due to varying ease of transfer between triggers of the same type; since pre-training only exposes the trigger-only models to various trigger types without using the actual poison triggers from the training data, the trigger-only models must transfer their knowledge of dissimilar triggers of the same type from pre-training to the full training phase. Note for the NPoE without R-drop ablation, while R-drop is intended to raise accuracy rather than lower ASR by improving the model's ability to ignore noisy labels, hyper-parameter tuning balances both these objectives. Thus, results reflect both an improvement in ASR and clean accuracy with the inclusion of R-drop since for a lower ASR, the accuracy will be higher and thus more likely to be the best setting.

Stylistic trigger. We additionally run experiments on attack settings that include the stylistic trigger. The stylistic trigger proves more challenging to defend against despite the lower ASR in the no-defense setting (Tab. 2). However, Nested PoE training is able to outperform the DPoE baseline in ASR for settings with the stylistic trigger. While, unlike the no-stylistic-trigger settings, ASR is not improved over the benign-training-only threshold, clean accuracy benefited from the use of defense strategies and is even higher than the benign setting.

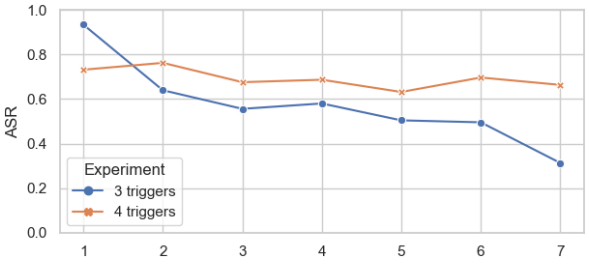

Figure 4: Results on the mixed trigger settings with the SST-2 dataset were robust to changes in the number of layers in the trigger-only models. Results are shown for models trained without R-drop denoising.

4.3 Analysis

Impact of Hyper-parameters. To examine whether our proposed NPoE is sensitive to the choice of hyper-parameters, we evaluate NPoE with different values of several hyper-parameters on SST-2 dataset under the mixed-trigger settings that contain three or four types of triggers, including the number of gate function layers (Appx. §A.2), number of trigger-only model layers (Fig. 4), and the PoE coefficient (Appx. §A.2). As shown in Appx. §A.2, the overall performance of NPoE only slightly fluctuates with different numbers of gate layers and different levels of the PoE coefficient, showing that NPoE remains effective within a reasonable range of hyper-parameter values. We can spot a slight decrease in ASR with the rise of the number of layers for the trigger-only models (Fig. 4). This is likely because a model with more layers has a stronger learning capacity, and the more backdoor shortcuts the trigger-only models learn, the cleaner the residual is for the main model, which results in a more robust main model and lower ASR. With the increase in the number of trigger-only experts, we can spot an improvement in defense performance Appx. §A.3. However, more expert models result in higher computational cost (Appx. §A.4). As a trade-off between defense performance and computation cost, we use four experts for all the experiments.

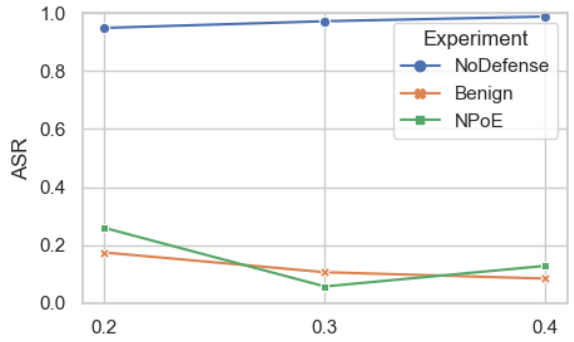

Figure 5: When doubling the poison rate of the three-trigger mixture of BadNet, InsertSent, and syntactic triggers in the SST-2 experiments, there was not an associated increase in ASR.

Higher Poison Rate. To examine the resistance of NPoE against more challenging attacks, we test it with higher poison rates on the SST-2 dataset under a mixture of three types of triggers. Fig. 5 shows a slight decrease in the ASR with the increase in poison rate. The reason for this trend may be that higher poison rates come with stronger shortcut features for the trigger-only models to learn, leaving the main model with cleaner, trigger-free signals.

5 Conclusion

In this paper, we propose Nested PoE, an ensemble-based training-time backdoor defense against data poisoning attacks. NPoE draws inspiration from debiasing and adapts the PoE framework by training a robust model in tandem with a trigger-only MoE ensemble. In particular, we focus on the mixed-trigger setting, where multiple backdoors coexist in the poisoned dataset, by using multiple trigger-only models that allow flexibility for the trigger-only ensemble to learn multiple triggers. In experiments on three NLP tasks, Nested PoE illustrates strong robustness against multiple triggers both separately and simultaneously.

Limitation

The primary limitation of Nested PoE is the large number of hyperparameters to tune. This includes the R-drop weight α, PoE weight β, number of layer in the gate model, and number of layers in each trigger-only model. One avenue not explored by this analysis is varying the sizes of the trigger-only models to capture different types of features that may serve as triggers. For example, it is probable the the ideal number of layers for a trigger-only model to learn the BadNet (rare tokens) trigger may be lower than the number required to learn the syntactic trigger. Further exploration of varied MoE structures to use in the Nested PoE framework is left to future work.

Ethical Considerations

Due to the simple and easy-to-implement nature of data-poisoning attacks, defense against them is a pressing issue. The techniques presented here are designed for defense and are unlikely to be misused for malicious purposes. The attacks discussed in this paper are all previously documented in published literature. Data used in the experiments comes from open-access data which is published and publicly available.

A Appendix

A.1 Dataset Statistics

The statistics of datasets used for experiments are listed in Tab. 3, including the number of training samples, the number of test samples, and their average length.

	# Training	# Testing	Avg. Length
SST-2	6.9k	1.8k	19.30
OffensEval	11.9k	0.8k	19.68
TREC	5.5k	0.4k	11.23

Table 3: Statistics of datasets involved in experiments.

A.2 Effect of PoE Coefficient and Number of Gate Layers

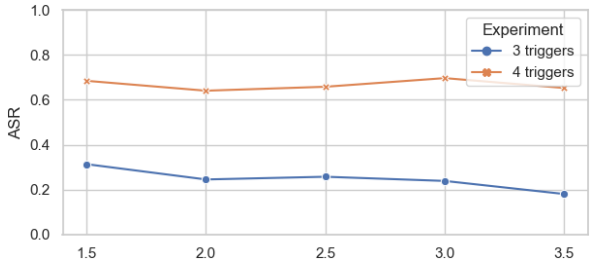

Figure 6: Results on the mixed trigger settings with the SST-2 dataset were robust to changes in the PoE coefficient. Results are shown for models trained without R-drop denoising to remove interference from additional unrelated hyper-parameters.

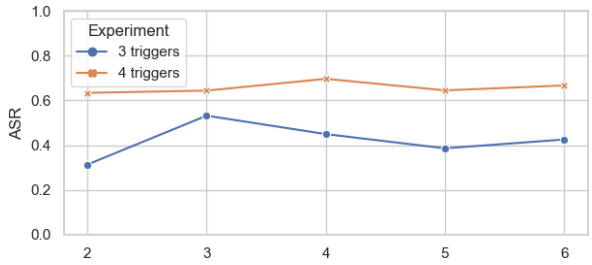

Figure 7: Results on the mixed trigger settings with the SST-2 dataset were robust to changes in the number of layers in the learned gate. Results are shown for models trained without R-drop denoising to remove interference from additional unrelated hyper-parameters.

As shown in Fig. 6, the performance (attack success rate) of NPoE is stable under the change of PoE coefficient, which shows that NPoE remains effective as long as the PoE coefficient is within a reasonable range. Performance of NPoE is similarly stable with change in number of layers in the gate model Fig. 7, indicating that the size of the

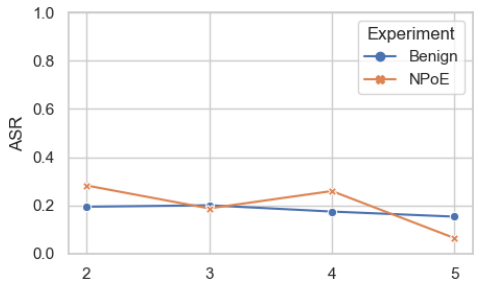

Figure 8: Defense performance with different numbers of experts on SST-2 dataset.

gate function does not have large effect on the effectiveness of NPoE since the gate operation is only for re-weighting the predictions of each trigger-only models.

A.3 Effect of Number of Experts

The effect of the number of experts is illustrated in Fig. 8. As the number of experts increases, we can see a boost in the ASR, which means better defense performance. This implies the necessity of incorporating multiple expert models for defending against multiple backdoors.

A.4 Training Cost

The computational cost of different training methods is shown in Tab. 4, where "it/s" stands for iterations per second. NoDefense represents the vanilla finetuning of the BERT-base model. With more expert models involved, it is more expensive to train NPoE. As a trade-off, we use 4 experts in our NPoE framework, which only doubles the cost of vanilla fine-tuning.

Method	Cost
NoDefense	14.28 it/s
DPoE (1 model)	10.35 it/s
NPoE (2 models)	6.96 it/s
NPoE (3 models)	6.07 it/s
NPoE (4 models)	7.27 it/s
NPoE (5 models)	5.99 it/s

V Attack: Taking advantage of Text Classifiers' horizontal vision

Anonymous ACL submission

Abstract

Text classification systems have continuously improved in performance over the years. However, nearly all current SOTA classifiers have a similar shortcoming, they process text in a horizontal manner. Vertically written words will not be recognized by a classifier. In contrast, humans are easily able to recognize and read words written both horizontally and vertically. Hence, a human adversary could write problematic words vertically and the meaning would still be preserved to other humans. We simulate such an attack, *VertAttack*. *VertAttack* identifies which words a classifier is reliant on and then rewrites those words vertically. We find that *VertAttack* is able to greatly drop the accuracy of 4 different transformer models on 5 datasets. For example, on the SST2 dataset, *VertAttack* is able to drop RoBERTa's accuracy from 94 to 13%. Furthermore, since *VertAttack* does not replace the word, meaning is easily preserved. We verify this via a human study and find that crowdworkers are able to correctly label 77% perturbed texts perturbed, compared to 81% of the original texts. We believe *VertAttack* offers a look into how humans might circumvent classifiers in the future and thus inspire a look into more robust algorithms.

1 Introduction

Automatic text classifiers have seen a continual increase in helping websites moderate and monitor products or people. Though they are helpful to reduce the work load of humans, they can be subject to problems like bias (Chuang et al., 2021; Zhou et al., 2021) and are vulnerable to adversarial attacks (Lei et al., 2022; Le et al., 2022). Research into text adversarial attacks has been on the rise in recent years. The reasons range from testing classifiers' robustness (Wang et al., 2022) to privacy concerns (Xie and Hong, 2022).

Current state-of-the-art (SOTA) attacks largely fall into character based attacks and word-based attacks. Character-based attacks change individual characters, by flipping character, introducing or removing whitespace (Gröndahl et al., 2018), or replacing characters with visually similar characters (Eger et al., 2019). Word-based attacks replace words with similar words which are less known to the target classifier (Li et al., 2020; Wang et al., 2022). One weakness of current SOTA attacks is that they constrain themselves to horizontal changes. That is, the final result is still read in a left-to-right (English) manner. This is a disadvantage because the attacker restricts themselves to the same domain as the classifier which is also only able to read text horizontally.

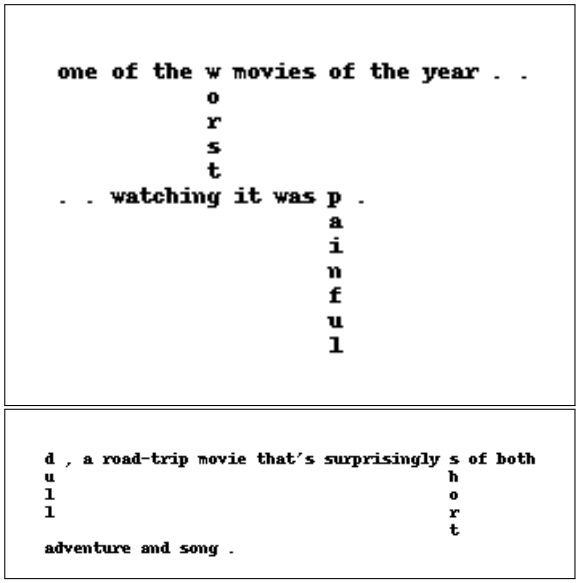

Figure 1: Examples of texts perturbed by VertAttack. Humans can still understand the vertically written words, while classifiers struggle to read.

Humans have the ability to read text in multiple directions, not just horizontally. Thus, a human attacker who wants to communicate a message to others, while avoiding a website automatically classifying that text, could write the words vertically and the meaning would still be preserved. We sim-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 719–732
June 16-21, 2024 ©2024 Association for Computational Linguistics

ulate this with *VertAttack*.

VertAttack exploits the current limitation of classifiers' inability to read text vertically. Specifically, *VertAttack* perturbs input text by changing information rich words from horizontally to vertically written. Our research makes the following contributions:

1. Propose an attack (*VertAttack*) to mimic how humans may subvert automatic classifiers. This attack exploits current classifiers' glaring weakness (inability to "read" vertical text).

2. Test *VertAttack* on 5 datasets, against 4 different classifiers. We further examine transferability of our attack. We find that when *VertAttack* has blackbox access to the classifier, it is able to drop classification accuracy from 83 - 95% down to 1 - 36%. We further compare *VertAttack* with two other text attacks, BERT-ATTACK and Textbugger. We find that, on average, *VertAttack* is able to drop classifiers' accuracy to 36.6% accuracy, which is lower than BERT-ATTACK (47.5%) and Textbugger (63.2%).

3. Verify *VertAttack*'s ability to be understood by humans via qualitative analysis. We find that humans are able to correctly classify 77% perturbed texts compared to 81% of the original texts.

4. Investigate initial defenses in terms of whitespace removal and find that if *VertAttack* a classifier reverses the algorithm it is able to mitigate the attack, but simpler whitespace preprocessing is not as effective.

5. Enhance *VertAttack* by allowing it to add in *chaff* to further disguise the text. This chaff greatly affects the reversal defense. Furthermore, we investigate how *VertAttack* affects classifiers using OCR to extract text from images.

The success of *VertAttack* shows a vulnerability in classifiers which humans may leverage to easily defeat them. We share code and perturbed texts for future research.

2 Threat Model

The examined threat model follows from prior research (Formento et al., 2023; Le et al., 2022; Deng et al., 2022). We assume blackbox knowledge of a classifier. That is, *VertAttack* has no internal knowledge of the classifier, but has access to the probabilities and label output by the model. *VertAttack* uses this for feedback (Section 4.1).

With prior research, there is an assumption that the feedback classifier is the same as the target classifier. However, websites rarely share the exact classifier used for moderating texts. Thus, we also examine the cases of where the feedback classifier differs from the target classifier as a transferability problem.

3 Attack Goals

Based on prior research (Lei et al., 2022; Zang et al., 2020; Li et al., 2019) VertAttack has 2 goals: 1. Modify text in such a way to cause an automated classifier to fail (misclassify). 2. Ensure modified retains the original meaning to humans. Thus, the attack is similar to obfuscation from classifiers.

Some previous text attack research have made the argument that attacks should be imperceptible to humans (Dyrmishi et al., 2023). However, this is not a unanimous requirement from text attacks, as many do not include it as a prerequisite (Alzantot et al., 2018; Ebrahimi et al., 2018; Eger et al., 2019; Li et al., 2021a). Furthermore, this would disqualify nearly all character-level attacks since humans do not naturally substitute characters in their writing (beyond mispellings). Finally, as stated, *VertAttack* simulates how humans can attack automated classifiers. Thus, we focus on the two aforementioned goals.

4 Methodology

Our proposed attack, *VertAttack*, can be divided into two main steps: 1) Word Selection, 2) Word Transformation. A visualization of the method can be seen in Figure 2.

4.1 Word Selection

Algorithm 1 Word Selection

Input: $text$
Output: $j \leftarrow$ PositionToModify
  $Score_{Orig} \leftarrow$ Classifier(text)
  $Drop_{Max} \leftarrow 0, i \leftarrow 0, j \leftarrow 0$
  while $i \neq len(text)$ **do**
    $Score_w \leftarrow$ Classifier(text/w)
    $Drop_w \leftarrow Score_{Orig} - Score_w$
    if $Drop_w > Drop_{Max}$ **then**
      $Drop_{Max} \leftarrow Drop_w$
      $j \leftarrow i$
    end if
    $i \leftarrow i + 1$
  end while

First the attack finds which word most helps

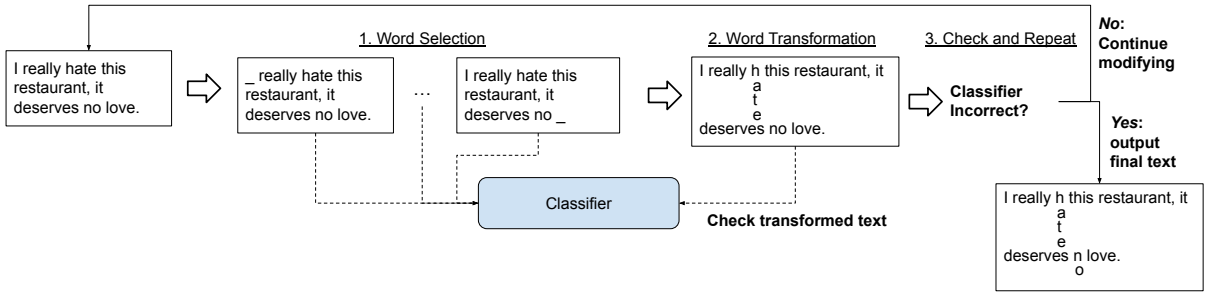

Figure 2: *VertAttack* basic overview. A word to transform is first selected from the input text and then transformed vertically. The classifier assists in providing feedback in the form of class probabilities. The process is repeated until the classifier misclassifies the text.

the classifier. We employ a greedy search method (Algorithm 1). In previous work this has been referred to as word importance (Jin et al., 2020) or greedy selection (Hsieh et al., 2019). The method removes one word[1] at a time and checks the change in classification probability from the original text. Each word is removed and then replaced until all probabilities are calculated. The word that causes the highest drop in probability is chosen as the word to be transformed.

4.2 Word Transformation

Algorithm 2 Word Transformation

Input: $text, perturb_{positions}$
Output: $text_m$

```
#_lines ← max length of words to be modified
k ← 0
while k < #_lines do
    i ← 0
    while i ≠ len(text) do
        if i ∈ perturb_positions then
            append text[i][k]
        else
            append word on first line
            or pad spaces equal to word length
        end if
        append space
        i ← i + 1
    end while
    Add newline char to text_m
    k ← k + 1
end while
```

Once a word is selected it is then transformed vertically (Algorithm 2). First, the number of lines needed (ie. length of word) for each selected word is calculated. Next, we iterate through each word of the original text. If a word is a non-selected word, then it is simply added to the final text. If the word is a selected word, then only the character of the corresponding line is chosen. For example, if "happy" is selected, and the line number is 2, then "a" is added to the final text. For all lines that only consist of whitespace and the vertical characters, the required whitespace is calculated by the length of each non-selected word.

Finally, we add a width constraint to the algorithm for practicality. The transformation is only run on that width (number of words) at a time and all text is combined at the end. For example, if there are 100 words and the width constraint is 10, then only 10 are modified at a time.

Once the transformations are applied, the classifier is queried again to see if the transformed text causes the classifier to misclassify. If so, the final text is produced. If not, then the algorithm repeats, however, this time the words that have been selected already are removed as candidates during the selection step.

5 Experimental Setup

To test the effectiveness of *VertAttack*, we evaluate the attack against several transformer classifiers across datasets examined in previous attack papers[2] (Li et al., 2020; Jin et al., 2020; Ren et al., 2019; Wang et al., 2022).

5.1 Datasets

We examine 4 binary task datasets and one multi-class task dataset. Following prior research (Li

[1]Here a word is defined as a token separated by whitespace.

[2]The majority of attacks were run on 56-core 256G processors. *VertAttack* was limited to 1 hour for each attacked text, after 1 hour the attack was noted as failure and no perturbations were made to the text.

et al., 2020), we randomly sampled up to 1000 examples for each dataset to attack. (QNLI contained 872 examples so all were used):

1. AG News - a collection of news articles divided into 4 categories (World, Sports, Business, Sci/Tech). Average text length is 38 words.

2. SST-2 - Stanford Sentiment Treebank, contains movie reviews labeled for sentiments (positive/negative) by humans. Average text length is 20 words.

3. CoLA - Corpus of Linguistic Acceptability, contains English sentences labeled grammatical correctness. Average text length is 8 words.

4. QNLI - Stanford Question Answering Dataset, contains question/answer pairs. A classifier must determine whether the context sentence contains the answer to the question. Note that we restrict *VertAttack* to modify the context sentence only. Average text length is 28 words.

5. Rotten Tomatoes (RT) - contains movie reviews from Rotten Tomatoes. Each review is labeled as positive or negative. Average text length is 21 words.

5.2 Classifiers

We examine a combination of up to 4 classifiers per dataset. At least 3 classifiers are examined per dataset to measure how well the attack transfers. We look at a combination of transformer models[3] (Morris et al., 2020):

1. BERT (base-uncased) - a fine-tuned version of BERT (Devlin et al., 2019) on the corresponding dataset. For example, for AG News, the bert-base-uncased model was fine-tuned on the AG News training data.

2. Albert - a fine-tuned version of the ALBERT model (Lan et al., 2019). ALBERT has a smaller memory footprint than BERT, since it shares weights across layers.

3. RoBERTa - a fine-tuned version of the RoBERTa model (Liu et al., 2019). RoBERTa has seen stronger classification results in recent years than BERT, due to choices made during pretraining.

4. DistilBERT - a fine-tuned version of DistilBERT (Sanh et al., 2020). DistilBERT is a lighter, faster version of BERT which was pretrained using BERT as a teacher for self-supervision.

[3]We leverage pretrained models via TextAttack: https://github.com/QData/TextAttack

Table 1: *VertAttack* results on datasets, accuracy is shown. The second column indicates which classifier was used to give feedback to VertAttack. Orig. = original accuracy without any attack. Rob. = RoBERTa, Disti. = Distilbert.

5.3 Metrics

To calculate the effectiveness of *VertAttack*, we examine 1 quantitative metric and 1 qualitative. For quantitative, we measure accuracy:

$$Accuracy = \frac{\#correctly_classified}{\#total_examples} \quad (1)$$

For qualitative, we measure human ability to understand the text. Specifically, we leverage crowdworkers as judges for the perturbed texts. We ask 3 crowdworkers to label each text (for class) and take the majority vote as a decision.

6 *VertAttack* Results

Our main *VertAttack* results are found in Table 1. The second column indicates which classifier is leveraged for feedback for VertAttack. We examine attacks where the feedback and target classifier are the same (diagonal rows), as well as transferability of attacks (non diagonal). Note that the former is the standard measurement in most attack papers. We make the following observations:

***VertAttack* causes large drops to classifier accuracy.** Our results demonstrate the effectiveness of *VertAttack* across datasets and classifiers. Specifically, when examining the cases where the feedback classifier is the same as the target classifier,

	BERT	Albert	Rob.	Disti.
Same	76.1	75.9	72.3	**58.7**
Diff.	**35.7**	43.3	45.4	39.06
All	48.3	53.3	53.8	**44.7**

Table 2: Average drops of *VertAttack* against the corresponding classifier across all datasets. Three averages are shown: "Same" indicates the average of the attacks where the feedback classifier was the same as the attacked. "Diff." indicate the set of attacks where the feedback classifier differed from the attacked."All" is the average for all drops against the classifier. Bold values indicate lowest drops.

Pred.	+	40	11
	-	8	41

Table 3: Confusion Matrices of human study results. Participants labeled 100 perturbed RT texts as positive (+) or negative (-) sentiment. Each text received 3 votes, a majority vote was taken.

we see up to 90 point drops. In AG News, *VertAttack* is able to drop BERT from 94.2% to 4.7%, Albert from 94.2 to 8.0, and RoBERTa from 94.7 to 20.2, which averages to 83 points. Similar drops from *VertAttack* are seen in the other datasets as well: SST-2 averages 80 points, CoLA averages 74 points, QNLI averages 56 points, and Rotten Tomatoes averages 71 points. Overall, these results support VertAttack's strength in fooling classification systems.

VertAttack's attacks transfer to other classifiers. Though not as strong, we find *VertAttack* to be successful even in cases of transferability. In the most effective case (the CoLA datasets), the transfer attacks cause an average drop of 51 points (max: 65, min: 40.1). These drops are detrimental to text classifiers' effectiveness and reliability. Slightly lesser drops are seen for SST-2, AG News, and Rotten Tomatoes which causes drops around 40 points on average. Finally, classifiers on the QNLI dataset see drops of 25 when the feedback classifier differs. In even the final cases, the attacks is a hinderance to classification methods and highlight their inability to process text as effectively as humans.

QNLI models most resilient to attack. Unlike the other datasets, which saw at least 1 classifier drop below 20% classification accuracy, QNLI classifiers dropped to only 32% in the lowest. This might be due to the difficulty of attacking multi-text inputs. We limited *VertAttack* to only attack the hypothesis and not the premise. We would most likely see a drop in accuracy if premise is allowed to be attacked as well, but we restricted to the hypothesis for a more realistic model where a user is proposing a hypothesis to a model's premise.

BERT and DistilBert show strength as most robust classifiers examined. To investigate resilience against VertAttack, we calculate three averages for each classifier, seen in Table 2: 1. The classifier used by *VertAttack* for feedback is the same as the target classifier (Same), 2. The classifier used by *VertAttack* is **different** than the target classifier (Diff.), 3. Inclusion of both 1 and 2 (All). Each score corresponds to the drop in accuracy against VertAttack. Thus, for resiliency, classifiers would like to have a lower drop in accuracy. We can see that DistilBert has the lowest drops in two cases (Same, All), while BERT has the lowest for the third (Diff.). However, BERT is examined in all 5 datasets, while DistilBert is only examined in 2. Thus, no final decision can be noted on most resilient between the two.

7 Human Study

To investigate humans' understanding of VertAttack's texts, we employed human crowdworkers to label a sampled set of texts which were perturbed by VertAttack. Specifically, we randomly sampled 100 of the 1000 texts from the Rotten Tomatoes dataset. We then asked crowdworkers to read the text and decide the sentiment of the text (positive or negative). For each text, we employed 3 crowdworkers[4], and took the majority vote of the labels. It should be noted that no instructions to read the texts vertically were given. More information on the instructions can be found in Appendix A.

The confusion matrix of results is in Table 3. Humans were able to identify sentiment correctly, 77% of the time, far greater than the 7 - 26% of the automated classifiers. This confirms that unlike the automated classifiers, humans are well prepared to read text in non-traditional manners.

For comparison, we also ran the same study with on the original, unperturbed 100 texts. This is also in Table 3 under the "Original" subtable. Humans are able to do slightly better on the unperturbed texts achieving an accuracy of 81%. However, VertAttack's percentage is only 4 points below (77%). This highlights that human misclassifications on

[4]Amazon Mechanical Turk

VertAttack's texts have more to do with the difficulty of some of the texts rather than due to perturbation.

8 Comparisons with other attacks

To further investigate how *VertAttack* performs in the adversarial text space, we compare to two other attacks, BERT-ATTACK (Li et al., 2020) and Textbugger (Li et al., 2019)[5]. BERT-Attack is similar to *VertAttack* as it is a word based attack. To select a word, BERT-ATTACK finds the importance score of a word by masking each word (one at a time) and comparing to the original logits. For replacement, BERT-ATTACK relies on BERT to give suggestions via its MLM training. Textbugger is a character based attack which tests inserting, deleting, swapping, or substituting characters. We run both attacks on the same 1000 examples from the Rotten Tomatoes dataset. The results can be seen in Table 4.

Overall, we find that BERT-ATTACK causes greater drops when the feedback classifier is the same as the attacked classifier, but *VertAttack* transfers better. Textbugger is weaker in both cases. Specifically, when the feedback classifier is the same (diagonal values), BERT-ATTACK causes classifiers to average 9.5% accuracy compared to VertAttack's 15.7% and Textbugger's 33.5%. However, for transferability (non diagonal values), *VertAttack* causes classifiers to average 47% accuracy, 19 points less than BERT-ATTACK's average of 66.5% and 31 points less than Textbugger's average of 78.1. Furthermore, when taking the overall averages (all cells) *VertAttack* drops classifiers to 36.6% accuracy while BERT-ATTACK averages 47.5% and Textbugger averages 63.2%.

9 Malicious Use - Offensive Language

To confirm the main results and demonstrate how VertAttack may be used maliciously, we apply VertAttack to "offensive" texts. We take a subset of OLID's (Zampieri et al., 2019) test set, labeled OFF (offensive). This results in 260 texts. We leveraged pretrained classifiers from Huggingface [6], trained on OLID training data. We examine 3 variations of transformer models, BERT, Albert, and XLNet (Yang et al., 2019). The full results are in Table 5.

[5]TextAttack was leveraged to simulate these attacks: github.com/QData/TextAttack

[6]https://huggingface.co/mohsenfayyaz

		Classifiers		
		BERT	Albert	RoBERTa
	Original	85.4	84.8	88.6
Vert A.	BERT	**6.7**	48.2	46.3
	Albert	*46*	14.7	*45.2*
	RoBERTa	56.3	*40.2*	25.8
Bert A.	BERT	22.9	52.3	74.8
	Albert	79	**1.9**	78.7
	RoBERTa	66.6	47.3	**3.6**
Textb.	BERT	46.2	52.3	74.8
	Albert	85.8	16.1	91.6
	RoBERTa	74.1	56.9	38.2

Table 4: *VertAttack* compared with BERT-Atttack and Textbugger. The second column indicates which classifier was used to give feedback to the attacks. Bold values indicate stronger attacks against that classifer. Italic values indicate strongest transfer attack.

		Classifiers		
	Feedback	BERT	Albert	XLNet
	Original	76.7	78.3	78.3
	BERT	1.3	23.8	27.5
	Albert	20	0	26.7
	XLNet	12.9	17.1	0.8

Table 5: *VertAttack* results on OLID dataset, on the OFF labeled (Offensive Language). Accuracy is shown. The second column indicates which classifier was used to give feedback to VertAttack.

VertAttack is able to greatly reduce the classification accuracy for all three models. When the feedback classifier is the same as the target, the accuracy drops to 1% or lower. When the classifiers differ, the accuracy is also low, in the range 13 - 28%. These results demonstrate how the attack can cause issues on popular social media websites which leverage automated classifiers to help curb offensive language.

10 Effect on OCR + Classifier

To guarantee the preservation of whitespace, we can write text to an image (as done in the human study). The question arises of how a classifier which leverages OCR to extract text from images would fare. We test this by first converting the modified text into an image using the PIL library[7]. Next, we use Tesseract OCR[8] to extract the text from the image and classify it. We test this on Rotten Tomatoes. The feedback and target classifiers use the text segmenter (Section 11). The results can be found in Table 6. We include a simple majority class baseline for comparison.

For OCR, we see accuracy increase in the cases

	RoBERTa	44.8	45.5	9.4
	VertAttack - Segmenter			
Seg.	BERT	10.0	44.7	53.6
	Albert	49.3	4.7	53.6
	RoBERTa	41.7	41.8	8.2

Table 7: *VertAttack* results on RT dataset with different whitespace preprocessing present, accuracy is shown. First column indicates which method the classifier used: Simple - remove all extraneous spaces in input text, Seg. - leverage word segmenter to process the input text. Second column indicates which classifier was used to give feedback to VertAttack. "*VertAttack* - X" indicates which method *VertAttack* used with classifier feedback.

when the target and feedback classifier are the same. For example, Albert classification changes from 13.6 to 35.7. When feedback and target classifiers differ, the accuracy is similar to the original attacked accuracy. All accuracies are below the simple majority class baseline of 53.3. Thus, even though OCR increase accuracy, it is still detrimental for a classifier. Furthermore, VertAttack could be further modified to target a classifier which includes OCR in the pipeline.

11 Initial Defenses

We investigate some initial steps automated classifiers might take to mitigate VertAttack's effectiveness. Since *VertAttack* introduces whitespace, simple solutions might be to reduce that whitespace. Thus, we look at three different approaches. First, we simply remove extraneous whitespace and limit at most 1 space between each token, denoted as **Simple**. Second, we leverage a text segmentation library[9] to remove whitespace and re-combine words, denoted as **Segment**. Finally, we assume the classifier has learned the algorithm for VertAttack and thus reverses it. That is, the classifier attempts to recombine vertical characters into words before classification. This is denoted as **Reverse**. The full algorithm can be found in the appendix (Appendix C).

11.1 Simple + Segment

For the first two approaches, we run them on the original attacked Rotten Tomato (RT) texts (from Table 1). We then modify *VertAttack* to have this information during its attacks as feedback, as changing the preprocessing method during classification puts the attack at a natural disadvantage since the feedback is no longer as reliable. The full results of these experiments are in Table 7.

We observe that when *VertAttack* includes a preprocessing method for feedback that is different than what the attacked classifier uses ("*VertAttack* - None"), the attack suffers. For example, examining the diagonal results, the simple preprocessing is able to raise Albert's classification accuracy from 14.7 to 29.7. The word segmentation approach raises it even higher (to 49.2). Similar results are seen across the table. The transferability results (feedback classifier differs from final classifier) also generally increase, but not nearly as strong. This follows as *VertAttack* is modifying texts based on a classifier that differs in preprocessing and hence the attack becomes a transferability problem itself.

When *VertAttack* has the same method in its feedback classifier, then the approaches are not as fruitful ("*VertAttack* - Simple", "*VertAttack* - Segmenter"). Again with Albert (on the diagonal), we actually see a decrease in classification accuracy from 14.7 to 13.6 for **Simple** and down to 4.7 for **Segmentation**. This indicates the importance of the feedback classifier as it can strongly affect VertAttack's perception of a strong attack and the importance of whitepace preprocessing for

classifiers if the attacker is not prepared.

11.2 Reverse

The **Reverse** preprocessing results can be found in Table 8. As can be observed, the algorithm is able to strongly combat VertAttack, increasing the accuracy from 6 - 24 to 84 - 87. However, we observe that it is not able to mitigate it entirely, as some texts are entirely written vertically and the algorithm is not able to distinguish when new lines of words begin. We next introduce an augmentation to VertAttack to combat the **Reverse** algorithm.

12 Enhancing VertAttack with Chaff

As demonstrated, if the classifier knows this type of attack is occurring, it can strongly mitigate it by reversing the algorithm. Thus, we enhance VertAttack by introducing chaff. Specifically, rather than inserting only whitespace vertically, an alphabet character has a chance of being inserted. This occurs at a probability p. For example, if $p = 10$, then there is a 10% probability that rather than whitespace, a character is inserted in the vertical lines. Note that to preserve readability we do not allow this for whitespace next to perturbed words (nor original whitespace). The full algorithm can be found in Appendix C.

We test chaff for $p = \{5, 10, 20, 30, 60\}$. The main results against the **Reverse** algorithm (Section 11.2) are in Table 9. The entire results can be found in Appendix D, which also includes the chaff against no prepocessing as well.

This enhancement hinders the ability to reverse the attack. **Reverse** is not able to identify non-perturbed characters. We see that accuracy drops from 84 to ... in the case of BERT. Similar trends are seen for Albert and RoBERTa as well. We see drop increase as p increases. This points to the reverse algorithm becoming less able to avoid the random inserted text.

We verify that readability is maintained, following the same process in the main human study (Section 7). The results can be seen in the Appendix

		Classifiers		
	Feedback	BERT	Albert	RoBERTa
	Original	85.4	84.8	88.6
	p = 10%			
None	BERT	6.0	49.1	46.3
	Albert	46.3	17.0	44.4
	RoBERTa	57.33	42.0	24.4
Reverse	BERT	64.8	70.7	71.6
	Albert	68.2	64.7	76.2
	RoBERTa	73.7	71.5	67.4
	p = 30%			
None	BERT	5.8	49.2	47.6
	Albert	44.7	19.6	44.3
	RoBERTa	55.5	42.3	23.7
Reverse	BERT	39.8	59.3	58.2
	Albert	58.1	40.1	64.5
	RoBERTa	63.8	65.8	40.5

Table 9: Results on RT dataset when chaff is added. "None" means no preprocessing is used and "Reverse" is the classifier attempting to reverse engineer VertAttack.

(Table 11). We observe some slight drop in human classification when chaff is increased, but text is understood by at least 1 human in 83% of texts.

This enhancement further demonstrates *VertAttack* as a strong representation of how humans can adjust to combat automatic classifiers.

13 Conclusion

We presented a new attack which exploits current classifiers' inability to understand text written vertically. Mimicking a human, *VertAttack* perturbs text by rewriting words in a vertical manner which humans are able to understand, but classifiers are not. We find drops in classification up to 86 points.

Furthermore, VertAttack produces texts which humans can understand. Human crowd workers verified this by labeling 77% perturbed texts correctly, compared to 81% of non perturbed texts.

When compared to other attacks, *VertAttack* causes stronger drops when transferability of attacks is included. *VertAttack* drops classifiers to 36.6% accuracy compared to 46.5% of BERT-Attack and 63.2% of Textbugger.

We explored initial results on how *VertAttack* affects classifiers with OCR. We found that these classifiers are more robust, but still vulnerable.

Finally, We investigated initial defenses against *VertAttack* and found that the methods are able to mitigate the attack as long as *VertAttack* does not enhance with chaff.

VertAttack causes strong drops and maintains meaning. Our hope is *VertAttack* may inspire future research into addressing this limitation of classifiers be robust against attacks inspired by humans.

14 Limitations

Here we note some limitations with our method and with our experiments. These limitations should be kept in mind when working and expanding on *VertAttack* so that they addressed or noted:

Websites are not guaranteed to preserve formatting of text produced by VertAttack. *VertAttack* produces text in which targeted words are vertically perturbed. It does this by adding in multiple newlines characters and padded whitespace to preserve readability. However, not all websites are guaranteed to preserve this additional whitespace. Some may completely remove extra newlines which will cause the produced text to greatly drop in readability. One solution to this is leveraging a module to write the text into an image (as seen in the examples (Figure 1). With an image, the formatting of text will be honored and readable to humans. Furthermore, this adds another layer to the attack as text would first need to be processed from the image for classification. However, not all websites allow images, and thus it is a noted limitation to be remedied in the future.

Our attacks focused exclusively on transformer classification models. Though transformers are the current kings of classification, not all websites might have the resources to employ these types of models and thus investigation into simpler models may be useful to confirm VertAttack's effectiveness. However, generally non-transformer models have struggled against adversarial attacks and in the past, and there seems to be no reason why they would fare any better against VertAttack.

Greedy word selection is time consuming. The selection method is the least efficient part of VertAttack. As noted, many previous attacks have leveraged a similar method (Section 4.1). This is due to lack of classifier knowledge in blackbox approaches, thus most tokens need to be checked in selection. However, there do exist more efficient approaches. For example, some style transfer algorithms use attention mechanisms to find the most important words (Wu et al., 2019). Thus, *VertAttack* could be further improved by improving the selection algorithm.

15 Ethical Considerations

By simulating adversarial attacks, such as *VertAttack*, concerns can arise over ethical implications. For example, introducing such a method might allow malicious users to more easily introduce harmful texts into websites and other spaces. This is a further concern as, for research, we make code and algorithms publicly available. This needs to be considered when introducing and studying any adversarial attack. However, we believe that in spite of the above possible wrongful uses, *VertAttack* can be helpful in studying both robustness and future understanding tasks of text classification systems. This is further emphasized as humans can naturally perform this attack and there is no dataset which collects these attacks done by humans. Hence, *VertAttack* provides a way to simulate and further study such attacks. Through this simulation, classifiers, defenses, and other related NLP systems can benefit in a public space. Our hope is not that this algorithm is ever used for malicious purposes, but to improve the aforementioned systems. Thus, we believe the benefits to outweigh any risks.

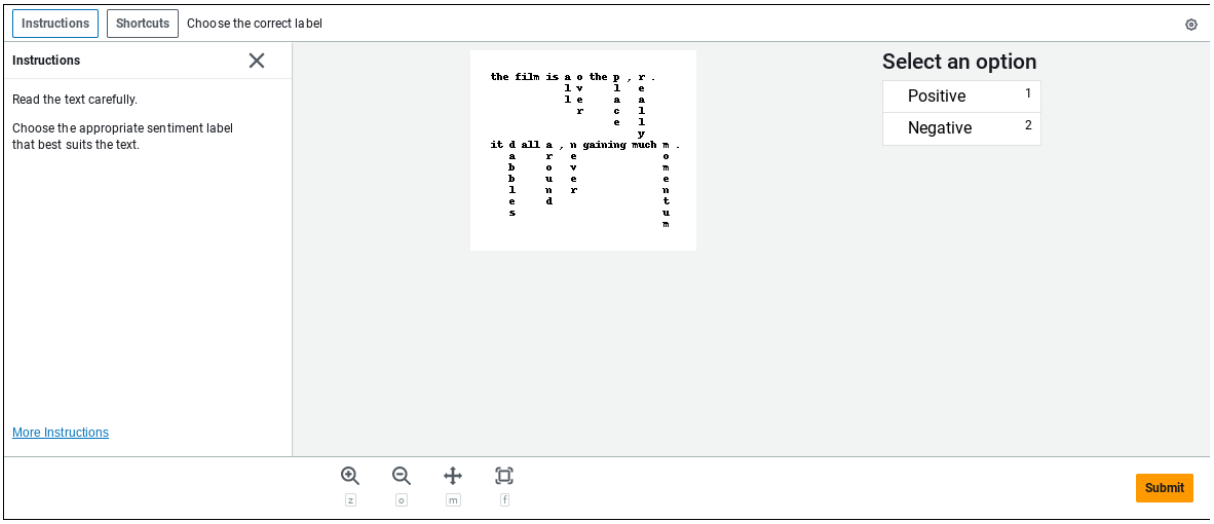

Figure 3: Instructions shown to Amazon Mechanical Turk crowdworkers.

A Human Study Details

For the human study we leveraged Amazon Mechanical Turk crowdworkers to annotate sentiment on Rotten Tomatoes text which were perturbed by VertAttack. The instructions provided to the participants can be seen in Figure 3. As can be seen, no instructions to read the text vertically were given. For each annotation of text, crowdworkers were paid $0.08. Each text received 3 annotations. As AMT does presents each text as a separate task, the 3 annotators for 1 text were rarely the same annotators for another task, thus annotator agreement was not calculated.

To present the texts, we leverage the PIL library in python to write the texts into simple images. An example of this can be seen in the example images (Figure 1). We chose to push the text onto images to avoid any website dependent presentation of the text (e.g. the worker viewer the text on a desktop versus on a phone).

B Related Work

Here we examine some of the other current SOTA attacks. We examine both word-based attacks and character-based attacks as *VertAttack* shares some characteristics with both.

Word-Based Attacks: Like *VertAttack*, current black-box SOTA word-based attacks attack a classifier by receiving feedback from that classifier. This feedback is in the form of label probabilities (Hsieh et al., 2019), or the logits of the classifier (Li et al., 2021b). Black-box, word-based attacks follow similar steps to *VertAttack*. First, they choose tokens for replacement, and then they leverage a tool to choose a replacement. This could be a transformer model (Li et al., 2020), a lexicon like WordNet (Ren et al., 2019), or word embeddings (Hsieh et al., 2019). Unlike, *VertAttack* current word-based attacks only operate in the horizontal space. That is, all words chosen for replacement are substituted for that word in place. Their goal is to find words which a classifier does not know well enough to make a correct classification. Thus, *VertAttack* is set apart by operating in the vertical space. Furthermore, *VertAttack* does not replace the selected word, thus meaning is more easily preserved.

Character-Based Attacks: Another common type of SOTA attack are character-based attacks which change text at the character level. These attacks generally aim to be more transferable than word attack and thus do not receive feedback from a classifier. Instead, the changes are applied at a random chance throughout the text. For example, whitespace might be removed (Gröndahl et al., 2018) or added or standard, English characters might be replaced with non-standard similar looking characters (e.g "a" → "@")(Eger et al., 2019). Both cases try to cause classifiers to see words as out-of-vocabulary. One downside is that character-level attacks can be mitigated more easily with proper preprocessing (Rusert et al., 2022). *VertAttack* is similar, in that it focuses on the characters of a word, however, *VertAttack* uses an internal classifier for feedback. Furthermore, due to the positioning of the characters, *VertAttack*'s changes are harder to correct with preprocessing of text.

C Reverse Algorithm

Algorithm 3 Reverse

Input: Perturbed Text
Output: Preprocessed Text
  Split_Text ← Text.Split('\n')
  $Drop_{Max} \leftarrow 0, i \leftarrow 0, j \leftarrow 0$
  $Top_Line \leftarrow 0$
  while $i \leq$ Split_Text.length() **do**
    $cur_line = Split_Text[i]$
    if $length(word) \in cur_line > 1$ **then**
      update previous top line, add to final text
      $Top_Line \leftarrow i$
    else
      store characters at positions
    end if
    $i \leftarrow i + 1$
  end while

The full reverse algorithm can be found in Algorithm 3. The algorithm first splits by new line characters. To combine vertically written characters, the algorithm appends them to the position in an original text line. An original text line is determined by those lines which have more than single characters. Note, the algorithm cannot just take the top line as the only text line as the width constraint in VertAttack adds vertical lines throughout the text.

D Chaff Full Results

Table 10 contains the results for all probabilities of chaff. As can be observed, as p increases, the effectiveness of the **reverse** decreases. However, this chaff does not add more to the original attack itself

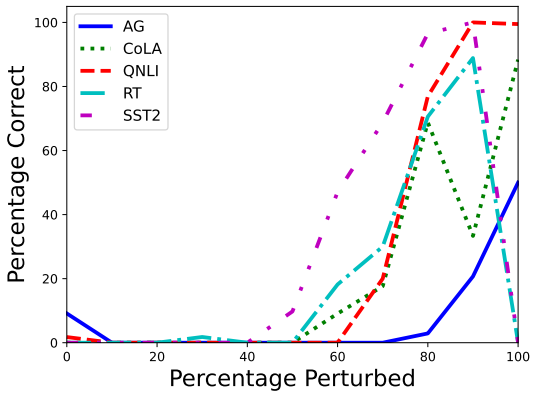

Figure 4: The classifiers' ability to correctly classify text as the amount of words perturbed increases. The classifier examined is BERT, when *VertAttack* uses BERT for feedback.

if the classifier is not trying to reverse engineer the algorithm.

Table 11 compares human evaluations of adding in chaff at a rate of 30%. We see a drop in correct responses but at least 1 human is able to correctly identify the sentiment in at least 83% of the texts.

E Analysis of Percentage of Words Perturbed

For additional understanding of VertAttack, we seek to analyze how the number of words modified by *VertAttack* affects the classifiers. One might postulate that as *VertAttack* modifies more words the classifier does worse, as more and more of the original text is lost. However, through our analysis we find the opposite to be true.

Figure 4 graphs BERT's classification ability versus percentage of text perturbed across the 5 examined datasets. Surprisingly, we see that as the percentage of words perturbed increases, the classifier is better equipped to make a correct classification. This may partially be due to a limitation with *VertAttack* compared to some other attacks. Other attacks are able to bring in new words whose embeddings can cause additional confusion for the classifier, but *VertAttack* does not.

Original and VertAttack are the same values from Table 3. Chaff $p = 30$ indicates that chaff is added to the perturbed text at 30% rate.

KDMCSE: Knowledge Distillation Multimodal Sentence Embeddings with Adaptive Angular margin Contrastive Learning

Cong-Duy Nguyen[1], **Thong Nguyen**[2], **Xiaobao Wu**[1], **Luu Anh Tuan**[1]
[1]Nanyang Technological University, Singapore
[2]National University of Singapore, Singapore

Abstract

Previous work on multimodal sentence embedding has proposed multimodal contrastive learning and achieved promising results. However, by taking the rest of the batch as negative samples without reviewing when forming contrastive pairs, those studies encountered many suspicious and noisy negative examples, significantly affecting the methods' overall performance. In this work, we propose KDMCSE (Knowledge Distillation Multimodal contrastive learning of Sentence Embeddings), a novel approach that enhances the discrimination and generalizability of multimodal representation and inherits the knowledge from the teacher model to learn the difference between positive and negative instances and via that, can detect noisy and wrong negative samples effectively before they are calculated in the contrastive objective. Furthermore, to overcome the limitation of modeling the variation within negative pairs, we introduce a new contrastive objective, AdapACSE (Adaptive Angular Margin Supervised Contrastive Learning for Multimodal sentence embeddings), that enhances the discriminative representation by strengthening the margin within the angular space while capturing varying semantics within the negative. Experimental results on widely used Semantic Textual Similarity (STS) benchmarks demonstrate the effectiveness of our approach. The source code is available at https://github.com/duyngtr16061999/KDMCSE.

1 Introduction

Learning sentence embeddings, which involves translating sentences into consistent-length vectors that capture their semantic connections, remains a pivotal task in the NLP field. While pretrained language models like BERT (Devlin et al., 2019) and RoBERTa (Liu et al., 2019) have witnessed immense success, studies indicate that the default sentence embeddings from these PLMs, without specific fine-tuning, may not perform as well as simply averaging Glove vectors (Pennington et al., 2014) in capturing semantic similarity (Reimers and Gurevych, 2019). Consequently, recent works (Li et al., 2020; Zhang et al., 2020; Su et al., 2021) are geared towards refining sentence embeddings from PLMs without supervision.

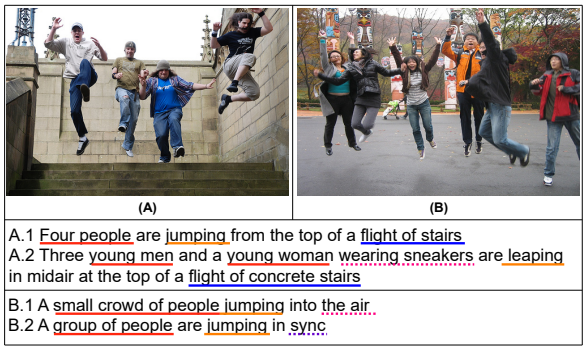

Figure 1: Example image-caption pairs in Flickr. Solid lines of the same color talk about the same instance, and a dot line means the additional information that does not occur in the other caption.

While text-centric models have made significant strides, their depth of understanding of sentence semantics remains a point of contention. True semantic understanding often stems from associations in the real world rather than mere textual statistics (Wang et al., 2019; Bender and Koller, 2020; Bisk et al., 2020; Wei et al., 2022). Numerous recent studies have explored the enhancement of language representations through visual information (Tan and Bansal, 2020b; Tang et al., 2021; Nguyen et al., 2023b). The recent multimodal contrast in sentence embedding learning (Zhang et al., 2022a) offers an encouraging direction. This method augments SimCSE with a multimodal contrastive objective, which seeks congruence between sentences and their associated images within a unified space. However, samples drawn randomly from grounded datasets during training can present semantic differences, subtle similarities, or over-

lapping attributes. For example, in Figure 1, two captions B.1 and B.2 describe the second image B, but also correctly represent the first image A. Due to their inherent noise, such samples can hinder the learning process. Mitigating this issue requires preemptively filtering out these semantically similar samples before loss calculation, ensuring a noise-reduced training environment. In addition, comparing two captions, A.1 and A.2, for the left image reveals that the latter offers a more comprehensive description, detailing aspects such as the individual's gender, attire, sneakers, and even the material of the stairs (concrete). Thus, using only visual images cannot capture the depth of language representations.

Furthermore, MCSE did not consider the distinctions between negative sample pairs while focusing on constructing pairs of positive and negative representations. As shown in Figure 2, although none of the captions perfectly describes the image, their levels of discrimination vary between pairs. On the contrary, the caption c registers a score of 0.49, hinting at its partial relevance to the image. Caption d, with a very weak score of 0.03, is completely unrelated. Consequently, within the feature space, both captions c and d should be substantially distanced from the accurate depiction. Furthermore, the gap between the true caption and caption d should considerably exceed that between the true caption and the caption c.

To address the aforementioned limitation of noisy negative sampling and complexity of linguistic representation, we present KDMCSE: a Knowledge Distillation Multimodal Contrastive Learning framework for Sentence Embeddings that utilizes CLIP (Radford et al., 2021) as the teacher model for both image and text modalities. Our approach harnesses images for multimodal objectives and textual representations derived from the CLIP text encoder. Relying solely on images falls short of capturing the nuances in sentence representation. Emulating the representation of the CLIP's textual encoder - especially when paired with image matching - can augment the richness of linguistic representations, transcending a mere alignment with visual features.

Moreover, in response to the identified challenge of diversity among negative pairs, we introduce AdapACSE: Adaptive Angular Margin Contrastive Learning. This method bolsters discriminative representation by amplifying the margin within the angular space, specifically accounting for the various semantics present in negative samples. Leveraging the teacher model, CLIP, we produce soft labels that signify the similarity between samples. Instead of merely utilizing feature representations as positive or negative samples during the multimodal objective, we employ CLIP's soft labels to intensely penalize samples exhibiting low similarity and provide leniency to pairs exhibiting certain resemblances.

Our contributions can be summarized as follows.

- We propose a novel multimodal framework for sentence embedding KDMCSE: Knowledge Distillation Multimodal Contrastive learning for Sentence Embedding. The knowledge of the teacher model is transferred to the student model through multimodal contrastive learning, spanning both text and visual modalities.
- We introduce self-supervised contrastive learning: AdapACSE that improves the discriminative representation of samples with varying degrees of similarity.
- We evaluate our approach using standard semantic textual similarity (STS) benchmarks and SentEval transfer tasks. Our method outperforms the performance of earlier state-of-the-art approaches.

2 Related Work

Sentence Representation Learning In previous research, sentence representations were typ-

ically learned by extending the principles of word2vec (Mikolov et al., 2013), predicting neighboring sentences (Kiros et al., 2015a; Hill et al., 2016; Logeswaran and Lee, 2018) or aggregating n-gram embeddings (Pagliardini et al., 2018), the pre-trained transformer-based model BERT (Li et al., 2020; Reimers and Gurevych, 2019) and its enhancements BERT-Flow (Li et al., 2020) and BERT-Whitening (Su et al., 2021). More recently, various studies have embraced the contrastive learning framework for learning sentence representation. These studies have proposed different methods to form contrastive pairs, either through various data transformation techniques (Yan et al., 2021; Zhang et al., 2020; Giorgi et al., 2021) or through encoders with distinct structures or parameters (Carlsson et al., 2021; Kim et al., 2021). A notable example is SimCSE (Gao et al., 2021), which employs dropout as a data augmentation strategy. Many studies in the field of sentence contrastive learning have made a significant contribution by focusing on the mining of challenging negative samples (Wang et al., 2022b; Zhou et al., 2022; Zhang et al., 2022b; Wang et al., 2022a; Wei et al., 2023; He et al., 2023).

Deep Metric Learning Objectives Contrastive learning (Chopra et al., 2005) has gained traction across multiple domains (Nguyen and Luu, 2021; Nguyen et al., 2022, 2024, 2023a; Wu et al., 2020, 2022, 2023a,b, 2024; Wei et al., 2024). Renowned training objectives such as N-Pair Loss (Sohn, 2016), Triplet Margin Loss (Balntas et al., 2016), and ArcCon (Zhang et al., 2022c) are deeply rooted in metric learning principles. In supervised tasks, objectives that leverage softmax have shown efficacy, especially when they integrate class centers and impose penalties on the distances between deep features and their corresponding centers. Among these, Center loss (Wen et al., 2016), SphereFace (Liu et al., 2017), CosFace (Wang et al., 2018), and ArcFace (Deng et al., 2018) stand out and are frequently used in computer vision and natural language processing applications. Nonetheless, these loss functions primarily aim at classification tasks, rendering them unsuitable for regression labels. ArcCSE (Zhang et al., 2022c) presents training objectives using additional margin tailored to enhance the discriminative prowess in pairwise relations and capture the entailment dynamics within triplet sentence structures.

Visually Grounded Representation Learning Numerous studies have underscored the advantages of integrating NLP models with visual insights to improve textual representation learning (Lazaridou et al. (2015); Kiela et al. (2018)). Based on the Skip-Thought model of Kiros et al. (2015b), Bordes et al. (2019) created a unified space that harmoniously accommodates both visual and textual dimensions. Recent pioneering efforts by Tan and Bansal (2020a), Tang et al. (2021) and (Nguyen et al., 2023b) have laid the foundation for vast language models using multimodal guidance, aiming to improve language understanding. Similarly, MCSE by Zhang et al. (2022a) suggested sentence embedding learning using a multimodal contrastive objective to align sentences with their respective images coherently. Distinguishing our work from Zhang et al. (2022a), we present an innovative angular margin contrastive learning framework, building upon the cutting-edge multimodal contrastive learning proposed by Zhang et al. (2022a). By weaving in this new contrastive technique, our goal is to push the envelope in STS by leveraging multimodal semantic data.

3 Method

3.1 Background: Unsupervised SimCSE and Multimodal Contrastive Learning MCSE

The idea of unsupervised SimCSE is to use dropout noise as a simple, yet effective, data augmentation strategy. Given a collection of sentences $\{x_i\}_{i=1}^m$, we construct a positive pair for each input x_i by encoding it twice using different dropout masks: $\boldsymbol{h}_i^z = g_\phi(f_\theta(x_i, z))$ and $\boldsymbol{h}_i^{z'} = g_\phi(f_\theta(x_i, z'))$, where z and z' denote different dropout masks[1], $f_\theta(\cdot)$ is a pre-trained language encoder such as BERT, and $g_\phi(\cdot)$ is a projection head[2] on top of the `[CLS]` token. The training objective is:

$$\ell_i^{\mathrm{S}} = -\log \frac{e^{\mathrm{sim}(\boldsymbol{h}_i^{z_i}, \boldsymbol{h}_i^{z_i'})/\tau}}{\sum_{j=1}^N e^{\mathrm{sim}(\boldsymbol{h}_i^{z_i}, \boldsymbol{h}_j^{z_j'})/\tau}}, \quad (1)$$

where N is the size of the mini-batch, τ is a temperature parameter, and $\mathrm{sim}(\boldsymbol{h}_1, \boldsymbol{h}_2)$ is the cosine similarity $\frac{\boldsymbol{h}_1^T \boldsymbol{h}_2}{\|\boldsymbol{h}_1\| \cdot \|\boldsymbol{h}_2\|}$. After training, the `[CLS]` token outputs of the language encoder are taken as the sentence embeddings.

[1]The standard dropout masks in Transformers are used.

[2]There is a MLP pooler layer over `[CLS]` in BERT's implementation. Gao et al. (2021) use it with reinitialization.

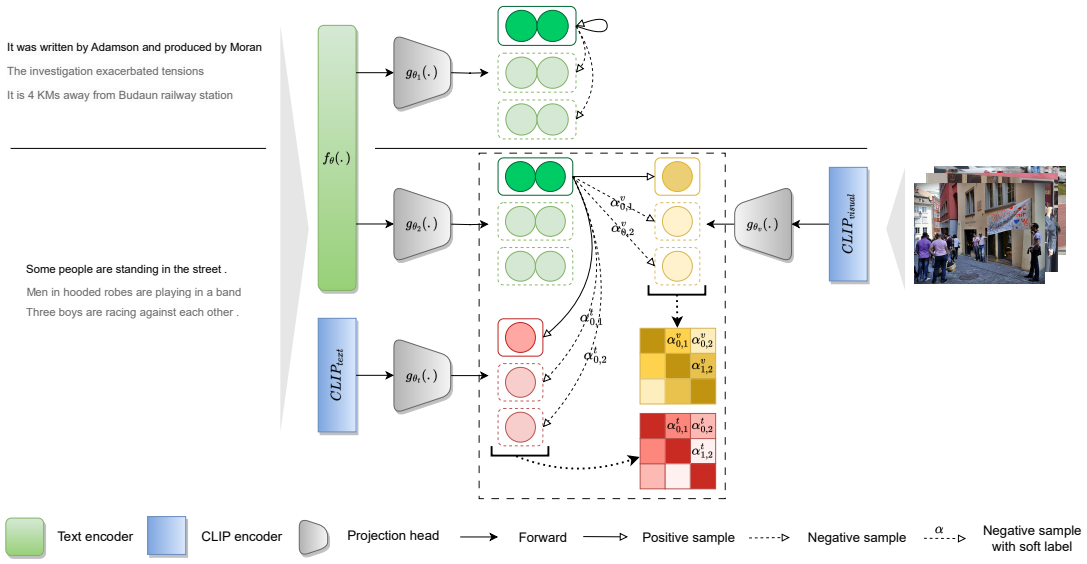

Figure 3: The overall architecture of KDMCSE. The upper part is the original SimCSE, the below part is the multimodal contrastive learning approach with knowledge distillation from CLIP model.

To take advantage of visual and textual information, MCSE (Zhang et al., 2022a) adopt SimCSE as the textual baseline and extend it with a multimodal contrastive learning objective:

$$\boldsymbol{s}_i^z = g_{\phi_1}(f_\theta(x_i, z)),\ \boldsymbol{v}_i = g_{\phi_2}(f^v(y_i))\ , \quad (2)$$

where $f^v(\cdot)$ is a pre-trained image encoder. $g_{\phi_1}(\cdot)$ and $g_{\phi_2}(\cdot)$ are two projection heads for text and image modalities. They define the multimodal contrastive learning objective as:

$$\ell_i^{\mathrm{M}} = -\sum_{z\in\{z_i,z_i'\}} \log \frac{e^{\mathrm{sim}(\boldsymbol{s}_i^z,\boldsymbol{v}_i)/\tau'}}{\sum_{j=1}^{N} e^{\mathrm{sim}(\boldsymbol{s}_i^z,\boldsymbol{v}_j)/\tau'}}\ , \quad (3)$$

3.2 Knowledge Distillation Multimodal Contrastive learning for Sentence Embedding

In addition to the multimodal objective, we present a Knowledge Distillation framework designed to harness both visual and textual insights from the vision-language model CLIP. An overview of our KDMCSE model can be found in Figure 3. Given a set of sentence-image pairs represented as $D = \{x_i, y_i\}_{i=1}^m$, we initially project the sentence x_i and the image y_i into a shared or grounded space.

$$\boldsymbol{s}_i^z = g_{\phi_g}(f_\theta(x_i, z)), \quad (4)$$

$$\boldsymbol{t}_i = g_{\phi_t}(\hat{\boldsymbol{t}}_i),\ \hat{\boldsymbol{t}}_i = CLIP_{text}(x_i)\ , \quad (5)$$

$$\boldsymbol{v}_i = g_{\phi_v}(\hat{\boldsymbol{v}}_i),\ \hat{\boldsymbol{v}}_i = CLIP_{visual}(y_i)\ , \quad (6)$$

where $CLIP_{text}, CLIP_{visual}$ are a pre-trained text and image CLIP encoder, $\hat{\boldsymbol{v}}_i$ and $\hat{\boldsymbol{t}}_i$ are the visual and text representation extracted from CLIP, $g_{\phi_g}(\cdot)$ is the projection heads for the language student model to project the sentence representation into grounded space, $g_{\phi_t}(\cdot)$ and $g_{\phi_v}(\cdot)$ are distinct projection heads of the teacher model for the text and image modality, respectively. During training, we freeze the pre-trained CLIP model.

Threshold Filtering During training, negative samples were randomly taken from data in Eq.3. We not only transfer CLIP's knowledge of the text and visual representation of each sample, but also leverage the similarity within samples in a batch. We calculate the cosine similarity:

$$\alpha_{i,j}^{m,n} = \frac{m_i \cdot n_j}{\|m_i\|_2 \|n_j\|_2},\ m,n \in \{\hat{v}, \hat{t}\} \quad (7)$$

where m, n are the defined modality (text or visual). Thus, as shown in Figure 4, we can generate four similarity mappings: text-text, visual-visual, text-visual, and visual-text. As we strive to align the sentence representation generated by the language encoder (text) with the information gleaned from the teacher model encompassing both sentence (text) and image (visual) data, we exclusively employ 'text-text' and 'text-visual' pairings for our soft labels. We define a threshold filter function to remove noisy negative samples:

$$\varphi_{i,j}^{m,n} = \begin{cases} 0 & if \quad \alpha_{i,j}^{m,n} < threshold \\ 1 & else \end{cases} \quad (8)$$

where $threshold$ is a fixed hyperparameter during

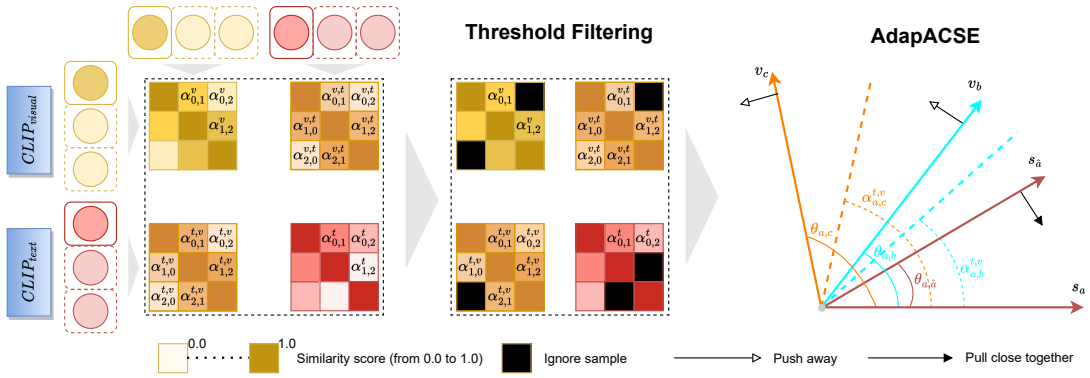

Figure 4: The overall framework of knowledge distillation with Adaptive Angular margin contrastive learning. The pipeline first calculates the soft-label similarity scores between text and visual representation, then we apply threshold filtering to remove the noisy negative pairs, and finally, we transfer the soft-label matrices into our proposed AdapACSE to flexibly find the margin. $s_{\hat{a}}$ is the positive sample for s_a, v_b and v_c are its negative counterparts. In particular, the difference in pairs $s_a - v_c$ is more pronounced than in $s_a - v_b$. As a result, the margin (depicted as a dashed line) for c (in orange) is greater than for b (in cyan).

training. The proposed contrastive objective with Threshold Filtering is defined as follows:

$$\ell_i^{\mathrm{m}} = -\sum_{z\in\{z_i,z_i'\}} \log \frac{e^{\mathrm{sim}(\boldsymbol{s}_i^z,\boldsymbol{m}_i)/\tau'}}{\sum_{j=1}^{N} \varphi_{i,j}^{t,m} e^{\mathrm{sim}(\boldsymbol{s}_i^z,\boldsymbol{m}_j)/\tau'}}, \tag{9}$$

where m is the modality (text or visual), $m \in \{t, v\}$, $\boldsymbol{m}_i$ is the projected representation of CLIP model, $\boldsymbol{m}_i \in \{\boldsymbol{v}_i, \boldsymbol{t}_i\}$.

3.3 Adaptive Angular margin Contrastive learning

Previous studies (Zhang et al., 2022c) introduced the ArcCSE objective. This was designed to increase the discriminative capacity between pairs and encapsulate the entailment relationship among triplet sentences. ArcCSE adds an additive angular margin m_c between positive pairs h_i^z and $h_i^{z'}$. Compared to Eq.1, it further pushed h_i towards the area where $\theta_{i,i'}$ becomes smaller and $\theta_{j,i}$ becomes larger, increasing the compactness of sentence representations with the same semantics and enlarging the discrepancy of different semantic representations. ArcCSE is defined as:

$$\ell_i^{\mathrm{ArcCSE}} = -\log \frac{e^{\phi\left(\theta_{i,i'}+m_c\right)/\tau}}{e^{\phi\left(\theta_{i,i'}+m\right)/\tau} + \sum_{j\neq i}^{n} e^{\phi(\theta_{j,i})/\tau}} \tag{10}$$

where ϕ is the *cos* function, angular $\theta_{i,j}$ is denoted as follows:

$$\theta_{i,j} = \arccos\left(\frac{h_i^T h_j}{\|h_i\| * \|h_j\|}\right) \tag{11}$$

where h_i is the vector representation, in this work, $h_i \in \{\boldsymbol{v}_i, \boldsymbol{t}_i, \boldsymbol{s}_i^z\}$.

There are distinct differences among the negative pairs, especially when we observe that the examples marked in red in Figure 2 serve as negative samples for the green caption. In this grounded space, the distance between the samples becomes crucial. We have refined the contrastive objective to harness the knowledge from the teacher model and to capture the magnitude of the differences between negative pairs. To address this challenge, we introduce a novel training objective, Adaptive Angular margin Contrastive Loss, AdapACSE, which is an adaptation of Eq.10. Instead of fixing margin m_c for all samples in the data, we adapt it to be flexible depending on its negative samples. This new objective improves sentence representation learning by an adaptive margin, $m_c\Delta_{i,j}$, between negative pairs h_i and h_j. Thus, if the $\Delta_{i,j}$ is large and the two samples i, j are much different, the margin is also large to push the representation away, and vice versa. Our approach is illustrated in the right part of Figure 4, we formalize this objective function as **AdapACSE**:

$$\ell_i^{\mathrm{AdapACSE}} = -\log \frac{e^{\phi\left(\theta_{i,i^*}\right)/\tau}}{e^{\phi\left(\theta_{i,i^*}\right)/\tau} + \sum_{j\neq i}^{n} e^{\phi(\theta_{i,j}-m_c\Delta_{i,j})/\tau}} \tag{12}$$

where $\Delta_{i,j} = |1 - \alpha_{i,j}|$ is the cosine distance between two samples i and j. Together with the threshold filtering contrastive learning, we rewrite the AdapACSE objective to be:

$$\ell_i^{\text{AdapACSE}'} = \ell_i^{m'} = -\log \frac{e^{\phi(\theta_{i,i^*})/\tau}}{e^{\phi(\theta_{i,i^*})/\tau} + \sum_{j \neq i}^{n} \varphi_{i,j}^{t,m} e^{\phi(\theta_{i,j} - m_c \Delta_{i,j})/\tau}} \tag{13}$$

Finally, we define our KDMCSE objective as follows:

$$\ell_i^{\text{KDMCSE}} = \frac{\ell_i^{\text{v}'} + \ell_i^{\text{t}'}}{2} \tag{14}$$

where $\ell_i^{\text{v}'}$ and $\ell_i^{\text{v}'}$ are AdapACSE Eq. 13 with t, v are text and visual modalities, respectively.

4 Experiments Setup

4.1 Dataset

We employ Flickr30k (Young et al., 2014) and MS-COCO (Lin et al., 2014) as our multimodal datasets. Flickr30k contains 29, 783 training images and MS-COCO has 82, 783 training images. Every image in these collections comes with multiple captions, usually five captions. As in Gao et al. (2021), we utilize Wiki1M for our text-based dataset, consisting of 10^6 sentences extracted randomly from English Wikipedia.

4.2 Implementation

Language Encoder - Student model We have implemented our work in the Hugging Face Transformers library[3] as described by (Wolf et al., 2020). We load our language encoder from the checkpoints of `bert-base-uncased` and `roberta-base`. Then, we fine-tune these foundation models with our introduced contrastive objective. To evaluate sentence embeddings, we use the 768-dimensional outputs of the `[CLS]` token preceding the MLP pooler layer from the transformer-based models.

Multimodal encoder - Teacher model Our teacher model is CLIP (Radford et al., 2021), the model's weights are initialized with pre-trained `clip-vit-base-patch32`, where `ViT-B/32 Transformer` architecture is built as an image encoder and the patch size P is 32. Because during training, the teacher model will not be fine-tuned, we will pre-extract image and text features $\hat{\boldsymbol{v}}, \hat{\boldsymbol{t}}$ to reduce the computation cost during the training phase.

MLP Projection Heads We use 4 different MLP modules $g_{\{\theta_1, \theta_2, \theta_t, \theta_v\}}$ to project different modalities and objectives. For the pure textual objective using the Wiki1M dataset, sentence embeddings are projected into a 768-dimensional space. For CLIP projection, both the sentence embeddings (student and teacher models) and the image feature vectors are projected into a shared 256-dimensional space.

Parameter Settings In line with the experimental setup described by Zhang et al. (2022a), we explored two primary training scenarios: *wiki+flickr* and *wiki+coco*. Mini-batches were drawn either from the Wiki1M corpus or from the respective caption datasets, with proportions reflecting their relative sizes. Our parameter choices were largely inspired by the guidelines provided by Gao et al. (2021). Specifically, we set the temperature parameters τ and τ', to 0.05. For model assessment, we performed evaluations on the STS-B dev set after every 125 training iteration, preserving the best performing checkpoint for our final evaluation. Regarding the BERT encoder, we adopted a learning rate of $3e-5$ and a batch size of 64. For RoBERTa, these parameters were adjusted to $1e-5$ and 128, respectively. Our training was executed on an A6000 GPU, with each experimental run spanning roughly 5-6 hours and equivalent to MCSE training time.

4.3 Evaluation

We evaluate our trained models on seven STS (Semantic Textual Similarity) tasks, including STS 2012-2016 (Agirre et al., 2012, 2013, 2014, 2015, 2016), the STS Benchmark (Cer et al., 2017), and SICK-Relatedness (Marelli et al., 2014). Each dataset is made up of pairs of sentences with the aim of assigning a similarity score to each pair. In alignment with Gao et al. (2021), we present the Spearman correlation (multiplied by 100) between the official annotations and our predicted scores in an "all" context. This means that we merge all subsets for each task and then provide a comprehensive Spearman correlation.

5 Experiments Results

5.1 Main Results

Following the methodology of previous studies, we conducted our model five times using the same hyperparameter settings. Averaged results are delineated in Table 1. A collective overview of our results reveals that our model consistently matches or exceeds the benchmarks set by baseline approaches. MCSE advances beyond SimCSE in the majority of STS evaluations. By integrating auxiliary visual and textual insights derived from the CLIP teacher model, our KDMCSE model showcases pronounced improvements in various downstream tasks. Specifically, when trained on Wiki1M and Flickr30k datasets, KDMCSE increases the performance metrics for BERT (from 77.3 to 78.6) and RoBERTa (from 78.3 to 79.1). Compared to MCSE-RoBERTa, our model exhibits comparable metrics on STS15 and STS-B, with a slight advancement on STS16. In the context of the *wiki+coco* dataset, KDMCSE-BERT notably surpasses other methods across most tasks, with scores rising from 76.6 to 77.9 (STS15 being the exception with a modest increase). Our RoBERTa encoder, when trained with the KDMCSE framework, showed higher average results (an increase from 77.6 to 78.0), where tasks such as STS12, STS14, and STS15 registered significant improvements, while others retained or slightly underperformed in comparison.

5.2 Alignment and Uniformity

The concepts of alignment and uniformity are closely linked to contrastive learning, serving as potential metrics to evaluate the quality of the representations derived (Wang and Isola, 2020). Alignment is a property that encourages encoders to produce analogous representations for instances that are alike. This can be quantified using the expected distance between the embeddings of positively paired instances.

$$\mathcal{L}_{align} \triangleq \mathop{\mathbb{E}}_{(x,x^+)\sim p_{\text{pos}}} \left\| f(x) - f(x^+) \right\|_2^2 . \quad (15)$$

And the *uniformity loss* prefers a uniform distribution in the hypersphere:

$$\mathcal{L}_{uniform} \triangleq \log \mathop{\mathbb{E}}_{x,y \overset{i.i.d.}{\sim} p_{\text{data}}} e^{-2\|f(x)-f(y)\|_2^2} . \quad (16)$$

To delve deeper into the mechanics of our methodology, we assess alignment and uniformity metrics using the STS-B development set. In our

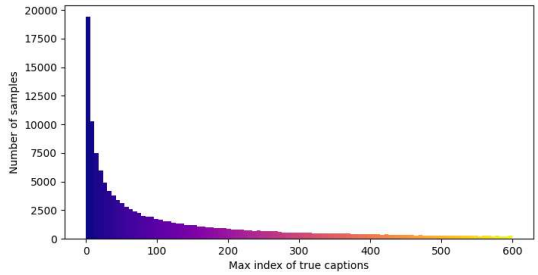

Figure 5: Statistic of the maximum index of true captions when sorting the similarity score between image and text of Flickr dataset.

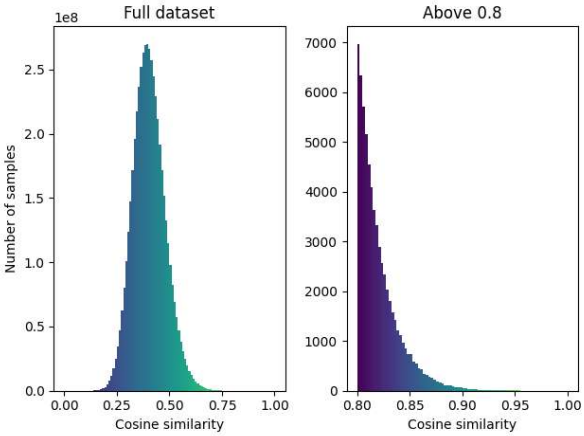

Figure 6: Statistic of the similarity score between image and text of Flickr dataset.

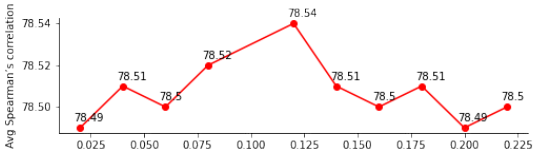

Figure 7: Impact of angular margin m in AdapACSE. The results are reported on average across 7 tasks, and our experiments are conducted on BERT encoder and in *wiki-flickr* setting.

comparison with MCSE, the results are presented in Table 2. Evidently, when compared to MCSE for both BERT and RoBERTa-based encoders, KDMCSE shows superior performance in both alignment and uniformity metrics. This not only reaffirms the foundational rationale of our method, but also suggests that AdapACSE can effectively enhance the caliber of sentence embeddings.

6 Analysis

6.1 Exploring the Impact of Angular Margin

In our AdapACSE loss function, the angular margin, represented as m, is critical to determining the discriminative capability. We conducted an experiment to better understand the impact of m by varying it in steps of 0.025 radians from 0.025 radians to 0.225 radians. The performance metrics averaged on all tasks are depicted in Figure 7. From the data, we discern an optimal performance when m is set to 0.125. Any deviation from this optimal point, be it an increase or decrease, results in a performance drop. This aligns with our preliminary hypotheses: A smaller value of m could have a negligible effect, whereas an overly large m could negatively skew the representations within the fusion space.

6.2 Threshold Filtering selection

In this section, we will show how to define the threshold hyperparameter during training. We make statistics based on text-text and text-visual similarity scores in the Flickr set, and select based on that statistic. We perform two calculations: (1) the histogram for the similarity threshold and (2) the position of the largest true captions (the annotation captions of that image) that align with the image when sorted with all captions in the dataset with that image. Looking at Figure 5, we see that most of the true captions of an image are in the top 100 (out of about 150,000 captions). However, there are still quite a few captions that, even though they accurately describe that image when sorted, can still be pushed to very far indexes (>200). This may be because there are still many similar images in the dataset, leading to captions that describe another image, but are still correct for this image. The image 6 shows that the scores are in a normal distribution. We focus more clearly on samples with high similarity and see that there are only a few pairs with similarity higher than 0.8. and decreases rapidly as it approaches 1.0. Based on the above statistics, we have chosen a threshold of about 0.85-0.9 to eliminate pairs in the contrastive learning objective.

7 Conclusion

In this paper, we introduce KDMCSE, a novel approach to sentence embedding learning that transfers knowledge from a vision and language model with a multimodal contrastive objective to not only align sentences and the corresponding image and text representations of the teacher model but also avoid noisy negative samples. Additionally, our innovative contrastive objective, AdapACSE, ad-

dresses the challenges associated with capturing nuanced differences within negative pairs, strengthening discriminative representation. Our framework lays the groundwork for continued exploration in this domain, fostering advancements in vision and language applications.

8 Limitations

In this study, we shed light on the promising enhancements of KDMCSE in STS benchmarks. However, it is imperative to acknowledge its limitations. In particular, there is a pronounced disparity in both the distribution and volume of word tokens when visual datasets are compared to traditional language corpora. Taking the Book Corpus and Wikipedia as instances, these standard language repositories house billions of words, spanning millions of unique tokens. In contrast, MS COCO, a frequently cited visual-grounded dataset, encompasses merely a million words and about a thousand unique tokens. Another challenge encountered in our methodology is the intricate correlation of the hyperparameter in our contrastive objective, which remains elusive. Its optimal configuration was determined not through systematic understanding, but rather through exhaustive fine-tuning across many experiments. Furthermore, the characterization of "semantic similarity" is highly dependent on the specific task at hand. Although we have seen significant advancements in STS benchmarks, there remains a need to evaluate the disparity in performance between text-only models and their multimodal counterparts across diverse benchmarks. This would provide a more holistic understanding of the efficacy of sentence representations in varied contexts.

Table 5: Ablation study on STS tasks. STS-B: STS Benchmark, SICK-R: SICK-Relatedness, Avg.: average across 7 tasks.. We train the MCSE models using additional CLIP text embeddings.

A Regularization

To validate the significance of our objectives, we select the best-performing models for each dataset and gradually run with three settings: our KDMCSE, KDMCSE without AdapACSE, and KDMCSE without threshold filtering. The results are presented in Table 3, indicating that the incorporation of all the proposed approaches leads to the best performance in all tasks. The second line shows that not applying threshold filtering can marginally harm performance. This result can be attributed to the fact that, during training, noisy negative samples do not often appear in the batch. In the last row of the table, we show that the removal of AdapACSE significantly affects the performance of both BERT and RoBERTa.

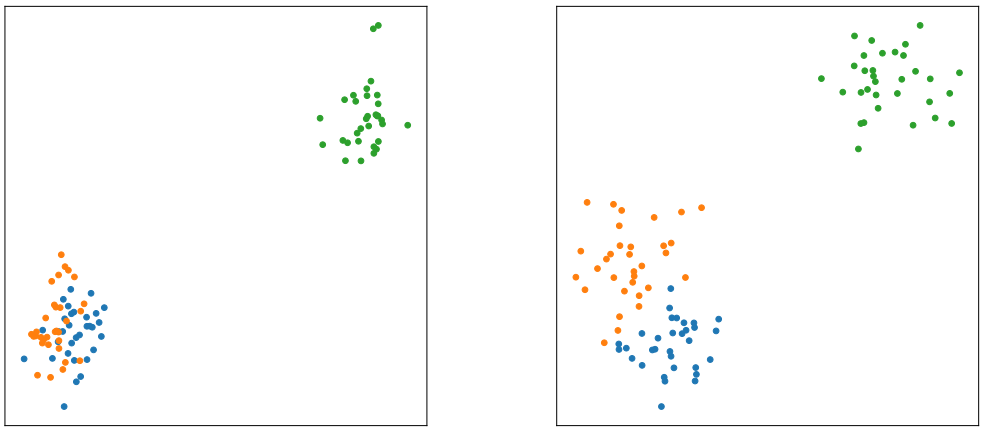
B Larger experiments on image-text paired data

To mitigate scalability and generalization concerns, we conducted extensive experiments using a significantly larger dataset containing one million image-text pairs sourced from the CC12 dataset, equivalent in sample size to Wiki1M. In Table 4, we present the results of these experiments. Our findings consistently demonstrate that our KDMCSE model surpasses MCSE in terms of average performance (Avg) across STS, across various subtasks within CC12M subsets.

C Impact of Adaptive Angular Margin Contrastive objective

To substantiate the significance of our objectives and ensure fairness in our comparisons, we carried out experiments involving MCSE with the inclusion of additional text embeddings from the CLIP text encoder. The results of these experiments are presented in Table 5. Our findings unequivocally indicate that our proposed contrastive objectives have a positive impact on the model's performance, thereby strengthening our core objectives.

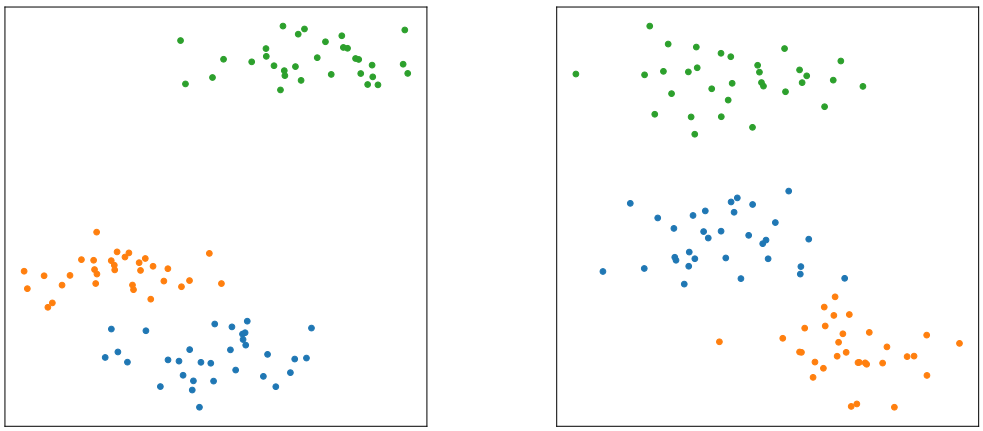
D KDMCSE algorithm



To enhance the presentation of our method, we provide a detailed description of our implementation, adhering to the pseudo code outlined in Algorithm 1.

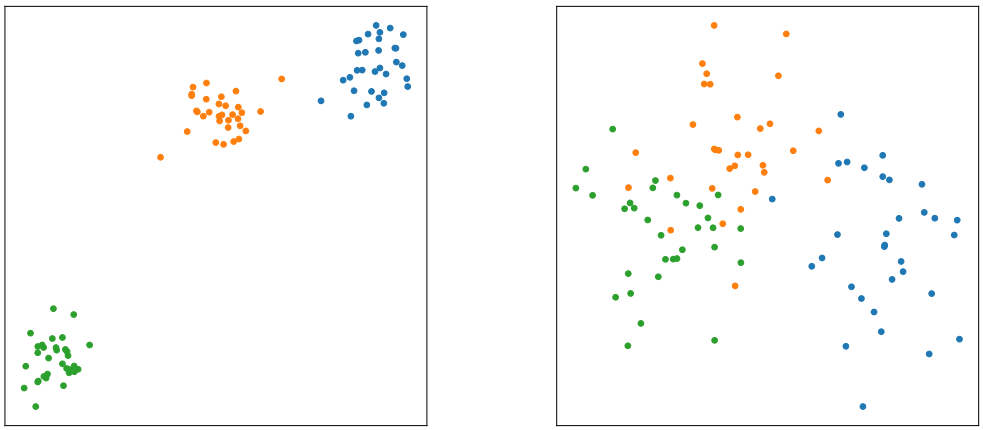
Algorithm 1 Our KDMCSE algorithm

Input:
Collection of sentences (text-only dataset) $D = \{x_i\}_{i=1}^{n}$
Collection of image-text pairs (multimodal dataset) $D^M = \{x_i, y_i\}_{i=1}^{n_m}$
Paired sample step $p = \left\lceil \frac{|D|}{|D^M|} \right\rceil$
for $t = 1, 2, 3, \ldots, iter$ **do**
  if not $t|p$ **then**
    Sample batch $\{x_i\}_{bs}$ from D
    // Forward through language model and projection
    $\boldsymbol{h}_i^z, \boldsymbol{h}_i^{z'} = g_\phi(f_\theta(x_i))$
    // Calculate loss
    $\frac{1}{bs}\sum_i^{bs} \ell_i^{\mathrm{S}}$
  else
    Sample batch $\{x_i, y_i\}_{bs}$ from D^M
    $\boldsymbol{s}_i^z = g_{\phi_g}(f_\theta(x_i, z))$
    $\boldsymbol{t}_i = g_{\phi_t}(\hat{\boldsymbol{t}}_i), \hat{\boldsymbol{t}}_i = CLIP_{text}(x_i)$
    $\boldsymbol{v}_i = g_{\phi_v}(\hat{\boldsymbol{v}}_i), \hat{\boldsymbol{v}}_i = CLIP_{visual}(y_i)$
    // Calculate cosine similarity
    $\alpha_{i,j}^{t,t} = \dfrac{\boldsymbol{s}_i \cdot \boldsymbol{t}_j}{\|\boldsymbol{s}_i\|_2 \|\boldsymbol{t}_j\|_2}$
    $\alpha_{i,j}^{t,v} = \dfrac{\boldsymbol{s}_i \cdot \boldsymbol{v}_j}{\|\boldsymbol{s}_i\|_2 \|\boldsymbol{v}_j\|_2}$
    // Calculate soft-label (text-text, text-visual)
    $tt_{score} = \dfrac{\hat{\boldsymbol{t}}_i \cdot \hat{\boldsymbol{t}}_j}{\|\hat{\boldsymbol{t}}_i\|_2 \|\hat{\boldsymbol{t}}_j\|_2}$
    $tv_{score} = \dfrac{\hat{\boldsymbol{t}}_i \cdot \hat{\boldsymbol{v}}_j}{\|\hat{\boldsymbol{t}}_i\|_2 \|\hat{\boldsymbol{v}}_j\|_2}$
    // Apply threshold filtering TF based on soft-label
    $TF(\alpha_{i,j}^{t,t})$
    $TF(\alpha_{i,j}^{t,v})$
    // Calculate AdapACSE loss
    $\frac{1}{bs}\sum_i^{bs} \ell_i^{\mathrm{KDMCSE}}$
  end if
end for



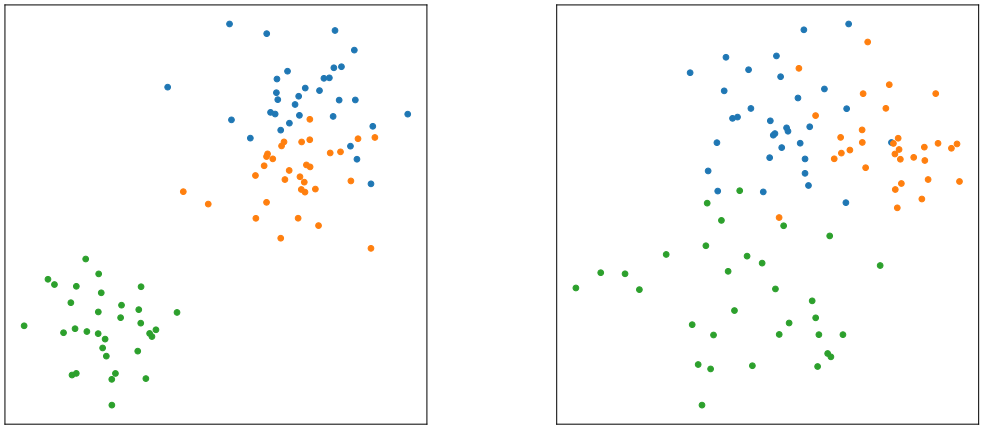
E Sentence embedding visualization

In this appendix, we provide visualization of sentence embedding of our KDMCSE and MCSE models, illustrated in Figures 8, 9, 10, 11 and 12. We visualize sentence representations by repeatedly processing three closely related sentences through the MCSE and KDMCSE models, employing various dropout masks to produce diverse representations for each sentence. Subsequently, we normalize the embeddings and apply t-SNE for dimensionality reduction, facilitating a clearer visualization of the data. For each example, we take three captions: two captions are almost similar in semantics (labeled with orange and blue), and the remaining caption (labeled with green) is different from the other two captions.



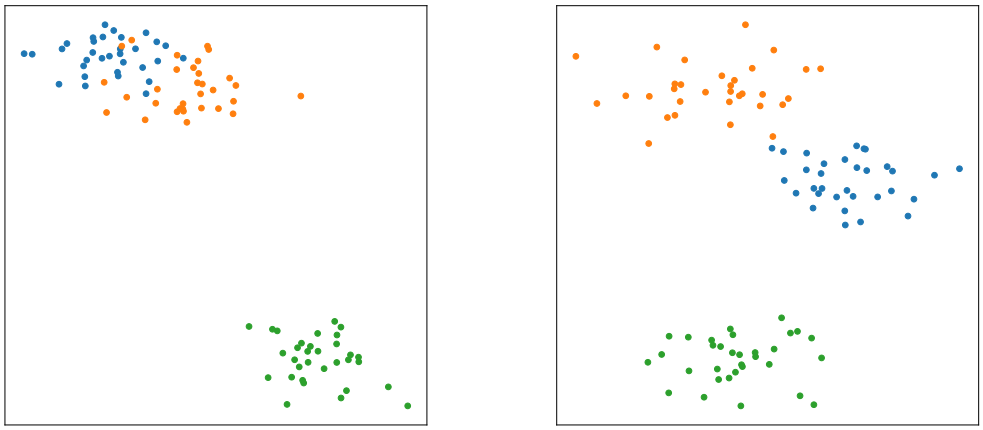
(a) KDMCSE (b) MCSE

Figure 8: Sentence 1: A white and black dog and a brown dog in sandy terrain. Sentence 2: Brown , black and white dog standing on a sandy slope. Sentence 3: Two girls stand up against a red wall.



(a) KDMCSE (b) MCSE

Figure 9: Sentence 1: An elderly man holding a pitchfork and doing some yard work. Sentence 2: An old bearded man is tilling the soil with a simple wooden plow , with a wooden fence and an old barn in the background. Sentence 3: A man in a red shirt is performing an aerial trick with a skateboard on a sidewalk.



(a) KDMCSE (b) MCSE

Figure 10: Sentence 1: A person wearing a blue shirt , rides a white horse along a dusty country road. Sentence 2: A man in a blue tee-shirt , wearing a cap , is riding a white horse down a dirt road , in a rural setting of grass and hills. Sentence 3: A man climbing a mountain.

(a) KDMCSE (b) MCSE

Figure 11: Sentence 1: A dog is jumping into a swimming pool after a duck. Sentence 2: A dog is jumping into a pool to get a duck floating there. Sentence 3: A white curly-haired dog runs with a stick in its mouth.

Abstract

In this project, we demonstrate that phoneme-based models for speech processing can achieve strong crosslinguistic generalizability to unseen languages. We curated the IPAPACK, a massively multilingual speech corpora with phonemic transcriptions, encompassing 115 languages from diverse language families, selectively checked by linguists. Based on the IPAPACK, we propose CLAP-IPA, a multilingual phoneme-speech contrastive embedding model capable of open-vocabulary matching between arbitrary speech signals and phonemic sequences. The proposed model was tested on 95 unseen languages, showing strong generalizability across languages. Temporal alignments between phonemes and speech signals also emerged from contrastive training, enabling zeroshot forced alignment in unseen languages. We further introduced a neural forced aligner IPA-ALIGNER by finetuning CLAP-IPA with the Forward-Sum loss to learn better phone-to-audio alignment. Evaluation results suggest that IPA-ALIGNER can generalize to unseen languages without adaptation.

1 Introduction

The diversity of human speech presents a formidable challenge to multilingual speech processing systems. Recently, accumulating evidence indicates that scaling up the multilingual data can tremendously improve the performance of multilingual speech processing (Conneau et al., 2020; Babu et al., 2021; Radford et al., 2023; Pratap et al., 2023). However, it remains incredibly difficult, if not impossible, to gather large-scale data from every language in the world. It is becoming increasingly critical to develop speech processing systems that generalize to arbitrary unseen languages.

Despite the seeming diversity, sounds of human speech are highly constrained by the anatomical structure of the human vocal tract, which is universally shared by all humans (Gick et al., 2013). Typological research has also shown that most, if not all, human speech can be represented by around 150 phonemes and diacritics (Moran et al., 2014; Gordon, 2016). The limited degrees of freedom in human articulation have enabled phoneticians and linguists to craft universal symbolic representations of human speech, that is, the **International Phonetic Alphabet (IPA)** (International Phonetic Association, 1999).

Prior studies have shown that phoneme-based ASR models generalize to unseen languages (Li et al., 2020; Xu et al., 2022; Glocker et al., 2023). In this project, we aim to provide yet another positive answer to this central question: **can we build multilingual speech processing systems that generalize to arbitrary languages through the use of universal IPA symbols?** Specifically, we focus on two classic tasks in speech processing, **key word spotting (KWS)** and **forced alignment**. KWS is a task of identifying specific keywords in streaming speech, whereas forced alignment refers to aligning intervals of a speech signal to a given sequence of phonetic symbols. Both tasks are relevant in many practical applications such as voice assistant, speech synthesis, language documentation, etc. Yet neither task has been tackled with general systems that generalize to all languages.

This study represents an attempt to build cross-linguistically generalizable systems for KWS and forced alignment. First, we present the IPAPACK, a multilingual speech corpora in 115 languages with phonemic transcriptions, totaling over 1000 hours and carefully checked by trained linguists. Secondly, with the IPAPACK, we proposed Contrastive Language-Audio Pretraining with International Phonetic Alphabet (CLAP-IPA), a phoneme-to-speech retrieval model with contrastive pretraining on phoneme-speech pairs. Evaluations on 95 unseen languages suggest that CLAP-IPA is capable of performing zero-shot open-vocabulary KWS in any language without adaption, including lan-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 750–772
June 16-21, 2024 ©2024 Association for Computational Linguistics

guages not seen during training.

Thirdly, we also introduce a multilingual forced alignment model, IPA-ALIGNER, that works for arbitrary languages. We noticed that alignments between phonemes and speech signals emerge from CLAP-IPA, even with only sequence-level contrastive learning. Crosslinguistic zero-shot forced alignment can be achieved with CLAP-IPA. After finetuning CLAP-IPA with an alignment loss, we propose IPA-ALIGNER that can provide crosslinguistic word-level and phone-level alignment generalizable to unseen languages. Finally, our analysis indicates that phonemes, being shared across all languages, enhance knowledge transfer within training data, serving as more effective modeling units than texts in current multilingual tasks.

We envision that our dataset and models will benefit more downstream tasks and applications in multilingual speech processing. To facilitate future research, we will release our dataset, scripts, and pre-trained models at: https://github.com/lingjzhu/clap-ipa.

2 Backgrounds

2.1 Spoken keyword detection and retrieval

Most research in keyword spotting focuses predominantly on English (e.g., Chen et al., 2014; Tang and Lin, 2018; Rybakov et al., 2020; Berg et al., 2021). In recent years, there has been increased interest in building multilingual keyword detection systems that can adapt to new words or new languages through few-shot learning (Mazumder et al., 2021a; Lei et al., 2023; Reuter et al., 2023). While texts are the primary modeling units in most systems, studies are showing the effectiveness of using IPA symbols to achieve open-vocabulary generalization (Tanaka et al., 2001; Shin et al., 2022; Lee and Cho, 2023; Reuter et al., 2023).

Another approach for keyword matching is based on contrastive learning frameworks, notably CLAP (Wu et al., 2023) and the subsequent CLARA (Noriy et al., 2023). Contrastive learning also enables keyword retrieval systems based on semantics rather than the surface acoustic form (Duquenne et al., 2021; Khurana et al., 2022; Zhu et al., 2022a). The contrastive learning paradigm has also been applied successfully to build open-vocabulary KWS systems (Nishu et al., 2023).

Nevertheless, existing multilingual KWS systems face limitations in terms of limited supported languages, and cannot achieve zero-shot adaptation. Built on these prior efforts, we scaled up the phoneme-based open-vocabulary KWS models to more languages to achieve crosslinguistic generalization.

2.2 Forced alignment

Forced alignment is another classic task in speech processing for segmenting speech into utterances, words, or phonemes. It is widely used for downstream tasks where phone or word durations are needed, including speech synthesis, speech assessment, language documentation, and speech corpora construction. Currently, some of the most popular forced alignment systems are still based on Hidden Markov Models (HMM), including the Montreal Forced Aligner (MFA) (McAuliffe et al., 2017), WebMAUS (Kisler et al., 2012) and Forced Alignment and Vowel Extraction (FAVE) (Rosenfelder et al., 2011). Recently, since neural networks gradually dominate speech processing, research in performing forced alignment with deep neural models is also gaining momentum (Kelley and Tucker, 2018; Kürzinger et al., 2020; Schulze-Forster et al., 2020; Teytaut and Roebel, 2021; Teytaut et al., 2022; Zhu et al., 2022c). Neural models usually exhibit stronger performance over HMM-based systems. However, forced alignment systems are mostly set up to work in monolingual settings. Scant attention has been paid to the building of multilingual forced alignment systems that can work for multilingual languages simultaneously.

3 Dataset curation

Most speech corpora are distributed as audio-text pairs. In comparison, phonemically transcribed speech corpora are rare. Unlike text transcription, transcribing speech signals into IPA, or phonemic transcriptions often require years of expertise in phonetics, making it hard to create high-quality phonemic datasets at scale. However, these IPA symbols provide a universal representation of speech sounds such that any language can be transcribed symbolically. So IPA symbols can be used as a proxy to train multilingual speech processing systems. As a first step, we created large-scale phonemic transcriptions for public speech corpora, encompassing 115 languages across language families. The transcription can be automated through **grapheme-to-phoneme conversion (G2P)**, a process of converting orthographic transcriptions into phonemic transcriptions through pronunciation dictionaries and/or statistical models.

	Train (hrs)	Dev (hrs)	Test (hrs)	Total (hrs)	Languages	Avg. Dur (hrs)

Table 1: Descriptive statistics of the IPAPACK and a selected subset of VoxCommunis (Ahn and Chodroff, 2022).

3.1 Phonemic transcriptions

We primarily made use of three existing multilingual speech datasets, FLEURS (Conneau et al., 2023), Multilingual Spoken Words Corpus (MSWC) (Mazumder et al., 2021b) and DoReCo (Paschen et al., 2020).

FLEURS We used two multilingual G2P systems, Epitran (Mortensen et al., 2018) and CharsiuG2P (Zhu et al., 2022b), to create phonemic transcriptions. As these two systems cover an overlapping but slightly different set of languages, combining them allowed us to maximize the diversity of languages. Before preprocessing, we removed any texts with Arabic numbers or code-switching, as G2P systems cannot process them correctly.

Yet some Asian languages do not explicitly mark word boundaries with spaces. For Mandarin Chinese, G2PW (Chen et al., 2022) was used to create the Pinyin romanizations, which were then mapped to IPA symbols. For Thai, we used PyThaiNLP (Phatthiyaphaibun et al., 2016) to perform word segmentation and G2P. For Japanese, the word segmentation was first performed with Fugashi (McCann, 2020) before G2P was applied.

MSWC As MSWC is a word-level speech corpus, creating phonemic transcriptions was straightforward. CharsiuG2P and Epitran were deployed to transcribe the orthographic words to phonemic sequences. To strike a balance between diversity and quantity, we limited the maximum frequency to 50 to prevent high-frequency words from dominating the dataset. For words with more than 50 samples, only 50 of them will be randomly selected from the pool. After filtering, we ended up with 2.3 million spoken words, amounting to around 613 hours.

DoReCo The original DoReCo data were distributed as hour-long recordings, so we segmented them into individual utterances based on the sentence boundaries in the provided annotations. For DoReCo, all languages were transcribed as phonemes using X-SAMPA (Wells, 1995) notations. We simply converted the X-SAMPA transcription to IPA symbols, as there is a one-to-one mapping between these two systems. Utterances with incomplete transcriptions or loud background noises were discarded.

3.2 Dataset validation

As G2P systems are based on rules or pronunciation dictionaries, they reflect how a word **should** be pronounced rather than how a word **is** pronounced. Given the high variability (e.g., phonetic reduction, coarticulation) in speech signals, it is not always possible for the G2P phonemic transcriptions to exactly match the audio. We were aware that a true transcription does not always exist for every utterance (Ladefoged and Halle, 1988; Ladefoged, 1990). Even trained phoneticians often disagree on the phonemic transcriptions of the same utterance, due to factors including psycho-acoustic constraints, phonetic training, and their mother tongue (Pitt et al., 2005; Heselwood, 2013).

Two authors (trained phoneticians) listened to at least ten random samples in each language to determine the transcription quality. We applied a relatively relaxed standard for the generated transcriptions: as long as the speech signal approximately matches more than 80% of the transcription, it is considered valid. While we made our best efforts to validate the transcription quality, we acknowledge that there are still transcription errors in the dataset. A summary of the IPAPACK is presented in Table 1. To augment our current dataset, we also included a filtered subset of VoxCommuis Corpus (Ahn and Chodroff, 2022), which is a multilingual speech corpora created in a similar workflow, though with slightly different pronunciation dictionaries and G2P tools. Detailed information on individual languages of the VoxCommuis Corpus is at Appendix A

4 Method

4.1 Contrastive learning for KWS

Here we adopt the same contrastive learning framework as CLAP (Wu et al., 2023), as it has been

proven to be one of the most effective strategies for learning high-quality cross-modal representations. There are two separate encoders to process phoneme sequence $\mathbf{P} \in \mathbb{R}^{N\times 1}$ and speech MFCC features $\mathbf{S} \in \mathbb{R}^{T\times K}$, transforming them into phoneme embedding and speech embedding. In this study, we use the **SigLIP loss**, a simpler sigmoid-based loss that is shown to be as effective as the softmax-based CLIP loss (Zhai et al., 2023). Given two normalized embeddings $\boldsymbol{x}_i \in \mathbb{R}^D = f_S(\mathbf{P}_i)$ and $\boldsymbol{y}_i \in \mathbb{R}^D = f_T(\mathbf{S}_i)$, it is defined as follows.

$$\mathcal{L} = -\frac{1}{|\mathcal{B}|}\sum_{i=1}^{|\mathcal{B}|}\sum_{j=1}^{|\mathcal{B}|}\underbrace{\log\frac{1}{1+e^{z_{ij}(-t\mathbf{x}_i\cdot\mathbf{y}_j+b)}}}_{\mathcal{L}_{ij}} \quad (1)$$

where t and b are learnable parameters that were updated during training. z_{ij} is the ground truth label, $z_{ij} = 1$ for positive pairs and $z_{ij} = -1$ for negative pairs. Following the recommendation by Zhai et al. (2023), we initialized $t = \log 10$ and $b = -10$.

Speech encoder The speech encoder has the same transformer encoder architecture as the Whisper's encoder. The weights were initialized with Whisper's pre-trained encoder weights, whereas the decoder was discarded. The original Whisper encoder does not accept attention masks, but these padding tokens can bias the model during pooling. So attention masks were also passed to the speech encoder and the final fixed-dimensional embedding through mean pooling on non-padded hidden states. For speech data augmentation, SpecAugment (Park et al., 2019) was applied during training using the default hyperparameters in Whisper training.

Phoneme tokenizer We trained a specialized tokenizer to encode all base IPA symbols and diacritics, including tonal notations, stress marks, and tie bars for affricates. Upon inspection, we noticed that the IPA transcriptions were inconsistent across languages. For example, tie bars were inconsistently labeled (e.g., [tʃ] vs. [t͡ʃ]) and stress marks tend to be a language-specific phenomenon (Gordon and Roettger, 2017). Yet we did not perform normalization on these idiosyncratic labels to preserve the diversity of our data. The phoneme tokenizer was trained using the unigram algorithm (Kudo, 2018) with `sentencepiece` package [1]. The tokenizer was trained on all phonemic transcriptions in our datasets, with a vocabulary of 450 and byte-fallback for unknown characters.

Phoneme encoder For the phoneme encoder, we used the BERT architecture (Devlin et al., 2019) with mean pooling of the final hidden states as the fixed-dimensional representation. The phoneme encoder was pre-trained on a corpus of phonemic transcriptions using standard masked language modeling (MLM) as detailed in (Devlin et al., 2019). Given that phoneme sequences are of less complexity than texts, the masking probability was set to 30%. The training data were pooled from diverse sources, including the IPAPACK, pronunciation dictionaries in CharsiuG2P (Zhu et al., 2022b), and Vox Communis (Ahn and Chodroff, 2022). The final pretraining corpus consists of 11 million samples in more than 110 languages. We pre-trained three phoneme encoders of different sizes, matching hyperparameters including the number of layers, hidden dimensions, and the number of attention heads to the corresponding Whisper encoder (`tiny`, `base` and `small`).

4.2 Forced alignment

We noticed that phoneme-to-speech alignment emerged from CLAP-IPA on the pairwise cosine similarity matrix computed with the token-wise hidden states of phone and speech encoders. We introduce a simple algorithm to derive the alignment between phonetic units and speech signals, with control over the temporal resolution of speech frames and the granularity of phonetic sequences.

Adaptive average pooling While we expect the forced aligned units to be natural phonetic units like phonemes and words, due to tokenization, the hidden states of phone encoders correspond to a character or byte unit rather than a natural phonetic unit. A sequence of phonemes or words of length N' might be tokenized into a character or byte sequence of length $N, N \geq N'$. We define an adaptive average-pooling mask $\mathbf{M}_p \in \mathbb{R}^{N'\times N}$ to downsample the hidden representations. Through this pooling mask, consecutive hidden states belonging to one phoneme or one word were averaged to one fixed dimensional vector, such that each output hidden state after pooling corresponds to a natural phonetic unit (see Fig 1). This ensures that our forced alignment algorithm works for any level of phonetic units.

We can also define a similar adaptive average-

[1] https://github.com/google/sentencepiece

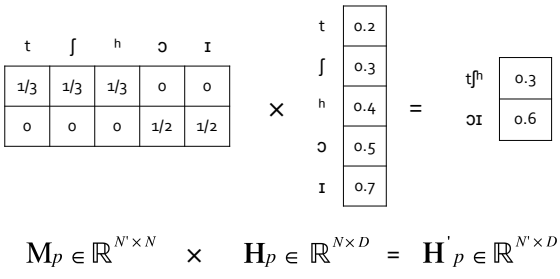

Figure 1: Illustration of adaptive average-pooling of phoneme representations, $\mathbf{M_p H_p} = \mathbf{H'_p}$.

pooling mask for speech representations $\mathbf{M}_s \in \mathbb{R}^{T' \times T}$ to downsample them from length T to T'. For word-level alignments that don't require high temporal resolution, we can compress the length of the speech hidden states by controlling the pooling window length and frameshift.

Zeroshot forced alignment Given two sequences of hidden states $\mathbf{H}_s \in \mathbb{R}^{T \times D}$ and $\mathbf{H}_p \in \mathbb{R}^{N \times D}$ produced by the speech encoder and phone encoders, adaptive average-pooling masks $\mathbf{M}_p \in \mathbb{R}^{N' \times N}$ and $\mathbf{M}_s \in \mathbb{R}^{T' \times T}$ are used to transform them into more compact representations $\mathbf{H'_s} \in \mathbb{R}^{T' \times D}$ and $\mathbf{H'_p} \in \mathbb{R}^{N' \times D}$.

$$\mathbf{H'_s} = \text{Normalize}(\mathbf{M_s H_s}, \text{dim=-1})$$
$$\mathbf{H'_p} = \text{Normalize}(\mathbf{M_p H_p}, \text{dim=-1})$$
$$\mathbf{D} = \mathbf{H'_s H'^{\top}_p} / \tau$$

where τ is the fixed temperature parameter and was set to 0.05 by default. The pairwise similarity matrix $\mathbf{D} \in \mathbb{R}^{T' \times N'}$ is used to derive the temporal monotonic alignment between phonetic units and speech frames through **dynamic time warping (DTW)**, even if CLAP-IPA had never between trained on alignment labels.

Finetuning To further enhance the performance of forced alignment, we introduce IPA-ALIGNER by finetuning CLAP-IPA with the **Forward-Sum Loss**, which has been shown to be effective in learning monotonic alignments between speech and phonemes (Shih et al., 2021; Badlani et al., 2022; Zhu et al., 2022c).

$$\mathcal{L} = \mathcal{L}_{ForwardSum}(\mathbf{D})$$

This alignment learning loss function relies on the forward-sum algorithm in classic HMMs to maximize the likelihood of text sequence given speech sequences, while enforcing the monotonic constraint of alignment (see Shih et al. (2021) for detailed derivations). The Forward-Sum loss requires a good prior alignment to converge to meaningful results, so we did not report failure results from randomly initialized models.

During finetuning, we only average-pooled the phoneme representations at the phoneme and kept the original speech representations (by setting $\mathbf{M}_s$ to the identity matrix $\mathbf{I}$). In inference, for phoneme alignment, we pooled the phoneme representations at the phoneme-level and kept the original speech representations. For word alignment, the phoneme representations were pooled at the word-level and the speech representations were average-pooled with a window length of 3 and a frameshift of 2.

5 Experiments

5.1 Training details

We trained three variants of models, CLAP-IPA-tiny, CLAP-IPA-base and CLAP-IPA-small, all of them were matched to the default encoder parameters of Whisper (Radford et al., 2023). The speech encoder and phoneme encoder were symmetric. Our training dataset included the training set of IPAPACK plus the VoxCommunis speech corpora (Ahn and Chodroff, 2022). By default, all models were trained with paired speech recordings and their phonemic transcriptions. For IPA-ALIGNER, we finetuned CLAP-IPA-tiny, CLAP-IPA-base and CLAP-IPA-small on the same data excluding MSWC-IPA. All detailed hyperparameters can be found in Appendix B.

For controlled comparison, we also trained two base models, CLAP-IPA-TEXT and CLAP-IPA-PHONE on the same FLEURS-IPA and MSWC-IPA subset either with only phonemic or text transcriptions. These two models were matched in total parameters, training data, and all other hyperparameters during training. In another controlled experiment, we trained CLAP-IPA-FLEURS and CLAP-IPA-VC either only on the FLEURS-IPA or the VoxCommunis, which would allow us to examine the impact of data size and language diversity.

5.2 Evaluation datasets

We evaluated the crosslinguistic generalizability of our models on several evaluation datasets covering a wide range of topologically diverse languages. Whenever possible, we made our best effort to include baseline models to contextualize our model performance. This was not always possible, because evaluating multilingual KWS and multilingual forced alignment on unseen languages are new tasks and in some cases we were not able to find

Table 3: Evaluation results on unseen languages.

open-source models for comparison. However, we hope that our models and results will become a baseline that spur more future research in this direction.

Libriphrase To compare with existing models, we first tested on a popular English KWS dataset, Libriphrase (Shin et al., 2022), as an out-of-domain evaluation dataset, since our models were not trained on their training sets. We used **Equal Error Rate (EER)** and the **Area under Curve (AUC)** scores to compare model performance, consistent with prior studies.

Unseen languages We also evaluated all models on five unseen languages with typological diversity from FLEURS-IPA and MSWC-IPA. We isolated five language from MSWC-IPA and FLEURS-IPA, namely, Vietnamese (`vie`), Tamil (`tam`), Hausa (`hau`), Georgian (`geo`) and Odia (`ori`). For FLEURS-IPA, the test sets of these five languages were directly used. However, for MSWC-IPA, due to data scarcity, we pooled all training, validation, and tests of these five languages together to form a larger and more challenging benchmark. We further evaluated 95 (81 unseen) languages from the UCLA phonetic Corpus (Li et al., 2021) and 14 unseen languages from DORECO-IPA. **Hit@1** and **Mean Average Precision (mAP)** were used to measure the cross-linguistic retrieval performance of all models. To avoid duplication, we only reported results on phoneme-to-speech retrieval, as the results of speech-to-phoneme and speech-to-speech retrieval were in the same range.

Word and phoneme boundaries To evaluate the performance of forced alignment, we made use of **F1** and **R-Value**, which were used in prior studies (Räsänen et al., 2009; Kreuk et al., 2020; Zhu et al., 2022c). If the predicted boundary is within the tolerance interval of the true boundary, it is considered a hit, otherwise a miss. Since each boundary marked the onset and the offset of consecutive phones, we only evaluated the phone onsets with a tolerance of 20ms and word onsets with a tolerance of 100ms. We used TIMIT (Garofolo et al., 1993) as the English benchmark. DORECO-IPA also contains phoneme-level and word-level alignments, so we partitioned the DORECO-IPA into seen and unseen evaluation sets. Yet IPA-ALIGNER was never trained on any segmentation labels.

6 Results

In this section, we summarize the main results for KWS and forced alignment.

KWS Evaluation results in Table 2 suggests that CLAP-IPA performs on par with the state-of-

Table 4: Evaluation of forced alignment on TIMIT. Baseline results were retrieved from Zhu et al. (2022c). The temporal resolution is 10ms for FAVE, MFA, Gentle, and WebMAUS and 20ms for the rest of the models.

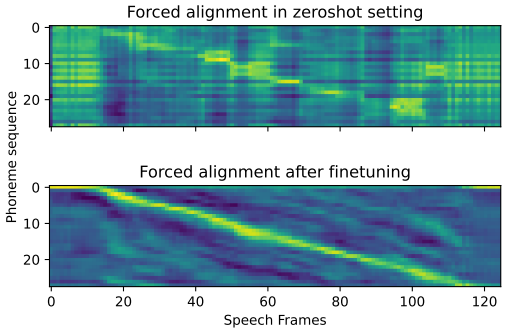

Figure 2: Illustration of forced alignment in an Evenki utterance. CLAP-IPA exhibits vague monotonic alignment without finetuning (**Top**). After finetuning, IPA-ALIGNER learns salient monotonic alignment between speech and phonemes (**Bottom**).

the-art models on LibrisPhrase-Easy, while not trained on the Libriphrase training set. Yet CLAP-IPA failed to outperform state-of-the-art CED (Nishu et al., 2023) in LibriPhrase-Hard, suggesting that language-specific finetuning is still necessary to maximize performance. Generally speaking, phoneme-based models are more effective than text-based models.

For unseen languages, Table 3 indicates that phoneme-based models do generalize successfully to unseen languages across datasets. In contrast, the text-based model performs poorly in unseen languages, suggesting that orthographic texts are not very useful for crosslinguistic speech processing. Utterance-level retrieval appears to be much easier than word-level retrieval, a pattern quite consistent across datasets. Model size correlates with performance in seen languages but not with crosslinguistic generalizability.

Forced alignment While not trained on forced alignment explicitly, CLAP-IPA shows some capabilities for crosslinguistic forced alignment even in zero-shot predictions on both seen and unseen languages (see Table 4 and Table 5). After finetuned with the ForwardSum loss, IPA-ALIGNER can perform competitively in English with some widely used HMM-based forced aligners, even though TIMIT was not part of its training dataset. For low-resource languages, IPA-ALIGNER also achieves good performance, regardless of whether the language has been seen during training or not.

7 Discussions

In this section, we provide more in-depth answers to our research questions with the major findings of our experiments.

Can phoneme-based models generalize cross-linguistically? The evaluation results for CLAP-IPA and IPA-ALIGNER in Table 3 and Table 5 indicate that phoneme-based model exhibits strong generalization capabilities cross-linguistically in both KWS and forced alignment, even to unseen languages in zero-shot predictions.

Generally speaking, all CLAP-IPA models perform better on utterance-level datasets (FLEURS-IPA and DORECO-IPA) than on word-level datasets (MSWC-IPA and UCLA Phonetic Corpus), because the longer the phoneme sequence, the more likely that it is distinct in a pool of candidates. For utterance-level datasets, CLAP-IPA models achieve near-perfect scores on unseen languages (see Table 3), indicating that phonemic representations do enable cross-linguistic generalization.

Table 6 shows that the similarity assigned by CLAP-IPA-small was highly consistent with human perception. The top-ranked crosslinguistic candidates were extremely similar in articulatory features and syllable structure to the query.

For forced alignment, even the zero-shot predictions using CLAP-IPA can perform segmentation in unseen languages, especially at the word level. Interestingly, there were no significant differences between performance over seen and unseen languages. Though this result could be biased by the

Table 5: Evaluation of forced alignment on DORECO-IPA. The word boundary metrics were calculated with 100ms tolerance, whereas the phone boundary was computed with 20ms tolerance.

Query	Output Type	Retrieved candidates (ranked from high to low)
étá	Most similar	ètá, éta, lāta, étá, ìtà, aitːa, mètá, meta̱, p͡tá, aita, ètɛ́, atˢa, àtá, eitə
	Most dissimilar	bɔ̃ti, tʲuːriʃ, sorŋgi, aβuˈru, mbúruù, sumbuŋ, buluz, ʃiʒìʒ, tʃungu

Table 6: Sample ranked phonemic sequences by CLAP-IPA-small, given the speech query [étá].

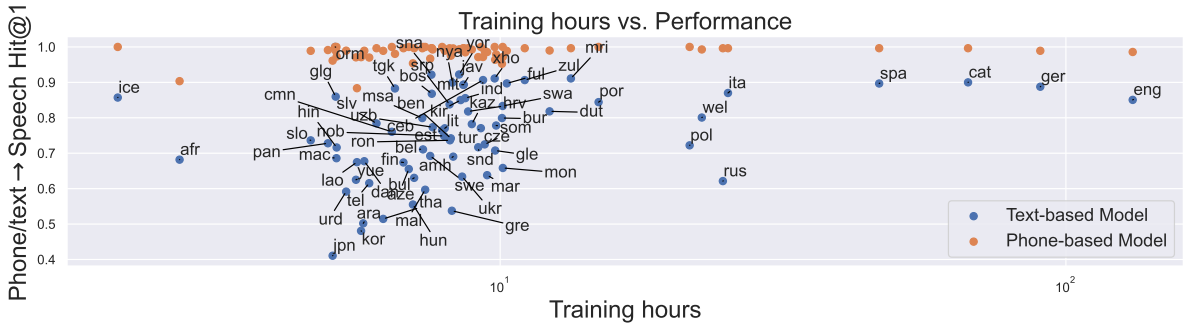

Figure 3: Correlation of model performance on individual languages with training hours by language. Languages are represented by their ISO 639-3 codes. While trained the exact same data, the phoneme-based model outperforms the text-based model in every single language, suggesting that phoneme-based modeling enables knowledge transfer across languages.

smaller number of unseen languages compared to seen languages (14 vs. 30), it still suggests that IPA-ALIGNER can perform crosslinguistic forced alignment without much adaptation. Finetuning the IPA-ALIGNER brings continued improvement over the zero-shot scenarios (see Fig 2).

Does the phoneme-based model generalize better cross-linguistically than the text-based model? Text-based models are struggling to generalize to unseen languages, as these unseen languages have their distinct writing systems (e.g, Vietnamese and Tamil) that are not seen in training languages. Comparison between the text-based and phoneme-based models in Table 2 and Table 3 clearly shows that it is the use of phonemes as modeling units that brings strong crosslinguistic generalizability, since they can represent all languages using the same set of symbols.

Do the training hours of individual languages predict the performance of multilingual models? The number of training hours for individual languages does not predict the performance of language in phoneme-based models. All languages benefit from the multilingual knowledge transfer in phoneme-based modeling.

It has been reported that there is a strong correlation between text-based multilingual ASR performance in individual languages and their training hours (Radford et al., 2023; Rouditchenko et al., 2023). We also confirm that, for text-based models, there is a moderate correlation between Hit@1 and the number of training hours (Spearman's ρ : 0.42;

$p \leq 0.0002$). However, this correlation was not significant for the phoneme-based model (Spearman's $\rho : 0.14$; $p = 0.22$). In Figure 3, the phoneme-based model outperforms the text-based model in every language by a large margin, especially for languages with less training data.

Since the orthography varies across languages and is usually not an accurate reflection of pronunciation, many low-resource languages are not reaping the full benefits of large-scale multilingual data in this cross-modal task in text-based models. Close inspection shows that the text-based model generalizes well to Hausa (Latin alphabet) but significantly underperforms in languages with non-Latin alphabet, such as Tamil, Vietnamese, Japanese, Arabic, and Cantonese.

In contrast, the phoneme-based model achieves near-perfect performance in retrieval in almost all seen and unseen languages (see Figure 3), making them extremely useful in low-resource and zero-resource scenarios. The efficiency of IPA representations in multilingual settings has also been observed in ASR (Feng et al., 2023).

Does multilingual models always hold advantages over monolingual models? At least in the current study, multilingual models might not hold an apparent advantage over well-engineered monolingual models in high-resource languages. As shown in Table 2 and Table 4, compared to other state-of-the-art KWS and forced alignment models, CLAP-IPA and IPA-ALIGNER was not able to outperform well-engineered monolingual models. Our multilingual models have not been trained on the training set of LibriPhrase or TIMIT, so some of the performance gaps might be caused by domain mismatch. Even with zero adaptations, multilingual models achieve close performance to monolingual models, suggesting that our approach is promising and may reach better results if scaled up.

Should we scale up the number of languages or number of training hours? We compared CLAP-IPA only trained on VoxCommunis (Ahn and Chodroff, 2022) or FLEURS-IPA. VoxCommunis has almost twice as many hours as FLEURS-IPA with roughly half of the languages. In Table 2 and 3, CLAP-IPA-VC trained on more hours of speech generally has similar performance as CLAP-IPA-FLEURS trained on a subset of the IPAPACK across metrics, which suggests that creating high-quality data is effective in achieving good performance. But this finding also suggests that we can achieve good crosslinguistic generalizability with fewer languages but longer hours using phoneme modeling. Given the empirical data distributions in real-life settings, scaling up training hours in a dozen of languages is much easier than scaling up the number of languages. The practical implication is that we might be able to build multilingual speech processing systems for many low-resource or zero-resource languages with large-scale data in a dozen relatively high-resource languages.

Is it feasible to scale up the creation of good-quality phonemic transcriptions in world languages? Despite our attempt, there are still multiple challenges for creating phonemic transcriptions. During our dataset construction, we were unable to process many languages due to the lack of pronunciation dictionaries, text transcriptions, or relevant NLP tools, especially the lack of good word segmentation tools for some East/Southeast Asian languages like Khmer. While available large-scale speech corpora nowadays encompass more than 1000 languages (Salesky et al., 2020; Pratap et al., 2023), textual or phonemic labels cannot be easily obtained for most of them, limiting their usage in many research applications.

Even for high-resource languages, preprocessing multilingual texts and normalizing the Unicode encodings for IPA symbols usually take tremendous effort, not to mention verifying these phonemic transcriptions for audio recordings. It remains unclear how biases or noises in G2P predictions will propagate to downstream multilingual tasks. Our endeavor marks a small step in creating good-quality phonemic transcriptions for more languages. However, there is still much work to be done to include a broader array of languages worldwide and to improve the quality of transcriptions.

8 Conclusions

With the carefully curated IPAPACK, we show that using IPA symbols as modeling units can effectively enable CLAP-IPA and IPA-ALIGNER to generalize to unseen languages, highlighting the benefits of incorporating linguistic knowledge into deep learning methods. We believe that the IPAPACK has great potential to benefit more tasks in multilingual speech processing, such as multilingual phoneme recognition, speech synthesis, and documenting endangered languages. In the future, we will continue to expand our dataset and models to include more diverse languages.

9 Ethical statement

Data Governance We adhered strictly to ethical practices in curating our datasets. The original FLEURS (Conneau et al., 2023), MSWC (Mazumder et al., 2021b), DoReCo (Paschen et al., 2020) and VoxCommunis (Ahn and Chodroff, 2022) corpora are distributed under the Creative Commons licenses. Therefore, we are permitted to re-process and re-distribute the original dataset with proper attributions. Some languages in the DoReCo corpus are under a Creative Commons Non-Commercial license. We reserved these languages to the test set in our corpora, such that our models have not been trained on data under commercially restrictive licenses. As required, we have also cited every individual language from the DoReCo Corpus in Table 11.

Potential Impact We believe that our dataset and models will contribute to the endeavor of building fair and inclusive speech processing systems for all languages and facilitating the documentation of endangered languages. However, we are aware that multilingual keyword-spotting technology could potentially be misused as surveillance tools for monitoring speech recordings in more languages, posing risks to users.

10 Limitations

Our study is still limited in several aspects. First, while we tried our best to inspect a subset of our dataset, it was impossible for us to examine all datasets in great detail. As a result, the constructed dataset might still be flawed in terms of audio quality and transcription quality (and many unicode errors). Secondly, the proposed models are still not optimized in terms of computational efficiency. Since most KWS applications are running on mobile devices with limited computational power, the proposed models still have too many model parameters to run efficiently on mobile devices. Moreover, speech sequences are usually much longer than text sequences. Self-attention with quadratic complexity might not be the most suitable architecture for processing speech. More efforts are needed to make such multilingual models efficient.

Thirdly, the number of languages studied in our paper is still limited and might be biased towards languages that are relatively high-resource. They are not representative of the global language landscape. There are many more low-resource or endangered languages we are not able to include due to the lack of various resources. To promote linguistic inclusion and fairness, we will continue to improve the language diversity of our research in the future.

Acknowledgements

This research was enabled in part through the computational resources and services provided by Advanced Research Computing at the University of British Columbia and in part through the support provided by the Digital Research Alliance of Canada. This study also benefits from the cloud computing credits awarded by Microsoft Azure through a pilot program with UBC Advanced Research Computing.

The authors would like to thank the four anonymous reviewers as well as the area chairs for their thoughtful comments and discussions, which helped improve this article considerably. We thank Emily P. Ahn and Eleanor Chodroff for creating and releasing the VoxCommunis, which inspired our data creation process. Finally, we acknowledge that this work is impossible without the pioneering efforts of many language researchers who collected and shared speech corpora across world languages.

A Dataset statistics

Table 9, 12 , 10, and 11 provide tabulated summaries of the detailed statistics of our curated datasets.

B Training hyperparameters

For pre-training, we trained three variants of BERT from scratch using only phonemic transcriptions. We adopted the AdamW optimizer with an initialized learning rate of $1e-4$ and cosine scheduling with a warm-up step of 1000. All models were trained for 60k iterations before stopping. All training processes were completed on a single V100 GPU of 32 GB.

All hyperparameters for CLAP-IPA models were listed in Table 7. By default, all models were trained on a single V100 with 32GB of memory. The training time for CLAP-IPA in 100k steps ranged from 17 hours for CLAP-IPA-tiny to 41 hours for CLAP-IPA-small.

All hyperparameters for IPA-ALIGNER models were listed in Table 8. All models were trained on a single V100 with 32GB of memory. The training time for IPA-ALIGNER before early stopping ranged from 5 hours for CLAP-IPA-tiny to 12 hours for CLAP-IPA-small.

Hyperparameters	CLAP-IPA-tiny	CLAP-IPA-base	CLAP-IPA-small
Hidden dimensions	384	512	768
Num. Layers	4	6	12
Num. Att. Heads	6	8	12
Intermediate size	1536	2048	3072
Parameters	16M	28.5M	96.2M
Initial learning rate	1e-4		
Scheduler	Cosine Scheduler		
Warm-up steps	500		
Total training steps	100k		
FLEURS-IPA batch size	64	64	32
MSWC-IPA batch size	512	512	256
DORECO-IPA batch size	64	64	32
VoxCommunis batch size	64	64	32
Gradient checkpointing	True		
Mixed Precision	float16		
Max. Gradient Norm for Gradient Clipping	10		

Table 7: Hyperparameters for training CLAP-IPA models.

Hyperparameters	CLAP-IPA-tiny	CLAP-IPA-base	CLAP-IPA-small
Hidden dimensions	384	512	768
Num. Layers	4	6	12
Num. Att. Heads	6	8	12
Intermediate size	1536	2048	3072
Parameters	16M	28.5M	96.2M
Initial learning rate	1e-5		
Scheduler	Cosine Scheduler		
Warm-up steps	100		
Maximum training steps	10k		
batch size	128		
Gradient checkpointing	True		
Mixed Precision	float16		
Max. Gradient Norm for Gradient Clipping	10		
Early stopping	True		
Stopping Criteria	the highest F1 on the TIMIT training set		

Table 8: Hyperparameters for training IPA-ALIGNER models.

Abstract

Gender bias in vision-language models (VLMs) can reinforce harmful stereotypes and discrimination. In this paper, we focus on mitigating gender bias towards vision-language tasks. We identify object hallucination as the essence of gender bias in VLMs. Existing VLMs tend to focus on salient or familiar attributes in images but ignore contextualized nuances. Moreover, most VLMs rely on the co-occurrence between specific objects and gender attributes to infer the ignored features, ultimately resulting in gender bias. We propose GAMA, a task-agnostic generation framework to mitigate gender bias. GAMA consists of two stages: narrative generation and answer inference. During narrative generation, GAMA yields all-sided but gender-obfuscated narratives, which prevents premature concentration on localized image features, especially gender attributes. During answer inference, GAMA integrates the image, generated narrative, and a task-specific question prompt to infer answers for different vision-language tasks. This approach allows the model to rethink gender attributes and answers. We conduct extensive experiments on GAMA, demonstrating its debiasing and generalization ability.[1]

1 Introduction

Vision-language models (VLMs) have attracted significant attention in recent years due to their widespread applications in image captioning (Li et al., 2020; Nguyen et al., 2022), image-text retrieval (Wang et al., 2020; Qu et al., 2021), and visual question answering (Antol et al., 2015; Jiang et al., 2020). Remarkable advancements have been achieved in these tasks, primarily measured by task performance metrics (Radford et al., 2021; Li et al., 2023a). However, there is a growing concern about the undesirable social bias (e.g., gender, race) in VLMs (Hendricks et al., 2018; Ross et al., 2021; Zhang et al., 2022). An example is presented in Figure 1 (bottom), implying stereotypes associating sports with masculinity. More alarmingly, biased VLMs have the potential to propagate and even exacerbate existing stereotypes and inequalities.

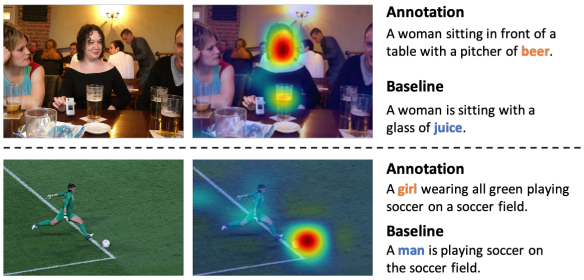

Figure 1: **Examples in image captioning with annotations and captions generated by a baseline model, SAT (Xu et al., 2015).** We overlay images with attention heatmaps of SAT on the right. In the top example, SAT focuses on the woman and predicts "juice", a word highly co-occurring with females. In the bottom example, the gender is incorrectly predicted, as "soccer" highly co-occurs with males in the training set.

Previous methods for mitigating social bias towards vision-language tasks can be grouped into two categories: 1) *task-specific methods* are designed for task-specific datasets and models, which mitigate bias by re-sampling datasets (Zhao et al., 2017; Wang et al., 2021), synthesizing negative samples for training (Hirota et al., 2023), or introducing debiasing modules or training objectives to task-specific models (Hendricks et al., 2018; Tang et al., 2021; Seth et al., 2023); and 2) *task-agnostic methods* aim to pre-train a debiased encoder for downstream tasks, most commonly by adopting an adversarial approach to remove unwanted features (Wang et al., 2019), or leveraging counterfactual samples to minimize biased representations (Zhang et al., 2022). Despite these efforts, task-specific

methods often lack generalization ability, while existing task-agnostic methods primarily address bias at the feature level and fall short of probing the essence of social bias.

In this work, we focus on gender bias as it is a crucial aspect of social bias. To address potential limitations in existing research, our initial step is to explore the essence of gender bias. We posit that gender bias is a manifestation of object hallucination in VLMs (Rohrbach et al., 2018). Specifically, models understand the form rather than the meaning.[2] This leads to a tendency for VLMs to focus on the most salient or familiar objects or attributes but ignore the rest of the image. Moreover, as depicted in Figure 1, VLMs are inclined to hallucinate objects that co-occur with gender words, and vice versa for gender attributes closely associated with specific objects in the training set. As a result, VLMs may generate answers containing objects or gender attributes inconsistent with the given image.

We propose GAMA, a novel task-agnostic generation framework to mitigate gender bias towards vision-language tasks. Unlike previous methods, GAMA is a multi-level method, addressing bias both in external object co-occurrences and in internal bias features. The framework comprises two stages: *narrative generation* and *answer inference*. During *narrative generation*, GAMA creates an all-sided narrative for a given image, which prevents premature focus on localized details. Besides, we disentangle features through contrastive learning (He et al., 2020; Chen et al., 2020) to obfuscate gender information in the generated narratives. This approach helps mitigate the influence of gender attributes on context generation. The trained model can seamlessly adapt to different vision-language tasks for narrative generation without retraining. During *answer inference*, the image, generated narrative, and task-specific question prompt are utilized to derive answers for different tasks. As gender information is obfuscated in generated narratives, the model is encouraged to rethink gender attributes in this stage, which contributes to more appropriate and unbiased answers.

We conduct extensive experiments to demonstrate the effectiveness of GAMA. First, GAMA is evaluated across two vision-language tasks: image captioning and image search. Additionally, zero-shot experiments are performed on two benchmarks for measuring gender bias, namely VisoGender (Hall et al., 2023) and VL-Bias (Zhang et al., 2022). Experimental results show that GAMA performs well against previous debiasing methods on task performance and gender bias mitigation. Notably, GAMA exhibits remarkable generalization ability on both benchmarks. Moreover, we showcase the effectiveness of our proposed modules in reducing object hallucination and gender bias. For further explanation, we probe the connection between object hallucination and gender bias.

[2]Following Bender and Koller (2020), we define *form* as the visible realization of vision and language, such as pixels or bytes in digital representations of text or image, and *meaning* as the relationship between form and external elements to vision and language, like communicative intent.

2 Related Work

2.1 Sources of gender bias

The growing popularity of multi-modality has prompted research into sources of gender bias in vision-language tasks. First, *datasets* are a prominent factor, as object labeling is closely linked to our conceptualization (Brown, 1958). Thus real-life stereotypes subtly infiltrate datasets. Hirota et al. (2022a) and Harrison et al. (2023) highlighted the underrepresentation of women in datasets. Second, *pre-trained VLMs* (PVLMs) have enhanced vision-language tasks by leveraging extensive knowledge from pre-training data. Consequently, PVLMs inherit such bias from both language and vision sources (Wang et al., 2019; Ross et al., 2021; Srinivasan and Bisk, 2022). Third, *model structures* may amplify gender bias in datasets (Zhao et al., 2017). Researchers have observed stereotype exaggeration in various task-specific VLMs (Kay et al., 2015; Bhargava and Forsyth, 2019; Wang et al., 2021).

Given these diverse bias sources, gender bias may not be effectively addressed by merely pre-processing data or debiasing pre-training features.

2.2 Gender bias mitigation

Research interest in gender bias mitigation for vision-language tasks has notably increased. Previous studies addressed gender bias in unimodal models, such as language (He et al., 2022; Shaikh et al., 2023) or vision (Wang et al., 2019; Steed and Caliskan, 2021). Zhou et al. (2022) uncovered both intra-modal and inter-modal gender bias. Previous work on gender bias mitigation for VLMs can be divided into three classes: 1) *adding debiasing modules to existing task-specific VLMs*, which aims to pre-process imbalanced training sets (Zhao et al.,

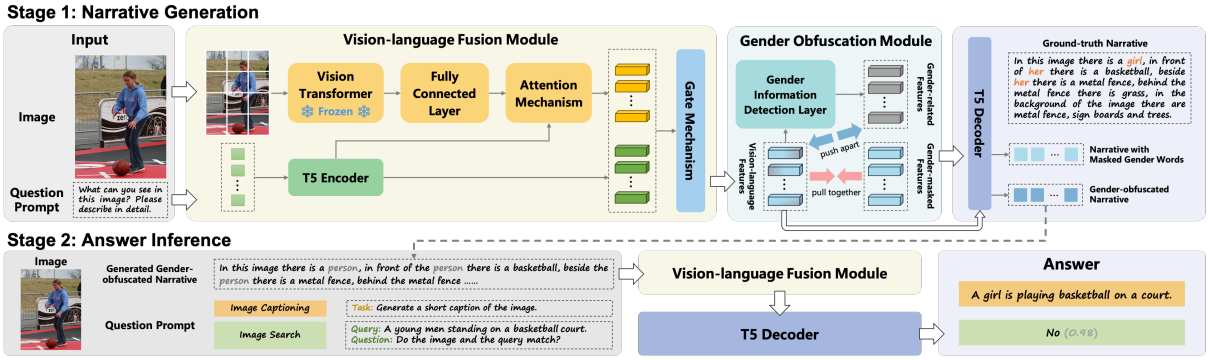

Figure 2: **The overall framework of GAMA.** We briefly provide task-specific question prompts and answers, which are detailed in Appendix C. We take the token probability of the decoder as the match score in image search.

2017), process intermediate features (Hendricks et al., 2018; Wang et al., 2021), or post-process biased model outputs (Hirota et al., 2023; Janghorbani and De Melo, 2023); 2) *re-designing training objectives of PVLMs* to produce debiased features through negative (Wang et al., 2019) or counterfactual (Zhang et al., 2022) samples; and 3) *proposing new model structures* designed to learn fair representations by capturing gender visual evidence (Tang et al., 2021), or adding a negative residual (Seth et al., 2023). However, previous studies superficially address gender bias by removing biased data or features and ignore the correlation between gender bias and object hallucination.

2.3 Object hallucination

Despite the great success of VLMs in vision-language tasks, they still suffer from object hallucination. Object hallucination refers to the fact that the content generated by the model contains objects inconsistent with or absent from the given image (Rohrbach et al., 2018). Rohrbach et al. (2018) proposed two metrics, CHAIRs and CHAIRi, to measure object hallucination. A recent approach, POPE (Li et al., 2023b), is a polling-based query method with enhanced flexibility. Efforts to mitigate object hallucination in VLMs fall into two categories. Some methods aim to disentangle object co-occurrence patterns. For instance, Biten et al. (2022) introduced object labels and altered objects in the captions, while Zhou et al. (2023) replaced error-prone objects with placeholder tags. Others focus on minimizing logical errors, such as leveraging chain-of-thought (CoT) prompting to generate intermediate reasoning chains as rationales (Zhang et al., 2023).

3 Method

In this section, we will first overview the framework of GAMA and then introduce the training data. Finally, we detail our model architecture.

3.1 Overview

GAMA is composed of two stages: narrative generation and answer inference, as illustrated in Figure 2. During narrative generation, GAMA takes an image and a question prompt as input to yield an all-sided but gender-obfuscated narrative. During answer inference, different vision-language tasks are formulated as generation tasks. GAMA utilizes the image, generated narrative, and task-specific question prompt to generate a task-specific answer. We formulate both stages as taking an image I and a text sequence $X = [x_1, x_2, \cdots, x_n]$ with n tokens as input and outputting a target sequence $Y = [y_1, y_2, \cdots, y_m]$ with m tokens.

The models in the two stages are trained independently. The trained narrative generation model can be applied to different tasks without retraining.

GAMA comprises three key modules: a vision-language fusion module to extract features in both stages, a gender obfuscation module to mask gender-related information during narrative generation, and a decoder for answer generation.

3.2 Training data

During narrative generation, GAMA strives to generate an all-sided narrative for the given image to avoid premature focus on localized details. To this end, we train the model with the Localized Narratives dataset (Voigtlaender et al., 2023) for Open Images (Kuznetsova et al., 2020). The dataset is crafted to depict image regions covered by a mouse trace, associating specific image regions with spe-

cific words in the narrative. Consequently, the narratives are spread throughout the entire image, rather than confined to specific localized regions.

3.3 Vision-language fusion module

The vision-language fusion module is designed to learn vision-language representations in two stages.

Encoder We use the T5 (Raffel et al., 2020) encoder to learn language representations, and a Vision Transformer (ViT) (Dosovitskiy et al., 2020) to extract vision features:

$$\mathbf{H}_l = \text{T5Encoder}([x_1, x_2, \cdots, x_n]), \quad (1)$$

$$\mathbf{H}_v = \mathbf{W}_1 \text{ViT}(I), \quad (2)$$

where $\mathbf{H}_l, \mathbf{H}_v \in \mathbb{R}^{n \times d}$, and d is the hidden dimension. $\mathbf{W}_1$ is a projection matrix to convert the shape of features extracted by the ViT. Notably, the parameters of the ViT are frozen.

Feature fusion We utilize an attention mechanism (Vaswani et al., 2017) to capture the interactions between language and vision features:

$$\hat{\mathbf{H}}_v = \text{Attention}(\mathbf{H}_l, \mathbf{H}_v, \mathbf{H}_v). \quad (3)$$

We aggregate $\mathbf{H}_l$ and $\hat{\mathbf{H}}_v$ with a gate mechanism (Li et al., 2022a; Fang and Feng, 2022). The gate λ and the fused features $\mathbf{H}$ are calculated as:

$$\lambda = \text{Sigmoid}(\mathbf{W}_2\mathbf{H}_l + \mathbf{W}_3\hat{\mathbf{H}}_v), \quad (4)$$

$$\mathbf{H} = (1 - \lambda) \cdot \mathbf{H}_l + \lambda \cdot \hat{\mathbf{H}}_v, \quad (5)$$

where $\mathbf{W}_2$ and $\mathbf{W}_3$ are trainable parameters.

3.4 Gender obfuscation module

The gender obfuscation module is employed during narrative generation to obfuscate gender information in narratives. This module prevents the model from biasing the context due to gender attributes.

Pre-processing First, we replace gender words with a special token `[GENDER]` and leave other words unchanged to obtain a narrative with masked gender words $\bar{Y} = [\bar{y}_1, \bar{y}_2, \cdots, \bar{y}_m]$.[3]

Gender information detection Then we construct the gender-masked features $\bar{\mathbf{H}}$. We detect gender-related features $\mathbf{H}_g$ and remove them from the vision-language features $\mathbf{H}$ as follows:

$$\mu = \text{Sigmoid}(\mathbf{W}_4\mathbf{H}), \quad (6)$$

$$\mathbf{H}_g = \mu \cdot \mathbf{H}, \quad (7)$$

$$\bar{\mathbf{H}} = \mathbf{H} - \mathbf{H}_g, \quad (8)$$

where $\mathbf{W}_4$ is a trainable parameter.

Contrastive loss Motivated by contrastive learning (He et al., 2020; Chen et al., 2020), we employ a contrastive loss to keep the vision-language features $\mathbf{H}$ close to the gender-masked features $\bar{\mathbf{H}}$ and away from the gender-related features $\mathbf{H}_g$. This approach helps obscure gender details as well as preserve context information. We define our contrastive loss as:

$$\mathcal{L}_{con} = -\log \frac{e^{\text{s}(\mathbf{H}, \bar{\mathbf{H}})/\tau}}{e^{\text{s}(\mathbf{H}, \bar{\mathbf{H}})/\tau} + e^{\text{s}(\mathbf{H}, \mathbf{H}_g)/\tau}}, \quad (9)$$

where $\text{s}(\mathbf{U}, \mathbf{V}) = \mathbf{U}^\top \mathbf{V} / \|\mathbf{U}\| \|\mathbf{V}\|$ denotes the cosine similarity between $\mathbf{U}$ and $\mathbf{V}$, and τ is a temperature hyper-parameter.

3.5 Decoder

The T5 decoder takes the encoder output $\tilde{\mathbf{H}}$, text sequence X, and previously generated tokens $\tilde{Y}_{<t}$ as inputs to get the t-th token probability distribution:

$$\tilde{\mathbf{h}}_t = \text{T5Decoder}(\tilde{\mathbf{H}}, X, \tilde{Y}_{<t}), \quad (10)$$

$$P(\tilde{y}_t | \tilde{\mathbf{H}}, X, \tilde{Y}_{<t}) = \text{Softmax}(\mathbf{W}_5 \tilde{\mathbf{h}}_t), \quad (11)$$

where $\mathbf{W}_5$ is a trainable parameter to map the hidden dimension to the vocabulary size. For each symbol $\tilde{a} \in \{\tilde{\mathbf{H}}, \tilde{\mathbf{h}}_t, \tilde{Y}_{<t}, \tilde{y}_t\}$, $\tilde{a}$ is either a or $\bar{a}$.

3.6 Training objective

During the training phase, we use the teacher forcing to train the models in the two stages. The models in two stages are trained independently.

Narrative generation In the narrative generation stage, we train the model with the cross-entropy loss on ground-truth narratives and narratives with masked gender words, which can be defined as:

$$\mathcal{L}_{ce} = -\sum_{t=1}^{m} \log P(y_t | \mathbf{H}, X, Y_{<t}), \quad (12)$$

$$\bar{\mathcal{L}}_{ce} = -\sum_{t=1}^{m} \log P(\bar{y}_t | \bar{\mathbf{H}}, X, \bar{Y}_{<t}). \quad (13)$$

In total, the narrative generation stage contains three losses, which can be formulated as:

$$\mathcal{L}_1 = \mathcal{L}_{con} + \mathcal{L}_{ce} + \bar{\mathcal{L}}_{ce}. \quad (14)$$

Answer inference The answer inference model is trained with a cross-entropy loss:

$$\mathcal{L}_2 = -\sum_{t=1}^{m} \log P(y_t | \mathbf{H}, X, Y_{<t}). \quad (15)$$

[3]The gender word list comes from Hirota et al. (2023), which can be found in Appendix A.

4 Experiment Setup

To demonstrate the effectiveness and generalization ability of GAMA, we conduct extensive experiments across two vision-language tasks (image captioning and image search) and two benchmarks for measuring gender bias (VisoGender (Hall et al., 2023) and VL-Bias (Zhang et al., 2022)).[4]

4.1 Datasets

The statistics of the datasets are listed in Table 1.

Gender label Following previous work (Hendricks et al., 2018; Wang et al., 2021; Hirota et al., 2023), we utilize ground-truth captions to label the gender attributes of images. Specifically, an image will be labeled as "male (female)" if at least one of its captions contains male (female) gender words and no captions contain female (male) words. Otherwise, it will be labeled as "neutral".

Narrative generation The Localized Narratives dataset (Voigtlaender et al., 2023) for Open Images (Kuznetsova et al., 2020) is utilized to train the narrative generation model.[5]

Image captioning We experiment on MSCOCO captions (Chen et al., 2015). Following Hirota et al. (2023), we use the original MSCOCO training set for training, a subset of the MSCOCO validation set from Zhao et al. (2021) for test,[6] and the remaining images for validation. Each image is associated with five human-annotated captions. Notably, no images in the test set are labeled as "neutral".

Image search Our evaluation for image search involves the MSCOCO (Chen et al., 2015) and Flickr30K (Young et al., 2014) datasets. Following Wang et al. (2021), we use the Karpathy split (Karpathy and Fei-Fei, 2015) for training and validation. As test sets in the Karpathy split are gender-unbalanced, we randomly select the same number of images with their gender-neutral queries [7] under "male", "female" and "neutral" labels for test.

[4]Due to space constraints, experiments on VL-Bias can be found in Appendix D.1.

[5]We ascertain the absence of any overlap between Localized Narratives and other test sets through the cosine similarity among image tensors with a threshold of 0.9. See Appendix D.2 for further studies on the training set size of Localized Narratives.

[6]Access the test split at https://princetonvisualai.github.io/imagecaptioning-bias/.

[7]The queries are available at https://github.com/eric-ai-lab/Mitigate-Gender-Bias-in-Image-Search.

Stage	Task	Dataset	Train	Dev	Test
1	Narrative Generation	Localized Narratives	507,444	41,691	126,020
2	Image Captioning	MSCOCO	82,783	29,724	10,780
	Image Search	MSCOCO	113,287	5,000	1,500
		Flickr30K	29,000	1,000	300
	VisoGender		/	/	690

Table 1: **The statistics of datasets.** We show the counts of images within each split of the datasets.

VisoGender VisoGender (Hall et al., 2023) benchmarks occupation-related gender bias in VLMs. VLMs are required to align images with correct gender pronouns in a resolution task and retrieve the top-K images for a gender-neutral caption of a given occupation in a retrieval task.

4.2 Baselines

Image captioning GAMA is compared with the following methods for image captioning: 1) **Equalizer** (Hendricks et al., 2018), which focuses on the "person" segmentation to make gender-specific predictions; 2) **GAIC**$_{es}$ (Tang et al., 2021), which encourages capturing gender visual evidence through self-guided visual attention; and 3) **LIBRA** (Hirota et al., 2023), which leverages state-of-the-art captioning models to generate high-quality captions and debiases through an additional editing model.

Image search We evaluate GAMA against the following methods for image search: 1) **SCAN-FS** (Wang et al., 2021), which applies a fair sampling method to the representative image search baseline SCAN (Lee et al., 2018); 2) **CLIP-clip** (Wang et al., 2021), which introduces a feature pruning algorithm to the features generated by the PVLM CLIP (Radford et al., 2021); and 3) **FairVLP** (Zhang et al., 2022), which trains the PVLM ALBEF (Li et al., 2021) with counterfactual samples to obtain debiased representations.

VisoGender Following Hall et al. (2023), we evaluate GAMA against state-of-the-art pre-trained vision-language encoders (**CLIP** (Radford et al., 2021), **OpenCLIP** (Cherti et al., 2023) trained on LAION 2B and 400M, **SLIP** (Mu et al., 2022), **DeCLIP** (Li et al., 2022b) and **FILIP** (Yao et al., 2022)) and pre-trained captioning models (**BLIP-2** (Li et al., 2023a) and **GIT** (Wang et al., 2022)).

Table 3: **Results of image search.** For gender bias metrics, closer to 0 is better. Baselines are reproduced with official implementation. We report the average across 3 runs. Note that we evaluate models with gender-balanced test sets instead of the Karpathy test sets utilized by Wang et al. (2021) and Zhang et al. (2022).

4.3 Metrics

We present metrics for evaluation, covering task performance, gender bias, and object hallucination. Calculation details are presented in Appendix B.

Task performance metrics are used to evaluate model performance on specific tasks. For *image captioning*, we use established referenced-based metrics BLEU-4 (Papineni et al., 2002), CIDEr (Vedantam et al., 2015), METEOR (Denkowski and Lavie, 2014) and SPICE (Anderson et al., 2016) as well as a reference-free metric CLIPScore (Hessel et al., 2021). For *image search*, we employ Recall@K to calculate the ratio of correct images in the top-K retrieved images.

Gender bias metrics are employed to measure the model performance on gender bias mitigation. For *image captioning*, we use LIC (Hirota et al., 2022b) to measure gender bias in the context of gender words, Error (Hendricks et al., 2018) to assess the gender misclassification ratio of generated captions, and BiasAmp (Zhao et al., 2017) to quantify bias amplification based on word-gender co-occurrence. For *image search*, we follow Wang et al. (2021) and adopt Bias@K to measure gender bias among the top-K images. For *VisoGender*, we follow the setting in Hall et al. (2023). The resolution accuracy gap (Δ_{RA}) is used to measure resolution bias, while Bias@K (Wang et al., 2021), Skew@K (Geyik et al., 2019) and NDKL (Geyik et al., 2019) are used to measure retrieval bias.

Object hallucination metrics are utilized to probe the connection between object hallucination and gender bias. CHAIRs and CHAIRi (Rohrbach et al., 2018) are used to evaluate incorrect object generation at the sentence and object levels, respectively. Rohrbach et al. (2018) used a synonym list (Lu et al., 2018) to map words to MSCOCO objects. We refine it with hierarchical object relationships.[8]

4.4 Implementation details

We use `flan-t5-base` (Chung et al., 2022) as the backbone. Our image encoder is `vit-base-patch16-384` (Dosovitskiy et al., 2020), and its parameters are frozen during training. For narrative generation, we set the temperature $\tau = 0.1$ and conduct further studies in Appendix D.2. Experiments on VisoGender are conducted on GAMA search models under a zero-shot setting. More details are presented in Appendix C.

5 Results and Analysis

In this section, we seek to answer the following research questions: **RQ1:** Does GAMA perform well across different vision-language tasks in task performance metrics and gender bias metrics? (Section 5.1) **RQ2:** Do our gender obfuscation module and two-stage framework help GAMA think before acting? (Section 5.2) **RQ3:** Are object hallucination and gender bias closely related? (Section

[8]Details can be found in Appendix B.2.

5.2) **RQ4:** Can GAMA be generalized to specialized datasets for gender bias measurement under a zero-shot setting? (Section 5.3)

5.1 Overall results

We conduct experiments on GAMA and baselines. Results on image captioning and image search are shown in Table 2 and Table 3, respectively.

To begin with, GAMA outperforms or closely aligns with the baselines in both two tasks. It is noteworthy that most of these baselines are tailored to a specific task. In contrast, GAMA is a task-agnostic method and can be easily applied to different vision-language tasks.

Then we compare GAMA with each baseline separately. First, GAMA comfortably outperforms Equalizer and GAIC$_{es}$. As Equalizer forces the model to focus on persons in images, it loses necessary information to generate the correct context of gender words. Similarly, GAIC$_{es}$ is designed to improve gender classification accuracy with additional gender evide nce. Therefore, these two baselines prove less effective.

Second, LIBRA achieves noticeable results with different captioning models. LIBRA considers gender bias manifested as gender misclassification as well as biased context. However, there are some problems. 1) LIBRA is limited by the performance of captioning models, as it is designed to revise their outputs. 2) LIBRA is designed to edit biased captions after a captioning model, but it is trained with synthesized data instead of actual model outputs, potentially causing error propagation. Consequently, the performance of LIBRA depends on the specific captioning model in use, rendering its results on gender bias metrics less stable.

Third, GAMA also performs better than SCAN-FS, CLIP-clip and FairVLP in image search. We observe that SCAN-FS and CLIP-clip exhibit overcorrection, leading to the underrepresentation of males. These baselines tackle gender bias mainly by removing biased data or features. Given the diverse sources of bias, it cannot be effectively mitigated by merely processing data or debiasing pre-training features.

Finally, we compare models on task performance and gender bias mitigation ability in Figure 3. Results show that GAMA strikes a good balance between task performance and gender bias mitigation.

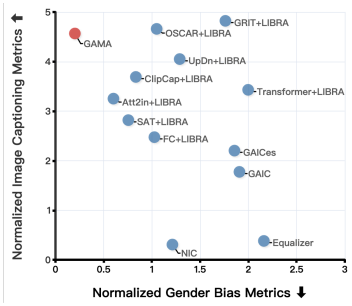

Figure 3: **Comparison on task performance and gender bias mitigation ability.** We normalize the metrics separately and sum the normalized gender bias metrics and image captioning metrics, respectively.

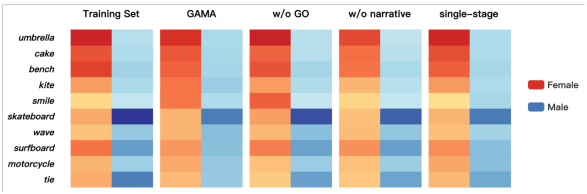

Figure 4: **Heatmap visualization of the co-occurrence frequency between gender attributes and certain words.** We respectively select five words highly co-occurring with females and males in the training set. We show the frequency of co-occurrence between gender attributes and words in the model predictions. Darker colors indicate higher frequencies.

5.2 Ablation study

To further explain the results, we carry out ablation studies on GAMA as well as explore the connection between object hallucination and gender bias in image captioning. Table 4 shows the results. We summarize the main observations as follows.

The gender obfuscation module mitigates gender bias in the context. First, this module effectively obfuscates gender-related information during narrative generation, leading to a reduction in the number of narratives with gender words. Next, the absence of this module is observed to cause an increase in the LIC score, indicating amplified gender bias in the generated context. Additionally, the BiasAmp score shows an increase. We speculate it is because GAMA without this module is exposed to direct gender information, leading to the generation of more words closely related to gender attributes. The rise in HR^g_C@10 and Figure 4 manifest that GAMA without this module hallucinates more objects that highly co-occur with gender words in the training set, thus affirming our hypothesis. Lastly, GAMA without generated narratives also achieves competitive results against previous

Model	Gender Bias Metrics ↓			Gender-related Statistics ↓	Object Hallucination Metrics ↓		Co-occurrence Statistics ↓	
	LIC	Error	BiasAmp	#Gender	CHAIRs	CHAIRi	HR^g_C@10	HR^o_C@10
GAMA	-1.1	3.4	-3.40	55.61	10.94	6.02	38.15	50.30
w/o GO ♦	0.5	3.1	-1.26	62.49	12.81	7.36	41.52	50.09
w/o narrative ★	-0.6	4.1	-2.87	/	13.02	7.84	41.37	51.94
single-stage ♣	-0.9	3.6	-2.13	/	12.40	7.02	39.91	51.76

Table 4: **Results of ablation studies.** #Gender denotes the proportion of generated narratives with gender words in the test set. Note that no images are labeled as "neutral" in the test set. CHAIRs and CHAIRi are calculated based on our refined synonym list. HR^o_C@10 (Li et al., 2023b) and HR^g_C@10 are used to quantify whether the model is prone to hallucinate objects that frequently co-occur with ground-truth objects and gender attributes, respectively, which are detailed in Appendix B.3. ♦: the gender obfuscation module (GO) is removed from narrative generation; ★: the model is trained to generate gender-obfuscated captions instead of gender-obfuscated narratives in the first stage; ♣: the narrative generation stage is removed, and GO is adopted in the answer inference stage. Note that the single-stage framework does not incorporate narratives as input.

GIT		0.84	-0.07	-0.27	/	/	/	/	/	/	/	/	/	/
GAMA	**Flickr30K**	0.81	0.06	0.09	0.04	0.42	0.01	0.26	0.26	0.15	0.17	0.12	0.18	0.07
	MSCOCO	0.82	0.04	-0.09	0.01	0.40	-0.04	0.24	0.26	0.14	0.18	0.11	0.17	0.08

Table 5: **Results of zero-shot experiments on VisoGender.** The best results are highlighted in green, and the second-best are in blue. The results of GAMA are obtained by the search models trained on MSCOCO and Flickr30K, respectively. Other results are retrieved from Hall et al. (2023). Occupation-object (OO) and occupation-participant (OP) cases denote the single-person and two-person resolution tasks, respectively. For Δ_{RA} and Bias@K, closer to 0 is better. We report mean and standard deviation (σ) for the retrieval task across all occupations.

debiasing methods. The results further demonstrate the effectiveness of the gender obfuscation module.

The two-stage framework can facilitate debiased answers. We note an increase in the Error score in the single-stage framework. The narrative generation stage is designed to prompt GAMA to grasp the overall image before giving ultimate answers. The rise in BiasAmp and HR^o_C@10 indicates that the single-stage framework relies more on word co-occurrence for answer generation. Hence, the two-stage framework serves as an effective method to prevent GAMA from prematurely focusing on localized features and hallucinating ignored objects.

Object hallucination and gender bias exhibit a close correlation. As shown in Table 4, mitigating gender bias leads to a decrease in object hallucination. Object hallucination mainly results from the frequent occurrence of certain objects (including persons) and the co-occurrence between objects in the training set (Li et al., 2023b). Similarly, gender bias is manifested as the overrepresentation of a certain gender or the high-frequency co-occurrence between gender attributes and objects in datasets. In essence, gender bias can be thought of as a form of object hallucination in VLMs. Consequently, efforts to mitigate gender bias in VLMs result in a simultaneous reduction of object hallucination.

5.3 Experiments on generalization ability

The datasets employed in the above experiments are not specifically constructed to detect gender bias in VLMs, which may contain gender bias in annotations, e.g., underrepresentation of women (Zhao et al., 2017; Harrison et al., 2023). Consequently, we turn to VisoGender for further experiments. As shown in Table 5, GAMA exhibits good overall performance across bias metrics for both tasks, further demonstrating its generalization ability and effectiveness in gender bias mitigation.

6 Conclusion

In this paper, we present GAMA, a two-stage task-agnostic generation framework to mitigate gender

bias towards vision-language tasks. GAMA is encouraged to gain a comprehensive understanding of images during narrative generation and to rethink gender attributes and answers during answer inference. Experimental results demonstrate GAMA's superiority in both task performance and gender bias metrics over previous methods. Furthermore, we conduct ablation studies and analyze the close connection between object hallucination and gender bias. Finally, we evaluate GAMA under a zero-shot setting to showcase its generalization ability. We hope that GAMA can contribute to the future exploration of fairness in VLMs.

Limitations

Following previous research (Wang et al., 2021; Hirota et al., 2023), we utilize a gender word list for pre-processing. Although prior studies have covered most gender words, some may still be omitted. One potential solution is to train a model to obfuscate gender information in a sentence via synthesized data.

Another consideration is the narrative generation model. Despite its generalization ability to various vision-language tasks and datasets, the model requires additional computing resources and datasets for training. Due to the boom in large VLMs (LVLMs), we will investigate the feasibility of generating gender-obfuscated narratives using these models.

Theoretically, we can replace the model for answer inference with any state-of-the-art task-specific generative model, which will explored in our future work.

Ethics Statement

In our paper, we focus on mitigating gender bias towards vision-language tasks. Due to the inherent challenges associated with human analysis, including substantial manual effort and time investment, we leverage existing datasets and benchmarks for gender bias measurement. While quantitative metrics provide valuable insights, we acknowledge their potential limitations in capturing nuanced gender bias. Additionally, current datasets and benchmarks only consider binary gender, which oversimplifies the intricate and diverse nature of gender identity. Therefore, GAMA remains to be improved. We hope that the advancements in GAMA, as presented in this paper, will serve as a catalyst for inspiring further valuable research in gender bias mitigation towards vision-language tasks.

A List of Gender Words

We use the gender words from Hirota et al. (2023), which are listed in Table 6.

B Metrics

B.1 Gender bias metrics

LIC As for LIC, we follow the method proposed by Hirota et al. (2022b).

First, we pre-process captions by masking gender words. To measure gender bias amplification in image captioning models, we need to quantify the difference between bias in the generated captions set $\hat{\mathcal{D}}$ and bias in the ground-truth captions in the training data $\mathcal{D}$. Then we train two gender classifiers f and $\hat{f}$ on the two masked caption sets $\mathcal{D}$ and $\hat{\mathcal{D}}$, respectively. Finally, we compare the accuracy of two gender classifiers as follows:

$$\text{LIC}_D = \frac{1}{|\mathcal{D}|} \sum_{(y,a)\in\mathcal{D}} s_a(y)\mathbb{1}[f(y) = a], \quad (16)$$

$$\text{LIC}_M = \frac{1}{|\hat{\mathcal{D}}|} \sum_{(\hat{y},a)\in\hat{\mathcal{D}}} \hat{s}_a(\hat{y})\mathbb{1}[\hat{f}(\hat{y}) = a], \quad (17)$$

$$\text{LIC} = \text{LIC}_M - \text{LIC}_D, \quad (18)$$

where y and $\hat{y}$ are the ground-truth caption and generated caption, respectively. We denote a as the gender label of the caption. $s_a(\cdot)$ and $\hat{s}_a(\cdot)$ are the probabilities that f and $\hat{f}$ classify the gender of the caption as a, respectively.

The higher accuracy of the classifier trained on the masked captions indicates that the context contains more information related to gender. LIC > 0 indicates that the model amplifies gender bias with respect to the training data, and mitigates it otherwise.

Following Hirota et al. (2023), we construct the classifiers with `bert-base-uncased` (Devlin et al., 2019) as the backbone and two fully connected layers with Leaky ReLU activation on top. We finetune the model for 5 epochs with a learning rate of 1×10^{-5}.

Error Error represents the ratio of gender misclassification in the generated captions. Following Hendricks et al. (2018) and Hirota et al. (2023), we utilize the gender word list to identify the gender label of the generated captions as detailed in Section 4.1. And "neutral" labels are not considered as errors.

Gender	Gender Words
Female	woman, female, lady, mother, girl, aunt, wife, actress, princess, waitress, sister, queen, chairwoman, policewoman, girlfriend, pregnant, daughter, she, her, hers, herself
Male	man, male, father, gentleman, boy, uncle, husband, actor, prince, waiter, son, brother, guy, emperor, dude, cowboy, boyfriend, chairman, policeman, he, his, him, himself

Table 6: Gender word list.

BiasAmp BiasAmp is proposed to quantify the bias amplification of the model. Following Zhao et al. (2017) and Hirota et al. (2023), we use the top $1,000$ common words in captions and filter the words that are not strongly associated with humans, leaving a set $\mathcal{L}$ of high-frequency words.[9]

We calculate the bias of the word $l \in \mathcal{L}$ on the gender $a \in \mathcal{A} = \{m, f\}$ as follows:

$$b_{a,l} = \frac{c_{a,l}}{\sum_{a\in\mathcal{A}} c_{a,l}}, \quad (19)$$

$$\hat{b}_{a,l} = \frac{\hat{c}_{a,l}}{\sum_{a\in\mathcal{A}} \hat{c}_{a,l}}, \quad (20)$$

where $c_{a,l}$ and $\hat{c}_{a,l}$ are the number of co-occurrences of a and l in the training data and in the model predictions, respectively. Then bias amplification is defined as:

$$\text{BiasAmp} = \frac{1}{\mathcal{L}} \sum_{a\in\mathcal{A},l\in\mathcal{L}} (\hat{b}_{a,l} - b_{a,l})\mathbb{1}[b_{a,l} > \frac{1}{|\mathcal{A}|}]. \quad (21)$$

BiasAmp > 0 indicates that gender bias is amplified by the model, and otherwise mitigated.

Bias@K Wang et al. (2021) proposed Bias@K to measure gender bias in image search by comparing the proportions of masculine and feminine images in search results. Let q denote the search query and $\mathcal{R}_q^K$ denote the top-K retrieved image set. The gender bias of $\mathcal{R}_q^K$ is defined as:

$$\text{Bias@K}(q) = \begin{cases} 0, & \text{if } N_m + N_f = 0 \\ \frac{N_m - N_f}{N_m + N_f}, & \text{otherwise} \end{cases}, \quad (22)$$

where N_m and N_f denote the number of images labeled "male" and "female" in $\mathcal{R}_q^K$, respectively. Then Bias@K is calculated as the average of Bias@K(q) over all queries.

[9]The word list in available at https://github.com/uclanlp/reducingbias.

A positive Bias@K indicates a higher frequency of retrieving images featuring males compared to females. This metric is most suitable when the candidate images are gender-balanced, as it does not consider the distribution of candidates.

MaxSkew@K Hall et al. (2023) measured the difference between the desired proportion of gender attributes in $\mathcal{R}_q^K$ and the actual proportion. Let $\mathcal{A} = \{m, f\}$ denote the gender attribute set. The skew of $\mathcal{R}_q^K$ for the gender attribute $a \in \mathcal{A}$ is defined as:

$$\text{Skew}_a@\text{K}(q) = \ln \frac{P_{\mathcal{R}_q^K,q,a}}{P_{d,q,a}}, \tag{23}$$

where $P_{d,q,a}$ and $P_{\mathcal{R}_q^K,q,a}$ are desired proportion of gender attributes in the test set and the actual proportion in $\mathcal{R}_q^K$, respectively.

Then we calculate the maximum value of Skew@K among all gender attributes for the retrieved images:

$$\text{MaxSkew}@\text{K}(q) = \max_{a \in \mathcal{A}} \text{Skew}_a@\text{K}(q), \tag{24}$$

Finally, MaxSkew@K is calculated as the average of MaxSkew@K(q) over all queries.

NDKL Geyik et al. (2019) and Hall et al. (2023) measured the distance of the prediction distribution from a fair distribution over all candidate results. Let $\mathcal{R}_q$ denote the candidate set of the query q. The NDKL of $\mathcal{R}_q$ is defined as:

$$\text{NDKL}(q) = \frac{1}{Z} \sum_{K=1}^{|\mathcal{R}_q|} \frac{1}{\log_2(K+1)} d_{KL}(D_{\mathcal{R}_q^K} \| D), \tag{25}$$

where $Z = \sum_{K=1}^{|\mathcal{R}_q|} \frac{1}{\log_2(K+1)}$ is a normalizing factor, and $d_{KL}(\cdot)$ denotes the KL-divergence. $D_{\mathcal{R}_q^K}$ and D denote the actual distribution of gender attributes over the top-K retrieved images and the desired distribution, respectively.

Resolution bias Hall et al. (2023) defined resolution accuracy (RA) as the proportion of correctly resolved pronouns. Let $\mathcal{O}$ denote the occupation set. We calculate the resolution accuracy of the gender attribute a on the occupation $o \in \mathcal{O}$ as:

$$RA_a(o) = \frac{\hat{n}_{a,o}}{n_{a,o}}, \tag{26}$$

where $n_{a,o}$ denotes the total number of pronouns of the gender attribute a in occupation o, and $\hat{n}_{a,o}$ denotes the number of correctly resolved pronouns of a in o.

Then the resolution bias on the occupation o is defined as the gender resolution accuracy gap:

$$\Delta_{RA}(o) = RA_m(o) - RA_f(o). \tag{27}$$

Finally, we calculate the resolution bias Δ_{RA} as the average of $\Delta_{RA}(o)$ over all occupations. $\Delta_{RA} > 0$ indicates that the model performs better in resolving males within occupations, and vice versa.

B.2 Object Hallucination Metrics

Definition CHAIR (Rohrbach et al., 2018) is a popular metric for object hallucination measurement with two variants, CHAIRi and CHAIRs. CHAIRi and CHAIRs evaluate object hallucination at the object and sentence levels, respectively. Let N_o^H denote the number of hallucinated objects, N_o denote the total number of mentioned objects, N_c^H denote the number of captions with hallucinated objects, and N_c denote the total number of captions. CHAIRi and CHAIRs are defined as:

$$\text{CHAIRi} = \frac{N_o^H}{N_o}, \tag{28}$$

$$\text{CHAIRs} = \frac{N_c^H}{N_c}. \tag{29}$$

CHAIRi describes the proportion of hallucinated objects among all generated objects. CHAIRs describes the proportion of generated captions with hallucinated objects.

Details Rohrbach et al. (2018) utilized a synonym list (Lu et al., 2018) to map words to MSCOCO objects (e.g., "player" to "person"). However, it is notable that the list is coarse-grained. For instance, it considers terms like "woman" and "man" as well as "purse" and "briefcase" as synonyms. Although "woman" and "man" both fall under the"person" class, and "purse" and "briefcase" belong to the category of bags, it is crucial to recognize that they represent distinct objects. Therefore, we refine the list with hierarchical object relationships among objects based on the fine-grained classes defined in NoCaps (Agrawal et al., 2019). If a word in a sub-category (e.g., "woman") is predicted in its super-category (e.g., "person"), we do not consider it as a hallucinated object. Conversely, if a word in a category (e.g., "woman") is predicted in its sibling category (e.g., "man"), we consider it as a hallucinated object.

B.3 Hit Ratio

Li et al. (2023b) utilized the hit ratio (HR_C^o) to measure the object co-occurrence in object hallucination. They demonstrated that VLMs mostly hallucinate objects that frequently co-occur with ground-truth objects in the image.

Let $\mathcal{H}_i$ denote the set of hallucinated objects in the i-th image, and $\mathcal{C}_o$ denote the set of the top-K frequently co-occurring objects with $\hat{o}$ in the training set. The top-K hit ratio of the probing object $\hat{o}$ is defined as:

$$\text{HR}_C^o@\text{K}(\hat{o}) = \frac{1}{M_{\hat{o}}} \sum_{i=1}^{M_{\hat{o}}} \frac{|\mathcal{H}_i \cap \mathcal{C}_{\hat{o}}|}{|\mathcal{H}_i|}, \tag{30}$$

where $M_{\hat{o}}$ is the total number of images containing $\hat{o}$.

Similarly, we define the top-K hit ratio of the probing gender a as:

$$\text{HR}_C^g@\text{K}(a) = \frac{1}{M_a} \sum_{i=1}^{M_a} \frac{|\mathcal{H}_i \cap \mathcal{C}_a|}{|\mathcal{H}_i|}, \tag{31}$$

where M_a is the total number of images with the gender label a, and $\mathcal{C}_a$ denotes the set of the top-K frequently co-occurring objects with the gender a.

C Implementation Details

We select the best models based on the loss on the validation set for all tasks. Following Hendricks et al. (2018) and Tang et al. (2021), we set the beam size as 5 during inference. Table 7 shows our hyperparameters for training in different tasks. Table 8 lists the input and output formats of GAMA.

We implement GAMA with PyTorch (Paszke et al., 2019) and Huggingface Transformers (Wolf et al., 2020). We train the models with a single NVIDIA Ge-Force RTX 4090 GPU. More implementation details can be found in our code.

Image search With a probability of 50%, we randomly sample the caption of another training image to create a negative pair for training. The model predicts answers with "yes" or "no" as shown in Table 8. We take the token probability of the decoder as the match score.

VisoGender In VisoGender, each occupation appears with two caption templates: a person with a possessive pronoun to an object (e.g., "the doctor and his/her stethoscope") and a person with a possessive pronoun to a participant (e.g., "the doctor and his/her patient"). We evaluate the performance of the trained GAMA search models on MSCOCO and Flickr30K without additional training, respectively. Our experiments on VisoGender follow the original setting proposed by Hall et al. (2023). In the resolution task, we provide the model with queries containing "his" and "her", respectively. We determine the answers based on the match scores. In the retrieval task, we use neutral queries incorporating the pronoun "their" and provide the model with candidate images featuring correct occupations with balanced gender distributions.

D Additional Experiments

D.1 Experiments on VL-Bias

We conduct experiments on VL-Bias (Zhang et al., 2022) under a zero-shot setting.

Dataset VL-Bias serves as a benchmark for measuring gender bias in VLMs, encompassing 52 activities and 13 occupations related to humans.[10] The dataset includes images sourced from the Internet, as well as existing image datasets such as MSCOCO (Chen et al., 2015) and Flickr30K (Young et al., 2014). The captions are in the format of "The {gender} is {target}", where "target" represents an activity (e.g., "shopping") or an occupation (e.g., "engineer"). In total, VL-Bias comprises 24K image-text pairs, including 13K pairs for the 52 activities and 11K for the 13 occupations.

Baselines Following Zhang et al. (2022), we evaluate GAMA against three common and effective debiasing methods: 1) Gender Swapping (**GS**) (Zhao et al., 2018), which swaps gender words in the input text to mitigate the effect of gender attributes, and is adapted to vision-language tasks based on CycleGAN (Zhu et al., 2017); 2) Dropout Regularization (**DR**) (Webster et al., 2020), which is designed to prevent model from overfitting to gender attributes by increasing the dropout rate; and 3) **FairVLP** (Zhang et al., 2022), which trains the PVLM ALBEF (Li et al., 2021) with counterfactual samples to obtain debiased representations.

Metrics Zhang et al. (2022) proposed the vision-language bias for VL-Bias. Let t denote a target word, and a denote the gender attribute. The vision-language bias on t towards a on an image-text pair

[10]The dataset is available at https://github.com/VL-Bias/VL-Bias.

Hyper-parameters	Narrative Generation	Image Captioning	Image Search	
			MSCOCO	Flickr30K
Hidden Dimension d	768	768	768	768
Maximum Epochs	15	10	5	5
Learning Rate	4×10^{-5}	1×10^{-4}	2×10^{-5}	3×10^{-5}
Weight Decay	0.01	0.01	0.01	0.01
Batch Size	20	24	32	32
Maximum Input Sequence Length	128	256	256	256
Maximum Output Sequence Length	128	64	3	3

Table 7: Hyper-parameter settings of GAMA.

Stage	Task	Input Sequence	Target Sequence
1	Narrative Generation	Task: What can you see in this image? Please describe it in detail. Answer:	[NARRATIVE]
2	Image Captioning	Context: [NARRATIVE]. Task: Generate a short caption of the image. Answer:	[CAPTION]
	Image Search	Context: [NARRATIVE]. Query: [CAPTION]. Question: Do the image and the query match? Answer:	Yes/No

Table 8: **The input and output formats of GAMA.** For image search, we take the token probability of the decoder as the match score. For the second stage, model-generated narratives are utilized instead of relying on ground-truth narratives from datasets.

s can be formulated as:

$$B_s(t,a) = \frac{P_T(t|s_c) - P_T(t|s)}{P_A(a|s_c) - P_A(a|s)}, \quad (32)$$

where s_c is the counterfactual image-text pair of s. $P_T(t|s)$ denotes the probability that the model predicts the masked target word as t, and $P_A(a|s)$ denotes the probability that the model predicts the masked gender word as a.

Let $\mathcal{A} = \{m, f\}$ denote the gender attribute set, and S_t denote all image-text pairs with the target t. The gender bias over the target t is defined as:

$$B_{VL}(t) = \frac{1}{|S_t|} \sum_{s \in S_t} B_s(t,m) - B_s(t,f). \quad (33)$$

A positive $B_{VL}(t)$ indicates that the target t is biased towards males, and vice versa. The gender bias of the dataset is calculated as the average of $B_{VL}(t)$ over all targets.

Implementation details As the baseline models are pre-trained on MSCOCO (Chen et al., 2015), we utilize the GAMA search model trained on MSCOCO for evaluation. We take the token probability of the decoder as the probability for a target or a gender attribute. Counterfactual texts are constructed by reversing the gender words, while counterfactual images are generated with an adversarial attack based on the official implementation of Zhang et al. (2022).

Experimental results As shown in Table 9, GAMA obtains remarkable debiasing performance against baselines. The results underscore its generalization ability as well as its effectiveness in gender bias mitigation.

Model	Activity 13K	Occupation 11K
GS	11.21	12.47
DR	11.17	13.52
FairVLP	6.97	7.74
GAMA	5.96	6.83

Table 9: **Results on VL-Bias.** The best results are highlighted in green. For the results, closer to 0 is better. The baseline results are retrieved from Zhang et al. (2022).

D.2 Further study

In this section, we analyze the impact of the temperature hyper-parameter, the data size of Localized Narratives (Voigtlaender et al., 2023), and the frozen parameters.

Temperature We show the results in Table 10. The contrastive loss with a larger temperature is less sensitive to the hard negative samples as discussed in prior work (Wang and Liu, 2021). Therefore, it is hard for GAMA with a large temperature to distinguish gender-related features from gender-masked features, leading to increased LIC and BiasAmp scores.

Data size Although we have demonstrated the effectiveness of the model without narrative generation in Section 5.2, we wonder about the influence of the data size on the results. Therefore, we conduct an ablation study on the training set size of

Temperature	Gender Bias Metrics↓			Image Captioning Metrics ↑				
	LIC	Error	BiasAmp	BLEU-4	CIDEr	METEOR	SPICE	CLIPScore
0.01	-1.4	3.5	-3.42	37.9	115.2	30.9	22.5	75.5
0.1	-1.1	3.4	-3.40	38.2	115.1	31.0	22.7	75.4
1	-0.7	3.3	-3.28	37.7	114.6	30.6	22.4	75.6

Table 10: Results of the ablation study on the temperature hyper-parameter.

Localized Narratives (Voigtlaender et al., 2023) for narrative generation.

As our objective is to alleviate gender bias, we randomly select the images categorized under the "Person" class for experiments. Results are illustrated in Table 11 and Table 12.

We observe that the data size seems to have little impact on GAMA's task performance and its gender bias mitigation ability in image captioning. However, the data size affects the generalization ability of GAMA on VisoGender. We consider that it is because a large training set enhances the zero-shot generalization ability of GAMA in narrative generation, thereby ensuring robust model performance during answer inference.

Parameters To minimize the cost of training the model, we investigate the feasibility of reducing additional training. We experiment with freezing a portion of the parameters in GAMA, and the results are summarized in Table 13 below.

Freezing the T5 encoder in GAMA leads to results that are only slightly inferior to those of unfrozen GAMA, which is an encouraging finding. However, the outcomes of freezing both the flan-T5 encoder and decoder are less promising. We think it is because the fusion of language features and vision features creates a new feature space, which is distinct from the original features learned by T5. Consequently, the frozen decoder cannot be effectively adapted to this new feature space.

Data Size	Gender Bias Metrics ↓			Image Captioning Metrics ↑				
	LIC	Error	BiasAmp	BLEU-4	CIDEr	METEOR	SPICE	CLIPScore

Abstract

Sentence embeddings are crucial in measuring semantic similarity. Most recent studies employed large language models (LLMs) to learn sentence embeddings. Existing LLMs mainly adopted autoregressive architecture without explicit backward dependency modeling. Therefore, we examined the effects of backward dependencies in LLMs for semantic similarity measurements. Concretely, we propose a novel model: backward dependency enhanced large language model (BeLLM). It learns sentence embeddings via transforming specific attention layers from uni- to bi-directional. We extensively experiment across various semantic textual similarity (STS) tasks and downstream applications. BeLLM achieves state-of-the-art performance in varying scenarios. It shows that auto-regressive LLMs benefit from backward dependencies for sentence embeddings. [1]

1 Introduction

Sentence embedding is fundamental in natural language processing (NLP). It captures essential semantics in text, benefiting various semantic similarity measurement scenarios (Gao et al., 2021), such as semantic matching (Lu et al., 2020) and clustering (Reimers and Gurevych, 2019).

In previous work, the primary efforts employed smaller-scale bi-directional models (Peters et al., 2018; Reimers and Gurevych, 2019; Gao et al., 2021) to extensively explore the context to learn sentence embeddings. However, in the paradigm revolution of LLMs and the increasingly large model scales, most advanced NLP models adopted autoregressive (decoder-only) architectures with forward dependency modeling only (Touvron et al., 2023). While some recent efforts used LLMs for sentence embeddings (Li and Li, 2023; Jiang et al., 2023), limited attention has been paid to studying how backward dependency affects sentence embedding learning in autoregressive architectures.

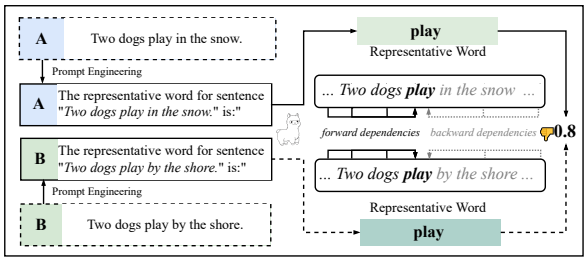

Figure 1: Two sample sentences A and B from STS-B dataset in dashed boxes. LLaMA predicted 0.8 similarity for A and B without backward dependency modeling (in grey). The ground-truth similarity is 0.5 because of differences in the playground in snow and shore.

To illustrate the potential help of backward dependencies in sentence embedding, Figure 1 illustrates two samples from STS-B (Cer et al., 2017) dataset. To enable LLaMA for sentence embeddings, we prompt it inspired by Jiang et al. (2023) and observe that LLaMA exhibits a very high similarity despite the different locations of events. The possible reason is that the uni-directional model LLaMA cannot extensively capture backward dependency, which indicates the relations between the representative word "play" and its different playgrounds. This observation highlights the potential benefits of engaging backward dependencies in LLMs for learning sentence embeddings.

To the best of our knowledge, *our work is the first to extensively investigate the effects of backward dependencies in autoregressive LLMs architectures for sentence embedding learning*.

We start our study with a pilot analysis to quantitatively examine the autoregressive capabilities of LLMs in capturing dependencies. It is observed that they are inferior to smaller-scale BERT in these capabilities. The results suggest the benefits of engaging backward dependencies in LLMs to en-

hance their dependency-capturing capabilities.

To incorporate backward dependency into LLMs, we propose a novel model, BeLLM, for sentence embedding learning. Our core idea is to convert specific attention layers in the transformer decoder from uni- to bi-directional. We first conduct a degradation experiment to determine which attention layers should be converted bi-directional. It aims to explore the relations between transformer decoder layers and the performance of STS tasks (for semantic similarity measurement). It is observed that when uni-directional layers exceed a turning point, the STS performance will notablely decrease. Furthermore, the turning point occurs at the penultimate layer for all LLMs we examined. We then convert the last layer bi-directional by removing their causal masks. In doing so, BeLLM involves both uni- and bi-directional layers to balance generation and dependency-capturing capabilities.

To train BeLLM, we first employ a representative word strategy to generate a representative word for a sentence via prompt engineering. Representative word embedding hence serves as the sentence embedding. Then, we apply contrastive learning (Gao et al., 2021) to pull embeddings of similar sentences close and push apart those not.

For experiments, we extensively evaluate sentence embeddings learned by BeLLM on various STS tasks. The main results indicate that BeLLM can significantly outperform previous SOTA on both the standard and the more challenging conditional STS tasks. For example, BeLLM achieves 49.74 Spearman's correlation compared to 47.50 from prior SOTA (Deshpande et al., 2023). It indicates that BeLLM is effective by introducing backward dependencies into LLMs. Then, our 7 downstream tasks experiments suggest that BeLLM's sentence embeddings can benefit various scenarios. Finally, a case study shows that BeLLM can better measure semantic similarities.

In summary, our contributions are three-fold:

• We explore the dependencies within LLMs and provide quantitative evidence that adding backward dependencies is helpful for sentence embeddings.

• We propose a novel backward dependency-enhanced large language model, BeLLM, to learn sentence embeddings in both uni- and bi-directions.

• Extensive experimental results demonstrate that BeLLM can obtain SOTA results across various STS tasks and downstream applications.

2 Quantitative Pilot Analysis

Before introducing BeLLM, we conduct a pilot analysis to explore how advanced LLMs capture dependencies in contexts. It is driven by the observations that mainstream LLMs (OpenAI, 2022; Touvron et al., 2023) employ an autoregressive architecture in an uni-directional manner. Intuitively, it lacks the ability to learn backward dependencies (Schuster and Paliwal, 1997), resulting in potential inferiority to capture dependencies compared to its bi-directional alternatives. Meanwhile, LLMs possess remarkable emergent abilities (Wei et al., 2022), implicitly benefit dependency capturing. We consequently conduct a pilot analysis to quantify whether explicit backward dependency modeling would benefit advanced autoregressive LLMs.

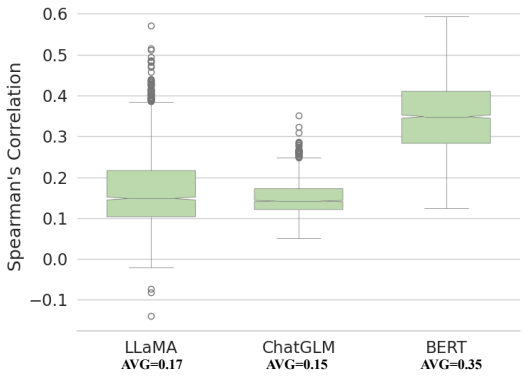

Figure 2: Box plot of the sentence-level Spearman correlation on the STS-B test set. The average sentence-level Spearman correlations for LLaMA, ChatGLM, and BERT are about 0.17, 0.15, and 0.35, respectively.

Our analysis is inspired by a phenomenon discovered by Ethayarajh (2019). The study qualitatively shows that bi-directional networks (e.g., ELMo (Peters et al., 2018) and BERT (Devlin et al., 2019)) demonstrate higher intra-sentence similarity (indicated by word similarities) than uni-directional networks (e.g., GPT-2). Here, we further explore this finding from a quantitative perspective.

Concretely, we experiment on the STS-B test set (Cer et al., 2017) and explore how models in uni- and bi-directional architectures capture dependencies. For the bi-directional model, we adopt BERT (base) and select the embedding of the "CLS" token as the pivot token to represent the sentence embedding. For the uni-directional, autoregressive architecture, we employ two representative LLMs: LLaMA (Touvron et al., 2023) (7B) and ChatGLM (Zeng et al., 2022) (6B). They offer two

different implementations of autoregressive architectures. For them, we choose the last token as the pivot token following (Ethayarajh, 2019). Based on pivot tokens, we compute their Spearman correlation with the remaining tokens in a sentence to reflect the dependency-capturing capabilities. The results are shown in a box plot in Figure 2.

The results indicate that BERT shows a higher Spearman correlation, implying its better capability to capture dependencies compared to LLaMA and ChatGLM. Interestingly, BERT achieves an average score that is about *twice* as high as that of LLaMA and ChatGLM. It is possibly attributed to BERT's bi-directional architecture allowing both forward and backward dependency modeling. In contrast, autoregressive models focus on forward dependencies only. The results imply the potential benefits of adding backward dependency modeling to autoregressive models for sentence embeddings.

3 BeLLM

The above analysis has revealed the potential benefits of adding backward dependencies to autoregressive LLMs. Consequently, this section will describe our proposed model, BeLLM, with bi-directional attention layers. Figure 3 shows the overall framework of BeLLM. Subsequent sections are organized as follows: Firstly, we present a degradation experiment to examine how to add backward layers. Then, we introduce the architectures of BeLLM, followed by the training methods.

3.1 Degradation Experiment

To enable BeLLM to model backward dependencies, we adopt a straightforward way to turn some uni-directional layers of LLMs into bi-directional ones. However, uni-directional layers are crucial to LLMs' language generation capabilities (Kaplan et al., 2020), which may affect representative word prediction for sentence embeddings (Section 3.3).

To practically balance uni- and bi-directional layers, we conduct a degradation experiment to explore the effects of uni-directional layer number on STS performance. Here, we gradually removed layers from the last to the first [2] to reduce generation capabilities and show the Standard STS benchmark results in Figure 4. The results present a *S*-shaped curve. It indicates that uni-directional layers are generally helpful to sentence embeddings. However, there is a *turning point* at the penultimate layer, exceeding which we observe a consistent performance drop for all three LLMs.

Such observations might be attributed to the extreme anisotropy (common-word biases) in the last layer of autoregressive LLMs, also shown in GPT-2's experiments (Ethayarajh, 2019). Consequently, we convert the last attention layer from uni- to bi-directional to introduce backward dependencies, yet keeping most layers uni-directional.

3.2 Model Architecture

BeLLM exhibits layers of auto-regressive LLM and BiLLM (bi-directional LLM) as follows.

For an input sentence s, we first obtain its word embeddings with the following formula:

$$\begin{aligned} \mathbf{x} &= \text{Embedding}^{LLM}(t) \\ t &= \text{Tokenizer}^{LLM}(s). \end{aligned} \tag{1}$$

We then fetch the layers from the first up to the penultimate layer denoted as $\text{LLM}^{1:n-1}$ (n indicates the layer number). They keep autoregressive architectures to handle language generation effectively and their attention computation is as follows:

$$\text{Attn}_i^{LLM}(\mathbf{Q}, \mathbf{K}, \mathbf{V}) = \text{SoftMax}(\frac{\mathbf{QK}}{\sqrt{d}} + \mathcal{M})\mathbf{V} \tag{2}$$

and

$$\mathcal{M} = \begin{bmatrix} 0 & -\infty & -\infty & -\infty & -\infty \\ 0 & 0 & -\infty & -\infty & -\infty \\ ... & ... & ... & ... & ... \\ 0 & 0 & 0 & 0 & -\infty \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \tag{3}$$

where Attn_i^{LLM} is the i-th head of multi-head self attention (Vaswani et al., 2017) in LLM. $\mathbf{Q} = \mathbf{W}^q\mathbf{x} + b$, $\mathbf{K} = \mathbf{W}^k\mathbf{x} + b$, $\mathbf{V} = \mathbf{W}^v\mathbf{x} + b$. $\mathcal{M}$ denotes the causal mask. It ensures that the i-th token is not visible to the $i+1...L$ tokens (L is the input token length) during attention computation, which is crucial to training language generation.

Based on the experiments in Section 3.1, for the last layer (after the turning point), we detach and transform it from uni- to bi-directional to obtain $\text{BiLLM}^{n-1:n}$. Its attention is computed as follows:

$$\text{Attn}_i^{BiLLM}(\mathbf{Q}, \mathbf{K}, \mathbf{V}) = \text{SoftMax}(\frac{\mathbf{QK}}{\sqrt{d}})\mathbf{V}, \tag{4}$$

To engage backward dependencies, we remove the casual mask to turn the last layer bi-directional inspired by Li et al. (2023).

[2] We did not remove it reversely, i.e., from first to last, as doing so would cause a malfunction in the generation ability.

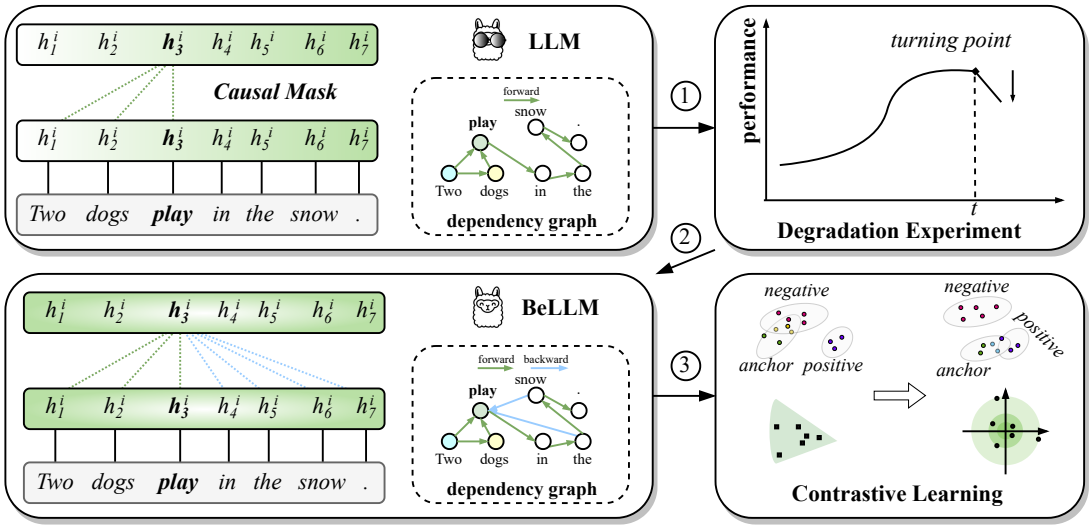

Figure 3: The overall framework of BeLLM. It includes three steps: 1) It first examines how to balance uni- and bi-directional layers with the degradation experiment and finds a turning point. 2) It transforms the attention layers after the turning point from uni- to bi-directional by removing the causal mask. 3) It employs contrastive learning to learn sentence embedding. Here, we visualize the dependencies of the representative word "play." LLM only captures the forward dependencies of "play" and BeLLM can capture both forward and backward dependencies.

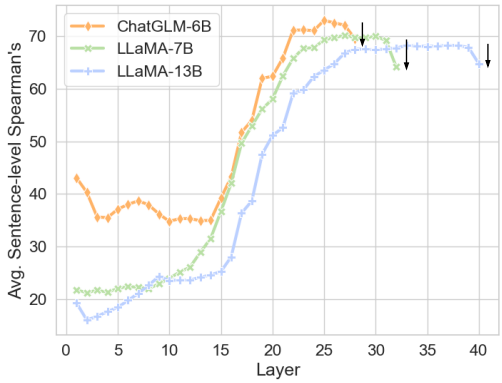

Figure 4: Degradation results on the Standard STS benchmark. X-axis: the number of uni-directional layers. Y-axis: the average Spearman's correlations computed with SentEval (Conneau and Kiela, 2018). The down arrow indicates a dramatic performance drop.

At last, we couple autoregressive LLM (retaining language generation capabilities) and BiLLM (the bi-directional last layer engaging forward and backward dependency modeling) components. The formula to represent BeLLM is as follows:

$$\mathbf{h} = \overrightarrow{\text{LLM}}^{1:n}(\mathbf{x}) + \overrightarrow{\text{BiLLM}}^{n-1:n}(\mathbf{x}). \quad (5)$$

3.3 Training Methods

In the training of BeLLM, we first generate the representative word of a given sentence as the pivot to learn its embedding. Concretely, we employ a prompt *The representative word for {sentence} is:"* for BeLLM to produce the representative word, where {sentence} is the placeholder for the actual sentence. Then, the embedding of the representative word serves as the sentence embedding.

Finally, to enable sentence similarity training, we adopt contrastive learning (Gao et al., 2021) to optimize the contrastive objective as follows:

$$\mathcal{L} = -\sum_i \log \frac{e^{cos(\mathbf{h}_i, \mathbf{h}_i^+)}/\tau}{\sum_{j=1}^{N}\left(e^{cos(\mathbf{h}_i, \mathbf{h}_j^+)/\tau} + e^{cos(\mathbf{h}_i, \mathbf{h}_j^-)/\tau}\right)}, \quad (6)$$

where N is the mini-batch size, $\mathbf{h}_i^+$ and $\mathbf{h}_i^-$ refer to the positive and negative samples of $\mathbf{h}_i$, respectively. τ is the temperature. $cos(a, b)$ is the cosine similarity function. This way, the embeddings of semantically similar sentences are pulled closer together while dissimilar ones are pushed apart.

Moreover, our training methods can potentially mitigate the common *anisotropy problem* in sentence embeddings, which constrains the embeddings' expressiveness. It happens because common words can bias sentence embeddings, rendering the learned embeddings to occupy a narrow cone in the vector space instead of distributing uniformly. The detailed discussions are shown in Appendix A.

4 Experimental Setup

Datasets. We evaluate sentence embeddings on STS tasks following the common practices. It includes the standard and conditional STS as follows.

Table 1: Spearman's correlation on the standard STS benchmark datasets. Higher scores indicate better sentence embedding performance. Results marked with † are obtained from (Reimers and Gurevych, 2019), those with ‡ are from (Gao et al., 2021), those with ♡ are from (Li and Li, 2023). ♢ indicates the sentence embedding model released by OpenAI, and its results are from (Muennighoff et al., 2022). Other results are based on reimplementation. For BeLLM, we report the average scores in five runs with standard deviation (std) expressed as a percentage (%) after $\pm$. BeLLM outperforms all baselines significantly on average (p-value < 1%, paired t-test).

Standard STS. The standard STS (S-STS) benchmark consists of seven STS tasks: STS 2012-2016 (Agirre et al., 2012, 2013, 2014, 2015, 2016), SICK-R (Marelli et al., 2014), and STS-B (Cer et al., 2017). They contain manual annotations of sentence similarities to test the effectiveness of sentence embeddings. For training and testing, we follow the prior work (Reimers and Gurevych, 2019; Gao et al., 2021) to train sentence embeddings on MNLI (Williams et al., 2018) and SNLI (Bowman et al., 2015) datasets. Then, the trained embeddings are evaluated on the S-STS benchmark datasets.

Conditional STS. To test sentence embeddings with a more challenging setup, we adopt the Conditional Semantic Textual Similarity (C-STS) benchmark (Deshpande et al., 2023). Here, the pairwise sentence similarity is labeled under varying conditions with details in Appendix B. We follow the setting of C-STS to train sentence embeddings and test them with the C-STS official evaluation API.

Evaluation Metrics. For the automatic evaluation of sentence embeddings, we follow previous studies to use Spearman's correlation. It compares the ranks of pairwise embeddings and assesses the ranked monotonic relations based on manual annotations. For the S-STS benchmark, we used the SentEval (Conneau and Kiela, 2018) toolkit and reported the results in the "all" setting following prior work. For C-STS, we reported Spearman's correlation returned by its official evaluation API.

Baselines and Comparisons. For **S-STS**, we considered widely adopted unsupervised and supervised sentence embedding baselines. 1) The unsupervised baselines include GloVe (Pennington et al., 2014) with average pooling , BERT-flow (Li et al., 2020), BERT-whitening (Su et al., 2021), and other BERT-based baselines trained with contrastive learning: IS-BERT (Zhang et al., 2020), CT-BERT (Carlsson et al., 2020), SimCSE (Gao et al., 2021), and DiffCSE (Chuang et al., 2022). 2) The supervised baselines include InferSent (Conneau et al., 2017), USE (Cer et al., 2018), SBERT (Reimers and Gurevych, 2019), AnglE (Li and Li, 2023), and supervised SimCSE. In addition to open-source models, we also compared with pop-

ular closed-source *openai-ada-002* (Muennighoff et al., 2022) embeddings.

For **C-STS**, we employed few-shot LLM of Flan-T5 (Chung et al., 2022), Tk-Instruct (Wang et al., 2022), GPT-3.5 (OpenAI, 2022), GPT-4 (OpenAI, 2023), and supervised SimCSE (fine-tuned) (Gao et al., 2021).

For baselines' benchmark results, we will report the scores from the original papers and prior work.

Model Settings. BeLLM employed LLaMA2-7B model (Touvron et al., 2023) as the backbone. For efficient training, we used the LoRA technique (Hu et al., 2021; Dettmers et al., 2024) for fine-tuning with $lora_r = 32$, $lora_alpha = 32$, and $lora_dropout = 0.1$. In this setting, the trainable parameters are about 80M, smaller than BERT-base's 110M. We trained the model on 4 RTX 3090 Ti GPUs. We chose the batch size by searching on the values $\{16, 32, 64, 128\}$. The initial learning rate was set to $2e-4$ via grid search on validation data. For a fair comparison with baselines, we set the random seed to 42 following SimCSE (Gao et al., 2021) for main experiments. We also test using different random seeds to verify BeLLM's robustness in the ablation study (Section 5.3).

5 Experimental Results

The following will first present the main results with intrinsic evaluation (Section 5.1), followed by the extrinsic transfer task results in Section 5.2. To provide more insight, we will then analyze the ablation study and case study results in Section 5.3 and 5.4, respectively. At last, we further examine the intra-sentence dependency of BeLLM to supplement the pilot analysis in Section 2.

5.1 Main Comparison Results

We first discuss the main results in S-STS and the more challenging C-STS benchmarks.

Standard STS. We show S-STS benchmark results in Table 1 and draw the following observations. First, supervised models generally outperform unsupervised models; it suggests that sentence embedding cannot be effectively learned by shallow features, and human supervision can provide positive help. Second, the LLM-based models perform better than the BERT-based models, implying that larger model scales help capture sentence semantics. Third, our proposed BeLLM model performs the best in all S-STS datasets. It consistently outperforms AnglE$_{LLaMA}$ and SimCSE$_{LLaMA}$, with 0.3% and 1.02% improvements in average score, respectively. These results indicate the effectiveness of incorporating backward dependencies into LLMs for sentence embeddings.

Table 2: Results on the C-STS benchmark. † denotes results from (Deshpande et al., 2023). Prompts for LLMs can be retrieved from (Deshpande et al., 2023). BeLLM results are the average in five runs. The reported standard deviation (std) value is expressed as a percentage (%) after the $\pm$ symbol. BeLLM outperforms all baselines significantly (p-value < 1%, paired t-test).

Conditional STS. To allow sentence embedding evaluation in a more challenging setup, we further employ the C-STS dataset to assess semantic similarities in conditions. Here, we devise a prompt to enable LLM to summarize the given sentence in one representative word by putting the conditions into the context. The prompt is as follows: *Given the context {condition}, summarize the sentence {sentence} in one word:"*, where {condition} and {sentence} are placeholders for the actual input condition and sentence, respectively.

The results are presented in Table 2. We observe that LLMs, such as GPT-3.5 and GPT-4, yield inferior results in few-shot settings compared to supervised SimCSE with fine-tuning. It implies that C-STS is challenging and cannot be well solved by few-shot LLMs; fine-tuning can helpfully boost the results of a smaller-scale model. Among fine-tuned models, the results are consistent with S-STS: larger model sizes and backward dependencies both contribute positively. Combining their effects, BeLLM achieves the SOTA performance. It demonstrates a 1.10% improvement over SimCSE$_{LLaMA}$ without modeling backward dependency and a remarkable 2.24% gain over the prior SOTA model, SimCSE (RoBERTa$_{large}$).

Table 3: Accuracy of transfer task results based on different sentence embeddings. †: results from Reimers and Gurevych (2019); ‡: results from Zhang et al. (2020); ⋆: results from Gao et al. (2021). ♢: results from Chuang et al. (2022); ♣: results from Jiang et al. (2023). BeLLM's results are the average of five runs. The reported standard deviation (std) value is expressed as a percentage (%) after the ± symbol. The paired t-test suggests that the average improvements of BeLLM compared to LLaMA are significant, with corresponding p-values of 4.06%.

5.2 Transfer Task Results

To assess the benefits of sentence embeddings in downstream tasks, we evaluate our model on seven transfer tasks: MR (Movie Reviews) (Pang and Lee, 2005), CR (Customer Reviews) (Hu and Liu, 2004), SUBJ (Subjectivity) (Pang and Lee, 2004), MPQA (Multi-Perspective Question Answering) (Wiebe et al., 2005), SST2 (Stanford Sentiment Treebank) (Socher et al., 2013), TREC (Text Retrieval Conference) (Voorhees and Tice, 2000), and MRPC (Microsoft Research Paraphrase Corpus) (Dolan et al., 2004). The transfer task results are measured by SentEval (Conneau and Kiela, 2018) toolkit. Following common practices, we train a logistic regression classifier using sentence embeddings as features and used default configurations of SentEval for a fair comparison.

The results are presented in Table 3. As can be seen, BeLLM achieves superior performance compared to the baselines, obtaining the best results on average and in 6 out of 7 tasks. These results indicate that incorporating backward dependencies to LLMs can helpfully learn sentence embeddings, which benefit downstream task performances.

5.3 Ablation Study

We have shown the overall effectiveness of BeLLM. Here, we further analyze the effects of its varying settings with an ablation study results in Table 4. From the *turning point* ablation results, we find bi-directional attention layers are useful to BeLLM, yet converting all attention layers into bi-directional results in deficient performance. It is possibly because uni-directional attention layers are crucial in language generation for representative word prediction. Consequently, finding a good balance of uni- and bi-directional attention layers plays a crucial role in sentence embeddings.

From the *model scale* results, we find that the 13B BeLLM outperforms the 7B BeLLM. This aligns with the finding that larger model scales are more effective in capturing sentence semantics, as indicated in the main findings.

From the *random seed* results, we follow Wu et al. (2023) to use different random seeds. It is observed that this yields even better performance than fixed ones, suggesting BeLLM is robust.

From the *bi-directional strategy* results, we observe that the "modification" strategy yields better results than the "addition" strategy. This implies that the increase in trainable parameters to LLMs by adding new attention layers will increase the difficulty of fine-tuning the model. It demonstrates that modifying the uni-directional attention layer by removing casual masks is effective.

5.4 Case Study

To better understand why BeLLM performs well, we conduct a text retrieval experiment on the test split of the flickr30k dataset (Young et al., 2014). It contains images, each with 5 captions. We used the first caption vector to retrieve the top 4 similar sentences using the faiss vector search framework (Johnson et al., 2019). For strict accuracy (correct cases only count for the top 4 retrieved captions exactly matching the 4 references), SimCSE$_{RoBERTa}$, SimCSE$_{LLaMA}$, and BeLLM obtains 16.4%, 18.4%, and 20.2%, respectively. It shows that BeLLM's sentence embeddings superi-

Ablation Models	Spearman's ρ
Turning Point	
BeLLM (*last bi-layer*) (default)	**86.26**
BeLLM (*no bi-layer*)	85.24
BeLLM (*all bi-layers*)	75.55
Model Scale	
BeLLM_{7B}	86.26
BeLLM_{13B}	**86.87**
Random Seed	
fixed random seed 42	86.26
different random seeds (3 runs)	**86.29**
Bi-directional Strategy	
Modification	**86.26**
Addition	84.35

Table 4: The results of BeLLM ablations with the average Spearman's correlation (Spearman's ρ) of S-STS. *Last bi-layer*: bi-directional layer at the last layer; no bi-layer and all bi-layers: the BeLLM ablation with no and all bi-directional layers. *Modification*: removing casual masks; *Addition*: adding new bi-directional layers.

orly reflect semantic similarities for retrieval.

We then examine a case in Table 5. In the query caption, "police officer" is the subject, and "female" is its subject modifier; their relations can be learned through forward dependency; "hat" and "sunglasses" are objects, and their relations to "police" should be indicated by backward dependency. $\text{SimCSE}_{RoBERTa}$ has a smaller model scale, which limits its ability to exploit global context. As a result, its top results even messed up the subject. Despite having a larger model scale, SimCSE_{LLaMA} exhibits inferior results due to the lack of backward dependency modeling. For this reason, most of the retrieved results missed 1-2 objects. On the contrary, BeLLM performs the best, and the top two captions exactly match the references. The results indicate the superiority of BeLLM in exploiting context to learn high-quality sentence embeddings.

5.5 Discussion of Enhanced Dependency

Finally, we experiment on the intra-sentence dependencies for BeLLM to supplement Section 2. Figure 5 depicts the dependencies change from NLI-trained LLaMA to BeLLM. As can be seen, BeLLM exhibits much higher overall Spearman's correlation scores than LLaMA. This evidence again demonstrates that transforming the last attention layer bi-directional effectively enhances the capabilities of capturing dependency and is helpful in exploiting sentence context for embeddings.

Q:	A female police officer wears an officer's hat and sunglasses.
	$\text{SimCSE}_{RoBERTa}$
#1	An officer stands next to a car on a city street.
#2	A police woman smiling and wearing sunglasses and a hat.
#3	Young, smiling, blond female police officer from New York standing outside on a sidewalk.
#4	An officer in a black uniform and hat stands to the left of a large structure with other officers in the background.
	SimCSE_{LLaMA}
#1	A female police officer in a cap and navy uniform smiles while wearing sunglasses outside of a shop.
#2	Young, smiling, blond female police officer from New York standing outside on a sidewalk.
#3	An officer stands next to a car on a city street.
#4	An officer in a black uniform and hat stands to the left of a large structure with other officers in the background.
	BeLLM
#1	A female police officer in a cap and navy uniform smiles while wearing sunglasses outside of a shop.
#2	A police woman smiling and wearing sunglasses and a hat.
#3	Young, smiling, blond female police officer from New York standing outside on a sidewalk.
#4	An attractive young New York City police woman pauses on the sidewalk.

Table 5: The top 4 retrieved sentences by RoBERTa, LLaMA, and BeLLM from the flickr30k dataset. The words with green color represent the keywords.

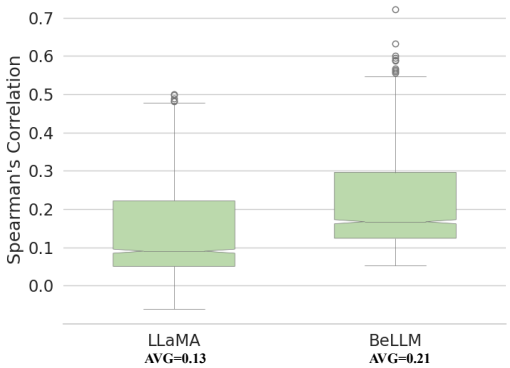

Figure 5: The sentence-level Spearman correlation plot for NLI-trained LLaMA and BeLLM on STS-B test set.

6 Related Work

BeLLM is in line with sentence embeddings. In contrast to early attempts focusing on embeddings on the word level (Mikolov et al., 2013), sentence embeddings capture sentence-level semantics to understand context better. Many previous studies adopted **unsupervised** approaches to utilize large-scale unlabeled text. Here, a popular method is

to use BERT-alike transformers (Li et al., 2020; Su et al., 2021) to encode sentence embeddings. Based on that, contrastive learning (Zhang et al., 2020; Gao et al., 2021; Chuang et al., 2022; Zhuo et al., 2023) was further exploited to explore semantic similarities for sentence embeddings with self-supervision.

To better align sentence embeddings to human senses, other prior studies (Conneau et al., 2017; Cer et al., 2018) employed labeled data for **supervised** sentence embedding learning. Here, pre-trained language models typically worked as the backbone architectures (Reimers and Gurevych, 2019; Su, 2022). Following that, there is growing attention to the use of pre-trained LLMs for sentence embeddings (Li and Li, 2023; Jiang et al., 2023). However, existing works employed commonly used autoregressive LLMs, neglecting the potential benefits of backward dependencies to sentence embeddings. Viewing this gap, we extensively explore the effects of backward dependencies in LLMs for sentence embeddings.

7 Conclusion

Our work has pointed out the benefits of coupling forward and backward dependencies in LLMs for sentence embeddings. We have introduced BeLLM, a novel LLM with backward dependency-enhanced sentence embedding learning. In extensive experiments, BeLLM has achieved state-of-the-art performance across varying STS and downstream tasks.

Limitations

BeLLM has large-scale parameters, which can hinder its efficiency when applied to real-world applications. Addressing this challenge is an essential aspect of our future work. We plan to optimize the model, ensuring it remains practical and efficient for real-world applications.

A Discussion of Anisotropy Problem

Our proposed representative word strategy and contrastive learning can mitigate the anisotropy issue.

Firstly, our proposed representative word strategy can help alleviate this issue since representative words are typically not high-frequency words. For instance, in our experiment using the BeLLM model, the representative word for the sentence "I am unhappy because it is raining" is "unhappy", which is not as commonly used as words like "it" and "is". Our quantitative experiment in the STS-B dataset indicates that approximately 91.74% of representative words are not high-frequency words.

Furthermore, the use of contrastive learning can alleviate this problem further. Here, we give a theoretical explanation. Following Wang and Isola (2020), the contrastive learning objective of Eq. 6 can be formulated as follows:

$$\mathcal{L}_{contrastive} = \mathbb{E}_{(x,x^+)\sim p_{pos}} \left[-f(x)^T f(x^+)/\tau \right] + \mathop{\mathbb{E}}_{\substack{(x,x^+)\sim p_{pos} \\ (x,x_i^-)\sim p_{data}}} \left[\log \left(e^{f(x)^T f(x^+)/\tau} + \sum_i e^{f(x_i^-)^T f(x)/\tau} \right) \right], \tag{7}$$

where x^+ and x^- are the positive and negative examples of x, respectively. p_{pos} denotes positive instances. p_{data} is uniform over finite samples $x_i{}_{i=1}^m$. $f(x)^T f(x^+)/\tau$ measures the alignment (similarity). Since the term $\sum e^{f(x_i^-)^T f(x)/\tau}$ is always positive, the loss function inherently favors smaller values for $\mathbb{E}\left[-f(x)^T f(x^+)/\tau\right]$, i.e., it can be optimized well. Suppose the encoder is perfectly aligned, i.e., $\mathbb{P}[f(x) = f(x^+)] = 1$, then minimizing Eq. 7 equally minimizes following equation:

$$\mathop{\mathbb{E}}_{\substack{(x,x^+)\sim p_{pos} \\ (x,x_i^-)\sim p_{data}}} \left[\log \left(e^{1/\tau} + \sum_i e^{f(x_i^-)^T f(x)/\tau} \right) \right], \tag{8}$$

To minimize it, all sentence embeddings should be pushed away from each other to form a *uniform* distribution. The uniform distribution of sentence embeddings can eliminate the effect of the common words and thus alleviate the anisotropy problem.

B Examples of CSTS

Table 6 shows an example of C-STS. Each sample in C-STS includes three fields: sentence 1, sentence 2, and condition. The sentence pair exhibits varying similarities based on different conditions. The same sentence pair can be classified as either high similarity or low similarity under different

Sentence 1: An older man holding a glass of wine while standing between two beautiful ladies.	
Sentence 2: A group of people gather around a table with bottles and glasses of wine.	
Condition	Similarity
The people's demeanor	5
The number of bottles	1

Table 6: An example from the C-STS validation set, where the same sentence pair has different similarities based on different conditions. A similarity score of 1 indicates dissimilar, while a score of 5 represents similar.

conditions. The scale ranges from 1 (dissimilar) to 5 (similar).

Assessing Factual Reliability of Large Language Model Knowledge

Abstract

The factual knowledge of LLMs is typically evaluated using accuracy, yet this metric does not capture the vulnerability of LLMs to hallucination-inducing factors like prompt and context variability. How do we evaluate the capabilities of LLMs to consistently produce factually correct answers? In this paper, we propose **MOdel kNowledge relIabiliTy scORe (MONITOR)**, a novel metric designed to directly measure LLMs' factual reliability. MONITOR is designed to compute the distance between the probability distributions of a valid output and its counterparts produced by the same LLM probing the same fact using different styles of prompts and contexts. Experiments on a comprehensive range of 12 LLMs demonstrate the effectiveness of MONITOR in evaluating the factual reliability of LLMs while maintaining a low computational overhead. In addition, we release the **FKTC** (Factual Knowledge Test Corpus) to foster research along this line[1].

1 Introduction

Recently, large pre-trained language models (LLMs) have been used as de facto storage for factual knowledge (Petroni et al., 2019). However, applying LLMs to real-world scenarios inevitably leads to language generation deviating from known facts (aka "factual hallucination" (Chang et al., 2023)) due to multiple causes. For example, Cao et al. (2021) argued that the performance of an LLM is over-estimated due to biased prompts overfitting datasets (also referred to as the framing effect in Jones and Steinhardt (2022)) and in-context information leakage.

Given the variability of LLMs' performance under different prompts and contexts, it becomes evident that relying solely on accuracy as an evaluation metric is insufficient. We also need to gauge how robust LLMs are to variations in prompting. In Figure 1 we show examples of factual probes where either the framing of the prompt, or the context to the prompt, is varied, leading to the issue of "accuracy instability".

(a) Prompt framing effect

(b) Effect of in-context interference

Figure 1: 'Accuracy instability" during language generation under various prompts.

Prompt framing effect: An LLM generates different predictions depending on how prompts are framed. Predictions are associated with prompts instead of factual knowledge learned in LLMs. As shown in Figure 1(a), for a fact represented in a triplet ⟨ *Cunter, is located in, Switzerland* ⟩ , the generated predictions for re-framed prompts *"Which country is Cunter situated?"* and *"Cunter is located in Switzerland. True or False?"* are non-factual.

Effect of in-context interference: An LLM leverages in-context information during its decoding stage, but this information may negatively affect an LLM's prediction during knowledge probing. As shown in Figure 1(b), for the same fact, when presented with a context *"England."* concatenated with the prompting question *"Which country is the location of Cunter?"*, an LLM generates a non-factual prediction *"England"*.

How do we assess the reliability of factual knowledge of LLMs under the effects of these hallucination-inducing factors? Investigations into the behaviors of language models during knowl-

edge probing (Petroni et al., 2019; Kassner and Schütze, 2020; Gupta, 2023) have mainly used metrics like precision and accuracy to quantify errors under a specified factor like prompt framing (Jones and Steinhardt, 2022) or mis-primed information (Kassner and Schütze, 2020). Despite the insights gained by showing the instability of LLMs during knowledge probing, these studies are subject to two limitations:

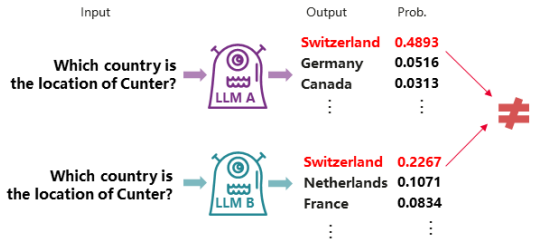

Figure 2: The same top-1 answer with different output probabilities from two LLMs.

No Exploration of Uncertainty. Metrics like top-one accuracy may capture the ordering of predictions in the output space, but they lack the resolution to reflect on the degree of factual knowledge being learned by LLMs. Figure 2 depicts an example where two LLMs (Models A and B) may produce the same result even though their output probabilities vary. By equating the performance of Model A with that of Model B, one introduces a level of approximation in representation, which can be regarded as a source of uncertainty. In this paper, we directly use the output probabilities and construct a high-resolution metric to perform knowledge assessment.

Limited Scope. Previous works focus on understanding the effect of variability of a specific type. We design experiments to investigate the combined effects of multiple causes of accuracy instability: prompt framing and in-context interference during knowledge assessment. In addition, few studies have experimented on LLMs with billions of parameters. In contrast, we investigate the knowledge reliability of 12 freely downloadable LLMs with a range of parameter sizes and origins (with and without instruction fine-tuning).[2]

In this paper, we propose a novel distance-based approach **MOdel kNowledge relIabiliTy scORe (MONITOR)** which captures the deviation of output probability distributions under contexts of prompting variance, interference from mispriming (Kassner and Schütze, 2020) and positively-primed prompts.

We perform experiments on a comprehensive set of knowledge probing tasks and investigate the effectiveness of MONITOR in assessing LLMs' factual reliability. Through experiments with a large variety of different facts, we show that a lower-MONITOR LLM is less likely to suffer from **"accuracy instability"** issue. Computing MONITOR takes only one-third GPU hours of those consumed by a comprehensive accuracy reliability study, making MONITOR a low-cost metric for assessing factual knowledge reliability of LLMs. **Our contributions are:**

1. We propose a novel method to assess the factual reliability of LLMs in the presence of the prompt framing effect and in-context interference. The proposed metric, MONITOR, can be used in conjunction with an end-to-end metric (i.e., accuracy) as part of a multi-dimensional approach to LLM knowledge evaluation.

2. We construct the **FKTC** (Factual Knowledge Test Corpus) by developing question answering probing prompts (210,171 prompts in total) based on 16,167 triplets of 20 fact datasets from T-REx corpus (Elsahar et al., 2018). We will release **FKTC** to the public to foster research works along this line.

2 Related Work

Petroni et al. (2019) demonstrated that factual knowledge can be directly extracted from language models without needing an external knowledge source. However, extracting knowledge (aka knowledge probing) from language models is error-prone due to various biases. For example, Elazar et al. (2021) showed that the consistency of knowledge extracted is generally low when the same fact is queried with different prompts. Many works in prompt engineering attempt to automatically construct prompts outperforming manual prompts (Shin et al., 2020; Jiang et al., 2020; Zhou et al., 2023; Kojima et al., 2022). Cao et al. (2021) argued that the decent performance of a language model is ascribed mainly to the application of these biased prompts, in other words "better" prompts are found to over-fit the answer distribution of the test set instead of reflecting on LLMs' generalization ability to predict factual knowledge.

[2]Only freely downloadable LLMs are used as we need to access to the output probability distributions.

LLMs are sensitive to in-context information. Kassner and Schütze (2020); Gupta (2023) showed that language models fail on most negated probes and are easily misled by misprimes added to the probing context. On the other hand, Zhao et al. (2021); Si et al. (2023); Webson and Pavlick (2022) found the presence of context biases in few-shot probing results. The works mentioned above focused on pinpointing issues affecting LLMs' factual prediction. Few studies were motivated to develop evaluation approaches insensitive to the hallucination-inducing causes. Recently, Raj et al. (2023) presented a framework for evaluating the consistency of LLMs based on accuracy. Zhu et al. (2023) designed a benchmark for assessing the robustness of LLMs to adversarial instruction attacks, measuring the corresponding end-to-end performance drops. Dong et al. (2023) proposed a new metric to measure factual knowledge capability under the bias caused by aliases (alternative names for entities or relations) by reducing the effect of entity and relation aliases in the factual probing. Without tackling other factors like the prompt framing effect and in-context interference (and their interactions), the scope of the study is limited.

3 LLMs in Hallucination

In this section, we investigate LLMs' accuracy under the influence of various hallucination-inducing causes mentioned above. We design five formats of prompts to demonstrate two categories of hallucination-inducing causes during knowledge probing (Table 1). Twelve LLMs with a wide range of parameter size (from 560 million to 30 billion parameters) are covered in this study and experiments (in Section 5), including foundation language models of OPT (Zhang et al., 2022), Galactica (Taylor et al., 2022), and instruction finetuned language model of BLOOMZ (Muennighoff et al., 2023), Vicuna (Zheng et al., 2023), Flan-T5 (Chung et al., 2022), WizardLM (Xu et al., 2023), Flan-UL2 (Tay, 2023; Tay et al., 2023), LLaMa-30b-instruct-2048 (upstage, 2023).

3.1 Effect of Prompt Framing on Accuracy

We design three probing templates based on the ⟨ "subject","relation","object" ⟩ to show the effect of prompt framing on LLMs, depicted below, and for each task, we use seven paraphrased prompts to ensure diversity:

Word Prediction (WP) Template: Given the "subject" and the prompt template, LLMs perform word prediction to complete the sentence, e.g., the template (1) in Table 1.

Prompt frames
(1) WP: [X] is located in _
(2) QA: Which country is [X] situated in?
(3) FC: Statement: [X] is located in [Y]. The statement is True of False?
In-context interference
(4) [Y]. Which country is the location of [X]?
(5) [Y_]. Which country is the location of [X]?

Table 1: Examples of designed probing task templates extending the P17 (a fact dataset containing 931 subject-object pairs with the "country" relation from T-REx (Elsahar et al., 2018)). [Y] is the object wrt the subject [X], [Y_] is an entity weakly related to [X].

Question-Answer (QA) Template: In the QA template, question prompts are constructed from paraphrasing templates in T-REx (Elsahar et al., 2018) targeting each fact. For example, a template "[X] is located in [Y]." for a triplet ⟨ [X], is located in, [Y] ⟩ can be paraphrased to "Which country is [X] situated in?".

Fact Checking (FC) Template: An FC prompt is designed as a verification statement based on a template in T-REx, e.g., "Statement: [X] is located in [Y]. The statement is True or False?". We build the positive checking probe (**FC-pos**) and negative checking probe (**FC-neg**) corresponding to whether the statement is factual or not. For a negative fact-checking prompt, we average the prediction accuracy for five random entities chosen from the same category.

The probing results are shown in Table 2 as accuracy in predicting P17 factual knowledge for each involved LLM under prompting biases presented in terms of WP, QA, and FC templates. The performances of LLMs in predicting the fact test data vary significantly under prompt variability. Abnormal performances of LLMs between QA and WP template-based probes (bold numbers of Vicuna-7b) and between the FC probes for positive and negative interference (bold numbers of BLOOMZ-1b1) are strong evidences of the prompt framing effect. The fluctuation under WP, QA, and FC templates shown as box plots in Figure 9 (Appendix A.1) further demonstrates the effect of prompt framing on the performances of LLMs.

3.2 Effect of In-context Interference

To explore the effect of in-context interference bias, we add probes with misprimed (Kassner and Schütze, 2020) interference by concatenating con-

LLMs	Size	WP	QA	FC-pos	FC-neg
BLOOMZ-560m	0.56	14.73	26.09	28.77	73.78

Table 3: The effect of probing the P17 fact dataset with QA templates (4) and (5) in Table 1, where "×" means experimental results with the original QA templates, "[Y]" means results using the factual information as in-context information, and "[Y_]" refers to results using non-factual in-context information of entities weakly related to "[X]".

texts in terms of factual/non-factual information preceding the associated QA prompt (template (2) in Table 1). Table 3 captures the accuracy of LLMs in a comparative study using factual entity probes and misprimes consisting of weakly associated entities. We observe a strong interference effect from nonfactual antecedents for all 12 LLMs. A factual entity (positive interference) can improve the accuracy by up to +43.67 while a weakly related entity (negative interference) reduces the accuracy by -66.00 at most.

4 Methodology

In this section, we introduce MONITOR, a distance-based score, to assess how the factual knowledge of LLMs is affected by the previously mentioned prompt framing and in-context interference.

Firstly, we introduce a new variable (i) to represent hallucination-inducing in-context information into the initial knowledge representation triplet $\langle$ *subject, relation, object* $\rangle$. The newly formed

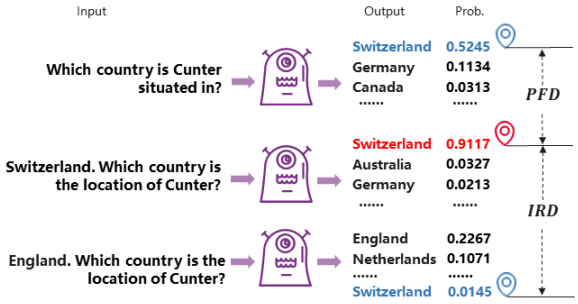

Figure 3: A primary anchor (in red font) corresponds to its multiple foreign anchors with different output probabilities (blue fonts) when an LLM is exposed to different prompts and context interference. "PFD" and "IRD" refer to the two distance measurements defined as the prompt-framing degree and interference-relevance degree.

knowledge representation quadruple can be expressed as $\langle\ s, r, o, i\ \rangle$. The information i can be further categorized into two variables: we use a factual object entity to implement a positive information i^+; and the negative information i^- represents interference when predicting o. For example, "England" is considered as an i^- when acting as a noisy condition to negatively affect an LLM in predicting a desirable outcome $\langle$ *Switzerland* $\rangle$ for a fact $\langle$ *Cunter, is located in, Switzerland* $\rangle$. Corresponding to an object, $P(o|s, r, i)$ is the probability of the model generating the object o with the conditions of subject s, prompt framing expression r, and the in-context information i.

To quantify the effect of i on LLMs, we establish **"anchor"** as a reference point, which is the gold answer with its probability in the output space. A "primary anchor" (shown as the red font "Switzerland 0.9117" in Figure 3) is defined as an enforced-accurate answer with its probability produced by an LLM in response to a knowledge probe. A primary anchor is produced by prompting an LLM with a QA template prefixed with positive information i^+ (i.e. template (4) in Table 1). A primary anchor has multiple **foreign anchors** with various output probabilities (i.e., "Switzerland" in blue fonts in Figure 3) when an LLM is exposed to different prompts and in-context interference. Foreign anchors are generated using paraphrased Templates (2)[3] and (5)[4] presented in Table 1. By calculating the distance (using the probability changes) between a primary anchor and its corresponding foreign anchors in the influenced output space, we

[3]QA template without in-context information
[4]QA template with negative in-context interference

can measure how reliable an LLM is in predicting facts in the test set.

MONITOR consists of two distance-based measurement components: Prompt-framing Degree (PFD) and Interference-relevance Degree (IRD).

4.1 Prompt-framing Degree

The prompt-framing degree (PFD) is the mean distance between the output probability distributions of a primary anchor ($P(o|s,r,i^+)$) and those produced by the same LLM using prompting frames r_j probing the same fact without any add-on context (foreign anchors $P(o|s,r_j)$). PFD evaluates the similarity of two output probabilities between prompting frame relation expressions r (the basic prompt framing) and r_j. It is defined as:

$$PFD = \frac{1}{R}\sum_{j=1}^{R}\frac{1}{L_c}\sum_{l=1}^{L_c}|P(o_c|s_c,r,i^+)_l - P(o_c|s_c,r_j)_l| \quad (1)$$

where R is the count of prompt framing expressions for a subject, and the count of subject and object in a fact dataset is S, $c \in \{1,...,S\}$. L_c is the length of the anchor in terms of the number of subwords in the c-th object. PFD is a cumulative metric for assessing an LLM's capability in producing output probability distributions sharing the same characteristics under various prompting frames. PFD has a value between 0 and 1. The smaller the value is, the more robust an LLM is under the effect of prompt framing.

4.2 Interference-relevance Degree

Interference-relevance Degree (IRD) is the distance between the output probability distributions of a primary anchor ($P(o|s,r,i^+)$) and the probability distributions generated by the same LLM under the influence of in-context interference (foreign anchors $P(o|s,r,i^-)$). IRD measures an LLM's capability to predict factual knowledge under the effect of in-context interference.

$$IRD = \frac{1}{M}\sum_{m=1}^{M}\frac{1}{L_c}\sum_{l=1}^{L_c}|P(o_c|s_c,r,i^+)_l - P(o_c|s_c,r,i_m^-)_l| \quad (2)$$

We define the count of positive and negative information as one and M, respectively, corresponding to an object. IRD has a value between 0 and 1. As positive contextual information likely leads to factual knowledge generation, a smaller value of IRD indicates a lower level of effect from in-context interference biases.

4.3 MONITOR

The prompt-framing degree PFD and interference-relevance degree IRD are integrated to produce the proposed model knowledge reliability score (MONITOR). MONITOR captures the quadratic interaction of PFD and IRD, as illustrated in Eq 3 for a specified number of quadruples $\langle\ s,r,o,i\ \rangle$, where the count of subject and object is S. A set of coefficients (α_{1-3}) is introduced to quantify the contributions from PFD, IRD, and their interaction on MONITOR. In this experiment, we consider an equal contribution scenario ($\alpha_1 = \alpha_2 = \alpha_3 = 0.33$). The smaller the value of MONITOR, the less degree an LLM is influenced by hallucination-induced factors when producing factual outputs. Taking the average output probabilities of primary anchors for an LLM as the denominator, MONITOR captures the degree of knowledge learned by an LLM when assessing its factual knowledge. MONITOR measures the effect of prompt framing and interference per unit of average primary anchor probability, demonstrating the strength of anchor representations.

LLMs are resource-hungry even during their inference phases. It is essential to ensure that an assessment metric is computation-efficient. Combining PFD, IRD, and their interaction in one metric can reduce the computation cost when evaluating factual reliability. Considering a fact dataset with R prompt frames, M negative interference, and one positive interference, there are $R \cdot M$ combinations required to compute the average accuracy (and accuracy range). In comparison, we only require $R + (1 + M)$ combinations to compute MONITOR. The computation complexity for calculating MONITOR ($O(R+M)$) is considerably lower than that of accuracy ($O(R \cdot M)$).

$$MONITOR = \frac{\sum_c^S \sqrt{\alpha_1 PFD^2 + \alpha_2 IRD^2 + \alpha_3 PFD * IRD}}{\sum_c^S \frac{1}{L_c}\sum_{l=1}^{L_c} P(o_c|s_c,r,i^+)_l} \quad (3)$$

5 Experiments and Results

In this section, we describe how to apply MONITOR to assess the factual knowledge of the 12 LLMs as mentioned above.

5.1 Data Setting

In this section, we describe how we develop a test corpus to accommodate prompts with various styles and in-context interference.

Expanding Probing Prompt: Based on 16,167 $\langle$ subject, relation, object $\rangle$ triplets from T-REx

LLMs	MONITOR ↓	avg↑	max ↑	min ↑	probs ↑
BLOOMZ-560m	0.701	27.770	40.411	15.062	0.467
BLOOMZ-1b1	0.692	30.055	43.369	16.654	0.501
Galactica-1b3	0.747	22.936	39.414	9.427	0.637
OPT-2b7	0.637	25.599	37.117	11.347	0.360
BLOOMZ-3b	0.686	30.638	44.760	16.760	0.610
Vicuna-7b	0.504	38.194	59.727	18.361	0.884
BLOOMZ-7b1	0.632	36.232	49.328	22.870	0.613
Flan-T5-XXL	0.630	32.968	48.864	19.868	0.798
Vicuna-13b	0.484	44.882	65.499	26.967	0.862
WizardLM-13b	0.560	**51.477**	66.036	**33.076**	0.774
Flan-UL2	0.684	32.723	51.442	16.319	0.711
LLaMa-30b-ins.	**0.479**	50.798	**71.188**	30.516	**0.909**
Correlation	Pearson			p-value	
r(MONITOR,avg acc)	**-0.846**			**0.001**	

Table 4: Results are evaluated on FKTC with "bold" numbers indicating the best measurement over the same column category. The "avg", "max", and "min" mean the average, maximum, and minimum accuracy across the 20 fact datasets. The "probs." depicts the probabilities of primary anchors. "↓" means a smaller measurement wins.

(Elsahar et al., 2018), we develop QA probing prompts. We expand the probing prompt dataset by paraphrasing using GPT-4 (OpenAI, 2023) to create seven prompt frames for each triplet. In order to maintain diversity of prompts, we choose prompts with a similarity score (BLEU) below a threshold (0.7). Moreover, we manually check the paraphrased prompts to ensure validity.

Adding In-context Interference: Based on the QA prompts constructed above, we create a test dataset to explore the effectiveness of MONITOR with in-context interference. The corpus FKTC stands for "Factual Knowledge Test Corpus". Following the template patterns (Templates 4 and 5) in Table 1, we concatenate interference information (in terms of positive and negative in-context information) with the probing question for each subject. The negative information is entities from the same category weakly related to the corresponding subject, sampled from all objects that share the same relation. This process is applied to all expanded templates presented in Table 10 (Appendix A.2).

After applying these two processes (expanding the probing prompts and adding in-context interference) we produce 210,171 prompts focusing on 20 fact datasets.

5.2 Results and Analysis

5.2.1 Results on FKTC

The results evaluated on FKTC are shown in Table 4, and the results of each fact dataset are shown in Table 11 (Appendix A.3), where MONITOR and the average accuracy (avg acc) are recorded for each LLM across the 20 fact datasets in our experiments. Each LLM's minimal and maximal accuracy are also recorded to show the accuracy variability.

As shown in Table 4, LLaMa-30b-ins. stands out as the most capable (with the smallest MONITOR 0.479) LLM, followed by Vicuna-13b (0.484) and Vicuna-7b (0.504). Even though MONITOR is a fundamentally different from an end-to-end metric (like accuracy), it correlates significantly with the average accuracy (0.846 Pearson coefficient). MONITOR adds a dimension to a point-measured metric (like accuracy) to show factual reliability of LLMs under prompt and context variability.

As shown in Table 5 (bold italic fonts), MONITOR can differentiate LLMs, for example, BLOOMZ-3b and Vicuna-7b, with a similar average accuracy on P37, by considering distance and probability information. We further discuss this in Subsection 5.2.3.

We present a detailed view of the knowledge assessment of LLMs by drilling down into specific facts. Unlike the results mentioned above, showing a general trend, the results disclosed here show more detailed insights. As shown in Table 5, the overall winning LLM (i.e., LLaMa-30b-ins.) can lose its edge in predicting a particular fact (P37).

5.2.2 Accuracy Instability

We analyze the LLMs' "accuracy instability" when predicting P1412[5] with the results captured in Table 6 and Figure 4. A variety of statistics, including the base accuracy ("base acc") and standard deviation ("std") of an LLM's accuracy, are recorded for comparisons. A significant correlation is observed between accuracy standard deviation and MONITOR (0.754), demonstrating that a lower-MONITOR LLM is less likely to suffer from "accuracy instability" (Figure 5). Furthermore, as shown in Figure 4, an LLM with a lower MONITOR has a smaller value of accuracy standard deviation when two LLMs with equivalent base accuracy are evaluated (bold fonts in Table 5). From an accuracy stability viewpoint, one may choose an LLM with a lower MONITOR. For example, we prefer Vicuna-13b over WizardLM-13b, as the MONITOR of Vicuna-13b is lower even though they have similar accuracy.

5.2.3 Resolution Characteristics

It can be observed in Table 4 that the correlation between MONITOR and average accuracy is sig-

[5]P1412: the fact dataset describing a relation of "languages spoken, written, and signed"

r(MONITOR,std)	**0.754**		**0.001**

Table 6: LLMs with lower MONITOR are strongly correlated with smaller values of accuracy standard deviation, indicating less influence from prompt and context variability. "base acc" is the accuracy associated with the base prompt evaluated on the P1412 fact dataset.

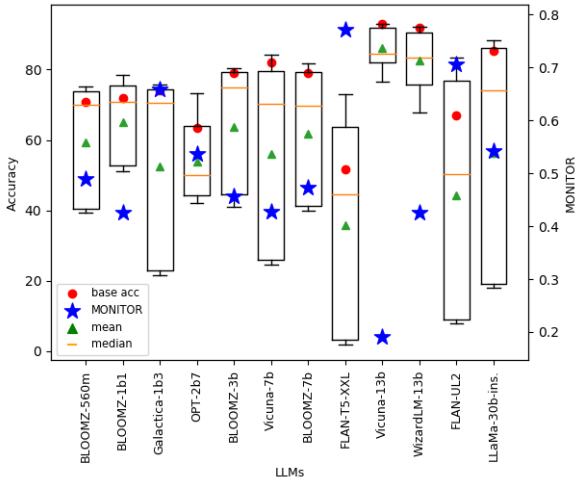

Figure 4: MONITOR can be used to differentiate LLMs' factual knowledge reliability when models with an equivalent base accuracy are evaluated. The box plots show the related distributions of accuracy when testing on P1412 fact dataset.

Base Prompt	What language is the official language of Haiti?		
effect	input	output BLOOMZ/Vicuna	prob. BLOOMZ/Vicuna
pos. context	French.{base}	French/French	0.761/**0.928**
neg. context	Irish.{base}	French/French	0.411/**0.622**
framing	{base}	French/French	0.527/**0.849**

Table 7: Vicuna-7b outperforms BLOOMZ-3b in MONITOR when evaluated on the P37 fact dataset by producing correct answers with higher output probabilities in response to positive, negative in-context interference and prompt framing effect. {base} refers to the base prompt.

nificant. How should one use MONITOR when assessing the reliability of LLM knowledge?

We regard MONITOR as a high-resolution metric because it directly uses output probabilities and their changes (in terms of anchored distance) induced by hallucination factors. MONITOR considers both the output (nominal or qualitative data) and the probability of the output (quantitative information). Comparatively, assessing LLMs' knowledge with an end-to-end metric, such as accuracy, is purely reliant on a nominal output from the softmax layer of a transformer. It is shown in Table 5 that two LLMs (BLOOMZ-3b vs. Vicuna-7b) with almost identical average accuracy on P37 fact dataset have two distinctive values of MONITOR (0.570 vs 0.432). Delving into the log file of the inference task, we gain in-depth insights into why Vicuna-7b outperforms BLOOMZ-3b in the reliability score. As shown in Table 7, despite their similarities in the accuracy measurement, Vicuna-7b has much higher output probabilities than those of BLOOMZ-3b, contributing to the discrepancies in MONITOR.

Additionally, we plot out the probability distribution of the above two LLMs with almost identical average accuracy but very distinctive MONITOR (Figure 10 Appendix (A.5). It can be observed that

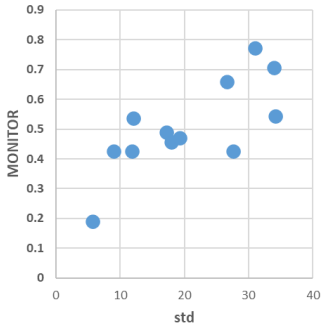

Figure 5: A significant correlation between MONITOR and accuracy standard deviation when testing the 12 LLMs on P1412 fact dataset, indicating lower-MONITOR models are less likely to suffer from the "accuracy instability" issue.

a more reliable LLM based on MONITOR, Vicuna-7b, has a much higher percentage of solid output probability (i.e., ≥ 0.8) than those of a volatile LLM (BLOOMZ-3b). It is recommended to adopt MONITOR when using accuracy alone cannot differentiate LLMs' knowledge reliability.

Cost	MONITOR	Average Accuracy	MONITOR-saved
GPU hours	14.4	42.7	2.97X

Table 8: GPU hours consumed calculating MONITOR and average accuracy on P1412 fact dataset for LLaMa-30b-ins."MONITOR-saved" denotes that GPU hours saved from using MONITOR compared to accuracy.

5.2.4 Lower Computation Cost

We compare the GPU hours consumed by LLaMa-30b-ins. in producing MONITOR and a full-scale accuracy reliability score (average accuracy). The experiment is to test the model on a specific fact dataset (P1412) using 8 NVIDIA V100 GPUs. It can be observed in Table 8 that using MONITOR leads to a 2.97-fold resource saving in GPU hours compared to applying an accuracy metric to a factual reliability evaluation. MONITOR is an economical method to add a dimension to LLM knowledge assessment when performing a full-scale reliability study on accuracy is not an option.

6 Discussion

6.1 Attribution of In-Context Interference

To demonstrate the resilience of LLMs with different MONITOR, we conduct an additional experiment by applying the Integrated Gradients (Sundararajan et al., 2017) technique implemented in Sarti et al. (2023). By examining and visualizing

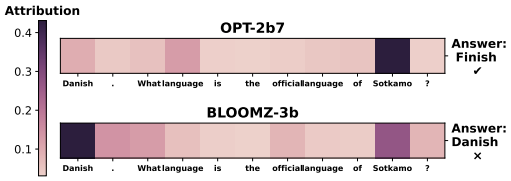

Figure 6: Visualizing model behaviors of BLOOMZ-3b and OPT-2b7 under the influence of an input with misprimed in-context interference. The input is *"Danish. What language is the official language of Sotkamo?"*.

the attribution of input features to the model's outputs, we can infer the reliability of LLMs with different MONITOR. We study the behaviors of two LLMs (OPT-2b7 vs. BLOOMZ-3b) with distinctive values of MONITOR (0.471 vs. 0.570). The heat map shown in Figure 6 illustrates that a more reliable model with a lower MONITOR, OPT-2b7, is less influenced by in-context interference.

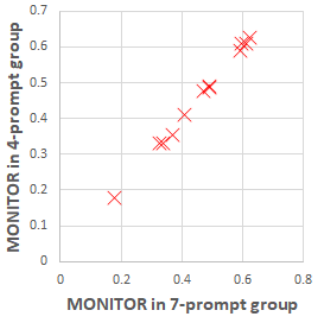

Figure 7: Significant correlation of MONITOR between the 7-prompt group and the 4-prompt group when assessing the reliability of 12 LLMs in the P178 fact dataset.

6.2 Prompt Ablation

We design an ablation study to investigate the consistency of MONITOR across different prompt settings by analyzing the MONITOR in the P178 fact dataset. The MONITOR from an expanded prompts group setting (consisting of seven prompts) and a sub-sampled group with four prompts are captured in Figure 7. We observe a strong linear correlation between MONITOR of the expanded group and those from the sub-sampled group, indicating the scalability of MONITOR across prompt settings. Additionally, it is noted that MONITOR ranks LLMs in a consistent order for different prompt settings as show in Figure 8.

6.3 Influence of Instruction Fine-tuning

Furthermore, in order to conduct a more detailed difference analysis between the foundation model

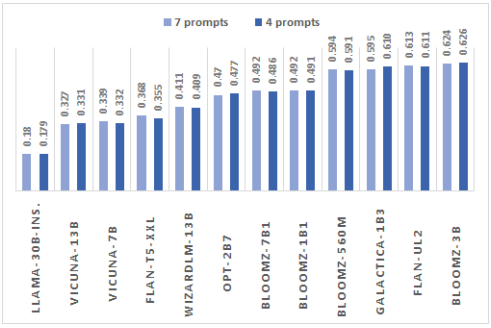

Figure 8: The consistency of MONITOR when assessing LLM's factual reliability in predicting P178 facts across different prompts settings.

and the instruction fine-tuned model, we compare the foundation model BLOOM-7b1 and instructed model BLOOMZ-7b1. Both models share the same architecture and are evaluated on the P1412 dataset, as illustrated in Table 12. The comparison reveals that the instruction fine-tuning (IFT) approaches have an impact on the probability distribution. Specifically, the probability of the primary anchor in the foundation BLOOM-7b1 is 0.137, significantly lower than that in the IFT BLOOMZ-7b1 (0.541), resulting in higher MONITOR values and lower accuracy. This observation further supports the notion that instruction fine-tuning can enhance the reliability of Language Models.

LLMs	MONITOR ↓	avg↑	max ↑	min ↑	probs ↑
BLOOM-7b1	0.813	13.985	55.782	1.361	0.137
BLOOMZ-7b1	0.471	58.904	81.863	39.828	0.541

Table 9: Results are evaluated on P1412 dataset with comparing between BLOOM-7b1 (foundation model) and BLOOMZ-7b1 (IFT model).

7 Conclusion

In this paper, we show that large language models are subject to the influence of various hallucination-inducing causes. We propose a novel distance-based metric, directly computing the output probabilities and their changes to address "accuracy instability" caused by the prompt framing effect and in-context interference. A comprehensive set of experiments demonstrates that the proposed MONITOR is a high-resolution economic method suitable for evaluating the reliability of large language model knowledge. MONITOR can be used in conjunction with an end-to-end metric (i.e., accuracy) as part of a multi-dimensional approach to LLM knowledge evaluation. The constructed FKTC, consisting of 210,171 question answering prompts on 20 fact datasets, will be made available to the public to foster research along this line.

Limitations

We focus on proposing MONITOR to assess the reliability of factual knowledge of LLMs during knowledge probing. Whether MONITOR can be generalized to a wider scope of tasks (e.g., summarization) warrants a future study. Additionally, the initial setup of contribution coefficients of PFD, IRD, and their interaction on MONITOR should be further investigated to establish an empirical benchmark. Currently MONITOR applies exact matching to obtain anchors to measure the reliability of LLM knowledge. Extending the automatic evaluation to anchors consisting of sentences is challenging. Our approach needs to access to the output probability distributions of an LLM, therefore is not applicable to SOTA commercialized LLMs such as GPT4. Additionally, FKTC is developed based on the latest version of T-REx benchmark dataset. The quality of the factual knowledge contents in FKTC is reliant on the alignment accuracy of T-REx. Even though we could argue that FKTC has already accommodated over 210 thousand prompts in the gold dataset to successfully support MONITOR in assessing LLMs behaviors under prompt and context variability, it can still be extended to host more knowledge categories.

Licensing and Intended Use

FKTC is based on a widely adopted T-REx benchmark dataset, which is publicly available under a Creative Commons Attribution-ShareAlike 4.0 International License. FKTC is released to the public under the same license, consistent with the original intended use.

A Appendix

A.1 Prompt Framing Effect

We paraphrase each fact dataset in three prompting templates (WP, QA, and FC) so that each template can be used to produce seven prompts. For example, the template "Which country is the location of [X]?" could be paraphrased as: "Which country is [X] situated in?", "Which country can [X] be found?", "Which country is the geographical position of [X]?", "Which country is the site of [X]?", "In Which country is [X] situated?", "Whereabouts is [X] located?". In this way, context diversity and semantic invariance are guaranteed. Figure 9 shows the "accuracy instability" of LLMs under the effect of prompt framing in predicting P17 facts based on three tasks (WP, QA, and FC).

A.2 Templates Examples

Table 10 shows all templates and corresponding prompts on 20 fact datasets.

A.3 MONITOR for All LLMs Experimented on FKTC

Table 11 shows the results of various LLMs evaluated on each fact dataset from FKTC.

A.4 Correlation between MONITOR and Accuracy

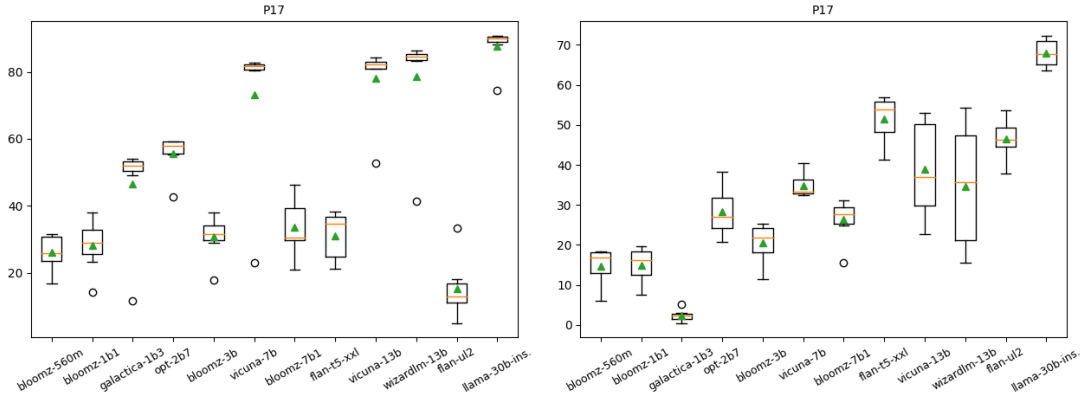

Table 12 shows the Pearson correlation between MONITOR and average accuracy, evaluated on the 20 fact datasets from FKTC corpus.

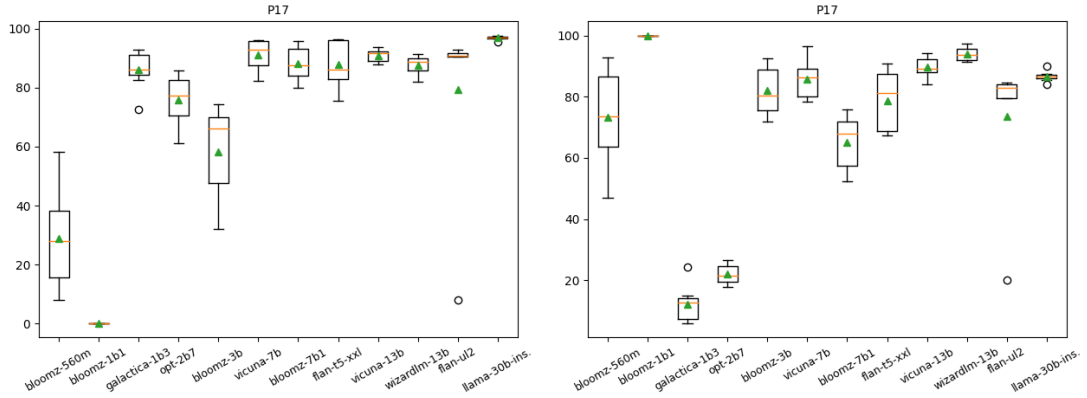
A.5 Probability Distribution

Figure 10 shows the probability distribution of two LLMs (BLOOMZ-3b and Vicuna-7b) with almost identical average accuracy but very distinctive MONITOR.



A.6 Analysis on LLMs Scale

To further verify if MONITOR of LLMs follows the law of scaling, where larger LLMs are more knowledge-reliable, we present how MONITOR changes across BLOOMZ series for each specific fact dataset (shown in Figure 11). While MONITOR of LLMs may not conform to the scaling law at the granularity of each fact, their aggregated values in a comprehensive scope of experiments do follow the rule of scale (shown in Figures 11-12).

(a) QA

(b) WP

(c) FC-pos

(d) FC-neg

Figure 9: Box plots show the "accuracy instability" of LLMs under the effect of prompt framing in predicting P17 based on three tasks (WP, QA, and FC).

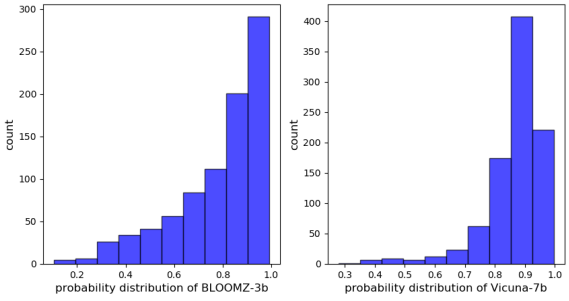


Figure 10: A comparison of the probability distribution of anchors between BLOOMZ-3b and Vicuna-7b on P37. The population percentages with a solid probability (i.e., ≥ 0.8) are **59%** and **85%** for BLOOMZ-3b and Vicuna-7b, respectively.

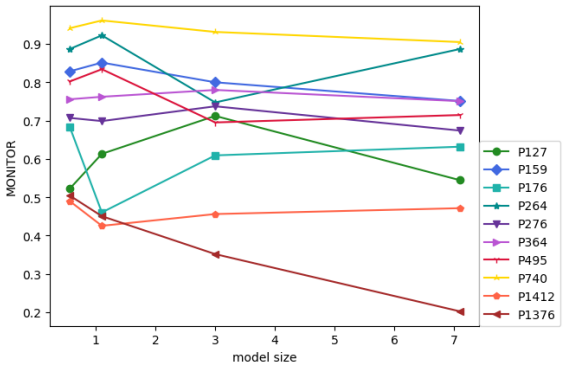

Figure 11: The BLOOMZ series adheres to the scale law for the specific facts with smaller MONITOR for bigger models. The horizontal axis represents the model's size in billions, and the vertical axis represents the results of MONITOR.

Fact	Relation	Object Type	Template	Prompt example	Count

Abstract

Dialogue response selection aims to select an appropriate response from several candidates based on a given user and system utterance history. Most existing works primarily focus on post-training and fine-tuning tailored for cross-encoders. However, there are no post-training methods tailored for dense encoders in dialogue response selection. We argue that when the current language model, based on dense dialogue systems (such as BERT), is employed as a dense encoder, it separately encodes dialogue context and response, leading to a struggle to achieve the alignment of both representations. Thus, we propose Dial-MAE (Dialogue Contextual Masking Auto-Encoder), a straightforward yet effective post-training technique tailored for dense encoders in dialogue response selection. Dial-MAE uses an asymmetric encoder-decoder architecture to compress the dialogue semantics into dense vectors, which achieves better alignment between the features of the dialogue context and response. Our experiments have demonstrated that Dial-MAE is highly effective, achieving state-of-the-art performance on two commonly evaluated benchmarks.

1 Introduction

The retrieval-based dialogue system is a popular research topic. Pre-trained language models (PLMs), especially deep bidirectional Transformer Language Models (LMs) like BERT encoder (Vaswani et al., 2017; Devlin et al., 2019), have been widely used in dialogue response. Common uses of deep LM are cross-encoder and bi-encoder (Gao and Callan, 2021). Recent works (Gu et al., 2020; Whang et al., 2021; Xu et al., 2021; Han et al., 2021; Zhang et al., 2022) on dialogue response retrieval systems are mostly based on cross-encoders, which feed both the dialogue context and response directly into LM and use attention over all tokens to output a relevance score. Although cross-encoders have relatively stronger performances, they need to compute the matches for every possible combination of context-response pairs, which is time-consuming (Lan et al., 2021). In practice, cross-encoders are often used for re-ranking after dialogue retrieval. In contrast, another common use of deep LM is the dense encoder, i.e. bi-encoder, which encodes dialogue context and response into the context vector and response vector respectively. The correlations between context and responses are computed using cosine similarity or dot product functions in vector space (Lan et al., 2021; Gao et al., 2022). The bi-encoders have a faster computational speed but usually perform worse than the cross-encoder.

Bi-encoders generally underperform compared to cross-encoders due to two main reasons below (Han et al., 2021; Gao and Callan, 2021; Lan et al., 2021). Firstly, bi-encoders encode dialogue context and responses separately, which lacks deep interaction like the cross-encoder (Han et al., 2021). We consider this as a potential information barrier that hinders the performance of bi-encoders, resulting in significant differences between the dense vector representations of the dialogue context and response vectors. Secondly, language models like BERT (Devlin et al., 2019) have not been trained to aggregate complex information into a single dense representation (Gao and Callan, 2021). Although using contrastive learning during the fine-tuning can alleviate the above two issues (Lan et al., 2021), the discussion regarding their mitigation with post-training remains absent in dialogue response selection. We argue that post-training a PLM specifically tailored for the dense dialogue retrieval is essential for achieving optimal performance.

In this paper, we focus on the above two issues and propose **Dial-MAE** (**Dial**ogue Contextual **M**asking **A**uto-**E**ncoder), a simple and effective post-training method tailored for the bi-encoder

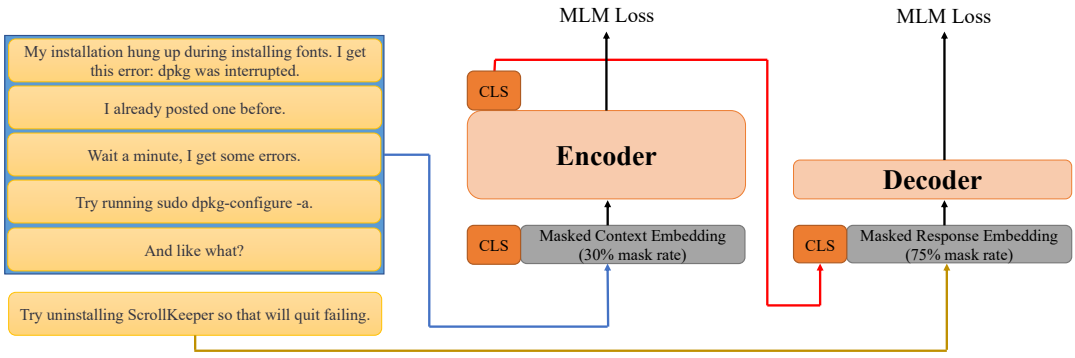

Figure 1: The model design for Dial-MAE. The input of the encoder is the dialogue context, and its next response and dialogue context embedding output by the encoder is used as the input to the decoder.

to compress dialogue semantic information and enhance the representation of dialogue-dense vectors. Our method provides a stronger foundation for model fine-tuning. Specifically, during the modeling process, we consider both the semantics of the dialogue context and the semantic relevance of the response.

As shown in Figure 1, we introduce an asymmetric encoder-decoder architecture. With the help of the dialogue context embedding [**CLS**] output by the encoder, the auxiliary task utilizes a weak decoder to reconstruct the masked response text. In other words, we employ the embedding of the dialogue context to directly generate responses. Therefore, even if the encoder side only receives the inputs of dialogue contexts, the output dialogue context embedding still needs to consider the correct response. This enables the dialogue context embedding [**CLS**] to incorporate contextual information. In addition, the encoder is required to directly predict the correct response when encoding the dialogue context, which breaks the information barrier between the context and the response. Therefore, the context and response features output by Dial-MAE are more similar, and our ablation experiments also prove this.

Furthermore, it is noteworthy that, similar to (Xiao et al., 2022; Gao and Callan, 2021), we apply asymmetric mask rates to the encoder and decoder. The decoder side has a higher mask rate than the encoder side. Such a design has the following advantage. Since the decoder has limited modeling capacity and high mask rate, the reconstruction on the decoder side is difficult to accomplish only by relying on masked response and rely more on the dialogue embedding output by the encoder, this forces the encoder to sufficiently aggregate the semantics of the dialogue context to aid the decoder in its MLM task (Xiao et al., 2022; Gao and Callan, 2021).

Our contributions are as follows:

1. We introduce Dial-MAE, a novel post-training method designed for bi-encoders, which utilizes dialogue context embeddings to generate responses, aiming to achieve feature alignment.

2. We design a novel asymmetric encoder-decoder architecture to enhance the representational power of dialogue embedding.

3. Experimental results show that in dialogue response retrieval, our method achieves state-of-the-art on two benchmarks with faster response speed.

2 Related Work

In this section, we first discuss traditional retrieval dialogue systems based on neural networks, and then we discuss current dialogue systems based on pre-trained language models.

2.1 Neural Dialogue Response Retrieval

Dialogue response selection aims to select the most appropriate response from a range of candidates. Earlier studies (Kadlec et al., 2015; Lowe et al., 2015) focused on single-turn response selection. Later, more and more studies paid attention to multi-turn dialogue response selection. Lowe et al. (2015) introduce a method that calculates the matching degree between dialogue and response based on Recurrent Neural Networks (RNNs). They also contributed a benchmark dataset named Ubuntu V1. In a similar vein, Kadlec

et al. (2015) advocate for the use of Convolutional Neural Networks (CNN) and Long Short-Term Memory (LSTM) as encoders to represent both the context and response. However, these methods do not explicitly treat each utterance as a unit, making it difficult to capture utterance-level discourse information. Zhou et al. (2016) propose a multi-view model that encodes both word-level and utterance-level representations. Meanwhile, to fully reflect the relationship between dialogue and response, Wu et al. (2017) suggest utilizing word embeddings and their sequential representations, encoded by Gated Recurrent Units (GRU), to construct a matching matrix between the dialogue context and response. With the popularity of attention mechanisms(Luong et al., 2015; Vaswani et al., 2017). Zhou et al. (2018) propose a deep attention-matching network that applies the attention mechanism to the response selection dialogue system. Furthermore, Tao et al. (2019) advocate for context and response matching by stacking multiple interaction blocks, providing a nuanced perspective. In a similar vein, Yuan et al. (2019) introduce a multi-hop selector network designed to identify relevant utterances in the context of response matching. However, most traditional retrieval models are lightweight networks, and their performance is difficult to compare with PLMs.

2.2 PLM-based Dialogue Response Retrieval

Since PLMs show impressive performances in various downstream NLP tasks(Devlin et al., 2019; Brown et al., 2020; Touvron et al., 2023; Su et al., 2023; Wu et al., 2023). More and more studies apply PLMs to response selection. BERT-VFT (Whang et al., 2020) first applies the pre-trained language model BERT to dialogue response selection, and achieves state-of-the-art results. SA-BERT (Gu et al., 2020) adds speaker embedding to the model, in order to make the model aware of the speaker change information. Multi-Task Learning is also an effective way, UMS$_{BERT+}$ (Whang et al., 2021) proposes a set of strategies, which aids the response selection model towards maintaining dialogue coherence. Alternatively, Xu et al. (2021) propose learning a context-response matching model with multiple auxiliary self-supervised tasks. However, these methods have the problem of not fully considering the relationship between each utterance in the context. BERT-FP (Han et al., 2021) proposes to classify the relationship between a given utterance and a target utterance into more fine-grained labels, which makes the model learn the semantic relevance and coherence between the utterances. Zhang et al. (2022) propose two-level supervised contrastive learning so that the learned dialogue representations can be further separated in the embedding space. In addition, DR-BERT(Lan et al., 2021) explores the transfer of techniques from dense passage retrieval community to dialogue response selection. Although DR-BERT (Lan et al., 2021) propose fine-tuning PLMs through contrastive learning to enhance the representation capability of dialogue-dense vectors, there has been no research on tailoring post-training tasks to enhance the representation ability of dialogue-dense vectors.

3 Methodology

This section first introduces masked language model pre-training as preliminary knowledge. Then we introduce detailed post-training, including the construction of data and the auxiliary task. Finally, we introduce the details of fine-tuning.

3.1 Masked Language Model Pre-training

MLM is an unsupervised method that masks parts of the input tokens and requires the Transformers-based LM to predict them based on the unmasked tokens. Formally, given an input sentence $X = [x_1, x_2, ..., x_n]$. We select a certain percentage of tokens from X and replace them with a special token $[\mathbf{MASK}]$ to get corrupted $\widetilde{X}$. We denote these tokens replaced by $[\mathbf{MASK}]$ as $m(X)$. Then, LM is used to transform the corrupted input into the hidden states:

$$[\mathbf{h}^l_{cls}, \mathbf{h}^l] = LM([CLS], \tilde{X}) \tag{1}$$

Here, $[\mathbf{CLS}]$ is a special token that is prepended at the beginning of the text. $\mathbf{h}^l_{cls}$ and $\mathbf{h}^l$ respectively represent the hidden states of the final layer output after the $[\mathbf{CLS}]$ and $\widetilde{X}$ pass through the LM, i.e., $\mathbf{h}^l = [\mathbf{h}^l_1, \mathbf{h}^l_2, ..., \mathbf{h}^l_n]$. For masked token, its corresponding hidden feature is used to predict the actual label. We formulate this process as:

$$\mathcal{L}_{mlm} = -\sum_{x_i \in m(X)} \log p(x_i | LM([CLS], \tilde{X})) \tag{2}$$

3.2 Dial-MAE: Dialogue Contextual Masking Auto-Encoder

Dial-MAE learns dialogue context information, which jointly models the semantics of the tokens inside a dialogue context and its response. We first describe how to build training data from all utterances of the dialogue session and then introduce the Dial-MAE post-training method. We randomly sample multiple consecutive utterances as context and the next utterance as its response. Multiple utterances of the context are connected using $[\mathbf{SEG}]$. For each dialogue scene, we sample multiple sets of such context and response pairs. The sampled context and response will serve as input to the encoder and decoder, respectively.

Then, we introduce the post-training design for Dial-MAE, as shown in Figure 1, we use an asymmetric encoder-decoder: A deep encoder to generate dialogue context embedding, and a shallow transformer-based decoder (e.g. one or two layers) for response reconstruction. We apply a BERT encoder $Enc(.)$ with 12 layers, which receives masked dialogue context as inputs. The deep encoder has enough parameters to learn good dialogue representations, following the common practice, we select the final hidden state from the $[\mathbf{CLS}]$ token as the dialogue context embedding. The decoder is designed to assist the encoder in learning a better semantic representation of the dialogue. The input of the decoder $Dec(.)$ is the masked response as well as the dialogue context embedding, and it reconstructs the masked response tokens with the help of the context embedding.

Through our design, the encoder $Enc(.)$ needs to predict the features of the correct response when encoding the dialogue context. This makes the dense encoder with behavior similar to that of a cross-encoder: simultaneously considering both the dialogue context and the response. The advantage of doing this is to achieve feature alignment between the dialogue context and response during the post-training. Meanwhile, since the auxiliary MLM task breaks down the information barrier between separately encoding the dialogue context and response, the encoded output's $[\mathbf{CLS}]$ hidden state encompasses information from both. Furthermore, it is worth noting that we employ an asymmetric masking operation(eg., 30% for encoder, 75% for decoder). On the decoder side, an aggressive mask rate and fewer model parameters will force its MLM task to rely more on the encoder's context embedding, which helps the encoder side aggregate complex information about the dialogue context into a dense vector.

Formally, we denote the dialogue context as c and the response as r. We apply random mask operation to context to get $\tilde{c}$, denoting these tokens replaced by $[\mathbf{MASK}]$ in context as $m_{enc}(c)$. Similarly, we apply a random masking operation with a higher masking ratio for response to get $\tilde{r}$, denoting these tokens replaced by $[\mathbf{MASK}]$ in response as $m_{dec}(r)$. The encoding process can be expressed as:

$$[\mathbf{h}^c_{cls}, \mathbf{h}^c] = Enc([CLS], \tilde{c}) \tag{3}$$

$$[\mathbf{h}^r_{cls}, \mathbf{h}^r] = Dec(\mathbf{h}^c_{cls}, \tilde{r}) \tag{4}$$

On the encoder side, the original context is learned to be reconstructed by optimizing the cross-entropy loss:

$$\mathcal{L}_{enc} = -\sum_{c_i \in m_{enc}(c)} \log p(c_i | Enc([CLS], \tilde{c})) \tag{5}$$

Differently, on the decoder side, the decoder reconstructs the original response with the help of the context embedding h^c_{cls}. We formulate this process as:

$$\mathcal{L}_{dec} = -\sum_{r_i \in m_{dec}(r)} \log p(r_i | Dec(h^c_{cls}, \tilde{r})) \tag{6}$$

Then, we add the encoder and decoder losses to obtain a summed loss:

$$\mathcal{L} = \mathcal{L}_{enc} + \mathcal{L}_{dec} \tag{7}$$

3.3 Fine-tuning for dialogue response selection

At the end of Dial-MAE post-training, fine-tuning is conducted on the downstream dialogue response selection to verify the effectiveness of post-training. As shown in Figure 2, in the fine-tuning stage, we only keep the encoder and discard the decoder. The encoder weights are used to initialize a dialogue context encoder f_c and a response encoder f_r, respectively.

The dialogue consists of a context c that includes multiple utterances and a response r with one utterance. After the dialogue context and response pass through the encoder, the context vector and response vector are respectively output. We train a dialogue response selection model using a contrastive learning loss function.

$$\mathcal{L}_{ft} = \frac{exp(d(c, r^+))}{exp(d(c, r^+)) + \sum_j exp(d(c, r^-_j))} \tag{8}$$

r^+ is the correct response corresponding to the dialogue context c. r^- represents negative samples within a mini-batch. At inference time, we use the dot product $d(c, r)$ to measure the similarity between the context vector and the response vector:

$$d(c, r) = f_c(c) \cdot f_r(r) \tag{9}$$

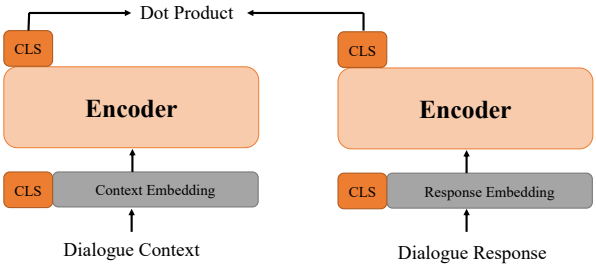

Figure 2: We discard the decoder, initialize the context encoder and response encoder using the encoder part of Dial-MAE, and fine-tune using contrastive learning. At inference time, We use a dot product to measure similarity.

4 Experiment

In this section, we first introduce our experimental details, including datasets, evaluation metrics, post-training, and fine-tuning. Then we introduce the experimental results.

4.1 Datasets

We tested our model on widely used benchmarks that include Ubuntu Corpus and E-commerce Corpus. The statistics for the two datasets are presented in Table 1.

1. **Ubuntu Corpus.** Ubuntu IRC Corpus V1 (Lowe et al., 2015) is a publicly available domain-specific dialogue dataset. Each set of conversations has two participants discussing how to troubleshoot Ubuntu systems.

2. **E-commerce Corpus.** E-commerce Corpus (Zhang et al., 2018) comprises genuine conversations in Chinese between customers and customer service personnel, collected from Taobao, a Chinese e-commerce platform.

4.2 Evaluation Metric

We evaluated our model using $R_{10}@k$, following previous studies (Han et al., 2021; Zhang et al., 2022), we evaluate our model using $R_{10}@k$. The notation $R_{10}@k$ represents Recall, indicating that among ten possible responses, the correct answer is included within the top k options.

Dataset	Ubuntu			E-commerce		
	train	val	test	train	val	test
context-response pairs	1M	500k	500k	1M	10k	10k
pos : neg	1:1	1:9	1:9	1:1	1:1	1:9
avg turns	10.13	10.11	10.11	5.11	5.48	5.64

Table 1: Statistics related to data for the Ubuntu and E-commerce Corpus.

4.3 Implementation Details

We first introduce the experimental setup for post-training, followed by the experimental setup for contrastive learning.

Post-training. Dial-MAE's encoder is initialized with a pre-trained 12-layer BERT-base model, while the decoder is initialized from scratch. Specifically, following the previous works, for the E-commerce dataset, we employ bert-base-chinese[1]. For the Ubuntu dataset, we utilize the bert-base-uncased[2]. We pre-train the model using the AdamW optimizer for a maximum of 15k steps, a global batch size of 1k, and a linear schedule with a warmup ratio of 0.1 on all two datasets. We set the input sequence lengths to 256 and 64 for the encoder and decoder, respectively. In fact, for the Chinese datasets E-commerce, we followed the parameter settings from Cot-MAE(Wu et al., 2023): The masking ratio of the encoder is 30%, the masking rate of the decoder is 45%, the learning ratio is 1e-4, and the decoder has two layers. Differently, for the English dataset Ubuntu, the masking ratio of the encoder is 30%, the masking ratio of the decoder is 75%, and the decoder is one layer. We also adjust the learning rate to 3e-4 to ensure the loss function converges. We set a widely used random seed as 42 for reproducibility. After post-training, we discard the decoder, only leaving the encoder for fine-tuning.

Fine-tuning. We fine-tune using contrastive learning on each dataset. During training, we follow (Lan et al., 2021) regarding every utterance in the dialogue sense as a response and its previous utterances as a context. Our model is optimized by AdamW optimizer, and the linear learning ratio scheduler is used. We tuned the hypermeters of individual tasks on their development sets. For

Table 2: Main experiment results on E-commerce Corpus and Ubuntu Corpus. **BERT**$_{+CL}$ means fine-tuning BERT using contrastive learning. The best score on a given dataset is marked in **bold**, and the second best is <u>underlined</u>. ♣ : According to the published code, for E-commerce, they adjusted the hyperparameters on the test set without cross-validation, we think the results are misleading, and this part has been removed. Two-tailed t-tests demonstrate statistically significant improvements of Dial-MAE over baselines ($* \leq 0.01$).

Ubuntu, we fine-tune for 5 epochs, the learning rate is set to 5e-5, and the batch size is set to 64. For E-commerce, we fine-tune for 2 epochs, the learning rate is set to 1e-4, and the batch size is set to 128. We set a widely used random seed as 42 for reproducibility.

4.4 Results and Discussions

We show the main results in Table 2, which shows that Dial-MAE achieves new state-of-the-art on the Ubuntu dataset and E-commerce dataset. We are able to achieve comparable performance to the state-of-the-art cross-encoders using a bi-encoder, and we have lower computational requirements compared to cross-encoders. Compared to BERT-FP, our model achieved an absolute improvement of 0.7%p in R_{10}@1 on the Ubuntu Corpus and 6%p in R_{10}@1 on the E-commerce. Compared to BERT-TL, our model achieves an absolute improvement of 0.8%p in R_{10}@1 on the Ubuntu Corpus and a slight improvement of 0.3%p in E-commerce. This suggests that our carefully tailored post-training method for the bi-encoder can achieve comparable performance to the complex-designed cross-encoder.

BERT$_{+CL}$ means fine-tuning BERT using contrastive learning. In comparison to BERT$_{+CL}$, Dial-MAE achieve an absolute improvement in R_{10}@1 by 3.1%p, 8.1%p on Ubuntu Corpus and E-commerce Corpus, respectively. This suggests that our custom post-training approach for dialogue retrieval models is effective. Aligning the features of the dialogue context and response during post-training enables improvements in contrastive fine-tuning. We believe the improvement comes from two aspects. On the one hand, the post-training method considers both the semantics of the tokens inside the context and its response. On the other hand, the asymmetric encoder-decoder structure with an asymmetric masking strategy facilitates post-training, which forces the encoder to learn better dialogue embeddings.

Models	Ubuntu			E-commerce		
	R_{10}@1	R_{10}@2	R_{10}@5	R_{10}@1	R_{10}@2	R_{10}@5
BERT$_{+CL}$	0.887	0.948	0.989	0.849	0.937	0.991
w/o Contrastive loss	0.205	0.341	0.647	0.141	0.242	0.466
Dial-MAE	**0.918**	**0.964**	**0.993**	**0.930**	**0.977**	**0.997**
w/o Contrastive loss	0.783	0.867	0.950	0.483	0.639	0.853

Table 3: Ablation results on the test sets of the two benchmarks.

4.5 Ablation Study

In this section, we analyze the experimental results to demonstrate the effectiveness of the proposed Dial-MAE method. In the following experimental analysis, due to high computing budgets, most experiments use Ubuntu Corpus.

The Impact of Auxilary Network. We remove the contrastive loss in BERT$_{+CL}$ and Dial-MAE, then evaluate their performance changes. As shown in Table 3, Dial-MAE achieved an absolute improvement in R_{10}@1 by 57.7%p, and 34.2%p on Ubuntu Corpus and E-commerce Corpus, respectively.

This suggests that our proposed post-training method effectively achieves the alignment of contextual representations, making the dialogue context more similar to the features of the response. We believe the gain comes from our auxiliary network helping the encoder aggregate dialogue contextual information. First, the encoder achieves feature alignment in the dialogue's contextual information by predicting the features of the correct response during the encoding of the context. Secondly, due to the small number of parameters of the decoder and the high mask rate on the decoder side, this will force the MLM task of the decoder to rely more on the dialogue context embedding output by the encoder. This enables the decoder to aggregate complex information about the dialogue context into a dense vector.

We then use contrastive learning to fine-tune the post-training models, and the performance of the models can be further improved. We also give the fine-tuning schedule on Ubuntu Corpus as shown in Figure 3, with the accuracy steadily improving as the training time increases, and Dial-MAE consistently outperforms BERT$_{+CL}$. This result shows that both the contrastive loss and the auxiliary MLM loss are crucial in our method. Both contrastive learning and our post-training method are effective in achieving dialogue context and response feature alignment, and their effects can be additive.

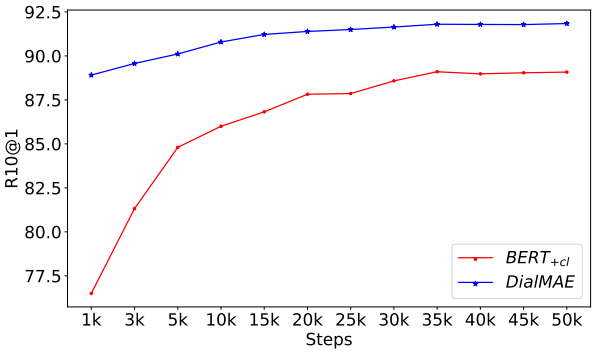

Figure 3: Fine-tuning schedules on the dev set of Ubuntu Corpus. A longer fine-tuning schedule gives a noticeable improvement. The performance of Dial-MAE is always better than BERT$_{+CL}$.

Enc	Dec	R_{10}@1	R_{10}@2	R_{10}@5
0.15	0	91.0	96.0	99.2
0.15	0.15	91.3	96.1	99.2
0.15	0.45	91.5	96.2	99.3
0.15	0.75	91.5	96.3	99.3
0.30	0.45	91.7	96.5	99.3
0.30	0.75	**91.9**	**96.5**	99.3
0.30	0.90	91.6	96.4	99.3
0.45	0.75	91.8	96.4	**99.4**

Table 4: Impact of mask rate on the dev set of Ubuntu Corpus. "Enc" denotes encoder, "Dec" denotes decoder. "Enc=0.15 Dec=0" means only using BERT's native MLM task without the decoder part.

Impact of Mask Rate. Wu et al. (2023) find that using a larger mask rate in both the encoder and decoder can enhance the performance of the contextual masking Auto-Encoder. As shown in Table 4, in our experiments, we find that an aggressive mask rate helps the learning of Dial-MAE. when the encoder mask rate equals 30%, and the decoder mask rate equals 75%, Dial-MAE achieves

the best performance. When the encoder mask rate stays below 30%, the performance of Dial-MAE improves as the decoder mask rate increases. When the encoder mask rate rises to 45%, Dial-MAE's performance declines slightly. We believe this is due to the encoder doesn't provide enough dialogue context semantic information when its mask rate is too high. In addition, from the experimental results, no matter what set of mask rates, Dial-MAE obviously exceeds the result of post-training for MLM tasks alone, which proves the robustness of Dial-MAE.

Impact of Decoder Layer Number. As shown in Figure 4, we further explore the impact of different decoder layer numbers on Dial-MAE performance. we find that using only one layer of the decoder yields the best results. Fewer decoder parameters can force the auxiliary MLM task to rely more on dialogue context embeddings output by the encoder. We believe that the more layers of the decoder, the stronger the decoding ability, and the decoder's dependence on context embedding will decrease, leading to insufficient constraints on encoder training. In general, no matter what set of layers, R@1 obviously exceeds the result of post-training for MLM tasks alone (Enc=0.15 Dec=0), as shown in Table 4, which proves the robustness of Dial-MAE.

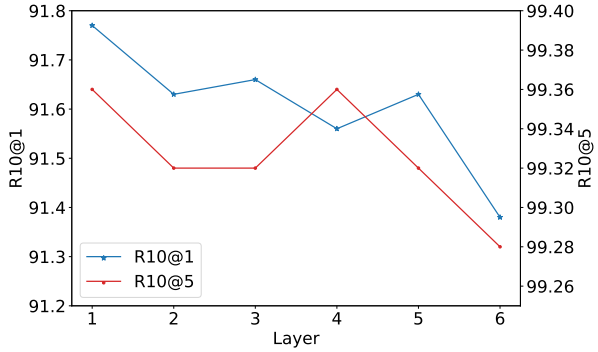

Figure 4: Impact of layer number on Ubuntu Corpus.

Compared with Dense Models. To further illustrate the effectiveness of our custom approach for bi-encoders in dialogue response selection, we compared it with state-of-the-art dense models in the Information Retrieval(IR) community. On the Ubuntu dataset, we fine-tune the dense models proposed by the IR community using contrastive learning, and the experimental results are shown in the table 5. During pre-training, the corpus of CoT-MAE(Wu et al., 2023) and RetroMAE(Xiao et al., 2022) contains an additional 3.2M documents dataset MS-MARCO(Nguyen et al., 2016) in addition to BooksCorpus and Wikipedia. However, our experimental results show that although the results of the three dense models have improved compared with BERT$_{+CL}$, they are still not as good as our proposed Dial-MAE. This shows that our proposed method is better suited for encoding dense vectors of dialogue than other dense models.

Models	R_{10}@1	R_{10}@2	R_{10}@5
BERT$_{+CL}$	89.2	95.1	99.2
Condenser(Gao and Callan, 2021)	89.4	95.4	99.1
RetroMAE(Xiao et al., 2022)	89.3	95.3	99.1
Cot-MAE(Wu et al., 2023)	89.8	95.9	99.2
Dial-MAE	**91.9**	**96.5**	**99.3**

Table 5: Comparison results of Dial-MAE and dense retrieval models on the Ubuntu dev set.

Qualitative Analysis. To qualitatively analyze our post-training method, as shown in Table 6, we provide the example. Dial-MAE can sort out the most appropriate response more accurately than BERT$_{+CL}$. The response sorted by BERT$_{+CL}$ have some token overlap with the dialogue context but are not semantically related. Compared with BERT$_{+CL}$, Dial-MAE can better understand dialogue semantics due to the joint modeling of context and response through post-training. This further demonstrates the effectiveness of our method.

Relevant	Model	Rank 1st response
		USER_A:I already have these disks in my system just want to migrate my current homefolder to the new drive. USER_B:Mount your new disk to a temporarely mount point move or copy your home folder to the new disc after that delete you old homedir than mount the new disk to _path_.
✗	BERT$_{+CL}$	USER_A: Do you use the ubuntu desktop or server i am using the desktop on my laptop i have only started with the server a little before _number_ came out maybe before april.
✓	Dial-MAE	USER_A: I presume i use gparted to get the mountpoints correct or am i wrong

Table 6: Examples of rank 1st response recalled by different models on the the Ubuntu Corpus.

5 Conclusion

In this paper, we propose a post-training method tailored for dialogue response, considering the semantics of dialogue context and its corresponding responses. Precisely, we leverage a shallow decoder to force the encoder output dialogue embeddings to be more expressive. Experimental results show that our post-training method leads to considerable improvements, achieving state-of-the-art on two benchmark datasets. We also demonstrate the effectiveness of Dial-MAE through ablation experiments. Specifically, both contrastive learning and our post-training method are effective in achieving dialogue context and response feature alignment, and their effects can be additive.

6 Limitations

Recently, generative conversational models based on large language models (LLMs) have demonstrated powerful performance. Despite the advantages of retrieval-based dialogue models in terms of computational cost and answer controllability, generative conversational systems based on LLMs surpass retrieval-based models in terms of answer diversity and flexibility. Furthermore, there has been much recent work exploring retrieval-augmented generation (RAG). In the future, we will further expand Dial-MAE to explore the effective integration with LLMs, using a dialogue response selection approach to attempt to address issues such as large model hallucinations and challenges related to knowledge updates. We hope that our work can also bring benefits to large language models.

Abstract

Large Language Models (LLMs) have demonstrated remarkable progress in utilizing tools, but their closed-source nature and high inference costs pose limitations on their adaptability, necessitating a valid method that leverages smaller, open-sourced models. In this paper, we introduce Toolink, a comprehensive framework that performs task-solving by first creating a toolkit and then integrating the planning and calling of tools through a chain-of-solving (CoS) approach. We first validate the efficacy of Toolink in harnessing the model's creativity and CoS ability on ChatGPT. Subsequently, we curate CoS-GPT, a chain-of-solving dataset designed for tool-using, and finetune the LLaMA-7B model. It results in LLaMA-CoS, a powerful open-source model with advanced tool-planning and tool-calling capabilities. Evaluation of diverse tasks from BIG-bench demonstrates its CoS ability matches that of ChatGPT while its performance surpasses the chain-of-thought approach. Further studies highlight the generalization of LLaMA-CoS to unseen tasks and showcase its capability in using toolkits not explicitly tailored for the target task, affirming its robustness in real-world scenarios. All codes and data are released[1].

1 Introduction

Large Language Models (LLMs) such as Codex (Chen et al., 2021), ChatGPT (OpenAI, 2022), and GPT4 (OpenAI, 2023) have made significant strides in code generation, in-context learning, and logical reasoning. However, they still struggle with precise calculations and accessing current information (Patel et al., 2021; Trivedi et al., 2022; Lu et al., 2022b). To address these issues, research has focused on equipping LLMs with tools such as calculators (Cobbe et al., 2021; Parisi et al., 2022; Schick et al., 2023), search engines (Carlini et al., 2021; Thoppilan et al., 2022; Schick et al., 2023), scratch pads (Nye et al., 2021), calendars (Schick et al., 2023), and image retrievers (Sheynin et al., 2022) to enhance their capabilities, thus benefiting various tasks including question-answering, math calculations, and long-form generation. Recent studies have also explored how LLMs can devise plans, make decisions, and perform tool invocations (Shen et al., 2023; Lu et al., 2023; Liang et al., 2023). By combining them into a pipeline, these frameworks aim to construct more advanced NLP systems for improved task performance.

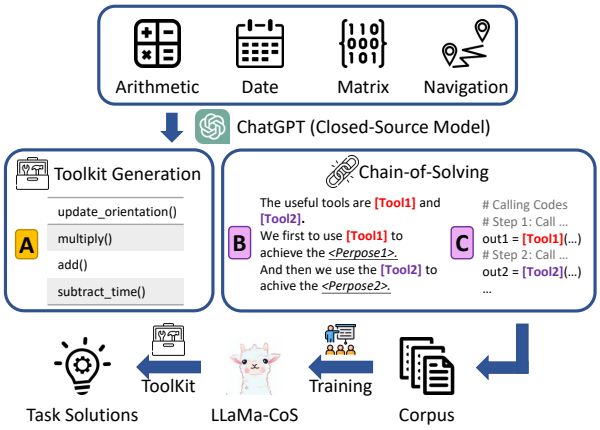

Figure 1: An illustration of Toolink, which decomposes tasks via toolkit creation and resolves queries through Chain-of-Solving (CoS). Toolink can be adapted to open-source LLaMA for enhanced tool usage.

However, current tool-using pipelines heavily rely on closed-source models with inaccessible parameters. It poses challenges particularly as follows: i) **Limited adaptability**: The closed-source nature of major LLMs prevents them from customization, resulting in a lack of flexibility to adapt to tasks with specific requirements. ii) **Low efficiency and high inference cost**: Many existing LLMs can only be accessed *online*, which imposes limitations on the inference rate and leads to high expense. iii) **Privacy and security concerns**: Each

query must be submitted to these closed-source LLMs to obtain a tool-using solution, which raises concerns regarding potential privacy breaches and compromises data security.

To address these challenges, we propose Toolink, a comprehensive framework to boost the tool-using ability of open-source models with the help of closed-source models. As shown in Figure 1, Toolink first decomposes the target task by creating a toolkit for problem-solving, and then leverages the open-source model to use tools to answer queries in a chain-of-solving (CoS) approach. Specifically, CoS disentangles the model's reasoning through two stages: *CoS-Planning*, which selects useful tools from the created toolkit and plans their usages based on the specific query; and *CoS-Calling*, which focuses on deriving the answer by performing tool invocations in code format according to the plan devised. To effectively train the open-source model in these abilities, we employ ChatGPT to curate CoS-GPT, a training dataset that aims to inspire the tool-using ability of open-source models through CoS. Specifically, we finetune LLaMA-7B (Touvron et al., 2023) into LLaMA-CoS, which is equipped with strong tool-using capabilities by linking toolkit creation with the chain of problem-solving.

LLaMA-CoS can solve the queries *offline* without uploading queries to closed-source models, ensuring data security and privacy. Experiments further illustrate that Toolink outperforms the chain-of-thought (CoT) (Wei et al., 2022) on diverse tasks from BIG-bench (Srivastava et al., 2022) and enables LLaMA-CoS to showcase comparable CoS ability to that of ChatGPT. In addition, LLaMA-CoS can generalize to unseen tasks by planning and calling tailored tools, and solve the target task with a toolkit not specifically tailored for it. These findings further affirm our framework's robustness in solving queries under real-world scenarios.

2 Related Work

Tool-based enhancement for LLMs. Language models have been enhanced with external tools to improve their expertise. Previous work focused on equipping the LLMs with different tools including a calculator to improve calculation accuracy (Cobbe et al., 2021; Parisi et al., 2022; Schick et al., 2023), search engine to inquire factual knowledge (Carlini et al., 2021; Thoppilan et al., 2022; Schick et al., 2023), Python interpreter to execute programs (Chen et al., 2022a; Gao et al., 2022), and retriever to search textual information (Khandelwal et al.; Borgeaud et al., 2022), etc.

More recent studies, such as HuggingGPT (Shen et al., 2023), Chameleon-LLM (Lu et al., 2023), VisualGPT (Wu et al., 2023) and TaskMatrix.AI (Liang et al., 2023), focus on assembling plannings, execution, and reasoning about tools into a robust pipeline. In addition to tool-using, ART (Paranjape et al., 2023) builds toolkits based on retrieved tasks from the manually built library, while LATM (Cai et al., 2023) and CREATOR (Qian et al., 2023) involve the LLMs' tool-making ability to offload their reasoning burden and raise task performance. In contrast to their prevalent use of closed-source LLMs to leverage tools, Toolink offers unique advantages of tool use for smaller, open-source models.

Adaptation of open-source models. One research direction focuses on effective tuning of open-source models, including the introduction of lightweight modules such as Adapter (Houlsby et al., 2019) and LoRA (Hu et al., 2021). These modules are adapted to various model types including LLaMA (Touvron et al., 2023), T5 (Raffel et al., 2020), and other Transformers-based architectures (Pfeiffer et al., 2020), to save computational resources. For instance, GOAT (Liu and Low, 2023) applies LoRA to improve LLaMA's arithmetic calculation ability, while LLaMA-Adapter (Zhang et al., 2023) adopts Adapter and zero-init attention to improve multi-modal task performance.

Other works have investigated how instruction tuning can make open-source models better understand and follow human requirements in both text format (Longpre et al., 2023; Ouyang et al., 2022) and visual domains (Liu et al., 2023). More recent works also investigate the curation of instruction following data (Taori et al., 2023; Peng et al., 2023) and construction of open-source tool-using agents (Qin et al., 2023; Zeng et al., 2023). Toolink builds upon the instruction-following paradigm and focuses on tool-using ability through the disentanglement of CoS-Planning and CoS-Calling, which makes learning more efficient.

3 Toolink Framework

As shown in Figure 2, Toolink first adopts toolkit creation to break down the target task through generating potential tools for task-solving (§ 3.1).

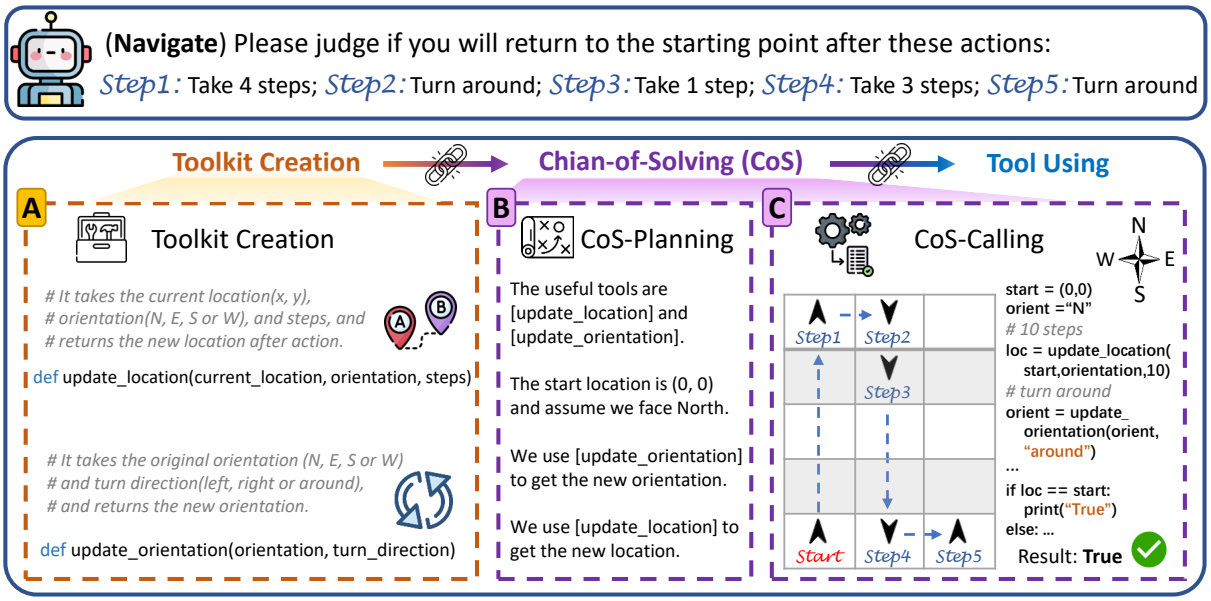

Figure 2: A problem solving chain of Toolink pipeline. We show an example from task Navigate. Toolink first creates a toolkit generally applicable to the task, and then approaches the specific query through CoS, which involves planning and calling of the created tools.

Then, the model links these created tools to address specific queries by selecting pertinent tools from the toolkit, planning their uses, and performing tool invocations (§ 3.2). This new reasoning approach, referred to as chain-of-solving (CoS), not only enables the effective and coherent application of tools but also facilitates the tool-using adaptation on the open-source model (§ 3.3).

3.1 Toolkit Creation

Toolkit creation decomposes a general task into modular and essential tools for problem-solving, facilitating more flexible tool utilization.

Overview. Given the target task T, toolkit creation breaks it down into more manageable components $t_1, t_2, ..., t_n$ through generating a toolkit $K_T = \{k_1, k_2, ..., k_n\}$, where $k_i (i \leq n)$ represents the tool to solve the subtask t_i. We illustrate our approach in Figure 2A, where the target task $T = \texttt{Navigate}$ is decomposed into t_1 (movement in a single direction) and t_2 (change of orientation). Each component is represented by a specific implementation encapsulated within a function tool.

Toolkit Making. We utilize ChatGPT for task decomposition. For each task T, we provide ChatGPT with a task description and a few data samples $D_{T\text{-}\texttt{sample}}$, expecting them to facilitate the model's understanding of task T's objective and identify commonalities among queries. The prompting details are presented in Appendix A and Figure 6. Note that our design requires only a few data points as demonstrations fed into the closed-source ChatGPT, leaving the entire testing set for local processing to maintain privacy.

Tool Details. Each tool k_i within the toolkit K_T is comprised of a concise introduction and its corresponding code implementation. The introduction provides a brief overview of k_i's utility, inputs, and outputs, facilitating effective planning and calling in subsequent steps.

3.2 Chain-of-Solving

Chain-of-solving (CoS) involves deliberate planning and decision-making for tool invocation, which bridges the gap between toolkit creation and downstream tool use for task query resolution. CoS is disentangled into CoS-Planning and CoS-Calling. This separation allows for a more transparent and interpretable reasoning path, thereby enhancing the applicability of CoS to open-source models.

CoS-Planing. The CoS-Planning stage entails selecting useful tools from a toolkit K_T in response to a specific query of task T. It employs natural language-based reasoning chains, referred to as a *plan*, to determine the most effective way to utilize the selected tools to solve the given query.

In Figure 2B, the model devises strategies for employing tools to update the location and orien-

Category	Set Name	Source	Number
Tool-Using	Tool-Planning	Augmented	4.4K
	Tool-Calling	Augmented	4.4K
Code Generation	Python-Simple	New	2.0K
	Python-Specific	New	2.0K

Common Sense	Date Understanding, Navigate
Logical Reasoning	Dyck Language, Boolean Expression
Decomposition	Tracking Shuffled Objects

Table 2: The categories of 8 BIG-bench tasks tested.

tation, with additional initial conditions that serve as a guiding hint. Planning plays a crucial role in establishing a link between toolkit creation and decision-making, thus reducing the cognitive burden associated with tool-use reasoning.

CoS-Calling. The CoS-Calling stage entails the utilization of selected tools and interpretation of the plan into program language to perform tool calls. The plan generated in the previous stage serves as the guidance for program implementation. During the tool execution, all results from the tool invocations are implicitly captured and used to extract the final answer for the given query.

Figure 2C illustrates this process, where the model simulates the entire navigation process using code as the underlying medium. In this example, the model derives the final correct answer, thereby demonstrating a successful CoS-Calling process.

3.3 Open-Source Model Adaptation

Considering the limited adaptability, high inference cost, and privacy concerns posed by closed-source models, we aim to enhance the CoS ability in open-source models. We propose the CoS-GPT, a specialized training dataset that emphasizes the planning and calling of tools, along with code generation. These elements are crucial for boosting the model's CoS ability. The statistics related to CoS-GPT are presented in Table 1. Furthermore, for each specific target task T, we employ $D_{T\texttt{-sample}}$ to generate a task-specific dataset. This is achieved by augmenting each sample query with suitable tools, thereby facilitating a more effective training of task T on the open-source models.

Construction of CoS-GPT. To enhance the open-source model's skills in applying tools for problem-solving, we construct CoS-GPT from scratch to improve the model's CoS ability from planning, calling, and coding. We include the first two aspects as they are essential for CoS within Toolink, and the last aspect as it serves as the medium for tool-using.

For data points about planning and calling, we enhance the AQUA-RAT (Ling et al., 2017), GSM8K (Cobbe et al., 2021), and TabMWP (Lu et al., 2022a) datasets, comprising graduate-level math problems, numerical reasoning tasks, and diverse table contents, with toolkits. Each query is augmented with a toolkit containing both useful and redundant tools. The model's objective for planning is to select and plan the use of useful tools, while for calling, the objective is to learn how to call the chosen tools through codes. We apply ChatGPT to simulate this process and utilize their responses for dataset construction. Please refer to Appendix E.1 for more details.

Data points for code generation encompass diverse sources, including augmentation from existing datasets, GitHub repositories, and newly generated data, detailed in Appendix E.2. Each query adheres to an instruction-following pattern and aims to enhance the open-source model's understanding of code while expanding its versatility in making informed decisions when performing CoS.

Construction of Task-Specific Data. For each target task T, we construct 200 tool-augmented data points (100 each for plan and call) from the publicly available samples $D_{T\texttt{-sample}}$, and use them to tune the open-source model together with CoS-GPT. Similar to the construction process for tool-using data in CoS-GPT, we first augment T with a toolkit K_T. Next, we employ ChatGPT to select useful tools for each query and generate the calling decision. The decision's output is compared against the standard answer, and minor adjustments may be made to ensure the augmented data's validity.

Open-Source Model Finetuning. Together with CoS-GPT, we apply the tool-augmented data points

from all target tasks to finetune the open-source model. We expect the derived tool-augmented open-source model to excel in applying useful tools for problem-solving. By planning and calling through CoS, this model links the created toolkit with specific queries, which realizes the final goal of the Toolink framework.

4 Experiments

To evaluate the effectiveness of Toolink, we first conduct a validation test using ChatGPT. We select eight distinct tasks from the BIG-bench dataset (Srivastava et al., 2022) to investigate whether Toolink can effectively leverage ChatGPT's creativity and tool-using capability to improve task performance.

Subsequently, we finetune the open-source LLaMA-7B model following the adaptation process outlined in § 3.3. This results in LLaMA-CoS, a model capable of linking the created toolkit with specific tool use through CoS. We evaluate the effectiveness of LLaMA-CoS in utilizing tools on the same set of eight tasks and showcase its excellence.

4.1 Validation Evaluation

Settings. To evaluate the effectiveness of Toolink, we conducted a validation test using ChatGPT on eight tasks of diverse categories from BIG-bench, as detailed in Table 2. For each task, we first employ ChatGPT to create a toolkit, outlined in § 3.1. The total number of tools in the toolkit created for each task is shown in Table 3, with the tool's implementation details provided in Appendix B. Equipped with these tools, ChatGPT is presented with instructions and demonstration examples to perform CoS for problem-solving, detailed in Appendix C.

Baselines. We compare CoS against two baselines: i) **Vanilla** baseline, where ChatGPT directly produces the final answer. ii) **CoT** baseline (Wei et al., 2022), where ChatGPT performs chain-of-thought reasoning before providing an answer.

Evaluations. We evaluate the ability of ChatGPT to leverage plans and calls to perform CoS. The accuracy is measured by matching the model's final output to the correct answer. In addition, we also evaluated the individual contributions of CoS-Planning and CoS-Calling separately.

During CoS-Planning, the model is asked to select useful tools and plan their uses given the created toolkit. The planning accuracy is thus measured by the following metric:

$$ACC = \max\{\frac{|K_{\texttt{correct}}| - |K_{\texttt{error}}|}{|K_{\texttt{correct}}| + |K_{\texttt{error}}|}, 0\}, \quad (1)$$

where $|K_{\texttt{correct}}|$ denotes the number of correct (useful) tools in the toolkit selected in the model's generated plan, while $|K_{\texttt{error}}|$ denotes the number of incorrect (redundant) tools selected.

During CoS-Calling, the model is asked to implement the plan using code as the medium, after the useful tools are selected. The accuracy is thus measured by matching the output from the final execution with the correct answer. Please refer to Appendix D for more details regarding the separated test of CoS-Planning and CoS-Calling.

Results. The results are presented in Table 3. ChatGPT which uses tools through the CoS approach achieves significantly improved performance compared to other baselines, with notable margins of superiority. Further, the accuracy for CoS-Calling and CoS-Planning individually is even higher, indicating successful reasoning in each step of CoS which links toolkit creation with specific uses. These findings affirm the validity of Toolink, establishing a strong basis for its potential transferability to smaller, open-sourced models.

4.2 Experiments on LLaMA-CoS

Our primary objective is to apply Toolink to smaller, open-sourced models. To this end, the models from the LLaMA family (Touvron et al., 2023) stand out due to their capability to perform reasoning and generate codes. Considering the affordability of computational resources, we select LLaMA-7B as the representative base model to evaluate the performance of Toolink on open-source models.

Obtaining LLaMA-CoS. We follow the adaptation process outlined in § 3.3 and finetune LLaMA-7B with CoS-GPT and eight sets of task-specific tool-augmented data. The eight tasks are the same ones as those we test in § 4.1. Applying the training setting detailed in Appendix F, we derive a powerful variant, LLaMA-CoS, that excels in using tools through CoS.

Settings. We use LLaMA-CoS as the representative finetuned open-source model for testing. Building upon the validation test conducted on ChatGPT, we evaluate LLaMA-CoS's performance on the same set of eight tasks from BIG-bench. We keep all the metrics the same as in § 4.1

Task	Arith.	Date U.	Matrix S.	Navigate	Chinese R.	Dyck L.	Boolean E.	Tracking S.	Average
Num. of Tools	5	3	5	2	2	4	2	4	3.38
Vanilla	77.78	68.67	40.90	65.16	0.0	19.40	80.70	23.67	47.03
CoT	79.44	68.67	80.46	87.96	0.0	19.42	75.88	40.78	56.58
CoS	100.00	69.28	93.67	85.30	95.14	52.46	97.37	99.11	**86.54**

CoS-Calling	100.00	90.96	97.44	88.44	95.67	98.55	93.42	100.00	95.56

Table 3: We record the number of tools in the toolkit created for each task and demonstrate the accuracy (%) of ChatGPT on 8 BIG-bench tasks under different settings. We report the results of Vanilla, CoT baselines, and our CoS method, and report the performance of CoS-Planning and CoS-Calling separately.

Method	Model	Arith.	Date U.	Matrix S.	Navigate	Chinese R.	Dyck L.	Boolean E.	Tracking S.
CoT (*Prompting w/ demo*)	Alpaca	19.89	39.76	5.62	47.11	0.0	0.0	57.46	0.44
	LLaMA-7B	39.44	33.73	12.58	39.70	0.0	2.90	50.44	14.22
	ChatGPT	79.44	68.67	80.46	87.96	0.0	19.42	75.88	40.78
CoT (*Tuned*)	LLaMA-CoT	50.44	49.40	70.82	71.64	0.0	35.27	62.72	28.44
CoS (*Prompting w/ demo*)	Alpaca	17.78	7.83	3.00	48.60	7.56	1.00	94.74	6.78
	LLaMA-7B	55.89	17.47	10.65	45.90	23.80	35.83	99.12	0.67
	ChatGPT	**100.00**	69.28	**93.67**	85.30	95.14	52.46	97.37	99.11
CoS (*Tuned*)	LLaMA-CoS	**100.00**	**74.10**	91.01	**99.56**	**95.44**	**98.21**	**100.00**	**99.56**

Table 4: The accuracy (%) of baselines and LLaMA-CoS on the 8 BIG-bench tasks. LLaMA-CoS employs planning and calling of tools, which beats all CoT baselines by large margins and is on par with ChatGPT's CoS ability.

Baselines. As a comparison to CoS, we employ the chain-of-thought (CoT) reasoning as the baseline. We evaluate both methods under two scenarios: i) Prompting with demonstrations on Alpaca, LLaMA-7B, and ChatGPT, and ii) Finetuning specifically on the LLaMA-7B model. We referred to the LLaMA-7B tuned with CoT data as LLaMA-CoT, while our model, LLaMA-CoS, is specially tuned for tool use through CoS.

Results. We present the results in Table 4. Notably, LLaMA-CoS achieves an impressive average accuracy of 94.74%, outperforming all the CoT baselines, whether tuned or not, by a substantial margin. Compared to ChatGPT, which exhibits strong reasoning and tool-using capabilities under the CoS setting, our tuned model can still achieve comparable performance. These results highlight the effectiveness of CoS in outperforming traditional CoT methods and demonstrate the successful transfer of tool-using abilities from closed-source LLMs to smaller, open-source models.

4.3 Results Analysis

Excellence in Both Planning and Calling. To comprehensively assess the CoS method, we similarly report the individual contribution of CoS-Planning and CoS-Calling in Table 5. Our results demonstrate that CoS-Planning and CoS-Calling separately surpass the performance achieved by CoT-based models on all tasks. This validates the model's proficiency in both stages during CoS and underscores the rationale behind designing CoS-Planning and CoS-Calling to promote effective tool use under the Toolink framework.

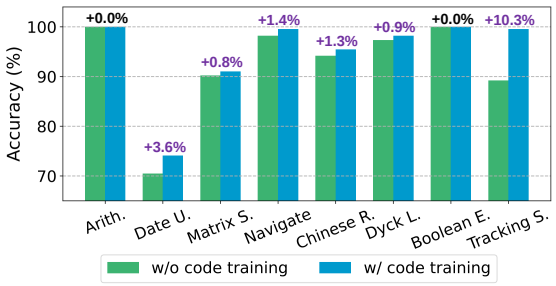

Figure 3: The improvement of performance when code generation data points are involved during training.

Necessity of Code Training. To evaluate the impact of code generation data in CoS-GPT, we compare the LLaMA-7B tuned with or without them. The results in Figure 3 indicate that LLaMA-CoS

Method	Model	Arith.	Date U.	Matrix S.	Navigate	Chinese R.	Dyck L.	Boolean E.	Tracking S.
CoS-Whole	LLaMA-CoS	**100.00**	74.10	91.01	99.56	95.44	98.21	100.00	99.56

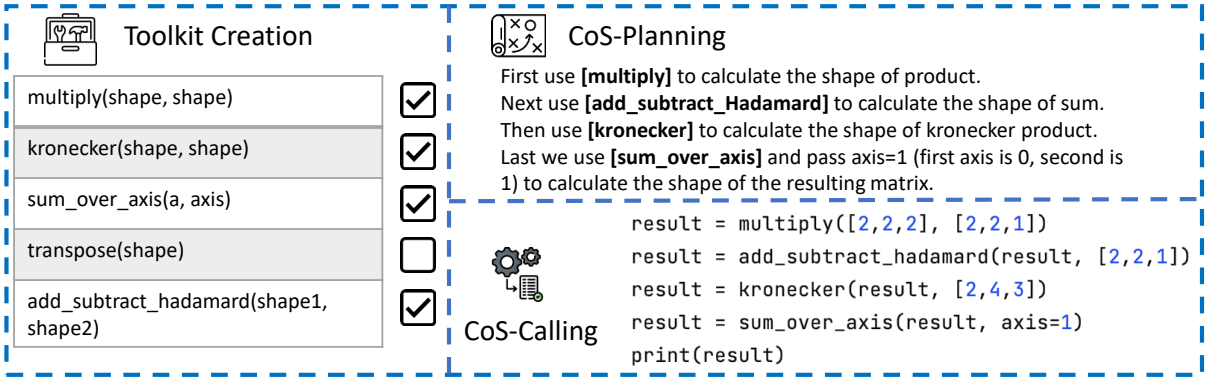
		Calling	**66.00**	32.75
FinQA	✗	*Planning*	**70.51**	50.15
		Calling	22.38	**32.38**
GSM8K	✗	*Planning*	**61.29**	53.83
		Calling	**57.25**	36.50

Table 6: The accuracy (%) of CoS-Planning and CoS-Calling on five diverse datasets applying LLaMA-CoS or ChatGPT. Results show that LLaMA-CoS generally beats ChatGPT and is robust to unseen tasks.

trained with code generation data achieves higher accuracy, with an average improvement of 1.4%. This validates the necessity of training on code generation together with CoS ability. By incorporating these data points, the model learns to leverage codes as the medium for tool-using more effectively, which ultimately enhances task performance.

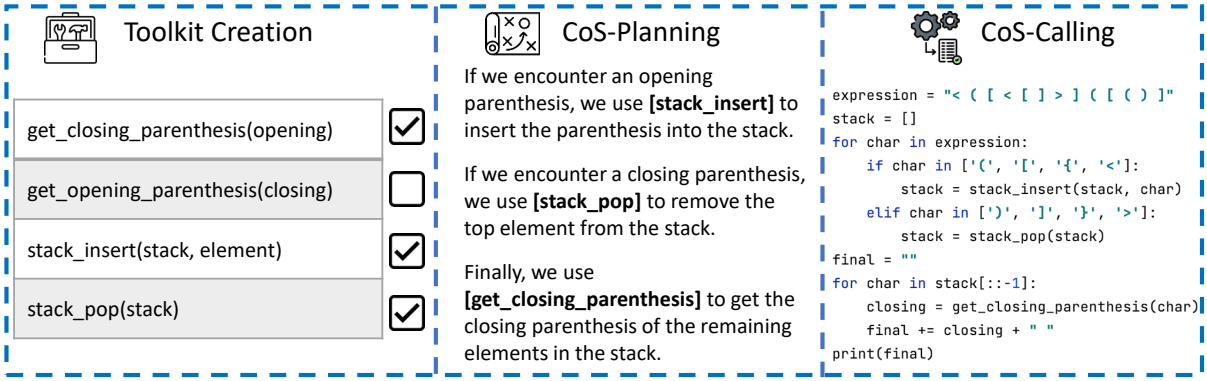
Error Analysis of LLaMA-7B and Alpaca. We discover from the results that the raw LLaMA-7B and Alpaca's performance lags far behind. To provide insights into why they fail to do CoS-Planning and CoS-Calling even with demonstrations, we conduct a detailed error analysis in fig. 4.



Upon analyzing the errors made by both models, we identified two primary tendencies: i) the models tend to learn the pattern but often overlook the utility of the tool and the purpose of the task; ii) they frequently exhibit disarray in reasoning and a misalignment between the tool plan and the tool call. These issues contribute significantly to the subpar performance of both models.

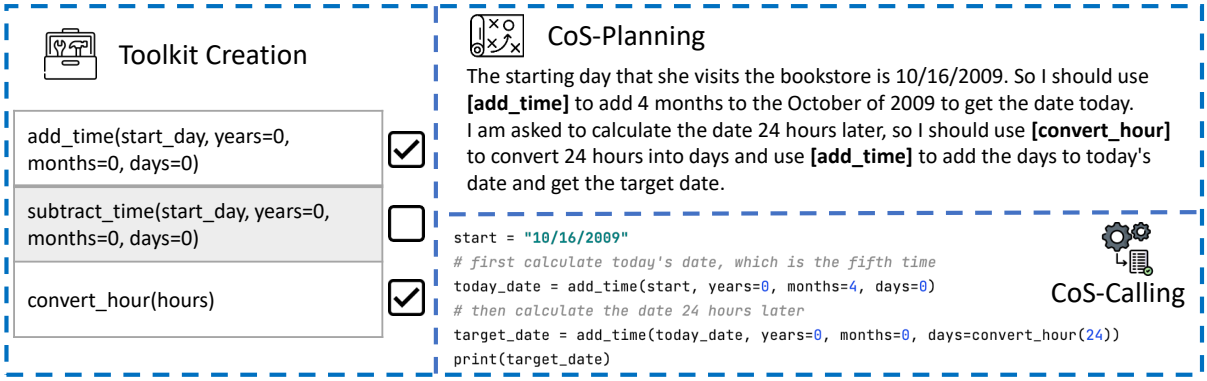
Diverse Usage of Toolkit. Throughout the experiments, LLaMA-CoS exhibits diverse CoS-Calling patterns. It is capable of sequentially calling different tools to achieve a specific purpose, using tools in a non-linear logic (in a loop or with conditions), or performing nested tool calls, where the output from one tool directly serves as the other tool's input. These abilities illustrate the robustness and adaptability of LLaMA-CoS across diverse scenarios. We provide case studies and more details in Appendix G and Figure 5.

5 Further Studies



In this section, we show the generalization of LLaMA-CoS to novel tasks and how it can use

Seqencial Tool Calling: Multiply a matrix of shape (2,2,2) with a matrix of shape (2,2,1). Add the result to a matrix of shape (2,2,1). Compute the kronecker product of the result with a matrix of shape (2,4,3). Sum the result over the second axis.



(a) Sequential Tool Calling.

Conditional Tool Calling: You are asked to to predict the closing parentheses of a Dyck-n prefix. What's the closing parentheses for prefix: < ([< [ ] >] ([( )] ?

(b) Conditional Tool Calling.

Nested Tool Calling: Jane visits the bookstore on the 16th of each month starting from the October of 2009. It is her 5th visit to the bookstore today. What is the date 24 hours later in MM/DD/YYYY?

(c) Nested Tool Calling.

Figure 5: Case Studies on the diverse CoS-Calling patterns in the main experiment.

Task	Toolkit Origin	LLaMA-CoS	ChatGPT
Dynamic Cnt.	*Raw*	97.50	80.83
	From Dyck L.	73.30	79.17
Unit Interp.	*Raw*	70.83	80.83
	From Arith.	65.83	80.00

Table 7: The accuracy (%) of ChatGPT and LLaMA-CoS, with toolkit newly created for the target task (*Raw*) or borrowed from other tasks. Our results show that both ChatGPT and LLaMA-CoS can utilize tools not specifically tailored for the target task through CoS.

toolkits that are not specially tailored for solving the target task. These studies aim to illustrate the robustness of LLaMA-CoS in utilizing tools through planning and calling.

5.1 Generalization to Novel Tasks

The eight evaluation tasks (Srivastava et al., 2022) we previously used all have data points presented during training, despite only leveraging a few publicly available samples. To showcase the generalization ability of LLaMA-CoS, we further test it on two new tasks: FinQA (Chen et al., 2022b) and GSM8K (Cobbe et al., 2021). FinQA involves questions based on financial report data, while GSM8K involves grade school math problems.

Together with AQUA-RAT, MATH, and TabMWP, whose data are presented in CoS-GPT (as detailed in § 3.3), we randomly select a maximum of 400 test data points from each of the five tasks, ensuring they *do not* appear in CoS-GPT. We augment each data point with a toolkit, following the method outlined in § 3.3 regarding how CoS-GPT is constructed. In experiments, we follow the CoS-Planning and CoS-Calling tests outlined in § 4.1.

We show in Table 6 that LLaMA-CoS achieves high accuracy in both planning and calling stages and could even beat ChatGPT in performance. This affirms the effectiveness and robustness of its CoS ability even applied to unseen tasks. As our tests encompass math, finance, table reasoning, etc, this finding also emphasizes **the robustness of LLaMA-CoS across diverse types of tasks**.

5.2 CoS on Generic Toolkit

We further explore the ability of LLaMA-CoS to use a generic toolkit instead of the one specifically tailored for the target task. In real-world scenarios, toolkits are usually designed to address diverse tasks rather than tailored for a single task. We expect LLaMA-CoS and ChatGPT can apply toolkits borrowed from other tasks to solve the target query in a CoS approach.

To validate this, we source two additional tasks from BIG-bench: Dynamic Counting and Unit Interpretation. For each task, we provide a toolkit created explicitly for the target task or borrowed from another task. Specifically, we pair Dynamic Counting and Unit Interpretation respectively with Dyck Language and Arithmetic.

Under these settings, we evaluate the performance of both LLaMA-CoS and ChatGPT in Table 7 and show that **both LLaMA-CoS and ChatGPT can utilize a generic toolkit borrowed from another task to solve target queries through CoS**. Though the performance still lags, these findings nevertheless confirm our assumption that CoS can increase the robustness of tool-using, and make our Toolink more applicable to real-world scenarios. We present more details in Appendix H.

6 Conclusions

We present Toolink, a tool-training framework that effectively applies toolkits to solve problems leveraging small, open-source language models. Toolink offers increased flexibility in adapting to diverse downstream tasks while addressing concerns related to high inference costs and privacy. Our main contributions include i) empirically implementing a framework that can effectively leverage open-source models' tool-using ability, ii) devising the chain-of-solving (CoS) method that links toolkit creation and tool use through robust planning and calling, and iii) releasing the CoS-GPT dataset that aims to enhance the model's CoS capabilities.

Specifically, our LLaMA-CoS model outperforms traditional CoT and achieves a comparable performance to ChatGPT concerning tool-using. We believe our study provides a solid foundation for future researchers to explore and enhance the tool-using capabilities of open-source models.

Limitations

Our experiments focus on equipping the open-source model with tool-using capabilities through the CoS approach, specifically in planning and calling, while excluding the ability to create toolkits. This limitation arises from the fact that the LLaMA-7B primarily relies on provided demonstrations and lacks the internal creativity required for toolkit cre-

ation. Moreover, the absence of enough training data further hampers the acquisition of this knowledge. We acknowledge this challenge posed by the transfer of the toolkit creation capability from closed-source models and leave it as an avenue for future research.

Additionally, it is important to note that though the tasks tested in our study include diverse toolkits and queries, they are mostly sourced from the BIG-bench dataset. To gain a more holistic understanding of the generalizability of our results, future research should expand the application of Toolink to a broader range of scenarios. This would enable a more comprehensive assessment of the framework's efficacy and applicability.

Ethics Statement

We consider the following issues in this paper:

- **Privacy** is a crucial aspect to consider when utilizing closed-source models such as ChatGPT and GPT4. These models have the potential to learn sensitive information internally, posing a risk to personal privacy. In contrast, Toolink addresses this concern by leveraging only a limited number of publicly available samples for toolkit creation, leaving the majority of testing queries blind to closed-source LLMs. This approach reduces the possibility of mishandling data and safeguards user privacy. By minimizing the exposure of sensitive information, Toolink mitigates the risks associated with privacy breaches when compared to closed-source models.
- **Transparency** is a key aspect that aims to enhance the interpretability and comprehensibility of AI systems from a human perspective. In Toolink, we prioritize transparency through the creation of toolkits that provide clear information about their utility, inputs, and outputs. Additionally, we disentangle the CoS into separate stages of planning and calling, which increases the interpretability of the model's reasoning for users. We also encourage future research to further document the specific scenarios in which our framework exhibits its maximum effectiveness, as well as to outline potential risks involved. This will contribute to a more comprehensive understanding of Toolink and facilitate informed decision-making.
- **Potential Bias** is another critical aspect that we prioritize addressing in our work. We acknowledge that bias and discrimination can inadvertently manifest through problematic examples present in the training data. To mitigate this concern, we adopt a meticulous approach to curate the CoS-GPT dataset, which consists of data points from various sources. We emphasize diversity to minimize the presence of potentially biased patterns during the data construction. Through these efforts, we aim to develop the model's tool-using and CoS ability that promotes equitable and unbiased outcomes, fostering trust and inclusiveness in the application of AI systems.

Appendix

A Prompt Pattern for ChatGPT Toolkit

We show the pattern of the prompt we apply for the creation of toolkits leveraging GPT-3.5-turbo in Figure 6. The temperature is set to 0.3 to ensure the model clearly follows the instructions while retaining its creativity to a certain extent. The max length during generation is set to 1024. The prompt shown mainly consists of the instruction for toolkit creation, the demonstration of the format, sample public data, and the task description.

B Toolkits for tasks from BIG-bench

We show in Figures 8 to 15 the toolkits that GPT-3.5-turbo created leveraging the prompt mentioned in the previous section. Notice that we show the final version of the toolkit, which may contain certain modifications based on human feedback. For instance, in Figure 10, we have integrated addition, subtraction, and hadamard operation into one single tool, as all of them do not change the shape of the given matrix. This will effectively reduce the redundant tools and help the model learn with ease.

C Settings for Chain-of-Solving

C.1 Choice of Instruction

To inspire the models' ability to plan and call the tools during chain-of-solving (CoS), we apply clear instructions to prompt the model. For CoS-Planning, we choose the instruction "*You are presented with a question and several tools that may be useful. Select the useful tools and plan how to solve the problem.*", while for CoS-Calling, we choose the instruction "*Use the tool given in the input to write code to solve the problem.*". This applies to all the settings, including the LLaMA-CoS because it is also tuned in an instruction-following way.

C.2 Details about Demonstrations

For all the experiments leveraging ChatGPT, despite the instructions, we also provide the model with demonstration examples to showcase the format of planning and calling, as well as to better leverage its potential. The temperature is set to 0.3 during generation, and the max output length is set to 1024.

For the raw LLaMA-7B and Alpaca baselines without being tuned, the demonstration examples are also applied to provide guidance, while the LLaMA-CoS tuned under our Toolink framework does not need demonstration examples as it is already tuned under the instruction-following paradigm.

D Separated Test of CoS-Planning and CoS-Calling

In Toolink, planning and calling are combined as a whole CoS process, where the plans generated by the model are again fed back to itself to help guide the generation of the final tool calling decision. To disentangle their functions and better understand their role, we employ tests to measure their accuracy separately.

D.1 CoS-Planning Details

For the CoS-Planning test, we provide the model with the instructions and all the available tools in the toolkit. In Figure 7, we showcase the format of the CoS-Planning prompt given to the model.

However, plans are generated in the form of natural language, whose accuracy is hard to measure. For simplicity, we instead only measure if the correct tools are called upon to solve the given problem.

Suppose $K_T = \{k_1, k_2, ..., k_N\}$ is the toolkit with N tools for task T. For a specific query, we denote the set of useful tools as $K_{\texttt{use}} \subseteq K_T$ and other redundant tools as $K_{\texttt{rdt}} \subseteq K_T$. Suppose the set of tools called upon during planning is $K_{\texttt{call}} \subseteq K_T$, then the correct tools called is denoted as $K_{\texttt{correct}} = K_{\texttt{call}} \cap K_{\texttt{use}}$, and the erroneous tools called $K_{\texttt{err}} = K_{\texttt{call}} \cap K_{\texttt{rdt}}$. These are the exact definitions of the variables that we apply in Equation (1).

If all the useful tools are called correctly and precisely, where $K_{\texttt{call}} = T_{\texttt{use}}$, the accuracy will be 1.00. Note that this metric is relatively strict because wrong calls will result in a reduction of accuracy.

D.2 CoS-Calling Details

For the CoS-Calling test, the standard (correct) plans will be provided to the model, instead of the plans that the model previously generated. The CoS-Calling test solely aims to investigate the model's ability to follow plans and generate the correct calling decisions. Besides the plans and instructions, only the useful tools with respect to the given query are provided in the prompt, instead

````
### Instruction:
You are asked to create a toolkit to solve the given task. Each tool in the toolkit should be a
Python function that is helpful to solve the problems in the task.
You will be given the related information about the task and the example queries to help you create
the useful tools.
For each tool you create, please first state the tool's name and its purpose, and then give its
implementation using python code. Please wrap the code in ```python … ```. You can create 2 to 5
tools for each task.

### Task 1
- Task Meta Information
The task asks the model to unscramble letters into a word. You should arrange the letters in correct
order and output a valid English word.
- Sample Queries
1. Q: Please unscramble the letters into a word, and write that word: imitedl  A: limited
2. Q: Please unscramble the letters into a word, and write that word: ermelonwat  A: watermelon
3. Q: Please unscramble the letters into a word, and write that word: ttlebo  A: bottle
Please create a toolkit including Python functions that are useful in solving the problem.
### Response
- Tool 1:
permutations: this tool takes in a given string, generates all possible permutations of it, and
returns them in a list.
```python
import itertools
def permutations(word):
    perms = [''.join(p) for p in itertools.permutations(word)]
    return perms
```
- Tool 2:
valid_word_lookup: this tool takes in a string, checks whether it's a valid English word, and returns
a bool value.
```python
import nltk
from nltk.corpus import words
def valid_word_lookup(word):
    nltk.download('words')
    english_words = set(words.words())
    return word.lower() in english_words
```

### Task 2
- Task Meta Information
[Meta Information of the Target Task]
- Sample Queries
[Sample Queries for Toolkit Generation in QA Format]
Please create a toolkit including Python functions that are useful in solving the problem.
### Response
````

Figure 6: The pattern of the prompt given to GPT-3.5-turbo to generate the toolkit.

of all the tools from the toolkit. We showcase the format of the prompt given to the model in Figure 7.

The accuracy of CoS-Calling is based on the matching of the model's output to the correct answer. For tasks Arithmetic and Chinese Remainder, the accuracy is evaluated in numerical format; for Matrix Shape, the accuracy is evaluated based on the matching of dimensions list; for all other tasks from BIG-bench, the accuracy is based on the matching of strings between the model's output and the correct answer.

E Dataset Construction

In this section, we provide more details about how CoS-GPT is constructed. We introduce respectively the construction of tool-using data (including planning and calling) and code generation data. All the data points aim to enhance the open-source model's CoS ability.

E.1 Construction of Tool-Using Data

For each query in AQUA-RAT, GSM8K, and TabMWP, we first utilize ChatGPT to create a diverse set of tools that are potentially relevant to the given query, forming the toolkit. We then provide this toolkit to ChatGPT and allow it to select the most suitable tools. Subsequently, we prompt ChatGPT to generate decision calls based on the selected tools and manually verify the correctness of the resulting outputs. If the final answer is correct,

```
Prompt Format for Tool Plan:
### Instruction:
You are presented with a question and several tools that may be useful. Select the useful tools and
plan how to solve the problem.
### Input:
- Question:
[Query from data]
- Available Tools:
1. [Name: Introduction about purpose, inputs, outputs]
2. [Name: Introduction about purpose, inputs, outputs]
...
### Response:
```

```
Prompt Format for Tool Call:
### Instruction:
[Query from data]
Use the tool given in the input to write python code to solve the problem.
### Input:
- Tool 1:
[Name: Introduction about purpose, inputs, outputs]
[Simplified Code Realization]
- Tool 2:
[Name: Introduction about purpose, inputs, outputs]
[Simplified Code Realization]
...
- Plan
[Plan from Model's Tool Plan Response or the Standard (Correct) Plan]
### Response:
```

Figure 7: The format of the data (and prompt) for CoS-Planning and CoS-Calling.

we divide ChatGPT's responses into two distinct components, representing the planning stage and the calling stage, which are then individually added to the dataset. In this manner, the validity of our data points can thus be guaranteed.

Throughout these steps of data construction, we also incorporate demonstration examples sampled from the constructed dataset, thereby expanding the dataset in a self-iterative manner. Figure 7 shows detailed information about the format of the query. Besides the query, we also provide the corresponding CoS-Planning or CoS-Calling response and the implementation of the toolkit with useful and redundant tools.

E.2 Construction of Code Generation Data

The code generation data in CoS-GPT are sourced from 6 different venues, including Python-Simple, Python-Specific, Math, Algorithm, LeetCode, and Rectification. The objective behind these categories is to enhance the model's proficiency in problem-solving through code utilization, calling existing packages, applying reasoning, employing algorithms, completing codes of challenging competitions, and engaging in self-rectification.

For Python-Simple and Python-Specific, the former aims to boost the models' ability to solve simple problems using codes, while the latter aims to enhance the model's ability to leverage code packages to solve more complex problems. Both these two sets are generated using ChatGPT. We prompt the model with instructions and demonstrations and gather the code snippets the model generated to solve the given problem.

The queries for the Math set are sampled from the training set of MathQA (Amini et al., 2019) and augmented with a code solution based on the given query and reasoning, leveraging ChatGPT. The generated programs are verified to ensure the output answer is the same as the correct one originally, thus ensuring the validity of the augmented data points. The Algorithm set is extracted from the open-source Python algorithm repository, with over 40 categories and more than a hundred diverse algorithms. For each algorithm, we ask ChatGPT to generate a query related to it and use a code snippet to solve the problem. The codes and corresponding queries are then gathered and formed into the instruction-following format.

For the LeetCode set, we directly extract the official open-sourced problems and the code answers from the website and form our data. The Rectification set is gathered from the error codes generated in the five sets before. The error tracebacks and the bad code snippet are fed into ChatGPT, and we leverage it to rectify the codes and generate a

correct code snippet that can solve the given query successfully. We gather the generated codes and execute them again, retaining only the ones that give a correct answer finally and form the set based on these valid data points.

F Main Experiment Setting Details

For our main experiment, we finetuned the LLaMA-7B model on four A100-80G GPUs, with a total batch size of 32 and a learning rate of 1e-5. For the model whose performance we demonstrate in Table 4 and Table 5, its training dataset consists of 1.6K target task-specific data points (8 tasks, 100 for planning and 100 for calling each), 4K tool-using data and 3K code-generation data randomly sampled respectively from the CoS-GPT dataset. We trained the LLaMA-7B on these data for 3 epochs and obtained LLaMA-CoS.

In addition, for the ablation study about the training on codes we perform in § 4.3, we apply 7K tool-using data and remove all the code-generation data points. We keep all the other settings the same in this study.

G Case Studies of Diverse CoS Patterns

In Figure 5, we present three case studies highlighting the diverse nature of LLaMA-CoS in applying planning and calling for tool-using.

Firstly, LLaMA-CoS exhibits the ability to generate sequential plans involving different tools. In the first case, the model simulates the operation on matrices step by step in a linear way and finally gets the correct result.

Secondly, LLaMA-CoS demonstrates proficiency in executing complex tool calls within branch-loop structures. In the second case, the model learns to use different stack operations based on the character met in the expression, and can call the useful tool in a loop structure.

Lastly, the model showcases its competence in performing nested tool invocations. In the third case, the model is able to directly pass the converted hour retrieved from the previous tool as the input parameter for the next tool, which illustrates a successful nested tool call.

These examples serve to show the robustness, versatility, and adaptability of LLaMA-CoS across a wide range of scenarios.

H CoS on Generic Toolkit Details

We source two new tasks, Dynamic Counting and Unit Interpretation, from the BIG-bench. We apply all the problems in Dynamic Counting for our test of toolkit generalization. However, for Unit Interpretation, we specifically select the data from LV 1 in order for the tools from task Arithmetic to be properly applied. To ensure fairness, we expand the dataset by interactively sampling new questions with similar patterns from ChatGPT and incorporating them until the dataset reaches its original full size. Note that we only aim to showcase the toolkit's generalization ability and compare the performance of LLaMA-CoS and ChatGPT within this work, so we deem expanding the dataset as fair and reasonable under our settings.

We show the toolkits specially tailored for these two new tasks in Figures 16 and 17. The LLaMA-CoS model we apply is still the model we have trained in the main experiment, detailed in Appendix F. All the other settings, including the ChatGPT applied under our framework, are kept the same as that in the main experiment.

Toolkit for task: Arithmetic

- **Tool 1:**

add: it takes in two numbers and returns their sum

```python
def add(a, b):
    return a + b
```

- **Tool 2:**

sub: it takes in two numbers a and b and returns a - b

```python
def sub(a, b):
    return a - b
```

- **Tool 3:**

mul: it takes in two numbers and returns their product

```python
def mul(a, b):
    return a * b
```

- **Tool 4:**

div: it takes in two numbers a and b and returns the integer value of a / b

```python
def div(a, b):
    return int(a / b)
```

- **Tool 5:**

mod: it takes in two numbers a and b and returns a % b

```python
def mod(a, b):
    return a % b
```

Figure 8: The toolkit for task Arithmetic.

Toolkit for task: Date Understanding

- **Tool 1:**

add_time: It takes in the start day in format MM/DD/YYYY, and calculate the date after y years, m months and d days. It returns a string in format MM/DD/YYYY.

```python
import datetime
def add_time(start_day, years=0, months=0, days=0):
    start_date = datetime.datetime.strptime(start_day, "%m/%d/%Y")
    new_date = start_date + datetime.timedelta(days=days)
    if new_date.month + months > 12:
        r = int((new_date.month + months) / 12)
        new_date = new_date.replace(year=new_date.year + years + r, month=(new_date.month + months - 1) % 12 + 1)
    else:
        new_date = new_date.replace(year=new_date.year + years, month=new_date.month + months)
    return new_date.strftime("%m/%d/%Y")
```

- **Tool 2:**

subtract_time: It takes in the start day in format MM/DD/YYYY, and calculate the date y years, m months and d days before this day. It returns a string in format MM/DD/YYYY.

```python
import datetime
def subtract_time(start_day, years=0, months=0, days=0):
    start_date = datetime.datetime.strptime(start_day, "%m/%d/%Y")
    new_date = start_date - datetime.timedelta(days=days)
    if new_date.month - months <= 0:
        r = int((new_date.month - months) / -12) + 1
        new_date = new_date.replace(year=new_date.year - years - r, month=(new_date.month - months - 1) % 12 + 1)
    else:
        new_date = new_date.replace(year=new_date.year - years, month=new_date.month - months)
    return new_date.strftime("%m/%d/%Y")
```

- **Tool 3:**

convert_hour: It takes the number of hours and convert it into days (integer).

```python
import math
def convert_hour(hours):
    days = math.ceil(hours / 24)
    return days
```

Figure 9: The toolkit for task Date Understanding.

Toolkit for task: Matrix Shape
- Tool 1:
multiply: it takes in two lists representing the shape of two matrix, and returns the shape of their product.
```python
def multiply(shape1, shape2):
    if shape1[1] != shape2[0]:
        raise ValueError("Matrix shapes are not compatible for multiplication.")
    result_shape = shape1[:-1] + [shape2[-1]]
    return result_shape
```
- Tool 2:
kronecker: it takes in two list representing the shape of two matrix, and returns the shape of their kronecker product.
```python
def kronecker(shape1, shape2):
    if len(shape1) != len(shape2):
        raise Exception("The number of dimensions of the two matrices is not equal")
    result_shape = [dim1 * dim2 for dim1, dim2 in zip(shape1, shape2)]
    return result_shape
```
- Tool 3:
sum_over_axis: it takes a list representing the shape of the matrix, and the dimension of the axis that is to be sum up. It returns the shape of the resulting matrix.
```python
def sum_over_axis(shape, axis):
    if axis >= len(shape):
        raise ValueError("Invalid axis dimension.")

    result_shape = shape[:axis] + shape[axis+1:]
    return result_shape
```
- Tool 4:
transpose: it takes a list representing the shape of a matrix to be transposed, and returns the shape of the resulting matrix.
```python
def transpose(shape):
    result_shape = list(reversed(shape))
    return result_shape
```
- Tool 5:
add_subtract_hadamard: it takes two lists representing the shape of two matrices for add, sbstract and hadamard, and returns the shape of the resulting matrix.
```python
def add_subtract_hadamard(shape1, shape2):
    assert shape1 == shape2
    return shape1
```

Figure 10: The toolkit for task Matrix Shape.

Toolkit for task: Navigation

- **Tool 1:**

update_orientation: It takes the original orientation(N, E, S or W) and turn direction(left, right or around), and returns the new orientation. It should be used only if not always face forward.

```python
def update_orientation(orientation, turn_direction):
    orientations = ["N", "E", "S", "W"]
    current_index = orientations.index(orientation)
    if turn_direction == "left":
        new_index = (current_index - 1) % 4
    elif turn_direction == "right":
        new_index = (current_index + 1) % 4
    elif turn_direction == "around":
        new_index = (current_index + 2) % 4
    else:
        raise ValueError("Invalid turn direction.")
    return orientations[new_index]
```

- **Tool 2:**

update_location: It takes the current location(x, y), orientation(N, E, S or W), and steps, and returns the new location after action.

```python
def update_location(current_location, orientation, steps):
    x, y = current_location
    if orientation == "N":
        new_location = (x, y + steps)
    elif orientation == "E":
        new_location = (x + steps, y)
    elif orientation == "S":
        new_location = (x, y - steps)
    elif orientation == "W":
        new_location = (x - steps, y)
    return new_location
```

Figure 11: The toolkit for task Navigation.

Toolkit for task: Chinese Remainder

- **Tool 1:**

divide_remain: it takes in a, b, and c, and checks if the remainder of a divided by b is equal to c.

```python
def divide_remain(a, b, c):
    return a % b == c
```

- **Tool 2:**

check_validity: it takes into a list of possible answers, and filters the list of answers based on the upper bound x.

```python
def check_validity(answers, x):
    return [answer for answer in answers if answer <= x]
```

Figure 12: The toolkit for task Chinese Remainder.

Toolkit for task: Dyck Language

- Tool 1:

get_closing_parenthesis: This tool takes in an opening parenthesis and returns the corresponding closing parenthesis.

```python
def get_closing_parenthesis(opening):
    openings = ['(', '[', '{', '<']
    closings = [')', ']', '}', '>']
    if opening in openings:
        return closings[openings.index(opening)]
    else:
        return None
```

- Tool 2:

get_opening_parenthesis: This tool takes in an closing parenthesis and returns the corresponding opening parenthesis.

```python
def get_opening_parenthesis(closing):
    openings = ['(', '[', '{', '<']
    closings = [')', ']', '}', '>']
    if closing in closings:
        return openings[closings.index(closing)]
    else:
        return None
```

- Tool 3:

stack_insert: This tool takes in a stack and an element and returns the stack with the element inserted at the top.

```python
def stack_insert(stack, element):
    stack.append(element)
    return stack
```

- Tool 4:

stack_pop: This tool takes in a stack and returns the stack with the top element removed.

```python
def stack_pop(stack):
    if len(stack) > 0:
        stack.pop()
    return stack
```

Figure 13: The toolkit for task Dyck Language.

Toolkit for task: Boolean Expression

- Tool 1:

evaluate_expression: this tool takes in an expression as a string, evaluates it using Python's eval() function, and returns the result.

```python
def evaluate_expression(expression):
    try:
        result = eval(expression)
        return result
    except SyntaxError:
        return "Invalid expression"
```

- Tool 2:

extract_valid_expressions: this tool takes in a string and extract the valid string that represents the expression.

```python
def extract_valid_expressions(question_string):
    expression = question_string.split(':')[1].split('is')[0].strip()
    return expression
```

Figure 14: The toolkit for task Boolean Expression.

Toolkit for task: Tracking Shuffled Objects

- **Tool 1:**

create_object_dict: this tool takes in a list of people and their initial object, and returns a dictionary mapping each person to their object.

```python
def create_object_dict(people, objects):
    object_dict = dict(zip(people, objects))
    return object_dict
```

- **Tool 2:**

update_object_dict: this tool takes in an object dictionary, a list of object trades, and updates the object dictionary based on the trades.

```python
def update_object_dict(object_dict, trades):
    for trade in trades:
        person1, person2 = trade.split(' and ')
        object_dict[person1], object_dict[person2] = object_dict[person2], object_dict[person1]
    return object_dict
```

- **Tool 3:**

parse_trades: this tool takes in a string of trades and returns a list of individual trades.

```python
def update_object_dict(object_dict, trades):
    def parse_trades(trades_str):
    trades = trades_str.split('. Then, ')
    trades[0] = trades[0].replace('At the start', '')
    trades[-1] = trades[-1].replace('At the end', '')
    return trades
```

- **Tool 4:**

get_final_object: this tool takes in a object dictionary and returns the object held by the target person finally.

```python
def get_final_object(object_dict, target_person):
    return object_dict[target_person]
```

Figure 15: The toolkit for task Tracking Shuffled Objects.

Toolkit for task: Dynamic Counting

- **Tool 1:**

get_closing_parenthesis: This tool takes in an opening parenthesis and returns the corresponding closing parenthesis.

```python
def get_closing_parenthesis(opening):
    pairs_open = {'(': ')', '[': ']', '{': '}', '<': '>'}
    if opening in pairs_open:
        return pairs_open[opening]
    else:
        return None
```

- **Tool 2:**

find_open_remaining: This tool takes in a sequence of parenthesis and returns the single reamining opening paraenthesis that is not closed.

```python
def find_open_remaining(parenthesis):
    parenthesis = parenthesis.split(" ")
    pairs_open = {'(': ')', '[': ']', '{': '}', '<': '>'}
    pairs_close = {')': '(', ']': '[', '}': '{', '>': '<'}
    stack = []
    for p in parenthesis:
        if p in pairs_open:
            stack.append(p)
        elif p in pairs_close:
            if pairs_close[p] in stack:
                stack.remove(pairs_close[p])
    return stack[0]
```

Figure 16: The toolkit for task Dynamic Counting.

Toolkit for task: Unit Interpretation (LV1)

- **Tool 1:**

same_ratio_calculate_first: This tool assumes that a : b = x : y. x is the first position. It takes in a, b and y and returns x.

```python
def same_ratio_calculate_first(a, b, y):
    return (a / b) * y
```

- **Tool 2:**

same_ratio_calculate_second: This tool assumes that a : b = x : y. y is the second position. It takes in a, b and x and returns y.

```python
def same_ratio_calculate_second(a, b, x):
    return (b / a) * x
```

Engineering Research Center of Machine Learning and Industry Intelligence, China
letianwang@stu.scu.edu.cn, {liuxianggen, lvjiancheng}@scu.edu.cn

Abstract

We propose Label Creative Generation (LCG), a new paradigm in multi-label data augmentation. Beyond repeating data points with fixed labels, LCG creates new data by exploring innovative label combinations. Within LCG, we introduce Tail-Driven Conditional Augmentation (TDCA), combining tail-driven label sampling and label-conditioned text generation for balanced, consistent data augmentation. Our approach has demonstrated a **100.21%** increase in PSP@1 across three datasets, successfully mitigating the long-tail effect in MLTC and markedly enhancing model performance.

1 Introduction

Multi-label Text Classification (MLTC), prevalent in fields such as sentiment analysis and recommendation systems, grapples with the dual challenges of an extensive label space and a pronounced long-tail distribution. This imbalance is exemplified in Wiki10-31K dataset, where a mere **1.5%** of labels have more than **100** training instances, leaving the vast majority with a scarcity of training data. Table 1 reveals that while numerous studies claim to have addressed or alleviated the long-tail issue, advancements in recent years, particularly on PSP@k, have been gradual. Relying solely on advancements in neural architectures appears to be ineffective over time. There is a need for data augmentation.

Method	Source	PSP@1	PSP@3	PSP@5
PfastreXML	Jain et al. (2016)	19.02	18.34	18.43
XML-CNN	Liu et al. (2017)	9.39	10.00	10.20

TDCA	**ours**	**46.31**	**39.02**	**36.92**

Table 1: Comparison of MLTC methods on Wiki10-31K using $PSP@k$, a widely used metric that assigns higher weights to tail labels for a more balanced evaluation.

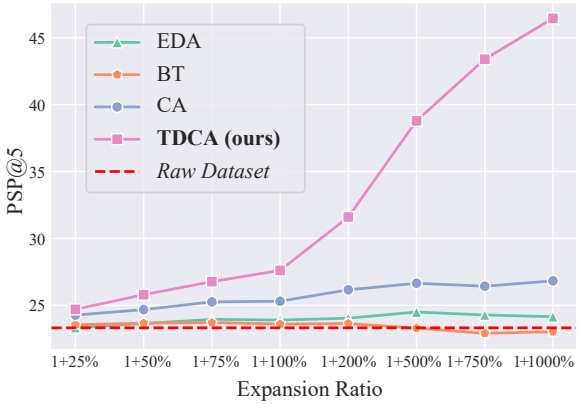

Figure 1: PSP@5 for various expansion ratios on MeSH-12K dataset, comparing four data augmentation methods: Easy Data Augmentation (EDA), Back-Translation (BT), Conditional Augmentation (CA), and TDCA. The Expansion Ratio (E/R) quantifies augmentation: 1 indicates no augmentation and $1 + x\%$ shows $x\%$ augmentation over the original dataset.

1.1 Inadequacies of Current DA Methods

Current data augmentation (DA) methods in text classification have shown promise, yet their effectiveness in MLTC remains limited. Prevailing DA strategies typically focus on employing various approaches to replicate data while maintaining labels unchanged. These methods fall into two distinct categories: paraphrase-based augmentation and conditional augmentation (CA). The former includes model-free methods like easy data augmentation (Wei and Zou, 2019), as well as model-required techniques such as back-translation (Sennrich et al., 2016; Edunov et al., 2018). CA employs conditional generation (often label-conditioned) for data augmentation to synthesize texts that are more controlled yet diverse (Li et al., 2020; Liu et al., 2020). Such strategies offered benefits in binary or multi-class text classification, often regarded as a means to bolster model robustness (Bayer et al., 2023). However, as illustrated in Figure 1, conventional approaches like EDA and BT are seldom effective and might even

June 16-21, 2024 ©2024 Association for Computational Linguistics

impede model performance, particularly at greater data expansion scales. CA shows improved performance but remains modest.

Intrinsically marked by the existence of multiple labels per instance, MLTC poses distinct challenges to conventional data augmentation methods. Paraphrasing-based approaches, which solely alter the text while maintaining its original intent and keeping the labels unchanged, fail to enhance performance by a large margin. Moreover, the noise introduced in the paraphrasing process can adversely affect model performance, a negative impact that becomes more pronounced with an increasing proportion of augmented data.

1.2 LLMs in MLTC

The recent validation of scaling laws in large language models (LLMs) like GPT (Brown et al., 2020; Bubeck et al., 2023) and LLaMa (Touvron et al., 2023a,b) has revolutionized previously infeasible tasks and advanced tasks that had plateaued. Research exploring LLMs in multi-label text classification has been emerging. For example, Kocon et al. (2023) evaluated ChatGPT in text classification, observing its lag behind traditional SOTA models, with the gap widening in complex classification scenarios. However, its performance in emotion recognition was noteworthy. Loukas et al. (2023) corroborated this, highlighting ChatGPT's potential in few-shot and zero-shot classification. This is in line with the training goal of LLMs, which involves predicting the next token from preceding ones.

Post-training on large-scale general corpora, their formidable understanding and common sense skills lend them efficacy in text generation tasks and common classification tasks with fewer categories (Ray, 2023). Nonetheless, they grapple with issues like hallucinations and prompt sensitivity, underperforming in knowledge-intensive tasks like large-scale information retrieval and fine-grained text classification (Li et al., 2023).

Given the extremely large number of labels, employing LLMs for MLTC directly is impractical. An alternative is leveraging LLMs for data augmentation, as explored in some recent works. AugGPT (Dai et al., 2023), for instance, continued with the conventional approach, employing ChatGPT for paraphrasing texts while preserving the original labels, yielding marginal improvements. Van Nooten and Daelemans (2023) took a more straightforward route. They provided ChatGPT with nine distinct labels along with the corresponding examples to generate additional text-labels pairs for tweet classification.

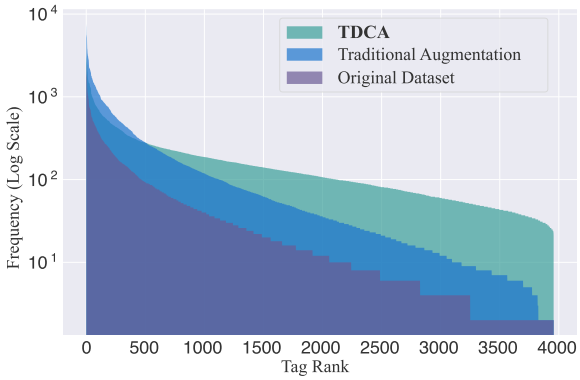

Figure 2: Tag frequency distribution post data augmentation. Compared to traditional data augmentation methods (EDA, BT, and CA), TDCA demonstrates more effective mitigation of the long-tail effect.

1.3 Create! Don't Repeat

The untapped potential of LLMs opens new avenues for conditional data generation to liberate us from the limitations of simply repeating existing data points, enabling the synthesis of entirely new ones. Hence, we introduce a new multi-label data augmentation paradigm, Label Creative Generation (LCG), and within LCG, we propose Tail-Driven Conditional Augmentation (TDCA). TDCA comprises (1) a Metropolis-Hastings algorithm based tail-driven label sampling for crafting more balanced label combinations with consideration of label correlations; and (2) a contrastive label-conditioned generation approach, which fine-tunes LLMs to generate texts that not only accurately reflect each label in the sampled label combinations but also emulate the style of the original dataset.

TDCA enables the transference of extensive correlations from head labels to tail labels through LLM. Our experimental results demonstrate a substantial alleviation of the long-tail effect, evidenced by a **100.21%** average enhancement in PSP@1 across Eurlex-4K, MeSH-12K, and Wiki10-30K datasets. Remarkably, with increasing expansion ratios, we observe an ascending trend in PSP@k, devoid of the detrimental noise impact commonly associated with traditional data augmentation methods, a finding corroborated by t-SNE visualizations in Figure 5. Ablation studies affirm the efficacy and validity of TCDA.

Our contributions are threefold:

1. We introduce a new paradigm in multi-label data augmentation, Label Creative Generation. This approach, to the best of our knowledge, is pioneering in the field as it does not rely on pre-existing label combinations but instead creates new ones.

2. Within the framework of LCG, we propose a novel method named Tail-Driven Conditional Augmentation. TDCA enables the generation of balanced label combinations through the construction of a dual-weighted label graph and employs tail-driven label sampling based on the Metropolis-Hastings algorithm. Moreover, it utilizes contrastive label-conditioned generation to produce augmented texts that are both representative of the assigned labels and coherent with the original dataset.

3. Our experiments conducted across three datasets show that TDCA significantly reduced the long-tail effect in MLTC. The results show notable improvements in PSP@1, P@10, and N@10, with increases of **100.21%**, **16.58%**, and **11.65%**, respectively.

2 Tail-Driven Conditional Augmentation

Multi-label Text Classification (MLTC) aims to assign a subset of labels $Y \subseteq L$ to each instance x, where $L = \{l_1, l_2, ..., l_N\}$ represents the entire possible label space. This task can be formalized as learning a mapping function $f(x) \rightarrow 2^L$, predicting the power set of L. The approach of TDCA is straightforward: It commences with tail-driven label sampling to create label combinations and proceeds to contrastive label-conditioned generation, synthesizing text that aligns with these labels.

2.1 Tail-Driven Label Sampling

In MLTC, two primary characteristics emerge: (1) Each instance is associated with multiple labels, which exhibit significant correlations; (2) As depicted in Table 2, multi-label datasets encounter a pronounced long-tail effect, with tail labels dominating the label space yet being represented in only a small fraction of training instances. To address this, a balanced and correlation-aware label sampling approach is necessary. Consequently, we present Tail-Driven Label Sampling, which incorporates the Dual-Weighted Label Graph and Metropolis-Hastings sampling.

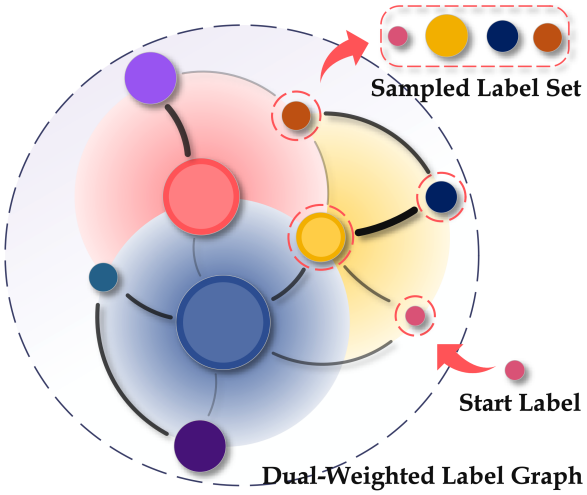

Figure 3: Tail-driven label sampling. Vertex size shows label frequency in the dataset, while edge thickness and color depth indicate label co-occurrence frequency.

2.1.1 Dual-Weighted Label Graph

The Dual-Weighted Label Graph (DWLG) is formally defined as $G = (V, E, W_v, W_e)$. It comprises vertices V, each signifying a distinct label, and edges E, linking pairs of vertices based on their co-occurrence in the dataset. Vertex weights are consolidated in $W_v = \{w_v(i) \mid i \in V\}$, with $w_v(i)$ representing the occurrence frequency of label i. The edge weights, denoted as $w_e(i, j)$ in W_e, capture the co-occurrence strength between labels i and j. This dual-weighted architecture yields an integrated perspective of both individual label properties and their interconnections, fundamental for advanced label sampling and data exploration[1].

2.1.2 Metropolis-Hastings Label Sampling

Employing the principles of Markov chain theory, Metropolis-Hastings (M-H) sampling (Metropolis et al., 1953; Hastings, 1970) can adeptly adjust to the target distribution, which is perfectly in tune with our aim to achieve a more balanced sampling strategy in long-tail distributions. We initiate M-H sampling of the DWLG by starting from a tail label, then iteratively transitions to other labels, directed by both the transition kernel and acceptance rate. This procedure is maintained until an adequate count of labels is sampled or a pre-determined step limit is reached.

Firstly, the transition kernel $q(i \rightarrow j)$ calculates the likelihood of moving from the current label i

[1]Our DWLG diverges from the traditional Label Correlation Graph concept introduced by Mittal et al. (2021), departing from random walk-based graph construction and incorporating dual weights for a clearer depiction of label dynamics.

Algorithm 1 Tail-Driven Label Sampling

Input:

G: Dual-Weighted Label Graph
$start$: Starting Label
$steps$: Number of M-H Steps
T: Temperature Parameter
$maxLabels$: Max Labels to Collect

Output:

$sampled$: Sampled Labels Set

$sampled \leftarrow \{start\}$
$current \leftarrow start$
for $i \leftarrow 1$ **to** $steps$ **do**
  $N \leftarrow$ GetNeighbors($current$, G)
  $next \leftarrow$ SampleNext(N)
  $accept \leftarrow$ Acceptance($current$, $next$, T)
  if $accept$ **then**
    $current \leftarrow next$
    $sampled \leftarrow sampled \cup \{next\}$
  end if
  if $|sampled| \geq maxLabels$ **then**
    break
  end if
end for
return $sampled$

to an alternative label j within the DWLG during sampling. Considering the inter-label correlations, we define $q(i \rightarrow j)$in the following manner:

$$q(i \rightarrow j) = \frac{e^{w_e(i,j)}}{\sum_{k \in \text{neighbors}(i)} e^{w_e(i,k)}}, \quad (1)$$

where $w_e(i, j)$ denotes the edge weight between labels i and j in the DWLG.

Then, drawing upon the principles of information entropy (Shannon, 1948), the target distribution $p(i)$ is defined to encapsulate the significance and scarcity of label i:

$$p(i) = \frac{e^{s(i)/T}}{\sum_k e^{s(k)/T}}. \quad (2)$$

Here, $s(i) = -\log(w_v(i))$ is the importance score of label i, and T is a temperature parameter that moderates the distribution's smoothness.

Finally, the acceptance rate $\alpha(i \rightarrow j)$ evaluates whether to accept the transition from label i to label j, thereby steering the sampling outcomes towards the target distribution:

$$\alpha(i \rightarrow j) = \min\left(1, \frac{p(j) \cdot q(j \rightarrow i)}{p(i) \cdot q(i \rightarrow j)}\right). \quad (3)$$

2.2 Contrastive Label-conditioned Generation

Conditional generation, recognized for its capability to produce texts that are both diverse and controlled, has improved data augmentation in binary and multi-class scenarios. However, previous studies have largely concentrated on the label-conditioned duplication of existing data points. The true potential of conditional generation extends far beyond this practice.

Integrating LLMs into conditional generation introduces several challenges. When dealing with a sampled labels set: (1) An excess of labels leads to extended input sequences, complicating LLMs' ability to reflect each label in the generated text, often causing omissions; (2) LLMs' sensitivity to prompt selection results in erratic text generation quality; (3) Existing LLMs, enhanced with RLHF, tend to generate superfluous explanatory content, which can be counterproductive for data augmentation; (4) Texts generated by LLMs exhibit stylistic discrepancies with the original dataset.

We fine-tune LLM on the original dataset to mitigate these issues. Inspired by Song et al. (2023) and Rafailov et al. (2023), we devised two targeted loss functions for multi-label classification dataset augmentation: Label Match Loss ($\mathcal{L}_{\mathcal{LM}}$), ensuring generated texts align with each input label, and Style Consistency Loss ($\mathcal{L}_{\mathcal{SC}}$), which aids in producing texts that are coherent, controllable, and in stylistic harmony with the original dataset.

2.2.1 Style Consistency Loss

Initially, a subset $\{X^1, Y^1; \ldots; X^n, Y^n\}$ is randomly extracted from the training set, wherein $X = \{x_1, \ldots, x_{|X|}\}$ denotes a text, comprising a series of tokens x, and $Y = \{y_1, \ldots, y_{|Y|}\}$ represents a set of multiple labels associated with X. Regarding Y, we concat it with a prompt to create a composite text $c(Y)$, such as "Generate text for the labels $[y_1, \ldots, y_{|Y^i|}]$" to serve as an input for the LLM. To ensure that the text X_{aug} produced by the LLM aligns with X, the Style Consistency Loss is as follows:

$$\mathcal{L}_{\mathcal{SC}} = -\sum_t \log P_\phi(x_t | c(Y), x_{1,\cdots,t-1}). \quad (4)$$

Here, ϕ signifies the parameters of the LLM. Given the input $c(Y)$ and the prior tokens $x_{1,\cdots,t-1}$, our goal is to fine-tune the model with greater probability to predict the next token x_t.

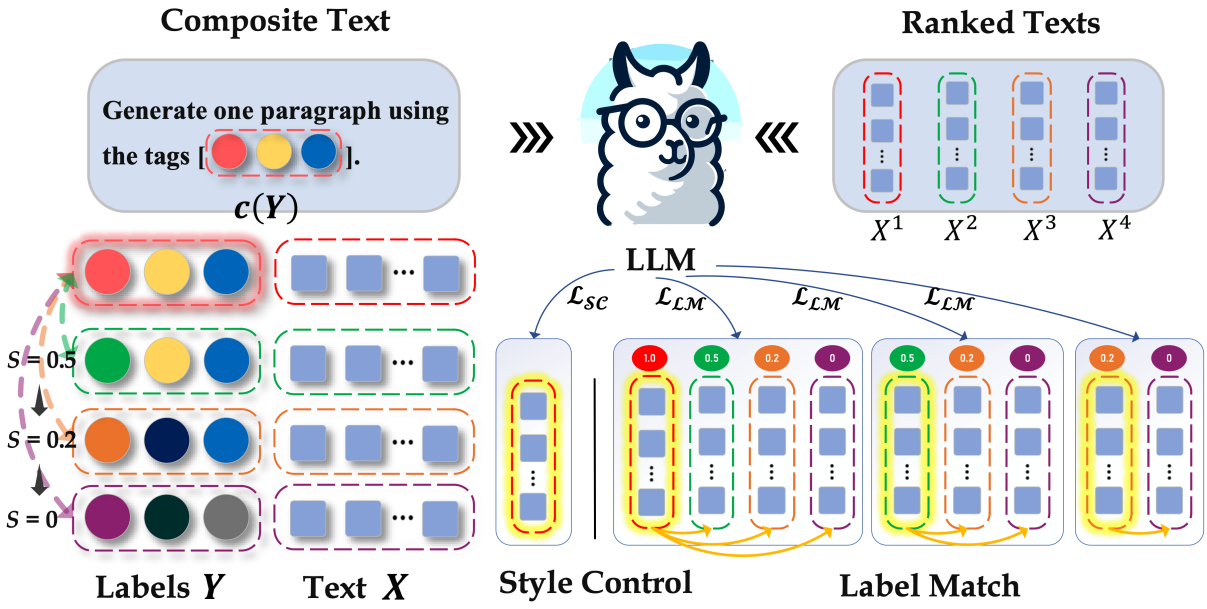

Figure 4: Fine-tuning LLM in Contrastive Label-conditioned Generation. $\mathcal{L}_{\mathcal{LM}}$ ensures alignment of generated texts with input labels. $\mathcal{L}_{\mathcal{SC}}$ supports the production of similar texts with the original dataset.

2.2.2 Label Match Loss

To effectively align the augmented input X_{aug} with the corresponding label combinations Y, we not only employ $\mathcal{L}_{\mathcal{SC}}$ to illustrate ideal generation but also aim to guide the LLM in distinguishing between good and bad ones. In the randomly selected subset of the training set $\{\boldsymbol{X^1}, \boldsymbol{Y^1}; X^2, Y^2; \ldots; X^n, Y^n\}$, where each Y^i is unique, the Jaccard similarity (Jaccard, 1912) is utilized to evaluate and rank the degrees of similarity, ranging from Y^1 and Y^2, to Y^1 and Y^n. For labels Y^1, its associated text X^1 is considered a **positive** example, while texts ranging from X^2 to X^n are deemed **negative** examples, exhibiting progressively higher degrees of dissimilarity.

We generalize the InfoNCE loss (van den Oord et al., 2018) using the Plackett-Luce model (Plackett, 1975; Luce, 1959), deriving the Label Match Loss as follows:

$$\mathcal{L}_{\mathcal{LM}} = -\sum_{i=1}^{n-1} \log \frac{\exp\left(\frac{r_\phi(X^i)}{\mathcal{T}_i^i}\right)}{\sum_{j=i}^{n} \exp\left(\frac{r_\phi(X^j)}{\mathcal{T}_i^j}\right)}, \quad (5)$$

where ϕ denotes the parameters of the LLM, $\mathcal{T}$ represents the temperature coefficient, and $r_\phi(X^i)$ indicates the likelihood of the LLM generating X^i. For the set $\{\boldsymbol{X^1}, \boldsymbol{Y^1}; X^2, Y^2; \ldots; X^n, Y^n\}$, we initially compare X^1 with each of $X^2, \ldots, X^n$, followed by a comparison of X^2 with $X^3, \ldots, X^n$, aiming to align the LLM-generated X_{aug} with the label Y. Specifically, $r_\phi(X)$ is defined as:

$$r_\phi(X) = \frac{1}{|X|} \sum_{t=1}^{|X|} \log P_\phi(x_t | c(Y^1), x_{1,\cdots,t-1}), \quad (6)$$

where X encompassing tokens $x_1, \cdots, x_{|X|}$, with $c(Y^1)$ representing the label of the positive sample integrated with the prompt.

Each comparison involves modulation of suppression for negative samples at varying degrees through temperature coefficients $\mathcal{T}$:

$$\mathcal{T}_i^{j>i} = \frac{1}{s(Y^1, Y^i) - s(Y^1, Y^j)}, \quad (7)$$

$$\mathcal{T}_i^i = \min_{j>i} \mathcal{T}_i^j. \quad (8)$$

Here, $s(Y^i, Y^j)$ denotes the Jaccard similarity between the label sets Y^i and Y^j.

2.2.3 Optimization Objective

Combining the label match loss and style consistency loss, the final loss function is:

$$\mathcal{L} = \mathcal{L}_{\mathcal{LM}} + \lambda \mathcal{L}_{\mathcal{SC}}. \quad (9)$$

The hyperparameter λ balances the importance of label matching and style consistency. Optimizing $\mathcal{L}$ ensures that the generated text is not only

Dataset	N_{Train}	N_{Test}	W_{Avg}	L_{Avg}	L_{Total}	$L_{>100}$	$L_{<10}$

Wiki10-30K	14,145	6,616	2,086.01	18.37	29,973	461	25,178

Table 2: Summary of datasets in Eurlex-4K, MeSH-12K, and Wiki10-30K. N_{Train}: Number of training instances, N_{Test}: Number of test instances, W_{Avg}: Average words per instance, L_{Avg}: Average labels per instance, L_{Total}: Total number of labels, $L_{>100}$: Labels with more than 100 instances, $L_{<10}$: Labels with less than 10 instances.

relevant to the sampled labels Y but also stylistically coherent with the actual text X, striking a balance between accuracy and authenticity.

3 Experiments

3.1 Datasets

We employ three benchmark datasets: Eurlex-4K, MeSH-12K, and Wiki10-30K ("K" denotes the label count within each dataset). **Eurlex-4K** (Loza Mencía and Fürnkranz, 2008) comprises a corpus of European Union legal documents. We utilize its raw text, as provided in Ye et al. (2020), without applying stemming or stop-word removal. **MeSH-12K**, a subset culled from the BioASQ datasets[2](Tsatsaronis et al., 2015), is composed of article titles and abstracts from PubMed, annotated with Medical Subject Headings (MeSH) as their labels. **Wiki10-30K**, originating from Wikipedia, is a refined iteration of Wiki10-31K[3] (Zubiaga, 2012). While prior studies merely utilized the label IDs in Wiki10-31K for classification, we undertook a meticulous review and cleansing of this dataset. This entailed the exclusion of content-lacking instances and labels constituted solely of punctuations (*e.g.*, ".", "!", "!!!") or NLTK-listed stopwords (*e.g.*, "and", "or"). More statistical information can be found in Table 2.

3.2 Evaluation Metrics

To assess the performance of each method, we use the following evaluation metrics: $P@k$, $PSP@k$, and $N@k$.

Precision at k ($P@k$) measures the precision of the top k predicted labels in matching the true labels. For an instance with its top-k predicted label set $\hat{Y}@k$ and actual label set Y, $P@k$ is defined as:

$$P@k = \frac{|\hat{Y}@k \cap Y|}{k}, \tag{10}$$

where $|\hat{Y}_k \cap Y|$ is the number of correct predictions in the top k labels. On the Wiki10-30K, if a model accurately predicts the head labels ($L_{>100} = 461$) and ignores the rest, it would achieve a $P@1$ of 90.8%. This high precision, however, overlooks the informative tail labels.

Propensity Scored Precision at k ($PSP@k$) mitigates this limitation by modifying precision to give higher weights to less frequent labels. Given the top-k predicted label set $\hat{Y}_k$ and the actual label set Y, $PSP@k$ is defined as:

$$PSP@k = \frac{\sum_{y \in \hat{Y}@k \cap Y} \frac{1}{\pi_y}}{k}. \tag{11}$$

Here, π_y represents the propensity score of label y, quantifying the likelihood of encountering label y in the training dataset.

Normalized Discounted Cumulative Gain at k ($N@k$) evaluates the ranking quality of predicted labels, considering both the relevance of the labels and their ranking positions. The Discounted Cumulative Gain (DCG) for a predicted label $\hat{y}_i$ at rank i is calculated as:

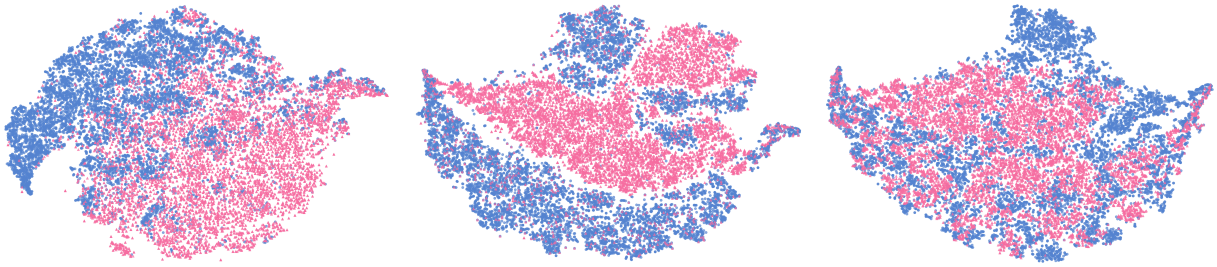
$$DCG@k = \sum_{i=1}^{k} \frac{\mathbb{I}(\hat{y}_i \in Y)}{\log_2(i+1)}, \tag{12}$$

where $\mathbb{I}(\cdot)$ is an indicator function. $N@k$ is the ratio of $DCG@k$ to $iDCG@k$:

$$iDCG@k = \sum_{i=1}^{\min(k,|Y|)} \frac{1}{\log_2(i+1)}. \tag{13}$$

$$N@k = \frac{DCG@k}{iDCG@k}. \tag{14}$$

3.3 Experiment Settings



We compare TDCA with three data augmentation baselines: EDA, BT, and CA. EDA (Wei and Zou, 2019) involves synonym replacement and random insertion/swap/deletion. In BT, we

Figure 5: A t-SNE (van der Maaten and Hinton, 2008) visualization of the MeSH-12K dataset comparing various text data augmentation methods: (a) BT, (b) EDA, and (c) our proposed TDCA, where ● represents original data, and ▲ represents augmented data.

select French, Chinese, Russian, Italian, and Spanish as intermediate languages for English paraphrasing via `nllb-200-distilled` model (Costa-jussà et al., 2022). CA and TDCA utilize LLaMa-based LLM, `Qwen-7B-Chat` (Bai et al., 2023), for label-conditioned text generation. For MLTC, we utilized LightXML (Jiang et al., 2021) with `bert-base-uncased` (Devlin et al., 2019). The EurLex-4K setup included a 1e-4 learning rate, 15 epochs, batch size of 16, and max token length of 512, with SWA (Izmailov et al., 2018) applied post 10 epochs (step size 200). For Wiki10-30K, we extended training to 30 epochs (SWA step size 300), maintaining other parameters. MeSH-12K followed the Wiki10-30K settings, with a batch size of 8 and a max token length of 256. TDCA utilized Metropolis-Hastings sampling from labels with <100 instances, with a 1000-step limit and temperature of 10. Fine-tuning involved a λ value of 0.2 for loss balance, 2 epochs, a 512 sequence length, and a 5e-6 learning rate. All experiments were conducted on 8 NVIDIA A100 GPUs.

4 Results

4.1 Performance Comparison

Performance assessments were carried out on the EurLex-4K, MeSH-12K, and Wiki10-30K on various expansion ratios to evaluate the effectiveness of our proposed TDCA compared to EDA, BT, and CA. As Table 3 indicates, all methods mitigated the long-tail effect in MLTC datasets to varying degrees: EDA and BT marginally enhanced $PSP@k (k = 1, 3, 5)$ by 1.89% and 1.95%, respectively. CA's diverse text generation led to a 9.45% increase, limited by unchanged labels. TDCA, integrating tail-driven sampling, impressively reduced the long-tail effect with an 85.61% improvement.

Moreover, data augmentation's effectiveness correlates with the number of dataset labels. TDCA enhanced $PSP@1$ by 16.46% on EurLex-4K, 98.78% on MeSH-12K, and 185.51% on Wiki10-30K. This result aligns with the expectation that more labels intensify the long-tail effect, enhancing the utility of data augmentation.

Table 4: Performance comparison of EDA, BT, TDCA, and three TDCA variants: CA (TDCA w/o M-H), TDCA w/o F-T, and CA w/o F-T across various expansion ratios in terms of $PSP@5$, $P@5$, and $N@5$. In the table, deeper shades of red indicate higher values, while deeper shades of green denote lower values.

Regarding $P@K$ and $N@K(k = 1, 3, 5, 10)$, label-conditioned augmentation methods, CA and TDCA, consistently improved performance, with CA increasing $P@K$ by 1.42% and $N@K$ by 1.09% on average, and TDCA by 8.16% and 5.95%. EDA and BT, however, had a marginal negative impact: EDA decreased $P@k$ and $N@K$ by 0.63% and 0.64%, while BT showed similar declines by 0.52% and 0.49%. This is further supported by t-SNE visualizations (Figure 5), where TDCA's augmented data demonstrate better integration with original data, unlike EDA and BT.

TDCA not only effectively counters the long-tail effect in MLTC datasets but also bolsters prediction precision and ranking quality. The improvements are progressive with larger values of k in all metrics, which indicates that label-conditioned augmentation is more adaptable to MLTC's extremely large label space. Furthermore, the quantitative experiments (Table 4) reveal that TDCA outperforms traditional methods at equivalent ratios. While EDA and BT exhibit increasingly negative effects with more augmented data, TDCA's benefits progressively amplify. For comprehensive details, refer to training logs in Appendix B.

The case study in Appendix A uncovers an intriguing aspect: the original dataset often exhibits an implicit link between labels and text, significantly challenging the learning process of models. The LLM-based CA and TDCA render these labels more explicit in the generated texts, facilitating an easier learning of correspondences.

4.2 Ablation Analysis

Table 4 presents the results of TDCA and its three variant models under different expansion ratios. These variants are: CA (TDCA without M-H based tail-driven sampling, *i.e.*, TDCA w/o M-H), TDCA w/o F-T (TDCA without contrastive label-conditioned fine-tuning), and CA w/o F-T (TDCA w/o M-H & F-T).

The varying shades of red (high) and green (low) in the table illustrate that TDCA and TDCA w/o F-T significantly outperform both CA (TDCA w/o M-H) and CA w/o F-T (TDCA w/o F-T & M-H) across all metrics. This highlights the pivotal role of M-H based tail-driven sampling in TDCA, validating our proposed Label Creative Generation. Furthermore, the comparison between TDCA and TDCA w/o F-T, as well as between CA and CA w/o F-T, confirms the effectiveness of contrastive fine-tuning. Overall, these results demonstrate that each component of the TDCA structure is effective and contributes to its overall performance.

5 Conclusion

In this paper, we introduce a new multi-label data augmentation paradigm named Label Creative Generation (LCG). Under LCG, we propose Tail-Driven Conditional Augmentation (TDCA). TDCA facilitates the creation of balanced label combinations by dual-weighted label graph and tail-driven label sampling. Furthermore, TDCA employs a contrastive label-conditioned generation to produce augmented texts that match each label and maintain consistency with the original dataset. Empirical evaluations on three datasets with varying label counts demonstrate the effectiveness of TDCA. Our approach significantly surpasses existing data augmentation methods, effectively mitigates the long-tail effect, and enhances model prediction performance in MLTC.

Limitations

- This method is primarily effective for textual labels with semantic content. It is less suited for labels represented by numerical IDs or non-descriptive identifiers.
- Compared to EDA and other non-model-based data augmentation techniques, our approach is more resource-intensive. However, its resource consumption is comparable to seq2seq model-based methods like back-translation.
- Due to computational resource constraints, we were unable to fully explore the upper limits of TDCA's performance improvements. On the EurLex dataset, we observed optimal expansion ratios between 400% to 500%. Beyond this range, performance tended to plateau or slightly decrease. In contrast, on the MeSH-12K and Wiki10-30K datasets, with more extensive labels, we experimented with expansion ratios up to 1000% and 3000%, respectively, without reaching an apparent performance ceiling.
- Our exploration did not extend to closed-source LLMs such as ChatGPT, Bard, or Claude, limited by API access. Nonetheless, considering the promising results achieved with the un-tuned Qwen-7B model (*i.e.*, TDCA w/o F-T in ablation study), we believe that employing closed-source LLMs via API calls can yield comparable or superior results.
- We observed limitations in fine-tuning (FT), potentially due to the simplicity of our data synthesis task (generating text from labels), where using prompts alone could teach a LLM this task. However, we believe that the LCG extends beyond this. For instance, in recommendation systems, LCG could be used on the MovieLens dataset to generate diverse user information for movie recommendations, such as address, age, postal code, etc. Nevertheless, relying solely on prompts for an LLM might fall short, whereas FT ensures this capability.

A Case Study

MeSH terms (labels)

Community Health Planning; Consultants; **Data Collection**; Delivery of Health Care, Integrated; **Evaluation Studies as Topic**; Health Care Surveys; **Health Plan Implementation**; Health Services Needs and Demand; Iowa; Public Health Administration; State Health Plans; **United States**

ORIGINAL

Determinants of successful community health system planning. Needs assessment and other community health planning projects are being conducted in many parts of the country. Whether these projects are successful, in that they lead to implementation of recommendations, has not been systematically assessed. This study describes how local public health officials in Iowa view the planning projects that were conducted in their communities. Planning projects occurred in over half of the counties in the state. Most were led by local public health agencies. Hospitals were participants in three-fourths of the projects. Successful implementation was associated with the number of planning techniques used and the breadth of representation on the steering committee. The most common recommendations related to the expansion of prevention/promotion services and community health nursing. Public health nursing had been integrated with local hospitals in one-third of the counties, with no reductions in performance.

EDA

BT

Determinants of successful community health system planning. Needs assessment and other community health planning projects are being carried out in many parts of the country. The success of these projects, because they lead to the implementation of recommendations, has not been systematically evaluated. This study describes how local public health officials in Iowa view planning projects in their communities. More than half of the counties in the state have planned projects. Most of them are led by local public health institutions. Hospitals are involved in three-quarters of the projects. The successful implementation is related to the number of planning technologies used and the representativeness of the steering committee. The most common suggestions involve expanding prevention/publicity services and community health care. In one third of counties, public health care has been integrated with local hospitals, but the performance has not declined.

CA

Evaluation of Community Health Planning Consultants in Iowa: A Survey of Data Collection and Delivery of Integrated Health Care Services. Community health planning consultants play a critical role in the implementation of state health plans and addressing the health services needs of communities. This study aimed to evaluate the effectiveness of community health planning consultants in Iowa in facilitating the delivery of integrated health care services. A survey was conducted among community health planning consultants to collect data on their roles, responsibilities, and experiences in implementing state health plans. The survey also assessed the challenges faced by consultants in collecting and analyzing data, delivering integrated health care services, and evaluating the impact of their interventions. The results showed that community health planning consultants in Iowa are effective in facilitating the delivery of integrated health care services, but face challenges in data collection and evaluation. The study recommends the development of standardized data collection tools and training programs for consultants to enhance their skills in data collection and analysis. Additionally, the study highlights the need for ongoing evaluation of the effectiveness of community health planning consultants in addressing the health services needs of communities and implementing state health plans.

Figure 6: Case study on the MeSH-12K dataset evaluating three traditional data augmentation methods: EDA, BT, and CA. Head labels (over 100 instances in training) are marked in red; tail labels (under 10 instances) in blue. The study finds that paraphrasing methods, EDA and BT, although effective in diversifying data, inadvertently add noise. CA-generated text is smooth and aligns with all MeSH terms (labels). Notably, the original dataset's text-label correspondence is often implicit, posing challenges in classifier training. For instance, **Consultants** are indirectly implicated through "local public health agencies" and "hospitals," and **Data Collection** is inferred from the context of health planning. The term **United States** is indirectly indicated by mentioning "Iowa." These nuances complicate classification, which is not simplified by mere paraphrasing. In contrast, CA's label-conditioned generation directly incorporates labels into the text, significantly aiding the classification of rare tail labels.

MeSH terms (labels)

Fanconi Anemia; Stress, Mechanical; Surface Properties; Syndrome; **Chromosomes, Human, Pair 13**; **Founder Effect**; **Mites**; **Thromboxane-A Synthase**; **Benzoquinones**; **Female**; **Thromboxane B2**; **Leukotrienes**

TDCA

Exploring the Role of Mechanical Stress and Surface Properties in Fanconi Anemia Syndrome: Insights from the Founder Effect, Chromosomes, and Mites. Fanconi Anemia (FA) is a rare genetic disorder characterized by chromosomal instability, bone marrow failure, and an increased risk of cancer. Previous studies have highlighted the involvement of oxidative stress in FA pathogenesis, but the role of mechanical stress and surface properties remains unclear. This review aims to examine the impact of mechanical stress and surface properties on FA, particularly in the context of the founder effect, chromosomes, and mites. We discuss the potential mechanisms through which these factors may contribute to FA, such as the activation of thromboxane-A synthase and the production of benzoquinones and leukotrienes. Additionally, we explore the role of gender in FA and the potential differential effects of these factors in female patients. By synthesizing current knowledge with insights from various research fields, this review sheds light on the complex interplay between mechanical stress, surface properties, and FA pathogenesis, providing a foundation for future investigations in this area.

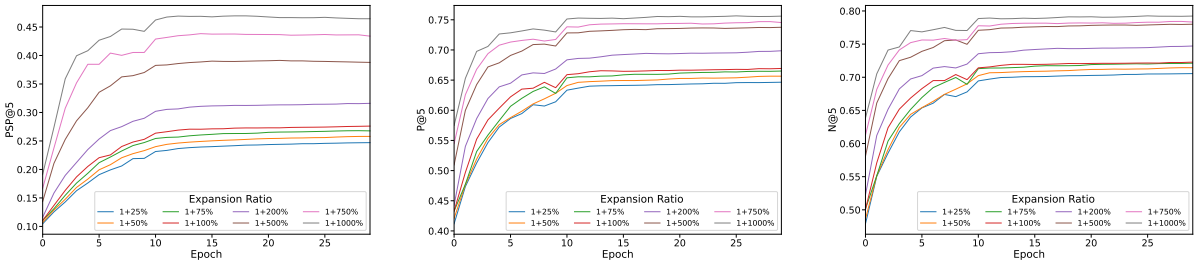
MeSH terms (labels)

Electronics; **Blood Urea Nitrogen**; Income; Oregon; Personal Autonomy; Ethnic Groups; **Hypercholesterolemia**; Hospital Administration; Computers; Health Knowledge, Attitudes, Practice; **Research Subjects**; **Cardiac Care Facilities**

TDCA

The Association between Income and Health Outcomes among Various Ethnic Groups in Oregon: A Study of Personal Autonomy, Hypercholesterolemia, and Hospital Administration Using Electronics and Computers: This study aimed to investigate the relationship between income and various health outcomes among different ethnic groups residing in Oregon. The study utilized electronic data and computer technology to analyze data from multiple sources, including hospital administration records, research subjects' health knowledge, attitudes and practices, and cardiac care facilities. Specifically, the study examined the impact of income on personal autonomy, blood urea nitrogen levels, and the prevalence of hypercholesterolemia within different ethnic groups. Results showed a significant association between income and personal autonomy, with lower income groups experiencing higher levels of restriction in decision-making about their health. Additionally, income was found to be positively correlated with blood urea nitrogen levels and the prevalence of hypercholesterolemia, suggesting that higher income may play a protective role against these health concerns. The implications of these findings for hospital administrations and future research on health disparities among various ethnic groups are discussed.

MeSH terms (labels)



Polyethylene Glycols; **Bacterial Proteins**; Point Mutation; **Regulon**; Antigens, CD4; **Transplantation Immunology**; **Calorimetry**; Deoxycholic Acid; **T-Lymphocytes**; **Receptors, Lymphocyte Homing**; Surface Properties; Mice, Inbred CBA

TDCA

Investigating the Impact of Polyethylene Glycols on Bacterial Proteins and Point Mutation in the Regulon of CD4 Antigens in Transplantation Immunology using Calorimetry and Deoxycholic Acid in CBA Mice. This study aims to explore the effects of polyethylene glycols (PEGs) on bacterial proteins and point mutation in the regulon of CD4 antigens in transplantation immunology. Through the use of calorimetry and deoxycholic acid, we will investigate how PEGs alter the surface properties of T-lymphocytes and receptors involved in lymphocyte homing. The study will be conducted in CBA mice, a commonly used model for transplantation research. Results from this study will provide valuable insights into the role of PEGs in modifying the immune response, potentially leading to the development of targeted therapies for transplantation immunology.

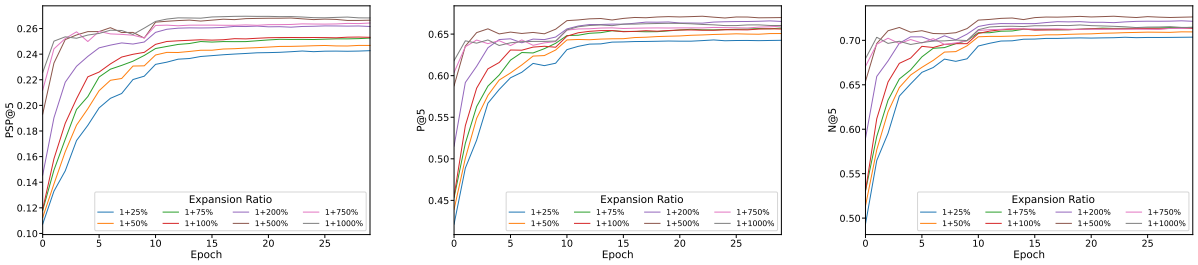


Figure 7: Illustration of TDCA performance on the MeSH-12K dataset. Similar to Figure 6, red indicates head labels (with over 100 instances in the training set), and blue denotes tail labels (with fewer than 10 instances). But TDCA exhibits fewer red head labels and a greater number of blue tail labels. Despite the low frequency of occurrence, the labels are still related due to the construction of the Dual-Weighted Label Graph and Tail-Driven Label Sampling, as seen in the first example: **Fanconi Anemia** is linked to **Chromosomes, Human, Pair 13** due to mutations causing this inherited disease. Similarly, **Syndrome** is a term that includes conditions like **Fanconi Anemia**. The enzyme **Thromboxane-A Synthase** is crucial in producing **Thromboxane B2**. Furthermore, **Leukotrienes**, known for their role in inflammation, can interact with **Thromboxane B2** during certain physiological or pathological conditions. These interrelations facilitate the LLMs' task of generating coherent texts, and the augmented data is meaningful in real-world contexts.

Neurocache: Efficient Vector Retrieval for Long-range Language Modeling

Ali Safaya
asafaya19@ku.edu.tr

Deniz Yuret
dyuret@ku.edu.tr

KUIS AI Center
Computer Engineering Department
Koç University

Abstract

This paper introduces Neurocache, an approach to extend the effective context size of large language models (LLMs) using an external vector cache to store its past states. Like recent vector retrieval approaches, Neurocache uses an efficient k-nearest-neighbor (kNN) algorithm to retrieve relevant past states and incorporate them into the attention process. Neurocache improves upon previous methods by (1) storing compressed states, which reduces cache size; (2) performing a single retrieval operation per token which increases inference speed; and (3) extending the retrieval window to neighboring states, which improves both language modeling and downstream task accuracy. Our experiments show the effectiveness of Neurocache both for models trained from scratch and for pre-trained models such as Llama2-7B and Mistral-7B when enhanced with the cache mechanism. We also compare Neurocache with text retrieval methods and show improvements in single-document question-answering and few-shot learning tasks. We made the source code available under: https://github.com/alisafaya/neurocache

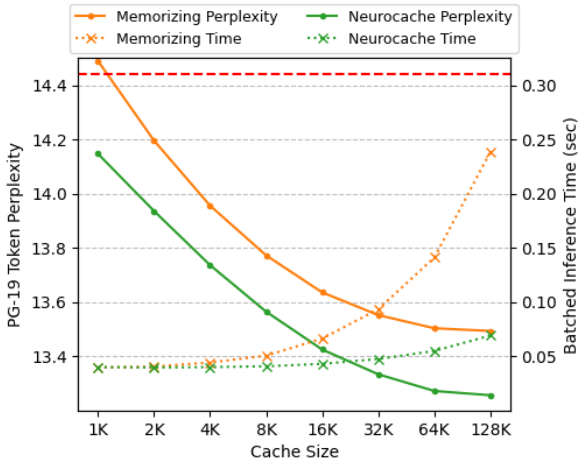

Figure 1: Performance and Scalability of Neurocache vs. Memorizing Transformers (Wu et al., 2022) on PG-19: The graph illustrates Neurocache's consistently lower token perplexity and faster inference times across various cache sizes on the Project Gutenberg-19 dataset, demonstrating its efficiency and scalability.

1 Introduction

Recent advancements in natural language processing have been significantly driven by the development of large language models (LLMs) such as GPT-3, GPT-4, Llama, and Llama2 (Brown et al., 2020; OpenAI, 2023; Touvron et al., 2023a,b). While demonstrating impressive capabilities, these models are constrained by limited context window sizes. This limitation becomes apparent in tasks that require understanding long documents, such as document summarization and academic literature review, where processing hundreds of thousands of tokens is necessary.

Various methods, including sparse attention (Child et al., 2019; Beltagy et al., 2020; Zaheer et al., 2020), have been explored to address this limitation. However, these approaches often struggle to utilize their extended contexts (Liu et al., 2023) fully. Recent research by Xu et al. (2023) shows that retrieval-augmented models with shorter contexts (4K tokens) can match the performance of models with longer contexts (16K/32K tokens), maintaining efficiency during inference. This emphasizes the potential of retrieval-augmented strategies in LLMs.

In response to these challenges, we introduce Neurocache. Neurocache employs an efficient k-nearest-neighbor (kNN) strategy for retrieving relevant past states from a compressed external vector cache. This approach is designed to optimize hidden state caching and retrieval, thereby enhancing language modeling quality and increasing inference speed.

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 870–883
June 16-21, 2024 ©2024 Association for Computational Linguistics

Neurocache advances over exiting methods by reducing the cache size through the storage of compressed states, performing a single retrieval operation per token to boost inference speed, and extending the retrieval window to include neighboring states for improved language modeling and downstream accuracy. Figure 1 illustrates the advantages of Neurocache in terms of inference speed and language modeling accuracy over methods like Memorizing Transformers (Wu et al., 2022).

Our evaluation of Neurocache encompasses both models trained from scratch and established pretrained models such as Llama2-7B and Mistral-7B (Touvron et al., 2023b; Jiang et al., 2023), demonstrating its effectiveness in enhancing language models for downstream tasks. Specifically, we highlight Neurocache's improvements in single-document question-answering and few-shot learning tasks when compared to traditional text retrieval methods. Moreover, Neurocache's integration extends the maximum context length of these models to 128K tokens, indicating its significant impact on long-document processing.

In summary, Neurocache represents a substantial step forward in addressing the challenges of processing long documents in LLMs, offering a blend of efficiency, adaptability, and enhanced performance. Our comprehensive experiments and analysis showcase Neurocache's potential in revolutionizing the understanding of long documents in natural language processing.

2 Related Work

Transformers have made significant advancements in natural language processing but face challenges in processing long contexts. Various methods have been developed to extend the context window while maintaining computational efficiency (Huang et al., 2023).

Recent methods include the continued training or fine-tuning of short-context language models (Nijkamp et al., 2023; Chen et al., 2023b), positional interpolation (Chen et al., 2023a), ALiBi (Press et al., 2022), and sparse and efficient attention designs (Child et al., 2019; Beltagy et al., 2020; Zaheer et al., 2020). These approaches reflect the evolving landscape of solutions for managing extended attention windows in large language models (LLMs).

However, language models still encounter difficulties in processing longer contexts (Liu et al., 2023). Studies have indicated that retrieval-augmented models with shorter contexts (4K) can surpass models with longer contexts (16K/32K) in performance (Xu et al., 2023).

Prominent strategies in this area are Text Retrieval and Vector Retrieval. Text Retrieval involves identifying and processing the most relevant segments of long documents. Vector Retrieval, on the other hand, integrates relevant hidden representations of the input, like hidden states or key-value pairs, into the model.

2.1 Text Retrieval

Text retrieval methods focus on processing relevant segments of long documents. Integrating retrieval mechanisms into language models, such as REALM (Guu et al., 2020), DPR (Karpukhin et al., 2020), RETRO (Borgeaud et al., 2021), and RALM (Ram et al., 2023), has enhanced model performance in various tasks.

A limitation of Text Retrieval is its dependency on external retrievers for identifying relevant segments of the context, often employing algorithms like BM25 (Robertson and Zaragoza, 2009), Contriever (Izacard et al., 2022), and others (Borgeaud et al., 2021; Ram et al., 2023; Karpukhin et al., 2020).

2.2 Vector Retrieval

Vector retrieval methods extend the context window by incorporating relevant hidden states from an external cache of past inputs' representations.

Memorizing Transformers present a novel adaptation to the traditional transformer decoder structure for handling lengthy documents. They process documents in smaller segments and use a dynamically updated external cache to track previous key-value pairs. These models employ an approximate k-nearest-neighbor (kNN) lookup over this cache, merging dense self-attention on the current context with external-attention over retrieved key-value pairs, thus effectively extending the context length (Wu et al., 2022).

Unlimiformer is a vector retrieval method, particularly suited for sequence-to-sequence models like BART (Lewis et al., 2020). It extends encoding length by using a kNN index over all input token hidden states, focusing on the top-k input tokens through kNN distance-based attention scores in each decoder layer's cross-attention head (Bertsch et al., 2023).

2.3 Neurocache

Neurocache is a vector retrieval method designed for processing long documents in large language models (LLMs). It employs a kNN strategy to efficiently retrieve compressed past states from an external vector cache. This approach contrasts with methods like Memorizing Transformers and Unlimiformer, particularly in terms of computational efficiency and cache size management.

Neurocache's notable features include storing compressed states to reduce cache size and performing a single retrieval operation per token, which accelerates inference speed. Additionally, it expands the retrieval window to include neighboring states, enhancing language modeling and downstream task performance.

Crucially, Neurocache shows adaptability with established pre-trained models like Llama2-7B and Mistral-7B, extending their maximum context length capabilities to 128K tokens. This adaptability demonstrates Neurocache's potential in improving long-document processing capabilities of current LLMs.

In this context, Neurocache presents a balanced approach to vector retrieval, combining efficiency and adaptability to enhance long-context processing in natural language processing models.

3 Method

3.1 Neurocache Overview

Neurocache addresses the challenge of processing long documents using Transformer decoders, leveraging a k-nearest-neighbor (kNN) search for efficient retrieval and integration of relevant past states. The process begins by segmenting the long text sequences into smaller segments, each containing n tokens, fitting the model's attention window size.

State Compression: Text segments are sequentially processed via a Transformer decoder stack (Vaswani et al., 2017). At the r^{th} layer of the decoder, hidden states $H^r \in \mathbb{R}^{n \times h}$ are acquired and subsequently projected into a compressed form $C \in \mathbb{R}^{n \times d}$ using a learned projection matrix W_p. This compression step enhances the efficiency for the subsequent kNN retrieval.

State Retrieval: For each compressed state $c \in \mathbb{R}^d$ within C, we identify the top-k most similar states $C_{ret} \in \mathbb{R}^{k \times d}$ from the cache $C_{cache} \in \mathbb{R}^{m \times d}$. This selection is based on the L2-distance between each state in C and the states in the cache.

Cache Updating: The cache C_{cache} is updated with the compressed states C, maintaining a fixed size of m entries. This is achieved by discarding the oldest n states, adhering to a First-In-First-Out strategy. The update occurs post-retrieval, reinforcing the commitment to retrieving only relevant past states.

Cache Augmented Layers: Using the states C_{ret} retrieved in the previous step. Starting from the $(r+1)^{th}$ layer, the cache-augmented layers L^j, where $j > r$, integrate a specialized attention mechanism. Each layer uses unique projection matrices W_k^j, W_v^j, and W_q^j to generate keys K_{ret}^j and values V_{ret}^j from C_{ret}, and queries Q^j from the hidden states H^j. The cache attention mechanism is defined as:

$$CA(Q, K_{ret}, V_{ret}) = \text{softmax}\left(\frac{QK_{ret}^T}{\sqrt{d_{key}}}\right)V_{ret}$$

In this formula, Q are the queries derived from H^j, while K_{ret}^j and V_{ret}^j are keys and values derived from C_{ret}, with d_{key} serving as a normalization factor. The output of cache attention is processed by an output matrix W_o^j before being combined with self-attention outputs through a residual connection.

Contextual Retrieval Window: When retrieving the top-k similar cached states, Neurocache also considers additional states surrounding these top-k states within a defined Retrieval Window. This expanded retrieval captures not only the most similar states but also their immediate neighbors, providing a richer context for the model's processing.

Consider the cached states $C_{cache} = [c_1, c_2, \ldots, c_m]$, and a query q for which the cached states c_i and c_j are identified as the top-2. With an even Retrieval Window size w, the retrieved set would include not just c_i and c_j, but also the cached states $[c_{i-(w/2)-1}, \ldots, c_{i+w/2}]$ and $[c_{j-(w/2)-1}, \ldots, c_{j+w/2}]$, truncated at the boundaries of the cache.

Extended Cache-Attention: We enhance the contextual awareness of each token during the cache-attention operation by granting access to the retrievals of preceding tokens. Similar to the contextual retrieval window, this feature broadens the current token's context.

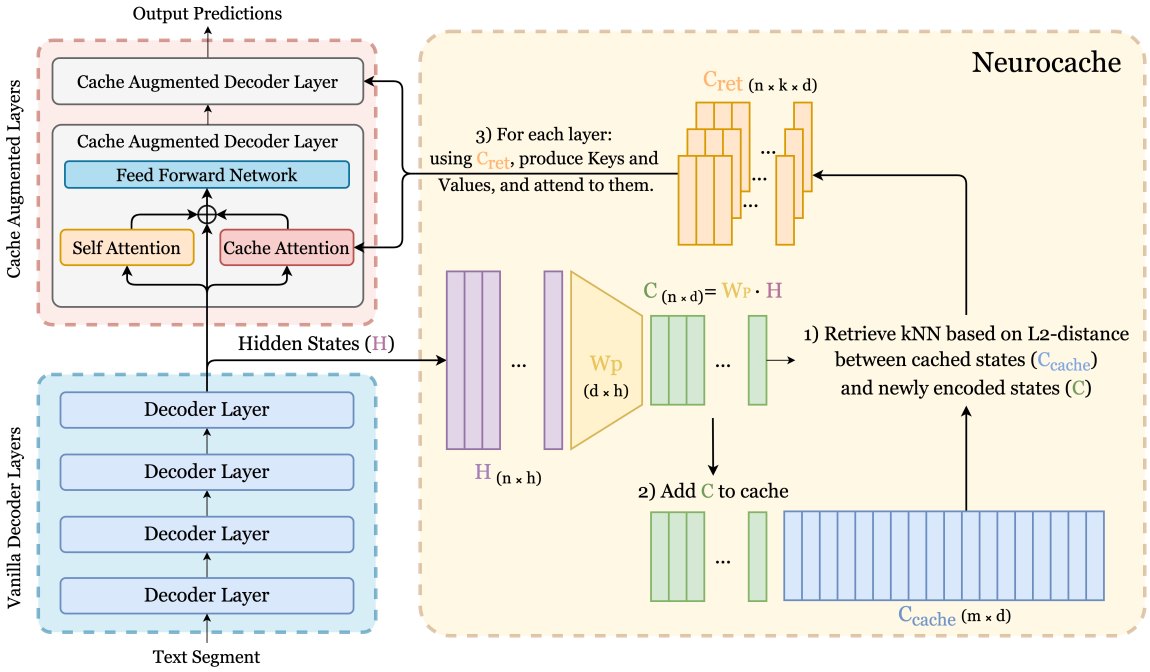

Figure 2: Documents are segmented into sequences of n tokens and processed sequentially through a Transformer decoder stack. For each text segment, mid-layer hidden states $H \in \mathbb{R}^{n \times h}$ are projected into a compact representation $C \in \mathbb{R}^{n \times d}$ using a learned weight matrix $W_p \in \mathbb{R}^{d \times h}$. This projection enhances the efficiency of kNN retrieval of the most relevant past states $C_{ret} \in \mathbb{R}^{n \times k \times d}$ from the cache C_{cache}. These states C_{ret} are used by cache-augmented layers to generate keys/values for cache attention. The output of cache attention is added to the self-attention output before being fed to the feed-forward network (FFN). Finally, the cache C_{cache} is updated to include C while maintaining a constant size of m entries.

Specifically, for a token positioned at i in a sequence, denoted as t_i, and with a predefined context size c, the cache-attention mechanism includes not only its own retrieved states C^i_{ret} but also the states retrieved for the preceding $c-1$ tokens. For example, if $c = 4$, the cache-attention for t_i would integrate the keys $K^{i-3:i}_{ret}$ and values $V^{i-3:i}_{ret}$ from tokens $t_{i-3:i}$.

Please refer to Appendix B for more detailed description on Neurocache.

3.2 Neurocache Adaptation

Adapting pre-trained decoder language models for Neurocache use is a straightforward process that significantly enhances their capability to efficiently process long documents. For the layers augmented with Neurocache, denoted as L^j where $j > r$, the adaptation involves initializing cache-attention weight matrices $(W^j_k, W^j_v, W^j_q, W^j_o)$ by duplicating weights from the corresponding self-attention layers of the pre-trained models. Simultaneously, the projection matrix W_p is randomly initialized to transform hidden states into compact forms suitable for Neurocache retrieval.

Furthermore, we integrate Low-Rank Adapters (LoRA) (Hu et al., 2022) into the feed-forward networks of the cache augmented layers. LoRA, introducing a minimal number of parameters, plays a key role in adapting the models to cache attention without compromising their original strengths.

During training, we freeze the original parameters of the pre-trained model and focus solely on training the newly added weights, specifically the LoRA weights, and the cache-attention weight matrices $(W^j_k, W^j_v, W^j_q, W^j_o)$, along with the projection matrix W_p. This training, using a causal language modeling objective on a corpus of long documents, enables the models to efficiently utilize the Neurocache system.

3.3 Retrieval Overhead

When analyzed per token, the computational overhead of retrieval in our method stems from the following components, which underline the primary computational efforts in the kNN retrieval.

Distance Computation: For each token, the relevance is assessed by calculating the L2-distance between the token's compressed hidden state $c \in \mathbb{R}^d$ and each of the m cached states, resulting in a complexity of $O(d \times m)$ per token, where d is the dimension of the compressed hidden state c and m is the total number of cached entries.

Method	Retrieval Frequency	Entry Size
Neurocache (Ours)	1	d
Memorizing Transformer	a	$2a \times f$
Unlimiformer	$l \times h$	e

Table 1: Space and time complexity of methods based on cache queries per token (Retrieval Frequency) and cache entry dimensions per token (Entry Size). Here, d is the compressed dimension in Neurocache, a the number of attention heads, f head size, e hidden size, and l layers with cache attention.

Top-k Search Over Distances: Identifying the top-k closest states from these distances involves a complexity of $O(m + k)$ for every token[1].

3.4 Comparative Analysis

The Neurocache model demonstrates computational advantage over alternatives like the Memorizing Transformer (Wu et al., 2022) and the Unlimiformer (Bertsch et al., 2023) by performing only one cache query per token. This approach significantly reduces the computational burden. In contrast, the Memorizing Transformer requires multiple cache queries for each token, specifically one for every attention head. Consequently, this leads to an a-fold increase in complexity per token, both for distance computation, $O(a \times d \times m)$, and top-k retrieval, $O(a \times (m + k))$, where a is the number of attention heads, and m is the cache size.

The Unlimiformer, needing $l \times a$ queries per token, further increases retrieval complexity. For instance, a Transformer with 24 layers and 12 attention heads in the Memorizing Transformer configuration would need 12 cache accesses per token. If the Unlimiformer uses half of its layers for augmentation, as per (Bertsch et al., 2023), the requirement rises to $12 \times 12 = 144$ cache accesses per token. Neurocache's strategy of one query per token significantly streamlines this process without compromising accuracy.

Table 1 outlines these models' retrieval frequency and cache entry size, emphasizing Neurocache's efficiency. The table compares the number of cache queries per token and each cache entry's size across the different methods.

4 Language Modeling

We assess Neurocache's effectiveness via two experimental approaches: pre-training language models from scratch and adapting established pre-trained models. For pre-training, TransformerXL (Dai et al., 2019) serves as our baseline, against which we compare Neurocache and Memorizing Transformer (Wu et al., 2022). In terms of adaptation, we focus on pre-trained models including OPT-1.3B, Llama2-7B, and Mistral-7B (Zhang et al., 2022; Touvron et al., 2023b; Jiang et al., 2023).

4.1 Datasets

Our experiments employ two distinct raw text corpora: PG-19, a well-established benchmark for long-form language modeling, and LongPile, a diverse dataset derived from the Pile.

PG-19: This corpus comprises a collection of books written in English and published before 1919, sourced from Project Gutenberg. It is recognized as a standard benchmark for evaluating models on long-form text (Rae et al., 2020; Wu et al., 2022; Hutchins et al., 2022).

LongPile: Extracted from the Pile corpus (Gao et al., 2020), LongPile features extensive documents from varied sources including "Books3," "Gutenberg (PG-19)," "OpenWebText2," "PileCC," and "Wikipedia (en)." The selection criterion ensures that each document surpasses 20K tokens, making it suitable for testing models' performance on longer texts.

4.2 Pre-training

Our baseline for pre-training is the TransformerXL model (Dai et al., 2019), which we compare against Neurocache and the Memorizing Transformer (Wu et al., 2022). In these experiments, both Neurocache and the Memorizing Transformer are configured with a fixed storage size of 16K during training, expanding to 128K for evaluation to assess their ability to generalize to larger storage sizes.

In Neurocache, we set the augmented layer threshold r at $3 * n_{layers}/4$, leading to the compression of outputs from the 9^{th} layer of a 12-layer model. The hidden states H, originally of size $h = 1024$, are compressed by a factor of 4, resulting in a reduced size of $d = 256$. We use a retrieval window $w = 2$ to fetch the top-k cached states and their right neighbors for cache-attention in layers 10 to 12. Extending cache-attention to include previous tokens' retrievals with $c = 2$, we set $k = 16$, resulting in 64 neighbors in total. This setup was determined through hyperparameter optimization

[1]We assume an algorithm with quicksort-style partitioning is used.

Model	Params	PG-19		LongPile	
		16K	128K	16K	128K
Training from scratch					
TRANSFORMERXL	184M	14.442	14.442	15.857	15.857
MEMORIZING TRANSFORMER	184M	13.636	13.494	14.966	14.818
NEUROCACHE	184M	**13.511**	**13.352**	**14.425**	**14.110**
Neurocache adaptation					
OPT-1.3B	1.3B	12.199	12.199	19.446	19.446
+NEUROCACHE	1.4B	**11.306**	**11.227**	**17.626**	**17.377**
LLAMA2-7B	6.7B	7.359	7.359	9.075	9.075
+NEUROCACHE	7.1B	**7.117**	**7.078**	**8.401**	**8.308**
MISTRAL-7B	7.2B	7.863	7.863	9.380	9.380
+NEUROCACHE	7.5B	**7.684**	**7.636**	**8.581**	**8.493**

Table 2: Comparison of token perplexity for different models and cache sizes on PG-19 and LongPile datasets. Neurocache outperforms Memorizing Transformer, and presents a significant reduction in perplexity across both pre-training and adaptation experiments, underscoring the adaptability to larger cache sizes.

(details in Appendix A). Additionally, we modify the FFN dimensionality of the Neurocache from 4096, consistent with the baseline and Memorizing Transformer, to 3776 to ensure parity in model sizes.

The Memorizing Transformer, adhering to its original design (Wu et al., 2022), caches key-value pairs from its 9^{th} layer. We align its retrieval setting with Neurocache by setting $k = 64$, thus retrieving the top-64 key-value pairs for each attention head per token.

The pre-training involves 100,000 steps with a batch size of 128 and a context size of 1,024. Adafactor (Shazeer and Stern, 2018) is used for optimization, with a learning rate warming up over the first 1,000 steps, peaking at 2×10^{-2}, and then decaying to 1×10^{-3}.

Neurocache's performance on the PG-19 and LongPile datasets surpasses that of the Memorizing Transformer, as evidenced by its lower token perplexities, detailed in Table 2. Additionally, we assess the scalability of Neurocache in comparison to Memorizing Transformers across various cache sizes. The results, illustrated in Figure 1, demonstrate Neurocache's computational advantage, maintaining its superior performance across different cache sizes.

4.3 Adaptation

We extend our adaptation strategy to pre-trained models such as OPT-1.3B, Llama2-7B, and Mistral-7B (Zhang et al., 2022; Touvron et al., 2023b; Jiang et al., 2023). The adaptation process is identical to that described in Section 3.2, ensuring a smooth integration of Neurocache with the pre-trained model weights.

We set the rank parameter r to 16, the scale parameter α to 32, and turn off bias in LoRA. Added weight matrices and adapter weights are trained on the PG-19 and LongPile datasets' training splits for 25,000 steps, employing the Adam optimizer (Kingma and Ba, 2015) with a decaying learning rate of 1×10^{-4}. We configured Neurocache using the same settings as the pre-training experiments. This adaptation process consumes approximately 200 Nvidia A100 GPU Hours per model.

The successful adaptation is evident in the significant improvement in token perplexity on both datasets, as detailed in Table 2. The subsequent section discusses the impact of these improvements on zero-shot performance in downstream tasks.

5 Downstream Evaluation

We assess the performance of models augmented with Neurocache, particularly Llama2-7B and Mistral-7B adapted on LongPile, using seven distinct downstream tasks from the LongBench suite (Bai et al., 2023). These tasks cover a range of scenarios, including single-document question-answering (QA), multi-document QA, and few-shot learning. We utilize a zero-shot evaluation approach for the single-document and multi-document QA tasks. Conversely, in the few-shot learning tasks, a small set of examples is provided to the models, serving as part of the extended context.

Method	*Single-doc QA*			*Multi-doc QA*		*Few-shot Learn.*	
	NQA F1	**QSP** F1	**MQA** F1	**HQA** F1	**MSQ** F1	**TREC** Acc.	**SAMS** R-L
Input avg. length	35.4K	5.3K	8.1K	17K	19K	7.8K	11.3K
LLAMA2-7B							
TRUNCATION	22.19	28.17	33.39	33.66	12.30	67.00	33.00
LONGLORA	21.92	27.58	30.10	29.17	11.05	69.50	30.29
TEXT RETRIEVAL	23.57	26.71	39.46	**38.51**	**18.89**	66.50	29.38
NEUROCACHE (Ours)	**23.62**	**28.32**	**41.23**	33.30	13.84	**72.00**	**42.77**

NEUROCACHE (Ours)	**20.08**	**31.01**	**44.15**	35.49	14.00	**70.00**	**35.86**

Table 3: Zero-shot performance comparison of LLAMA2-7B and MISTRAL-7B using various long document processing methods on the LONGBENCH benchmark tasks. Metrics include F1, Accuracy (Acc.), and Rouge-L (R-L). NEUROCACHE excels in *Single-doc QA* and *Few-shot Learning* but faces challenges in *Multi-doc QA* compared to text retrieval. Document lengths are provided for reference.

5.1 Datasets

The datasets in this evaluation present unique challenges, with average token lengths ranging from 5K to 35K, underscoring the need to process long texts effectively.

5.1.1 Single-document QA

NarrativeQA (NQA) is a question-answering dataset consisting of books from Project Gutenberg and movie scripts. It includes about 30 question-answer pairs per document, providing a robust test for QA systems (Kočiský et al., 2018).

Qasper (QSP) contains questions and answers extracted from NLP papers. This dataset offers diverse question types, such as abstractive, extractive, yes/no, and unanswerable questions, making it a comprehensive testbed for QA models (Dasigi et al., 2021).

MultiFieldQA (MQA) is designed to test a model's ability to understand long contexts across various fields, including legal documents, government reports, and academic papers. It poses a challenge with its questions dispersed throughout lengthy documents (Bai et al., 2023).

5.1.2 Multi-document QA

HotpotQA (HQA) is a multi-document, Wikipedia-based QA dataset. It requires reading and reasoning across multiple documents and includes questions necessitating sentence-level supporting facts for complex reasoning (Yang et al., 2018).

MuSiQue (MSQ) focuses on multihop reasoning in QA. It constructs multi-hop questions from simpler, single-hop ones, demanding a systematic approach and detailed control over the question formation process (Trivedi et al., 2022).

5.1.3 Few-shot Learning

SAMSum (SAMS) presents a dialogue summarization challenge with its dataset of messenger-like conversations and human-annotated summaries[2]. It tests a model's ability to condense conversational data into coherent summaries (Gliwa et al., 2019).

TREC serves as a dataset for few-shot learning tasks in question type classification. Models are tasked with categorizing questions into predefined categories, providing a test of their classification abilities (Li and Roth, 2002).

5.2 Models

In addition to Neurocache, our evaluation includes three distinct approaches for extending the input length of pre-trained language models. These approaches are Input Truncation, Text Retrieval, and Position Interpolation (PI).

Truncation: This approach employs the original Llama2-7B and Mistral-7B models without long-context-specific modifications. Here, inputs exceeding the maximum size of 4,096 tokens are truncated from the middle following (Bai et al., 2023). This baseline serves as a reference to evalu-

[2]We use the `rouge` package: https://github.com/pltrdy/rouge

ate the effectiveness of other methods in processing extended documents.

Text Retrieval: Contrasting with Neurocache, this approach involves selecting the most relevant text segments to include in the input, keeping the total length within the model's maximum input size. We divide the context into 200-word chunks, retrieving the top-7 chunks using Contriever (Izacard et al., 2022). These chunks, along with the input, are then processed by the model. Using the top-7 chunks balances performance and the 4K token limit. This method, used in previous work (Bai et al., 2023; Xu et al., 2023), differs from Neurocache, which dynamically integrates relevant information from the entire document via cache-augmented layers.

Position Interpolation (PI): PI (Chen et al., 2023a) linearly down-scales input position indices to fit the original context window size, avoiding high attention scores that could disrupt the self-attention mechanism. LongLoRA (Chen et al., 2023b), leveraging PI, offers an efficient fine-tuning method to expand the context size of pre-trained models. It uses a sparse local attention mechanism, enabling computation savings while retaining performance. The fully fine-tuned LongLoRA model[3], based on Llama2-7B, extends the maximum input length to 16K tokens, aiming to assess the effectiveness of efficient full-attention methods for longer documents.

Neurocache: We utilize the Neurocache-adapted Llama2-7B and Mistral-7B models in our evaluation. These adaptations follow the configuration detailed in Section 4 for pre-training. The models operate with a fixed cache size of 16K, accommodating the length of most datasets in our study. We split the documents into 2,048-token segments, processing them sequentially to populate the cache. Subsequently, the input, embedded within the prompt, is fed to the model, which then generates the corresponding answer.

5.3 Evaluation Setting

All evaluated models in this study are only pre-trained and not fine-tuned on the downstream tasks. They are assessed in a zero-shot setting, employing greedy decoding for output generation.

As outlined by LongBench (Bai et al., 2023), the model's task is to produce an answer given input and context sequences. In single-doc QA tasks, the input is a question paired with the document as context. For multi-doc QA, the input consists of multiple concatenated documents. In few-shot learning tasks, such as TREC and SAMSum, the context includes a set of examples, and the input is a question or dialogue, respectively. The input and answer are typically concise, while the context can be a long sequence extending to thousands of tokens.

If the combined length of input and context exceeds the model's maximum input capacity, only the context is truncated. This truncation is done from the middle of the context sequence, following the approach in (Bai et al., 2023). We utilize prompt templates provided by LongBench for consistency. Neurocache and LongLoRA operate with a maximum length of 16K tokens, truncating contexts longer than this limit. In contrast, the Text Retrieval method processes the entire context, regardless of length. To ensure comparability, all models are evaluated on identical hardware with a batch size of 1.

5.4 Results

The zero-shot evaluation results across various downstream tasks are summarized in Table 3. We compare the performance of Llama2-7B and Mistral-7B, in their original and Neurocache-adapted forms, against other long document processing methods.

Single-document QA: In tasks like NarrativeQA, Qasper, and MultiFieldQA, Neurocache-adapted models show superior performance, demonstrating their effectiveness in processing long contexts within single documents.

Multi-document QA: Performance in multi-doc QA tasks, such as HotpotQA, reveals a varied picture. While Neurocache-adapted models are competitive, they fall short of Text Retrieval methods. For instance, in HotpotQA, Text Retrieval with the Mistral-7B model achieves the highest F1 score of 40.92. This finding suggests that, despite Neurocache's effectiveness in single-doc scenarios, it may be less effective in multi-doc contexts compared to text retrieval approaches.

Few-shot Learning: In few-shot learning tasks like SAMSum and TREC, Neurocache shows strong performance, particularly indicated by improved Rouge-L scores in SAMSum. This under-

[3] https://huggingface.co/Yukang/Llama-2-7b-longlora-16k-ft

scores its capability to leverage few-shot examples for generating accurate summaries.

These findings illustrate the strengths and challenges of different methods in handling long documents in language models. Neurocache excels in single-document and few-shot learning scenarios, while Text Retrieval methods have an edge in multi-document tasks.

6 Conclusion

This paper introduced Neurocache, an approach designed to improve long document processing in language models. Neurocache employs a k-nearest-neighbor (kNN) strategy for integrating relevant past states from compressed hidden representations, thus extending the context window of Transformer decoders. Notably, Neurocache enhances the maximum context length of models like Llama2-7B and Mistral-7B to 128K tokens.

Our findings indicate that Neurocache offers improvements in inference speed and language modeling accuracy. It demonstrates proficiency in single-document question-answering and few-shot learning, though it faces challenges in multi-document scenarios. Neurocache's competitive performance and adaptability highlight its potential utility in various applications.

In summary, Neurocache contributes to the field by enabling more efficient handling of extended contexts in existing language models. Future work may explore further optimizations for multi-document tasks and the extension of Neurocache to different model architectures and domains.

7 Limitations

While Neurocache demonstrates progress in long document processing with language models, several limitations should be noted. Our evaluation is confined to datasets like PG-19 and LongPile, and tasks from the LongBench suite. These datasets, despite their diversity, might not fully represent all long-context scenarios. Performance may vary in specialized domains like technical documents or source code, which have distinct content characteristics.

A notable limitation is Neurocache's performance in multi-document scenarios, suggesting potential challenges in contexts that require integration of information from multiple sources. This aspect is crucial for applications involving comprehensive data synthesis from various documents.

In terms of bias, Neurocache depends on the underlying language models and datasets for training and evaluation. Consequently, any inherent biases in these components could influence Neurocache's outputs. An explicit analysis of model biases was not conducted in this study, highlighting an area for future exploration.

Another critical point is our reliance on a zero-shot setting for evaluation. The performance of Neurocache might differ if fine-tuning on downstream tasks or instruction datasets was employed. This limitation suggests that our current findings may not fully capture the model's adaptability and efficiency in diverse application scenarios.

In conclusion, while Neurocache presents a step forward in handling long documents in natural language processing, its effectiveness is influenced by the nature of the data, model architecture, and specific task requirements. Understanding these limitations is vital for assessing its practical applicability and guiding future improvements.

A Optimizing Neurocache Hyperparameters

Effective processing of long documents in Neurocache depends on the optimal tuning of various retrieval hyperparameters. To this end, we conduct a comprehensive hyperparameter search focused on language modeling performance using the Project Gutenberg-19 (PG) dataset.

Our exploration encompasses a range of values for key hyperparameters: the number of retrieved neighbors (k) with values in the set $[None, 8, 16, 32, 64, 128, 256]$, the retrieval window size (w) tested with $[1, 2, 4]$, the cache-attention context size (c) evaluated at $[1, 2, 4]$, and the encoding dimension of hidden states (d) explored across $[1024, 512, 256, 128, 64]$. This systematic investigation aims to identify the optimal configurations that enhance Neurocache's efficiency and effectiveness in handling large-scale textual data.

Number of Retrieved Neighbors (k): The influence of k, the number of retrieved neighbors, on model performance is examined. Table 4 shows that increasing k generally leads to a decrease in perplexity, indicating improved performance. However, the computational cost also increases proportionally with k. We pick $k = 64$ due to the diminishing returns and the increasing cost of larger values.

k	PG (16K)	PG (64K)
None	14.739	14.739
8	14.362	14.398
16	14.242	14.259
32	14.186	14.190
64	14.117	14.118
128	14.069	14.037
256	14.052	13.988

Table 4: Perplexity for varying number of neighbors k.

Retrieval Window Size (w): Adjusting w while fixing the total number of neighbors at 64, we find that a window size of $w = 2$ is optimal, as per Table 5. This setting likely benefits the model's causal processing by including both the top-k entry and the subsequent one. We fix $w = 2$ for the subsequent experiments.

k	w	PG (16K)	PG (64K)
64	1	14.117	14.118
32	2	**13.720**	**13.578**
16	4	13.745	13.596

Table 5: Perplexity for varying retrieval window size w.

Attention Context Size (c): Table 6 shows that the cache-attention context size $c = 2$ achieves the lowest perplexity, indicating optimal performance when extending cache-attention to both the current and previous tokens' retrievals. We fix $c = 2$ for the subsequent experiments.

k	c	PG (16K)	PG (64K)
32	1	13.720	13.578
16	2	**13.704**	**13.564**
8	4	13.791	13.661

Table 6: Perplexity for varying context size c.

Encoding hidden states (d): Finally, we assess the impact of encoding hidden states into smaller dimensions d, as compared to the original $h = 1,024$. Table 7 demonstrate performance degradation as smaller sizes of compression are used.

d	PG (16K)	PG (64K)
1024	13.704	13.564
512	13.740	13.594
256	13.779	13.641
128	13.853	13.730
64	13.983	13.891

Table 7: Perplexity for varying d.

B Neurocache Algorithm

- The cache C_{cache} is initialized to store compact representations, with a maximum capacity of m entries.
- The long document D is segmented into sequences of n tokens each.

Algorithm 1 Neurocache Processing

Require: Long document D, Segment size n, Number of transformer layers L, Number of lower layers r, Cache memory size m, Projection dimensions h to d, Number of nearest states k
Ensure: Updated cache C_{cache} after processing each segment

Initialize cache C_{cache} with size $m \times d$
Divide document D into segments $S = (s_1, s_2, \ldots)$
for each segment $s \in S$ **do**
    $H^r \leftarrow$ Process s through lower r standard decoder layers
    $C \leftarrow W_p \cdot H^r$ ▷ Project hidden states to compact representation
    $C_{ret} \leftarrow$ Retrieve top-k nearest states from C_{cache} based on L2-distance to C
    for $j \leftarrow r + 1$ to L **do**
        $Q^j \leftarrow W_q^j \cdot H^j$ ▷ Generate queries for cache attention
        $K_{ret}^j \leftarrow W_k^j \cdot C_{ret}$ ▷ Generate keys for cache attention
        $V_{ret}^j \leftarrow W_v^j \cdot C_{ret}$ ▷ Generate values for cache attention
        $CA \leftarrow$ Apply cache attention using $Q^j, K_{ret}^j, V_{ret}^j$
        $CA \leftarrow CA \cdot W_o^j$ ▷ Apply output projection for cache attention
        $H^j \leftarrow$ Combine CA with self-attention outputs and H^j
    end for
    Update cache C_{cache} with C, discard oldest if cache exceeds m
end for

- Each segment s_i undergoes sequential processing through the transformer decoder layers.
- At the middle r^{th} layer, the hidden states H^r are converted into a compact representation C.
- The nearest cached states C_{ret} to C are retrieved from C using a k-nearest-neighbor (kNN) method.
- In each augmented layer $j > r$, cache attention is calculated using the generated queries Q^j, keys K_{ret}^j, and values V_{ret}^j.
- The output of cache attention CA is merged with the self-attention outputs and subsequently processed through a feed-forward network (FFN).
- After processing each segment, the cache C is updated with the new compact representation C, and the oldest entries are discarded as needed to maintain the cache size.

The cache-attention mechanism in the augmented layers is designed to focus on the most relevant information retrieved from the cache, akin to the approach in Memorizing Transformers (Wu et al., 2022). Cache-attention implementation is given in Figure 3.

```
def cache_attention(
    ret_keys,
    ret_vals,
    queries
  ):
  # Attention computation over states retrieved from the cache.
  # ret_keys: Retrieved keys (bsz, n_queries, n_heads, n_neighbors, head_dim)
  # ret_vals: Retrieved values (bsz, n_queries, n_heads, n_neighbors, head_dim)
  # queries: Queries (bsz, n_queries, n_heads, head_dim)

  # Calculate attention weights.
  ret_attn = einsum("...qhd,...khd->...qk", queries, ret_keys)
  ret_attn = softmax(ret_attn, dim=-1)

  # Compute the weighted sum of extended values.
  attn_output = einsum("...qk,...khd->...qhd", ret_attn, ret_vals)
  return attn_output
```

Figure 3: This implementation showcases the cache-attention computation in the model. It calculates the attention weights through a dot product between the queries and keys, applies a softmax to obtain probabilities, and then computes the weighted sum of the extended values to generate the final attention output.

Unveiling the Generalization Power of Fine-Tuned Large Language Models*

Abstract

While Large Language Models (LLMs) have demonstrated exceptional multitasking abilities, fine-tuning these models on downstream, domain-specific datasets is often necessary to yield superior performance on test sets compared to their counterparts without fine-tuning. However, the comprehensive effects of fine-tuning on the LLMs' generalization ability are not fully understood. This paper delves into the differences between original, unmodified LLMs and their fine-tuned variants. Our primary investigation centers on whether fine-tuning affects the generalization ability intrinsic to LLMs. To elaborate on this, we conduct extensive experiments across five distinct language tasks on various datasets. Our main findings reveal that models fine-tuned on generation and classification tasks exhibit dissimilar behaviors in generalizing to different domains and tasks. Intriguingly, we observe that integrating the in-context learning strategy during fine-tuning on generation tasks can enhance the model's generalization ability. Through this systematic investigation, we aim to contribute valuable insights into the evolving landscape of fine-tuning practices for LLMs. The code and data are available at https://github.com/LHRYANG/Generalization_of_FT-LLM.

1 Introduction

The transformative impact of in-context learning (ICL) (Brown et al., 2020; Wei et al., 2022b; Rubin et al., 2022; Liu et al., 2023; Chowdhery et al., 2022; Wang et al., 2023b) in LLMs, as demonstrated by models like Llama-2 (tou, 2023) and GPT-3 (Brown et al., 2020), marks a significant advancement in the field of artificial intelligence. This learning paradigm allows LLMs to adapt to various tasks by leveraging multiple demonstration examples presented within a prompt, without training the LLMs. However, when it comes to a specific task, fine-tuning often achieves better performance than ICL, which has been substantiated by recent studies (Shi et al., 2023; Jiao et al., 2023; Wang et al., 2023a; Zhang et al., 2023).

There are some works studying the properties of fine-tuning and ICL for LLMs. For example, Wei et al. (2022a) reveal that *multi-task* fine-tuning can enhance an LLM's zero-shot and ICL capabilities. It indicates that fine-tuning, when applied across multiple tasks, does not merely improve performance on those seen tasks but also augments the model's inherent learning abilities. The work of Mosbach et al. (2023) highlights that in terms of the out-of-domain generalization in classification tasks, *few-shot* fine-tuning and ICL exhibit similar levels of generalization. Wang et al. (2023c) find that fine-tuning may overly tailor the model to task-specific formats, potentially compromising its adaptability to other new tasks.

In this paper, we conduct a comprehensive study on how *task-specific* (not multi-task or few-shot) fine-tuning affects the generalization ability of LLMs. To provide a thorough analysis, we design a series of experiments encompassing a diverse range of datasets and tasks, covering both classification and generation tasks. For each task, we designate a specific dataset as the training set. The remaining selected datasets are subsequently divided into two groups: in-domain datasets, closely aligned with the training set in terms of content and structure, and out-of-domain datasets, which possess significant differences. With these datasets, our research investigates two critical questions: i) the ability of fine-tuned LLMs to adapt to both in-domain and out-of-domain test sets, and ii) the impact of fine-tuning on the ICL ability of LLMs across different types of tasks.

We find that models fine-tuned on text genera-

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 884–899
June 16-21, 2024 ©2024 Association for Computational Linguistics

tion and classification tasks exhibit different behaviors when evaluated on test sets. Specifically, we observe that models fine-tuned for classification tasks tend to exhibit positive transfer when applied to out-of-domain datasets of the same fine-tuning/test task type. In contrast, models fine-tuned on generation tasks frequently experience negative transfer under similar conditions. Interestingly, while fine-tuning the LLMs on generation tasks generally does not detrimentally affect their performance on classification tasks, the reverse is not true; models fine-tuned on classification tasks typically fail to work on generation tasks. Moreover, we experimentally observe that integrating the ICL strategy during fine-tuning on generation tasks can enhance an LLM's generalization ability. We also investigate other factors, such as training data size and the number of in-context examples. We hope this study offers comprehensive insights into fine-tuning strategies for LLMs, not only in enhancing task-specific performance but also in fostering broader generalization abilities.

2 Related Work

2.1 Large Language Models

The emergence and evolution of Large Language Models (LLMs) have significantly impacted the field of natural language processing and beyond. Seminal works like BERT (Devlin et al., 2019) and GPT-2 (Radford et al., 2019) laid the foundation for understanding context and semantics in textual language. The advent of GPT-3 (Brown et al., 2020) demonstrated remarkable abilities in generating human-like text, paving the way for more advanced models like GPT-4 (OpenAI, 2023) and open-sourced Llama-2 (tou, 2023). These models, with vast number of parameters and pre-trained on gaint corpus, have shown exceptional skills in understanding and solving various tasks in a zero- or few-shot manner (Sun et al., 2023).

2.2 Fine-tuning vs. In-Context Learning

Fine-tuning (FT) has been a predominant approach for adapting Pre-trained Language Models (PLMs) to specific tasks, e.g., dialogue system (Xu et al., 2022). This process involves additional training of a PLM on a smaller, task-specific dataset. This technique has been proven effective in tailoring models like BERT and GPT-2 for specialized applications, from classification tasks (Devlin et al., 2019; Liu et al., 2019) to generation tasks (Yang et al., 2021; Gehrmann et al., 2019). In the era of LLMs, in-context learning (ICL) (Kossen et al., 2023; Han et al., 2023) has emerged as a novel paradigm for distilling knowledge from powerful models, particularly highlighted in LLMs like GPT-3 (Brown et al., 2020) and Llama-2 (tou, 2023). ICL leverages the models' intrinsic capabilities to understand and generate responses, most of which are learned during unsupervised pre-training (Zhou et al., 2023; Gudibande et al., 2023), based on given contexts enclosed in the prompt, without the need for explicit task-specific training. For instance, Brown et al. (2020) demonstrate the effectiveness of ICL in a wide range of tasks, by merely providing a few examples within the prompt.

The debate between FT and ICL hinges on the trade-off between specialization and generalization. While FT offers more tailored and often higher-performing models for specific tasks, it can lead to a loss of the model's generalization abilities, as discussed by Chen et al. (2020). ICL, on the other hand, maintains the model's broad applicability but may exhibit suboptimal performance in specific tasks, as observed by Shi et al. (2023). Recently, Mosbach et al. (2023) discovered that both few-shot FT and ICL can achieve a similar generalization on out-of-domain test sets. In contrast, our work focuses on larger-set FT instead of few-shot FT. Wang et al. (2023c) identified that format specialization is a critical factor contributing to the diminished ICL abilities in fine-tuned LLMs. In our experiment, we observed similar phenomena, particularly when models fine-tuned on classification tasks were evaluated on generation tasks. However, in other scenarios, the impact of format specialization appeared to be less pronounced. Anil et al. (2022) found that incorporating several in-context examples during FT is helpful for length generalization for text. We further expand this idea and find that this approach is also indeed valuable in preserving or even enhancing the fine-tuned models' generalization ability.

3 Evaluation Design

This study delves into the effects of task-specific fine-tuning on the generalization ability of LLMs. We aim to uncover whether LLMs, once fine-tuned on a dataset of a particular language task, can still perform well on i) (data-level) in-domain and out-of-domain test sets of the same task type and ii) (task-level) different tasks.

Task	Train	In-domain Test	Out-of-domain Test
Summary Generation	XSum	XSum XLSum	PeerRead CNN/DailyMail
Question Generation	Socialqa	Socialqa	Tweetqa Sciqa
Sentiment Classification	Amazon	Amazon AmazonFood	SST2 Yelp
Paraphrase Detection	Paws	Paws	QQP STS-B
Natural Language Inference	MNLI	MNLI-1 MNLI-2	RTE GPTNLI

Table 1: Summary of tasks & datasets

3.1 Evaluation Taxonomy

To comprehensively assess the performance of fine-tuned LLMs across various tasks and datasets (Table 1), our study encloses three distinct settings, characterized by increasing levels of generality:

1. **Same Task, In-domain Datasets:** Given the same fine-tuning/test task, such as summary generation, we assess the fine-tuned LLMs using datasets that are aligned with their training data (in-domain), e.g., models fine-tuned on XSum and tested on XLSum (denoted as XSum → XLSum).
2. **Same Task, Out-of-domain Datasets:** Despite being evaluated on the same task, this setting focuses on the out-of-domain generalization by testing the fine-tuned LLMs on datasets with distinct features compared to the training set, e.g., XSum → PeerRead.
3. **Different Tasks:** In this setting, we examine the capability of LLMs, fine-tuned on one task type, to adapt across different task types, thereby evaluating the LLMs' cross-task generalization, e.g., XSum → Socialqa (summary to question generation) and XSum → Amazon (generation to classification).

Through such varied settings (in-domain vs. out-of-domain data and same vs. different tasks), we can clearly understand the generalization ability of the fine-tuned LLMs and explore the boundaries of their applicability across different data distributions and task types.

3.2 Evaluation Benchmarks

To achieve a comprehensive and reliable evaluation, we carefully select the evaluation benchmarks, ensuring the validity and generality of the experimental findings. In detail, our study encompasses five widely used language tasks: summarization and question generation, sentiment classification, natural language inference, and paraphrase detection. These tasks can be broadly categorized into *generation* and *classification*, i.e., the first two focus on text generation, and the last three on classification.

As shown in Table 1, for each task, we select three or four datasets, where one is used for fine-tuning the LLMs, and the others serve as the test sets. We endeavor to ensure that the test datasets are within the same domain or span different domains as the training set. This approach can evaluate the LLMs' generalization in familiar contexts and to new domains (in- and out-of-domain). We briefly introduce the tasks and datasets below. The full descriptions can be found in Appx. A.

Summary Generation This task aims to generate a summary based on the given article. We select XSum (Narayan et al., 2018), XLSum (Hasan et al., 2021), PeerRead (Kang et al., 2018), and CNN/DailyMail (Hermann et al., 2015). XSum is used as the training set. The test set of XSum itself and XLSum serve as the in-domain test sets. The others are regarded as out-of-domain datasets.

Question Generation Given a paragraph and an answer, question generation infers the corresponding question. We select Socialqa (Sap et al., 2019), Tweetqa (Xiong et al., 2019), and Sciqa (Welbl et al., 2017). We choose Socialqa as the training set and its test set for in-domain testing. Tweetqa and Sciqa are used as the out-of-domain test sets.

Sentiment Classification Sentiment classification identifies the positive/negative emotions expressed in the text. This evaluation involves Amazon review (Keung et al., 2020), AmazonFood review (McAuley and Leskovec, 2013), SST2 (Wang et al., 2019), and Yelp[1]. Note that the target for Yelp is a rating score ranging from 1 to 5, while the label for other datasets is positive or negative. We convert the ratings in Yelp to binary labels with negative below 3.5 and positive above 3.5. Amazon is used to fine-tune LLMs; Amazon and Amazonfood act as the in-domain test dataset, while SST2 and Yelp are the out-of-domain sets.

Paraphrase Detection This task involves classifying if two given text segments using different wordings express the same meaning. We select Paws (Zhang et al., 2019), QQP, and STS-B (Wang

[1] https://huggingface.co/datasets/yelp_review_full

et al., 2018). Since STS-B is labeled using 1 to 5 similarity scores, we perform a similar processing step as YELP, i.e., if the rating is above 3.5, the two texts are paraphrased. The Paws and itself are used as the training and in-domain test set. The other datasets are the out-of-domain datasets.

Natural Language Inference Given a pair of text segments, typically referred to as premise and hypothesis, this task determines the relationship between them, i.e., if the hypothesis is entailment, contradiction, or neutral based on the premise information. We use MNLI (Williams et al., 2018) as the training set, MNLI matched (MNLI-1) and MNLI mismatched (MNLI-2) as the in-domain test sets, RTE (Wang et al., 2018) and GPTNLI[2] as the out-of-domain test sets.

3.3 Experimental Setup

Models & Metrics We conduct all experiments using the open-sourced Llama-2-7b (tou, 2023) due to its popularity in the NLP community. In the evaluation, we use the Rouge-L[3] metric for generation tasks and the accuracy for classification tasks.

Training Details For each task-specific training set, we fine-tune the Llama-2 models using subsets of varying sizes: 2,000, 4,000, and 6,000 samples, which enables us to analyze how different training sizes impact the model's performance.

To standardize our training process, we treat classification tasks as text generation. Specifically, we use the language modeling head to predict labels in the text form during training, as suggested in previous works (Schick and Schütze, 2021; Liu et al., 2022). During the evaluation phase, we only choose the probabilities associated with these predefined labels as the models' predictions and then select the output with the highest probability as the predicted label. Details about the labels used for classification tasks and prompt formats can be found in Appx. B and Appx. C, respectively.

The models are fine-tuned with 2 epochs. We employ the AdamW (Loshchilov and Hutter, 2019) optimizer with a learning rate of 0.002. The generation length is set to 60 for generation tasks and 5 for classification tasks.

Testing Details Our primary aim is to evaluate the generalization ability of the fine-tuned LLMs. For this, we employ distinct approaches based on the testing datasets and task types, as in Sec. 3.1. When evaluating the models on datasets that match the task type of the fine-tuning set (Setting 1 and 2), we adopt two strategies: a 0-shot prompting approach with no in-context examples (normal testing after training), and in-context learning (ICL), where a set of in-context examples are provided. On the other hand, in scenarios where the testing task type of the test sets differs from that of the training set (Setting 3), the usage of ICL becomes necessary. This technique is essential to inform the model about the nature of the task to be performed. Notably, for classification tasks, we still show 0-shot inference performance, since only the label probabilities are considered.

Specifically, for generation tasks, the models are evaluated with 1, 2, or 4 in-context examples. For binary classification tasks, including sentiment analysis and paraphrase detection, we report results using 2, 4, and 6 in-context examples. Regarding Natural Language Inference (NLI), which contains three label categories, we showcase results with 3, 5, and 7 in-context examples. Among all these evaluation variations, we ensure that every category is presented at least once in the in-context examples.

4 Results and Findings

4.1 Same Task, In-domain Datasets

In Figure 1, we first present the results of fine-tuned Llama-2 models on in-domain testing datasets of the same fine-tune/test task type (Setting 1). The following key findings can be drawn:

Fine-tuned models without in-context learning (ICL) can generally perform better than baseline Llama-2 using ICL. The fine-tuned models, trained with varying sample sizes (2K, 4K, 6K), exhibit superior 0-shot (w/o ICL) performance compared to the original baseline Llama2 using ICL across most datasets, notably XLSum, Socialqa, MNLI-1, MNLI-2, and Paws; see Figure 1 (b) (c) (d) (g) and (h). The only exception is observed in the sentiment classification task (Amazon and AmazonFood), where fine-tuned models slightly underperform compared to baseline Llama-2 using ICL. This could be attributed to Llama-2's inherent expertise in sentiment analysis, as indicated by its high 0-shot performance. In such cases, additional fine-tuning might not significantly enhance or could potentially impair performance, possibly due to overfitting or conflicting training data.

[3] https://huggingface.co/spaces/evaluate-metric/rouge

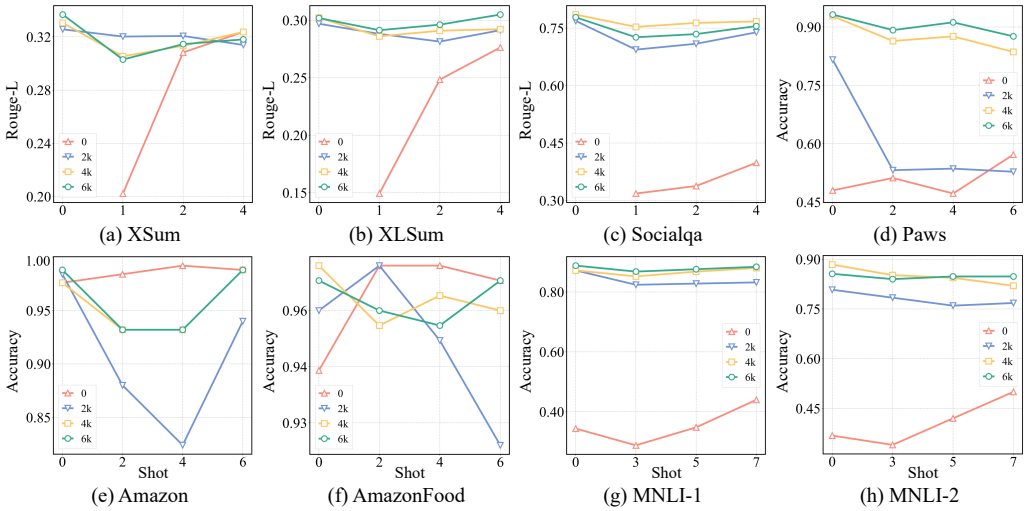

Figure 1: **In-domain** dataset testing performance comparisons of baseline Llama-2 (0 training samples, orange line) and its fine-tuned variants ($2K, 4K, 6K$ training samples). Shot denotes the number of in-context examples. The caption for each subfigure refers to the test set. The corresponding training set can be found in Table 1. The 0-shot results of the baseline Llama model in (a), (b) and (c) are not presented since in scenarios where in-context examples are absent (0-shot), baseline models generally struggle to execute the tasks effectively, even when the prompt explicitly outlines the task requirements.

Fine-tuned LLMs often perform worse using in-context learning than the zero-shot setting. From Figure 1, compared to baseline Llama-2, the fine-tuned models benefit little from the ICL. This trend suggests that while fine-tuning enhances a model's 0-shot in-domain generalization, the additional in-context examples during inference are not always necessary and helpful. The drop in performance might be due to the model becoming more specialized after fine-tuning, reducing its adaptability to new contexts. The performance correlation with the number of in-context shots remains unclear for the fine-tuned models. In comparison, baseline Llama-2 shows an overall positive tendency in performance with increased in-context shots. This improvement trend suggests that LLMs without task-specific fine-tuning are more effective in leveraging the in-context examples to understand the specialized task. These observations can indicate that once LLMs have been fine-tuned on sufficient data, their ability to benefit from ICL diminishes.

Fine-tuning with more samples may not consistently improve performance on the test set. Generally, the models fine-tuned with 4K or 6K samples outperform the 2K models on most test sets. However, the degree of improvement is not consistent. On XSum (Figure 1 (a)), for instance, fine-tuned models demonstrate only a slight performance increase with larger training sets, changing from 2K to 6K training examples. In contrast, on Paws (Figure 1 (d)), models show marked performance gains as the number of training samples increased from 2K to 4K, with accuracy jumping from 81.6% to 93.2%. We also find that increasing the training size from 4K to 6K brings subtle or even negative impacts. These findings suggest that the relationship between the volume of fine-tuning data and in-domain test performance is task-dependent and not straightforward.

4.2 Same Task, Out-of-domain Datasets

We then show the results of the fine-tuned Llama-2 on out-of-domain testing datasets of the same task type (Setting 2). We derive the following observations based on Figure 2:

Fine-tuned models underperform compared to the baseline model on generation tasks, yet outperform on classification tasks. For the out-of-domain testing results, a clear distinction emerges based on the task categories, i.e., between generation and classification tasks. In generation testing datasets ((a) PeerRead, (b) CNN/DailyMail, (c) Tweetqa, and (d) Sciqa in Figure 2), fine-tuned models perform worse than baseline models, and this gap persists regardless of the number of in-context examples provided. Notably, there lacks a performance growth with more training examples in datasets like CNN/DailyMail, Tweetqa and Sciqa, suggesting that the generalization ability of fine-tuned LLMs is impaired.

On the other hand, in the context of sentiment classification tasks, the best performance of the

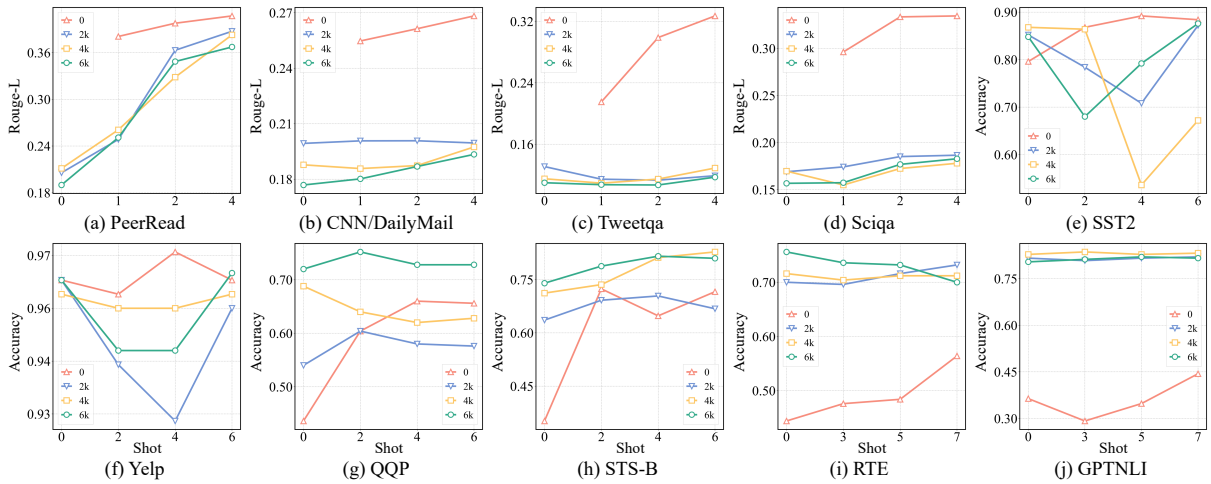

Figure 2: **Out-of-domain** dataset testing performance comparisons of baseline Llama-2 (0 training samples, orange line) and its fine-tuned variants ($2K, 4K, 6K$ training samples).

fine-tuned models is on par with the baseline Llama-2, which means the fine-tuned LLMs' sentiment knowledge is unlikely to be lost; see Figure 2 (e) and (f). Another notable observation is that the fine-tuned models exhibit larger variability using different ICL shots. This indicates that the performance is more sensitive to the in-context examples for the sentiment classification task. For other classification tasks (i.e., paraphrase detection and natural language inference), fine-tuned models consistently outperform the baseline Llama-2, as shown in Figure 2 (g)-(j).

The diverging effects of fine-tuning on generation and classification tasks for out-of-domain testing may originate from the difference in task output space constraints. The output space of classification tasks is inherently predefined and limited, enabling fine-tuned LLMs to apply their inherited and adapted knowledge relatively easily to new domains. In contrast, the output space of out-of-domain generation datasets largely deviates from that of the training set. Despite being given a few in-context examples, fine-tuned models may still find it challenging to reason about the expansive range of possible outputs in new domains.

4.3 Different Tasks

Last, we test whether the generalization ability of fine-tuned models is preserved on cross-task testing datasets (Setting 3). The evaluation for each testing set is performed using models fine-tuned on 2K training samples from other tasks. Due to space limitations, our analysis is confined to five test sets: XSum, Socialqa, Amazon, Paws, and MNLI-1. The following findings are mainly based on the first row of Figure 3:

The generalization through fine-tuning exhibits significant variability and highly depends on the training data. When assessing performance on classification tasks, i.e., Amazon, MNLI, and Paws, it becomes evident that the model's fine-tuning source greatly affects its efficacy. Fine-tuning on a dataset like Amazon negatively impacts performance on the MNLI-1 test set, whereas fine-tuning on XSum significantly boosts it; see Figure 3 (b). In parallel, for generation tasks, training on Socialqa hurt the performance on XSum while training on XSum has little impact on Socialqa; see Figure 3 (d) and (e). These intricate patterns suggest that the effectiveness of fine-tuning is not easily predictable and likely intertwines with dataset characteristics, fine-tuning procedures, etc.

Models fine-tuned on classification tasks fail to generalize to generation tasks. From Figure 3 (d) and (e), fine-tuning the models on classification data leads to almost zero Rouge-L scores for generation tasks. Upon examining the outputs, it becomes evident that these models predominantly generate classification labels rather than coherent text, a manifestation of output space specialization, which aligns with the findings of Wang et al. (2023c). Two potential reasons exist. Firstly, the model's output space may be constrained to the category labels seen during fine-tuning, inhibiting its ability to generate other tokens. The second may be induced by the prompt format, as listed as Prompt-1 in Table 5. The prompts for different tasks have the same start "###", which could confuse the model and cause it to misinterpret inputs from other tasks as if they belong to its training task. To further investigate the influence of prompt

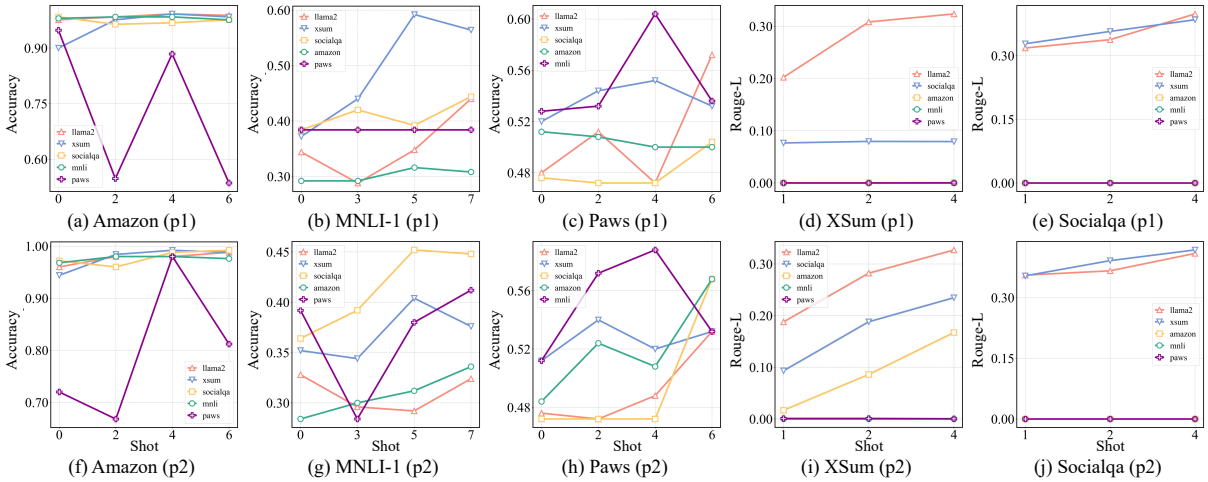

Figure 3: **Cross-task** performance comparisons of baseline Llama-2 (0 training samples, orange line) and models fine-tuned on other tasks. The caption for each subfigure refers to the test set. The legends denote the training data. The first row is the results using the Prompt-1 (p1) and the second row is the results using the Prompt-2 (p2) format. The detailed prompt formats can be found in Appx. C.

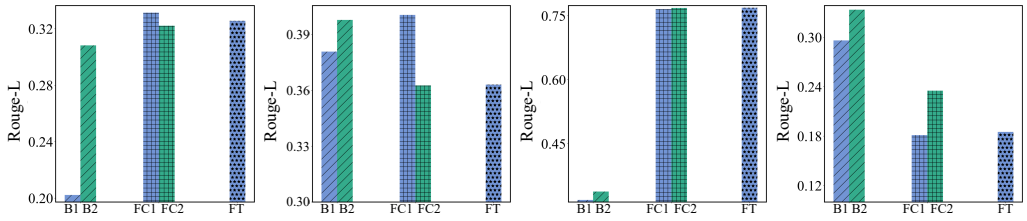
format, we introduced a distinct set of prompts that avoid uniform starting sequences (Prompt-2 in Table 5). The corresponding results are shown in the second row of Figure 3. Comparing the first and second rows, we find that the cross-task evaluation on classification tasks is more sensitive to the prompt format than the generation task evaluation. Moreover, from Figure 3 (i), the model fine-tuned on Amazon starts to work on XSum with such new prompts. Yet, for Socialqa (subfigure (j)), the fine-tuning on Amazon still fails to succeed. Hence, the prompt format is crucial for cross-task generalization, but identifying a universally effective format remains to be explored.

5 Fine-tuning with In-context Learning on Generation Tasks Helps Improve the Generalization Ability of LLMs

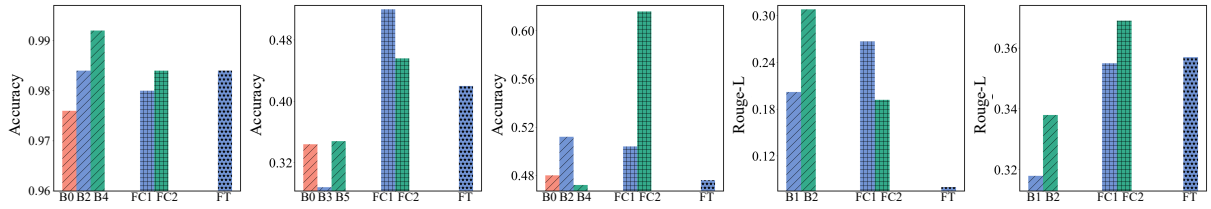
In Sec. 4.2, our analysis reveals that LLMs fine-tuned on classification tasks exhibit robust generalization capabilities under out-of-domain scenarios. However, for generation tasks, the fine-tuned models consistently fall short compared to baseline.



In this section, we aim to show that Fine-Tuning with In-Context Learning (FTICL) can help improve LLMs' out-of-domain generalization for generation tasks. FTICL leverages the strengths of both fine-tuning and ICL. Specifically, instead of directly forwarding the original input into LLMs during fine-tuning, FTICL prepends in-context examples to the input and forwards the LLMs with this newly constructed input. Note that this strategy has also been adopted to mitigate other fine-tuning issues. For example, Anil et al. (2022) find that FTICL leads to a substantial improvement in terms of input length generalization.

In our experiment, we fine-tune the FTICL models using 2,000 samples. For each generation task, we train two models with 1 or 2 in-context examples prepended in input, respectively. The results are presented in Figure 4 and Figure 5. The following findings regarding generalization are organized in terms of the same or different fine-tuning/test tasks.

5.1 Same Task



We investigate the effects of FTICL across datasets sharing the same fine-tuning/test task type. We fine-tune models on the training sets of the XSum and Socialqa datasets, respectively. These models are then evaluated both on their respective test sets and on distinct out-of-domain test sets. The main results of these evaluations are presented in Figure 4. Due to space limitations, we only report the typical results on XSum, PeerRead, Socialqa, and Sciqa. From subfigures (a) and (c), we can see that FTICL models preserve or even slightly enhance the performance on the corresponding test sets of the training set compared with vanilla fine-tuning.

When we extend our analysis to out-of-domain test sets of the same fine-tuning/test task type, we find **models fine-tuned using FTICL achieve a better out-of-domain generalization performance than the vanilla fine-tuned models**. The FTICL models can sometimes even surpass the baseline model without fine-tuning. For instance, as shown in Figure 4 (b), the FTICL model with

(a) XSum → XSum (b) XSum → PeerRead (c) Socialqa → Socialqa (d) Socialqa → Sciqa

Figure 4: **Same fine-tuning/test task type evaluation of FTICL with generation tasks.** Bn represents the baseline Llama-2 model with n in-context examples during inference. FCn denotes the FTICL models fine-tuned with n in-context examples. FT is the vanilla fine-tuned model without in-context learning. For FCn and FT, we fine-tune with 2,000 samples, perform both 0-shot and few-shot evaluations, and report the results with the best performance.

(a) Socialqa → Amazon (b) Socialqa → MNLI-1 (c) Socialqa → Paws (d) Socialqa → XSum (e) XSum → Socialqa

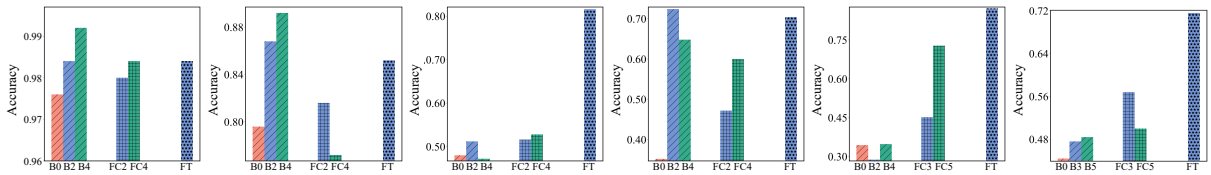
Figure 5: **Cross-task performance of FTICL with generation tasks.** For the classification task evaluation, we also report the 0-shot performance (B0) for the baseline Llama-2.

one in-context example during fine-tuning (FC1) showcases a remarkable gain over the vanilla fine-tuned model (FT) on PeerRead, surpassing even the baseline Llama-2 model using in-context learning (B1 and B2). For Sciqa, although FC2 lags behind B1 and B2, it still performs better than FT; see Figure 4 (d). These observations reveal that FTICL may mitigate catastrophic forgetting for generation tasks by allowing the model to retain its learned capabilities more effectively than the vanilla fine-tuning method.

5.2 Different Tasks

Besides enhanced out-of-domain generalization, we also demonstrate that models utilizing FTICL exhibit superior cross-task generalization capabilities. The results are shown in Figure 5.

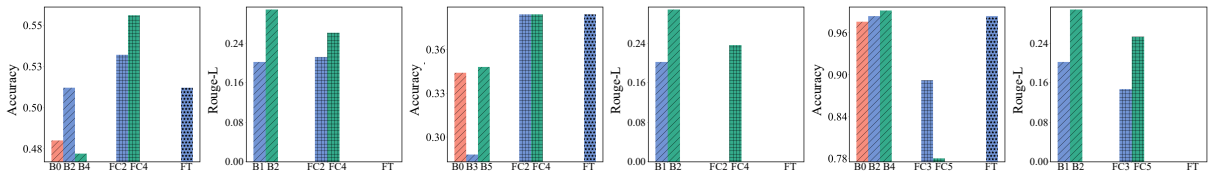
FTICL trained on generation tasks achieves a better cross-task generalization than vanilla fine-tuning. We can observe FTICL models fine-tuned on Socialqa achieve at least comparable performance on Amazon, shown in Figure 5 (a), and exhibit superior results over both the baseline Llama-2 and the vanilla fine-tuned models when evaluated on MNLI and Paws; see Figure 5 (b) and (c). We can also see FC1 in subfigure (d) and FC1, FC2 in subfigure (e) outperform the vanilla fine-tuned (FT) models and can be even on par with or surpass the baseline Llama-2 for the cross summary and question generation task evaluations. The results show that fine-tuning with ICL is better than directly fine-tuning on generation tasks.



5.3 Potential Reason

We provide one hypothesis that could drive the success of FTICL in enhancing LLMs' generalization: **FTICL tends to deviate less from the original LLM than vanilla fine-tuning.** In other words, FTICL models preserve more general knowledge inherent in LLMs. To support this, we calculate the average parameter weight difference between the fine-tuned models (FTICL and FT) and the original Llama-2. Experimental results show consistency with our hypothesis: on Socialqa, FTICL ($7.95e-05$) vs. FT ($8.54e-05$); on XSum, FTICL ($8.03e-05$) vs. FT ($1.0e-04$). The potential reason is that the provided in-context examples encourage the LLM to leverage its existing knowledge to solve new tasks.

5.4 FTICL on Classificaion Tasks



We also analyse the performance of FTICL on classification tasks and find that this strategy **does not** help improve the generalization ability of LLMs as shown in Figure 6 and Figure 7.

For the classification tasks, as shown in Figure 6 (a) (c), and (e), when evaluated on the in-

(a) Amazon → Amazon (b) Amazon → SST2 (c) Paws → Paws (d) Paws → STS-B (e) MNLI → MNLI-1 (f) MNLI → RTE

Figure 6: **Same fine-tuning/test task type evaluation of FTICL models fine-tuned on classification tasks.**

(a) Amazon → Paws (b) Amazon → XSum (c) Paws → MNLI-1 (d) Paws → XSum (e) MNLI → Amazon (f) MNLI → XSum

Figure 7: **Cross-task performance for FTICL models fine-tuned on classification tasks.**

domain test set of the corresponding training set, fine-tuning with in-context learning (FTICL) models generally perform worse than vanilla fine-tuned models. For the out-of-domain test sets, we find FTICL models can generally outperform the baseline Llama but lag behind vanilla FT models; see Figure 6 (b) (d) (f). The reason for this phenomenon may be that classification tasks are more sensitive to the in-context examples. We also hypothesize that the optimization process plays a pivotal role. Specifically, for classification tasks, we observed that the final loss of models fine-tuned with in-context learning (FTICL) tends to be higher compared to vanilla fine-tuning (FT), with challenges in further reducing the loss. This phenomenon might stem from the model's tendency to be lazy. Specifically, for generation tasks (e.g., summary), the model must learn to leverage contextually relevant information (e.g., the article to be summarized) to generate appropriate outputs (e.g., target summary). However, for classification tasks, in-context examples could inadvertently act as distractors since all the labels are provided in the in-context examples. It may lead the model to copy labels directly from in-context examples rather than leveraging the corresponding relevant information. This could also explain the difficulty in loss reduction. A better optimizer could possibly solve this problem. The above observations suggest that for classification tasks, it is better to adopt the vanilla fine-tuning approach instead of FTICL.

Lastly, Figure 7 shows the cross-task performance of FTICL, where the models are fine-tuned with classification tasks. In Figure 7 (a) (c), and (e), for cross-task classification tasks, we find the cross-task transfer effects are not clear. For example, training on Amazon has a positive effect on Paws, while training on MNLI has a negative effect on Amazon. Meanwhile, as shown in Figure 7 (b) (d), and (f), we can see that FTICL models for generation task evaluation outperform vanilla fine-tuned models, which means FTICL can help alleviate the output space specialization issue mentioned in Sec. 4.3.

6 Conclusion

This study comprehensively investigates the effects of fine-tuning on the LLMs' generalization ability. We conduct systematic experiments by evaluating the fine-tuned LLMs across various training data and language tasks. Experimental results indicate that dissimilar generalization ability after fine-tuning arises from the nature of generation or classification tasks. Further, we show that fine-tuning with in-context learning can enhance the generalization capability for generation tasks. We hope our findings can inspire future advancements in understanding and effectively utilizing LLMs to solve new tasks.

Limitations

In this work, we study the LLMs' generalization ability between fine-tuned variants and their original counterparts and explore the effective fine-tuning strategies. This work has two limitations: i) The underlying reasons for the difference between models fine-tuned on classification tasks and generation tasks remain under-examined. ii) The intricate operational mechanisms behind the fine-tuning with in-context learning method have yet to

be exhaustively understood. iii) We do not study the recently more advanced tuning strategies such as RLHF (Stiennon et al., 2020; Kirk et al., 2024). We leave these more in-depth analyses as our future work.

A Dataset Information

We provide more dataset information (including the data sources and examples) in Table 2 and Table 3. It should be noted that for the summary generation task, although both XSum (Narayan et al., 2018) and CNN/DailyMail (Hermann et al., 2015) are from new articles, they are not in the same domain. There are two reasons. First, XSum is from BBC News, and CNN/DailyMail is from CNN and DailyMail news. There exist style differences for different news. Another more important reason is that XSum is a one-sentence summary dataset, while CNN/DailyMail is a multiple-sentence summary dataset; see Table 2.

B Classification Labels

In Table 4, we illustrate the tokens that need to be generated during training for the language classification tasks. We ensure the labels between different tasks have no intersection with each other. This can avoid the target specialization issue when evaluating a dataset in one task type using models trained on a dataset of a different task type.

C Prompt Format

In Table 5, we detail the prompt formats employed for each task in our experiments. Throughout the training phase, the model is trained using Prompt-1. Note that Prompt-1 is also the default choice during the testing phase. To ensure a comprehensive evaluation, particularly in cross-task scenarios where the influence of the prompt format is a crucial consideration, we additionally report results obtained using Prompt-2. This approach allows us to assess the impact of different prompt structures on model performance.

Task	Dataset	Source	Example
Summary Generation	XSum (Narayan et al., 2018)	BBC news	**Input:** Electrician Carl Holdsworth has set up holographic video footage of Mr and Mrs Claus behind the windows of his Chaddesden house... **Output:** Festive revellers have travelled for miles to see Father Christmas and his wife apparently living in a Derby home.
	XLSum (Hasan et al., 2021)	BBC news	**Input:** Jack McLinden, who has multiple health conditions, experienced joining his heroes on the pitch before their game against Newcastle United on Monday... **Output:** A 14-year-old Everton fan has made history by becoming football's first "remote" match-day mascot - with the aid of a robot.
	PeerRead (Kang et al., 2018)	Scientific peer reviews	**Input:** We explore techniques to maximize the effectiveness of discourse information in the task of authorship attribution... **Output:** Leveraging Discourse Information Effectively for Authorship Attribution.
	CNN/DailyMail (Hermann et al., 2015)	CNN news and DailyMail	**Input:** Chris Brown sat alone in court for 35 minutes on Friday while his lawyer talked with the judge and prosecutor behind closed doors in his probation violation case... **Output:** Judge orders Brown to come back to court on June 10. Prosecutors accuse Brown of not finishing 180 days of community labor.
Question Generation	Socialqa (Sap et al., 2019)	Social Commonsense	**Input:** Sydney is always respected by Kai. They were able to make up Kai's mind. **Answer:** thank Sydney sincerely **Output:** What will happen to Kai?
	Tweetga (Xiong et al., 2019)	Twitter	**Input:** Getting taxis is a nightmare - local drivers confused with new street layout, translations on phone app! **Answer:** getting taxis **Output:** what does ben have nightmares of?
	Sciqa (Welbl et al., 2017)	School Science Textbooks	**Input:** Archaea live everywhere on Earth, including extreme environments. **Answer:** everywhere **Output:** Where do archea live?
Sentiment Classification	Amazon (Keung et al., 2020)	Product review	**Input:** I will not use it again. Made my dogs feel bad. One of my dogs lost hair because of this product. I had to end up washing my dogs to remove as must as possible. **Output:** negative
	AmazonFood (McAuley and Leskovec, 2013)	Food review	**Input:** Great taste, texture, flavor, and works well with any recipe! Wonderful pricing, too! Gluten free products are so expensive normally! Definitely recommend this! **Output:** positive
	SST2 (Wang et al., 2019)	Moview review	**Input:** In its dry and forceful way, it delivers the same message as Jiri Menzel's Closely Watched Trains and Danis Tanovic's No Man's Land. **Output:** positive
	Yelp	Yelp review	**Input:** Service sucks! They're usually understaffed and we were told to wait an hour for a table to be cleaned. There was only 1 chef and after we sat we waited for our food for 20 minutes!!!! Even the appetizers took 20 minutes. Will never recommend this place to anyone again. Big big mistake. **Output:** negative

Table 2: Dataset Description #1

Task	Dataset	Source	Example
Paraphrase Detection	Paws (Wang et al., 2018)	Wikipedia	**Input 1:** Windows XP Mode runs Windows XP in a virtual machine , and displays applications within separate windows on the Windows 7 desktop. **Input 2:** Windows XP - Mode executes Windows XP on a separate machine and displays applications in virtual windows on the Windows 7 desktop. **Output:** no
	QQP (Wang et al., 2018)	Quora Question	**Input 1:** How do I develop the patience to read books? **Input 2:** How can I develop patience and love towards reading? **Output:** yes
	STS-B (Wang et al., 2018)	Misc.	**Input 1:** US postpones missile test over N Korea tensions **Input 2:** Embassies staying put in N. Korea despite tension **Output:** no
Natural Language Inference	MNLI (Williams et al., 2018)	Misc.	**Input 1:** i think that's great there's a few places in Houston where they're trying that out i don't know if it's the if they've done it citywide yet or not where they have the color coded uh bags and uh bins **Input 2:** There are a couple places in Houston where it's being tried. **Output:** entailment
	RTE (Wang et al., 2018)	d Wikipedia	**Input 1:** The third, and most remote possibility, was considered to be a so-called Jamaican coalition, again based on the party colours, between the Christian Democrats, the FDP and the Greens. **Input 2:** It seems unlikely that there will be a coalition between Gerhard Schroeder's Social Democrats and Angela Merkel's Christian Democratic Union. **Output:** neutral
	GPTNLI	Misc.	**Input 1:** The Great Horned Owl has a tuft of feathers around its face that makes it look like an old man's white mustache. **Input 2:** The Great Horned Owl is bald. **Output:** contradiction

Abstract

Logical reasoning has been an ongoing pursuit in the field of AI. Despite significant advancements made by large language models (LLMs), they still struggle with complex logical reasoning problems. To enhance reasoning performance, one promising direction is scalable oversight, which requires LLMs to identify their own errors and then improve by themselves. Various self-verification methods have been proposed in pursuit of this goal. Nevertheless, whether existing models understand their own errors well is still under investigation. In this paper, we take a closer look at the self-verification abilities of LLMs in the context of logical reasoning, focusing on their ability to identify logical fallacies accurately. We introduce a dataset, FALLACIES, containing 232 types of reasoning fallacies categorized in a hierarchical taxonomy. By conducting exhaustive experiments on FALLACIES, we obtain comprehensive and detailed analyses of a series of models on their verification abilities. Our main findings suggest that existing LLMs could struggle to identify fallacious reasoning steps accurately and may fall short of guaranteeing the validity of self-verification methods. Drawing from these observations, we offer suggestions for future research and practical applications of self-verification methods.[1]

1 Introduction

Logical reasoning is not only a crucial aspect of human intelligence but also one of the long-term pursuits of artificial intelligence (McCarthy, 1989). It is indispensable in intelligent systems, enabling problem-solving, decision-making, and critical thinking. Large language models (LLMs) have recently achieved remarkable advancements in a wide range of tasks (OpenAI, 2023). Being prompted appropriately, LLMs exhibit the emergent ability to "reason" step by step like humans (Wei et al., 2022a,b). Nonetheless, increasing research suggests that LLMs struggle with intricate logical reasoning problems, occasionally producing unfaithful reasoning steps fraught with logical fallacies (Arkoudas, 2023; Liu et al., 2023a; Pan et al., 2023; Hong et al., 2023).

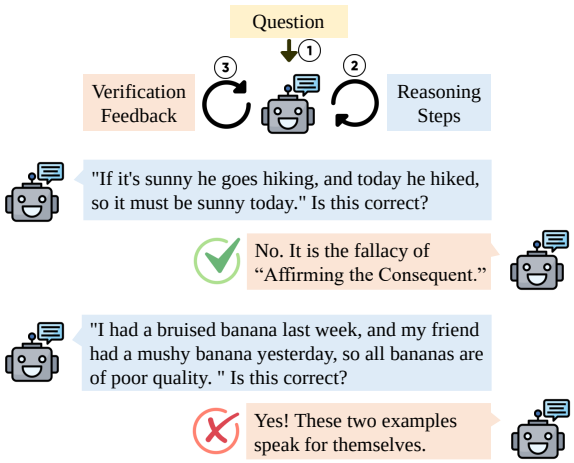

Figure 1: The self-verification approach requires LLMs to identify the fallacious steps in their own reasoning process. However, LLMs might be susceptible to certain types of fallacies and fail to identify them, leading to the potential failure of self-verification.

To tackle this issue, a prevalent and promising approach is scalable oversight (Bowman et al., 2022), where the LLMs could be boosted based on their own evaluation signals (Leike and Sutskever, 2023). In this regard, various strategies of self-verification using LLMs are proposed to enhance reasoning performance (Ling et al., 2023; Weng et al., 2022; Xie et al., 2023; Madaan et al., 2023; Miao et al., 2023). As shown in Figure 1, the LLMs first generate the reasoning process and then self-verify their own output. The verification results are then used to refine the output or further improve the models. Their *assumption* is that LLMs can reliably identify fallacious reasoning steps.

Though empirical evidence demonstrates their

preliminary success, a thorough and comprehensive evaluation of the underlying assumption remains unexplored. First, these efforts typically use the performance of the final task (e.g., answer accuracy) to illustrate their effectiveness. However, this is a proxy metric that does not directly reflect the ability of LLMs to identify logical fallacies. LLMs might possibly arrive at the correct answer despite the existence of fallacious intermediate steps (Wei et al., 2022b; Creswell et al., 2023; Lanham et al., 2023). Second, they are usually only concerned with *whether or not* the reasoning step is fallacious, rather than *what type of* fallacy exists in the step, which could be informative for the self-improvement of LLMs. Such an oversimplification precludes a definitive analysis of the LLMs' ability to identify different types of fallacies.

In this paper, we provide a comprehensive evaluation of the verification abilities of LLMs in logical reasoning. Specifically, we collect a dataset, FALLACIES, containing 4,640 reasoning steps for 232 types of fallacies. We evaluate whether LLMs can distinguish between correct and fallacious reasoning steps. Such directed evaluation can provide a more accurate reflection of the verification abilities of LLMs, as it steers away from proxy metrics and delves straight into the actual performance in identifying fallacious steps. Compared to previous datasets, our dataset features more types of fallacies, a larger scale, more fine-grained reasoning, and explicit premises and conclusions. Furthermore, we adopt a hierarchical taxonomy of fallacies, which divides fallacies into two main categories and nine subcategories, allowing for a more systematic approach toward analyzing the verification abilities of LLMs across varying aspects.

We conduct exhaustive experiments on a range of LLMs. First, experimental results show that most LLMs struggle with accurately identifying the fallacious steps. Most LLMs only achieved an overall accuracy rate of less than 80%, suggesting that LLMs could lack sufficient logical verification abilities. Thus, we should be more cautious about the self-verification methods of LLMs. Second, the performance of LLMs can be remarkably imbalanced in different types of fallacies. Most LLMs perform much worse at identifying fallacies related to logical structure than those related to content, pointing toward key directions for improving LLMs' verification and reasoning abilities. Third, we also find that LLMs encounter challenges when it comes to classifying different types of fallacies. Presenting LLMs with the definitions of fallacies does not appear to improve their ability to recognize fallacies. This raises a call for further research to delve into the underlying mechanisms through which LLMs understand reasoning and fallacies. In summary, we present a comprehensive evaluation of the verification abilities of LLMs and highlight their limitations in identifying fallacies, urging the community to apply the self-verification methods with caution.

2 Related Work

2.1 Language Models for Logical Reasoning

Compared with traditional symbol-based logic reasoning systems, using language models to directly reason over natural language is a more flexible and popular approach (Yu et al., 2023; Yang et al., 2023b). Many efforts have been devoted to improving the logical reasoning abilities of language models from different perspectives, including fine-tuning methods (Clark et al., 2020; Dalvi et al., 2021), pre-training methods (Pi et al., 2022; Jiao et al., 2022), and modular methods (Hong et al., 2022; Yang et al., 2022). As the model scale increases, specially designed prompts (e.g., Chain-of-Thought prompts (Wei et al., 2022b)) can elicit the step-by-step reasoning abilities of LLMs, achieving remarkable improvement in multiple reasoning tasks (Chu et al., 2023). However, some studies find that LLMs still struggle with complex logical reasoning problems (Arkoudas, 2023) and could be susceptible to logical fallacies (Payandeh et al., 2023). There is still a lack of comprehensive research to investigate the understanding of LLMs on different logical fallacies.

2.2 Self-Verification with Large Language Models

A prevalent method to enhance the capacity of LLMs is through learning and correction via high-quality verification feedback. This feedback proves instrumental in various aspects of model optimization. For instance, it can be used to fine-tune the models (Ouyang et al., 2022; Scheurer et al., 2023; Chen et al., 2023a; Zelikman et al., 2022; Wang et al., 2023; Bai et al., 2022; Huang et al., 2022). In addition, verification feedback can be utilized to re-rank the model outputs (Lightman et al., 2023; Weng et al., 2022; He et al., 2023; Ni et al., 2023; Ling et al., 2023). It can also be em-

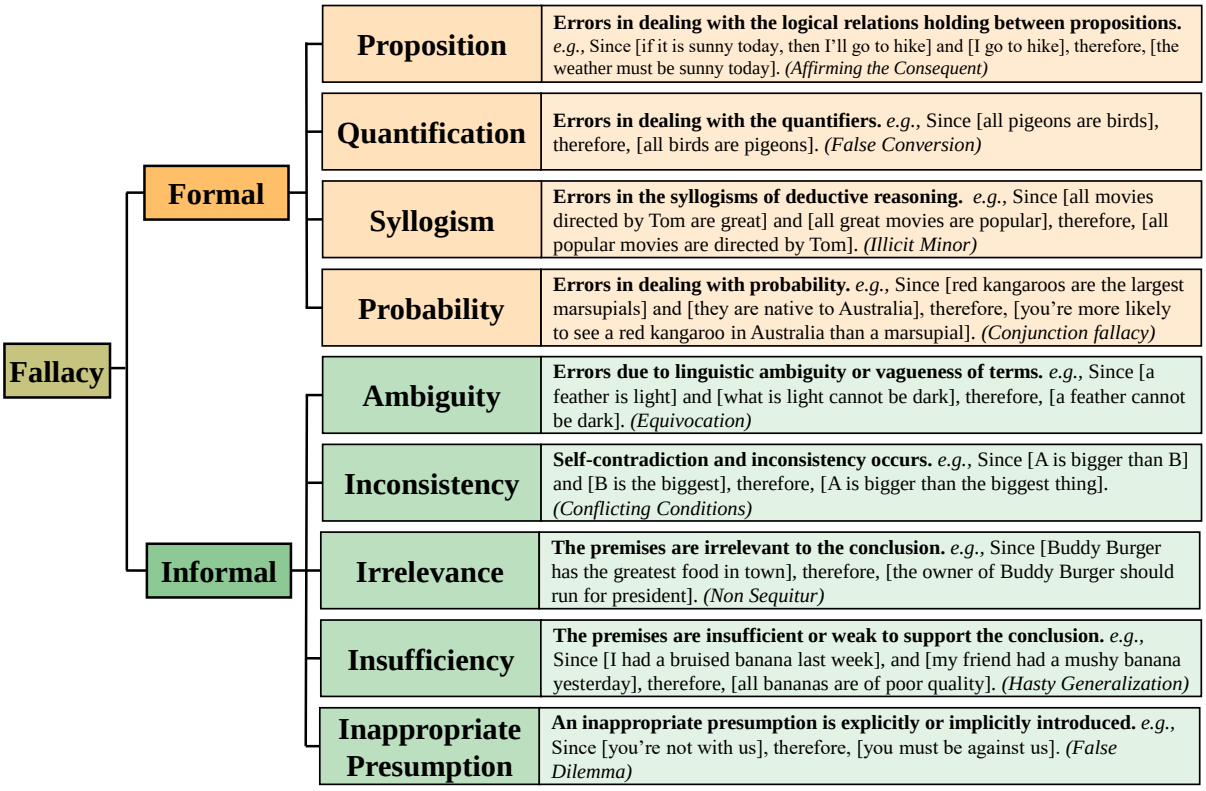

Figure 2: The hierarchical taxonomy of fallacies. For each sub-category, we present its definition and an example of a fallacy within the sub-category. We use square brackets to indicate the premises and conclusions.

ployed to refine the outputs (Madaan et al., 2023; Shinn et al., 2023; Chen et al., 2023b) and guide the generation process of the models (Yao et al., 2023; Xie et al., 2023). A straightforward approach to collecting feedback is to collect directly from humans (Ouyang et al., 2022; Fernandes et al., 2023), but this could prove to be costly and unable to provide instant feedback. Alternatively, collecting feedback from external tools (Gou et al., 2023; Chern et al., 2023) or metrics (Jung et al., 2022) could be more feasible but limited to specific tasks. Thus, some researchers turn to use large language models themselves to provide verification feedback (Ling et al., 2023; Weng et al., 2022; Xie et al., 2023; Madaan et al., 2023; Miao et al., 2023), which is more scalable. Nonetheless, recent papers (Huang et al., 2023; Valmeekam et al., 2023) have raised doubts about the self-verification abilities of the LLMs. For instance, Huang et al. (2023) find that LLMs struggle to self-correct their responses without external feedback. However, they still leave some open questions for subsequent research, such as what exactly the performance of LLMs is to verify a single reasoning step. In this paper, we delve deeply into this subject, critically examining the verification abilities of LLMs from the perspective of logical reasoning.

inappropriate presumption (inappr.)	54

Table 1: Distribution of 232 fallacies in FALLACIES.

3 FALLACIES

This section outlines the design principles and process of constructing our dataset FALLACIES.

3.1 Design Principles

Covering more comprehensive error types: We propose to evaluate the verification abilities of LLMs on a wider range of types of errors. Relying solely on a single existing dataset of logi-

cal reasoning might pose a challenge in drawing comprehensive conclusions, as it may struggle to cover the types of errors that can occur in realistic scenarios. For example, synthetic datasets (e.g., ProofWriter (Tafjord et al., 2021)) are generated from fixed logic templates and vocabularies, which could leave out the reasoning errors caused by verbal ambiguity.

Hierarchical fallacy taxonomy: We propose to categorize reasoning errors at a fine-grained, hierarchical level. This approach enables a more thorough assessment of the performance of LLMs across various types of fallacies and offers a more comprehensive perspective on their effectiveness. Meanwhile, we ensure that each reasoning step exclusively pertains to a single type of fallacy to prevent different types of fallacies from potentially confounding one another.

Clarifying the premises and conclusions: The third principle is to indicate the premises and conclusions of the reasoning step explicitly. Reasoning is the process of concluding based on known information, and the validity of reasoning cannot be properly judged without providing premise information. Factors like linguistic omissions and implied background knowledge can complicate reasoning in natural language. Consequently, in our dataset, we strive to ensure that each step is a complete unit of reasoning that contains enough information to verify its correctness.

3.2 Taxonomy of Fallacy

A fallacy is an error in reasoning (Bennett, 2012; Jevons, 1872). It focuses more on whether the conclusion of an argument can be logically deduced from the premises rather than on factual errors or other aspects (Lau, 2011). Identifying logical fallacies is essential for a judicious reasoning system. Without the ability to identify logical fallacies, a reasoning system may lack essential critical thinking skills, leaving it susceptible to illogical arguments and deliberate manipulation.

Fallacies can be classified into two primary categories: **Formal Fallacies**, errors due to invalid logical structures or inference patterns, and **Informal Fallacies**, errors due to the content of premises and conclusions. Based on specific causes of error, we divide each main category into several subcategories. Each subcategory contains several finest-grained fallacies, divided based on more detailed causes of errors. Figure 2 demonstrates our hierarchical taxonomy of fallacies. We derive this taxonomy by integrating multiple scholarly resources (Fieser and Dowden, 2011; Magnus, 2005; Rescher and Schagrin, 2023).

3.3 Data Collection

We first collect 232 types of fallacies from classic academic books (Bennett, 2012; Fieser and Dowden, 2011). The authors of these books carefully collect these fallacies from many available academic resources (including peer-reviewed journals, encyclopedias, and books), covering a substantial portion of common errors in logical reasoning. We collect the definition of each fallacy, i.e., an article containing the description and examples of that fallacy. These definitions are used in academic books to help humans understand the meaning of fallacies. Figure 3 in the Appendix shows an example of the definition. We then assign these 232 fallacies to appropriate categories according to the taxonomy in Sec. 3.2. Table 1 shows the distribution of fallacies. Detailed categorizations and descriptions of these fallacies are in Appendix Table 11.

Then, we collect fallacious and correct reasoning steps. Considering that directly creating fallacious steps from scratch can be challenging, we adopt a strategy in which powerful LLMs first generate candidates, and then we let human experts revise them. Specifically, we ask GPT-4 (OpenAI, 2023) to generate fallacious steps based on the collected definitions of fallacies. To generate diverse steps covering a wider range of domains, we explicitly require the model to generate around a theme, a randomly sampled noun from ConceptNet (Speer et al., 2017). Detailed prompt can be found in Appendix A. Subsequently, human experts carefully proofread and refine these candidates to ensure they fall within the corresponding fallacies. Meanwhile, we require experts to make each step a single inference (Dagan et al., 2013), rather than complex reasoning that involves multiple intermediate steps.

We require the experts to fix the fallacious steps to collect the correct contrastive steps. The experts make as few modifications as possible to turn the fallacious steps into correct ones, which do not contain any reasoning errors. For instance, the fallacious step of the fallacy of *Affirming the Consequent* in Figure 2 can be fixed into *"Since [if it is sunny today, then I'll go to hike] and [It is sunny today], therefore, [I'll go to hike today]."* More contrastive samples can be found in Table 4.

Dataset	Number of Fallacies	Number of Steps	Taxonomy of Fallacy	Granularity of Reasoning	Explicit Premises and Conclusions	Identifying Fallacy from Correct Reasoning
Stab and Gurevych (2017)	1	1,029	No	Coarse	No	**Yes**
Habernal et al. (2018)	1	2,085	No	Coarse	No	**Yes**
Jin et al. (2022)	13	2,449	Coarse	Coarse	No	No
FALLACIES (Ours)	**232**	**4,640**	**Fine & Hierarchical**	**Fine**	**Yes**	**Yes**

Table 2: Comparison of FALLACIES with existing fallacy-related datasets.

In this way, we obtain ten fallacious and ten correct steps for each of the 232 types of fallacies. To check data quality, we ask three additional experts to re-annotate 50 randomly sampled steps. They annotate each step as a correct step, a fallacious step that belongs to the corresponding fallacy, or a fallacious step that does not belong to the corresponding fallacy. Their average agreement with the labels achieves 0.856 (Cohen's Kappa), indicating the high quality of our data.

3.4 Comparison with Existing Dataset

We compare our dataset and existing fallacy-related datasets in Table 2. FALLACIES holds significant advantages across multiple dimensions. It encompasses a broader spectrum of fallacy types, presenting a fine-grained and hierarchical taxonomy of fallacies. Additionally, FALLACIES stands out for its clarity and subtlety, avoiding ambiguous judgments about the correctness of reasoning. We make explicit the premises and conclusions of each reasoning step and the granularity of reasoning in FALLACIES is finer. In contrast to the most recent dataset (Jin et al., 2022), which contained only fallacious reasoning, our dataset includes both correct and fallacious reasoning steps.

4 Experiments

4.1 Models and Prompts

We test a range of common LLMs, including GPT-4 (OpenAI, 2023), GPT-3.5 (Peng et al., 2023), Llama2 (Touvron et al., 2023), Vicuna (Zheng et al., 2023), WizardLM (Xu et al., 2023), Flan-T5 (Chung et al., 2022), Falcon (Almazrouei et al., 2023), Baichuan2 (Yang et al., 2023a), ChatGLM (Du et al., 2022), and InternLM (Team, 2023). We use the default generation parameters in the models' configuration files.[2] Details about the models (e.g., the version numbers) can be found in Table 7 in the Appendix. We evaluate the models

[2]For GPT-4 and GPT-3.5, we set the temperature parameter to 0. Experiments were conducted mainly in Nov. 2023.

Prompt for Identifying Fallacious Steps

Is the following reasoning step correct? You can only answer "Yes" or "No."
{reasoning step}

using the same simple prompt in the zero-shot setting. For the prompt selection, we followed the experience of previous work (Liu et al., 2023b) and carefully designed and experimented with several different styles of prompts. In the end, we chose a prompt that worked well for all models as our prompt. Appendix B presents a detailed ablation analysis of prompt selection, as well as experiments under few-shot setting.

4.2 Metrics

We evaluate LLMs on 4,640 steps in FALLACIES. We calculate the accuracy for each type of fallacy separately. The accuracy of a higher-level category is the (macro) average of the accuracies of its subcategories. Ultimately, we take the average accuracy on formal and informal categories as the overall accuracy.

4.3 Can LLMs accurately identify fallacious steps?

Table 3 shows the accuracies of the different models for identifying fallacious steps on FALLACIES. Based on the experimental results, we have the following observations.

Identifying fallacious steps is still challenging for LLMs. Most LLMs struggle with accurately identifying the fallacious steps. As shown in Table 3, the performance of most LLMs in this binary classification task ranges from 60% to 80%, indicating the complexity of this task. The best result is achieved by GPT-4, which reaches an overall average accuracy of 87.7%. However, this may still fall short of guaranteeing the validity of the self-verification approach since it is only the performance of identifying single-step fallacies. For a long argument comprising multiple reasoning steps, the overall verification performance for the

Model	Formal					Informal						Avg.

Formal → Proposition → Denying the Antecedent
- Since [if you have a pinna, then you can hear] and [you do not have a pinna], therefore, [you cannot hear]. **Prediction:** Yes. ✗
- Since [if you do not have a pinna, then you cannot hear] and [you do not have a pinna], therefore, [you cannot hear]. **Prediction:** Yes. ✓

Formal → Syllogism → Exclusive Premises
- Since [no psychologists are proponents of shock therapy] and [some proponents of shock therapy are not doctors], therefore, [some doctors are not psychologists]. **Prediction:** Yes. ✗
- Since [no psychologists are proponents of shock therapy] and [some doctors are proponents of shock therapy], therefore, [some doctors are not psychologists]. **Prediction:** Yes. ✓

Informal → Irrelevance → Appeal to Pity
- Since [my horse's stirrups are broken] and [I thus had to make a pitiful 10-mile walk in the pouring rain to get home], therefore, [the broken stirrups should be replaced by the store for free]. **Prediction:** No. ✓
- Since [my horse's stirrups are broken] and [the stirrups were under warranty], therefore, [the broken stirrups should be replaced by the store for free]. **Prediction:** Yes. ✓

Informal → Insufficiency → Questionable Cause
- Since [grebos are often seen during rainstorms] and [rainstorms cause floods], therefore, [grebos cause floods]. **Prediction:** No. ✓
- Since [grebos are often seen during rainstorms] and [rainstorms cause floods], therefore, [grebos can be seen during floods]. **Prediction:** No. ✗

Table 4: Contrastive reasoning steps in FALLACIES and verification predictions of GPT-4. Fallacious steps (the first sentence of each cell) are in red and correct ones (the second sentence of each cell) in green. ✓ and ✗ indicates whether the prediction matches the label or not.

entire argument could be the product of the verification performances of each individual step. Consequently, the overall verification performance of the argument might decrease exponentially with the number of steps in it. These results suggest that we need further research on existing self-verification methods to understand how they work and under what situations they can provide correct verification feedback.

Formal fallacy is more difficult than informal fallacy for LLMs. The performance of most LLMs on formal fallacies is much lower than on informal fallacies. For example, GPT-3.5 achieves 87.9% accuracy on formal fallacies, while it achieves only 74.1% accuracy on informal fallacies. As stated in Sec. 3.2, formal fallacies are more related to the logical structure of reasoning and require a greater emphasis on the understanding and utilization of formal logic. On the other hand, informal fallacies focus more on the content and semantics of the reasoning and may involve factors such as linguistic expression, semantic understanding, and semantic relevance. Therefore, the differences in the performance of LLMs across different types of fallacies may stem from their ability to understand logical structures and semantic meanings, i.e., the models present some challenges in dealing with the logical structures under the natural language, whereas they perform better in dealing with issues related to content and semantics. Taking a more fine-grained view, among formal fallacies, most models typically perform well on syllogism fallacies and poorly on proposition and probability fallacies. For informal fallacies, most models perform worse on ambiguity fallacies and have closer performance on the remaining four sub-categories.

The performance of the same model on different types of fallacies can be remarkably im-

Table 5: Accuracy results (%) on classifying the fallacy types of fallacious steps.

balanced. For example, the model Qwen-14B achieves an impressive 91.7% accuracy on the inconsistency fallacies but drops to a mere 67.5% on probability fallacies. This highlights a key observation that models may have superior verification abilities on some types of fallacy but are not necessarily equally well adapted to other types of fallacy. Such imbalance performance could be particularly important for practical applications, as different types of fallacies are not always evenly distributed in a given dataset or scenario, and certain types of fallacies might be more frequent. Therefore, we should not rely on a particular dataset when using or researching self-verification methods. Instead, we need to comprehensively consider the performance of the methods in dealing with different fallacies and scenarios.

GPT-4 achieves superior performance, particularly in identifying formal fallacies. Compared to the other models, GPT-4 achieves the best results in overall average accuracy. This gap is insignificant on informal fallacies, where models such as WizardLM-13B, Vicuna-13B, and Qwen-14B have comparable or even better average accuracies than GPT-4 on informal fallacies. However, on formal fallacies, GPT-4's accuracy is 13.5% higher than the second-best model (88.2% for GPT-4 compared to 74.7% for the second-best model Qwen-14B). The results suggest that GPT-4 demonstrates superior abilities in identifying fallacies related to logical structures than other LLMs. However, there is still room to improve the performance of GPT-4. Table 4 demonstrates the prediction results of GPT-4 in some cases. It can be seen that GPT-4 can also fail on some challenging samples.

Prompt for Classifying Fallacy Types

You are a logical fallacy classifier. Given an incorrect reasoning step, your task is to identify its type of fallacy. Answer by choosing one of these fallacies:
{(1) Affirming the Consequent
(2) Denying the Antecedent
. . . . . .
(232) Alleged Certainty}
You should only answer the name of the fallacy.
What type of fallacy does the following reasoning step belong to?
{reasoning step}

4.4 Can LLMs distinguish types of logical fallacies?

In addition to whether LLMs can identify between correct and incorrect, we are also interested in whether LLMs can distinguish between different types of fallacies. Classifying types of fallacies requires the model to understand not only the pattern of errors in reasoning but also where the errors occur and why they may occur, which requires a higher level of reasoning ability. Given an error reasoning step, we require the model to recognize the error pattern within it and classify it as one of the 232 fallacies. We conduct experiments on the 2,320 fallacy steps in FALLACIES and calculate the macro average accuracy. Previous work has also explored this task and named it "logical fallacy

Model	Formal	Informal	Avg.
Flan-T5-Large	62.3 (+1.3)	65.5 (-8.1)	63.9 (-3.4)
Flan-T5-xl	56.6 (-11.3)	67.1 (-7.0)	61.8 (-9.2)

Vicuna-13B	61.6 (-8.2)	67.7 (-18.7)	64.6 (-13.5)
Qwen-14B	71.1 (-3.6)	79.2 (-9.0)	75.2 (-6.3)
GPT-3.5	75.1 (+1.0)	75.7 (-12.2)	75.4 (-5.6)
GPT-4	91.2 (+3.0)	84.9 (-2.3)	88.0 (+0.3)

Table 6: Accuracy results (%) of identifying fallacious steps given the definitions of corresponding fallacies. We present the performance variations in the case with the definitions in parentheses compared to the case without definitions.

detection" (Jin et al., 2022). However, they only classify over 13 types of fallacies, whereas our task requires classifying over 232 types. Our task is more challenging and allows for fine-grained and hierarchical analysis. We evaluate the model using the same prompt in a zero-shot setting.

Table 5 shows the results. First, this task is very challenging for the existing LLMs. The models' performances are poor, with less than 10% overall accuracy, except for three models, GPT-4, GPT-3.5, and Flan-T5-xxl. For example, Vicuna-13B can achieve 78.1% accuracy on identifying fallacious steps, but only 4.2% accuracy on this task. Among all the models, GPT-4 performs the best, achieving an overall accuracy of 35.0%. This indicates that GPT-4 can recognize and classify the reasoning error patterns to a certain degree, showing a stronger reasoning ability than other models. Nevertheless, there is still substantial room for improvement. Further research may be required to achieve higher accuracy and enhance reasoning ability.

It is worth noting that on this task, the models typically perform better on formal than informal fallacies. This is inconsistent with the observation in identifying fallacious steps (Table 3). When identifying fallacious steps, models typically perform worse on formal fallacies and better on informal fallacies. There could be various reasons for this inconsistency. One possible explanation is that the models might just know the names of the fallacies rather than having an in-depth understanding of what these fallacies are. In determining whether there is an error in reasoning, the models might not be relying directly on their understanding of reasoning or fallacies but on some other abilities, which thus contributes to this inconsistency.

Prompt for Identifying Fallacious Steps Given Fallacy Definition

You are a trained model capable of identifying the logical fallacy known as {fallacy}.
This is the definition for {fallacy}: {fallacy definition}
Is the following reasoning step correct? You can only answer "Yes" or "No."
{reasoning step}

4.5 Can LLMs understand fallacies better from their definitions?

We test whether LLMs can perform better in identifying fallacious steps given the fallacy definition. Specifically, for each step in FALLACIES, we add the name and definition of its corresponding fallacy to the prompt of LLMs in advance. We then ask the model to determine whether the reasoning step is correct as before. As stated in Sec. 3.3, the definitions of fallacies are gathered from academic sources. An example of the definition can be found in Figure 3 in the Appendix.

We can observe a surprising trend by analyzing the results in Table 6. When definitions of corresponding fallacies are provided in advance, most models' performance decreases rather than improves. For instance, the overall accuracy of Vicuna-13B decreases from 78.1% to 64.6%, with a 13.5% decrease. These results suggest that providing definitions may hurt models' performance.

The reasons for this phenomenon deserve further exploration. One possible reason is that, in pre-trained data, the definitions and the fallacies themselves may not co-occur frequently, resulting in a mismatch with the current setting. Moreover, the mechanism by which the models judge fallacies has not yet been fully clarified. In this case, even if the definitions are provided, the models fail to improve performance. Instead, the prompt becomes complex with the addition of definitions, possibly interfering with their decision-making process. These observations inspire us that more intensive research is called to understand what are the mechanisms by which LLMs understand the reasoning and fallacies.

5 Conclusion

In this paper, we take a closer look at the verification abilities of LLMs in logical reasoning. We collect a dataset containing 232 fallacies and propose a hierarchical taxonomy of fallacies. Our main experimental finding is that most LLMs still struggle to identify fallacies in logical reasoning accurately. This implies that it may be overly optimistic to expect LLMs to be able to inherently identify errors and conduct self-verification reasoning, at least with respect to the current state of technology. Therefore, researchers and practitioners should be more cautious in using self-verification methods. We call for more research to explore the potentials and limitations of self-verification methods to steer LLMs towards improved accuracy and reliability.

Limitations

In this paper, we present an intensive investigation and evaluation of the verification abilities of Large Language Models (LLMs) for logical reasoning. Although we have reached some findings, we are also aware that there is still some room for improvement and future research areas worth exploring.

Firstly, we conduct experiments only on the most common LLMs. Such a limitation comes from two main reasons: one is due to the limitation of computational resources of our research team; and the other is the barrier of access to certain closed-source models. This results in our inability to perform detailed experiments on all types and all scales of models. Thus, our results may not fully reflect the abilities of all LLMs. In future studies, it is worthwhile to turn our attention to more types and scales of models to provide a more comprehensive evaluation of their abilities.

Second, our study focused mainly on the aspect of logical reasoning. Reasoning in real-world applications often encompasses other types of reasoning, such as numerical reasoning. It would be interesting to extend our research to more types of reasoning. By doing so, we can reveal the boundaries of the abilities of LLMs in these areas, which can enhance our deeper understanding of the performance of LLMs. Meanwhile, it would also help us to figure out how we can improve the accuracy and robustness of the reasoning of LLMs.

This article follows the ACL Code of Ethics. To the best of our knowledge, our work is foundational research, and we do not find obvious risks related to malicious harmful effects, environmental impact, fairness considerations, or privacy considerations.

A Details of Data Collection

To generate candidate fallacious steps, we prompt GPT-4 with the following content. Figure 3 shows an example of the fallacy definition. Note that the steps generated by GPT-4 are only used as candidates. We then have human experts proofread and revise them to ensure the quality of the data. We invited 10 well-trained graduate students from universities as human expert annotators. They have passed the graduate school entrance exam and have well logical reasoning skills. They have undergone rigorous training in areas including Mathematical Logic, Computer Science, Programming, and Statistics.

Prompt for Generating Candidate Fallacious Steps

You are a faulty reasoner. I will describe a logical fallacy to you, and then you generate a reasoning step that belongs to this logical fallacy.
Here is the description: {fallacy definition}
Now, generate a reasoning step that contains this type of logical fallacy. The generated step should be related to this element: {entity}
Use square brackets [] to include propositions. The format of the output is "Since [XXX] and [XXX], therefore, [XXX]

In the end of the appendix, Table 11 shows the detailed categorizations and descriptions of the 232 fallacies in our dataset.

B Details of Experiments

B.1 Models

Table 7 shows the version and source URL of the LLMs used in our experiments. For all series of LLMs, we select their versions of instruction fine-tuned or chat fine-tuned, since these models are closest to realistic applications. We follow the licences of these models to use them.

B.2 Prompt Selection

To select suitable prompts and to explore the impact of prompts on model performance, we conduct an ablation study on the prompts. Table 8 demonstrates the prompts we used. Prompt 1 is the simplest prompt. The model is expected to answer "Yes" for the correct reasoning steps and "No" for the incorrect reasoning steps. Prompt 2, alternatively, replaces the response "Yes/No" with "True/False." Prompt 3 adopts a Chain-of-Thought-style prompt (Kojima et al., 2022) that allows the model to generate some relevant rationales before giving the prediction. Prompt 4 describes the task in more detail. Moreover, in contrast to Prompt 1, Prompt 4 requires the model to answer "Yes" for incorrect reasoning steps (which contain logical fallacies) and "No" to correct reasoning steps (which do not contain logical fallacies).

Table 9 demonstrates the results. We can find that Prompt 1 works well for all models. For Prompt 2, some of the models show significant performance degradation after replacing the response words. Prompt 3 introduces chains of thought, but does not achieve significant performance gains on all models. For Prompt 4, although it describes the task in more detail, it does not seem to help improve the LLMs' performance. Among all the models, GPT-4 exhibits the strongest robustness to prompts, achieving similar performance with different prompts. Comprehensively, we finally chose Prompt 1 as our prompt.

B.3 Few-shot Setting

We also conduct experiments under few-shot setting. We include four demonstrations in the prompt, covering the correct and fallacious steps related to formal and informal fallacies.

Prompt for Identifying Fallacious Steps under Few-shot Setting

Is the following reasoning step correct? You can only answer "Yes" or "No."
Since [If it's raining then the streets are wet] and [It's raining now], therefore, [The streets are wet].
Yes.
Since [I found a shell on the beach] and [this shell was beautifully shaped and colored], therefore, [all shells are beautifully shaped and colored].
No.
Since [I am at home or I am in the city] and [I am at home], therefore, [I am not in the city].
No.
Since [heavy snowfall often leads to traffic jams] and [traffic jams cause delays], therefore, [heavy snowfall can lead to delays].
Yes.
{reasoning step}

Table 10 demonstrates the performance of identifying fallacious steps under few-shot setting. We can find that most of the LLMs achieve comparable performance under few-shot setting compared to that under zero-shot setting. Moreover, our findings in Sec 4.3 stand under the few-shot setting as well.

The **description** of the fallacy of type "Affirming the Consequent" is "An error in formal logic where if the consequent is said to be true, the antecedent is said to be true, as a result."

The **abstract logical form** is

If P then Q.
Q.
Therefore, P.

The following are **some examples and their explanations** of the fallacy of type "Affirming the Consequent."

Example #1:

If taxes are lowered, I will have more money to spend.
I have more money to spend.
Therefore, taxes must have been lowered.

Explanation: I could have had more money to spend simply because I gave up crack-cocaine, prostitute solicitation, and baby-seal-clubbing expeditions.

Example #2:

If it's brown, flush it down.
I flushed it down.
Therefore, it was brown.

Explanation: No! I did not have to follow the, "if it's yellow, let it mellow" rule -- in fact, if I did follow that rule I would probably still be single. The stated rule is simply, "if it's brown" (the antecedent), then (implied), "flush it down" (the consequent). From this, we cannot imply that we can ONLY flush it down if it is brown.

Figure 3: The definition of the fallacy of "Affirming the Consequent", one of 232 types of fallacies in our dataset.

Table 10: Accuracy results (%) of identifying fallacious steps under few-shot setting.

Category	Name of Fallacy	Description of Fallacy
Formal-Proposition	Affirming the Consequent	An error in formal logic where if the consequent is said to be true, the antecedent is said to be true, as a result.
	Denying the Antecedent	It is a fallacy where in a standard if/then premise, the antecedent (what comes after the "if") is made not true, then it is concluded that the consequent (what comes after the "then") is not true.
	Negating Antecedent and Consequent	The valid form of this argument is as follows: If P then Q. Therefore, if not-Q then not-P.
	Commutation of Conditionals	Switching the antecedent and the consequent in a logical argument.
	Affirming a Disjunct	Making the false assumption that when presented with an either/or possibility, that if one of the options is true that the other one must be false.
	Denying a Conjunct	A formal fallacy in which the first premise states that at least one of the two conjuncts (antecedent and consequent) is false and concludes that the other conjunct must be true.
Formal-Quantification	False Conversion	The formal fallacy where the subject and the predicate terms of the proposition are switched (conversion) in the conclusion, in a proposition that uses "all" in its premise (type "A" forms), or "some/not" (type "O" forms).
	Unwarranted Contrast	Assuming that implicature means implication, when it logically does not.
	Quantifier Shift Fallacy	A fallacy of reversing the order of two quantifiers.
	Existential Fallacy	A formal logical fallacy, which is committed when a categorical syllogism employs two universal premises ("all") to arrive at a particular ("some") conclusion.
	Fallacy of Every and All	When an argument contains both universal quantifiers and existential quantifiers (all, some, none, every) with different meanings, and the order of the quantifiers is reversed.
	Illicit Contraposition	A formal fallacy where switching the subject and predicate terms of a categorical proposition, then negating each, results in an invalid argument form.
Formal-Syllogism	Fallacy of the Undistributed Middle	A formal fallacy in a categorical syllogism where the middle term, or the term that does not appear in the conclusion, is not distributed to the other two terms.
	Exclusive Premises	A standard form categorical syllogism that has two negative premises either in the form of "no X are Y" or "some X are not Y".
	Fallacy of Four Terms	This fallacy occurs in a categorical syllogism when the syllogism has four terms rather than the requisite three.
	Illicit Substitution of Identicals	A fallacy due to confusing the knowing of a thing (extension) with the knowing of it under all its various names or descriptions (intension).
	Illicit Minor	Any form of a categorical syllogism in which the minor term is distributed in the conclusion, but not in the minor premise.
	Illicit Major	Any form of a categorical syllogism in which the major term is distributed in the conclusion, but not in the major premise.
	Negative Conclusion from Affirmative Premises	The conclusion of a standard form categorical syllogism is negative, but both of the premises are positive.
	Affirmative Conclusion from a Negative Premise	The conclusion of a standard form categorical syllogism is affirmative, but at least one of the premises is negative.
Formal-Probability	Gamblers Fallacy	Reasoning that, in a situation that is pure random chance, the outcome can be affected by previous outcomes.
	Hot Hand Fallacy	The irrational belief that if you win or lose several chance games in a row, you are either "hot" or "cold," respectively, meaning that the streak is likely to continue and has to do with something other than pure probability.

	Conjunction Fallacy	This occurs when one estimates a conjunctive statement (this and that) to be more probable than at least one of its component statements.
	Disjunction Fallacy	It occurs when one estimates a disjunctive statement (this or that) to be less probable than at least one of its component statements.
Informal-Ambiguity	Argument of the Beard	When one argues that no useful distinction can be made between two extremes, just because there is no definable moment or point on the spectrum where the two extremes meet.
	Appeal to Extremes	Erroneously attempting to make a reasonable argument into an absurd one, by taking the argument to the extremes.
	Type Token Fallacy	The type-token fallacy is committed when a word can refer to either a type (representing an abstract descriptive concept) or a token (representing an object that instantiates a concept) and is used in a way that makes it unclear which it refers to.
	Use Mention Error	Confusing the word used to describe a thing, with the thing itself.
	Reification	When an abstraction is treated as if it were a concrete, real event or physical entity – when an idea is treated as if had a real existence.
	Fake Precision	Using implausibly precise statistics to give the appearance of truth and certainty, or using a negligible difference in data to draw incorrect inferences.
	No True Scotsman	When a universal (“all”, “every”, etc.) claim is refuted, rather than conceding the point or meaningfully revising the claim, the claim is altered by going from universal to specific, and failing to give any objective criteria for the specificity.
	Contextomy	Removing a passage from its surrounding matter in such a way as to distort its intended meaning.
	Stolen Concept Fallacy	Requiring the truth of the something that you are simultaneously trying to disprove.
	Anthropomorphism	The attributing of human characteristics and purposes to inanimate objects, animals, plants, or other natural phenomena, or to gods.
	Accent Fallacy	When the meaning of a word, sentence, or entire idea is interpreted differently by changing where the accent falls.
	Ambiguity Fallacy	When an unclear phrase with multiple definitions is used within the argument; therefore, does not support the conclusion.
	Alphabet Soup	The deliberate and excessive use of acronyms and abbreviations to appear more knowledgeable in the subject or confuse others.
	Equivocation	Using an ambiguous term in more than one sense, thus making an argument misleading.
	Modal Scope Fallacy	Making a formal argument invalid by confusing the scope of what is actually necessary or possible.
Informal-Inconsistency	Inconsistency	In terms of a fallacious argument, two or more propositions are asserted that cannot both possibly be true.
	Conflicting Conditions	When the argument is self-contradictory and cannot possibly be true.
	Kettle Logic	Making (usually) multiple, contradicting arguments, in an attempt to support a single point or idea.
Informal-Irrelevance	Political Correctness Fallacy	It is the assumption or admission that two or more groups, individuals, or ideas of groups or individuals, are equal, of equal value, or both true, based on the recent phenomenon of political correctness.
	Appeal to Complexity	Concluding that because you don’t understand something, it must not be true, it’s improbable, or the argument must be flawed.
	Statement of Conversion	Accepting the truth of a claim based on a conversion story without considering any evidence for the truth of the claim.
	Appeal to the Moon	Using the argument, “If we can put a man on the moon, we could...” as evidence for the argument.
	Quantum Physics Fallacy	Using quantum physics in an attempt to support your claim, when in no way is your claim related to quantum physics.

fact to fiction fallacy	Attempting to support a narrative or argument with facts that don't support the narrative or argument.
Non Sequitur	Evidence or reason is irrelevant or adds very little support to the conclusion.
Inflation of Conflict	Reasoning that because authorities cannot agree precisely on an issue, no conclusions can be reached at all, and minimizing the credibility of the authorities, as a result.
Argument by Fast Talking	When fast talking is seen as intelligence and/or confidence in the truth of one's argument; therefore, seen as evidence of the truth of the argument itself.
Appeal to Intuition	Evaluating an argument based on "intuition" or "gut feeling" that is unable to be articulated, rather than evaluating the argument using reason.
Appeal to Closure	Accepting evidence on the basis of wanting closure, or to be done with the issue.
Appeal to Definition	Using a dictionary's limited definition of a term as evidence that term cannot have another meaning, expanded meaning, or even conflicting meaning.
Spiritual Fallacy	Insisting that something meant to be literal is actually "spiritual" as an explanation or justification for something that otherwise would not fit in an explanation.
gish gallop	Overwhelming an interlocutor with as many arguments as possible, without regard for accuracy or strength of the arguments.
Denying the Correlative	Introducing alternatives when, in fact, there are none.
Red Herring	Attempting to redirect the argument to another issue to which the person doing the redirecting can better respond.
Strawman Fallacy	Substituting a person's actual position or argument with a distorted, exaggerated, or misrepresented version of the position of the argument.
Avoiding the Issue	When an arguer responds to an argument by not addressing the points of the argument.
Logic Chopping	Using the technical tools of logic in an unhelpful and pedantic manner by focusing on trivial details instead of directly addressing the main issue in dispute.
Meaningless Question	Asking a question that cannot be answered with any sort of rational meaning.
Failure to Elucidate	When the definition is made more difficult to understand than the word or concept being defined.
Argument by Gibberish	When incomprehensible jargon or plain incoherent gibberish is used to give the appearance of a strong argument, in place of evidence or valid reasons to accept the argument.
Hypnotic Bait and Switch	Stating several uncontroversially true statements in succession, followed by a claim that the arguer wants the audience to accept as true.
Traitorous Critic Fallacy	Responding to criticism by attacking a person's perceived favorability to an out-group or dislike to the in-group as the underlying reason for the criticism rather than addressing the criticism itself, and suggesting that they stay away from the issue and/or leave the in-group.
Having Your Cake	Making an argument, or responding to one, in such a way that it does not make it at all clear what your position is.
Appeal to Common Belief	When the claim that most or many people in general or of a particular group accept a belief as true is presented as evidence for the claim.
Appeal to Popularity	Using the popularity of a premise or proposition as evidence for its truthfulness.
Appeal to Common Sense	Asserting that your conclusion or facts are just "common sense" when, in fact, they are not.
Appeal to Common Folk	In place of evidence, attempting to establish a connection to the audience based on being a "regular person" just like each of them.

Appeal to Trust	The belief that if a source is considered trustworthy or untrustworthy, then any information from that source must be true or false, respectively.
Argument from Age	The misconception that previous generations had superior wisdom to modern man, thus conclusions that rely on this wisdom are seen accepted as true or more true than they actually are.
Appeal to Heaven	Asserting the conclusion must be accepted because it is the "will of God" or "the will of the gods".
Appeal to Tradition	Using historical preferences of the people (tradition), either in general or as specific as the historical preferences of a single individual, as evidence that the historical preference is correct.
Etymological Fallacy	The assumption that the present-day meaning of a word should be/is similar to the historical meaning.
Genetic Fallacy	Basing the truth claim of an argument on the origin of its claims or premises.
Appeal to Celebrity	Accepting a claim of a celebrity based on his or her celebrity status, not on the strength of the argument.
Appeal to Authority	Insisting that a claim is true simply because a valid authority or expert on the issue said it was true, without any other supporting evidence offered.
Appeal to False Authority	Using an alleged authority as evidence in your argument when the authority is not really an authority on the facts relevant to the argument.
Argument from False Authority	When a person making a claim is presented as an expert who should be trusted when his or her expertise is not in the area being discussed.
Blind Authority Fallacy	Asserting that a proposition is true solely on the authority making the claim.
Argument by Personal Charm	When an argument is made stronger by the personal characteristics of the person making the argument, often referred to as "charm".
Argument to the Purse	Concluding that the truth value of the argument is true or false based on the financial status of the author of the argument or the money value associated with the truth.
Ad Hominem Circumstantial	Suggesting that the person who is making the argument is biased or predisposed to take a particular stance, and therefore, the argument is necessarily invalid.
Gadarene Swine Fallacy	The assumption that because an individual is not in formation with the group, that the individual must be the one off course.
Ad Hominem Tu quoque	Claiming the argument is flawed by pointing out that the one making the argument is not acting consistently with the claims of the argument.
Bulverism	It is the assumption and assertion that an argument is flawed or false because of the arguer's characteristic associated with the arguer's identity.
Righteousness Fallacy	Assuming that just because a person's intentions are good, they have the truth or facts on their side.
Self Righteousness Fallacy	Assuming that just because your intentions are good, you have the truth or facts on your side.
Reductio ad Hitlerum	The attempt to make an argument analogous with Hitler or the Nazi party.
Ad Hominem Guilt by Association	When the source is viewed negatively because of its association with another person or group who is already viewed negatively.
Identity Fallacy	When one's argument is evaluated based on their physical or social identity when the strength of the argument is independent of identity.
Appeal to Stupidity	Attempting to get the audience to devalue reason and intellectual discourse, or devaluing reason and intellectual discourse based on the rhetoric of an arguer.

Ad Hominem Abusive	Attacking the person making the argument, rather than the argument itself, when the attack on the person is completely irrelevant to the argument the person is making.
Ad Fidentia	Attacking the person's self-confidence in place of the argument or the evidence.
appeal to loyalty	When one is either implicitly or explicitly encouraged to consider loyalty when evaluating the argument when the truth of the argument is independent of loyalty.
Appeal to Accomplishment	When the argument being made is sheltered from criticism based on the level of accomplishment of the one making the argument.
Scapegoating	Unfairly blaming an unpopular person or group of people for a problem or a person or group that is an easy target for such blame.
Fallacy of Opposition	Asserting that those who disagree with you must be wrong and not thinking straight, primarily based on the fact that they are the opposition.
Proof by Intimidation	Making an argument purposely difficult to understand in an attempt to intimidate your audience into accepting it, or accepting an argument without evidence or being intimidated to question the authority or a priori assumptions of the one making the argument.
Poisoning the Well	To prime the audience with adverse information about the opponent from the start, in an attempt to make your claim more acceptable or discount the credibility of your opponent's claim.
Wishful Thinking	When the desire for something to be true is used in place of/or as evidence for the truthfulness of the claim.
Appeal to Faith	It is the assertion that one must have (the right kind of) faith in order to understand the argument.
Notable Effort	Accepting good effort as a valid reason to accept the truth of the conclusion, even though the effort is unrelated to the truth.
Prejudicial Language	Loaded or emotive terms used to attach value or moral goodness to believing the proposition.
Special Pleading	Applying standards, principles, and/or rules to other people or circumstances, while making oneself or certain circumstances exempt from the same critical criteria, without providing adequate justification.
If By Whiskey	A response to a question that is contingent on the questioner's opinions and makes use of words with strong connotations.
Overextended Outrage	One or more statistically rare cases are implied to be the norm or the trend (without evidence) for the purpose of expressing or inciting outrage toward an entire group.
Appeal to Ridicule	Presenting the argument in such a way that makes the argument look ridiculous, usually by misrepresenting the argument or the use of exaggeration.
Argument by Emotive Language	Substituting facts and evidence with words that stir up emotion, with the attempt to manipulate others into accepting the truth of the argument.
Style Over Substance	When the arguer embellishes the argument with compelling language or rhetoric, and/or visual aesthetics.
Appeal to Anger	When the emotions of anger, hatred, or rage are substituted for evidence in an argument.
Appeal to Pity	The attempt to distract from the truth of the conclusion by the use of pity.
Appeal to Emotion	This is the general category of many fallacies that use emotion in place of reason in order to attempt to win the argument.
Appeal to Flattery	When an attempt is made to win support for an argument, not by the strength of the argument, but by using flattery on those whom you want to accept your argument.
Appeal to Spite	Substituting spite (petty ill will or hatred with the disposition to irritate, annoy, or thwart) for evidence in an argument, or as a reason to support or reject a claim.

	pragmatic fallacy	Claiming that something is true because the person making the claim has experienced, or is referring to someone who has experienced, some practical benefit from believing the thing to be true.
	Appeal to Force	When force, coercion, or even a threat of force is used in place of a reason in an attempt to justify a conclusion.
	Appeal to Fear	When fear, not based on evidence or reason, is being used as the primary motivator to get others to accept an idea, proposition, or conclusion.
Informal-Insufficiency	Fallacy of Composition	Inferring that something is true of the whole from the fact that it is true of some part of the whole.
	Fallacy of Division	Inferring that something is true of one or more of the parts from the fact that it is true of the whole.
	Stereotyping the fallacy	The general beliefs that we use to categorize people, objects, and events while assuming those beliefs are accurate generalizations of the whole group.
	Ecological Fallacy	The interpretation of statistical data where inferences about the nature of individuals are deduced from inference for the group to which those individuals belong.
	Oversimplified Cause Fallacy	When a contributing factor is assumed to be the cause, or when a complex array of causal factors is reduced to a single cause.
	Accident Fallacy	When an attempt is made to apply a general rule to all situations when clearly there are exceptions to the rule.
	mcnamara fallacy	When a decision is based solely on quantitative observations (i.e., metrics, hard data, statistics) and all qualitative factors are ignored.
	Overwhelming Exception	A generalization that is technically accurate, but has one or more qualifications which eliminate so many cases that the resulting argument is significantly weaker than the arguer implies.
	Reductio ad Absurdum	A mode of argumentation or a form of argument in which a proposition is disproven by following its implications logically to an absurd conclusion.
	Nirvana Fallacy	Comparing a realistic solution with an idealized one, and discounting or even dismissing the realistic solution.
	Relative Privation	Trying to make a scenario appear better or worse by comparing it to the best or worst case scenario.
	imposter fallacy	When one suggests or claims, with insufficient evidence, that the group outliers who are viewed as damaging to the group are primarily made up of infiltrators of another group with the purpose of making the infiltrated group look bad.
	Misleading Vividness	A small number of dramatic and vivid events are taken to outweigh a significant amount of statistical evidence.
	Appeal to Possibility	When a conclusion is assumed not because it is probably true, but because it is possible that it is true, no matter how improbable.
	Rights To Ought Fallacy	When one conflates a reason for one's rights (constitutional or other) with what one should do.
	Psychogenetic Fallacy	Inferring some psychological reason why an argument is made then assuming it is invalid, as a result.
	Weak Analogy	When an analogy is used to prove or disprove an argument, but the analogy is too dissimilar to be effective, that is, it is unlike the argument more than it is like the argument.
	Extended Analogy	Suggesting that because two things are alike in some way and one of those things is like something else, then both things must be like that "something else".
	Appeal to Equality	An assertion is deemed true or false based on an assumed pretense of equality, where what exactly is "equal" is not made clear, and not supported by the argument.
	False Equivalence	An argument or claim in which two completely opposing arguments appear to be logically equivalent when in fact they are not.

Galileo Fallacy	The claim that because an idea is forbidden, prosecuted, detested, or otherwise mocked, it must be true, or should be given more credibility.
Post Designation	Drawing a conclusion from correlations observed in a given sample, but only after the sample has already been drawn, and without declaring in advance what correlations the experimenter was expecting to find.
Just In Case Fallacy	Making an argument based on the worst-case scenario rather than the most probable scenario, allowing fear to prevail over reason.
Selective Attention	Focusing your attention on certain aspects of the argument while completely ignoring or missing other parts.
nutpicking fallacy	When someone presents an atypical or weak member of a group as if they are a typical or strong representative.
Biased Sample Fallacy	Drawing a conclusion about a population based on a sample that is biased, or chosen in order to make it appear the population on average is different than it actually is.
Survivorship Fallacy	In its general form, the survivorship fallacy is basing a conclusion on a limited number of "winner" testimonies due to the fact we cannot or do not hear the testimonies of the losers.
Spotlight Fallacy	Assuming that the media's coverage of a certain class or category is representative of the class or category in whole.
Hasty Generalization	Drawing a conclusion based on a small sample size, rather than looking at statistics that are much more in line with the typical or average situation.
Incomplete Comparison	An incomplete assertion that cannot possibly be refuted. This is popular in advertising.
Texas Sharpshooter Fallacy	Ignoring the difference while focusing on the similarities, thus coming to an inaccurate conclusion.
Faulty Comparison	Comparing one thing to another that is really not related, in order to make one thing look more or less desirable than it really is.
Base Rate Fallacy	Ignoring statistical information in favor of using irrelevant information, that one incorrectly believes to be relevant, to make a judgment.
Least Plausible Hypothesis	Choosing more unreasonable explanations for phenomena over more defensible ones.
Far Fetched Hypothesis	Offering a bizarre (far-fetched) hypothesis as the correct explanation without first ruling out more mundane explanations.
Cherry Picking	When only select evidence is presented in order to persuade the audience to accept a position, and evidence that would go against the position is withheld.
Argument by Selective Reading	When a series of arguments or claims is made and the opponent acts as if the weakest argument was the best one made.
deceptive sharing	Sharing an article, post, or meme on social media with the intent to influence public perception to perceive a statistically rare event as a common event.
Multiple Comparisons Fallacy	Claiming that unexpected trends that occur through random chance alone in a data set with a large number of variables are meaningful.
Magical Thinking	Making causal connections or correlations between two events not based on logic or evidence, but primarily based on superstition.
Slippery Slope	When a relatively insignificant first event is suggested to lead to a more significant event, which in turn leads to a more significant event, and so on, until some ultimate, significant event is reached, where the connection of each event is not only unwarranted but with each step it becomes more and more improbable.
Sunk Cost Fallacy	Reasoning that further investment is warranted on the fact that the resources already invested will be lost otherwise, not taking into consideration the overall losses involved in the further investment.
Jumping to Conclusions	Drawing a conclusion without taking the needed time to evaluate the evidence or reason through the argument.

	Argument from Silence	Drawing a conclusion based on the silence of the opponent, when the opponent is refusing to give evidence for any reason.
	Argument from Hearsay	Presenting the testimony of a source that is not an eyewitness to the event in question.
	Anonymous Authority	When an unspecified source is used as evidence for the claim.
	Insignificant Cause	An explanation that posits one minor factor, out of several that contributed, as its sole cause.
	Just Because Fallacy	Refusing to respond to give reasons or evidence for a claim by stating yourself as the ultimate authority on the matter.
	Appeal to the Law	When following the law is assumed to be the morally correct thing to do, without justification, or when breaking the law is assumed to be the morally wrong thing to do, without justification.
	Appeal to Normality	Using social norms to determine what is good or bad.
	False Effect	Claiming that the cause is true or false based on what we know about the effect in a claim of causality that has not been properly established.
	Appeal to Consequences	Concluding that an idea or proposition is true or false because the consequences of it being true or false are desirable or undesirable.
	Retrogressive Causation	Invoking the cause to eliminate the effect, or calling on the source to relieve the effect of the source.
	Confusing Currently Unexplained with Unexplainable	Making the assumption that what cannot currently be explained is, therefore, unexplainable (impossible to explain).
	Appeal to Desperation	Arguing that your conclusion, solution, or proposition is right based on the fact that something must be done, and your solution is "something."
	Regression Fallacy	Ascribing a cause where none exists in situations where natural fluctuations exist while failing to account for these natural fluctuations.
	Causal Reductionism	Assuming a single cause or reason when there were actually multiple causes or reasons.
	Questionable Cause	Concluding that one thing caused another, simply because they are regularly associated.
Informal-Inappropriate Presumption	Hedging	Refining your claim simply to avoid counter evidence and then acting as if your revised claim is the same as the original.
	Circular Definition	A circular definition is defining a term by using the term in the definition.
	Homunculus Fallacy	An argument that accounts for a phenomenon in terms of the very phenomenon that it is supposed to explain, which results in an infinite regress.
	Circular Reasoning	A type of reasoning in which the proposition is supported by the premises, which is supported by the proposition.
	Tokenism	Interpreting a token gesture as an adequate substitute for the real thing.
	Appeal to Novelty	Claiming that something that is new or modern is superior to the status quo, based exclusively on its newness.
	Two Wrongs Make a Right	When a person attempts to justify an action against another person because the other person did take or would take the same action against him or her.
	Appeal to Nature	When used as a fallacy, the belief or suggestion that “natural” is better than “unnatural” based on its naturalness.
	Naturalistic Fallacy	When the conclusion expresses what ought to be, based only on what is, or what ought not to be, based on what is not.
	Moralistic Fallacy	When the conclusion expresses what is, based only on what one believes ought to be, or what isn’t is based on what one believes ought not to be.
	Suppressed Correlative	The attempt to redefine a correlative (one of two mutually exclusive options) so that one alternative encompasses the other, i.e. making one alternative impossible.

Historians Fallacy	Judging a person's decision in the light of new information not available at the time.
Willed Ignorance	Refusing to change one's mind or consider conflicting information based on a desire to maintain one's existing beliefs.
Appeal to Coincidence	Concluding that a result is due to chance when the evidence strongly suggests otherwise.
Argument from Incredulity	Concluding that because you can't or refuse to believe something, it must not be true, improbable, or the argument must be flawed.
Argument by Pigheadedness	This is a refusal to accept a well-proven argument for one of many reasons related to stubbornness.
Argument by Repetition	Repeating an argument or a premise over and over again in place of better supporting evidence.
Definist Fallacy	Defining a term in such a way that makes one's position much easier to defend.
Limited Scope	The theory doesn't explain anything other than the phenomenon it explains (that one thing), and at best, is likely to be incomplete.
Moving the Goalposts	Demanding from an opponent that he or she address more and more points after the initial counter-argument has been satisfied refusing to concede or accept the opponent's argument.
Argument from Fallacy	Concluding that the truth value of an argument is false based on the fact that the argument contains a fallacy.
False Dilemma	When only two choices are presented yet more exist, or a spectrum of possible choices exists between two extremes.
Argument from Ignorance	The assumption of a conclusion or fact based primarily on lack of evidence to the contrary.
Alternative Advance	When one is presented with just two choices, both of which are essentially the same, just worded differently.
Shifting of the Burden of Proof	Making a claim that needs justification, then demanding that the opponent justifies the opposite of the claim.
Proving Non Existence	Demanding that one proves the non-existence of something in place of providing adequate evidence for the existence of that something.
Proof Surrogate	A claim masquerading as proof or evidence, when no such proof or evidence is actually being offered.
Rationalization	Offering false or inauthentic excuses for our claim because we know the real reasons are much less persuasive or more embarrassing to share, or harsher than the manufactured ones given.
Spin Doctoring	Presenting information in a deceptive way that results in others interpreting the information in such a way that does not reflect reality but is how you want the information to be interpreted.
Lying with Statistics	Presenting statistical data in a very biased way.
Ad Hoc Rescue	When we desperately want to be right and hold on to certain beliefs, we begin to make up excuses without no real evidence as to why our belief could be.
False Attribution	Appealing to an irrelevant, unqualified, unidentified, biased, or fabricated source in support of an argument (modern usage).
Amazing Familiarity	The argument contains information that seems impossible to have obtained—like it came from an omniscient author.
Ludic Fallacy	Assuming flawless statistical models apply to situations where they actually don't.
Missing Data Fallacy	Refusing to admit ignorance to the hypothesis and/or the conclusion, but insisting that your ignorance has to do with missing data that validate both the hypothesis and conclusion.
Begging the Question	Any form of argument where the conclusion is assumed in one of the premises.
Complex Question Fallacy	A question that has a presupposition built in, which implies something but protects the one asking the question from accusations of false claims.

	Package Deal Fallacy	Assuming things that are often grouped together must always be grouped together, or the assumption that the ungrouping will have significantly more severe effects than anticipated.
	Subjectivist Fallacy	Claiming something is true for one person, but not for someone else when, in fact, it is true for everyone (objective) as demonstrated by empirical evidence.
	Distinction Without a Difference	The assertion that a position is different from another position based on the language when, in fact, both positions are the same – at least in practice or practical terms.
	Hypothesis Contrary to Fact	Offering a poorly supported claim about what might have happened in the past or future, if (the hypothetical part) circumstances or conditions were different.
	Shoehorning	The process of force-fitting some current affair into one's personal, political, or religious agenda.
	Appeal to Self-evident Truth	Making the claim that something is "self-evident" when it is not self-evident in place of arguing a claim with reason.
	Subverted Support	The attempt to explain some phenomenon that does not actually occur or there is no evidence that it does.
	Double Standard	Judging two situations by different standards when, in fact, you should be using the same standard.
	Fantasy Projection	Confusing subjective experiences, usually very emotionally charged, with objective reality, then suggesting or demanding that others accept the subjective experience as objective reality.
	Argument to Moderation	Asserting that given any two positions, there exists a compromise between them that must be correct.
	Broken Window Fallacy	The illusion that destruction and money spent in recovery from destruction, is a net-benefit to society.
	Self Sealing Argument	An argument or position is self-sealing if and only if no evidence can be brought against it no matter what.
	Unfalsifiability	Confidently asserting that a theory or hypothesis is true or false even though the theory or hypothesis cannot possibly be contradicted by an observation or the outcome of any physical experiment, usually without strong evidence or good reasons.
	Conspiracy Theory	Explaining that your claim cannot be proven or verified because the truth is being hidden and/or evidence destroyed by a group of two or more people.
	Confusing an Explanation with an Excuse	Treating an explanation of a fact as if it were a justification of the fact, a valid reason for the fact, or evidence for the fact.
	Limited Depth	Failing to appeal to an underlying cause, and instead simply appealing to membership in a category.
	Alleged Certainty	Asserting a conclusion without evidence or premises, through a statement that makes the conclusion appear certain when, in fact, it is not.

Table 11: Categorizations and descriptions of the fallacies in our dataset.

Exploring Self-supervised Logic-enhanced Training for Large Language Models

Abstract

Traditional attempts to enhance the logical reasoning abilities of language models often rely on supervised fine-tuning, limiting their generalization to new tasks or domains. Large Language Models (LLMs), with their capacity to condense vast knowledge, can effectively tackle many tasks. Yet, our experiments reveal a gap in their performance on logical reasoning benchmarks when compared to state-of-the-art fine-tuning based models. To bridge this gap, we present LogicLLM, a first-of-its-kind, fully self-supervised framework for integrating logical reasoning capabilities into LLMs, and activating them via in-context learning. We apply this to two LLM series, FLAN-T5 and LLaMA, with parameter sizes from 3 billion to 33 billion. LogicLLM demonstrates its effectiveness through successful improvements on two logical reasoning benchmarks (ReClor and LogiQA-v2). Additionally, LogicLLM based on FLAN-T5-11B attains comparable results to ChatGPT, and evaluations with LLaMA-based models on three language understanding benchmarks (RACE, MMLU and Big-Bench-Hard) confirm that the improvements come without compromising the model's general language understanding capabilities.[1]

1 Introduction

Logical reasoning serves as a bedrock for negotiation, debate and writing, underpinning our ability to engage with complex cognitive tasks (Yu et al., 2020). An example of logic reasoning in natural language is shown in Figure 1. As the complexity of relations and expressions presented in this task defy straightforward conversion into symbolic or formal languages, perfecting logical reasoning within language models has proven to be a significant challenge (Zhong et al., 2021).

Context: Archaeologists have studied human skeletons unearthed in the Andes from 900 to 2800 years ago. Some chemical isotopic compositions extracted from them reflect that people there ate corn at that time. The corn culture led to the population growth in the Andes. Several large-scale wars at that time were also related to the competition for scarce soil suitable for planting corn. The war led to the continuous change and development of the social system. Therefore, they concluded that agriculture promoted the development of ancient Andean society.
Question: Which of the followings, if true, questions the above conclusion most?
Options:
A: Inca civilization in the Andes experienced several major social changes as early as 2800 years ago
B: People in the Andes mainly fished along the coast 3600 years ago, and did not gradually migrate inland until about 2800
C: Other chemical isotopes extracted from human bones reflect that people also ate potatoes and beans at that time
D: Social system of the Andean region has central and local governments, and then derived a variety of social forms
Answer: A

Figure 1: An example logical reasoning task from LogiQA-v2 dataset (Liu et al., 2020). The relations between different constituents, e.g., *agriculture* and *development of Andean society*, include various predicates, and it is hard to be converted into logical form through either first-order logic or formal language.

Past attempts to incorporate logical reasoning into language models primarily focused on integrating knowledge about logic. For instance, Huang et al. (2021) employed graph neural networks to capture relational semantics, while Wang et al. (2022) used data augmentation to implement first-order logic. These techniques, however, are constrained by their need for extensive annotated training data, which hinders the model's ability to generalize across different tasks due to disparities in data distribution and optimization objectives.

Conversely, recent breakthroughs in Large Language Models (LLMs) like PaLM (Chowdhery et al., 2022), LLaMA (Touvron et al., 2023), ChatGPT[2], GPT-4 (OpenAI, 2023), and Bard[3] offer a promising alternative. These LLMs effectively encapsulate a vast array of knowledge and tackle diverse tasks with minimal specialization, guided by human instruction. Despite their potential, our

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 926–941
June 16-21, 2024 ©2024 Association for Computational Linguistics

experiments on logical reasoning benchmarks revealed deficiencies in their logical reasoning capabilities as shown later in our experiments.

Contemporary efforts to fortify LLMs' specific capabilities fall broadly into two categories. The first employs external tools or APIs (Schick et al., 2023; Mialon et al., 2023; Cheng et al., 2022; Gao et al., 2022; Chen et al., 2022), aiding LLMs in argument parsing and semantic understanding. Yet, these tools' utility for logical reasoning remains limited due to the absence of a symbolic language for problem descriptions. The second category, instruction tuning, relies on data augmentation or enriched human feedback but struggles due to the scarcity of task-specific data and high annotation costs (Ouyang et al., 2022; Xu et al., 2023). In this work, we pivot away from these traditional methods and introduce LogicLLM, which performs self-supervised logic-enhanced meta-training for LLMs. It tackles two primary challenges: 1) synthesising logic-consistent data from raw texts ensuring fully self-supervised training, and 2) effectively incorporating logic prior into LLMs while preventing learning problems, such as memorization, forgetting and generalization.

To tackle the first challenge, LogicLLM emphasizes the necessity of understanding and exploiting **fuzzy logical consistency**. As mentioned previously, strict formal logic is often absent in natural language, we instead treat the **relational consistency** between different perspectives of relational expressions as an approximation to fuzzy logic consistency[4]. In fact, ensuring logical consistency in a discourse is a key requirement for text coherence and effective information conveyance (Jurafsky and Martin, 2009). We devise a method that inspects the implicit intra-sentence relation of entity pairs at the discourse level to extract logically consistent examples from Wikipedia articles (Figure 2). Specifically, we posit that direct and indirect relations of an anchor entity pair should be logically consistent, as they are derived from the "same" context. For the second challenge, LogicLLM adopts an auto-regressive objective optimizing on the logically consistent relation instances directly to make it seamlessly adapt to its pretraining objective. It tasks the model with generating the alternative perspective (indirect or direct) given a direct or indirect description of the anchor entity pair. We further employ counterfactual data augmentation through entity replacement to enforce relation-centric reasoning, which not only avoids the model's tendency to merely recall results from memory but also ensures the preservation of the logic-enhanced aspect of the learning process.

LogicLLM is task-agnostic and does not require any annotations, making it adaptable to various logical reasoning tasks. We have conducted experiments across two distinct LLM series, FLAN-T5 (Longpre et al., 2023) and LLaMA (Touvron et al., 2023), encompassing a variety of parameter sizes. These experiments are designed to investigate two main questions: (1) Can the logical reasoning capabilities be exclusively improved through self-supervised meta-training for LLMs, thereby circumventing the need for task-specific supervised fine-tuning? (2) How does the logic-enhanced meta training affect the LLM's language understanding capabilities, i.e., does it suffer from forgetting or generalization issues?

In response to the first question, our findings suggest that LLMs trained with the LogicLLM objective demonstrate superior performance on logical reasoning benchmarks, eliminating the need for further fine-tuning. Our LogicLLM based on FLAN-T5-11B attain comparable results to ChatGPT on two logic reasoning benchmarks, ReClor (Yu et al., 2020) and LogiQA-v2 (Liu et al., 2022a), highlighting the feasibility of enhancing logical reasoning abilities through self-supervised training alone.

Regarding the second question, our evaluations with LLaMA-based models on three general language understanding benchmarks - RACE (Lai et al., 2017), MMLU (Hendrycks et al., 2021) and BIG-Bench-Hard (BBH) (Suzgun et al., 2022), confirm that the enhanced logical reasoning capabilities do not compromise the model's overall language understanding on MMLU and BBH. In fact, the learned logic ability appears to boost the model's performance in RACE.

2 Related Work

2.1 Large Language Models

In recent years, Large Language Models with in-context learning have emerged as a groundbreaking paradigm in the field of NLP. Unlike the traditional fine-tuning approach, in-context learning leverages natural language instructions or a small number

[4]In this paper, we will use the term **logical consistency** to represent **consistency in fuzzy logic** for simplification, which is further described by relational consistency. This means that the relationship between a **logically consistent** data pair has a higher degree of logical consistency but cannot be strictly proved considering the diverse expressions of relations.

of annotated examples as demonstrations to predict responses for new instances. This unique approach empowers LLMs to serve as a versatile tool for handling multiple tasks without requiring task-specific training. However, recent evaluations of LLMs (Qin et al., 2023; Bang et al., 2023; Jiao et al., 2023; Laskar et al., 2023; Wang et al., 2023a) have revealed a limitation in their ability to learn complex skills like logic and planning through language modeling alone. To address this, even the training of GPT-4 has incorporated labeled matching datasets to enhance its performance in solving math word problems (OpenAI, 2023). Nevertheless, due to the vast amount of data used in pre-training LLMs, annotated data for specific capabilities may be severely undersampled, and the cost of obtaining annotations should not be overlooked. Therefore, it remains crucial to develop various self-supervised or weakly-supervised training methods that do not rely on human annotation. These approaches are essential for constructing more robust and versatile LLMs that can perform a wider range of tasks with higher proficiency and lower resource.

2.2 Reasoning in Natural Language

Previous research aimed at natural language reasoning tasks can be broadly classified into three categories. The first category involves explicit prior knowledge, such as discourse structure or linguistic knowledge, to model implicit reasoning processes (Gao et al., 2020; Huang et al., 2021). The second category is neural-symbolic reasoning, where variables are first parsed, and then predefined programs are executed to obtain final results (Wang et al., 2022; Zhong et al., 2021). However, a significant challenge with these methods is the requirement of a robust semantic parser and a self-contained symbolic system for extracting variables or arguments, which is impractical for logic reasoning based on natural language. The third category encompasses methods that focus on general domain pre-training for reasoning via denoising auto-encoding (Jiao et al., 2021; Deng et al., 2021; Liu et al., 2022b). Nevertheless, restricted by the poor task generalization of discriminative models with few parameters, these methods are still in demand of task-specific fine-tuning to activate learned knowledge.

Our approach in this paper falls within the third category, which improves the efforts of MERIt (Jiao et al., 2022) by transforming it into auto-regressive framework to better align the nature of LLMs as generative model. We also drop the usage of knowledge graph enabling enhancing the logic of LLMs through purely self-supervised learning.

3 LogicLLM

Figure 2 shows the framework of LogicLLM. It involves three main steps: 1) Logic-consistent Data Construction (Section 3.1), which synthesises the logic-consistent data using relation discrimination between entity pairs; 2) Counterfactual Data Augmentation (Section 3.2), which augments the logic-consistent training data by entity sampling and replacement; 3) LLM Training (Section 3.3), which performs continual training of LLMs using the training data generated by the previous two steps.

3.1 Logically consistent Data Construction

Ensuring logical consistency in discourse and pragmatics is a fundamental prerequisite for natural language to effectively convey information and maintain coherence. Consequently, logically consistent data is prevalent in text documents and various techniques can be applied to extract them. In this study, we implement this by inspecting intra-sentence relation of entity pairs at the discourse level to extract logically consistent examples from Wikipedia.

Direct relation Given an arbitrary paragraph and an anchor entity pair $\langle e_i, e_j \rangle$, **we assume there exists an *implicit* relation s_k between $\langle e_i, e_j \rangle$ if one sentence directly mentioning them can be found.** This comes from the distant supervision (Mintz et al., 2009) and has been employed and extended in self-supervised training by previous work (Deng et al., 2021). For example, the instance ① in Figure 2 is a direct relation. To this end, we simply treat $\langle e_i, s_k, e_j \rangle$ as the direct relation triplet for further data construction.

Indirect relation Entities e_i and e_j can be indirectly connected through multiple sentences within the input paragraph. In such situations, we identify a chain of triplets, such as $\langle e_i, s_{i+1}, e_{i+1}, \cdots, s_j, e_j \rangle$, which represents an indirect relation between the entity pair $\langle e_i, e_j \rangle$ through the relation composition of serial relation triplets $\langle e_i, s_{i+1}, e_{i+1} \rangle$, $\langle e_{i+1}, s_{i+2}, e_{i+2} \rangle$, $\cdots$, $\langle e_{j-1}, s_j, e_j \rangle$. For example, instance ② in Figure 2 demonstrates an indirect relation.[5]

[5] In practice, we find 87% indirect relations are composed of two relation triplets, 12% contain three triplets, and less than 1% have more than 4 triplets. This prevents the logical consistency be weakened by long context.

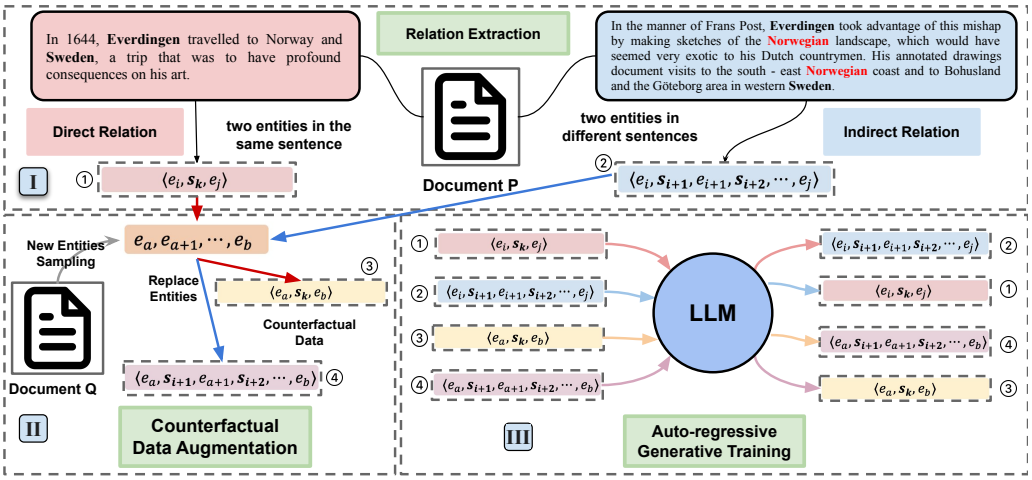

Figure 2: The LogicLLM framework. P and Q are two arbitrary paragraphs from Wikipedia. In Step 1, we extract intra-sentence relations ①: $\langle e_i, s_k, e_j \rangle$, and the compositions of them ②: $\langle e_i, s_{i+1}, e_{i+1}, \cdots, s_j, e_j \rangle$ from P for an entity pair $\langle e_i, e_j \rangle$; ① and ② are direct and indirection relations, respectively. Here s_k is a relation, represented by the sentence that mentions $\langle e_i, e_j \rangle$. ① and ② are viewed as logically consistent since both of them describe the "same" relation between $\langle e_i, e_j \rangle$ from different view. In Part I of the figure, e_i refers to *Everdigen* and e_j represents *Sweden*. The intermediate entity is *Norwegian* here. The direct relation on the left says that *Everdigen* has traveled to *Sweden*, and the indirect relation implies the fact that *Everdigen* has probably visited *Sweden* as well as its nearby area, otherwise he could not complete the sketches of *Norwegian*, demonstrating the fuzzy logic consistency with high probability. Step 2 is the process of counterfactual data augmentation, where counterfactual relation composition is generated by random entity replacement. ③ and ④ are the counterfactual augmentations of ① and ②, respectively. Finally, in Step 3, the LLM is optimized to generate direct/indirect relations with their logically consistent indirect/direct counterparts as inputs. Here, ①→ ②, ②→ ①, ③→ ④, and ④→ ③ are considered.

Logical consistency Intuitively, the direct and indirect relations between $\langle e_i, e_j \rangle$ should be logically consistent since they are derived from same context and describing the same entity pairs. Instances ① and ② in Figure 2 exemplify logically consistent relations. By establishing implicit connections between single-step and multi-hop reasoning, LLMs gain the ability to understand relation composition process between s_k and $\langle s_{i+1}, s_{i+2}, \cdots, s_{j-1} \rangle$. This capability consequently enhances the LLMs' logical reasoning abilities.

To retrieve logically consistent relation pairs, we follow a two-step process. First, we recognize all entities within each paragraph via distant annotation from WikiData (Wang et al., 2021). And secondly, we enumerate every possible entity pair and search for a series of sentences and check if both direct and indirect relations can be extracted.

3.2 Counterfactual Data Augmentation

The work we have described in Section 3.1 produces logically consistent data that correlates entities and relations within reasoning paths. To enhance entity-irrelevant reasoning and ensure LLM focuses more on the process of relational composition rather than the entities themselves, we have additionally introduced counterfactual data augmentation. This approach, similar to the method suggested by Jiao et al. (2022), includes the random replacement of entities.

To create counterfactual examples of $\langle e_i, e_j \rangle$ within paragraph P, we initially select a random paragraph, denoted as Q, from a separate document. Subsequently, we sample a new set of entities, such as $e_a, e_{a+1}, \cdots, e_b$ from Q. The head and tail entities in the original relation instances of $\langle e_i, e_j \rangle$ are then substituted by these randomly sampled entities, maintaining the relationships unchanged. For instance, after substituting e_i and e_j with e_a and e_b, ③ and ④ become the counterfactual augmentations of ① and ②, respectively. In our research, we postulate that the logic-consistency between s_k and $s_{i+1}, e_{i+1}, s_{i+2}, \cdots, s_{j-1}$ remains undisturbed in the counterfactual examples. This assertion is based on the idea that logical relationships within a paragraph's context are primarily driven by shared entities and their interconnections rather than the specific entities themselves.

3.3 Training Objective

During the training phase, we apply continual training to LLMs using logic-consistent data. Drawing

inspiration from the success of in-context learning, we treat one relation from a logic-consistent relation pair as the in-context example and task the LLM with generating the other relation. As depicted in Figure 2, using the logic-consistent pair $\langle ①, ② \rangle$ as an example, when ① is given as the conditional input, the LLM is expected to produce ② as the output, and vice versa. This process intuitively forces the LLM to reason the logic-consistent connections between the input and output relations since they are from the same context and the entity pairs of ① and ② are both e_i and e_j.

Formally, we denote the data extracted from Section 3.1 and Section 3.2 as $D = \{\langle R_i^1, R_i^2 \rangle\}_{i=1}^N$, where N represents the number of training examples, and $\langle R_i^1, R_i^2 \rangle$ is the i-th logic-consistent record. Here, R_i^1 refers to the direct relation-related instance, while R_i^2 represents the instance with an indirect relation. The goal of LLM training is to minimize the negative log-likelihood function as follows:

$$\begin{aligned}\mathcal{L}_{\text{logic}} &= -\sum_{i=1}^{N}[\log P(R_i^1|R_i^2) + \log P(R_i^2|R_i^1)] \\ &= -\sum_{i=1}^{N}[\sum_{j=1}^{|R_i^1|} \log P(R_{i,j}^1|R_{i,<j}^1, R_i^2) \\ &\quad + \sum_{j=1}^{|R_i^2|} \log P(R_{i,j}^2|R_{i,<j}^2, R_i^1)],\end{aligned} \tag{1}$$

where $R_{i,j}^1$, $R_{i,j}^2$ denotes the j-th token of R_i^1 and R_i^2, respectively.

Furthermore, we incorporate the another causal language modeling loss $\mathcal{L}_{\text{lm}}$ to mitigate the catastrophic forgetting problem. Both $\mathcal{L}_{\text{lm}}$ and $\mathcal{L}_{\text{logic}}$ are implemented as auto-regressive decoding. The only difference is that they sample from different data source. $\mathcal{L}_{\text{lm}}$ continuously samples data from the subset of training corpus used during the last-stage pre-training, i.e., Wikipedia paragraphs for LLaMA series models, and FLAN-collection-v2 for FLAN-T5 series models. Therefore, the overall training objective is defined as:

$$\mathcal{L} = \mathcal{L}_{\text{logic}} + \mathcal{L}_{\text{lm}}. \tag{2}$$

During training, for each forward-backward, we randomly sample two mini-batches with the same size from the datasets for logic-enhanced training and language modeling, respectively, and merge them into a single one.

4 Experiment

We integrate our pre-training approach into two prominent LLMs: LLaMA (Touvron et al., 2023) and FLAN-T5 (Wei et al., 2022a). These models boast parameter sizes ranging from 3 billion to 30 billion. To thoroughly evaluate the capability of LLMs from various angles, we have carefully selected five datasets representing three distinct categories. ReClor (Yu et al., 2020) and LogiQA-V2 (Liu et al., 2020) are two logical reasoning benchmarks sourced respectively from standardized graduate admission examinations and logical examination papers intended for reading comprehension. RACE (Lai et al., 2017) is a reading comprehension task that assesses general reasoning abilities. MMLU (Hendrycks et al., 2021) is used for measuring the learned knowledge and massive multitask language understanding, and BIG-Bench-Hard (BBH) (Suzgun et al., 2022) is a collection of multiple challenging tasks where LLMs fall behind human being. By employing MMLU and BBH, we aim to verify whether the logic-oriented meta-training negatively impacts the models' ability to generalize across a wide range of tasks. Due to space limitation, more implementation details can be found in Appendix A.

5 Results and Analysis

5.1 Logical Reasoning

Table 1 shows the results on ReClor and LogiQA-v2 under zero-shot setting. From the table we can find that the performance of LLaMA-based models is notably lower compared to ChatGPT. By training LLaMA models with LogicLLM, we observe significant enhancement in their zero-shot logical

reasoning capabilities. For instance, on LLaMA-13B and LLaMA-33B, the average improvements across the four dataset splits are 3.2 and 3.7 points, respectively. The benefits are more substantial than those observed in the 7B models (0.9 points), which aligns with the findings on emergent abilities (Wei et al., 2022b). This could be attributed to the fact that larger models possess stronger generalization abilities and better apply their learned capabilities to different tasks. We also conducted experiments on Falcon-40B (Penedo et al., 2023), and found that LogicLLM brings an average improvement of 3.2 points.

Consistent with LLaMA-based models, we can draw similar conclusions for those based on FLAN-T5, where logic-oriented meta-training also yields improvements for both FLAN-T5-3B and FLAN-T5-11B. For FLAN-T5-11B, our model achieves accuracies of 61.2 and 61.1 on the development and test sets of ReClor, respectively. On the development and test sets of LogiQA-v2, our logic-oriented FLAN-T5-11B model achieves accuracies of 56.0 and 54.0, respectively. Notably, on the development set of ReClor, our logic-oriented FLAN-T5-11B model outperforms ChatGPT by a significant margin of 4.8 accuracy points. Similarly, on the development and test sets of LogiQA-v2, our logic-oriented FLAN-T5-11B model surpasses ChatGPT by 1.5 and 1.3 accuracy points, respectively. These overall results indicate that instruction tuning on multiple supervised datasets, such as the FLAN collection, can still be improved for learning logic. We hypothesize that this may be attributed to the sparsity of reasoning-relevant data in the entire collection and the conflicts between different tasks.

5.2 Hybrid Reasoning and Application

In addition to logical reasoning in text, we are also curious about whether logic-enhanced training contributes to general language understanding (RACE), and maintain the general capabilities on massive knowledge based tasks (MMLU). To investigate this, we evaluate the performance of the enhanced LLaMA models on these two datasets.

As shown in Table 2, from 7B to 33B, LogicLLM can consistently improve the performance on RACE, except the one of LLaMA-33B w/ LogicLLMon the test set. Specifically, LLaMA-7B w/ LogicLLM obtain around 4.2 absolute improvements, and LLaMA-13B w/ LogicLLM achieves 1.5 improvements, which has verified that the logic-enhanced training is also beneficial to general reasoning and reading comprehension. Additionally, we find that LogicLLM can also benefits the massive multitask language understanding (MMLU) on LLaMA-7B and 13B. We find that the improvements of both RACE and MMLU on LLaMA-33B are marginal, probably because low-rank adaptation have restricted the generalization.

5.3 Pre-training Strategy

LogicLLM draws inspiration from the contrastive learning framework for logical reasoning, i.e., MERIt, which has demonstrated its efficacy in fine-tuning based approaches. As mentioned earlier, we hypothesize that contrastive learning may be inadequate for LLM with in-context learning. To validate this assumption, we examine the effects of contrastive learning (*ctr*) and auto-regressive generation (*ar*). In the case of contrastive learning, we adopt the methodology of MERIt to construct logically inconsistent instances and optimize the model by maximizing the distance between logically consistent instances and the inconsistent counterparts. Referring to the table, it can be observed that LogicLLM (*ctr*) fails to yield significant improvements

compared to LLaMA-13B, except for the dev set of ReClor. Conversely, the auto-regressive models consistently outperform both the baseline models and the contrastive methods by considerable margins across all dataset splits. We propose two primary reasons to explain the superiority of auto-regressive models over the contrastive approach.

First, the heuristic construction process for negative candidates used in contrastive learning fails to identify true contradictory relations, resulting in randomly chosen negative samples that lack logically opposite relationships with the positive instances. To this end, the contrastive learning process can degrade into a positive-only optimization process, which is similar to auto-regressive learning but receives less token-level supervision.

Second, the divergence between the training objectives of contrastive learning and auto-regressive generation undermines the model's ability to effectively do in-context reasoning. Contrastive learning primarily focuses on discriminating positive pairs from negative pairs based on a *global* semantic perspective. Auto-regressive models, on the other hand, accumulate their ability through *local* token prediction. During inference, LLMs are expected to understand instruction, and jointly consider the logical relations between different hypothesises within single input. By placing emphasis on fine-grained relations, the auto-regressive objective can better support in-context learning, enabling the model to grasp the nuanced connections and reasoning processes required for logical understanding.

Moreover, the auto-regressive objective significantly reduces computation costs during training by eliminating the need for negative candidates encoding. The streamlining of training process leads to more efficient and resource-friendly training without sacrificing performance. We also add another experiment by adjusting the ratio between counterfactual data and the normal ones as 1:1, and the comparison reveal that mixing more counterfactual data can also benefit the performance, which could be especially useful for low-resource domain, like finance and multi-lingual LLMs.

In summary, considering the advantages in both performance and training cost, the auto-regressive variant proves to be a superior choice for incorporating logic reasoning into LLMs.

Table 4: Ablation study to explore if LogicLLM can be combined with instruction tuning. For FLAN-T5 , we use the subset of FLAN collection. For LLaMA, we introduce GPT4All (Anand et al., 2023).

5.4 Factors Relevant to Logic Prior

In Table 3, we also present the ablation results on LLaMA-33B when the counterfactual data augmentation strategy is omitted. Without the inclusion of counterfactual data, LogicLLM degrades into a conditional generative task that can be solved through memorization, as each sample has its own prototypes within Wikipedia.

As indicated in the table, even without the augmentation (*no aug.*), LogicLLM still contributes to the enhancement of logical reasoning abilities, albeit with more limited improvements. However, the introduction of counterfactual data augmentation to eliminate memorization effects can further amplify the benefits. The overall experimental results point out that relation construction serves as effective supervision signal for introducing logic prior. We leave the work about developing novel techniques to prevent memorization but less involve factual noise as future work.

5.5 Compatibility with Instruction Tuning

Instruction tuning has served as a critical step to make LLMs better in following human instruction, and/or generating with less toxic. In this section, we hope to study if LogicLLM can be well integrated with supervised instruction tuning so that LogicLLM has the potential to serve as a basic approach to train logic-enhanced foundation model before building applications. For FLAN-T5, we directly use the same subset of FLAN collection with our approach as the instruction tuning data. For LLaMA models, we introduce GPT4All (Anand et al., 2023) data for extra supervision. During training, we simply sum the loss of instruction tuning and LogicLLM in multitask training manner to keep the same data ratio.

Model	Normal	Normal (Anony.)	C.F.	C.F. (Anony.)
ChatGPT	94%	77.4% (-16.6%)	49.2%	65.0% (+14.8%)
GPT-4	99.8%	99.2% (-0.6%)	71.4%	94.2% (+22.8%)

Table 5: The ratio of consistent data deemed by ChatGPT and GPT-4. *Anony.* refers to *anonymization* and *C.F.* is the simplification of *Counterfactual*.

As shown in Table 4, on most dataset splits, LogicLLM can achieve additional improvements compared with the instruction tuning-only baselines. Specifically, we find that the improvements are more significant on ReClor that those on LogiQA-v2. One possible reason is that the language style in LogiQA-v2 is more close to formal language, leaving a gap with the natural user questions.

5.6 Data Assumption Auto-Verification

In order to verify the rationality of our assumption that the *direct* and *indirect* relations are logically consistent, we employ ChatGPT and GPT-4 for automatic evaluations. Specifically, we randomly sample 1,000 examples from the development set for our pre-training with the ratio of normal data and counterfactual ones as 1:1. For each data pair, we ask ChatGPT/GPT-4 to determine if the relation between the target entities are logically consistent. The prompt we used is shown in Appendix E. We have involved four different settings. Beside the normal data and the counterfactual ones, we have also applied anonymization (Qiu et al., 2020) to them to decouple the background knowledge from entity. Specifically, the target entities are replaced with [X] and [Y], and for counterfactual data, the other replaced entities during data augmentation are not further anonymized. Some cases can also be found in Appendix E for clearer understanding.

Our results are shown in Tabel 5, from which we can observe that: (1) for normal data, ChatGPT and GPT-4 deem that the logically consistent data occupie high ratios, which has initially verified the rationality of our data construction assumption. (2) For counterfactual data, the ratios significantly decrease. Yet, in the view of GPT-4, there is still more than 70% of logically consistent data in the whole corpus. (3) When combined with entity anonymization, the ratios become much higher for counterfactual data, i.e., nearly 15% absolute improvements for ChatGPT and 23% for GPT-4. Besides, the ratio of normal data decreases significantly for ChatGPT, but is less perturbed for GPT-4. The observation further demonstrates that most counterfactual data should also hold the assumption since the anonymization only remove the backgrounds of entities, yet leaving the context as original. And the great variation brought by counterfactual data augmentation also reveals the potential weakness of current LLMs on identifying the true causal relations.

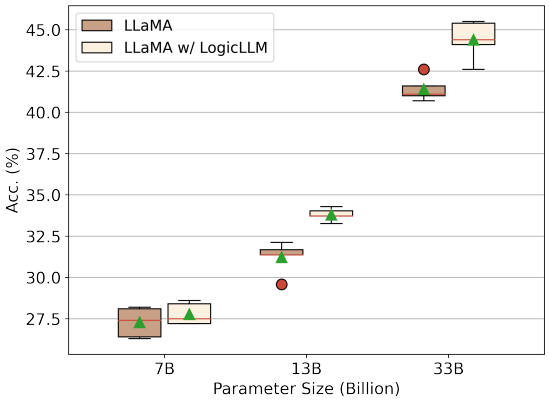

Figure 3: Results of 5 experiments with different option input orders across different model sizes on the test set of LogiQA-v2. **Brown circular marker**: outlier, **green triangle**: arithmetic mean value.

5.7 Robustness

By training LLMs on logic-consistent data and counterfactual augmentations, they are exposed to a wide range of input variations. This exposure helps them become less sensitive to minor perturbations such as shuffling of input options. To determine the robustness of LogicLLM , we conducted experiments on LogiQA-v2 using models of varying sizes. We shuffled the input order of different options and reperformed the inference process.

Figure 3 illustrates the findings of our experiments. We observed that LLaMA exhibited higher variance across different input option orders, as indicated by the greater spread in results. The circular outlier values that indicate specific input orders causing significant variations, leading to substantially higher or lower performance results. Our observation is consistent with the recent findings of Wang et al. (2023b), suggesting that the normal LLMs heavily suffer from position bias. In contrast, when LLaMA is enhanced with LogicLLM, it achieves more stable performance across different parameter sizes. Moreover, the averaged performance of LLaMA w/ LogicLLM is significantly superior to that of LLaMA alone. These results show that LogicLLM produces consistent and improved results compared to traditional LLMs, demonstrat-

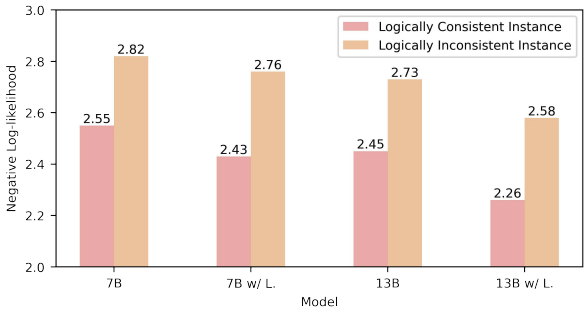

Figure 4: The averaged log-likelihood value of different models on the self-constructed logically consistent and inconsistent instances, respectively. w/ L. refers to the models augmented with LogicLLM.

ing the value of incorporating logic-enhanced training techniques into LLMs.

5.8 Training Quality Analysis

In order to analyze the quality of our meta-training, we have constructed a test set using the framework of MERIt (Jiao et al., 2022), which contains both logically consistent and inconsistent data. We have measured the log-likelihood on each sample as illustrated by Equation 1, and report the averaged results in Figure 4.

As shown in the figure, for logically consistent data, LogicLLM significantly reduced the negative log-likelihood. Moreover, the 7B-based model with LogicLLM surpasses the performance of LLaMA-13B. Notably, the disparity between the negative log-likelihood of logically consistent and inconsistent instances is further amplified, highlighting the effectiveness of LogicLLM in logical relation reconstruction. Furthermore, our experiments suggest a decrease in the negative log-likelihood for logically inconsistent data. This observation exposes a weakness in the contrastive learning-based method, i.e., MERIt, wherein the heuristic process for generating negative candidates introduces considerable noise. Consequently, some negative instances may not genuinely present contradictory logical relations.

6 Conclusion

In this paper, we have explored the feasibility and effectiveness of enhancing logical reasoning of LLMs via purely self-supervised training. We evaluate the performance based on two LLM series, i.e., FLAN-T5 and LLaMA. The experimental results on two logical reasoning benchmarks, LogiQA-v2 and ReClor, demonstrate the effectiveness of our method. And the performance on RACE, MMLU and Big-Bench-Hard have also verified that the framework do not hurt the generalization of LLMs. Finally, we have analyzed the factors relevant to logic during training, and the compability with supervised instruction tuning. We hope the analysis could bring new insights to future research.

Besides, we sincerely appreciate the valuable comments from all the reviewers to help us make the paper polished. We also greatly thank to Chengwei Qin and Professor Aixin Sun for their kind suggestions.

Limitations

In this paper, we have explored the feasibility to introduce logical reasoning capability into LLMs via purely self-supervised meta-training. Though the results have demonstrated significant improvements on logical reasoning benchmarks, there are also some limitations:

Randomness from Diverse Prompt/Instruction. In our experiments, we find that the performance of LLMs, especially those never optimized by instruction tuning, is varying to different prompts. We try to reduce the variance by (1) using simpler prompt (as shown in Section D or (2) using the released prompt by commonly accepted benchmark or leaderboard, e.g., MMLU, Big-Bench-Hard and Chain-of-Thought Hub (Fu et al., 2023). Nevertheless, this still cannot entirely keep the certainty of the experimental results.

Non-uniform Evaluation Strategy. Currently, there is no *de facto* technical standard for LLMs evaluation. Some work just let language models generate the response and match the content. However, this can be unfair for non-instruction-tuned models since they often cannot generate meaningful and complete sentences, especially those under 13 billion parameters.

Scaling. Due to the resource limitation, we can only scale the method into models with 40 billion parameters under the help of low-rank adaptation.

w/ CoT	58.8	57.7	—	53.1

Table 6: The overall accuracy of LLMs, i.e., ChatGPT (GPT-3.5-turbo) and LLaMA, and existing state-of-the-art methods (Jiao et al., 2022) on logical reasoning benchmarks. The evaluation of LLMs follows zero-shot in-context learning setting, where the models are expected to decode the answer based on the given instruction, context, and question.

A Implementation Details

A.1 LLM Prompting

In order to evaluate the generalization capabilities of LLMs across different tasks after post-training, we adopt a prompting-based approach. Here, the input to the LLMs is structured as `Instruction [Exemplars] Task input`. The instruction is tailored to the specific task at hand, while exemplars are utilized only in a few-shot setting. Each exemplar comprises both the task input and its corresponding output. For tasks such as multiple-choice question answering, the task input is a concatenation of the context, the question, and all potential options. The correct option index is used as the output. Besides, in a Chain-of-Thought (CoT) setting, we include a reasoning process formulated in natural language between the task input and output.

A.2 Data

We have constructed our self-supervised logic-enhanced training data from Wikipedia, where we directly used the paragraph corpus pre-processed by Qin et al. (2021). We have constructed around 200K logically consistent sample pairs. After that, we further performed counterfactual data augmentation with the ratio of 1:3, and finally induced 800K training sample pairs in total. The data construction process mainly follows the original setting of Jiao et al. (2022) except two differences. First, we remove the usage of knowledge graph for relation annotation to enable fully self-supervision and simplify the construction workflow. Secondly, we have dropped the negative candidates since we employed auto-regressive training.

	High	Middle	Weighted
LLaMA-7B	46.9	61.1	51.0
LLaMA-7B (Ours)	—	—	32.3
LLaMA-13B	47.2	61.6	51.4
LLaMA-13B (Ours)	—	—	**54.5**
LLaMA-33B	48.3	64.1	52.9
LLaMA-33B (Ours)	—	—	**68.1**

Table 7: The comparison on RACE dataset between our reproduced results and those reported by the opriginal paper of LLaMA.

For language modeling, we employed different dataset with respect to the data used in their last stage training. For FLAN-T5 series models, we used the subset of FLAN-collection-v2 (Longpre et al., 2023); while for LLaMA series models, we used the same Wikipedia paragraphs from the corpus of Qin et al. (2021).

A.3 Hyper-parameters of Training

During the pre-training process, we set the batch size to 4,096, which is implemented using gradient accumulation. The maximum sequence length is truncated at 1,024 for the FLAN collection and 512 for the MERIt corpus. For the FLAN-T5 series models, we conduct training steps for 200 iterations, while for the LLaMA series models, we perform training steps for 500 iterations. The learning rates are set as follows: 1e-4 for FLAN-T5-3B, 5e-5 for FLAN-T5-11B, 1e-5 for LLaMA-7B, and 5e-6 for LLaMA-13B. To carry out the training process, we utilize 8 NVIDIA A100 80G GPUs. However, due to hardware limitations, models larger than 13B are trained using QLoRA (Dettmers et al., 2023), a low-rank adaptation approach specifically designed for quantized LLMs. We follow the setting used in QLoRA with α as 16 and r as 64. All linear layers are used for adaptation and the LoRA dropout is 0.05. The learning rate for LLaMA-33B and Falcon-40B is set as 5e-4.

A.4 Evaluation

To ensure a fair comparison, we maintain consistency across different models for each dataset. This involves using identical instructions and few-shot samples. We use accuracy as the evaluation metric across all experiments. The prompts for different dataset can be found in Appendix D.

Model / Dataset	Zero-shot	Direct	CoT
LLaMA-7B	24.9	30.4	**27.0**
w/ LogicLLM	**25.2**	**30.8**	25.9
LLaMA-13B	25.0	34.7	32.3
w/ LogicLLM	**26.3**	**35.0**	**33.9**
FLAN-T5-3B	38.0	40.2	35.1
w/ LogicLLM & FLAN	**40.5**	**41.2**	**36.7**
FLAN-T5-11B	43.0	**42.6**	**40.9**
w/ LogicLLM & FLAN	**44.1**	36.2	40.2

Table 8: The accuracy of LLaMA and FLAN-T5 based models on BIG-Bench-Hard. *Direct* refer to few-shot setting through direct prompting, where only the final answer is given. Instead, in *CoT* setting, the reasoning process is also concatenated. The exemplars used for direct few-shot prompting and CoT prompting are consistent in each task, which are officially provided.

B Interpretation for Different Results on RACE

In this section, we will discuss the different results on RACE between ours and those reported by the original paper of LLaMA. Specifically, Touvron et al. (2023) do not report the weighted results, so we convert them by ourselves. The results are shown in Table 7. From the table we can find that only LLaMA-7B cannot match the performance reported by the authors. On LLaMA-13B and LLaMA-33B, our reproduced accuracies are much higher than the reported ones, which can help address the concern of unfair comparison, and demonstrate the effectiveness of our proposed LogicLLM.

C Logic-enhanced Meta-training for Complex Task Understanding

We evaluated the performance of logic-enhanced pre-trained models on BIG-Bench-Hard, a benchmark comprising challenging tasks where human performance surpasses that of LLMs. Table 8 presents the results achieved by the LLaMA and FLAN-T5 models under three evaluation settings: zero-shot, direct few-shot, and CoT.

In the zero-shot setting, our logic-enhanced meta-training significantly improves all four investigated models. For instance, the zero-shot accuracies of LLaMA-13B and FLAN-T5-T5-11B are 25.0% and 38.0%, respectively. When combined with the LogicLLM model, the accuracy scores of LLaMA-13B and FLAN-T5-11B improve to 26.3% and 44.1%, respectively. Some tasks included in BBH require free-form answers thus we cannot evaluate the models by selecting the candidate with

lowest perplexity or log likelihood. Instead, we need to follow the evaluation of API-based models, which employs regularization expression to capture the answer from the response. However, smaller language models, especially those without being instruction tuned, fail to accept diverse instruction, and generate structured response. As a result, the absolute performance under zero-setting setting of LLaMA-based models are relatively limited.

On the other hand, the direct few-shot results outperform the zero-shot results in three out of four models, with the exception of FLAN-T5-11B. Similarly, logic-enhanced meta-training boosts the performance of models, except for FLAN-T5-11B. In the CoT setting, our method further enhances the performances of LLaMA-13B and FLAN-T5-3B. However, the best direct few-shot and CoT results (42.6% and 40.9%, respectively) are both inferior to the best zero-shot result (44.1%). Notably, the CoT results on FLAN-T5-3B are significantly worse than the zero-shot and direct few-shot results. These observations suggest the potential drawback that learning CoT from annotated training data, i.e., FLAN collection, has difficulty in generalizing to different task categories, for example, learning CoT from math word problem solving and solving logical puzzles. We provide further discussion on these findings in Appendix G.

D Prompt Template

D.1 ReClor

```
Answer the following question with the given context through logical reasoning:

Context: #Context

Question: #Question

Options:
A: #Option A.
B: #Option B.
C: #Option C.
D: #Option D.

The answer is
```

D.2 LogiQA-v2 & RACE

```
Answer the following question with the given context:

Context: #Context

Question: #Question

Options:
A: #Option A.
B: #Option B.
C: #Option C.
D: #Option D.

The answer is
```

D.3 MMLU

```
The following are multiple choice questions (with answers) about #Subject.

#Question

A: #Option A.
B: #Option B.
C: #Option C.
D: #Option D.

Answer:
```

E Auto-Verification Cases for Logical Consistency

E.1 Prompt Template

```
[User]:

Determine whether the relation between "[Entity A]" and "[Entity B]" in the given two sentences are logically consistent.

Directly give the answer from either Yes or No.

Sentence 1:

[Sentence(s) 1]

Sentence 2:

[Sentence(s) 2]

[ChatGPT/GPT-4]:

Yes/No.
```

E.2 Normal Version

```
[User]:

Determine whether the relation between "Everdingen" and "Sweden" in the given two sentences are logically consistent.

Sentence 1:

In the manner of Frans Post, Everdingen took advantage of this mishap by making sketches of the Norwegian landscape, which would have seemed very exotic to his Dutch countrymen. His annotated drawings document visits to the south - east Norwegian coast and to Bohusland and the Göteborg area in western Sweden.
```

Sentence 2:

In 1644 **Everdingen** travelled to Norway and **Sweden**, a trip that was to have profound consequences on his art.

The output should either be Yes or No.

[ChatGPT]:

Yes.

E.3 Counterfactual Version

[User]:

Determine whether the relation between "**Nicholas Roerich**" and "**Master**" in the given two sentences are logically consistent.

Sentence 1:

In the manner of Frans Post, **Nicholas Roerich** took advantage of this mishap by making sketches of the Canal del Dique landscape, which would have seemed very exotic to his Dutch countrymen. His annotated drawings document visits to the south - east Canal del Dique coast and to Bohusland and the Göteborg area in western **Master**.

Sentence 2:

In 1644 Nicholas Roerich travelled to Norway and Master , a trip that was to have profound consequences on his art .

The output should either be Yes or No.

[ChatGPT]:

No.

Entity replacement:

- Everdingen $\rightarrow$ Nicholas Roerich;
- Sweden $\rightarrow$ Master;
- Norwegian (connecting entity) $\rightarrow$ Canal del Dique;

E.4 Anonymized Version

[User]:

Determine whether the relation between "**[X]**" and "**[Y]**" in the given two sentences are logically consistent.

Sentence 1:

In the manner of Frans Post, **[X]** took advantage of this mishap by making sketches of the Canal del Dique landscape , which would have seemed very exotic to his Dutch countrymen. His annotated drawings document visits to the south - east Canal del Dique coast and to Bohusland and the Göteborg area in western **[Y]**.

Sentence 2:

In 1644 **[X]** travelled to Norway and **[Y]**, a trip that was to have profound consequences on his art .

The output should either be Yes or No.

[ChatGPT]:

Yes.

Model / Dataset	ReClor Dev Acc.	ReClor Test Acc.	LogiQA-v2 Dev Acc.	LogiQA-v2 Test Acc.
zero-shot				
ChatGPT	56.6	61.2	54.5	52.7
w/ CoT	58.8	57.7	54.5	53.1
5-shot				
ChatGPT	61.0	**63.0**	55.1	54.5
w/ CoT	**62.0**	62.5	47.6	**55.6**
w/ CoT + Cate.	N/A	N/A	**55.8**	55.0

Table 9: The results on logical reasoning benchmarks with enhanced Chain-of-Thought prompting.

F Discussion about Different Perspectives of Logical Reasoning

In our opinion, logic can be reflected through multiple aspects. Here, we use a simple logic rule to discuss the different perspectives:

$$(\alpha \rightarrow \beta) \wedge (\beta \rightarrow \gamma) \leftrightarrow \alpha \rightarrow \gamma. \quad (3)$$

The above equation shows the simplest case of first-order logic reasoning, where α, β and γ are different variables, and $\wedge$ is *logical and*. We can also introduce the necessary logical connectives in natural language to make it easier for understanding:

$$\text{IF } \alpha \rightarrow \beta \text{ AND } \beta \rightarrow \gamma, \text{ THEN } \alpha \rightarrow \gamma. \quad (4)$$

It should be noted that, in symbolic logic, we often ignore the actual meaning of relations. However, we can always find a path, i.e., a series of relation triplets from knowledge graph to transform the

above symbolic form into natural language based logical reasoning process:

$$\text{IF } \alpha \xrightarrow{r_1} \beta \text{ AND } \beta \xrightarrow{r_2} \gamma, \text{ THEN } \alpha \xrightarrow{r_3} \gamma. \tag{5}$$

One example here can be: r_1 refers to *is the father of*, r_2 refers to *is the mother of*, and r_3 refers to *is the grandpa of*.

From the above discussion, we can conclude that (1) logical connectives focus on discourse-level connections, (2) symbolic logic can be viewed as the simplified version of logical reasoning in natural language, where we focus more on the formal rules of atomic logic operations, and (3) relational reasoning concentrates on the actual logic operations built on world knowledge. Both of what we have discussed in the paper and the reviewers have mentioned in comments, i.e., logical connectives, are indeed different perspectives of logical reasoning. They do not contradict to each other, and discussing them separately is beneficial to make the problem easier. Besides, there are also several studies also discuss logical reasoning from the relational reasoning perspective (Wong et al., 2023; Xu et al., 2021; Zeng et al., 2021; Wang et al., 2022). And Figure 1 also shows the case emphasizing relational reasoning.

G Weakness of LLMs on Logical Reasoning

Table 9 showcases the evaluation results of LLMs' performance in both few-shot and CoT settings. The intermediate reasoning process is automatically generated by ChatGPT using the prompt *"Let's think step by step."* In the case of zero-shot CoT, we include the suffix prompt *"So the answer is"* to guide the models in summarizing and concluding the answer. For few-shot CoT, the reasoning process is initially generated for each sample in the training set. Subsequently, we retain the samples where the final prediction is correct, following the steps outlined in zero-shot CoT. During testing, we randomly select samples from the retained candidates, as well as the automatically generated CoT, to serve as exemplars.

However, our observations indicate that both few-shot learning and the use of CoT do not significantly improve the models' performance. For example, ChatGPT w/ CoT performs much worse than that without CoT on the development set of LogiQA-v2. One potential reason for this is that the selected samples differ substantially from the target example. To investigate further, we incorporate reasoning category information during exemplar selection. In LogiQA-V2, each question is annotated with a reasoning category, such as categorical reasoning, sufficient conditional reasoning, or necessary conditional reasoning. For few-shot CoT prompting, we only consider candidates that share at least two common reasoning categories. This particular variant is denoted as *"ChatGPT w/ CoT + Cate."* in the table.

Despite these efforts, we find that carefully selecting prompting exemplars only provides limited improvement. The results indicate that LLMs struggle to comprehend the reasoning structure from a limited number of observed examples. Consequently, they face challenges in effectively learning the mapping between input-label and input-rationale-label. Additionally, as shown in Table 1, we observe that LogicLLM also contributes minimally to addressing this issue. We recognize the need for further investigation in this area and leave it as a potential avenue for future research.

MATHSENSEI: A Tool-Augmented Large Language Model for Mathematical Reasoning

Debrup Das*[1], Debopriyo Banerjee[2], Somak Aditya[1], and Ashish Kulkarni[2]

Abstract

Tool-augmented Large Language Models (*TALM*s) are known to enhance the skillset of large language models (LLMs), thereby, leading to their improved reasoning abilities across many tasks. While, *TALM*s have been successfully employed in different question-answering benchmarks, their efficacy on complex mathematical reasoning benchmarks, and the potential complementary benefits offered by tools for knowledge retrieval and mathematical equation solving are open research questions. In this work, we present MATHSENSEI, a tool-augmented large language model for mathematical reasoning. We study the complementary benefits of the tools - knowledge retriever (Bing Web Search), program generator + executor (Python), and symbolic equation solver (WolframAlpha-API) through evaluations on mathematical reasoning datasets. We perform exhaustive ablations on MATH, a popular dataset for evaluating mathematical reasoning on diverse mathematical disciplines. We also conduct experiments involving well-known tool planners to study the impact of tool sequencing on the model performance. MATHSENSEI *achieves 13.5% better accuracy over* `gpt-3.5-turbo` *with Chain-of-Thought on the MATH dataset. We further observe that TALMs are not as effective for simpler math word problems (in GSM-8K), and the benefit increases as the complexity and required knowledge increases (progressively over AQuA, MMLU-Math, and higher level complex questions in MATH).* The code and data are available at https://github.com/Debrup-61/MathSensei

1 Introduction

State-of-the-art Large language models (LLMs), including gpt-3.5-turbo, GPT-4, and open-source counterparts, such as Llama 2 have demonstrated impressive performance across a broad spectrum of NLP tasks (Brown et al., 2020; Radford et al., 2019; Chowdhery et al., 2024; OpenAI, 2023). However, their consistent failure on established reasoning dimensions, such as mathematical, commonsense, abductive, and multi-hop reasoning (Lu et al., 2023b; Cobbe et al., 2021; Huang and Chang, 2023) have led the research community to explore various solutions for enhancing their reasoning abilities. This pursuit has given rise to techniques, such as - (1) **intelligent prompting variations**, such as chain of thought (Wei et al., 2022), program of thought (Chen et al., 2023c), tree of thoughts (Yao et al., 2023), and self-refinement (Madaan et al., 2023), (2) **program-guided solving** that generates python code as intermediate steps and offloads execution to a symbolic interpreter (Gao et al., 2023), (3) **multi-model interaction frameworks**, such as Multi-agent Debate (Du et al., 2023; Liang et al., 2023) and Round-Table Conference (Chen et al., 2023b), 4) **tool-augmented LLMs** powered by external symbolic tools, APIs, and libraries (Schick et al., 2023; Lu et al., 2023a; Paranjape et al., 2023; Yang and Narasimhan, 2023; Xie et al., 2023).

In this work, we study the effectiveness of tool-augmented LLMs (*TALM*) applied to problems involving mathematical reasoning. Recent advancements in *TALM* frameworks, such as Chameleon (Lu et al., 2023a), OlaGPT (Xie et al., 2023), ART (Paranjape et al., 2023), and SocraticAI (Yang and Narasimhan, 2023) have explored the effectiveness of incorporating external tools for solving knowledge-intensive reasoning tasks and fundamental mathematical problems (such as, arithmetic and algebra). However, the effectiveness of *TALM* framework is yet to be validated on mathematical reasoning tasks involving complex computations. In this context, it is imperative to assess the suitability of specific tool combinations across diverse mathematical domains (e.g., PreAlgebra, Calculus, Geometry, Intermediate Algebra, Probability) at varying levels of difficulty. This motivated us to undertake a thorough evaluation of *TALM* framework in the context of complex mathematical reasoning tasks. We propose and develop MATHSENSEI, a *TALM*-based framework, comprising a distinct set of tools (also referred to as modules), combined in a sequential fashion. These modules include LLM-based components, such as - knowledge retriever (KR), python code generator (PG), code refiner (CR), , and solution generator (SG); and APIs, such as - Bing-Web-Search-API (BS) and WolframAlpha-API (WA). As illustrated in Fig. 1, MATHSENSEI adopts the modular architecture

TALM	Math Discipline	Form	Search	Python	WAlpha	Plan	Tool-Study
OlaGPT	Algebra	MCQ	✓	✗	✗	Plan-And-Solve	✗
Chameleon	✗	✗	✓	✓	✗	Plan-And-Solve	✗
ART	Algebra	Open	✓	✓	✗	Call-as-req	✗
MATHSENSEI	Algebra, Precalculus, Geometry, Probability, Number Theory & more	Both	✓	✓	✓	Both	✓

Table 1: Comparison of MATHSENSEI with state-of-the-art Tool-Augmented LLMs; **Form** - Question-Answer Format (MCQ with multiple options, Open/Subjective), **Search** - Use of Web Search, **Python** - Python code guided problem solving, **WAlpha** - WolframAlpha, **Tool-Study** - Study of each tool, **Plan** - Planning Strategy used; **Plan-And-Solve** - Determine the sequence of tools to be executed beforehand, **Call-as-req** - Dynamically decide to call tool when required at a step during execution.

from Chameleon (Lu et al., 2023a). Through systematic experiments of MATHSENSEI, we aim to discern the effectiveness of each module in addressing specific types of mathematical problems, having varying levels of difficulty.

Our extensive ablations (varying the set and order of modules), show that complex mathematical problems, spanning different subdomains can be benefited by specific types, combinations, and *order* of the modules. This further highlights the need for planning strategies. We evaluate two advanced planning techniques within our pipeline, investigating methodologies such as Plan-And-Solve (Lu et al., 2023a) and REACT (Yao et al., 2022) with MATHSENSEI.

We make the following contributions:

1. We comprehensively evaluate the effectiveness of *TALM* frameworks across multiple mathematical datasets, such as GSM-8K, AQUA-RAT, MATH, MMLU-Math, encompassing diverse mathematical problem types and tasks. Compared to MATH, MMLU-Math, our experiments on simpler mathematical datasets (e.g., GSM-8K, AQUA-RAT) reveal minimal benefit of using multiple modules on top of CoT prompting.

2. Through systematic ablations by varying the set and order of modules in our framework, we observe that complex mathematical problems spanning different domains (such as, algebra, calculus, number theory, and probability from the MATH dataset) can be benefited by certain types, combinations, and *order* of these modules. We observe that the BS module outperforms the KR module for retrieving relevant knowledge for mathematical problems. The setting of WA+BS+SG outperforms PG+SG, demonstrating that program-guided solving techniques (Gao et al., 2023; Drori et al., 2022) may not be universally suitable for all mathematical problems. These findings motivate the necessity of exploiting better planning techniques.

Our best configuration of MATHSENSEI, PG+WA+SG achieves an impressive performance accuracy of 47.6 % on the MATH dataset, surpassing `gpt-3.5-turbo`() with Chain-of-Thought (CoT) prompting by 13.5% (Chen et al., 2023a). The same setting shows a performance gain of +11.6% over GPT-4 (with CoT prompting) on Intermediate Algebra problems. For Precalculus, GPT-4 (with CoT prompting) has an accuracy of 26.7%, which gets improved to 28.9% by our WA+PG+SG setting. Improvements on AQuA-RAT and MMLU-Math are lower, 2.4% and 3.3% respectively, showing the efficacy decreases as requirement of external knowledge decreases.

3. We quantify the performance of state-of-the-art planning techniques, such as Plan-And-Solve and REACT coupled with tool-augmented LLMs on the MATH dataset. However, we do not observe benefit of using the planners over our best configurations of PG+WA+SG, which may indicate a need for developing targeted planning strategies for mathematical *TALMs*. We include our Planning related experiments in the Appendix.

2 Related Work

Prompting Techniques. Large Language Models (LLMs) employing prompting strategies such as Chain-of-Thought (CoT) (Wei et al., 2022) and Program-of-Thought (POT) (Chen et al., 2023c) have demonstrated commendable performance on simple mathematical datasets such as GSM-8K (Cobbe et al., 2021). However, their efficacy diminishes for datasets requiring complex computations and advanced mathematical knowledge. For instance, on the MATH dataset, GPT-4 exhibits a notably low accuracy of around 50%. Several variations of these strategies have been explored to improve accuracy in reasoning tasks. (Madaan et al., 2023) proposed *self-refine* that involves iteratively refining the initial output by utilizing feedback from the same model. (Zhou et al., 2024) employs code-based self-verification, by utilizing python code to check simple constraints that the LLM generated output should satisfy and correcting the output if necessary. Similarly, Progressive-Hint-Prompting (Zheng et al., 2023) involves multiple turns of interactions, using previously generated answers as hints for subsequent turns. Similar to POT prompting, PAL (Program Aided language models) (Gao et al., 2023) adopts a program-guided solving paradigm. It reads natural language problems, generates programs as intermediate reasoning steps, and delegates the solution step to a runtime environment, such as a Python interpreter. Across 13 natural language reasoning tasks within Big-Bench-Hard (Suzgun et al., 2023), they observe that program-guided solving consistently outperforms significantly larger models.

In our Tool-augmented framework (MATHSENSEI), we incorporate several such techniques. We adopt CoT prompting for the text generation modules, and use the methodology by (Gao et al., 2023) to generate python code (using libraries like `sympy`) based on the current context and mathematical question; followed by execution of the code using python interpreter. While (Gao et al., 2023) focuses on elementary level MWP (Math Word problems) and simple arithmetic datasets such as ASDIV (Miao et al., 2020) and SingleEQ (Koncel-Kedziorski et al., 2015), we explore complex mathematical datasets spanning diverse math problem types (MATH, AQUA (Ling et al., 2017), MMLU-Math). Following *self-refine*, we employ a code refinement module to iteratively rectify syntactical errors in the original generated code, using error messages from the interpreter.

Tool-Augmented LLMs. The emerging trend of tool-augmented LLMs has garnered increasing attention within the research community. Large language models, trained on the objective of next-token prediction, excel at generating tokens based on probabilistic patterns in their training data, making them effective in data-intensive tasks. However, their proficiency falls short in capturing nuanced reasoning or token relationships, particularly in mathematical domains. Consequently, there are instances or specific question types where it would be advantageous for an LLM to leverage support from specialized tools or modules. For instance, consider a question requiring the solution to the roots of a 4th-degree polynomial. The LLM, upon generating a special token followed by a query, can pause its generation and invoke a mathematics computing platform WolframAlpha. WolframAlpha, in turn, can utilize its API to process the query and return the answer to the LLM, which can then continue its generation. Toolformer (Schick et al., 2023) leverages data annotated with such tool calls (using special tokens for tools) and responses to train language models to employ tools as needed in a self-supervised manner. Similarly, the tool-augmented LLM framework CHAMELEON (Lu et al., 2023a) adopts a plug-and-play approach to utilize tools sequentially. In their setup, the sequence of execution of the tools is predetermined based on a target task; the output of each tool is added to the context for subsequent downstream tools in the pipeline. They perform evaluation on multi-modal knowledge-intensive datasets, such as ScienceQA and TabMWP. Similarly, frameworks such as ART (Paranjape et al., 2023) engage in multi-step reasoning, where each step is linked to a tool call. Utilizing search and code tools, ART tackles various tasks across datasets such as MMLU (Hendrycks et al., 2021a)and BigBench (Srivastava et al., 2023).

Our work adopts the generic backbone of popular tool-augmented LLM frameworks such as Toolformer and CHAMELEON. In comparison to the previous work, we distinguish ourselves by conducting a comprehensive analysis and comparison specific to tools useful for addressing diverse mathematical problems. Notably, CHAMELEON lacks evaluation on mathematical datasets, and ART focuses exclusively on algebra, leading to gaps in the assessment of tool-augmented LLMs. Furthermore, our study incorporates a comparison of planning techniques within tool-augmented LLM frameworks for mathematical reasoning, an aspect not adequately addressed in the current literature. To the best of our knowledge, planning techniques like REACT (Yao et al., 2022) have primarily been tested on knowledge-intensive reasoning datasets such as FEVER (Thorne et al., 2018) and HotpotQA (Yang et al., 2018).

3 Methodology

We first discuss some notations to formalize the problem. Let M denote the set of modules[1] (each performing a specific task), p_i be the input prompt for module m_i, and Q be the set of mathematical queries.

3.1 Problem Formulation

Given an input mathematical query $q \in Q$, the objective is to provide the final correct answer a by executing

[1]The modules can be viewed as external tools, where each module $m \in M$ can be either powered by LLMs, such as Python code generators, Knowledge Retrievers, or they can be non-LLM API tools, such as WolframAlpha, Bing Web Search.

the set of relevant modules. Let $[m_1, \ldots, m_t]$, be the ordered sequence of chosen modules for answering q, and $[o_1, \ldots, o_t]$ be the output sequence of the t modules. Let, s_i, f_i, and c_i denote the instruction, in-context example(s), and context, respectively, that we use for module m_i. The input prompt p_i, corresponding to module m_i is defined as:

$$p_i = \langle s_i; f_i; c_i \rangle \tag{1}$$

where context c_i is defined as:

$$c_i = \begin{cases} [q], \text{ if } i = 1; \\ [c_{i-1}; o_{i-1}], \text{ for } i = 2, \ldots, t \end{cases} \tag{2}$$

Here, $x; y$ denotes concatenation of x and y.

3.2 Modules

In this section, we present a brief overview of the tools or modules that we use in our study. We show the list of model/api used for each module in Table 8. A detailed description of the prompts used in each module is presented in the Appendix section.

• **LLM-based Knowledge Retrieval (KR) -** For this module, we design a prompt to extract relevant knowledge from a pre-trained LLM (taking any one from the list of models mentioned in Table 8) in the form of concepts, formulas, mathematical expressions, theorems, definitions, and hints on how to solve a corresponding mathematical question. An example prompt and output is shown in Table 19 in Appendix.

• **Bing Web Search (BS) -** This module queries the `Bing-Web-Search-API` (🌐) to extract the most relevant snippets which may contain similar questions and concepts required for solving a mathematical problem. For similar questions search, we directly query the `API` with the mathematical question. In case of concepts search, we first use an LLM (either gpt-3.5-turbo or text-davinci-003) to generate a query corresponding to the input question, and then call the `API` to retrieve relevant concepts (refer to Fig. 2 for an example).

• **WolframAlpha (WA) -** This module (comprising multiple components) calls the `WolframAlpha-API` using a query in the Wolfram language, retrieving the mathematical information from this knowledge base and utilizing the capabilities of its computation engine. First we employ an LLM to generate contextualized thoughts. Subsequently, based on the generated thought, the next component formulates a Wolfram code language query (referred to as the *"Final Query"*). On passing this query as input to the WolframAlpha-API, we get a `JSON` dictionary object. We extract all the useful information from this dictionary (using an LLM-based extractor) and add it to the context of next module. An overview of the **WA** module is presented in Fig. 3.

• **Python Generator+Executor (PG) -** We use an LLM that takes as input the current context as a part of a well-structured prompt (shown in Fig. 4). The LLM is explicitly instructed to use the `sympy` library for accessing a set of mathematical operations and data structures

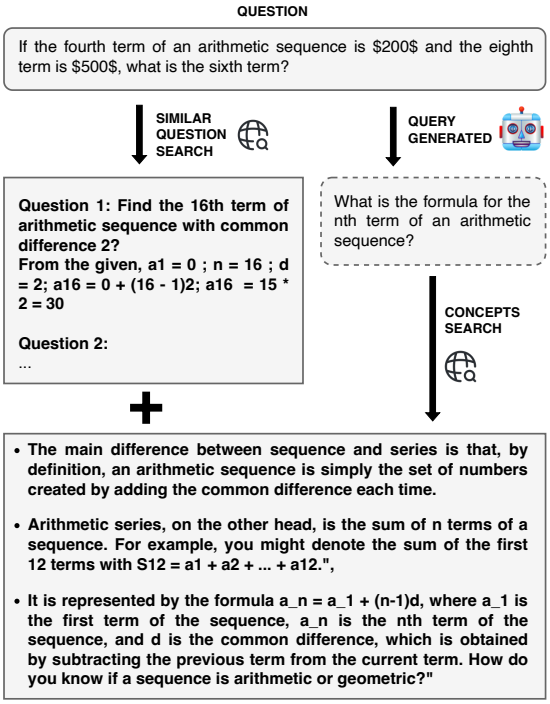

Figure 2: Overview of the BS module; We concatenate the similar questions and concepts (which is then used by a downstream module).

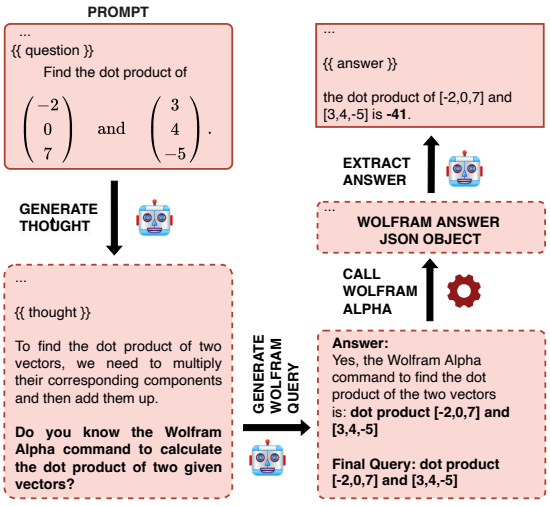

Figure 3: Overview of the WA⚙ module.

required. Based on the prompt, the module generates an (executable) Python code, which on execution returns some output(s) or an error message. We handle syntax errors using two setups:

- **Without refinement**: Here, if generated code produces syntax errors, we omit the output of PG from the context for next module.
- **Code-Refinement** (CR): Here, we feed the error message along with the incorrect program to a code-fixing LLM which then generates a corrected python code and rationales of fixed errors given

as "*Errors fixed*". We also add the information of common errors from our qualitative analysis in the system prompt to aid the code refinement process. An output for the code refinement setup from the MATH dataset is presented in Fig. 4 (Appendix).

• **Solution Generator (SG) -** The solution generator is the final module in all settings. It takes the output from the pipeline and compiles a step-by-step solution based on all the context of previous modules. The final step is prompted to produce the answer of the question. It outputs the final answer enclosed within $\\$\\$boxed{}$\$ for the MATH dataset.

4 Experimental Setup

We first introduce the mathematical datasets used in our study (§4.1), followed by the experiments that we perform with various combinations of modules (§4.2). We use `gpt-3.5-turbo` as the default LLM in LLM-based modules unless mentioned otherwise. This is mainly because it is more accessible and cheaper compared to GPT-4. For querying a search-engine, we use `Bing-Web-Search-API`. Please refer to 23 in Appendix for details about online resources that we use.

4.1 Datasets

MATH. The MATH dataset (Hendrycks et al., 2021b) serves as the primary dataset for our work. It covers *5000* mathematical problems, which are categorized into seven subject types (*Precalculus, Prealgebra, Algebra, Geometry, Intermediate Algebra, Counting and Probability, and Number Theory*) and *five levels* of difficulty (ranging from 1 to 5, where 1 denotes the least difficult and 5 denotes the most difficult). Our choice of the MATH dataset is motivated by its unique characteristics: Unlike many datasets, scaling up LLMs (in terms of model parameters) does not necessarily enhance accuracy on MATH. The dataset also poses intricate challenges, going beyond simple arithmetic or high school mathematics problems.

AQUA-RAT. The AQUA-RAT dataset (Ling et al., 2017) contains *253 algebraic math word problems* with rationales. Unlike the MATH datset, it has a *multiple-choice* answer format with five options. It allows us to evaluate MATHSENSEI on mathematical problems in the domain of algebra.

GSM-8K. GSM-8K (Cobbe et al., 2021) contains *high school level math word problems* which require basic arithmetic operations (addition, subtraction, multiplication, and division) to reach the final answer. The final answer is always an integer value. We use all 1319 examples from GSM-8K test set for evaluation.

MMLU-Math. The MMLU dataset (Hendrycks et al., 2021a) covers *57* diverse tasks (including *elementary mathematics*, *US history*, *computer science*, *etc.*), which require extensive problem solving abilities and world knowledge. For this work, we use the mathematical test subset of MMLU, known as MMLU-Math that contains *974* mathematical questions spanning 5 types - *abstract algebra, elementary mathematics, high-school mathematics, college mathematics*, and *formal logic*. Similar to AQUA-RAT, MMLU-Math also has a *multiple-choice* answer format.

4.2 Experiments

We conduct several experiments by meticulous analysis of individual modules **in the domain of complex mathematical reasoning**, through systematic ablations on the module sequences. For some of our ablations, we use different variants of OpenAI models, such as text-davinci-002 and text-davinci-003 other than the default gpt-3.5-turbo. We also employ models from the Llama family, such as Llama-2-7B and Phind-Code-Llama-34B-V2. We use accuracy as our evaluation metric for comparing different settings. Our experiments enquire the following questions:

• What is the impact of adding LLM generated mathematical knowledge relevant to the question **[KR module]** before invoking the Solution Generator module **[SG module]**? (§5.1)

• How does Bing Web Search **[BS module]** compare against the LLM-based knowledge generation **[KR module]** for the task of adding relevant mathematical knowledge and information to the problem solving process? (§5.1, §5.2)

• What is the utility of augmenting mathematical knowledge-bases, such as WolframAlpha **[WA module]** with LLMs for solving problems across different levels of complexity? How does it compare against the paradigm of program-guided solving? (§5.3)

• What are the benefits of using program-guided complex problem solving **[PG module]**, and impact of LLM-based code refinement **[CR module]** in case of syntactical errors? (§5.4)

• What is the effect of using **multiple modules together**? How does the benefit vary with the **difficulty level, mathematical subject type, and dataset?** (§5.5)

• How to plan effective utilization of these modules? How does non-adaptive planning strategies **[Plan-And-Solve]** compare against dynamic planning strategies such as **[REACT]** which uses a thought, action, and observation based mechanism. (Appendix A)

5 Effects of Adding Modules over LLMs

Here, we present results and analyze the impact of adding individual modules on top of the original LLM CoT variant (termed SG): KR in §5.1, BS in §5.2, PG in §5.4, and WA in §5.3. For each module, we also provide ablations over different LLMs (as applicable).

5.1 LLM-Based Knowledge Retrieval (KR)

Recently, Chameleon (Lu et al., 2023a) demonstrated an accuracy boost for knowledge intensive QA datasets, such as ScienceQA and TabMWP by using the KR module. Skills-In-Context prompting (Chen et al., 2023a)

Model	Ovr Acc
text-davinci-002 (🤖)	22.8
text-davinci-003 (🤖)	27.1
Llama2-7B (🦙)	28.4
gpt-3.5-turbo (🤖)	34.4

Table 2: Performance of different backbone models used for KR module in the KR+SG setting. For all settings, we use `gpt-3.5-turbo` as the default LLM for the SG module.

also shows similar results by utilizing some basic skills (such as mathematical theorems) during generation. Following the literature, we investigate the impact of adding relevant knowledge (such as mathematical concepts and formulae) using an LLM-based KR module in the context of SG module, and examine the efficacy of the KR+SG setting on the MATH dataset (Table 4). We also ablate over different LLMs (Table 2) to power the KR module, while fixing the SG module to `gpt-3.5-turbo`.

Results. As shown in of Table 4, the extra knowledge retrieved by the KR module is useful only for problems in Algebra, PreAlgebra, and Probability domains. Moreover, the overall accuracy drops steadily as we change **KR's** LLM from `gpt-3.5-turbo` to other variants (shown in Table 2). This indicates that, generic LLMs (such as those mentioned in Table 2) are not equipped with mathematical concepts of other domains (Precalculus, Geometry, Number Theory, Intermediate Algebra). After analyzing different LLM variants for the KR module, we find that the knowledge retrieved by weaker LLMs heavily degrades performance of the downstream SG module. This motivated us to explore the impact of search engine-based knowledge retrieval (detailed in §5.2).

5.2 Bing Web Search (BS)

We investigate the advantages of adding a search engine-based knowledge retrieval module (BS) as an alternative of KR for **similar questions search** and **concepts search** before applying SG.

Results. In Table 3, we observe that BS+SG setting is a clear winner over the SG setting, when `gpt-3.5-turbo` is used for generating the `Bing-Web-Search-API` query and getting final solution from SG. This holds true even if the stand-alone SG is varied between `text-davinci-003` ($+22.5\%$) and `gpt-3.5-turbo` ($+4.2\%$). Thus, augmenting LLMs with knowledge (relevant to a mathematical question) retrieved from the web proves to be beneficial in improving problem solving capabilities. The use of `text-davinci-003` alone or in combination with `gpt-3.5-turbo` for BS and SG modules, diminishes the performance of both BS+SG and SG settings, which is expected (Ye et al., 2023).

	Setting		
LLMs	(🌐+✅)	(⚙️+✅)	(✅)
(🤖+🤖)	38.7	42.6	-
(🤖+🤖)	27.4	35.6	-

(🤖)	-	-	34.5
(🤖)	-	-	16.2

Table 3: Ablations of BS+SG (🌐+✅), WA+SG (⚙️+✅), and SG (✅) settings using different combination of LLMs, such as `gpt-3.5-turbo` (🤖) and `text-davinci-003` (🤖) on the MATH dataset.

5.3 WolframAlpha Search (WA)

We compare the performance of WA+SG and SG settings on the MATH dataset in Table 3. We perform ablations with text-davinci-003 and gpt-3.5-turbo as the LLMs used in WA for query generation and answer extraction.

Results. From Table 3, we observe that WA+SG outperforms the SG approach by 8.1%, when both WA and SG are powered by `gpt-3.5-turbo`. This shows a clear and significant contribution of complementary strengths coming from the knowledge retrieved through WolframAlpha. Furthermore, it is notable that the observed benefits of the WA module cannot be solely attributed to the characteristics of the LLMs employed for query generation or answer extraction. This is evident from the substantial performance gains (around 10.8%) achieved, even after enabling both WA and SG with a comparatively weaker model, such as `text-davinci-003`. Additionally, the mix of `text-davinci-003` and `gpt-3.5-turbo` for the WA+SG setting demonstrates superior performance compared to SG with `gpt-3.5-turbo`, achieving improvements of 1.1% and 3.3%, respectively. Thus, showcasing meaningful positive impact of augmenting WA with the stand-alone SG module.

5.4 Python Generator (PG)

In this section, we investigate the effectiveness of the Python Generator (PG) module in using python code, and an interpreter to solve mathematical problems (utilizing external symbolic libraries from `Sympy`). Following, PAL (Program Aided Language Models) (Gao et al., 2023), Program of thought (Chen et al., 2023c), our PG module consists of a a program generator and an executor. The generated code and corresponding output are added in context of the next module in sequence. We present the results of the PG+SG setting in Table 4 for the MATH dataset. For MATH, we present three variations: (i) PG+SG with no code refinement, (ii) PG+CR+SG with code refinement, and (iii) PG′[🎵]+SG (where PG′[🎵] denotes the use of Phind-CodeLLama-34B-V2 model for PG. We choose **Phind-CodeLLama-34B-V2** for our

Table 4: Comparison of our Modular Settings to Published Baselines on **MATH**. We use `gpt-3.5-turbo` (🤖) as the default LLM for each setting (except one row). For PG′[🔏]+SG (🐍+✅) setting, we use `Phind-CodeLlama-34B-V2` as the underlying LLM for the PG🐍 module (while keeping `gpt-3.5-turbo` (🤖) as the default LLM for SG✅ module); Alg: Algebra, P.Cal: Precalculus, P.Alg: Prealgebra, Geom: Geometry, Prob: Probability, N.Th: Number Theory, Int.Alg: Intermediate Algebra; We have taken the first four baseline results from SKiC (Chen et al., 2023a), and following two baselines from (Zhou et al., 2024).

ablation since it is the best model from the huggingface Code-LLM leaderboards. The Phind family of models are finetuned versions of CodeLlama-34B on a Phind dataset consisting of 80k high quality programming problems and solutions.

Results In Table 4, we observe that the PG+SG setting using the `sympy` library without code refinement can improve upon the performance accuracy of SG on the MATH dataset by a margin of 10.1%. We find that a majority of problems in MATH require complex computations such as solving equations, representation of complex mathematical objects such as vectors, solving problems in Geometry, some of which are hurdles for the Solution generator module since text representations alone fail to capture such complexities. Libraries such as `Sympy`, on the other hand, has support for symbolically representing such objects using well defined functions, classes, methods, and sub-packages. We find that this helps PG outperform SG on all mathematical types in MATH. The outcomes of our experiment with PG+CR+SG setting only yields marginal enhancements on overall accuracy. We also observe a drop in the accuracy by 5% when using Phind-CodeLLama-34B-V2 as the LLM in PG module.

5.5 Results of Multiple Module Experiments

We experiment with various module combinations on four datasets MATH, AQUA-RAT, GSM-8K, and MMLU-Math and report in Tabs. 4 & 6. Our findings reveal that distinct modules exhibit specialized efficacy in addressing specific categories of mathematical problems. On the **MATH** dataset, (1) **WA** emerges as a valuable resource for tackling intricate mathematical subdomains, particularly in Intermediate Algebra **(Int.Alg)** and Number Theory **(N.Th)**. The PG+WA+SG setting outperforms SG by 19% on Int.Alg. We conduct a qualitative analysis of PG+SG on 106 randomly sampled questions from MATH spanning all types and difficulty levels, presented in Table 13. We find that the majority of errors in **Int.Alg** arise from python code execution errors and the inability of python code to represent complex math objects in this subdomain. In contrast, the **WA** module effectively interacts with the API using both natural language and symbolic queries (Table 15) to address these issues, resulting in substantial enhancements.(2) For Algebra-related problems (**Prealgebra** and **Algebra**) having complex computations, the generation of Python code guided by PG and the `Sympy` library proves to be an effective choice. The WA+PG+SG setting elevates the performance of SG by 15.8% on Algebra. The PG+SG setting performance is also significantly better compared to SG (10.4%) on Prealgebra showing the utility of code representations over natural language in this subdomain. (3) Table 9 presents an examination of the variations in accuracy among various settings as a function of the problem levels (1-5) in the MATH dataset. Our analysis reveals a consistent improvement of over 10% across all levels with diverse modular configurations. This reaffirms the importance of judiciously selecting tools and configurations based on the specific features and attributes of the given problem.

Effectiveness of MATHSENSEI on MMLU-Math. Results in Table 6 reveal that the BS+PG+SG configuration enhances the accuracy of the SG setting by 3.3%. As the performance is gain is low, we further perform a type wise analysis in Table 5. We observe that, other than **Formal Logic** (FL), adding different modules show substantial improvements in different types, such as 17% in College Math, 11.7% in High School Math, 7.5% in Elementary Math. More specifically we find that: (1) The PG+WA+SG setting improves the accuracy of the SG setting from 84.6% to 92.1% on **Elementary mathematics** problems. (2) Interestingly, problems in **Formal logic** are best solved using SG alone. The drop in performance for the PG+SG setting **(53.9 -> 49.5)** is due to the inability of PG to adequately represent predicate logic, First Order Logic (FOL) sentences through python code, (3) For **College Mathematics**, the WolframAlpha module demonstrates highest efficacy, as evidenced by the substantial benefits observed in both the WA+SG and WA+PG+SG settings. Notably, WA+SG outperforms the SG setting by a significant margin of 17%. Our analysis in MMLU-Math further supports the complementary benefit of the tools used in MATHSENSEI framework for various mathematical types.

Decreased Effectiveness of MATHSENSEI on GSM-8K, and AQUA-RAT. From Table 6, we observe marginal improvements of using multiple modules on **AQUA-RAT** and **GSM-8K**, over the standalone SG module. Both datasets comprise simpler algebraic and arithmetic word problems. GSM-8K consists of problems requiring simple arithmetic operations such as addition, subtraction, etc. and its complexity stems from linguistic diversity. We conduct a case study on a randomly sampled set of 20 examples from **GSM-8K**, where PG+SG is incorrect and SG is correct, we find that 18 (out of 20) have incorrect outputs generated by **PG** (due to reasoning errors) (Table 13). For all these 18 examples, the LLM generated python code tries to solve a simple problem by using complex objects in `Sympy`, which in turn degrades the performance. For the remaining two examples, one has an execution error, while for the other one, **SG** alters the correct PG answer to incorrect. Similar to GSM-8K, **AQUA-RAT** primarily focuses on problems that require generic language-based reasoning skills. We find that settings with tools mostly hurt the performance compared to **SG**. This is attributed to the fact that WA and BS are unnecessary for addressing straightforward problems, and invoking them often introduces noisy and irrelevant information into the context of SG. As we saw previously in case of GSM-8K, a significant proportion of errors in PG+SG (+) can be linked to the application of `Sympy` for simple problems (Table 13). These outcomes highlight the diminishing utility of employing additional modules for tasks requiring minimal external knowledge.

5.6 Insights from Qualitative Analysis of Modules

We consider an example from the MATH dataset and present a qualitative analysis of the responses generated by different settings in Table 7. We observe that SG and PG+SG are unable to capture the fine-grained nuances in the input question (repetition of characters in the word "NINE"), leading to reasoning errors. On the other hand, the BS+SG and WA+SG settings avoid committing such errors. This demands a need for a careful examination of the strengths and limitations of the individual modules, which we discuss in details in this section.

Bing Web Search (BS). Previous investigations of retrieval-augmented generation (RAG) (Lewis et al., 2021) and Self-RAG (Asai et al., 2023) have shown that conditional generation using retrieval-based approaches improves factuality in knowledge intensive tasks such as question answering, fact verification, etc. We observe similar benefits of employing retrieval-based methods in the domain of complex mathematical reasoning. The BS module retrieves useful information (such as formulas, concepts and similar questions) from the Web,

QUESTION: Determine the number of ways to arrange the letters of the word NINE. **GOLD ANSWER:** $\boxed{12}$

SG ( ):

There are 4 distinct letters in the word NINE. The number of ways to arrange 4 distinct letters is 4! = 24. Therefore, the answer is $\boxed{24}$.

SG module misses the repeated characters in NINE.

PG+SG (+)

```
from sympy import *
word = 'NINE'
numperm=factorial(len(word));
print(numperm);
...
```

The word NINE has 4 letters.The number of ways to arrange 4 distinct letters is 4! = 24. Therefore, the answer is $\boxed{24}$.

PG module ignores the repeated characters.

BS+SG (+)

Retrieved Example: In the word "BANANA", there are 6 letters but only 3 distinct letters ...repeated letters.
Retrieved Formula: nPr = n!/(n1! n2! ... nr!) ...Therefore, the answer is 4!/ (2! 1! 1!) = $\boxed{12}$.

BS module retrieves similar examples and relevant formula from the Web.

WA+SG (+)

We call the Permutations function on the word NINE to find all possible arrangements of the letters. The answer from WolframAlpha is EINN, ENIN, ..., NINE. Therefore, the answer is $\boxed{12}$.

WA module generates the correct query: Permutations[NINE] to solve the given question and final SG answer is grounded on WA output.

Table 7: Qualitative Analysis of the Responses generated by different Settings for a given MATH example.

improving the effectiveness of the downstream SG module. As shown in Table 7, the BS module retrieves an informative example of a similar question (permutations of the letters in the word "BANANA", having repeated characters) and the correct formula of permutations with repetitions, which aids the SG module in correctly reasoning about the final solution. However, our current implementation of the BS module also has certain limitations. We directly use the raw output returned by the Bing Web Search API v7, which is **noisy** in certain cases. Additionally, we do not employ any **critique mechanism** to check the relative importance of multiple pieces of the retrieved information. We also observe a significant reduction in performance on GSM-8K after adding the BS module to SG. This calls for a component which can effectively decide when it is required to retrieve knowledge and when it is not necessary (future research).

WolframAlpha (WA). The WA module overcomes the limitations of SG by harnessing the computational power and intelligence of the WolframAlpha engine. In cases, where the query to the WolframAlpha-API is syntactically and logically correct for solving a mathematical question, the returned answer is guaranteed to be correct, which is then processed by the SG module to compile the final answer. From Figure 6, we observe maximum benefit of WolframAlpha module for problems in the subdomains of Algebra and Intermediate Algebra (primarily for difficulty levels greater than one). We demonstrate the utility and limitations of the WA module in Tables 16 and 14, respectively. The limitations of the WA module are mostly associated with: (1) Logical errors in LLM-generated WA API Queries (Example 1 in Table 14), (2) Wrong interpretation of correct WA response by the downstream SG module (Example 2 in Table 14), (3) Single line WA response, which restricts the ability of downstream SG module to generate step-by-step reasoning (Example 3 in Table 14).

Python Generator (PG). As mentioned in Section 5.4, the Sympy library offers strong capabilities to the PG module for **MATH**. The deterministic program executor also helps in avoiding common errors committed by the standalone SG module. We found the PG module to be most useful in solving *Algebra*, *Prealgebra* and *Number Theory* problems. The example presented in Table 17 demonstrates the advantage of using the PG module over the SG module. The primary errors of the PG module in *Intermediate Algebra* and *Prealgebra* are mainly due to inability of the generated python code to express **complex objects (syntax errors)** and **boundary cases**, respectively. In the case of *Geometry* and *Precalculus* problems, a large proportion of errors are caused due to **lack of understanding the plots/figures** (expressed in latex format) accompanying the question. Table 12 presents examples of common syntactical errors (from the MATH dataset) of the PG module, and Table 13 summarizes the different error types of PG+SG setting. Similar to PoT (Chen et al., 2023c), we found the PG module to be less effective for simpler arithmetic problems (removal of Sympy improves the performance by 2-3%). However, the overall performance of SG and PG+SG still remains quite similar. In Table 18, we present an example from GSM-8K where PG+SG commits a reasoning error while the SG setting is correct.

6 Conclusion

We introduce a Tool-augmented Large Language Model (TALM) framework, aka MATHSENSEI, targeted for Mathematical Reasoning. We utilize tools for web-based knowledge retrieval, program generation and execution and symbolic equation solving. We perform extensive ablations over the individual tools, along with varying the order and combination on complex mathematical reasoning datasets (such as MATH). Our best configuration achieves a 13.5% improvement over `gpt-3.5-turbo` (with CoT prompting) on MATH. Our experiments with tool-sequencing methods does not improve over our best configuration. We also observe that benefit of mathematical *TALM*s are minimal for simpler math word problems (in GSM-8k) and its benefit increases as the required complexity and knowledge for the problem increases through AQuA, MMLU-Math.

Limitations

We propose a Tool-Augmented LLM framework (*TALM*), uniquely targeted towards complex mathematical reasoning. Here, we discuss three types of limitations: 1) choice of the set of tools, 2) variants of the PG module for simpler problems and 3) developing mathematical *TALM*-specific planning methods.

1. Here, we choose tools, which intuitively offers knowledge about complex mathematical disciplines and complex equation solving capabilities such as Python with `sympy` library, `WolframAlpha-API` and Bing Web Search API. However, we have not explored other solvers which are targeted towards logical complexity or adding commonsense knowledge. In future, a more universal *TALM* can target adding Z3, SAT solvers and OMCS knowledge base query capabilities.

2. Our Program Generator (PG) module is not only inspired by the program-guided solving methods, but also targetedly use `sympy` library to access complex mathematical equation solving skills. Such skills may not be required for simpler math word problems, as present in GSM-8k. In future, we plan to work on generalizing the PG module so that it is adaptive for simpler problems and focuses mainly on representing the problems in code, only accessing `sympy` capabilities when required.

3. Lastly, we worked on vanilla adaptation of the available planning or tool-sequencing methods directly in the mathematical *TALM* (or MATHSENSEI) context. From our experiments, it is clear that we need to develop more efficient planners that can dynamically choose a sequence of tools based on the problem type (say WA+PG+SG for algebra and PG+CR+SG for Probability), striking a balance between planning beforehand (Plan-And-Solve) and example-wise planning (REACT). We hope our work will inspire researchers to work on such planning methods for mathematical *TALM*s.

A Planning Experiments

We explore two state-of-the-art planning strategies based following the Chameleon (Lu et al., 2023a) and the REACT (Yao et al., 2022) frameworks and report in in Table 10.

Plan-And-Solve Within the Plan-And-Solve (PAS) framework, a dynamic planner (LLM), generates a plan for a given mathematical problem before the start of execution. In our context, the plan consists of the sequence of modules to be run. Notably, this planning approach is inherently non-adaptive, as the strategy lacks the capability to determine the next module based on feedback and the output of the previously executed modules. To instruct the planner LLM, we provide input prompts containing information about each module, along with few-shot examples representing a possible sequence. The prompts utilized for the planner model are detailed in Table 22.

MATHSENSEI with REACT Planner. The previous modular settings, have a fixed order of execution of the modules. However, we also wish to test out settings where there is power given to the central LLM to call different modules as and when required. This is done by executing (thought, action request, action execution) triplets. The thought serves as a summary of what we have till now in relation to answering the question, the action request is the specific action we wish to take in the next step, and the action execution step calls the necessary module from the modules library to execute the action. An overview of the REACT setting applied to the MATH dataset is presented in Fig. 5. The results for this setting corresponding to each problem type is presented in Table 10.

Results. We evaluate the performance of Plan-And-Solve and REACT on a randomly sampled subset of the MATH dataset of 3100 examples(for which REACT converges). The results show that simple vanilla implementation of the above planners is not sufficient for surpassing our best configuration PG+WA+SG. In particular, the majority of errors for REACT, were as a result of the failure of REACT to converge to a final solution (finish thought state). The variation of the accuracy as a function of the level of the problem (Table 11) shows, REACT* can surpass Plan-And-Solve (PAS) by a small percentage, however it still lags behind our best settings.

Unlike planning in traditional closed world setup datasets such as Blocksworld, Logistics, Depot planning, etc., the task of planning in the mathematical reasoning domain presents multiple differences: Firstly, the set of possible actions is not finite as we can query each tool/module with any input string. Moreover, there are no preconditions that need to be satisfied for executing a particular action which makes the planning space much more unbounded. This can lead to long planning chains with (thought,action,execution) triplets where there may be multiple irrelevant actions. As seen from our work, the strengths and limitations of each tool also varies with the type of datasets, subdomains and difficulty levels, which makes the problem non-trivial. Hence, it turns out to be overwhelming to propose a novel planning strategy in this paper. We plan to explore this issue as a future research direction. A planner with a novel architecture and sufficient mathematical knowledge may be required to tackle this aspect.

Here we report the absolute count of errors across different subjects.

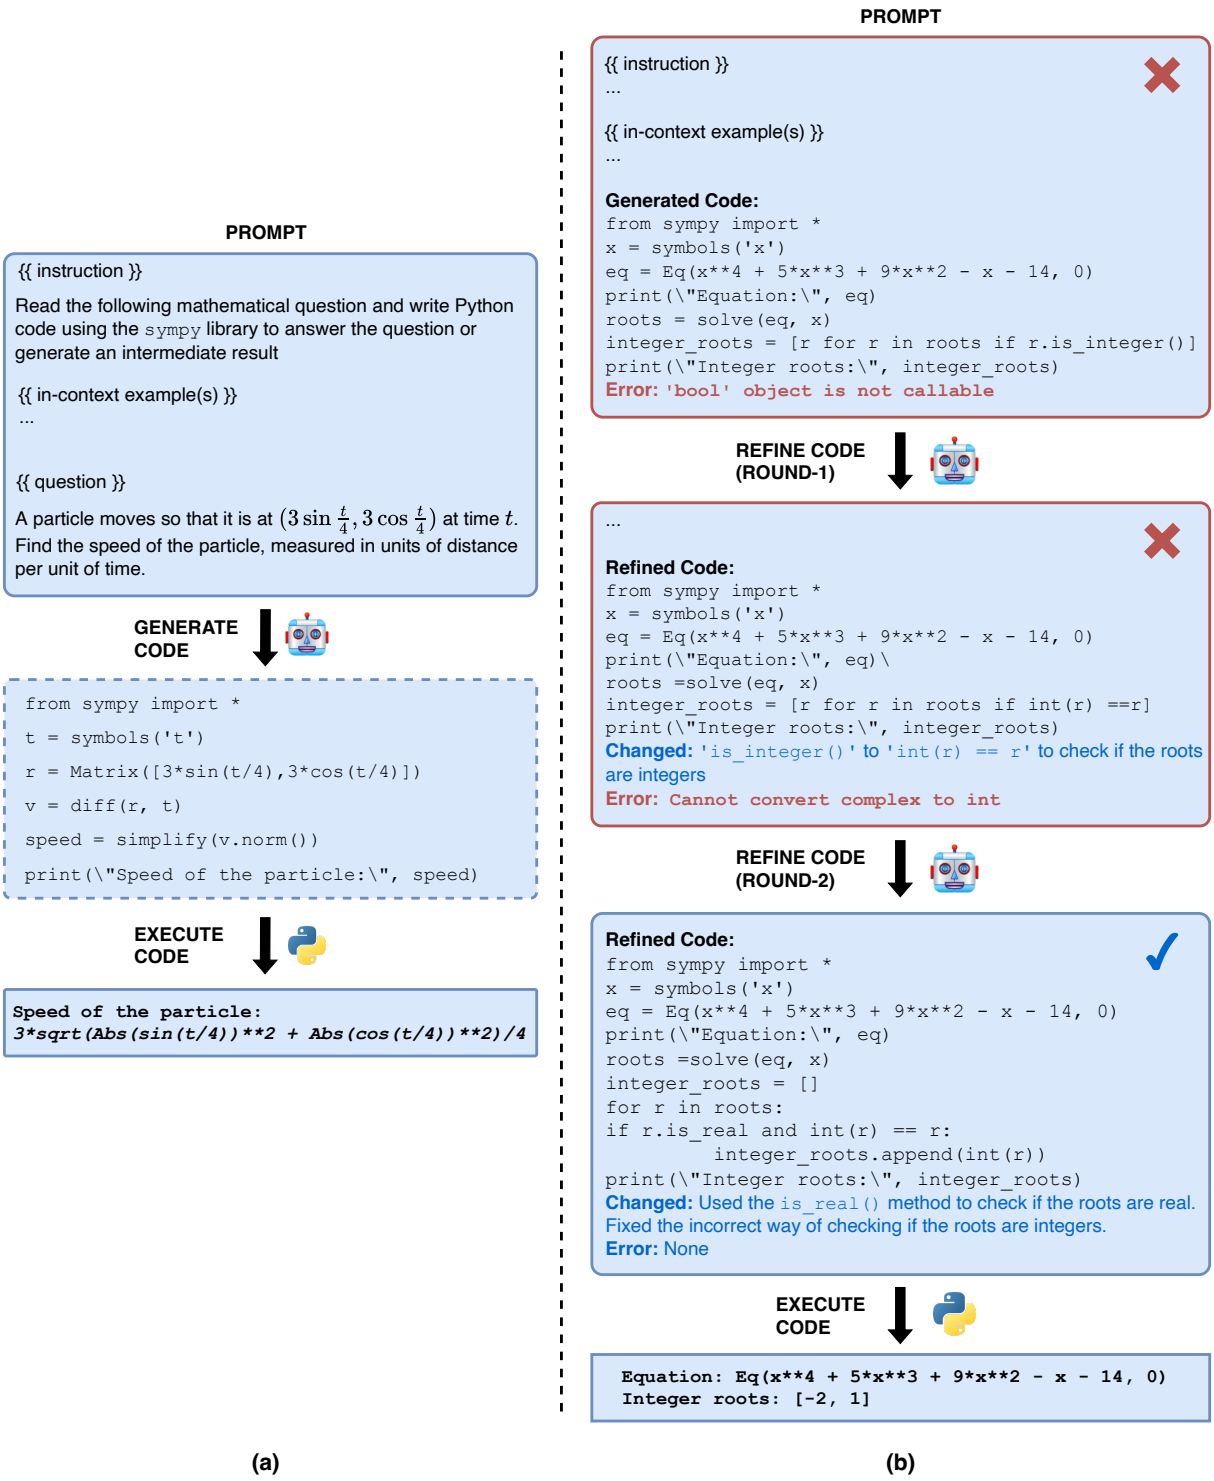

Figure 4: Overview of (a) Python Generator Module and (b) Code Refiner Module

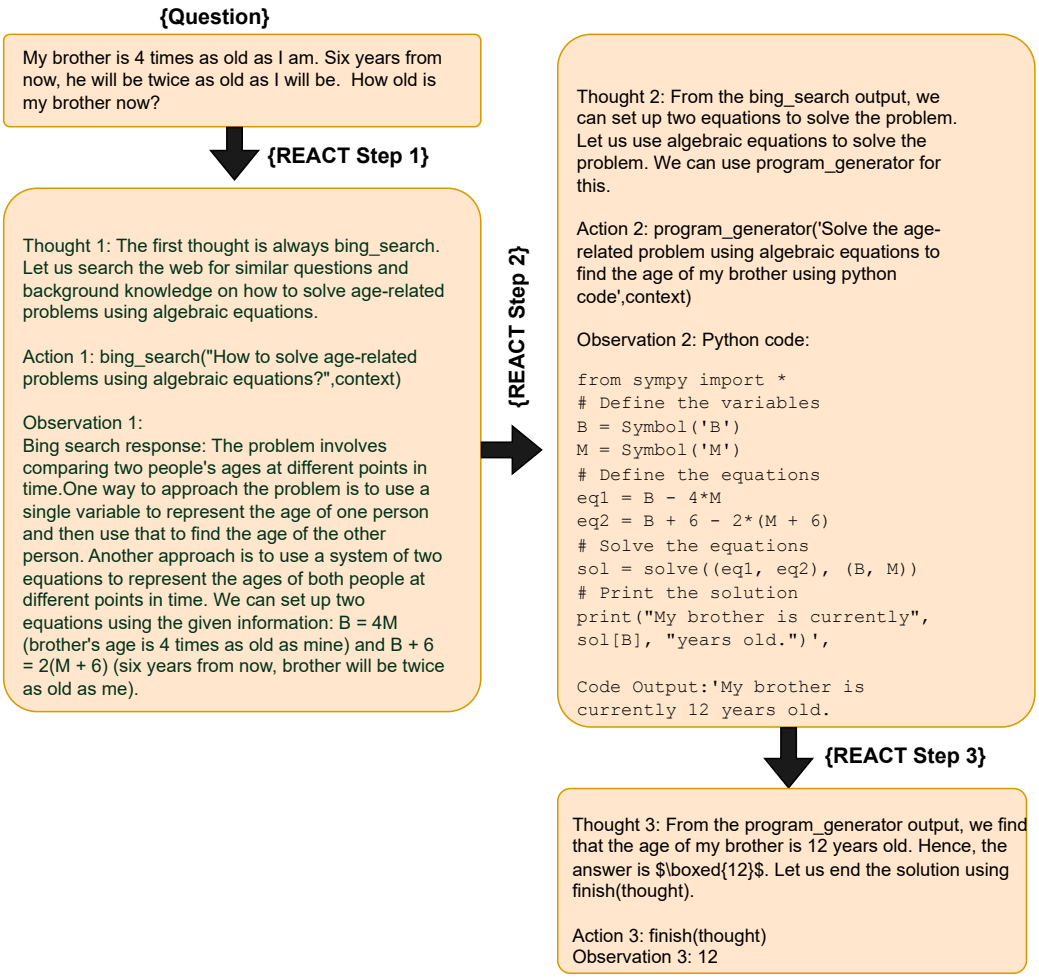

Figure 5: Generated output for example from the MATH dataset for the REACT planning setting.

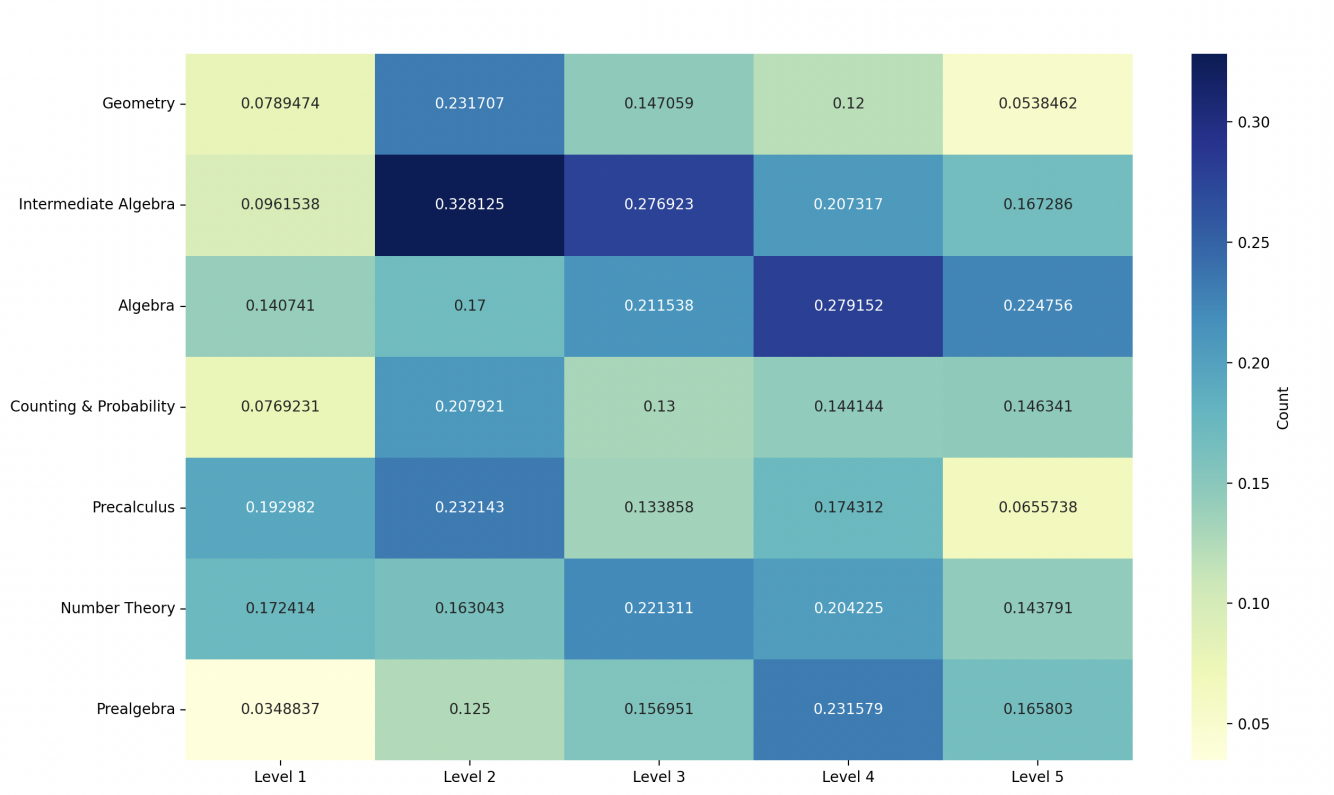

Figure 6: Distribution of examples where WA+SG (+) is correct and SG () is wrong, across problem types and level of difficulty (1-5). The values are normalized by number of examples in each (subject - level) combination.

Setting: WA+SG (✿+✔)		
QUESTION 1: The positive integers up to 2007 are alternately subtracted and added: $[1-2+3-4+\cdots+2001-2002+2003-2004+2005-2006+2007.]$ What is the value of the expression? **GOLD ANSWER:** $\boxed{1004}$	**QUESTION 2:** When the expression $-2x^2-20x-53$ is written in the form $a(x+d)^2+e$, where a, d, and e are constants, what is the sum a+d+e? **GOLD ANSWER:** $\boxed{0}$	**QUESTION 3:** Solve $\frac{2x^2+x+3}{x^2+x+1} = \frac{2x+1}{x+1}$ for x. **GOLD ANSWER:** $\boxed{-2}$
WA API Query: Sum$[(-1)^n * n, \{n, 1, 2007\}]$ [*INCORRECT; since it finds negative of the required answer*] *CORRECT* Query : Sum$[(-1)^{(n+1)} * n, \{n, 1, 2007\}]$	**WA API Query:** CompleteSquare$[-2x^2-20x-53]$ [*CORRECT*]	**WA API Query:** solve $(2x^2+x+3)/(x^2+x+1) = (2x+1)/(x+1)$ for x [*CORRECT*]
WA Output: Yes, the answer is -1004 . [*Logical errors in LLM generated WA API queries*].	**WA Output:** Yes, the answer from this object is: $-2(x+5)^2-3$ [*CORRECT*]	**WA Output:** Yes, the answer is x = -2 [*Since WA module returns a single line answer (in many cases), the downstream SG module fails to provide a step-by-step reasoning.*]
SG Output: We use the Wolfram Alpha API to evaluate the expression Sum$[(-1)^n * n, n, 1, 2007]$. The answer from Wolfram Alpha is -1004. Therefore, the answer is $\boxed{-1004}$ [*INCORRECT*]	**SG Output:** From WolframAlpha response, we find $-2x^2-20x-53 = -2(x+5)^2-3$.Thus we have $a=-2$, $d=-5$, and $e=-3$. So, $a+d+e=-2-5-3=-10$. Therefore, the answer is $\boxed{-10}$ [*INCORRECT; wrong interpretation of correct WA response by the downstream SG module. Value of d should be +5 and not -5.*]	**SG Output** We call the WolframAlpha API to solve the given equation.The answer from Wolfram Alpha is x = -2. Therefore, the answer is $\boxed{-2}$ [*CORRECT; but lacks reasoning chains*]

Table 14: Limitations of the WA Module in WA+SG (✿+✔) setting.

WA Query
$Sum[i^k, \{k, 1, 259\}]$
$Solve[\{725x + 727y == 1500, 729x + 731y == 1508\}, \{x, y\}]$
FactorInteger[3105]
$maximize[y/x, (x-3)^2 + (y-3)^2 == 6]$
period of $cos(bx)$

Table 15: Examples of generated WolframAlpha (WA) Queries.

QUESTION 1: Find the remainder when $x^5 + x^4 + x^3 + x^2 + x$ is divided by $x^3 - 4x$

GOLD ANSWER: $\boxed{5x^2 + 21x}$

QUESTION 2: Let P be the point $(0, 5)$, let Q be the point $(6, 9)$, and let R be the point $(12, 0)$. Determine the area of right-angled $\triangle PQR$.

GOLD ANSWER: $\boxed{39}$

Setting: SG

Response:
The result of the division is $x^2 + 5x + \frac{5x}{x^3 - 4x}$

[*INCORRECT; Calculation error in intermediate step*]

Response:
$QR = \sqrt{(12-6)^2 + (0-9)^2} = \sqrt{180}$

[*INCORRECT; Error in distance calculation in intermediate step.*]

Setting: WA+SG

WA API Query:
PolynomialRemainder[$x^5 + x^4 + x^3 + x^2 + x, x^3 - 4x, x$]
[CORRECT]

WA Output:
Yes, the answer is $5x^2 + 21x$
[*CORRECT*]

SG Output:
The answer from Wolfram Alpha is found to be $5x^2 + 21x$. Therefore, the answer is $\boxed{5x^2 + 21x}$
[*CORRECT*]

WA API Query:
triangle((0,5),(6,9),(12,0))
[*CORRECT*]

WA Output:
Yes, the answer is: Triangle shape: right triangle; Edge lengths: $(2\sqrt{13}, 3\sqrt{13}, 13) \approx (7.211, 10.816, 13)$; - Area: 39; Perimeter: $13 + 5\sqrt{13} \approx 31.027$; Interior angles: $cos^{-1}(3/\sqrt{13})$ rad; $cos^{-1}(2/\sqrt{1})$ rad; $\pi/2$ rad $\approx$ (0.588 rad, 0.982 rad, 1.570 rad); Interior angle sum: $180° = \pi$ rad ≈ 3.142 rad.
[*CORRECT*]

SG Output:
We call the Wolfram Alpha API to find the area of the triangle formed by the points $(0, 5)$, $(6, 9)$, and $(12, 0)$; The answer from Wolfram Alpha is found to be 39; Therefore, the answer is $\boxed{39}$
[*CORRECT*]

Table 16: Utility of the WA module in WA+SG (+) setting.

QUESTION: The average of Amys, Ben, and Chris's ages is 6. Four years ago, Chris was the same age as Amy is now. In four years, Ben's age will be 35 of Amy's age at that time. How many years old is Chris now?

GOLD ANSWER: $\boxed{10}$

Setting: SG (✅)

Response:

$\frac{1}{3}(a+b+c) = 6; \quad c-4 = a; \quad b+4 = \frac{3}{5}(a+4).$

Simplifying the third equation, we get $5b + 20 = 3a + 12$. Substituting $c = a + 4$ into the first equation and simplifying, we get $a + b = 10$.

[*INCORRECT; Correct equation: 2a +b =14*]

Setting: PG+SG (🐍+✅)

Response:

```
from sympy import *
a, b, c = symbols('a b c')
eq1 = Eq((a+b+c)/3, 6)
eq2 = Eq(c-4, a)
eq3 = Eq(b+4, Rational(3,5)*(a+4))
sol = solve((eq1, eq2, eq3), (a, b, c))
print("Chris's age is", sol[c], "years old")
```

[Leverages the classes **Rational**, **Eq** and method **solve** from Sympy]

PG Output: Chris's age is **10** years old

SG Output: Let Amy's age be a, Ben's age be b, and Chris's age be c. The average of their ages is $\frac{a+b+c}{3} = 6$, Four years ago, Chris's age was c-4, which was the same as Amy's age at that time, so $c - 4 = a$, In four years, Ben's age will be $b + 4$, which will be $\frac{3}{5}$ of Amy's age at that time, so $b + 4 = \frac{3}{5}(a + 4)$, Solving the system of equations gives $a = 6$, $b = 2$, and $c = 10$. Therefore, the answer is $\boxed{10}$ years old.

[*CORRECT*]

Table 17: Utility of the PG module in PG+SG (🐍+✅) setting.

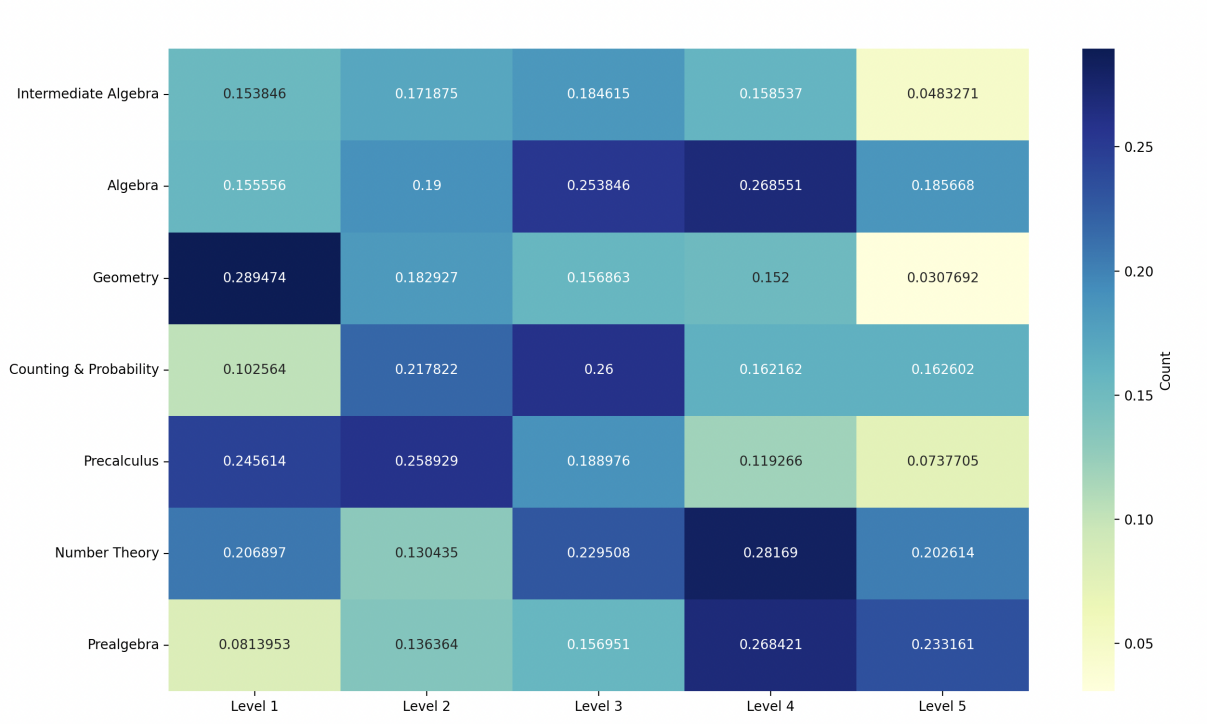

Figure 7: Distribution of examples where PG+SG (+) is correct and SG ( ) is wrong, across problem types and level of difficulty (1-5). The values are normalized by number of examples in each (subject - level) combination.

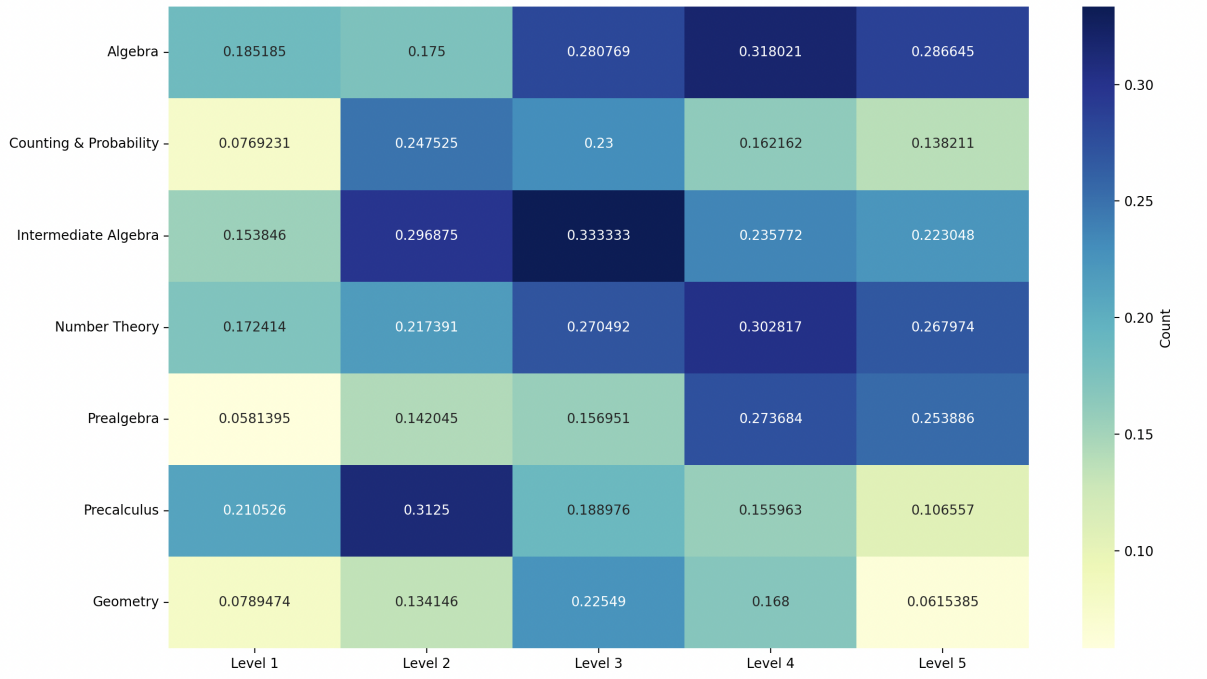

Figure 8: Distribution of examples where PG+WA+SG (+ +) is correct and SG ( ) is wrong, across problem types and level of difficulty (1-5). The values are normalized by number of examples in each (subject - level) combination.

QUESTION: Uriah's book bag is getting too heavy for him. He needs to remove 15 pounds from it. His comic books weigh 1/4 pound each and his toys weigh 1/2 pound each. If he removes 30 comic books, how many toys does he need to remove?

GOLD ANSWER: 30 comic books weigh 7.5 pounds because 30 x .25 = «30*.25=7.5»7.5 He needs to remove 7.5 more pounds because 15 - 7.5 = 7.5 He needs to remove 15 toys because 7.5 / .5 = 15

Setting: SG (✓)

Response:

We know that Uriah needs to remove a total of 15 pounds from his bag. He removes 30 comic books, which weigh a total of 30*(1/4) = 7.5 pounds. So he still needs to remove 15 - 7.5 = 7.5 pounds.Let the number of toys he needs to remove be x.The weight of x toys is x*(1/2) = 0.5x pounds. We need to solve the equation 0.5x = 7.5 to find x. Solving for x, we get x = 15. Therefore, Uriah needs to remove 15 toys from his bag. The answer is 15. [*CORRECT*]

Setting: PG+SG (🐍+✓)

Response:

```
from sympy import *
x = symbols('x')
eq = Eq((1/4)*(30-x) + (1/2)*x, 15)        [Wrong equation - reasoning error]
print("Equation:",eq)
sol = solve(eq, x)
print("Solution x:",sol)
ans = 30 - sol[0]
print("Toys to remove:",ans)
```

PG Output: Equation: Eq(0.25*x + 7.5, 15); Solution x: [30.0000000000000]; Toys to remove: 0;

SG Output: From Python code we get that Uriah needs to remove 0 toys. The answer is 0. [*INCORRECT*]

Table 18: Demonstration of a Reasoning Error committed by the PG module in PG+SG (🐍+✓) setting in a GSM-8K problem.

INSTRUCTION

Read the following question, generate the background knowledge or relevant mathematical information as the context information that could be helpful for answering the question.

IN-CONTEXT EXAMPLES

Question: The smallest distance between the origin and a point on the graph of [$y = \frac{1}{2}x^2 - 9$] can be expressed as a. Find a^2.
Modules used till now: []
Mathematics Problem Type: Algebra
Level of Problem: Level 5
Knowledge:
- The question involves the concept of distance between two points in a coordinate system.
- The distance between the origin and a point (x, y) on the graph is given by the formula $\sqrt{(x^2 + y^2)}$.
- Minimizing $(x^2 + y^2)$ is same as minimizing $\sqrt{(x^2 + y^2)}$.
- Substitute $y = 1/2x^2 - 9$ into the equation to get $x^2 + (1/2x^2 - 9)^2$.
- Take derivative of above equation and set it to 0.

... **[More few shot examples]**

INPUT QUESTION

Question: What is the following value when expressed as a common fraction: $\frac{1}{2^1} + \frac{1}{2^2} + \frac{1}{2^3} + \cdots + \frac{1}{2^8} + \frac{1}{2^9} + \frac{1}{2^{10}}$?

Mathematics Problem Type: Algebra
Level of Problem: Level 4

OUTPUT

Knowledge:
- The question involves understanding of geometric series in mathematics.
- A geometric series is a series of numbers where each term is obtained by multiplying the previous term by a fixed constant, called the common ratio.
- The sum of the first n terms of a geometric series is given by the formula $S_n = a(1 - r^n)/(1 - r)$, where a is the first term and r is the common ratio.
- In this case, the first term is 1/2 and the common ratio is also 1/2.
- We need to find the sum of the first 10 terms of the series, which can be calculated using the above formula.

Table 19: LLM-based Knowledge Retrieval Prompt

INSTRUCTION

Read the following question to generate thought, Query for searching Bing Web Search API, that will help to solve the entire problem or specific subproblems in the question.

IN-CONTEXT EXAMPLES

Question: When the expression $-2x^2 - 20x - 53$ is written in the form $a(x + d)^2 + e$, where a, d, and e are constants, what is the sum $a + d + e$?
Modules used till now: []
Mathematics Problem Type: Algebra
Level of Problem: Level 5
Thought: Since the question involves completing the square let us search how to complete the square.
Query: How do we complete the square of a quadratic equation?

Question: A circle is circumscribed about an equilateral triangle with side lengths of 6 units each. What is the area of the circle, in square units? Express your answer in terms of π.
Modules used till now: []
Mathematics Problem Type: Geometry
Level of Problem: Level 5
Thought: To solve this problem, we can search how to find the circumradius of an equilateral triangle.
Query: How to find the circumradius of an equilateral triangle?

... **[More few shot examples]**

INPUT QUESTION

Question: The point $P = (1, 2, 3)$ is reflected in the xy-plane, then its image Q is rotated by 180° about the x-axis to produce R, and finally, R is translated by 5 units in the positive-y direction to produce S. What are the coordinates of S?
Mathematics Problem Type: Precalculus
Level of Problem: Level 3

OUTPUT

Thought: To solve this problem, we can search the web for formulas related to reflection, rotation and translation.
Query: What are the formulas for reflection, rotation, and translation in 3D space?

Table 20: Bing Web Search Query generator Prompt for Concepts Search

INSTRUCTION

Read the following question to generate thought, answer and final query for searching Wolfram Alpha API, that is being used to solve the problem or specific subproblems.

IN-CONTEXT EXAMPLES

Question: When the expression $-2x^2 - 20x - 53$ is written in the form $a(x + d)^2 + e$, where a, d, and e are constants, what is the sum $a + d + e$?
Modules used till now: []
Mathematics Problem Type: Algebra
Level of Problem: Level 5
Thought: To find the answer to the problem, we need to rewrite the quadratic expression $-2x^2 - 20x - 53$ in the form $a(x + d)^2 + e$, where a, d, and e are constants. Then, we find the sum a+d+e. Do you know the Wolfram Alpha command to do this?
Answer: Yes, the Wolfram Alpha command to factor the given quadratic expression is: factor$(-2x^2 - 20x - 53)$
Final Query: factor$(-2x^2 - 20x - 53)$

Question: Harold tosses a nickel four times. What is the probability that he gets at least as many heads as tails?
Modules used till now: []
Mathematics Problem Type: Counting and Probability
Level of Problem: Level 5
Thought: To find the probability that Harold gets at least as many heads as tails when tossing a nickel four times, we can use combinatorial techniques to count the favorable outcomes. However, to simplify the calculations, we can leverage Wolfram Alpha to compute the probability efficiently. Do you know the Wolfram Alpha command to find the probability for this problem?
Answer: Yes, the Wolfram Alpha command to find the probability of getting at least as many heads as tails when tossing a nickel four times is: $Binomial[4, k] * (1/2)^4$, where k ranges from 2 to 4 (inclusive).
Final Query: $Sum[Binomial[4, k] * (1/2)^4, k, 2, 4]$

... **[More few shot examples]**

INPUT QUESTION

Question: Find the constant c such that $(x^2 - 4x + 3)(x + 5) - (x^2 + 4x - 5)(x - c) = 0$ for all x.

OUTPUT

Thought: To find the constant c such that the given expression is equal to zero for all x, we can expand the expression and collect like terms. Do you know the Wolfram Alpha command to do this?

Answer: Yes, the Wolfram Alpha command to expand the given expression and set it equal to zero is: expand $((x^2 - 4x + 3)(x + 5) - (x^2 + 4x - 5)(x - c)) = 0$

Final Query: expand $((x^2 - 4x + 3)(x + 5) - (x^2 + 4x - 5)(x - c)) = 0$

Table 21: Wolfram Alpha API Query generator Prompt

INSTRUCTION

You need to act as a policy model, that given a question, determines the sequence of modules that can be executed sequentially to solve the question.

The modules are defined as follows:
- wolfram-alpha-search: Calls the Wolfram-Alpha API to solve the given question or intermediate steps in the question.
- bing-search: Retrieves similar questions, background knowledge, useful information using the Bing Web Search API.
- python-generator: This module generates an executable python program that can solve the given question using the Sympy library.
- solution-generator: This module generates a detailed solution to the question based on the already generated context. Normally, solution-generator will incorporate the information from wolfram-alpha-search, bing-search, python-generator. It is always the last module to be executed.

IN-CONTEXT EXAMPLES

Question: Determine the number of ways to arrange the letters of the word ELEVEN.
Modules: ['bing-search','solution-generator']

INPUT QUESTION

Question: If the numbers 4, 5 and 6 are each used exactly once to replace the letters in the expression $A(B - C)$, what is the least possible result?

OUTPUT

Modules: ['python-generator', 'solution-generator']

Abstract

Coherence evaluation aims to assess the organization and structure of a discourse, which remains challenging even in the era of large language models. Due to the scarcity of annotated data, data augmentation is commonly used for training coherence evaluation models. However, previous augmentations for this task primarily rely on heuristic rules, lacking designing criteria as guidance. In this paper, we take inspiration from linguistic theory of discourse structure, and propose a data augmentation framework named CoUDA. CoUDA breaks down discourse coherence into global and local aspects, and designs augmentation strategies for both aspects, respectively. Especially for local coherence, we propose a novel generative strategy for constructing augmentation samples, which involves post-pretraining a generative model and applying two controlling mechanisms to control the difficulty of generated samples. During inference, CoUDA also jointly evaluates both global and local aspects to comprehensively assess the overall coherence of a discourse. Extensive experiments in coherence evaluation show that, with only 233M parameters, CoUDA achieves state-of-the-art performance in both pointwise scoring and pairwise ranking tasks, even surpassing recent GPT-3.5 and GPT-4 based metrics. [1]

1 Introduction

Coherence is a vital aspect of communication that evaluates the structure and organization of discourse (Halliday and Hasan, 1976; Grosz and Sidner, 1986). Consequently, models capable of evaluating coherence of the given text are widely applicable in both discourse generation and assessment. While recent large language models show strong performance in various tasks (Brown et al., 2020), they have not presented superiority in coherence evaluation compared with the fine-tuning based models (Fu et al., 2023). Considering both computational efficiency and evaluation performance a good evaluation metric should possess, in this paper, we focus on modeling coherence via a fine-tuning based lightweight model.

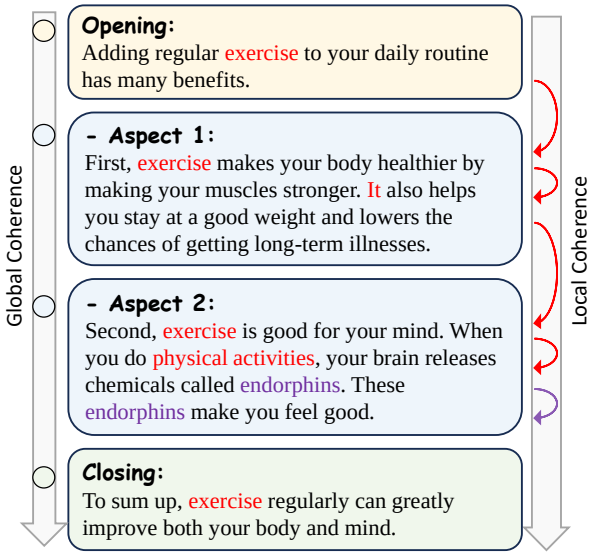

Figure 1: Example for global coherence and local coherence in a discourse. Globally, the discourse is well-structured, with a opening sentence to introduce the argument, five sentences to give evidence from two aspects, and a closing sentence for conclusion. Locally, the focused items, which is denoted in Red and Purple, transfers smoothly from sentence to sentence.

Due to the scarcity of human-annotated data, data augmentation techniques are commonly employed in training a coherence evaluation model (Li and Jurafsky, 2017; Jwalapuram et al., 2022). As human-written discourses naturally possess coherence and can thus serve as positive samples, previous research has focused on constructing negative samples, primarily through rule-based methods such as swapping or shuffling sentences (Barzilay and Lapata, 2008; Shen et al., 2021; Jwalapuram et al., 2022). However, as these methods

Proceedings of the 2024 Conference of the North American Chapter of the Association for Computational Linguistics: Human Language Technologies (Volume 1: Long Papers), pages 967–978
June 16-21, 2024 ©2024 Association for Computational Linguistics

are heuristically inspired without any design criteria as guidance, they suffer from weak correlation with human judgements (Mohiuddin et al., 2021). This brings up the research question: To effectively model coherence, can we find reasonable criterium as guidance to design augmentation strategies?

According to Grosz and Sidner (1986), discourse coherence is mainly determined by two aspects: the organization of discourse segments (i.e. *global coherence*), and the transition of attention or focused items (i.e. *local coherence*). Examples for these two aspects of coherence are presented in Figure 1. This inspires us to the designing criteria that a good data augmentation strategy should uniformly cover these two aspects of coherence. Following the criteria, we propose a **Co**herence evaluation framework via **U**nified **D**ata **A**ugmentation, namely **CoUDA**, which unifies both global and local aspects of coherence throughout training and inference phase.

CoUDA involves global and local augmentation to capture the corresponding aspects of coherence. Regarding global augmentation, we construct negative samples through shuffling, which disrupts the original order of the sentences to induce global incoherence. For local augmentation, our target is to construct negative samples that contain sentences incoherent with the context. While prior rule-based methods, such as swapping a sentence with another from a different text (Shen et al., 2021), can also introduce local incoherence, their constructed samples often lack diversity and complexity, potentially failing to capture nuanced aspects of local coherence. To address this, we propose a novel generative augmentation strategy that involves post-pretraining a generative model, and applying two controlling mechanisms to manipulate the difficulty of generated samples. By sampling from a generative model, and applying difficulty control, we construct high-quality negative samples to disrupt local coherence. Finally, in inference phase, we design a unified scoring strategy to incorporate both aspects of coherence for overall assessment.

While previous research on coherence evaluation has traditionally adhered to a pairwise ranking setup, we have pioneered a pointwise coherence scoring setting that we believe is more relevant in real-world scenarios. On SummEval(Fabbri et al., 2021), our CoUDA exhibits remarkable improvements in pointwise scoring compared to prior methods, including GPT-4-based metrics. Despite not being specifically tailored for pairwise ranking, our model outperforms previous ranking models on both the INSTED-CNN and INSTED-WIKI datasets (Shen et al., 2021). Furthermore, CoUDA is a lightweight model with only 233M parameters. To sum up, our contributions are as follows:

- We propose CoUDA, a data augmentation framework inspired by linguistic theory of discourse structure, which uniformly models both global and local coherence aspects of a discourse.
- We propose a novel generative augmentation strategy, which utilizes the power of the pretrained language model via post-pretraining and two mechanisms for sample difficulty control.
- Comprehensive experiments in coherence evaluation show CoUDA with only 233M parameters achieves SOTA performance, even surpassing GPT-3.5 and GPT-4 based metrics.

2 CoUDA Framework

In this section, we introduce our CoUDA framework, as illustrated in Figure 2. First, we use global and local augmentation to create negative samples that have relatively poor global coherence and local coherence, respectively. To be specific, we use sentence shuffling for global augmentation, and design a generative strategy for local augmentation. Our generative strategy involves post-pretraining a generative model, and applying two controlling mechanisms to control the difficulty of generated samples. Then we combine the constructed negative samples with the original discourses, which serves as positive samples, to train our metric model for coherence/incoherence classification. In inference phase, we utilize a unified scoring strategy to incorporate global and local coherence for overall assessment.

2.1 Preliminaries

Task Formulation. Given a discourse that contains multiple sentences $D = \{s_1, s_2, \ldots, s_n\}$, the goal of a coherence evaluator f_θ is to assess its degree of coherence by a logit score $f_\theta(D) \in [0, 1]$ (the higher the better). Ideally, $f_\theta(D) = 1$ represents that D is perfectly coherent, while $f_\theta(D) = 0$ indicates the opposite. Different from previous work that additionally relies on references (Zhao et al., 2022) or source inputs (Zhong et al., 2022), we evaluate coherence in this more concise framework that solely takes the discourse as the input.

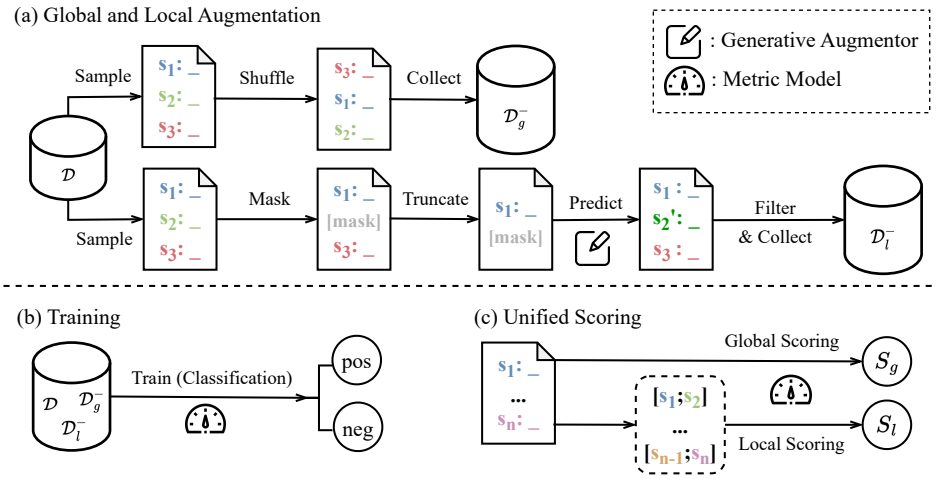

Figure 2: Overview of our proposed CoUDA framework. (a): First, we use global and local augmentation to create negative samples $\mathcal{D}_g^-$ and $\mathcal{D}_l^-$, respectively. (b): Then, we combine $\mathcal{D}_g^-$ and $\mathcal{D}_l^-$ with the original discourses $\mathcal{D}$ to train our metric model via coherence/incoherence classification. (c): In inference phase, our metric model scores the whole discourse for global score S_g, and scores each consecutive sentence pairs for local score S_l. S_g and S_l are combined to produce the final coherence score.

That is more appropriate for evaluation as coherence is an intrinsic quality of a discourse.

Data Augmentation. Data augmentation aims to artificially create additional training samples by manipulating existing data. For a discriminative setting, we need both positive and negative samples for training. In terms of coherence evaluation, since a natural discourse D is intrinsically coherent, we focus on applying data augmentation to construct negative samples, i.e. incoherent samples D^-. Afterwards, the created incoherent discourses D^- and the original discourse D respectively serve as negative and positive samples to train f_θ.

In the following, we introduce how we construct our two types of negative samples via *global augmentation* and *local augmentation* in details.

2.2 Global Augmentation

To construct samples that have relatively poor global coherence, we disrupt the original appropriate organization of sentences in D. Concretely, we shuffle the order of sentences in D to effectively disrupt its global coherence. As illustrated in Figure 2(a), by shuffling $D = \{s_1, s_2, s_3\}$, we can construct a negative sample $D_g^- = \{s_3, s_1, s_2\}$.

2.3 Local Augmentation

Local augmentation aims to construct samples with relatively poor local coherence using the original discourse D. Intuitively, we can realize it by replacing a sentence $s_k \in D$ with a substitute s'_k that is incoherent with the leftover discourse $D\backslash s_k$. This is based on the insight that, through such a replacement, s'_k will decrease local coherence of the discourse by introducing an incoherent transition of attention between sentences.

Subsequently, the most important question is how to find a suitable s'_k in practice. However, most prior studies introduce such incoherent elements via heuristic rules, resulting in s'_k that has **very weak relevance or even irrelevant** with the remaining discourse $D\backslash s_k$. For example, INSteD (Shen et al., 2021) obtains s'_k by extracting sentence of the highest n-gram overlap with s_k from another discourse. As a result, their introduced local augmentation samples are too easy to train a powerful coherence evaluator.

To construct samples with a higher level of local incoherence, we propose to construct s'_k in a generative way. Specifically, we train a generative augmentor G to reconstruct s_k based on $D\backslash s_k$ and use its generated sentence $s'_k \sim G(s_k|D\backslash s_k)$ to replace s_k. The strong performance of pretrained generation model will ensure s'_k to meet the basic standard of fluency and relevance with regard to $D\backslash s_k$. Meanwhile, due to the intrinsic limitation of autoregressive generation, the reconstructed s'_k will frequently be incoherent with $D\backslash s_k$, making it possible to construct negative samples in a generative way. To further ensure that s'_k conveys the local incoherence we expect, we design two controlling mechanisms during the inference of G.

These two mechanisms, *context truncation* and *coherence filtering* , constraints s'_k to be neither too strong (perfectly coherent with $D \backslash s_k$) nor too easy (the incoherence that is too obvious). Overall, by replacing s_k with s'_k, we construct a much stronger negative sample, which conveys high-level local incoherence while maintaining the basic relevance and fluency with $D \backslash s_k$. In the following, we will introduce our *generative augmentor*, *context truncation* and *coherence filtering* in details.

Generative Augmentor. Given discourse D, we uniformly sample s_k from D's non-opening and non-closing sentences. Next, we train a text generation model G by learning to reconstruct s_k based on the leftover discourse $D \backslash s_k$. Following recent popular text generation paradigm, this can be done by selecting G as a transformer-based sequence-to-sequence model and maximizing the likelihood of $G(s|D \backslash s_k)$ autoregressively.

We also notice that Gap Sentences Generation (GSG), the pretraining task of PEGASUS (Zhang et al., 2020), takes the similar form of reconstructing sentences. But we cannot directly apply PEGASUS as G, because GSG is specially designed for summarization, which requires predicting multiple salient sentences in the discourse. By contrast, our sentence reconstruction task aims to capture the coherence relation between an arbitrary sentence s and the leftover discourse. In practice, we also find s'_k generated by PEGASUS often serve as summaries of the leftover discourse, rather than being coherent with it. Thus, instead of directly applying PEGASUS, we leverage this similarity of tasks and use PEGASUS for initialization. In this way, we inherit the effectiveness of pretrained model.

After the generative augmentor is trained, we use it to predict s'_k with two controlling mechanisms:

Context Truncation. Due to the strong generation ability of generative augmentor, s'_k may be highly coherent with $D \backslash s_k$, which is not the negative sample we expect. To ensure s'_k to convey the local incoherence, we develop a context truncation mechanism to restrict the model's generation to only partially coherent with the context. Specifically, given $D \backslash s_k = \{s_1, s_2, ..., [mask], ..., s_n\}$ with s_k masked, we randomly choose to truncate the context before or after the mask token, i.e., the input for our generative augmentor is either $\{s_1, s_2, ..., [mask]\}$ or $\{[mask], ..., s_n\}$. Take the former as an example, without information from subsequent text, the model is only able to generate predictions that are coherent with preceding text.

Coherence Filtering. In addition to context truncation, we also perform coherence filtering to remove negative samples that are too easy. We utilize UniEval (Zhong et al., 2022) to score the coherence of each sample and eliminates samples with coherence scores below a filtering threshold δ.

2.4 Training and Unified Scoring

Training. We combine the original discourses with negative samples constructed via global and local augmentation to train our metric model, as illustrated in Figure 2(b). We utilize the classification setup, based on findings (Steen and Markert, 2022) that indicate its superior performance in coherence evaluation and downstream tasks, as opposed to the commonly used pairwise ranking setup. Specifically, we train our metric model to distinguish each sample as coherent or incoherent through binary cross entropy loss. For implementation details, please refer to Appendix A.

Unified Scoring. For a comprehensive evaluation of discourse coherence, our CoUDA further includes a unified scoring strategy, as presented in Figure 2(c). Specifically, our model first assigns a score conditioned on the whole discourse to represent its global coherence level:

$$S_g = f_\theta(D) \tag{1}$$

Then, since global scoring may fail to effectively capture the fine-grained coherence between sentences, we extract consecutive sentence pairs $[s_i; s_{i+1}]$ from the discourse and have our model evaluate the inter-sentential coherence S_l^i of each pairs, where $1 \leq i \leq n-1$:

$$S_l^i = f_\theta([s_i; s_{i+1}]) \tag{2}$$

Notably, although our model is trained for scoring the whole discourse, rather than sentence pairs, the training data includes discourse samples with only two sentences. As a result, our model can generalize to scoring sentence pairs as well. Afterwards, we obtain local coherence score for discourse D by averaging each sentence pair's coherence score:

$$S_l = \text{Average}(\{S_l^1, ..., S_l^{n-1}\}) \tag{3}$$

The global and local scores are then combined via interpolation to form the overall coherence score:

$$\text{Score} = (1-\lambda) \cdot S_g + \lambda \cdot S_l \tag{4}$$

where $\lambda \in [0, 1]$ controls the weight. This unified design also aligns with the coherence rating process of human readers, who consider both discourse organization as a whole, and smooth transitions of focused items between adjacent sentences.

3 Experimental Setup

3.1 Evaluation Tasks

We perform meta-evaluation on the proposed metric model in two task settings, i.e. pointwise scoring and pairwise ranking.

Pointwise Scoring involves assigning coherence scores to text summarization samples and evaluating the correlation between model-assigned scores and human-rated scores. This task closely simulates real-world scenarios. To determine the accuracy of the assigned scores, we compute the correlation coefficients between the model-generated scores and human ratings using *Spearman* (Sedgwick, 2014), *Pearson* (Sedgwick, 2012), and *Kendall's tau* (Abdi, 2007). Following previous work, these correlation scores are reported at both *sample-level* and *dataset-level* (See Appendix A for their definitions).

Pairwise ranking requires the metric models to determine the more coherent option when presented with two candidates. This task serves as an alternative when absolute scores are unavailable, relying solely on relative coherence rankings. For this task, we use accuracy as performance metric.

3.2 Evaluation Datasets

For pointwise scoring, we evaluate model performance on SUMMEVAL (Fabbri et al., 2021), which is a meta-evaluation benchmark for summarization that contains 100 articles with summaries generated by 16 different systems. For each summary, it offers human annotated scores in terms of fluency, coherence, consistency, and relevance.[2]

In pairwise ranking, we evaluate model performance on INSTED (Shen et al., 2021), which is an intruder sentence detection dataset constructed using discourses from CNN and Wikipedia. We denote these two parts as INSTED-CNN and INSTED-WIKI. In this dataset, incoherent discourses are created by randomly substituting a sentence with another one selected using n-gram overlap from different discourses.

[2]In this paper, we focus on discourse coherence, so we neglect coherence evaluation datasets on dialogue.

3.3 Baselines Models

Though more applicable in real scenarios, few work in coherence evaluation has pioneered in pointwise scoring. For a comprehensive performance comparison, we include baselines models from three categories: **1) Pairwise Coherence Evaluators**: UNC (Moon et al., 2019) and MULTINEG (Jwalapuram et al., 2022). UNC captures different levels of coherence via a LSTM-based Siamese architecture; MULTINEG[3] mines hard negative samples constructed via sentence shuffling to train pairwise coherence ranking models. 2) **General Evaluators**: BARTSCORE (Yuan et al., 2021), UNIEVAL (Zhong et al., 2022). BARTSCORE treats text evaluation as a generation task, utilizing BART to assign quality scores for a specific dimension. UNIEVAL reframes text evaluation as a Boolean Question Answering task. Backboned with T5, it is trained with rule-based local augmentation for coherence evaluation. **3) Large Language Models**: G-EVAL (Liu et al., 2023) uses LLMs with chain-of-thoughts to assign quality scores. We experiment with two versions using GPT-3.5-Turbo / GPT-4, respectively denoted as G-EVAL-3.5 / 4. We include more details about using UNIEVAL and G-EVAL in Appendix C and D, respectively.

3.4 Details of Synthetic Data

Data Source. We obtain positive part of data for our framework by sampling from CNN (Nallapati et al., 2016) and Wikipedia (Yang et al., 2015). For CNN, we utilize its source documents rather than summaries, because the latter is constructed by combining bullet points, hence lacks coherence. For each source document, we randomly select 2 to 5 leading sentences, enabling our metric model to generalize to different lengths. The same length constraint is applied on Wikipedia as well. Concretely, we sample 10,000 documents each from CNN and Wikipedia, hence obtaining 20,000 positive samples.

Statistics. For global coherence, we perform permutation on 5,000 positive samples, and acquire 5,000 negative samples for this aspect. For local coherence, we perform gap sentence generation on the remaining 15,000 positive samples using

[3]The original MULTINEG model is backboned with XLNet and trained on the WSJ dataset. For fair comparison, we retrained this model from ALBERT-xxlarge, using the same part of Wikipedia and CNN data. Notably, due to its use of two encoders, MULTINEG has twice the number of parameters compared to COUDA.

Model	#Param. ↓	Sample-Level ↑			Dataset-Level ↑		
		ρ	r	τ	ρ	r	τ
UNC	-	18.8	27.8	14.1	19.8	24.3	14.0
MULTINEG	466M	44.6	48.1	34.0	47.7	47.8	34.3
BARTSCORE	406M	44.8	45.8	34.2	40.8	43.4	29.2
UNIEVAL	770M	56.7	57.8	43.6	58.7	55.6	42.3
G-EVAL-3.5	>10B	47.0	48.4	40.3	43.5	43.8	35.3
G-EVAL-4†	>100B	58.2	-	45.7	-	-	-
COUDA (*ours*)	233M	**60.0**	**62.1**	**46.0**	**65.6**	**64.2**	**47.8**

Table 1: Sample-level and dataset-level Spearman (ρ) / Pearson (r) / Kendall (τ) correlations with human ratings on SUMMEVAL. Best results in each column are denoted **in Bold**. † denotes results reported in the original paper. With only 233M parameters, COUDA largely outperforms previous methods, including GPT-4 based methods.

Model	CNN	Wiki
UNC	96.4	60.5
MULTINEG	94.2	72.1
BARTSCORE	70.7	58.8
UNIEVAL	92.0	77.3
G-EVAL-3.5	82.2	58.5
COUDA	**98.5**	**79.1**

Table 2: Pairwise ranking accuracy on the CNN and Wikipedia split of INSTED.

generative augmentor with context truncation. By setting threshold δ for confidence filtering to 0.5, we obtain 10,889 positive and negative pairs for this aspect. Hence, the final size of our synthetic data (including positive samples) is 31,778. We split it into 30,000 / 1,178 for training and validation.

3.5 Implementation Details.

Our metric model utilizes ALBERT (Lan et al., 2020) as the backbone, benefiting from its sentence order prediction task during pretraining to capture information flow between sentences. Specifically, we use ALBERT-xxlarge with a total of 233M parameters. We set batch size to 32 and learning rate to $1e^{-5}$. Convergence is reached within 3,000 steps. We use the best performing checkpoint on the validation part of synthetic data. Details about generative augmentor are presented in Appendix A. In terms of hyperparameters λ and δ, we simply set both of them to 0.5.

4 Results

In this section, we show that COUDA framework achieves impressive coherence evaluation results on pointwise scoring and pairwise ranking tasks, even when compared with GPT-4 based models. We report average scores across 3 runs with different random seeds.

4.1 Results on SUMMEVAL

Table 1 presents the sample-level and dataset-level correlations of each model with human ratings on SUMMEVAL. Since UNC and MULTINEG are trained through pairwise ranking, their performance on for pointwise scoring is relatively limited. BARTSCORE and UNIEVAL are general evaluators for multiple dimensions such as informativeness and coherence. The former lacks specific training for these dimensions, leading to lower performance, while the latter gain significant improvement through tailored training for coherence. However, UNIEVAL still relies on heuristic rules for augmentation, resulting in limited improvements. The third block presents the results of G-EVAL-3.5 and G-EVAL-4, built upon GPT-3.5-TURBO and GPT-4, respectively. Since there are no exact description of how many parameters GPT-3.5/4 takes, we estimate them as >10B and >100B.

Among baselines models, G-EVAL-4 achieves highest correlation with human ratings, followed by UNIEVAL, which demonstrates strong performance, even surpassing G-EVAL-3.5. Compared with UNIEVAL, COUDA consistently shows its superiority on both sample-level correlation (+3.3/+4.3/+2.4 in ρ, r, τ) and dataset-level correlation (+6.9/+8.7/+5.4 in ρ, r, τ). With only 233M parameters, it also surpasses G-EVAL-4 in both sample-level Spearman and Kendall correlations by 1.8 and 0.3 points, respectively. This remarkable improvement consolidates the efficacy of our designing criteria. Additionally, we notice that performance gain in dataset-level correlation

+ C.T. + filter $\delta = 0.6$	**55.7**	**55.3**	**42.8**	**58.0**	**55.9**	**42.0**
+ C.T. + filter $\delta = 0.8$	46.3	42.7	35.9	49.5	41.5	35.7

Table 4: Analysis of our controlling mechanisms for local augmentation. *C.T.* stands for context truncation. δ is the threshold for confidence filtering.

is much greater than that of sample-level.

4.2 Results on INSTED

Table 2 presents each model's pairwise ranking accuracy on INSTED-WIKI and INSTED-CNN. Both MULTINEG and UNC achieves impressive accuracy. We suppose it is because they are exactly trained using the pairwise ranking setup. UNIEVAL also achieves competitive results, which means that specialized training for coherence greatly enhances model performance. Surprisingly, G-EVAL-3.5 obtains merely above chance accuracy on INSTED-WIKI, indicating that current LLMs are unreliable in pairwise ranking tasks, necessitating further investigation and attention from researchers. Our COUDA, though not directly trained under pairwise ranking settings, achieves best results on both INSTED-CNN and INSTED-WIKI, with a performance gain of 2.2 and 1.8 points, respectively.

5 Comparison of Augmentation Methods

In this section, we validate the advantage of our unified data augmentation strategy for coherence scoring over previous data augmentation strategies.

Compared Data Augmentation Methods. Coherence evaluation emphasizes the sentence structure and organization of a discourse. Due to this special focus, data augmentation strategies designed for other tasks, e.g. EDA (Wei and Zou, 2019), are not directly applicable. Instead, we compare following data augmentation strategies for generating negative samples: **1) G:** Global augmentation via sentence shuffling (Barzilay and Lapata, 2008), which is also adopted in our framework. **2) $\mathbf{L_R}$:** Rule-based local augmentation through sentence intrusion, which employs n-gram overlap to select locally incoherent samples (Shen et al., 2021). **3) $\mathbf{L_G}$:** Our generative local augmentation strategy. **4) $\mathbf{G + L_R}$ or $\mathbf{G + L_G}$:** Combination of global and local augmentation methods.

Global vs. Local vs. Unified. In Table 3, we can see that unifying global and local augmentation data yields the best human correlation, better than using global or local augmentation alone. This aligns well with the linguistic theory of discourse structure that the organization of discourse segments (global coherence), and the transition of attention or focused items (local coherence) are two key factors of discourse coherence, from which our unified data augmentation framework are inspired.

Generative vs. Rule-based. Further, we compare the result of generative augmentation vs. rule-based augmentation for modeling local coherence. First, metric model trained with L_G outperforms that of L_R by a large margin on both sample-level correlation (+3.8/+3.0/+3.0 in ρ, r, τ) and dataset-level correlation (+3.5/+1.5/+2.4 in ρ, r, τ). Second, when combined with global augmentation, $G + L_G$ yields significantly superior performance than $G + L_R$. Based on these two aspects, we can conclude that our generative strategy is more effective than rule-based methods.

6 Analysis

Unified Scoring. First, we study the effectiveness of our unified scoring strategy. Experiment results are demonstrated in Figure 3. First, both global and local scores are beneficial in improving human correlation. Additionally, global scores correlate better with human ratings than local scores.

Controlling Mechanisms. We then analyze the effect of our difficulty controlling mechanisms in local augmentation. Specifically, we train our metric model separately on local augmentation data constructed under different settings to compare

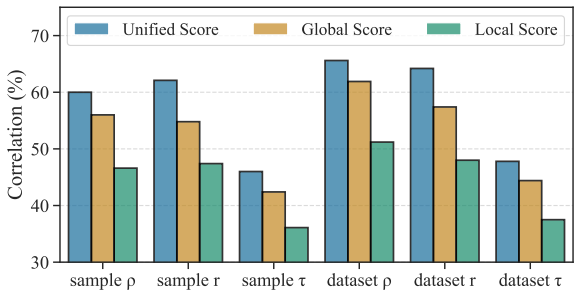

Figure 3: Ablation study of global and local scores in our unified scoring strategy.

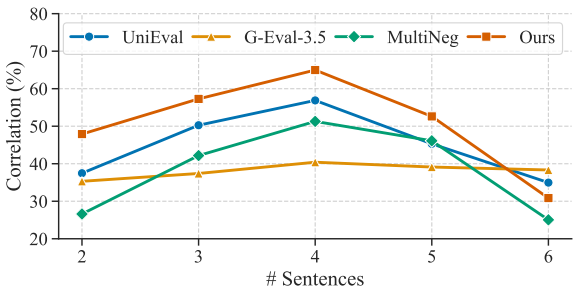

Figure 4: Average of dataset-level Spearman / Pearson / Kendall correlation on SUMMEVAL w.r.t. discourses containing different numbers of sentences.

their impacts. Table 4 presents the results. First, we can see that context truncation contributes a significant portion of performance, without which our generative augmentor suffers a severe performance drop of more than 20 points. This demonstrates the effectiveness of constructing partially coherent samples. Second, we find that our confidence filtering mechanism, through which we filter out easy negative samples, also helps model performance. We found that 0.6 is an optimal threshold that can filter out easy examples while ensuring enough amount of training data. We have also provided a case study in Appendix B.

Discourse Length. We compare our model's performance with strong baselines (MULTINEG, MULTINEG, G-EVAL-3.5) w.r.t. different discourse length. Concretely, we categorize all 1,600 system summaries of SUMMEVAL into different groups according to the sentence numbers they have. We calculate the average of dataset-level Spearman / Pearson / Kendall correlation as defined in Equation 6 for each group. Figure 4 presents the results. On average, our model achieves best results when target discourse contains no more than 5 sentences. As the discourse length increases, all models suffer from performance drop, with G-EVAL-3.5 being the only exception, which renders very steady correlation against length variance. Since each training sample we construct contains no more than 5 sentences (see Appendix A), we assume COUDA's performance drop can be alleviated by training on samples with more sentences.

7 Related Work

7.1 Coherence Evaluation

Coherence evaluation measures the organization and structure of a discourse. Due to the paucity of human-annotated training data, previous work has mainly focused on two synthetic tasks: permutation detection and sentence intrusion detection. Permutation detection task (Barzilay and Lapata, 2005; Elsner et al., 2007; Barzilay and Lapata, 2008; Li and Jurafsky, 2017) requires the model to distinguish original discourse from its sentence shuffled version. Sentence intrusion detection task (Shen et al., 2021) determines whether a discourse contains an intruder sentence from another discourse.

A series of methods have been proposed for these synthetic tasks. Barzilay and Lapata (2005, 2008) introduced the popular entity-based model using Centering Theory (Grosz et al., 1995). It was further extended to combine with entity-specific features (Elsner and Charniak, 2011), convolutional neural networks (Tien Nguyen and Joty, 2017), and graph neural networks (Mesgar et al., 2021). Jwalapuram et al. (2022) attempted to improve model generalization by training their model purely through self-supervision, with negative samples mined from permutation space. Instead, we propose to improve evaluation performance by unifying different aspects of discourse coherence, as inspired by linguistic theory of discourse structure (Grosz and Sidner, 1986). UNC (Moon et al., 2019) captured different levels of coherence via a Siamese architecture that involved bi-linear projection and lightweight convolution-pooling. By contrast, we address this from the perspective of data augmentation rather than model architecture.

7.2 General Evaluators

We denote evaluators capable of assessing multiple quality dimensions by altering input and output contents (Yuan et al., 2021), or adopting different formulas (Scialom et al., 2021; Zhong et al., 2022) as general evaluators. A leading trend is to utilize generation model for quality assess-

ment, such as BARTSCORE (Yuan et al., 2021), UNIEVAL (Zhong et al., 2022). Apart from that, DISCOSCORE (Zhao et al., 2022) compared the focus matrix between the candidate and the reference to calculate the overall quality score.

With the rise of large language models (LLMs), there has been a growing tendency to use LLMs for evaluation purpose (Wang et al., 2023a; Fu et al., 2023; Wang et al., 2023b; Liu et al., 2023). Wang et al. (2023a) adopted ChatGPT for NLG evaluation and achieved competitive results in terms of correlation with human judgments. Liu et al. (2020) used LLMs with chain-of-thought and a form-filling paradigm to assess the quality of text.

8 Conclusion

We propose a unified data augmentation framework called COUDA, with the designing criteria to unify both global and local aspects of coherence, as inspired by linguistic theory of discourse structure. This data framework includes global and local augmentation, a classification paradigm for training and a unified scoring strategy for inference. We specifically propose a novel generative augmentation strategy, which involves post-pretraining a generative model, and applying two controlling mechanisms to control the difficulty of generated samples. With only 233M parameters, our framework achieves remarkable improvement over previous methods, including GPT-4 based metrics.

Limitations

Our work is still limited in some aspects, particularly in handling extra long discourses. Note that our framework requires assigning coherence scores to all adjacent sentence pairs. While this approach allows for detailed modeling of local coherence between sentences, it may be slow when dealing with documents that contain a large number of sentences.

Ethics Statement

Our work complies with the ACL Ethics Policy. Since all datasets we used are publicly available, we have not identified any significant ethical considerations associated with our work.

A Details of Data, Generative Augmentor, and Correlation Calculation

Details of Generative Augmentor. Our generative augmentor is initialized with PEGASUS-Large using the checkpoint in Huggingface. We train it on the positive samples mentioned above, with batch size set to 32. Convergence is reached within 5,000 steps. To avoid data leakage in training and prediction, we split our positive samples into part A and part B, each with 20,000 samples. We first train our model solely on part A, and use it to construct negative samples for part B. Then we train a new model solely on part B, and use it to construct negative samples for part A.

Sample-Level and Dataset-Level Correlation. Suppose we have n documents in a dataset, for each document $d_i, i \in \{1, ..., n\}$, we have J system outputs. Let $o_{ij}, j \in \{1, ..., J\}$ be the output of the j^{th} system for the i^{th} document, K be a correlation measure, f_θ and f_h be metric model and human evaluation, respectively, sample-level correlation and dataset-level correlations can be calculated as follows:

(1) *Sample-level* correlation.

$$K^{sample} = \frac{1}{n}\sum_{i=1}^{n} K([f_\theta(o_{i1}), ..., f_\theta(o_{iJ})], [f_h(o_{i1}), ..., f_h(o_{iJ})]) \quad (5)$$

(2) *Dataset-level* correlation.

$$K^{dataset} = K([f_\theta(o_{11}), ..., f_\theta(o_{nJ})], [f_h(o_{11}), ..., f_h(o_{nJ})]) \quad (6)$$

B Case Study

We demonstrate an example of substitute sentences selected or generated using different methods in Table 5. RULE selects the substitute sentence through n-gram overlap, resulting in a relatively easy samples, as the selected sentence is very incoherent with the context. PEGASUS generates a sentence that summarizes the remainder, rather than being coherent with the context. The prediction of our generative augmentor is highly coherent with the context, making it difficult to be distinguished as negative. Through context truncation, we obtain a partially coherent prediction, which is only coherent with proceeding sentences.

Context
The cities of Annecy, Munich and Pyeongchang will battle it out to host the 2018 Winter Olympics. **[mask]** The International Olympic Committee have confirmed they have received applications from France, Germany and South Korea ahead of this week's deadline.
Predictions
RULE: Thousands of South Koreans gathered at the foot of a ski jump well past midnight in a passionate display of excitement that included fireworks, singing, dancing, picnicking and kimchi – the traditional Korean side dish.
PEGASUS: The cities of Annecy, Munich and Pyeongchang will battle it out to host the 2018 Winter Olympics.
Generative Augmentor (GA): The French resort of Annecy, the German city of Munich and the South Korean city of Pyeongchang have all submitted bids to host.
GA w/ Context Truncation: The International Olympic Committee's Executive Board will meet on Wednesday in Copenhagen to pick the host.

Table 6: Performance Comparison of UniEval w/ or w/o Source Document.

C Performance Comparison of UniEval w/ or w/o Source Document

Recall that UNIEVAL requires a source document as input when assessing coherence. Since our framework solely takes the discourse as input, we set its source document to empty string for fair comparison. In this section, we conduct additional experiments to explore how the source document influences coherence evaluation for UNIEVAL. Results are presented in Table 6. It can be observed that whether the source is provided does not have a significant impact on the performance of UNIEVAL. This further consolidates our assumption that coherence is an intrinsic quality of discourse that its evaluation does not require other inputs. Furthermore, even with original source provided to UNIEVAL, COUDA's performance remains substantially superior, verifying the effectiveness of our proposed

[Task Introduction]

You will be given two discourse. Your task is to rate both discourses on one metric. Please make sure you read and understand these instructions carefully. Please keep this document open while reviewing, and refer to it as needed.

[Evaluation Criteria]

Coherence (1-5) - the collective quality of all sentences. We align this dimension with the DUC quality question of structure and coherence whereby 'the summary should be well-structured and well-organized. The summary should not just be a heap of related information, but should build from sentence to sentence to a coherent body of information about a topic'.

[Evaluation Steps]

{Evaluation steps generate through CoT}

[Discourse A]

{discourse A}

[Discourse B]

{discourse B}

Please avoid assigning same coherence score to A and B, because we want to pick the more coherent one.

Output with the following format:

The score of A: <score>

The score of B: <score>

Figure 5: Skewed Template for G-Eval-3.5 in pairwise ranking. We adopt the Balanced Position Calibration strategy proposed by Wang et al. (2023b) to alleviate positional bias of LLMs

method.

D Skewed Template to use G-Eval for Pairwise Ranking

Skewed template to use G-Eval for pairwise ranking is presented in Figure 5. We adopt the Balanced Position Calibration strategy proposed by Wang et al. (2023b) to alleviate positional bias of LLMs.

E The choice of Weight Parameter λ

Figure 6 shows the results of varying weight parameter λ for global and local coherence score. We see that the best weight for Spearman correlation and Kendall correlation is around 0.4, while the best weight for Pearson correlation is around 0.6.

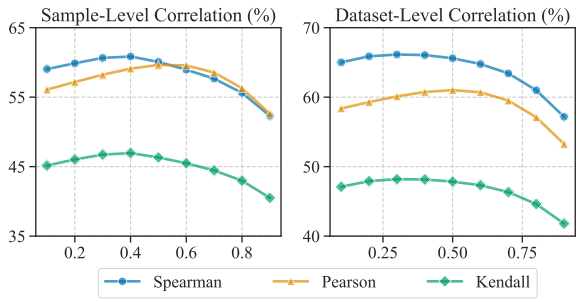

Figure 6: Sample-level correlation and dataset-level correlation on SUMMEVAL with different weight parameter $\lambda \in [0, 1]$ for global and local coherence score.

MEDIT: Multilingual Text Editing via Instruction Tuning

Abstract

We introduce MEDIT, a multilingual extension to COEDIT – the recent state-of-the-art text editing models for writing assistance. MEDIT models are trained by fine-tuning multilingual large, pre-trained language models (LLMs) via instruction tuning. They are designed to take instructions from the user specifying the attributes of the desired text in the form of natural language instructions, such as *Grammatik korrigieren* (German) or 이 텍스트를 단순화 (Korean). We build MEDIT by curating data from multiple publicly available human-annotated text editing datasets for three text editing tasks (Grammatical Error Correction (GEC), Text Simplification, and Paraphrasing) across diverse languages belonging to six different language families. We detail the design and training of MEDIT models and demonstrate their strong performance on many multilingual text editing benchmarks against other multilingual LLMs. We also find that MEDIT generalizes effectively to new languages over multilingual baselines. We publicly release our data, code, and trained models.[1]

1 Introduction

Large language models (LLMs) have made remarkable progress toward generating fluent and coherent text in a wide variety of tasks and domains to support writing assistance (Brown et al. 2020b; OpenAI 2023; Touvron et al. 2023; *inter alia*). In particular, LLMs have been adapted to perform many complex text editing tasks like GEC (Wu et al., 2023; Coyne and Sakaguchi, 2023; Fang et al., 2023b), text simplification (Baez and Saggion, 2023; Saggion et al., 2022), paraphrasing (Witteveen and Andrews, 2019; Niu et al., 2021), and formality and tone rewriting (Reif et al., 2022; Luo et al., 2023), among others. However, most of these works are restricted to single tasks, with few works adapting LLMs to perform high-quality text editing across multiple tasks (Schick et al., 2023; Raheja et al., 2023; Laban et al., 2023). A lot of these improvements have been driven by fine-tuning large language models (LLMs) with task-specific instruction tuning, resulting in remarkable zero-shot generalization abilities (Sanh et al. 2022; Ouyang et al. 2022; Chung et al. 2022; *inter alia*).

At the same time, significant research effort has been dedicated to leveraging and enhancing the multilingual capabilities of LLMs (Lin et al., 2022). These abilities can be improved using methods such as continued pre-training with abundant monolingual data (Yang et al., 2023b; Cui et al., 2023) or language-specific instruction-tuning (Zhu et al., 2023; Li et al., 2023). However, in the case of continued pre-training, the lack of high-

Multilingual Editing

Parafrasee la oración: Hoy iré a la escuela a estudiar español.
Hoy asistiré a la escuela para aprender español.

문법 오류 수정: 우리는 어제 행사에서 즐거운 시간을보내겠습니다.
우리는 어제 행사에서 즐거운 시간을보냈습니다.

Cross-lingual Editing

文を簡略化してください: Meteorologists often regard a storm surge as the most treacherous facet of a hurricane.
A storm surge is considered a hurricane's most dangerous aspect.

Figure 1: **Examples illustrating multilingual and cross-lingual text editing.** The editing instructions are described in bold. Note that the input and output texts are always in the same language. The monolingual vs. cross-lingual setting is determined by comparing the language of the edit instruction to the language of the input text.

Japanese	ja	Japonic
Korean	ko	Koreanic
Spanish	es	Romance

Table 1: **Set of Languages.** The seven languages, along with the ISO-639-1 code and their language family, on which we train and evaluate our models.

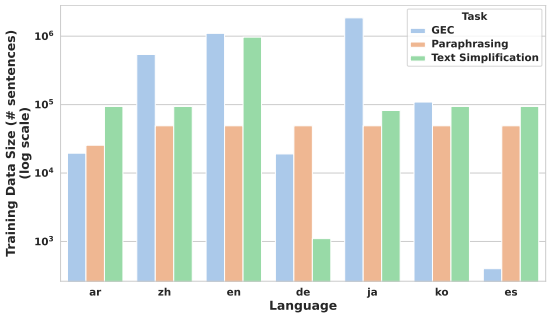

Figure 2: **Data distribution for each of the three tasks and seven languages on which we train.** The amount of data is shown in a log scale to aid visualization.

quality web-scale data often restricts the ability to improve LLMs capabilities in less-represented languages in the same way that English data can be expanded. Moreover, while numerous multilingual instruction-tuned models have been developed (Muennighoff et al., 2023; Workshop, 2023; Xue et al., 2021; Li et al., 2023; Wei et al., 2023), our analyses show that without further task-specific fine-tuning, these models are not suitable for carrying out high-quality text-editing tasks (§ 5.1). In the context of text editing tasks, multiple previous works have developed high-quality, general-purpose LLMs on non-English languages, restricting themselves, however, on either specific tasks (Rothe et al., 2021; Sun et al., 2022; Kementchedjhieva and Søgaard, 2023; Ryan et al., 2023; Krishna et al., 2022; Lai et al., 2022) or specific languages (Alhafni et al., 2023; Anschütz et al., 2023). Overall, the aforementioned factors have limited the availability of high-quality *multilingual text editing* (MTE) models, which has limited their usability for writing assistance across multiple tasks in languages beyond English.

We address these gaps with MEDIT, a multitask, multilingual extension of COEDIT (Raheja et al., 2023). MEDIT models can perform text editing operations for three popular tasks: Grammatical Error Correction, Paraphrasing, and Text Simplification, in multilingual and cross-lingual settings (Figure 1) across a diverse set of seven languages, spanning six different language families (Table 1).

To build MEDIT, we fine-tune several multilingual LLMs of varying sizes on carefully curated, largely human-annotated, parallel corpora of over 200k instructional input-output pairs, using publicly available datasets (Table 4) for different text editing tasks. We evaluate the performance of our models extensively on text editing benchmarks in both multilingual and cross-lingual settings to demonstrate their effectiveness.

Our contributions are as follows:

- This work, to the best of our knowledge, is the first to investigate multi-task, multilingual text editing via instruction tuning.
- Our models achieve strong performance on multiple text editing tasks across numerous languages and are publicly released for fostering further MTE research.
- Through a comprehensive set of controlled experiments, we provide insights on how model performance on multilingual text editing tasks is affected by various choices like model architecture, model scale, and training data mixtures.

2 Related Work

Multi-lingual LLMs for Text Editing There is an extensive body of prior literature that has leveraged LLMs for various multi-lingual text editing tasks. These works have proposed models for text editing tasks like GEC (Rothe et al., 2021; Sun et al., 2022), paraphrasing (Chowdhury et al., 2022), formality style transfer (Briakou et al., 2021), and text simplification (Mallinson et al., 2020; Martin et al., 2022; Ryan et al., 2023). However, all of these prior approaches have proposed task-specific multi-lingual models. In contrast, we propose a single unified text-editing model for all the considered tasks by leveraging the power of instruction-tuning and task-specific fine-tuning, which enables our multi-lingual models to generalize to multiple text-editing tasks.

Multi-lingual Instruction-Tuning While numerous multi-lingual instruction fine-tuned models like Muennighoff et al. (2023); Wei et al. (2023) and Li et al. (2023) have been developed, they are not focused or tailored for text editing tasks, which we address by task-specific fine-tuning. Specific

to text editing, many prior works have explored instruction tuning capable of performing multiple text editing tasks with a single model, such as GEC, simplification, sentence fusion, style transfer, and paraphrasing, to name a few (Mallinson et al., 2022; Du et al., 2022; Kim et al., 2022; Schick et al., 2023; Raheja et al., 2023). However, while they are able to support multi-task text editing, they are generally mono-lingual and typically restricted to specific languages (predominantly English). Thus, our work addresses this gap by proposing multilingual, instruction-tuned models for multiple text editing and revision tasks.

3 MEDIT

3.1 Tasks and Languages

We chose a broad set of languages to ensure coverage and chose text editing tasks that had multilingual, publicly available human-annotated datasets to ensure high data quality. Another criteria was to choose languages at the intersection of the publicly available corpora we could find across a large set of languages for all the tasks we considered. We refer to this as the MEDIT dataset.

Table 1 describes the languages covered in our work, whereas Figure 2 depicts the amounts of training datasets that were available for all tasks and languages we considered. Appendix A details all the training and testing datasets.

3.2 Models

We fine-tune different versions of pre-trained multilingual LLMs (both encoder-decoder/sequence-to-sequence (Seq2Seq) and decoder-only/causal language models (CLM)) on the MEDIT dataset using cross-entropy loss. The details of the MEDIT models are described in § 4.2, whereas the training details are summarized in § 4.3.

4 Experiments

4.1 No-Edits Baseline

We first evaluate a no-edits baseline, where the output is simply a copy of the source input without the instruction. This strategy performs reasonably well on tasks where the target output largely overlaps with the input (e.g., GEC).

4.2 Multilingual LLMs

mT5 (Xue et al., 2021) is a multilingual variant of T5 (Raffel et al., 2020), trained on the mC4 dataset, a multilingual variant of the C4 dataset extended to 101 languages. We experiment with three variants of mT5 – LARGE (770M), XL (3B), and XXL (13B) parameters.

mT0 (Muennighoff et al., 2023) is a family of multilingual Seq2Seq models capable of zero-shot following human instructions in dozens of languages. We use the mt0-LARGE (1.2B), mt0-XL (3.7B), and mt0-XXL (13B) models. These models are constructed by fine-tuning mT5 models on the xP3 cross-lingual task mixture dataset, which consists of multilingual datasets with English prompts. As a result, mT0 models are better suited for following English prompts. We also use the mt0-XXL-MT variant, which is fine-tuned on the xP3mt dataset and is better suited for prompting in non-English.

BLOOMZ (Muennighoff et al., 2023) is a family of multilingual Causal Language Models (CLMs) constructed by fine-tuning BLOOM (Workshop, 2023) on the xP3 dataset. We use BLOOMZ-3b and BLOOMZ-7b1 models for our experiments.

PolyLM (Wei et al., 2023) is a set of multilingual LLMs trained on 640B tokens. We experiment with the `PolyLM-MultiAlpaca-13B` model, which is PolyLM-13B model fine-tuned on the `MultiAlpaca` dataset, consisting of 132k samples of multilingual instructions.

Bactrian-X (Li et al., 2023) is a collection of lightweight adapters for LLaMA (7B and 13B) (Touvron et al., 2023) and BLOOM (7B) (Workshop, 2023) on the Bactrian-X dataset, which is a multilingual parallel dataset comprising 3.4 million instruction–response pairs across 52 languages. For simplicity, we only compare against its higher-performant LLaMA-adapted versions.

4.2.1 Large-Pretrained Decoder-only Models

We also conduct zero-shot evaluations against state-of-the-art decoder-only LLMs that have shown impressive multilingual capabilities on a variety of NLP tasks leveraging the power of in-context learning (Lai et al., 2023; OpenAI, 2023).

GPT3.5 (also referred to as ChatGPT),[2] is an improved version of GPT3 (Brown et al., 2020a) optimized for chat. We use the `gpt-3.5-turbo0613` model from the OpenAI API.[3]

[2] https://openai.com/blog/chatgpt
[3] https://api.openai.com

GPT4 (OpenAI, 2023) is the latest iteration of the GPT models and is also optimized for chat. We use the `gpt-4-0613` model from the OpenAI API.

While we recognize that these models may not be explicitly optimized or trained for multi-lingual settings, considering that they have been trained on massive amounts of web-scale data, these models have been shown to have multi-lingual capabilities (Lai et al., 2023), hence, we consider them as one of our baseline groups.

4.3 Training Setup

We perform instruction tuning for all our models by crafting custom prompts for each of the 21 task-language combinations (seven languages, three tasks). Similar to CoEdIT, for each task-language combination, depending on the number of ways the instructions can be translated without altering the meaning, we write between 14 and 27 instructions by automatically translating each one from English and verifying the accuracy of the translations by asking native language speakers to evaluate and correct them. The total number of task-language instructions is 365, which can be found in Appendix D. We explore three different multilingual and cross-lingual instructional settings, depending on the language of the prompt, where the editing instruction could be in (a) **English**, (b) the same language as the text being edited (**Native**), and (c) a random language which may or may not be the same as the language of the text being edited (**Random**). With this definition, English and Random are cross-lingual text editing tasks, and Native is a multilingual text editing task. In all settings, the input-output pairs are in the same language, but only the language of the instruction changes.

We train all models on 8xA100 80G GPU instances for five epochs. For the PolyLM and Bactrian-X models (>7B parameters), we also use LoRA (Hu et al., 2022) to lower the number of trainable parameters and increase the batch size.

4.4 Evaluation

For GEC evaluation, we follow prior work on each language we report on and use the appropriate GEC metric accordingly. Mainly, we use the MaxMatch (M^2) Scorer (Dahlmeier and Ng, 2012), ERRANT (Bryant et al., 2017), and GLEU (Napoles et al., 2015, 2016) as our evaluation metrics. The M^2 Scorer and ERRANT compare the edits made by a GEC system against annotated reference edits and calculate the precision (P), recall (R), and $F_{0.5}$ (i.e., weighing precision twice as much as recall). GLEU computes the precision of the n-grams that overlap with the references but not the original texts and penalizes n-grams that overlap with the original texts but not the references.

For simplification, we follow Ryan et al. (2023) and use SARI (Xu et al., 2016a) and BLEU (Papineni et al., 2002) for evaluation. SARI is the average of the F1 score for adding, keeping, and deleting n-grams ($n \in 1, 2, 3, 4$) and has been shown to correlate with human judgments of simplicity (Xu et al., 2016a). BLEU, on the other hand, is a common metric in machine translation and is used as a check for grammatical and meaning preservation. We compute all metrics using the EASSE evaluation suite (Alva-Manchego et al., 2019).

We evaluate paraphrasing on two criteria and metrics: diversity and semantic similarity. For diversity, we use Self-BLEU (Zhu et al., 2018) to measure the diversity of the paraphrases relative to the given source and reference texts. We use Semantic Similarity to measure meaning preservation. Specifically, we use *m*USE (Yang et al., 2020) for this, as it is the best-performing multilingual sentence similarity model that supports all the languages in our work. We also considered other notable works that have made significant progress on multilingual sentence similarity, such as Multilingual-SBERT (Reimers and Gurevych, 2020) and LaBSE (Feng et al., 2022). However, we found them unsuitable for our purposes as they were either limited by the languages they support or suffered from lower performance for multilingual sentence similarity.

5 Quantitative Results: MTE Quality

We split the models into three main groups. The first group (a) consists of the "no edits" baseline, the second group (b) is the untrained baseline, where models are evaluated in a zero-shot setting without any task-specific fine-tuning, while the third group (c) is our set of multi-lingual models trained on task-specific datasets. For all our experiments, we aggregate the models' performance by text editing tasks. Specifically, we aggregate the metrics for each task using the harmonic means of its constituents. Specifically, we use (1-Self-BLEU)[4] and Semantic Accuracy for Paraphrasing, SARI and BLEU for Simplification, and $F_{0.5}$ and GLEU for GEC. We scale all metrics to lie between

[4]We subtract Self-BLEU from 1 because lower is better in terms of making changes to the source text.

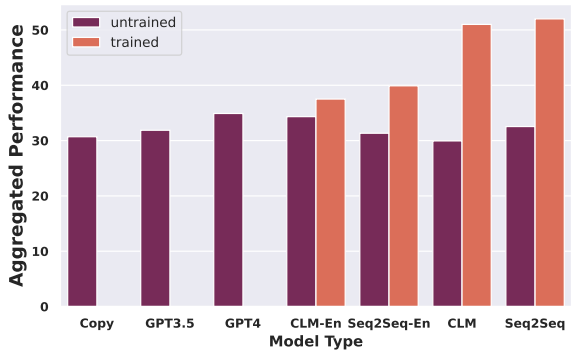

Figure 3: **Overall performance comparison of all baselines against trained models.** We calculate the aggregated performance across all tasks using the harmonic mean of task-specific scores. Baselines are "No Edits (Copy)", "English-only" ("-En,"), and our trained models are marked as "CLM" and "Seq2Seq," respectively. The aggregated performance is calculated as described in § 5.

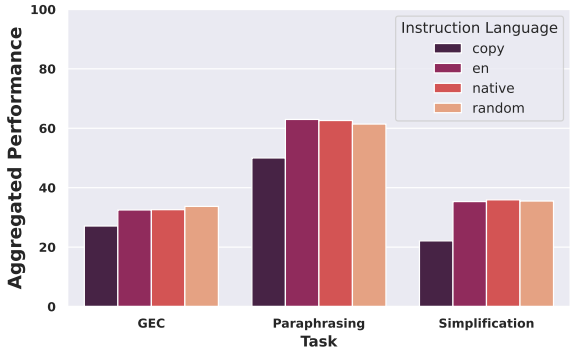

Figure 4: **Aggregated performance on different tasks broken down by instruction language**. Apart from some minor fluctuation, there is no significant impact of instruction language on our results.

0 and 100. We show full results on all models in Appendix C for the best-performing setup.

5.1 Baselines

In Figure 3, we report the results of our trained models against various baselines by aggregating the performance on all tasks (as detailed in § 5).

No Edits (Copy) Baseline We observe that not making any edits leads to a performance that is on par with the untrained versions of all models, which highlights the limitations of the n-gram overlap-based metrics.

Untrained Baseline Similar to Raheja et al. (2023), a core contribution of this work is to push the performance of small- (∼1B parameters) to medium-sized (1-15B parameters) LLMs for common text editing tasks across multiple languages. This drives the need for fine-tuning task-specific and language-specific datasets. For this work, we compare our fine-tuned models against their non-fine-tuned counterparts. We find a substantial gap between the untrained models and their trained counterparts, highlighting the impact of task- and language-specific fine-tuning for the tasks.

English-Only Baseline In this experiment, we analyze the ability of multilingual LLMs to adapt to different text editing tasks across different languages by fine-tuning them in the most prominent high-resource language (English). We fine-tune all the multi-lingual models on just the English subsets of the training data, as it is the largest in terms of quality and quantity. This experiment tests the need for language-specific data. Similar to the previous result, we observe that the gap between the untrained versions of English-only models is relatively small vs. the ones trained on the full dataset; it increases significantly with language-specific fine-tuning.

State-of-the-art LLMs Additionally, we also evaluate against the most powerful commercially available LLMs on their ability to perform MTE. Specifically, we evaluate GPT3.5 and GPT-4 in a zero-shot setting. Although these models have been shown to exhibit strong zero-shot performance on a variety of NLP tasks, we find that the overall performance of both models is close to most untrained baselines. This can be attributed to the rather limited multilingual capabilities of GPT3.5, which often lead to outputs being generated in other languages (English in particular). To some extent, the verbosity of responses is highly detrimental to the performance, especially for GPT4 as it gets penalized by the automatic metrics (especially for GEC).

The rest of this section analyzes different aspects of the quantitative performance of our models.

5.2 Model Performance by Language

In this section, we analyze the performance of different MTE models by language (Figure 5). It is interesting to note that Paraphrasing exhibits a rather steady performance across languages. This can partially be attributed to the weakness of the evaluation metrics as they rely mostly on n-gram overlap, on the multilingual pre-training of the LLMs where they are exposed to medium-large corpora of nearly all the languages, but also that with the increase in the model size and fine-tuning, they

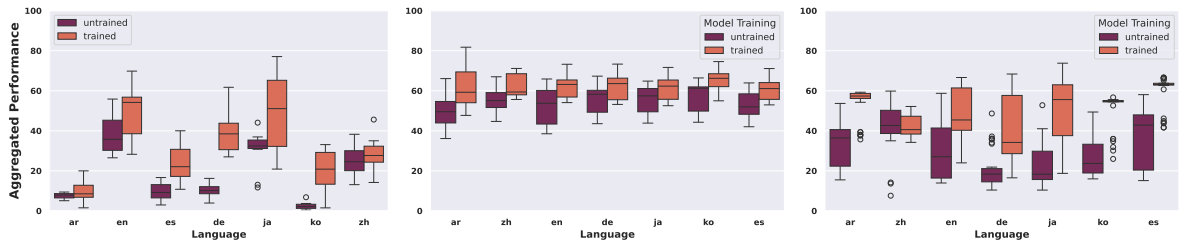

Figure 5: **Aggregated model performance by language** (for GEC, Paraphrasing, and Simplification). For each task, we aggregate the relevant metrics as described in § 5 and split them by model training.

tend to make fewer changes, thus, leading to higher scores. For simplification, the variance in the performance across languages can be attributed to the amount and quality of training data available for each task. For instance, for German, only 1.1k training data points were available, which leads to models not only showing a great improvement in performance with fine tuning, but also a great variance. Similarly, the training data is very noisy for Japanese, which leads to a similar effect. For GEC, we observe that the performance varies a lot by language, indicating the challenging nature of the task. This can be partially attributed to the frequency and the type of errors in each dataset, a phenomenon we see in Arabic datasets. For instance, Arabic datasets contain subtle and frequent errors made by native/L1 speakers, whereas the data for all other languages consists of sparse and infrequency errors made by L2 learners, which could explain the abnormally low quality (on Arabic GEC) of our best-performing model. Moreover, the quality of the training GEC data available also leads to varying performance across languages.

5.3 Language of Instruction

Here, we analyze the effect of the language of the instruction used to instruct the model. As mentioned in § 4.3, we have three configurations for this set of experiments:

English-language Instructions We train the first set of multilingual MEDIT models with just English instructions. These are MTE models capable of performing cross-lingual text editing, trained on data where the instruction is always in English.

Native-language Instructions We train the next set of multi-lingual MEDIT models with instructions in their native language. These models are capable of performing MTE, where the language of edit instructions is the same as the language of texts being edited.

Randomized-language Instructions Finally, we also explore the cross-lingual text editing (Figure 1) abilities of multi-lingual LLMs. To do so, we modify our dataset by appending an edit instruction from a randomly chosen language (different from the language of the edited source-target text pair) and train our models on this cross-lingual-prompted dataset.

Figure 4 shows the effect of instruction language on performance on all three tasks. We note that there is no significant difference in performance between the different settings. This is likely because in each setting, owing to its multilingual instructional pre-training, the model is able to adapt well to the language of the instruction in the fine-tuning phase, hence focusing mostly on the specific tasks.

5.4 Effect of Model Architecture

We present the task-specific results across each model type in Figure 6, observing that CLMs generally are either on par or outperform the rest of the models with GPT3.5, yielding the lowest results.

BLEU relies on n-gram overlap artificially boosting the scores, which highlights the disadvantage of the Copy baseline. Also, GPT3.5 and GPT4 consistently perform poorly in comparison to the rest of the models, which is especially surprising given GPT4's multilingual capability. In addition, this could be an artifact of the metrics since RLHF can produce excellent results that have little overlap with the references, and future human studies may shed more light on the issue.

CLMs and Seq2Seq models perform similarly on GEC and Paraphrasing, while Seq2Seq performs better on simplification. We posit that this discrepancy happens due to shorter generations from the Seq2Seq models since we observe that the seq2seq models generate significantly shorter sequences than the expected distribution ($D = 0.06, p < 0.001$),[5] increasing the BLEU scores, which are

[5]Using a two-tailed Kolmogorov-Smirnov test, compared

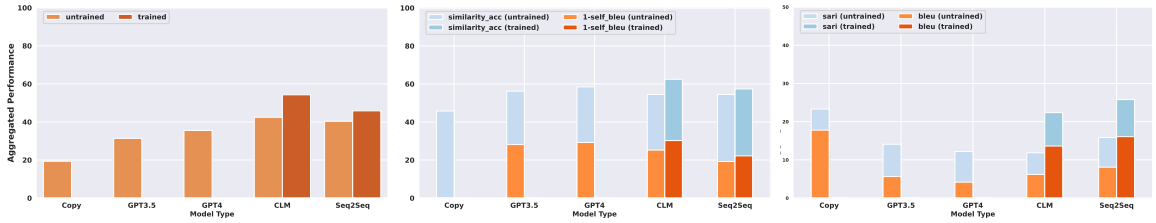

Figure 6: **Aggregated performance by model type** (for GEC, Paraphrasing, and Simplification). For each task, we aggregate the relevant metrics as described in § 4.4 and split them by model type (CLM vs Seq2Seq), including the copy baseline.

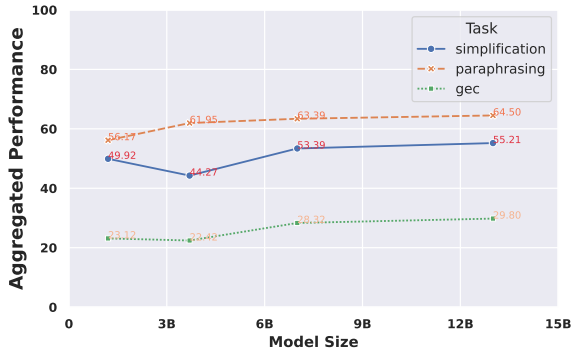

Figure 7: **Aggregated model performance on different tasks broken down by parameter size.** For visualization reasons, we group the 1.2B and 1.7B models and the 7B and 7.1B models together.

sensitive to the prediction length, whereas CLMs tend to generate longer sequences ($D = 0.27, p < 0.001$). Looking at the SARI scores, we observe that the two model types do not differ significantly ($p > .05$), indicating similar performance overall.

5.5 Effect of Model Scale

In Figure 7, we describe the overall performance of MTE models by size aggregated over the three tasks. It is evident that scaling model size generally increases overall performance significantly, thus reinforcing the effectiveness of model scaling. We also note that all three tasks display similar trends, with relative improvements being the greatest in GEC (**28.8%**) and Paraphrasing (**14.8%**).

5.6 Effect of Task-specific Data

To understand the effect of task-specific data on model performance, we systematically ablate the proportion of training data for each task. Specifically, we conduct three groups by varying the amounts of training data across a given task between 0%, 10%, 50%, and 100% while keeping the amount of training data across other tasks at 100%, the results of which are shown in Figure 8. We observe that: (a) Performance on the ablated task generally improves as the amount of training data for that task increases, as expected. As the proportion of training data increases, so does the performance on the specific task. (b) We also note a synergistic relationship between some tasks where training data from one task helps improve performance on a different task. For example, as we add training examples from GEC, we also notice an improvement in model performance on simplification (58.90 vs 45.20) and paraphrasing (65.30 vs 58.34). Similar trends also hold when we add data for the other two tasks. We believe our model (which is inherently multi-task) enables us to leverage such synergy between text editing tasks better, as compared to task-specific models.

Task	Language	Dataset	Test Size	Metric	MEDIT	SOTA
GEC	Romanian	RoGEC	1518	GLEU	45.58	–
	Hindi	HiWikEd	13187	ERRANT GLEU	32.61 68.91	49.4 80

Table 2: **Zero-shot evaluation results on the language generalization experiments.** We present the scores achieved by our best-performing model (**Our score**) along with the current **SOTA** results[6]. Wherever possible, we report the metrics reported in the SOTA papers, and if not available, we report commonly used ones by the literature. Note that we focus only on languages that the LLMs have seen during pre-training § 5.7.

against the distribution of lengths of the reference texts.

[6]Test datasets for new languages include: RO-GEC: (Cotet et al., 2020), HI-GEC: (Sonawane et al., 2020), IT-SIMP: (Tonelli et al., 2016; Brunato et al., 2016), HI-SIMP: (Kumar et al., 2022), FR-PARA: (Yang et al., 2019), HI-PARA: (Kumar et al., 2022).

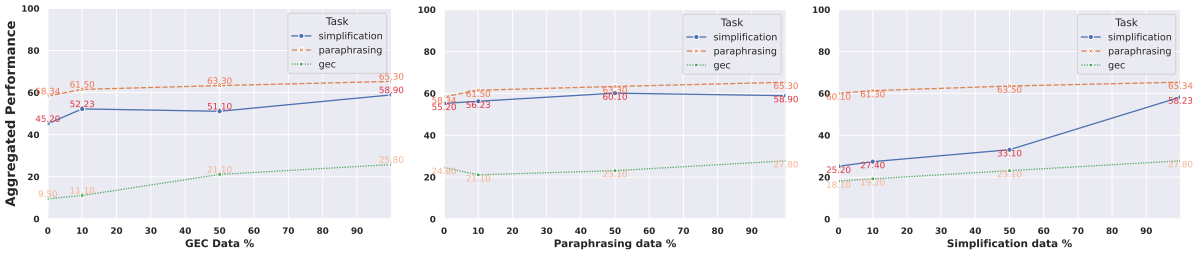

Figure 8: **Aggregated model performance by varying amounts of data samples**: (0% to 100%) by task (in the order: GEC, Paraphrasing, Simplification). We aggregate the scores as described in § 5.

5.7 Generalization to new languages

We also explore the capabilities of our MEDIT models on new languages. For every task, we chose two new languages not present in the training set: one related to the language families covered in our training dataset (Table 1) and one belonging to a language family not present in the training dataset. We only considered the languages that the underlying LLM had as part of its pre-training corpora so as to ensure the models had some understanding of the languages in question. Table 2 provides a summary of the languages considered and the datasets they were sourced from, as well as the results of the language generalization experiments. We follow the same metrics for all the tasks as in § 4.4.

MEDIT models are competitive on many unseen languages as compared to the monolingual state-of-the-art, especially on `it`-Simplification, and `hi`-GEC and Paraphrasing.[7]

6 Human Evaluations

We conduct human evaluations of our model outputs by proficient linguists (and native language speakers of the respective languages) on 50 test inputs (per task- language) to ensure they meet the instructional task-specific constraints across the various languages since text editing is often subjective, and automatic metrics are often limited in their effectiveness and accuracy. We evaluate our best-performing MEDIT model[8] based on its strong performance (Table 5). Specifically, we conduct a qualitative evaluation where each annotator is shown an instructional input and output from the model and asked to rate the quality of the output on three criteria: **fluency** (Is the output grammatically correct and sound like it was written by a native speaker of the language?), **adequacy** (does the output preserve the meaning of the input?), and **accuracy** (did the model make the desired edits according to the given edit instructions?) of the edited texts, on a Likert scale ranging from *Very Bad* to *Very Good*. We collect two annotations for each data point and adjudicate the conflicting judgments with the annotators. The annotation guidelines are provided in Appendix E. Table 3 shows the results of the evaluation. The expert annotators generally rate the model outputs as *Good* or *Very Good* across nearly all languages. For Arabic, the preferences are more balanced across the scale and sometimes even leaning towards the *Bad* or *Very Bad* across all criteria, which confirms our findings on the automatic metrics as well, indicating that while our model performs very well on languages such as English, German, Chinese, and Spanish, it still has a long way to go in terms of performance for languages such as Arabic in terms of quality, and on Chinese, Japanese, Korean, and Spanish on accuracy.

	Language	V. Good	Good	Neutral	Bad	V. Bad
FLUENCY	Arabic	25.00	14.29	17.86	14.29	28.57
	Chinese	56.67	13.33	23.33	3.33	3.33
	English	56.67	23.33	13.33	3.33	3.33
	German	30.0	56.67	3.33	6.67	3.33
	Japanese	50.0	4.54	22.72	13.63	9.09
	Korean	39.13	21.74	17.39	13.04	8.70
	Spanish	63.33	10.00	13.33	10.00	3.33
ADEQUACY	Arabic	21.43	14.29	10.71	25.00	28.57
	Chinese	56.67	16.67	6.67	10	10.0
	English	62.33	18.32	9.09	9.09	1.16
	German	33.33	63.33	0.0	3.33	0.0
	Japanese	63.63	4.55	4.55	18.18	9.09
	Korean	41.67	16.67	12.50	20.83	8.33
	Spanish	60.0	6.67	6.67	13.33	13.33
ACCURACY	Arabic	21.43	3.57	10.71	35.71	28.57
	Chinese	3.45	13.79	17.24	51.72	13.79
	English	37.93	32.23	8.33	18.18	3.33
	German	30.0	40.0	23.33	6.67	0.0
	Japanese	34.48	10.34	3.45	20.69	31.03
	Korean	18.52	18.52	11.11	14.81	37.04
	Spanish	37.93	24.14	6.90	3.45	27.59

Table 3: **Results of the human evaluation of the model output across three criteria.** For each of the criteria, expert human annotators rate the system output, and we note the frequency of their rating (%).

[7] Since no multilingual models have attempted to perform the considered tasks in the respective languages, we are unable to report the metrics on others. We also do not provide any comparisons if the language-specific metrics either do not exist or are reported using different metrics.

[8] `bactrian-x-llama-13b-merged`

7 Conclusions

We present MEDIT – an open-sourced dataset and set of multilingual instruction-tuned LLMs capable of following natural language instructions in seven languages to perform various textual editing tasks. It is the first publicly available set of models that heavily outperforms numerous multilingual LLMs on multiple tasks in different languages. Positive feedback from human evaluations shows that MEDIT can assist writers with various aspects of the text revision process at scale by following natural language instructions in multiple languages. Experiments on various multilingual NLP tasks demonstrate that MEDIT models outperform both their corresponding non-fine-tuned and fine-tuned models on other multilingual instruction datasets for text editing, in addition to achieving strong performance on languages unseen during the task-specific fine-tuning. By making our data/models publicly available, we hope to help make advances in multilingual intelligent writing assistants.

Limitations

In this work, we have developed and evaluated instruction-tuned LLMs capable of editing text in multiple languages. However, this work has several limitations that can be improved in future research.

Despite our attempts to cover a diverse set of seven languages, there are still a number of languages that have not been included in our research, largely because of the lack of high-quality, human-annotated text editing data. Our system can be extended to include more languages in the future to better understand the generalization of these models to new languages, and create more accessible and ubiquitous writing assistants.

Secondly, for training and evaluation, we primarily use datasets that are publicly available in specific languages, and sometimes we generate instructions in English and translate them into multiple languages using Google Translate (for example, for simplification tasks). Despite the fact that our approach allows us to support multiple languages with reasonable development costs, data generated and translated might contain unexpected noise. Moreover, they might not best represent expert-annotated edits in different languages. In order to further improve multilingual LLMs for text editing, future research can use human-generated data for training and evaluation.

Thirdly, our system leverages numerous LLMs with billions of parameters. Considering the computing resources required for running and developing these models, replicating the results may prove difficult (which we try to address by sharing our models publicly).

Lastly, our evaluations focus only on the performance of the models on benchmark datasets for text editing, which, in turn, focus primarily on measuring superficial characteristics based on n-gram overlaps. These evaluations are limited as they do not test for the more nuanced aspects of text editing, such as fluency, coherence, and meaning preservation. The lack of human evaluations makes assessing these nuanced characteristics difficult. Future work in this direction could look at robust and scalable evaluation metrics for multilingual text editing.

Ethics Statement

While our models offer several advantages to make intelligent writing assistance more accessible, we do recognize their potential limitations. Since our work mainly focuses on text editing, we are able to avoid many issues involving generating harmful text. Although there is still a possibility of small meaning changes for stylistic tasks due to the lack of user-specific context (Kulkarni and Raheja, 2023), we try to reduce the chance of hallucinations by constraining the generation to strictly editing tasks in order to reduce the chance of adding any new information or perpetuating biases.

Moreover, due to the multilingual settings, there is a risk of our models generating responses that are discriminatory, biased, or contain false information. Hence, our models, when fine-tuned on the text editing datasets, may inadvertently learn or propagate these problematic patterns. To address these concerns and minimize potential harm, we are dedicated to mitigating the risks associated with the use of our models in future research. We strongly advocate for the responsible use of our models to prevent any unintended negative consequences.

Acknowledgments

We sincerely thank Christoph Stuber, David Rojas, Ryan Koo, Samuel Lou, Sofia Mac Gregor, Yuko Okubo, and all the annotators for their immense help, invaluable linguistic expertise, and insightful feedback on the model quality and evaluations. We also thank Max Gubin, Dongyeop Kang, and the anonymous reviewers for their helpful suggestions.

A Training and Evaluation Datasets

A.1 Grammatical Error Correction

Arabic We report on three publicly available Arabic GEC datasets. The first two come from the QALB-2014 (Mohit et al., 2014) and QALB-2015 (Rozovskaya et al., 2015) shared tasks. The third is the newly created ZAEBUC dataset (Habash and Palfreyman, 2022; Alhafni et al., 2023). QALB-2014 consists of native/L1 user comments from the Aljazeera news website, whereas QALB-2015 consists of essays written by Arabic L2 learners with various levels of proficiency. It is worth noting that the QALB-2015 dataset has two test sets consisting of L1 and L2 data. In this work, we report results on the L1 test set. The ZAEBUC dataset comprises essays written by native Arabic speakers, which were manually corrected. We use the MaxMatch (M^2) Scorer (Dahlmeier and Ng, 2012) for the evaluation.

English When it comes to English, we use the Write & Improve + LOCNESS (W&I) corpus released in the Building Educational Applications (BEA) shared task on GEC (Bryant et al., 2019). We also use the NAIST Lang-8 corpus (Tajiri et al., 2012), which is one of the largest and most widely used datasets for English GEC. To test our systems, we use the JFLEG (Napoles et al., 2017) dataset. We use GLEU (Napoles et al., 2015, 2016) for the evaluation.

German For German, we use the Falko-MERLIN corpus (Boyd, 2018), which consists of sentences written by L2 learners that were manually corrected. We use the MaxMatch (M^2) Scorer (Dahlmeier and Ng, 2012) for the evaluation.

Spanish For Spanish, we use the publicly available COWS-L2H (Davidson et al., 2020) dataset. COWS-L2H consists of essays written by Spanish L2 learners at the university level in the United States. We use ERRANT (Bryant et al., 2017) for the evaluation.

Chinese For Chinese, we use the data that is part of the NLPCC18 shared task (Zhao et al., 2018). The training data used in the shared task was collected from the NAIST Lang-8 corpus (Tajiri et al., 2012), whereas the test data consists of manually corrected sentences written by Chinese L2 learners. We use GLEU (Napoles et al., 2015, 2016) for the evaluation.

Japanese For Japanese, we use the NAIST Lang-8 corpus (Mizumoto et al., 2011) to train our systems. For evaluation, we use the Japanese L2 TEC-JL dataset (Koyama et al., 2020). We use GLEU (Napoles et al., 2015, 2016) for the evaluation.

Korean We use the recently created Kor-Union dataset (Yoon et al., 2023). Kor-Union was created by collecting and combining GEC data from various sources. This includes essays written by Korean native/L1 speakers and L2 learners. We use the MaxMatch (M^2) Scorer (Dahlmeier and Ng, 2012) for the evaluation.

A.2 Paraphrasing

Arabic For training, we use the Arabic SemEval Paraphrasing (ASEP) corpus, which sourced three existing Arabic semantic similarity datasets released during SemEval 2017 Task 1 (Cer et al., 2017), consisting of roughly 1100 sentence pairs. For our purposes, similar to them, we only keep the sentence pairs with a semantic similarity score $\geq$ 3.25, which leads to 603 pairs. We also inverted the pairs for training, leading to a total of 1.2k training pairs. For evaluation, we use the evaluation dataset that was used for SemEval 2017 Track 1, but with the same similarity threshold as the training data, consisting of 67 sentence pairs. This evaluation set consists of sentences from the SNLI Corpus (Bowman et al., 2015) that were human-translated into Arabic, provided by CMU-Qatar by native Arabic speakers with strong English skills.

We also source from the Arabic Question Similarity (Shared Task 8) organized at the Workshop on NLP Solutions for Under-Resourced Languages (NSURL 2019) (Seelawi et al., 2019). The dataset was developed by mawdoo, and consists of 12k pairs for training and 3715 for testing. For both training and evaluation, we filter the semantically similar pairs (similarity score of 1), which leaves us with 10.7k training and 1.7k test pairs.

We also use the Arabic Paraphrasing Benchmark (APB) dataset (Alian et al., 2019), which consists of 1010 Arabic sentence pairs that are collected from different Arabic books. Paraphrasing was performed manually using six transformation procedures (i.e., addition, deletion, expansion, permutation, reduction, and replacement). Similar to other evaluation sets, we only keep the sentence pairs with a semantic similarity score $\geq$ 3.25, which leads to 286 pairs.

Table 4: **Datasets used to train and evaluate MEDIT.** With the exceptions of Spanish GEC and German Simplification, every other dataset contains >10k examples for all our experiments.

English Paraphrase Adversaries from Word Scrambling (PAWS) is a dataset that contains pairs of sentences with a high lexical overlap (Zhang et al., 2019). We use the PAWS dataset for training and evaluation.

German, Spanish, Japanese, Korean, Chinese We use the Cross-lingual Paraphrase Adversaries from Word Scrambling (Yang et al., 2019) dataset (PAWS-X), which was created by translating a subset of the PAWS validation and test sets to six other languages by professional translators.

A.3 Simplification

We draw on a variety of existing text simplification datasets in various languages. Table 4 shows the different simplification datasets we draw on in our work and also outlines the training, development, and test settings.

A major issue with text simplification is the absence of publicly available, human-annotated, sentence-level parallel corpora for some of the languages we considered, such as Arabic, Spanish, and Korean. Therefore, we addressed this by translating the Text Simplification datasets for English to these three languages, in which the parallel data is absent. One potential limitation of this approach could be the poor quality of the translation models, which could negatively impact the overall data quality. Therefore, we use the latest Google Translate API[9] to construct the translated data, and further verify the quality of the translated text with human annotators (native speakers) for a subset of the data. We chose the Google API since it performed best amongst the other open-source machine translation

[9] https://cloud.google.com/translate/docs/advanced/translating-text-v3

models and APIs we tested[10][11].

English For English, we used Wikilarge (Zhang and Lapata, 2017), WikiAuto (Jiang et al., 2020), and Newsela (Xu et al., 2015) datasets for training. WikiAuto is a neural CRF-aligned corpus of original and simple Wikipedia documents that are automatically aligned to generate sentence pairs, whereas the Newsela (Xu et al., 2015) dataset contains automatically aligned sentence pairs from documents that are generated by professional writers at Newsela for various grade levels. For testing, we use ASSET (Alva-Manchego et al., 2020), which contains ten high-quality human written simplifications for each of the 2,390 sentences from the TurkCorpus (Xu et al., 2016b).

German We use the GEOLino (Mallinson et al., 2020) and TextComplexityDE (Seiffe et al., 2022) datasets for both training and testing. GEOLinoTest contains text about nature, physics, and people from GeoLino, a children's magazine that was manually simplified by a German linguist to a five to seven-year-old reading level. TextComplexityDE contains 250 complex sentences from German Wikipedia that native speakers manually simplified.

Japanese We use the EasyJapanese (Maruyama and Yamamoto, 2018) and EasyJapaneseExtended (Maruyama and Yamamoto, 2018) datasets for training and testing. EasyJapanese contains 50k sentence pairs that were manually created by five students by simplifying text from the Tanaka corpus (Tanaka, 2001). The EasyJapaneseExtended dataset contains an additional 34.4k sentences from the Tanaka corpus with simplifications crowdsourced.

Arabic, Spanish, Korean For Arabic, Spanish and Korean, as there were no publicly available sentence-level parallel datasets available, we translated the English simplification datasets. Specifically, we translated the English Newsela dataset for training and ASSET for testing using the Google Translate API, giving us 94k and 359 examples for training and testing, respectively.

Chinese We found no publicly available dataset for training Chinese Simplification. Therefore, we again translated the English Newsela training dataset into Chinese. However, for the testing set, we use the CSS (Yang et al., 2023a) dataset. CSS consists of two human-written simplifications for each of the 383 original sentences from the PFR corpus. [12]

B Data Preparation

For Seq2Seq models, we prepend the task-specific instructions to the input to the encoder for each language, performing a full parameter update on the entire sequence. We construct the CLM datasets by wrapping each example in model-specific instructions[13] computing the loss *only* on the target text; hence, in the Native and Random settings, the model does not optimize for the specific "translated" instructions.
