Introduction

This year marks the 20th edition of the *Workshop on Innovative Use of NLP for Building Educational Applications*. As in previous years, we are happy to welcome a plethora of work on various aspects and types of educational applications – from traditionally popular tasks around language learning to novel applications related to teaching math and programming languages. This year, we have also extended BEA to a 2-day event, which allowed us to accept more valuable work from our authors: in total, we received a record number of 169 submissions, and from these, we have accepted 12 papers as talks and 63 as poster and demo presentations, for an overall acceptance rate of 44 percent. As in previous years, we have put the main emphasis on the high quality of research when selecting the papers to be accepted, but we also hope that we have managed to bring together a diverse program. One aspect in which BEA continues to excel is the range of languages that are covered by the work submitted and presented at our workshop: this year, accepted papers feature work on educational applications developed for Arabic, English, Estonian, Finnish, Germanic languages, Indian languages, Italian, Romanian, Russian, and Spanish.

In addition to the diverse oral, poster and demo presentations, this year, Kostiantyn Omelianchuk from Grammarly will give a keynote on *How LLMs Are Reshaping GEC: Training, Evaluation, and Task Framing*. BEA 2025 will also include, for the first time, a half-day tutorial on *LLMs for Education: Understanding the Needs of Stakeholders, Current Capabilities and the Path Forward*. Finally, BEA 2025 has hosted a shared task on *Pedagogical Ability Assessment of AI-powered Tutors*, which attracted a large number of participants, and the program includes an oral presentation on the shared task from the organizers as well as extended poster sessions for shared tasks participants presenting their systems.

Last but not least, we would like to thank everyone who has been involved in organizing the BEA workshop this year. We are particularly grateful to our sponsors who keep providing their support to BEA: this year, our sponsors include Cambridge University Press & Assessment, Duolingo English Test, Grammarly, National Board of Medical Examiners, SigIQ.ai, and Squirrel Ai Learning.

BEA 2025 Organizing Committee

Organizing Committee

General Chair

Ekaterina Kochmar, MBZUAI

Program Chairs

Andrea Horbach, Hildesheim University
Ronja Laarmann-Quante, Ruhr University Bochum
Marie Bexte, FernUniversität in Hagen

Publication Chair

Anaïs Tack, KU Leuven, imec

Shared Tasks Chairs

Victoria Yaneva, National Board of Medical Examiners
Bashar Alhafni, MBZUAI

Sponsorship Chair

Zheng Yuan, University of Sheffield
Jill Burstein, Duolingo

Program Committee

Chairs

Bashar Alhafni, MBZUAI
Marie Bexte, FernUniversität in Hagen
Jill Burstein, Duolingo
Andrea Horbach, CAU Kiel
Ekaterina Kochmar, MBZUAI
Ronja Laarmann-Quante, Ruhr University Bochum
Anaïs Tack, KU Leuven; imec; UCLouvain
Victoria Yaneva, National Board of Medical Examiners
Zheng Yuan, University of Sheffield

Program Committee

Rania Abdelghani, Hector Institute of Educational Sciences and Psychology, University of Tübingen
Tazin Afrin, NBME
Syeda Sabrina Akter, George Mason University
Ali Al-Laith, University of Copenhagen
Giora Alexandron, Weizmann Institute of Science
David Alfter, Gothenburg University
Jatin Ambasana, Indian Institute of Technology Bombay
Jiyuan An, Beijing Language and Culture University
Antonios Anastasopoulos, George Mason University
Nico Andersen, DIPF | Leibniz Institute for Research and Information in Education
Aitor Arronte Alvarez, University of Hawaii at Manoa
Yuya Asano, University of Pittsburgh
Nischal Ashok Kumar, University of Massachusetts Amherst
Berk Atil, Pennsylvania State University
Shiva Baghel, Extramarks
Xiaoyu Bai, University of Potsdam
Jinhyun Bang, Samsung Research
Stefano Banno, University of Cambridge
Mohmaed Basem, MSA University
Michael Gringo Angelo Bayona, Trinity College Dublin
Lee Becker, Pearson
Beata Beigman Klebanov, Educational Testing Service
Milena Belosevic, Bielefeld University
Enrico Benedetti, Utrecht University
Luca Benedetto, University of Cambridge
Maryam Berijanlian, Michigan State University
Kay Berkling, Cooperative State University, Karlsruhe
Ummugul Bezirhan, Boston College, TIMSS and PIRLS International Study Center
Krishnakant Bhatt, IIT Bombay
Souvik Bhattacharyya, Lowe's
Abhidip Bhattacharyya, University of Massachusetts, Amherst
Serge Bibauw, Université catholique de Louvain
Louise Bloch, University of Applied Sciences and Arts Dortmund
Allison Bradford, University of California, Berkeley

Ted Briscoe, MBZUAI
Dominique Brunato, Institute of Computational Linguistics A. Zampolli"(ILC-CNR), Pisa
Ana-Maria Bucur, Interdisciplinary School of Doctoral Studies

Keynote Talk

How LLMs Are Reshaping GEC: Training, Evaluation, and Task Framing

Kostiantyn Omelianchuk
Grammarly

Abstract: This keynote will explore the evolving role of Large Language Models (LLMs) in training and evaluating Grammatical Error Correction (GEC) systems, using Grammarly as a case study. It will cover the shift from primarily using human-annotated corpora to semi-synthetic data generation approaches, examining its impact on model training, evaluation practices, and overall task definition. Key topics include task definition challenges, trade-offs between data types, observed biases in models, and recent advances in LLM-based evaluation techniques. The talk will also explore scalable approaches for multilingual GEC and outline implications for future research.

Bio: Kostiantyn Omelianchuk is an Applied Research Scientist and Area Tech Lead at Grammarly, where he works on practical applications of NLP, with a primary interest in Grammatical Error Correction (GEC). He has over nine years of experience in the field and has co-authored several papers, including GECToR: Grammatical Error Correction – Tag, Not Rewrite, a widely used approach in the GEC community. His research explores edit-based modeling, the use of large language models for text correction and simplification, and the transition from human-annotated to synthetic data for training and evaluation. His recent work focuses on multilingual GEC, LLM-based evaluation methods, and synthetic data generation.

Table of Contents

Large Language Models for Education: Understanding the Needs of Stakeholders, Current Capabilities and the Path Forward

Sankalan Pal Chowdhury, Nico Daheim, Ekaterina Kochmar, Jakub Macina, Donya Rooein, Mrinmaya Sachan and Shashank Sonkar 1

Comparing human and LLM proofreading in L2 writing: Impact on lexical and syntactic features

Hakyung Sung, Karla Csuros and Min-Chang Sung 11

MateInfoUB: A Real-World Benchmark for Testing LLMs in Competitive, Multilingual, and Multimodal Educational Tasks

Marius Dumitran, Mihnea Buca and Theodor Moroianu 24

Unsupervised Automatic Short Answer Grading and Essay Scoring: A Weakly Supervised Explainable Approach

Felipe Urrutia, Cristian Buc, Roberto Araya and Valentin Barriere 38

A Survey on Automated Distractor Evaluation in Multiple-Choice Tasks

Luca Benedetto, Shiva Taslimipoor and Paula Buttery 55

Alignment Drift in CEFR-prompted LLMs for Interactive Spanish Tutoring

Mina Almasi and Ross Kristensen-McLachlan 70

Leveraging Generative AI for Enhancing Automated Assessment in Programming Education Contests

Stefan Dascalescu, Marius Dumitran and Mihai Alexandru Vasiluta 89

Can LLMs Effectively Simulate Human Learners? Teachers' Insights from Tutoring LLM Students

Daria Martynova, Jakub Macina, Nico Daheim, Nilay Yalcin, Xiaoyu Zhang and Mrinmaya Sachan 100

Adapting LLMs for Minimal-edit Grammatical Error Correction

Ryszard Staruch, Filip Gralinski and Daniel Dzienisiewicz 118

COGENT: A Curriculum-oriented Framework for Generating Grade-appropriate Educational Content

Zhengyuan Liu, Stella Xin Yin, Dion Hoe-Lian Goh and Nancy Chen 129

Is Lunch Free Yet? Overcoming the Cold-Start Problem in Supervised Content Scoring using Zero-Shot LLM-Generated Training Data

Marie Bexte and Torsten Zesch 144

Transformer Architectures for Vocabulary Test Item Difficulty Prediction

Lucy Skidmore, Mariano Felice and Karen Dunn 160

Automatic concept extraction for learning domain modeling: A weakly supervised approach using contextualized word embeddings

Kordula De Kuthy, Leander Gurrbach and Detmar Meurers 175

Towards a Real-time Swedish Speech Analyzer for Language Learning Games: A Hybrid AI Approach to Language Assessment

Tianyi Geng and David Alfter 186

Multilingual Grammatical Error Annotation: Combining Language-Agnostic Framework with Language-Specific Flexibility

Mengyang Qiu, Tran Minh Nguyen, Zihao Huang, Zelong Li, Yang Gu, Qingyu Gao, SILIANG LIU and Jungyeul Park 202

Program

Thursday, July 31, 2025

09:00 - 10:30 *Tutorial Session A*

10:30 - 11:00 *Coffee Break*

11:00 - 12:30 *Tutorial Session B*

12:30 - 14:00 *Lunch Break / Birds of a Feather*

14:00 - 15:30 *Oral Session A*

A Bayesian Approach to Inferring Prerequisite Structures and Topic Difficulty in Language Learning

Anh-Duc Vu, Jue Hou, Anisia Katinskaia, Ching-Fan Sheu and Roman Yangarber

Enhancing Arabic Automated Essay Scoring with Synthetic Data and Error Injection

Chatrine Qwaider, Bashar Alhafni, Kirill Chirkunov, Nizar Habash and Ted Briscoe

Alignment Drift in CEFR-prompted LLMs for Interactive Spanish Tutoring

Mina Almasi and Ross Kristensen-McLachlan

You Shall Know a Word's Difficulty by the Family It Keeps: Word Family Features in Personalised Word Difficulty Classifiers for L2 Spanish

Jasper Degraeuwe

Assessing Critical Thinking Components in Romanian Secondary School Textbooks: A Data Mining Approach to the ROTEX Corpus

Madalina Chitez, Liviu Dinu, Marius Micluta-Campeanu, Ana-Maria Bucur and Roxana Rogobete

Unsupervised Automatic Short Answer Grading and Essay Scoring: A Weakly Supervised Explainable Approach

Felipe Urrutia, Cristian Buc, Roberto Araya and Valentin Barriere

15:30 - 16:00 *Coffee Break*

16:00 - 17:30 *Poster Session A*

Thursday, July 31, 2025 (continued)

A Survey on Automated Distractor Evaluation in Multiple-Choice Tasks

Luca Benedetto, Shiva Taslimipour and Paula Buttery

Increasing the Generalizability of Similarity-Based Essay Scoring Through Cross-Prompt Training

Marie Bexte, Yuning Ding and Andrea Horbach

Automatic concept extraction for learning domain modeling: A weakly supervised approach using contextualized word embeddings

Kordula De Kuthy, Leander Gurrbach and Detmar Meurers

Automated Scoring of a German Written Elicited Imitation Test

Mihail Chifligarov, Jammila Laâguidi, Max Schellenberg, Alexander Dill, Anna Timukova, Anastasia Drackert and Ronja Laarmann-Quante

Challenges for AI in Multimodal STEM Assessments: a Human-AI Comparison

Aymeric de Chillaz, Anna Sotnikova, Patrick Jermann and Antoine Bosselut

Don't Score too Early! Evaluating Argument Mining Models on Incomplete Essays

Nils-Jonathan Schaller, Yuning Ding, Thorben Jansen and Andrea Horbach

LangEye: Toward 'Anytime' Learner-Driven Vocabulary Learning From Real-World Objects

Mariana Shimabukuro, Deval Panchal and Christopher Collins

Explaining Holistic Essay Scores in Comparative Judgment Assessments by Predicting Scores on Rubrics

Michiel De Vrindt, Renske Bouwer, Wim Van Den Noortgate, Marije Lesterhuis and Anaïs Tack

Name of Thrones: How Do LLMs Rank Student Names in Status Hierarchies Based on Race and Gender?

Annabella Sakunkoo and Jonathan Sakunkoo

Enhancing Security and Strengthening Defenses in Automated Short-Answer Grading Systems

Sahar Yarmohammadtoosky, Yiyun Zhou, Victoria Yaneva, Peter Baldwin, Saed Rezayi, Brian Clauser and Polina Harik

EduCSW: Building a Mandarin-English Code-Switched Generation Pipeline for Computer Science Learning

Ruishi Chen and Yiling Zhao

Thursday, July 31, 2025 (continued)

Paragraph-level Error Correction and Explanation Generation: Case Study for Estonian

Martin Vainikko, Taavi Kamarik, Karina Kert, Krista Liin, Silvia Maine, Kais Allkivi, Annekatrin Kaivapalu and Mark Fishel

Can LLMs Reliably Simulate Real Students' Abilities in Mathematics and Reading Comprehension?

KV Aditya Srivatsa, Kaushal Maurya and Ekaterina Kochmar

Transformer Architectures for Vocabulary Test Item Difficulty Prediction

Lucy Skidmore, Mariano Felice and Karen Dunn

Comparing human and LLM proofreading in L2 writing: Impact on lexical and syntactic features

Hakyung Sung, Karla Csuros and Min-Chang Sung

MateInfoUB: A Real-World Benchmark for Testing LLMs in Competitive, Multilingual, and Multimodal Educational Tasks

Marius Dumitran, Mihnea Buca and Theodor Moroianu

Investigating Methods for Mapping Learning Objectives to Bloom's Revised Taxonomy in Course Descriptions for Higher Education

Zahra Kolagar, Frank Zalkow and Alessandra Zarcone

Using NLI to Identify Potential Collocation Transfer in L2 English

Haiyin Yang, Zoey Liu and Stefanie Wulff

Improving In-context Learning Example Retrieval for Classroom Discussion Assessment with Re-ranking and Label Ratio Regulation

Nhat Tran, Diane Litman, Benjamin Pierce, Richard Correnti and Lindsay Clare Matsumura

Comparing Behavioral Patterns of LLM and Human Tutors: A Population-level Analysis with the CIMA Dataset

Aayush Kucheria, Nitin Sawhney and Arto Hellas

UPSC2M: Benchmarking Adaptive Learning from Two Million MCQ Attempts

Kevin Shi and Karttikeya Mangalam

Multilingual Grammatical Error Annotation: Combining Language-Agnostic Framework with Language-Specific Flexibility

Mengyang Qiu, Tran Minh Nguyen, Zihao Huang, Zelong Li, Yang Gu, Qingyu Gao, SILIANG LIU and Jungyeul Park

Thursday, July 31, 2025 (continued)

Automatic Generation of Inference Making Questions for Reading Comprehension Assessments

Wanjing (Anyu) Ma, Michael Flor and Zuowei Wang

Lessons Learned in Assessing Student Reflections with LLMs

Mohamed Elaraby and Diane Litman

Automated L2 Proficiency Scoring: Weak Supervision, Large Language Models, and Statistical Guarantees

Aitor Arronte Alvarez and Naiyi Xie Fincham

Advances in Auto-Grading with Large Language Models: A Cross-Disciplinary Survey

Tania Amanda Nkoyo Frederick Eneye, Chukwuebuka Fortunate Ijezue, Ahmad Imam Amjad, Maaz Amjad, Sabur Butt and Gerardo Castañeda-Garza

Exploring LLMs for Predicting Tutor Strategy and Student Outcomes in Dialogues

Fareya Ikram, Alexander Scarlatos and Andrew Lan

Temporalizing Confidence: Evaluation of Chain-of-Thought Reasoning with Signal Temporal Logic

Zhenjiang Mao, Artem Bisliouk, Rohith Nama and Ivan Ruchkin

18:00 - 21:00 *Workshop Dinner*

Friday, August 1, 2025

09:00 - 09:45 *Keynote Talk by Kostia Omelianchuk*

09:45 - 10:30 *Oral Session B*

LLMs in alliance with Edit-based models: advancing In-Context Learning for Grammatical Error Correction by Specific Example Selection
Alexey Sorokin and Regina Nasyrova

Findings of the BEA 2025 Shared Task on Pedagogical Ability Assessment of AI-powered Tutors
Ekaterina Kochmar, Kaushal Maurya, Kseniia Petukhova, KV Aditya Srivatsa, Anaïs Tack and Justin Vasselli

MSA at BEA 2025 Shared Task: Disagreement-Aware Instruction Tuning for Multi-Dimensional Evaluation of LLMs as Math Tutors
Baraa Hikal, Mohmaed Basem, Islam Oshallah and Ali Hamdi

10:30 - 11:00 *Coffee Break*

11:00 - 12:30 *Poster Session B*

Leveraging Generative AI for Enhancing Automated Assessment in Programming Education Contests
Stefan Dascalescu, Marius Dumitran and Mihai Alexandru Vasiluta

Is Lunch Free Yet? Overcoming the Cold-Start Problem in Supervised Content Scoring using Zero-Shot LLM-Generated Training Data
Marie Bexte and Torsten Zesch

Towards a Real-time Swedish Speech Analyzer for Language Learning Games: A Hybrid AI Approach to Language Assessment
Tianyi Geng and David Alfter

LEVOS: Leveraging Vocabulary Overlap with Sanskrit to Generate Technical Lexicons in Indian Languages
Karthika N J, Krishnakant Bhatt, Ganesh Ramakrishnan and Preethi Jyothi

The Need for Truly Graded Lexical Complexity Prediction
David Alfter

Friday, August 1, 2025 (continued)

Educators' Perceptions of Large Language Models as Tutors: Comparing Human and AI Tutors in a Blind Text-only Setting

Sankalan Pal Chowdhury, Terry Jingchen Zhang, Donya Rooein, Dirk Hovy, Tanja Käser and Mrinmaya Sachan

Costs and Benefits of AI-Enabled Topic Modeling in P-20 Research: The Case of School Improvement Plans

Syeda Sabrina Akter, Seth Hunter, David Woo and Antonios Anastasopoulos

Are Large Language Models for Education Reliable Across Languages?

Vansh Gupta, Sankalan Pal Chowdhury, Vilém Zouhar, Donya Rooein and Mrinmaya Sachan

Span Labeling with Large Language Models: Shell vs. Meat

Phoebe Mulcaire and Nitin Madnani

STAIR-AIG: Optimizing the Automated Item Generation Process through Human-AI Collaboration for Critical Thinking Assessment

Euigyum Kim, Seewoo Li, Salah Khalil and Hyo Jeong Shin

End-to-End Automated Item Generation and Scoring for Adaptive English Writing Assessment with Large Language Models

Kamel Nebhi, Amrita Panesar and Hans Bantilan

bea-jh at BEA 2025 Shared Task: Evaluating AI-powered Tutors through Pedagogically-Informed Reasoning

Jihyeon Roh and Jinhyun Bang

K-NLPers at BEA 2025 Shared Task: Evaluating the Quality of AI Tutor Responses with GPT-4.1

Geon Park, Jiwoo Song, Gihyeon Choi, Juoh Sun and Harksoo Kim

IALab UC at BEA 2025 Shared Task: LLM-Powered Expert Pedagogical Feature Extraction

Sofía Correa Busquets, Valentina Córdova Véliz and Jorge Baier

TBA at BEA 2025 Shared Task: Transfer-Learning from DARE-TIES Merged Models for the Pedagogical Ability Assessment of LLM-Powered Math Tutors

Sebastian Gombert, Fabian Zehner and Hendrik Drachler

COGENT: A Curriculum-oriented Framework for Generating Grade-appropriate Educational Content

Zhengyuan Liu, Stella Xin Yin, Dion Hoe-Lian Goh and Nancy Chen

Friday, August 1, 2025 (continued)

Analyzing Interview Questions via Bloom's Taxonomy to Enhance the Design Thinking Process

Fatemeh Kazemi Vanhari, Christopher Anand and Charles Welch

Exploring LLM-Based Assessment of Italian Middle School Writing: A Pilot Study

Adriana Mirabella and Dominique Brunato

Beyond Linear Digital Reading: An LLM-Powered Concept Mapping Approach for Reducing Cognitive Load

Junzhi Han and Jinho D. Choi

BLCU-ICALL at BEA 2025 Shared Task: Multi-Strategy Evaluation of AI Tutors

Jiyuan An, Xiang Fu, Bo Liu, Xuquan Zong, Cunliang Kong, Shuliang Liu, Shuo Wang, Zhenghao Liu, Liner Yang, Hanghang Fan and Erhong Yang

Jinan Smart Education at BEA 2025 Shared Task: Dual Encoder Architecture for Tutor Identification via Semantic Understanding of Pedagogical Conversations

Lei Chen

CU at BEA 2025 Shared Task: A BERT-Based Cross-Attention Approach for Evaluating Pedagogical Responses in Dialogue

Zhihao Lyu

SYSUpporter Team at BEA 2025 Shared Task: Class Compensation and Assignment Optimization for LLM-generated Tutor Identification

Longfeng Chen, Zeyu Huang, Zheng Xiao, Yawen Zeng and Jin Xu

Emergent Wisdom at BEA 2025 Shared Task: From Lexical Understanding to Reflective Reasoning for Pedagogical Ability Assessment

Raunak Jain and Srinivasan Rengarajan

Henry at BEA 2025 Shared Task: Improving AI Tutor's Guidance Evaluation Through Context-Aware Distillation

Henry Pit

TutorMind at BEA 2025 Shared Task: Leveraging Fine-Tuned LLMs and Data Augmentation for Mistake Identification

FATIMA DEKMAK, Christian Khairallah and Wissam Antoun

BD at BEA 2025 Shared Task: MPNet Ensembles for Pedagogical Mistake Identification and Localization in AI Tutor Responses

Shadman Rohan, Ishita Sur Apan, Muhtasim Shochcho, Md Fahim, Mohammad Rahman, AKM Mahbubur Rahman and Amin Ali

Friday, August 1, 2025 (continued)

LLM-Assisted, Iterative Curriculum Writing: A Human-Centered AI Approach in Finnish Higher Education

Leo Huovinen and Mika Hämäläinen

12:30 - 14:00 *Lunch Break / Birds of a Feather*

14:00 - 15:30 *Poster Session C*

Can LLMs Effectively Simulate Human Learners? Teachers' Insights from Tutoring LLM Students

Daria Martynova, Jakub Macina, Nico Daheim, Nilay Yalcin, Xiaoyu Zhang and Mrinmaya Sachan

Adapting LLMs for Minimal-edit Grammatical Error Correction

Ryszard Staruch, Filip Gralinski and Daniel Dzienisiewicz

Do LLMs Give Psychometrically Plausible Responses in Educational Assessments?

Andreas Säuberli, Diego Frassinelli and Barbara Plank

Towards Automatic Formal Feedback on Scientific Documents

Louise Bloch, Johannes Rückert and Christoph Friedrich

Transformer-Based Real-Word Spelling Error Feedback with Configurable Confusion Sets

Torsten Zesch, Dominic Gardner and Marie Bexte

Unsupervised Sentence Readability Estimation Based on Parallel Corpora for Text Simplification

Rina Miyata, Toru Urakawa, Hideaki Tamori and Tomoyuki Kajiwara

Exploiting the English Vocabulary Profile for L2 word-level vocabulary assessment with LLMs

Stefano Banno, Kate Knill and Mark Gales

Improving AI assistants embedded in short e-learning courses with limited textual content

Jacek Marciniak, Marek Kubis, Michał Gulczyński, Adam Szpilkowski, Adam Wiczarek and Marcin Szczepański

GermDetect: Verb Placement Error Detection Datasets for Learners of Germanic Languages

Noah-Manuel Michael and Andrea Horbach

Friday, August 1, 2025 (continued)

Automated Scoring of Communication Skills in Physician-Patient Interaction: Balancing Performance and Scalability

Saed Rezayi, Le An Ha, Yiyun Zhou, Andrew Houriet, Angelo D'Addario, Peter Baldwin, Polina Harik, Ann King and Victoria Yaneva

Can GPTZero's AI Vocabulary Distinguish Between LLM-Generated and Student-Written Essays?

Veronica Schmalz and Anaïs Tack

A Framework for Proficiency-Aligned Grammar Practice in LLM-Based Dialogue Systems

Luisa Ribeiro-Flucht, Xiaobin Chen and Detmar Meurers

RETUYT-INCO at BEA 2025 Shared Task: How Far Can Lightweight Models Go in AI-powered Tutor Evaluation?

Santiago Góngora, Ignacio Sastre, Santiago Robaina, Ignacio Remersaro, Luis Chiruzzo and Aiala Rosá

Archaeology at BEA 2025 Shared Task: Are Simple Baselines Good Enough?

Ana Roşu, Jany-Gabriel Ispas and Sergiu Nisioi

NLIP at BEA 2025 Shared Task: Evaluation of Pedagogical Ability of AI Tutors

Trishita Saha, Shrenik Ganguli and Maunendra Sankar Desarkar

LLM-based post-editing as reference-free GEC evaluation

Robert Östling, Murathan Kurfali and Andrew Caines

Estimation of Text Difficulty in the Context of Language Learning

Anisia Katinskaia, Anh-Duc Vu, Jue Hou, Ulla Vanhatalo, Yiheng Wu and Roman Yangarber

Exploring task formulation strategies to evaluate the coherence of classroom discussions with GPT-4o

Yuya Asano, Beata Beigman Klebanov and Jamie Mikeska

EyeLLM: Using Lookback Fixations to Enhance Human-LLM Alignment for Text Completion

Astha Singh, Mark Torrance and Evgeny Chukharev

Decoding Actionability: A Computational Analysis of Teacher Observation Feedback

Large Language Models for Education: Understanding the Needs of Stakeholders, Current Capabilities and the Path Forward

Sankalan Pal Chowdhury¹, Nico Daheim², Ekaterina Kochmar³,
Jakub Macina¹, Donya Rooein⁴, Mrinmaya Sachan¹, Shashank Sonkar⁵
¹ETH Zurich, ²TU Darmstadt, ³MBZUAI, ⁴Bocconi University, ⁵Rice University
Alphabetical order of presenters, Correspondence to: mrinmaya.sachan@inf.ethz.ch

Motivation and Objectives: Recent advancements in Large Language Models (LLMs) have opened unprecedented opportunities in education but the current development goals of LLMs stand in contrast to the requirements of educational applications. This tutorial aims to bridge the gap between two major communities: Natural Language Processing (NLP) researchers and Artificial Intelligence in Education (AIED) practitioners. Our objectives are: (1) to help NLP researchers understand the requirements and challenges of education, enabling them to develop LLMs that align with educational needs, and (2) to enable educators and AIED practitioners to gain a deeper understanding of the capabilities and limitations of current NLP technologies, fostering effective integration of LLMs in educational contexts. By facilitating cross-disciplinary dialog, we aim to uncover the potential of LLMs in education.

First, we identify several critical challenges: *LLMs must be aligned to complement established pedagogical theories and educational practices*, incorporating principles such as scaffolding (Macina et al., 2023b; Sonkar et al., 2024a) or Socratic questioning (Shridhar et al., 2022), effective feedback mechanisms (Daheim et al., 2024), and cognitive load management (Settles and Meeder, 2016). This ensures that AI systems enhance rather than undermine learning processes. We emphasize that *LLMs need to be integrated with existing AIED technologies*, including knowledge tracing models and intelligent tutoring systems (ITS). As highlighted by UNESCO (Miao and Cukurova, 2024), we also need to explore *human-AI collaboration* to preserve human agency while leveraging the benefits of LLMs. The use of LLMs also raises ethical concerns about *data privacy and security* and *fairness* for students, necessitating robust safeguards. Finally, *AI literacy* among educators, students, and policymakers is important for ensuring that stakeholders understand their potential and limitations.

1 Tutorial Overview and Structure

1. LLMs meet AIED (60 min)

Intro to LLMs (20 min)
Learning science, AIED foundations (20 min)
Misalignment b/w LLMs & AIED (20 min)

2. Case Studies & Coffee Break (120 min)

Intelligent Tutoring Systems (30 min)
Coffee break (30 min)
Automated feedback & assessment (20 min)
Content (e.g. problem) generation (20 min)
Student modeling and adaptivity (20 min)

3. Closing Discussion (30 min)

LLM development for education
Human, ethical and societal aspects
Closing remarks

We will begin with an introduction of key LLM technologies and AIED usecases, focussing on the needs of stakeholders in education, such as pedagogy, and opportunities to harness LLMs for education applications. Then, we will outline how these needs stand in contrast with current LLM development which instead focusses on solving correctness. Afterwards, we will delve into a series of case studies that highlight how LLMs can be adapted for: (1) robust, personalized, and scalable conversational tutoring systems; (2) adaptive and personalized content generation of educational material, lesson plans, and assessments; (3) grading and delivery of detailed and personalized feedback on student work. We will examine the current capabilities of LLMs in these domains, discussing recent research findings and practical applications. The tutorial will interweave the applications with critical challenges such as pedagogical alignment, ethical considerations, and human factors in AI-assisted education. We finally conclude with a discussion of LLM development for education that emphasizes human, ethical, and societal aspects.

2 LLMs Meet AIED

LLM Training & AIED Requirements LLMs offer significant potential in education but require careful tuning to align with pedagogical goals. For instance, LLMs tend to provide direct answers instead of scaffolding learning which can hinder learning (Macina et al., 2023b; Sonkar et al., 2024a). We will first discuss how LLMs are trained using supervised fine-Tuning (SFT) (Wei et al., 2022), instruction tuning, and reinforcement-learning-based optimization methods (Ziegler et al., 2019; Rafailov et al., 2023). Connected to this, we also highlight the shortcomings of current benchmarks (Hendrycks et al., 2020; Cobbe et al., 2021; Hendrycks et al., 2021) that are used to evaluate LLMs, mainly for solving accuracy. Evaluation of AIED systems is different from this, as pedagogical factors play a large role and have dominated the development of educational systems (Graesser et al., 2005). We highlight these educational needs from different perspectives and show how LLM development goals do not align to them. For example, students require space to think and learn, also by making mistakes (Macina et al., 2023a; Sonkar et al., 2024a), and teachers require flexible student simulations (Markel et al., 2023).

Human Factors & Ethical Considerations: Integrating LLMs into educational contexts brings several human-centered challenges that must be addressed to ensure effective and ethical use. For example, teachers are often not included in the development loop (Shankar et al., 2024), but gaining their trust, also through model explainability (Cortez et al., 2024) is important. We will discuss how instructors can be included effectively, for example, to decide, when and which NLP models to use or which inputs to give to the models. We will also discuss how they can modify the generated outcomes as needed (Lu et al., 2023) and prompt architectures to provide responses to MCQs based on student simulations (Lu and Wang, 2024).

The application of LLMs in schools also raises ethical considerations related to attribution, plagiarism, and the potential for AI-generated content to be presented as original work. To address these issues, universities and educational authorities must strengthen and enforce academic integrity policies while educating students about responsible AI use. Promoting awareness and developing guidelines is essential in maintaining the integrity of academic work in the age of GenAI (Okaiyeto et al., 2023).

3 LLMs for Educational Applications

3.1 Intelligent Tutoring Systems (ITSs)

ITSs have long been the focus of AIED developments including systems such as AutoTutor-based (Nye et al., 2014), example-tracing tutors (Alevan et al., 2009) or Cognitive tutor (Anderson et al., 1997). However, they require extensive human authoring. While LLMs hold great promise to overcome this and enable applications like student tutoring (Chen et al., 2024) or teacher training (Gregorcic et al., 2024; Markel et al., 2023). Yet, they still face limitations, such as generating factually incorrect responses or not offering sufficient pedagogy (Sonkar et al., 2023).

In this tutorial, we will cover a range of works that attempt to alleviate these shortcomings, for example, such that use LLMs within structured dialogs (Schmucker et al., 2024; Pal Chowdhury et al., 2024), data-driven approaches to adding scaffolding capabilities (Macina et al., 2023a; Sonkar et al., 2023; Jurenka and et al., 2024), and mitigating hallucinations by adding intermediate reasoning steps for prompted LLMs (Wang et al., 2024b; Daheim et al., 2024). As large amounts of dialog tutoring data can be hard to collect, we will also discuss synthetic data creation methods (Wang et al., 2024a; Chevalier et al., 2024).

Finally, we will touch upon evaluation protocols that, ideally, should include relevant stakeholders and evaluate learning effectiveness. Such studies include using LLMs in real classrooms, for example, for computer science (Nie et al., 2024) or math education (Cheng et al., 2024), or using LLMs as student simulations to evaluate the effectiveness of automatic dialog tutors (Macina et al., 2023a). Such student simulations can also be effective for teacher training (Gregorcic et al., 2024; Wang and Demszky, 2023) and training teaching assistants (Markel et al., 2023).

3.2 Automated Feedback and Assessment

Hint and Feedback mechanisms play an important role in determining learning outcomes. We will discuss studies that show both the potential and limitations of LLMs in generating quality feedback. (McNichols et al., 2024) show fine-tuned LLMs have limited generalization capabilities. Contrarily, (Dai et al., 2024) find GPT-4 outperforms human instructors in important aspects of effective feedback dimensions such as feeding-up, feeding-forward, and process level. However, student dynamics are

complex; (Nazaretsky et al., 2024) highlights a preference for human-generated feedback when students know its source. We will discuss solutions to overcome these challenges such as reinforcement learning (Scarlatos et al., 2024) and LLM-based student simulation models (Phung et al., 2024).

Another important aspect of feedback is its emotional and motivational impact on students. We will discuss the importance of affective feedback (Li et al., 2024a; Baral et al., 2023). We will also explore how LLMs can be used to provide not just cognitive but also emotional support, offering praise (Thomas et al., 2023) and addressing negative self-talk (Thomas et al., 2024). Additionally, we will touch on ongoing efforts to integrate AI-driven emotional assessment in educational settings (Vistorte et al., 2024) to create empathetic learning environments.

Finally, we'll shift our focus to **automatic assessment**. We will review their performance in Automated Short/Long Answer Grading (Kortemeyer, 2023a; Sonkar et al., 2024b) and Automated Essay Grading (AEG) (Mizumoto and Eguchi, 2023), referencing open-source benchmarks (Ruseti et al., 2024; Dzikovska et al., 2013; Blanchard et al., 2013) for these tasks. Next we will summarize some findings on the real-world deployment of LLMs for grading, which show promise despite certain limitations. We will start with studies on math grading (Morris et al., 2024; Gandolfi, 2024) including those which involve handwritten recognition (Liu et al., 2024a). We will also expand the analysis to other subjects like physics (Kortemeyer, 2023b), computer science (Nilsson and Tuvsedt, 2023), and biology (Mackey et al., 2023) to highlight their capabilities and limitation across domains. We will also explore hybrid grading strategies that incorporate human oversight to enhance reliability (Kaya and Cicekli, 2024).

3.3 Educational Content Generation

LLM-generated content serves teachers (e.g., for curating lessons and exercises) and students (e.g., for writing essays and problem-solving). We will examine studies that use controllable generation to adapt LLMs to diverse learners based on difficulty, grade level, and readability score (Rooein et al., 2023; Kew et al., 2023). We will also discuss LLMs in controlled content generation, focusing on readability scores (Imperial and Tayyar Madabushi, 2023) and novel prompting techniques for difficulty assessment (Rooein et al., 2024).

We will also explore strategies to control and align generated questions with students' abilities, expert requirements, and question taxonomies like Bloom's (Elkins et al., 2024; Hwang et al., 2023). We will mention studies on improving adaptability in question generation (Scaria et al., 2024; Wang et al., 2022) and cover methods like PFQS (Li and Zhang, 2024) for improved control by generating answer outlines before question generation. Evaluation of generated educational questions typically involves expert assessments (Scaria et al., 2024; Biancini et al., 2024), while tools like SQUET (Moore et al., 2024) offer automated quality evaluation. However, challenges remain, as studies show GPT models underperforming in evaluating the pedagogical quality of generated questions (Bulathwela et al., 2023).

Finally, we will also discuss multimodal and multilingual LLMs in education – research has demonstrated the effectiveness of multimodal learning in enhancing educational outcomes, e.g., in science (Bewersdorff et al., 2024). These findings are supported by learning theories emphasizing the cognitive benefits of integrating multiple modes of information, such as combining multimodal representations like text and images (Mayer, 2024).

3.4 Adaptivity and Personalization

In this section, we will discuss personalized learning's potential to address diverse student needs, based on educational theories emphasizing tailored learning experiences. We discuss knowledge space theory (Doignon and Falmagne, 1985), Vygotsky's Zone of Proximal Development (Vygotsky, 1978), and Ebbinghaus's memory model (Ebbinghaus, 1913), which have influenced applications like Duolingo's spaced repetition (Settles and Meeder, 2016) and ETS's assessments (Carlson and von Davier, 2017). We then introduce Knowledge Tracing (KT) techniques, from basic Rasch models (Rasch, 1960) and Item Response Theory (IRT) (Lord, 1980) to advanced Bayesian Knowledge Tracing (Corbett and Anderson, 1994) and Deep Knowledge Tracing (Piech et al., 2015).

Traditionally, KT models have focused on question IDs rather than textual content due to dataset limitations. However, the attention mechanism is well-suited for sequence modeling tasks like knowledge tracing. We will cover models such as MC-QStudentBert (Parsa Neshaei et al., 2024), AKT (Ghosh et al., 2020), SAKT (Pandey and Karypis, 2019), Dtransformer (Yin et al., 2023), and SAINT

(Choi et al., 2020), which leverage attention mechanisms to capture complex relationships between knowledge components and student interactions. The emergence of datasets with auxiliary information, like XES3G5M (Liu et al., 2024b), has facilitated the application of pre-trained LLMs in KT, as explored in works like (Lee et al., 2024).

LLMs have also expanded the scope of KT by enabling adaptive exercise generation (Cui and Sachan, 2023; Srivastava and Goodman, 2021) and domain-specific modifications to transformer architecture, e.g. SparseKT (Huang et al., 2023) which models student behaviors like forgetting (Im et al., 2023). LLMs have also been used in student simulation models like OKT (Liu et al., 2022), which predicts actual student textual responses. Despite these advances, challenges remain, such as LLMs' limited context windows which hinder capturing long-range learning trajectories (Li et al., 2024b).

4 Vision and Path Forward

AI in education offers significant opportunities but requires careful technical, ethical, regulatory, and pedagogical consideration. Requirements include balancing technology with human agency, inclusion, and diversity (Miao and Cukurova, 2024), addressing privacy (Baraniuk, 2024; Leitner et al., 2019; O'Hara and Straus, 2022) and transparency (Holmes et al., 2022), promoting AI literacy (Su et al., 2023; Su and Yang, 2023), but also developing LLMs that meet pedagogical goals. We aim to build a common ground between various stakeholders, namely policymakers, educators, developers, and researchers, which can form a basis for human-centered AI development in education.

5 Diversity & Inclusion considerations

Our tutorial aims to bring together NLP, LS and AIED researchers as well as practitioners. The tutorial is designed to be understandable to an audience with a range of backgrounds. Our group of presenters is made up of diverse backgrounds, seniority-levels, genders, and affiliations.

6 About the Speakers

Sankalan Pal Chowdhury is a second year PhD student in the ETH-EPFL Joint Doctoral Program for Learning Science, advised by Mrinmaya Sachan and Tanja Käser. His research focuses on improving tutoring abilities of LLMs. His work has been published in EMNLP, TACL and L@S.

Nico Daheim is a third year ELLIS PhD student advised by Iryna Gurevych and Mrinmaya Sachan. He works on making LLMs equitable dialog tutors that provide students with personalized opportunities to learn. His works have been published at EMNLP, NAACL, EACL, ICLR and ICML.

Ekaterina Kochmar is an Assistant Professor at the NLP Department at MBZUAI, where she conducts research at the intersection of AI, NLP, and ITSs. She is the current President of SIGEDU and has been involved in organizing BEA since 2013.

Jakub Macina is a fourth year PhD at ETH advised by Mrinmaya Sachan and Manu Kapur. His research focuses on understanding and improving generative models' reasoning and pedagogical capabilities. His work has been published in venues such as ACL, EMNLP, and RecSys.

Donya Rooein is a Postdoc at Bocconi University; her work revolves around leveraging NLP for Education. She explores the synergy between machine learning, linguistics, and practitioner insights to enhance education systems. Her work has been published in different ML, NLP, and AIED venues, including NAACL, WWW, and EdMedia.

Mrinmaya Sachan is an Assistant Professor at ETH Zurich, focusing on NLP and its interface with Education. His group has published relevant research on the challenges of Pedagogy and LLMs, Educational Chatbots and Tutors, Student Modeling and Assessment across various NLP and Education-focused venues.

Shashank Sonkar is a final-year PhD student at Rice University advised by Richard G. Baraniuk. His work focuses on pedagogical alignment of LLMs, learner modeling, and intelligent assessment. His work has been published in EMNLP, COLING, AIED, EDM, and LAK.

7 Type of Tutorial & Target Audience

The tutorial will be **introductory** and present research from the fields of NLP, AIED and learning sciences. We will discuss seminal as well as recent papers to build a common ground for participants. Therefore, we welcome participants from any of these backgrounds. While it is helpful to have knowledge of either NLP / ML or learning sciences, it is not a requirement. The tutorial will be self-contained and welcomes an estimated 50-100 attendees based on recent BEA iterations. We will recommend the attendees a small reading list comprising of papers listed in the appendix.

Abstract

This study examines the lexical and syntactic interventions of human and LLM proofreading aimed at improving overall intelligibility in identical second language writings, and evaluates the consistency of outcomes across three LLMs (ChatGPT-4o, Llama3.1-8b, Deepseek-r1-8b). Findings show that both human and LLM proofreading enhance bigram lexical features, which may contribute to better coherence and contextual connectedness between adjacent words. However, LLM proofreading exhibits a more generative approach, extensively reworking vocabulary and sentence structures, such as employing more diverse and sophisticated vocabulary and incorporating a greater number of adjective modifiers in noun phrases. The proofreading outcomes are highly consistent in major lexical and syntactic features across the three models.

1 Introduction

The use of generative large language models (LLMs) in second language (L2) writing has gained popularity for providing real-time feedback on vocabulary, grammar, and style (e.g., Han et al., 2024; Meyer et al., 2024). These models offer immediate corrective suggestions, enhancing the precision and quality of L2 writing—a role once largely filled by human editors with expertise. As LLMs increasingly replace or supplement human intervention, questions arise about their impact on L2 writings.

While previous studies have concentrated on general error correction through LLM proofreading (e.g., Heintz et al., 2022; Su et al., 2023; Wu et al., 2023; Katinskaia and Yangarber, 2024), recent studies have shown that LLMs do not consistently outperform state-of-the-art supervised grammatical error correction models on minimal-edit benchmarks, often producing more fluency-oriented rewrites instead (Davis et al., 2024). This tendency stems in

part from the fact that LLMs, by default, generate transformative fluency corrections rather than minimal edits when processing ungrammatical text (e.g., Coyne et al., 2023; Fang et al., 2023; Loem et al., 2023). However, little research has examined how this generative rewriting behavior affects broader lexical and syntactic characteristics of L2 writing compared to human proofreading, especially when the proofreading goal extends beyond grammatical accuracy to overall intelligibility. Moreover, it remains unclear whether different LLMs yield consistent proofreading outcomes. This study addresses these gaps by posing three guiding questions: (1) What are the similarities and differences in lexical features between human proofreading and LLM proofreading of L2 writings? (2) What are the similarities and differences in syntactic features between human proofreading and LLM proofreading of L2 writings? (3) Do three different LLMs provide consistent proofreading outcomes in terms of lexical and syntactic features in L2 writing?

Our findings show that while both human and LLM proofreading enhance lexical and syntactic features, LLMs are more likely to make more extensive lexical and syntactic edits. By quantifying these changes through a range of lexical and syntactic indices, we reveal that LLMs favor more generative rewrites, which may improve fluency but risk altering nuance or inflating perceived proficiency.

2 Background

2.1 Proofreading in L2 writing

Proofreading is a complex issue in writing research, particularly for L2 writers, as it involves varying scopes of interventions. Traditional definitions of proofreading often restrict it to surface-level error correction that focuses on resolving orthographic and grammatical errors without altering content (Carduner, 2007; Hyatt et al., 2017). However, research shows that professional human proofreaders

*Contributed equally to the study.

occasionally restructure content to improve the logical flow of ideas and make the writing easier to understand (Salter-Dvorak, 2019). Noting these varying practices in proofreading, Harwood et al. (2009, p. 167) provided a quite general definition of proofreading as “[any] third-party interventions (entailing written alteration) on assessed work in progress.”

Previous studies have shown that human proofreading displays variability not just in scope, but also in quality. Harwood (2018) found that 14 proofreaders made between 113 and 472 changes to the same L2 learner essay, with some interventions improving clarity and others introducing new errors, leading to inconsistent quality. Similarly, Shafto (2015) argued that proofreading is a highly attention-dependent task, meaning that symptoms such as tiredness can heavily impact human proofreaders’ ability to detect and correct ungrammatical and unnatural expressions.

The debate surrounding the adequacy of L2 proofreading is also characterized by varying perspectives from stakeholders (i.e., students, faculty, researchers). While L2 students often seek proofreading services to improve their grades or enhance their writing skills, some faculty view such assistance as a form of academic dishonesty (Salter-Dvorak, 2019; Turner, 2011). Despite these divergent opinions, there is a general consensus that proofreaders can significantly enhance language accuracy and clarity in L2 writing, provided that the original authorial voice is maintained (Turner, 2024; Warschauer et al., 2023; Zou and Huang, 2024).

2.2 LLMs in L2 writing and proofreading

While automated written corrective feedback has been present in L2 classrooms for over a decade (cf. Wilson et al., 2014), recent research is now exploring how LLM assistants can be incorporated into holistic writing workflows (Zhao, 2024). Researchers examine the integration of the LLM in prewriting (Xiao, 2024) and postwriting stages (Osawa, 2024), as well as its role in fostering metacognitive skills through iterative revisions that include editing and proofreading (Su et al., 2023; Warschauer et al., 2023; Zou and Huang, 2024).

Among these LLM integrations, several studies have highlighted the capabilities of LLM proofreading (or more broadly, editing). For instance, Su et al. (2023) found that ChatGPT effectively assessed grammar, clarified meaning, and sug-

gested lexical and syntactic refinements. Similarly, Yan and Zhang (2024) observed that ChatGPT identified and corrected a range of linguistic errors—including lexical (e.g., word choice, idioms), grammatical (e.g., verb tense, articles), structural (e.g., run-on or fragmented sentences), mechanical (e.g., spelling, punctuation), and stylistic (e.g., formality) aspects.

Few studies have compared LLM proofreading directly to human revisions. For instance, Heintz et al. (2022) compared outputs edited by LLMs with those revised by human editors using sentences written by non-native English speakers. They found that while Wordvice AI¹ achieved near-human accuracy (77%) in correcting grammar and spelling errors, it lagged behind human editors in areas like vocabulary refinement and fluency adjustments. Similarly, Jiang et al. (2023) analyzed 2,197 T-units² and 1,410 sentences from weekly writing samples of 41 Chinese students in an online high school language program at a U.S. university. They found that ChatGPT-4 achieved high precision (88%) in correcting errors at the T-unit level (in comparison to human judgments), but sometimes overcorrected valid sentences or misinterpreted context-dependent issues, such as ambiguous word order and culturally embedded idioms.

2.3 Summary of findings and research gaps

To briefly summarize, previous research has demonstrated that proofreading in L2 writing is highly variable in both scope and quality, with interventions ranging from surface-level corrections to content restructuring. Recently, LLMs have been shown to offer performance comparable to, or even surpassing, that of human editors in L2 writing proofreading, although they exhibit limitations in context-sensitive judgment and cultural awareness.

Despite these insights, still little is known about the fine-grained linguistic interventions that could be made by LLMs compared to human proofreaders. Additionally, existing research has focused primarily on grammatical error detection and correction, overlooking broader language use. For example, although LLMs may facilitate vocabulary expansion, it remains unclear how their suggestions differ from those of human proofreaders, and detailed syntactic changes remain underexplored.

¹<https://wordvice.ai/proofreading>

²A T-unit is often defined as the minimal grammatical unit, comprising a single independent clause plus any subordinate clauses or dependent phrases attached to it (Lu, 2010).

Moreover, most studies have examined only one type of LLM, leaving open the question of whether these linguistic changes are specific to one model or generalizable across other LLMs.

3 Methods

3.1 Dataset

This study utilizes the ICNALE Edited Essays dataset, one of the publicly available corpora within the International Corpus Network of Asian Learners of English (ICNALE) project (Ishikawa, 2018, 2021). The dataset comprises 656 essays written by 328 L2 learners and their edited versions produced by professional native English-speaking proofreaders.

The L2 participants were college students learning English in ten regional contexts: Japan (JPN), Korea (KOR), China (CHN), Taiwan (TWN), Indonesia (IDN), Thailand (THA), Hong Kong (HKG), the Philippines (PHL), Pakistan (PAK), and Singapore (SIN). Each participant wrote two argumentative essays in response to the prompts: (1) “It is important for college students to have a part-time job” and (2) “Smoking should be completely banned at all restaurants”.

3.1.1 Rationale for dataset selection and representativeness

The ICNALE dataset was chosen for three main reasons. First, it provides paired original and professionally proofread versions, allowing for direct comparison with LLM-generated outputs. Second, it includes explicit L2 proficiency labels, facilitating stratified analyses across proficiency levels. Last, it offers balanced regional coverage across ten Asian countries or regions (see Table 1). However, we acknowledge that broad generalizations to other genres or demographic groups (e.g., narrative writing, younger learners) must be made with caution.

3.1.2 Proficiency band

All participants were classified into four L2 proficiency bands (linked to the Common European Framework of Reference for Languages) based on their recent scores in standardized English tests (e.g., TOEFL, TOEIC) or their performance in a standard receptive vocabulary test³ (Nation and

³The vocabulary test consists of 50 multiple-choice items designed to measure vocabulary knowledge within the 1,000–5,000 word range. A typical item (from the 4,000-word level) presents a short sentence containing a target word and asks

Beglar, 2007). Table 1 shows the proficiency distribution of each regional learner group.

Region	A2_0	B1_1	B1_2	B2_0	Total
JPN	10	10	10	10	40
KOR	10	10	10	10	40
CHN	10	10	10	10	40
TWN	10	10	10	10	40
IDN	10	10	10	3	33
THA	10	10	10	2	32
HKG	–	10	10	10	30
PHL	–	10	10	10	30
PAK	–	10	10	3	23
SIN	–	–	10	10	20
Total	60	90	100	78	328

Table 1: Distribution of participants by region and proficiency

3.1.3 Proofreading process and proofreader profiles

The ICNALE project recruited five experienced proofreaders with strong academic backgrounds and extensive experience in editing scholarly work. Their profiles are summarized in Table 2.

ID	Age	Sex	Degree	Experience (years)	L1 English
A	28	Female	BA	3	Canadian
B	32	Female	MS	5	Australian
C	27	Female	BS	3	American
D	38	Female	BS	10	British
E	31	Female	PhD	2	Australian

Table 2: Profiles of proofreaders in the ICNALE project

As documented in the ICNALE project, the professional proofreaders were tasked with editing errors and inappropriate wording to ensure that each essay became fully intelligible (Ishikawa, 2021, p. 496). No standardized rubric or adjudication mechanism was imposed at the original corpus compilation stage. All revisions were performed in MS Word using the Track Changes function, which allowed every edit, addition, or deletion to be recorded.

A calibration study in which all five proofreaders revised the same eight essays revealed substantial variability in editing behavior (cf. Ishikawa, 2018, p. 122). The number of edited word tokens ranged from 40.00 to 59.63—a difference of 19.63 tokens, or 40.97% of the average. Ishikawa (2021) attributed this variation to the inherent subjectivity of human editing, shaped by individual judgments of intelligibility.

test-takers to select the most appropriate definition.

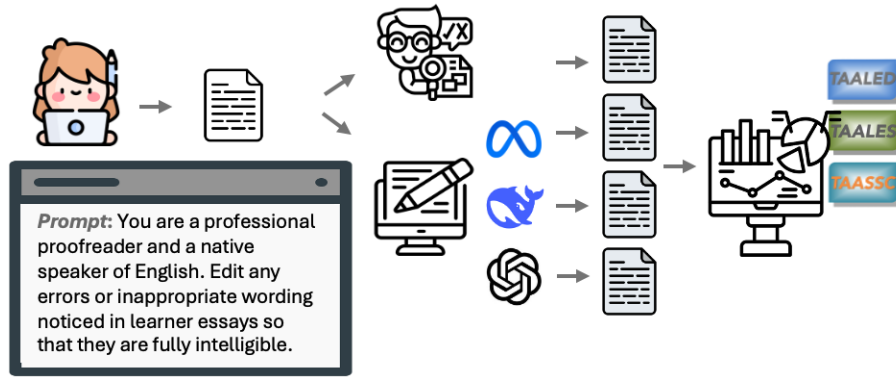

Figure 1: Overview of the experiment

3.2 LLM selection and prompt design

Figure 1 outlines the experiment. First, to compare the human proofreading in the ICNALE project with LLM proofreading, we selected three text-generating LLMs: GPT-4o (used in ChatGPT, accessed via OpenAI’s API; Achiam et al., 2023, hence we called them *Chatgpt-4o*), *Llama3.1-8b* (Touvron et al., 2023), and *Deepseek-r1-8b* (Guo et al., 2025). ChatGPT-4o was chosen due to its widespread accessibility, although its underlying parameter count and architecture remain proprietary. In contrast, both *Llama3.1-8b* and *Deepseek-r1-8b* are open models with 8 billion parameters that are lightweight enough for local installations, with *Deepseek-r1-8b* being a distilled version of *Llama3.1-8b*.

Each model was tasked with reading the original L2 writings and generating a proofread version based solely on a standardized prompt, with no access to additional learner information. The exact prompt used was as follows: “You are a professional proofreader and a native speaker of English. Edit any errors or inappropriate wording noticed in learner essays so that they are fully intelligible. Return only the final edited version of the essay. Do not include any explanations, comments, reasoning, or additional thoughts in your response.” This prompt was designed to align with the instructions given to ICNALE proofreaders—“They were asked to edit any error or inappropriate wording noticed in learner essays so that they could be fully intelligible. They were also required not to ‘rewrite’ the original texts, that is, not to add new content or to alter organization” (Ishikawa, 2021, p. 496)—ensuring consistency with the human proofreading protocol for fair comparison.

3.3 Lexical and syntactic analyses

The proofread-and-generated texts, along with the learner and edited texts in the ICNALE dataset, were processed to extract lexical and syntactic features using the source codes of publicly available NLP tools: TAALED (cf. Kyle et al., 2024), TAALES (cf. Kyle et al., 2018) and TAASSC (cf. Kyle and Crossley, 2018). We measured lexical and syntactic aspects of the learner and proofread essays based on the concept of linguistic complexity, which provides a descriptive-analytic framework for L2 production (Bulté and Housen, 2012; Bulté et al., 2024).

3.3.1 Lexical features

Lexical features were evaluated in terms of two aspects: diversity and sophistication. Lexical diversity indices reflect vocabulary variation and repetition, with higher scores indicating a broader vocabulary range and fewer repetitions. In this study, we employ common measures such as the number of unique words and the moving-average type-token ratio—the latter mitigating the impact of text length on traditional lexical diversity measures (Kyle et al., 2024).

Lexical sophistication indices, on the other hand, focus on measuring the use of advanced words (Laufer and Nation, 1995; Meara and Bell, 2001). They are typically assessed based on relative word frequency, semantic concreteness, and domain or register distinctiveness, with less frequent, less concrete, and more domain-specific words generally considered more sophisticated (Kyle et al., 2018). We also incorporate the concept of ngram sophistication by analyzing associations and dependency relations within bigrams (Kyle and Eguchi, 2021).

3.3.2 Syntactic features

Syntactic features can be examined from multiple perspectives. Traditional approaches, such as measuring the average length of T-units, focus on the overall length of syntactic structures and operate under the assumption that longer units generally indicate greater complexity (Lu, 2010, 2011).

In contrast, fine-grained syntactic complexity indices (Kyle and Crossley, 2018) provide a more nuanced analysis by capturing specific structural characteristics rather than relying on surface-level measures like sentence length. These indices are often categorized into clausal-level (e.g., nominal subjects per clause), phrasal-level (e.g., dependents per nominal, including adjectives and prepositions), and morphosyntactic-level features (e.g., use of past tense).

To the best of our knowledge, there is no consensus on which fine-grained indices reliably capture syntactic complexity as perceived by human judges. Nevertheless, L2 writing studies suggest that higher-proficiency learners (identified by human ratings) tend to use more elaborated noun phrases (e.g., Biber et al., 2011).

3.4 Statistical methods

3.4.1 Evaluating linguistic features across groups

Prior to statistical analyses, we confirmed that the five groups of texts (i.e., original [ORIG], human-proofread [EDIT], and the three LLM-proofread versions) were largely comparable in length.⁴ This comparability, with the exception of Deepseek-r1-8b, indicates that subsequent improvements in lexical and syntactic domains are not simply due to different text lengths.

We calculated a range of 49 lexical and 143 syntactic indices from every text in the five groups and identified features showing significant between-group variance in two stages. First, we conducted visual inspection of box plots to exclude the indices with a great number of outliers, little individual variance, and/or unnoticeable mean differences. Second, we applied a linear mixed-effects model to each index, using Group (e.g., ORIG, EDIT, ChatGPT-4o) as a categorical fixed effect with ORIG as the baseline. Proficiency was included as a fixed effect that interacted with Group,

⁴The differences in the number of word tokens relative to the original text were: EDIT: -1.02, ChatGPT-4o: +6.13, Llama3.1-8b: -3.38, and Deepseek-r1-8b: -15.11***.

and Participants were included as a random effect. We retained only those models that converged successfully to ensure reliable estimates. From these convergent models, we focused primarily on the main effect of the proofreading mode, while also examining whether any observed mode effects were moderated by Proficiency. These procedures yielded six lexical and nine syntactic indices. Detailed descriptions of each index are provided in Appendix A.

For each of these indices, we reported the results of four pairwise comparisons, between ORIG and human or LLM proofreading, from the linear mixed-effects models. To avoid a Type I error due to multiple comparisons, we applied a Bonferroni adjustment to the alpha level, reducing it from .05 to .0125.

3.4.2 Evaluating consistency across LLMs

The linear mixed-effects analyses informed us that the cross-model evaluation should exclude five more syntactic features, which showed multicollinearity or overlapping metrics. For the rest ten features,⁵ we calculated the standardized z-scores so that each metric contributed equally to a composite measure of overall lexical and syntactic complexity.

Next, we restructured the data so that each row represented an essay and each column contained the composite score derived from the output of a different model, treating these composite scores as “ratings” of the same essay. We then calculated the Pearson correlation coefficients between the ratings for every pair of models’ proofread output and computed Cronbach’s alpha (Cronbach, 1951) across these scores to assess their overall consistency. All datasets and code used for this analysis are available in the supplementary repository: https://osf.io/mhtpg/?view_only=13ce0959a80e4d498b6761aba197bc83.

4 Results

4.1 Lexical features

Table 3 summarizes the analysis of the selected lexical sophistication and diversity features. First, all proofreading modes, including human editing, led to significantly higher bigram mutual information (raw_bg_MI) scores. This finding suggests that

⁵Lexical features: *matr*, *b_concreteness*, *mcd*, *usf*, *cw_lemma_freq_log*, and *raw_bg_MI*; Syntactic features: *nonfinite_prop*, *amod_dep*, *nominalization*, and *be_mv*.

Index	EDIT	ChatGPT-4o	Llama3.1-8b	Deepseek-r1-8b
raw_bg_MI	+0.35 / 1.80***	+0.65 / 3.30***	+0.62 / 3.17***	+0.60 / 3.03***
usf	-1.37 / 0.15	-9.21 / 0.99***	-8.48 / 0.91***	-12.09 / 1.30***
b_concreteness	+0.00 / 0.02	-0.15 / 0.83***	-0.12 / 0.67***	-0.21 / 1.11***
cw_lemma_freq_log	-0.02 / 0.03	-0.30 / 0.54***	-0.26 / 0.47***	-0.37 / 0.67***
mattr	+0.01 / 0.18	+0.07 / 2.20***	+0.08 / 2.63***	+0.10 / 3.41***
ntypes	+0.63 / 0.05	+19.98 / 1.68***	+16.68 / 1.40***	+16.80 / 1.41***

Table 3: Lexical features compared; For each index, two numbers are shown: the value on the *left* indicates the unstandardized main effect coefficient, while the value on the *right* (following the backslash) represents the standardized coefficient, calculated as the ratio of the coefficient to the residual standard deviation of the dependent variable; Significance vs. ORIG is marked ($*p < 0.0125$, $**p < 0.0025$, $***p < 0.00025$); negative values are red and positive values are blue; interaction effects are omitted.

Figure 2: raw_bg_MI compared across ORIG, EDIT, and LLM-proofread texts by proficiency

Figure 3: mattr compared across ORIG, EDIT, and LLM-proofread texts by proficiency

both human and LLM proofreading improved the lexical sophistication in terms of the coherence or contextual connectedness of adjacent words. However, LLM proofreading substantially increased raw_bg_MI to the extent that differences between lower and higher proficiency levels became less distinguishable (Figure 2).

In contrast, only the LLM-proofread texts showed significant changes in additional lexical sophistication measures, including a shift toward more contextually distinctive words (usf), less concrete words (b_concreteness), and lower-frequency content words (cw_lemma_freq_log). Human proofreading, by comparison, did not produce significant differences in these measures.

As for lexical diversity, significant improvements were observed only in the LLM-proofread texts, with increases in metrics such as mattr (Figure 3) and ntypes, indicating a broader range of vocabulary use.

4.2 Syntactic features

Table 4 summarizes the analysis of the selected syntactic features. Regarding the mean length of T-units (mltu), neither human nor LLM proofreading produced a consistent pattern: human proofreading (EDIT) and ChatGPT-4o tended to reduce T-unit length, while Llama3.1-8b and Deepseek-r1-8b tended to increase it, suggesting no uniform effect on the length of minimal grammatical units.

At the clause level, all LLM-proofread texts showed a significant increase in the total number of clauses (all_clauses) compared to the original learner essays, with Deepseek-r1-8b exhibiting the largest effect. Moreover, LLM-proofread texts contained a higher proportion of nonfinite clauses (nonfinite_prop), whereas human editing resulted in a slight reduction in this index.

At the phrase level, LLM proofreading increased the number of noun phrases (np), along with a rise in noun phrase dependencies (np_deps). This

Index	EDIT	ChatGPT-4o	Llama3.1-8b	Deepseek-r1-8b
mltu	-115.49 / 0.31	-105.73 / 0.28	+44.26 / 0.12	+118.42 / 0.31
all_clauses	+15.55 / 0.10	+133.76 / 0.84 ^{***}	+99.12 / 0.62 ^{***}	+179.00 / 1.12 ^{***}
nonfinite_prop	-1.33 / 0.29	+2.01 / 0.44 ^{***}	+2.63 / 0.57 ^{***}	+5.52 / 1.20 ^{***}
np	-21.30 / 0.08	+91.96 / 0.36 ^{**}	+41.27 / 0.16	+194.91 / 0.76 ^{***}
np_deps	-35.03 / 0.08	+79.21 / 0.17	+91.91 / 0.20	+217.81 / 0.47 ^{**}
amod_dep	+17.54 / 0.01	+137.65 / 0.75 ^{***}	+127.44 / 0.70 ^{***}	+204.54 / 1.12 ^{***}
nominalization	+58.12 / 0.40 ^{**}	+152.04 / 1.05 ^{***}	+102.85 / 0.71 ^{***}	+213.63 / 1.47 ^{***}
be_mv	+10.37 / 0.12	-56.53 / 0.63 ^{***}	-41.60 / 0.47 ^{**}	-84.02 / 0.94 ^{***}
past_tense	-15.80 / 0.29	-17.38 / 0.32	-17.77 / 0.32	-19.31 / 0.35 ^{**}

Table 4: Syntactic features compared; Interpretation of the table follows the same conventions described in Table 3

Figure 4: amod_dep compared across ORIG, EDIT, and LLM-proofread texts by proficiency

suggests that LLM proofreading not only added more noun phrases but also enriched their internal structure. In particular, the marked increase in adjective modifier dependencies (amod_dep; e.g., “various jobs”) suggests that LLM outputs favor more descriptive noun phrases (Figure 4).

At the morphological-syntactic level, both human and LLM proofreading showed significant increases in nominalization, but the increases were more pronounced in the LLM outputs (Figure 5). In contrast, the non-auxiliary use of the main verb “be” declined significantly under LLM proofreading, while human proofreading showed only a slight increase (be_mv). Additionally, all proofreading modes consistently reduced the use of past tense (past_tense).

4.3 Cross-model consistency

Based on the features that demonstrated meaningful group differences—and after removing indices with multicollinearity and conceptual overlap—we

Figure 5: nominalization compared across ORIG, EDIT, and LLM-proofread texts by proficiency

Pair	Lexical	Syntax
ChatGPT-4o – Llama3.1-8b	0.70	0.62
ChatGPT-4o – Deepseek-r1-8b	0.60	0.53
Llama3.1-8b – Deepseek-r1-8b	0.56	0.65

Table 5: Pairwise Pearson correlations for lexical and syntactic features across LLMs

selected ten lexical or syntactic features. The composite lexical and syntactic scores exhibit strong internal consistency across the LLMs, with Cronbach’s alpha values of 0.83 and 0.81, respectively.

Table 5 presents the pairwise Pearson correlations among the three LLM proofreading models. For lexical features, ChatGPT-4o and Llama3.1-8b correlate at 0.70, while Deepseek-r1-8b correlates at 0.60 with ChatGPT-4o and 0.56 with Llama3.1-8b. For syntactic features, the corresponding correlations are 0.62, 0.53, and 0.65. These findings suggest that, despite minor variations, particularly with Deepseek-r1-8b, the LLMs tended to modify

vocabulary and syntactic structures in a relatively consistent manner when proofreading L2 writings, as measured by our selected indices.

5 Discussions

We compared the lexical and syntactic features of original L2 writings with those of texts that were proofread by human and LLMs. We also evaluated the consistency of LLM proofreading across different models.

Lexical features We found significant increases in bigram association strength, a ngram-level index of lexical sophistication, across all the proofreading modes. However, only LLM-proofread texts demonstrated notable changes in both word-level sophistication and diversity. Together, these results suggest that while both human and LLM proofreading improved the natural sequence of vocabulary—thus, enhancing the intelligibility of L2 writings—LLM proofreading provided an additional boost in lexical diversity and sophistication. In fact, this boost sometimes reduced or even eliminated typical differences between proficiency levels. Given that lexical sophistication and diversity are important constructs when evaluating L2 writing proficiency (Kyle et al., 2018, 2021), texts produced using LLM proofreading may obscure learners’ true writing abilities and artificially inflate their advanced language skills, ultimately undermining accurate assessment and long-term development.

We also observed that LLMs often replaced repeated words with alternative expressions—even when such changes are unwarranted—calling for caution. For example, “I often can smell” became “I often catch a whiff”, altering the intended meaning. Consequently, L2 writers using LLM proofreading should be mindful of unintended shifts in meaning or style and double-check suggested edits.

Syntactic features Compared with the marked lexical shifts, syntactic edits were subtler but still distinct pattern of edits. First, both human and LLM proofreading consistently reduced past-tense verbs, favoring present or neutral tense—a pattern often associated with factual, persuasive prose (Burrough-Boenisch, 2003; Fang and Maglio, 2024).

However, LLMs made more extensive structural modifications, including a higher proportion of non-finite clauses (e.g., “Because the company that need worker will ask the job experiences” → “Compa-

nies looking to hire often require prior work experience”) and a marked increase in adjective modifier dependencies (e.g., “become the social problem” → “become a significant social problem”). They also introduced more nominalizations (e.g., “we should...” → “(our) primary responsibility”) and reduced the non-auxiliary use of the main verb “be” (e.g., “is not the first” → “should not take precedence”).

Meanwhile, although the increase in overall noun complexity following LLM proofreading was not statistically robust (dp_deps), the gains were primarily driven by the insertion of adjective modifiers rather than by broader grammatical restructuring. For example, the structural complexity of noun phrases involving prepositional phrases (e.g., “disadvantages of works”) or coordination (e.g., “advantages and disadvantages”) remained largely unchanged.

Cross-model consistency We found that the three LLMs exhibit generally consistent proofreading performance in terms of the major lexical and syntactic features. We speculate that this consistency arises from fundamental similarities in how they are trained and optimized for language generation tasks. Consequently, while different LLMs may produce distinct outputs, their overall patterns of lexical enhancement and syntactic restructuring remain comparable.

6 Conclusions

Our study shows that while both human and LLM proofreading improve lexical and syntactic features in L2 writing, LLMs typically implement more generative edits, reworking vocabulary and sentence structures to a greater extent. Although these changes may enhance clarity and style, they risk overshadowing the original meaning or authorial voice and potentially inflate apparent language proficiency.

This finding has important implications for L2 writing practice. Acknowledging the great similarities in proofreading outcomes across different LLMs, more attention should be given to the question of “how to use LLM-proofreading effectively” rather than “what LLM to use for proofreading.” This key question can be addressed in reference to the observations that we have reported above, such as non-mandatory lexical substitution and excessive syntactic restructuring. Being aware of these tendencies in LLM-proofreading, L2 writers can

better maintain control over their writing process while strategically making use of LLMs for linguistic improvements.

Limitations

This study has several limitations. First, the same proofreading directive may be interpreted differently by human and LLM proofreaders, potentially affecting the nature and extent of the modifications.

Second, the analysis lacks qualitative comparisons between original and edited texts, which could reveal subtler aspects of the revisions. As one reviewer noted, LLM-proofread essays may appear more sophisticated but sometimes sacrifice coherence or introduce unintended nuances, making them harder to read. A more systematic qualitative analysis (ideally supported by human perception data comparing human- and LLM-proofread texts) would clarify whether LLM edits genuinely improve writing quality or simply enhance surface-level features.

Third, the task effects and proficiency-level constraints limit generalizability: our analysis focused solely on argumentative writing by Asian university-level students who already possess a certain level of L2 English proficiency. Consequently, these findings may not extend to other types of writing or to L2 groups with different backgrounds.

A Descriptions of the selected indices

Index	Description
Lexical indices	
n _{types}	Counts the number of unique words, taking into account their part-of-speech.
m _{attr}	Computes the type-token ratio over a 50-word sliding window.
b _{concreteness}	Uses psycholinguistic norms to assess word concreteness across categories based on large-scale ratings, indicating how tangible or abstract a word is perceived to be (Brysbaert et al., 2014).
usf	Measures the number of distinct stimuli that elicit a target word in a word association experiment; lower USF scores suggest the use of words that are more contextually distinct (Nelson et al., 1998).
cw _{lemma_freq_log}	Represents the logarithm of lemma frequencies for content words, computed with reference to an English web corpus (Schäfer and Bildhauer, 2012).
raw _{bg_MI}	Calculates raw bigram mutual Information to quantify the strength of association between consecutive words, with higher values indicating a stronger collocational relationship; this is measured against an English web corpus.
Syntactic indices	
m _{ltu}	Measures the average length of T-units, where a T-unit is defined as a main clause plus any subordinate clause(s) attached to it.
all _{clauses}	Counts the total number of clauses in the text (normed by 10,000 words).
nonfinite _{prop}	Computes the proportion of nonfinite clauses (e.g., gerunds, infinitives) relative to the total number of clauses.
np	Counts the total number of noun phrases, highlighting the nominal complexity within sentence structures (normed by 10,000 words).
np _{deps}	Counts the number of internal dependencies within noun phrases (e.g., adjectives, prepositions, coordinations) (normed by 10,000 words).
amod _{dep}	Measures the frequency of adjective modifier dependencies (normed by 10,000 words).
nominalization	Counts the frequency of nominalizations (i.e., words that convert verbs or adjectives into noun forms) identified by tokens containing predefined suffixes such as <i>-al</i> , <i>-ness</i> , among others (normed by 10,000 words).
be _{mv}	Measures the frequency of the verb “be” when used as a main verb (excluding its auxiliary function) (normed by 10,000 words).
past _{tense}	Measures the frequency of past tense verbs (normed by 10,000 words).

MateInfoUB: A Real-World Benchmark for Testing LLMs in Competitive, Multilingual, and Multimodal Educational Tasks

Dumitran Adrian Marius, Theodor-Pierre Moroianu and Bucă Mihnea-Vicentiu

University of Bucharest

Faculty of Mathematics and Computer Science

marius.dumitran@unibuc.ro {theodor.moroianu, mihneavicentiu}@gmail.com

Abstract

The rapid advancement of Large Language Models (LLMs) has transformed various domains, particularly computer science (CS) education. These models exhibit remarkable capabilities in code-related tasks and problem-solving, raising questions about their potential and limitations in advanced CS contexts. This study presents a novel bilingual (English–Romanian) multimodal (text and image) dataset of multiple-choice questions derived from a high-level computer science competition. A particularity of our dataset is that the problems are conceived such that some of them are easier solved using reasoning on paper, while for others writing code is more efficient. We systematically evaluate State of The Art LLMs on this dataset, analyzing their performance on theoretical programming tasks. Our findings reveal the strengths and limitations of current LLMs, including the influence of language choice (English vs. Romanian), providing insights into their applicability in CS education and competition settings. We also address critical ethical considerations surrounding educational integrity and the fairness of assessments in the context of LLM usage. These discussions aim to inform future educational practices and policies. To support further research, our dataset will be made publicly available in both English and Romanian. Additionally, we release an educational application tailored for Romanian students, enabling them to self-assess using the dataset in an interactive and practice-oriented environment.

1 Introduction

In recent years, LLMs have demonstrated revolutionary potential in natural language processing and code generation, enabling applications such as automated code writing systems and algorithmic problem-solving (Raihan et al., 2024; Rasheed et al., 2025). For instance, models like GPT-o3 exhibit remarkable proficiency in code generation

and problem-solving (OpenAI et al., 2025), yet their deployment in high-stakes domains remains constrained by efficiency and reliability challenges.

In the educational domain, LLMs exhibit considerable promise for enabling personalized learning and automating feedback; however, their capacity to manage complex, competition-level programming challenges—particularly in bilingual or non-English contexts—remains underexplored, with emerging critiques questioning their reliability in high-stakes scenarios, such as mathematical reasoning. Recent analyses, such as (Petrov et al., 2025; Mirzadeh et al., 2024; Hendrycks et al., 2021) reveal that LLMs frequently produce plausible-sounding but logically flawed solutions, raising concerns about their suitability for rigorous assessments. While benchmarks like HumanEval (Chen et al., 2021; Yu et al., 2024) and MBPP (Austin et al., 2021) evaluate general coding proficiency, they often neglect pedagogical dynamics, such as adaptive scaffolding for learners or ethical alignment with institutional values. Furthermore, studies caution that deploying LLMs in multilingual environments amplifies risks of semantic misinterpretation and cultural misalignment, necessitating rigorous scrutiny of their pedagogical robustness. (Rystrøm et al., 2025; Marchisio et al., 2024)

Our work aims to address this gap by conducting a rigorous evaluation of LLMs using a bilingual dataset, thus shedding light on their strengths, weaknesses, and the nuances of language-specific performance. Our dataset is uniquely comprised of multiple-choice questions that were originally administered as part of a pre-university exam for prospective students. This setting not only simulates a high-stakes assessment environment, but also provides rich insights into the performance of LLMs on tasks that require both theoretical knowledge and practical application. Our approach allows us to identify key strengths and limitations of state-of-the-art LLMs, highlighting scenarios

where additional context either bolsters performance or introduces redundancy and inefficiency. By dissecting performance variations across languages and problem types, we provide a nuanced understanding of how LLMs navigate complex educational assessments, such as those encountered in advanced computer science competitions and early university admissions. Moreover, our study raises important ethical considerations, as the use of automated assessments in educational settings must balance technological innovation with fairness and academic integrity.

Finally, to encourage further exploration and replication, the bilingual dataset¹ developed through this work will be made publicly available, offering a valuable resource for future research in both educational technology and competitive programming evaluation and an educational application² tailored for Romanian students, enabling them to self-assess using the dataset in an interactive and practice-oriented environment.

Main Contributions

The main contributions of our work can be summarized as follows:

- We introduce a novel **multimodal and bilingual dataset** comprising *Romanian* and *English*. The dataset includes **100 multiple-choice questions**, all enriched with extensive solutions in Romanian. This paper focuses specifically on benchmarking LLM performance on the Multiple Choice Question (MCQ) portion, including its multimodal aspects; the programming problems are provided as part of the dataset release for completeness and future research but are not evaluated here. We consider the evaluation of complex coding problems a distinct challenge requiring separate methodologies.
- Our dataset is uniquely designed so that multiple-choice problems can be solved through either mathematical and algorithmic reasoning or by generating executable Python code. Crucially, the benchmark tasks the LLMs with autonomously determining the most suitable approach—producing either direct answers or executable Python code.

- We provide an open-source **educational application** enabling students to interactively attempt and practice all problems included in our dataset, thereby facilitating practical engagement and learning.

Related Work

The evaluation of LLMs for code generation has advanced significantly, supported by benchmarks that measure functional correctness and problem-solving capability. Seminal datasets such as HumanEval (Chen et al., 2021; Yu et al., 2024) and MBPP (Mostly Basic Python Problems) (Austin et al., 2021) have become standard, focusing on generating standalone code from English-language prompts (Paul et al., 2024). While effective for assessing basic coding abilities, these benchmarks often emphasize isolated tasks, neglecting integrated reasoning, debugging, and pedagogical scaffolding (Fujisawa et al., 2024; Zhang et al., 2024). They also overlook ethical alignment (Abdulhai et al., 2024), which is critical in educational deployments.

Recent datasets attempt to address these gaps. APPS (Hendrycks et al., 2021) and CodeContests (Quan et al., 2025) introduce complex algorithmic problems from competitive programming, pushing models toward more advanced problem-solving. However, these datasets are monolingual and insufficiently capture linguistic diversity (Marchisio et al., 2024), despite growing evidence that non-English prompts introduce semantic errors and cultural misalignment (Rystrøm et al., 2025).

In educational contexts, systems for automated feedback (Sarsa et al., 2022) and personalized tutoring (Wu and Hu, 2023; Petrov et al., 2025) rarely engage with high-stakes scenarios such as programming competitions or university admissions. This leads to concerns about fairness (Mouselinos et al., 2023), academic integrity (Huang et al., 2025), and linguistic exclusion (Gao et al., 2024).

Multilingual benchmarks like DS-1000 (Lai et al., 2022) and MultiPL-E (Cassano et al., 2022) broaden the scope but primarily target English programming tasks rather than bilingual educational assessments. Studies reveal that language choice affects problem comprehension (Moumoula et al., 2025), with LLMs showing systematic bias in non-English settings and often generating plausible yet logically flawed responses (Petrov et al., 2025; Mirzadeh et al., 2024). As a result, emerging frameworks call for pairing benchmarks with fairness audits (Du et al., 2025) and cultural robustness

¹<https://huggingface.co/datasets/EHollower/MateInfoUB>

²<https://mateinfo-ub.github.io/>

evaluations (Rystrøm et al., 2025).

Several recent benchmarks have expanded beyond single-turn code generation to include interaction and feedback mechanisms. MINT introduces multi-turn tool use and natural language feedback (Wang et al., 2024), while InterCode and AppWorld emphasize coding with execution feedback and app-driven interaction (Yang et al., 2023; Trivedi et al., 2024). SciCode curates scientific computing tasks (Tian et al., 2024), and XCODEEVAL targets multilingual, multitask code understanding and generation (Khan et al., 2023). However, these benchmarks largely isolate competencies: tool use is decoupled from theoretical reasoning, and scientific or multilingual problems are rarely embedded in pedagogically structured tasks.

Unlike existing benchmarks that focus on isolated coding tasks, our dataset integrates theoretical understanding with practical implementation through hybrid problem formats. Each item in the dataset focuses on one or more core competencies: code synthesis, mathematical reasoning, and algorithmic thinking. This flexible format mirrors the diversity of real-world computer science assessments and addresses the "theoretical blind spots" highlighted by (Chan et al., 2024), where language models struggle when reasoning is detached from implementation. By evaluating symbolic manipulation alongside executable code generation, our dataset offers a more comprehensive measure of educational readiness.

2 Data Collection and Examples

The problem set used in our study is derived from **MateInfoUB**, an annual computer science contest specifically aimed at 12th-grade students. This contest also functions as an admission exam for the Faculty of Mathematics and Computer Science at the University of Bucharest. The competition is structured into two phases:

- **Phase 1:** An online round consisting of challenging multiple-choice questions. Students have access to a programming environment, but are restricted to using only publicly available resources. The use of forums, messengers, or Large Language Models (LLMs) is strictly prohibited.
- **Phase 2:** A live programming contest modeled after the International Olympiad in Informatics (IOI) format, featuring four programming problems. Students' solutions can earn

partial points based on correctness and efficiency.

Our work exclusively focuses on the first phase of the contest, and our dataset is obtained directly from the contest organizers in Romanian, currently also available online³. Extensive solutions accompanying each problem, manually written by the authors and by undergraduate students as part of their academic practice (*practică*) at the university are also available for reference and further research.

Some tasks are accompanied by an image containing a code snippet, a diagram, a graph or similar. For those tasks, we augment the statement with a clear textual description of the image's content.

Our final dataset is composed of the problems with statements and multiple choice answers in Romanian, as well as their direct translation in English. The translations are generated automatically, by using *Gemini 2.0 Flash* with very strict instructions enforcing a verbatim translation. The English translations are then manually checked for correctness.

In the following, we provide two examples that illustrate the characteristics of the dataset.

Example: Multimodal Problem Requiring Visual Analysis

Figure 1 presents a typical multiple-choice question from our dataset. The problem requires determining the number of distinct Minimum Spanning Trees (MSTs) present in the provided graph. Problems of this nature are challenging for LLMs, as solutions depend significantly on visual interpretation and structural observation of the graph. Previous studies have noted similar limitations in visual reasoning tasks performed by LLMs (Liu et al., 2023).

Figure 2 presents another multiple choice question from our dataset. Given a map that illustrates a river with two banks and four islands linked by eight bridges, the task asks for the minimum number of additional bridges that must be built so that a tourist can cross each bridge exactly once. Problems of this nature are challenging for LLMs because they require integrating visual-spatial reasoning with graph-theoretical concepts, such as identifying Eulerian paths, which are not explicitly stated, but must be inferred from the structure of the image or diagram.

³<https://mateinfo-ub.github.io/#/toate-datele>

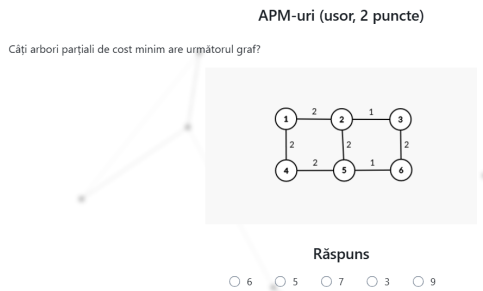

Figure 1: Example multiple-choice problem requiring visual analysis (in Romanian); English translation: "AMP-uri (easy, 2 points); How many minimum spanning trees does the following graph have?"

Koningsberg (easy, 2 points)

The adjacent map is given.

The map represents a river (blue), two banks and four islands (green), as well as eight bridges (black).

What is the minimum number of bridges that need to be built so that a tourist can cross all bridges exactly once?

Careful: the tourist can start his route wherever he wants (on a bank or on an island) and can also finish the route wherever he wants.

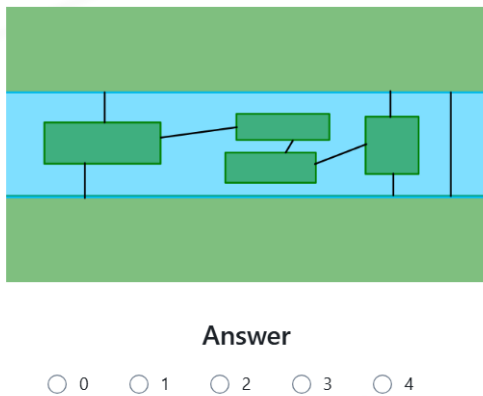

Figure 2: Example multiple-choice problem requiring visual analysis (in English).

3 Benchmarking

In this section, we present a comprehensive overview of our benchmarking strategy designed to evaluate various aspects of Large Language Models (LLMs) performance on our bilingual, multimodal dataset. The benchmarking aims to highlight differences in performance across multiple dimensions, including language, presentation modality, availability of multiple-choice options, and problem-solving approaches.

3.1 Methodology

Our evaluation is based on state-of-the-art LLM models from various vendors, namely *gemini-2.0-flash* and *gemini-2.5-pro-exp-03-25* from *Google AI Studio*, *mistral-large-latest* (April 2025) from *Mistral AI*, and *meta-llama/Llama-3.3-70B-Instruct-Turbo-Free*, *deepseek-ai/DeepSeek-R1* and *deepseek-ai/DeepSeek-V3* from *Together AI* (Together AI, 2025)

We use the models via the exposed API, starting a new chat instance for each task. We provide the models with the task's statement and the multiple-choice answers. We then instruct the models to provide reasoning steps, followed by either an answer or a Python script that computes the answer.

For minimizing benchmarking frictions, we clearly provide the models with the expected output format, which resembles XML. While very forgiving, in some instances, the models fail to adhere to it (if, for instance, their answer exceeds the API's length limit). In such situations, we consider the models' answers incorrect.

3.2 Evaluation Baseline

We evaluate the accuracy of our models on the original tasks. Due to the multiple choice nature of the tasks, verifying the correctness of the models' solutions is trivial. We run each model on each problem 3 times, for minimizing the randomness caused by the LLMs' seed selection. We chose to use the models' default API settings (i.e., without forcing temperature to 0) to reflect typical usage and obtain realistic levels of correctness, confidence, and creativity, as would be experienced by a standard user.

3.3 AI vs. Human Contestants

As our dataset comes from real contests, we compare the performance of the models with the results obtained during the 2021, 2022, 2023, and 2024 editions of the contest. We evaluated the models by measuring their percentile scores compared to the results of the students who qualified for the final stage of the contest.

3.4 Original Romanian Baseline vs. English Translations

LLMs have been notoriously bad at reasoning in languages other than English. By comparing our baseline benchmark with the performance of LLMs on English translations of the statements, we gain

insights about the model’s effectiveness in a language typically underrepresented in NLP research, as opposed to English.

A comparative analysis of English and Romanian benchmarks highlights language-specific challenges and differences in LLM capabilities between languages.

3.5 Original Multiple-Choice vs. No Multiple-Choice Variants

We investigate how the presence or absence of multiple choice answer options affects LLM performance. By removing the multiple-choice framework, we challenge the models’ capability to generate answers without guidance from predefined options.

3.6 Chain-of-Thought vs. Direct Answer

In our benchmarks, when prompting the models for an answer, we ask the models to provide a detailed description of the solution. The models thus respond with reasoning steps to solve the task, followed by the answer.

We measure how the performance of the models is impacted by the absence of the reasoning steps, by prompting the models to directly output the answer, without justifying it.

3.7 Answer-only vs. Hybrid Approach

Finally, we conduct experiments to compare LLM’s performance across two different reasoning strategies:

- **Hybrid approach:** The model autonomously chooses whether to solve the problem via code generation or direct reasoning (our baseline).
- **Think-only:** The model is restricted to providing direct theoretical or conceptual solutions, without the possibility of running *python* code.

We do not consider the third option (forcing the model to produce *python* code), as we experimentally see the model can write a trivial script printing a hard-coded answer, making the experiment uninteresting.

4 Results

In this section, we present the findings of our benchmarking evaluations.

Overall, our analyses suggest significant variations in LLMs performance across different scenarios.

We acknowledge that the outreach of benchmarks might be limited by the size relatively small of our dataset, but our measurements suggest the following trends:

- **Language Comparison:** Our measurements indicate various differences in model accuracy and problem-solving capabilities when problems are presented in Romanian versus English, with some models benefiting from a verbatim translation of the statements to English, a language they are more familiar with, while others perform better when exposed to the original statements.
- **Multiple-choice Contexts:** We observe that the availability of multiple-choice options slightly improves model accuracy compared to scenarios where these options are not provided.
- **Reasoning Strategies:** Benchmarks indicate a promising performance of hybrid strategies, where models autonomously select between code generation and direct reasoning, outperforming exclusive reasoning approaches.
- **Human Performance Comparison:** Comparing the performance of models with the performance of high school students taking part in the contest, we find that newer models consistently outperform most students.
- **Breadth of Capabilities:** Models demonstrate a broader range of problem-solving skills than originally anticipated, effectively addressing a very diverse set of exercises. In particular, of the 100 exercises in our dataset, all but three were solved by at least one model, highlighting their versatility and adaptability to different types of problems.

Detailed findings from each of our experiments are discussed in the following sections.

4.1 Baseline and comparison with human rankings

We find models quite capable, with newer models capable of solving most tasks. On average, models achieve a difficulty-weighted accuracy of 52%

(easy problems are worth 2 points, medium problems 3 points, and hard problems 5 points). A complete breakdown of the accuracy of the models is available in Table 1.

Model	Easy (%)	Medium (%)	Hard (%)
Gemini 2.5 Exp	96.7	85.6	76.7
Gemini 2.0 Flash	71.3	60.0	35.0
Llama 3.3 70B	51.3	31.1	18.3
DeepSeek R1	54.0	34.4	21.7
DeepSeek V3	72.0	63.3	30.0
Mistral Large	62.0	43.3	31.7

Table 1: Performance metrics for different models across difficulty levels in Romanian (larger is better).

One can see that *Gemini 2.5*, a reasoning-focused model, outperforms all others, including *DeepSeek R1*. However, upon closer examination, we found that *DeepSeek R1* frequently produces answers that exceed the API’s maximum response length, leading to truncation and, consequently, incorrect outputs.

In some cases, such as when attempting to manually solve complex counting problems, the model’s output becomes excessively long. We consider it most appropriate to adhere to the API vendor’s configured maximum response length and treat truncated or incomplete answers as incorrect.

As we have data on the scores obtained by students qualified in the *2021*, *2022*, *2023* and *2024* editions of the contest, we can compute the percentile (i.e. the percentage of students doing better than the model) of the qualified students. The results are available in Table 2.

Model	2021	2022	2023	2024
DeepSeek V3	38.22	27.12	26.15	9.95
Gemini 2.5 Exp	0.64	1.69	0.51	0.00
Gemini 2.0 Flash	50.96	55.93	56.41	1.05
Llama 3.3 70B	100.00	100.00	100.00	100.00
DeepSeek R1	100.00	100.00	79.49	100.00
Mistral Large	100.00	92.09	85.64	9.95

Table 2: Average percentiles of models compared to real students across different years (smaller is better).

Models show a constant improvement over the years, which we theorize can be explained by a combination of the following hypotheses:

- Older contests have more ad-hoc problems, which models tend to struggle with.
- Starting in 2022, the UK stopped its financial support for EU students, including Romania.

Thus, many students exploring alternative opportunities took part in the contest. As alternative abroad universities grew in popularity among high school students, interest in the contest could have decreased.

- The student participating in the contest in 2022, 2023 and 2024 were the most impacted by the *Covid-19* remote studying mandates during early high school.

We strongly believe that our dataset is not tainted (i.e., that models were not trained on it). While the statements were publicly available before we started our research, we are the first to compile a dataset that maps these problems to their corresponding answers.

In other words, while it is plausible that model training corpora may have included the raw statements, the solutions could not have been included, since all tasks are original, and our dataset is the first to pair them with verified multiple-choice answers.

4.2 Original language vs. English translation

Our experiments show that most models perform better on the Romanian version of the questions than on the English one. This gap likely arises from two factors. First, our English statements are verbatim translations of the original Romanian text, which can lose nuance and clarity and introduce artifacts (translationese) that impair model understanding.

Second, since the raw Romanian problems were publicly available before our work, it is plausible that models encountered those during training, whereas our English translations are novel; thus, they effectively function as a partial unseen validation set. We therefore consider the benchmark bilingual, while acknowledging that translation quality and prior exposure may both contribute to the observed performance drop.

The *DeepSeek* family of models sees a 10% gain in accuracy when solving the English variant, suggesting reduced multilingual abilities of the models.

The results of the experiment are available in Table 3.

4.3 Multiple-choice options provided vs. not provided

We observe a slight decline in performance when the multiple choice variants are not provided, which

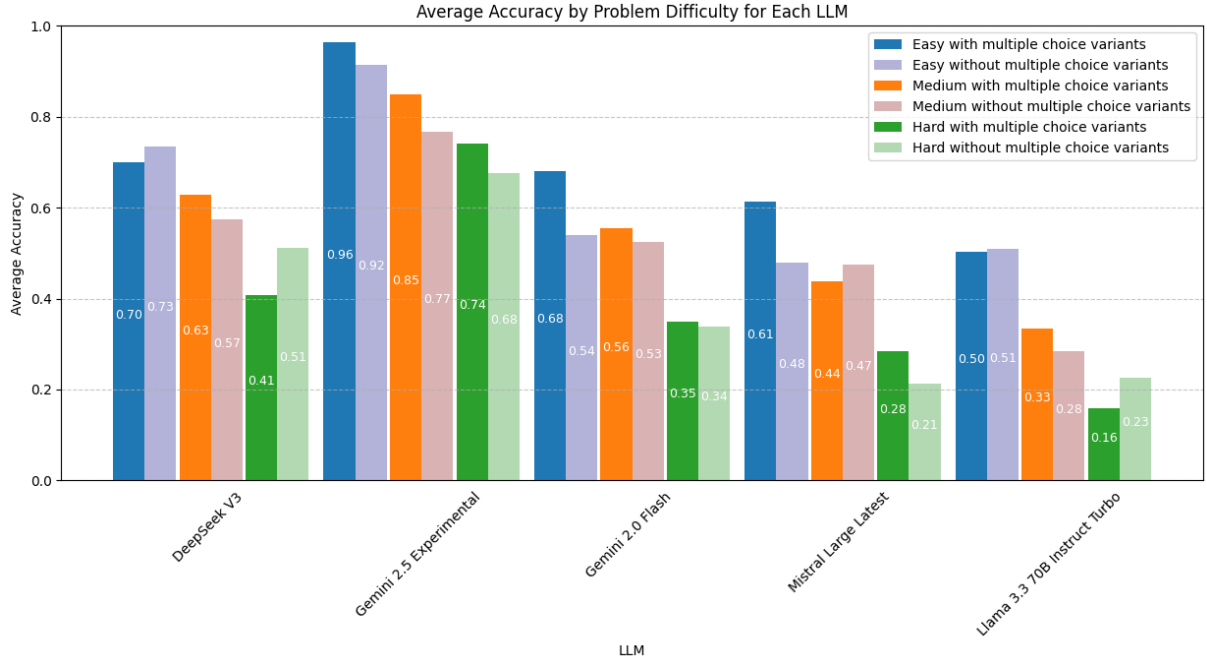

Figure 3: Performance of models when the multiple choice options are provided vs when they are not.

Model	English (%)	Romanian (%)
DeepSeek V3	0.61	0.55
Gemini 2.5 Exp	0.84	0.86
Gemini 2.0 Flash	0.50	0.55
Llama 3.3 70B	0.33	0.34
DeepSeek R1	0.52	0.37
Mistral Large	0.43	0.46
Overall Average	0.54	0.52

Table 3: Average scores for models across different languages.

aligns with the contests’ design goals of making the variants unhelpful for solving the tasks. Considering that models tend to *guess* an answer and hallucinate a justification when they cannot solve the task, we believe that the difference is caused by models having a higher chance of *guessing* the correct answer. The results can be seen in Figure 3.

4.4 Chain-of-Thought vs. Direct Answer

We observe a slight decline in performance when models are only prompted for the answer, as opposed to first providing a justification, or reasoning. While we expect *reasoning* models like *Gemini 2.5 Exp* and *DeepSeek-R1* to be invariant to the change (due to their own reasoning process), *DeepSeek-R1*’s internal chain-of-thought reasoning increases in length, which causes some of its answers to be truncated and invalidated. The full results are available in Table 4.

Model	Easy	Medium	Hard	Average
With Reasoning				
DeepSeek V3	0.70	0.63	0.41	0.58
Gemini 2.5 Exp	0.96	0.85	0.74	0.85
Gemini 2.0 Flash	0.68	0.56	0.35	0.53
Llama 3.3 70B	0.50	0.33	0.16	0.33
DeepSeek R1	0.65	0.43	0.26	0.45
Mistral Large	0.61	0.44	0.28	0.45
Overall Average				0.53
Without Reasoning				
DeepSeek V3	0.73	0.54	0.48	0.58
Gemini 2.5 Exp	0.95	0.81	0.79	0.85
Gemini 2.0 Flash	0.56	0.50	0.11	0.39
Llama 3.3 70B	0.53	0.27	0.19	0.33
DeepSeek R1	0.28	0.12	0.00	0.13
Mistral Large	0.48	0.35	0.15	0.33
Overall Average				0.43

Table 4: Comparison of average scores with and without reasoning for various models.

4.5 Answer-only vs. Hybrid Approach

In Figure 4, we can see the distribution of *python* answers and direct answers, when the models can choose unconstrained how to provide an answer for a given task (i.e., models can freely pick between providing a direct answer and providing a *python* code).

When *Python* is no longer allowed, the models perform unexpectedly worse, as more than half of their answers rely on executing *Python* code. We

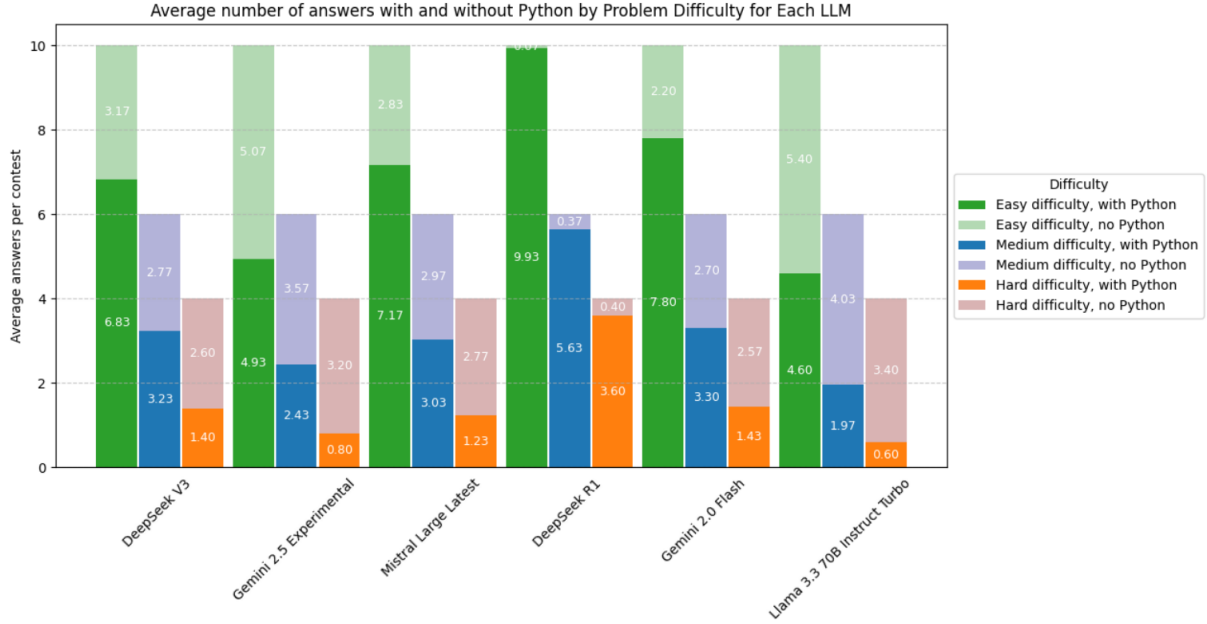

Figure 4: Percentage of direct answers vs *python* answers when the models are given the choice between the two. Columns are scaled the number of tasks of each difficulty (10 easy, 6 medium, 4 hard).

run the experiment on a subset of the models, and the results are available in Table 5.

Model	Easy	Medium	Hard
Python Code Allowed			
DeepSeek V3	0.70	0.63	0.41
Gemini 2.0 Flash	0.68	0.56	0.35
Python Code Not Allowed			
DeepSeek V3	0.65	0.48	0.28
Gemini 2.0 Flash	0.59	0.43	0.20

Table 5: Comparison of average scores for DeepSeek V3 and Gemini 2.0 Flash with and without Python code.

4.6 Discussion of Benchmark Results

Our findings have two key implications for computer-science education. First, assessments should combine tool-enabled tasks with those requiring scaffolding and manual reasoning to accurately gauge student mastery. Second, instructors and contest organizers should monitor for anomalous solution patterns—such as perfectly formatted code or implausibly high confidence scores—to detect unauthorized LLM use.

We also provide descriptive plots covering the experiments contained in our research. They are available in Appendix B.

5 Application

In parallel with our experiments, and inspired by our dataset, we develop a web-based application, which can be used as a training ground of students looking to compete in the contest.

The application is freely accessible online ⁴ and, among others, allows students to:

- Preview the statements of all editions of the contest.
- Simulate an edition of the contest.
- Automatically grade their attempt.

The application is implemented in *React*, and is hosted on *Github Pages*. Due to its limited functionalities, it does not require any kind of dynamic backend, and all of its assets, including statements, solutions, and images, can be packaged statically, making deployment easier.

Screenshots of the application and a description of its functionalities are available in the Appendix A.

6 Future Work

Several avenues for further research are highlighted by our preliminary findings and current limitations. Key directions include:

⁴<https://mateinfo-ub.github.io/>

- **Expanded Benchmarking:** Conducting extensive experiments involving additional competitive programming datasets (potentially using cross-validation) and further expanding multilingual analyses. This could also involve analyzing model performance over varying levels of intrinsic **problem complexity**.
- **Live Contest-Based Evaluation:** Introducing the second phase featuring a plethora of programming contests modeled after the International Olympiad in Informatics (IOI), with multiple problems graded on partial correctness and efficiency. This would enable a deeper analysis of LLMs' algorithmic reasoning and problem-solving capabilities in a structured, task-oriented environment.
- **Fine-Tuning and Contextual Support:** Investigating the impact of fine-tuning LLMs on domain-specific data, leveraging RAG methods, or exploring the effect of providing incremental **contextual hints or scaffolding** to guide model reasoning.
- **Model Efficiency and Scalability:** Exploring methods to optimize model inference times and computational efficiency for real-world educational deployment.
- **Enhanced Ethical Solutions:** Developing and evaluating robust technological and educational solutions that address challenges of academic integrity related to the use of LLM.

Pursuing these directions can deepen the understanding of LLM capabilities and limitations, contributing to their sustainable and ethical integration in education.

Limitations

Although our study provides valuable insights into Large Language Models' (LLMs) performance on bilingual educational assessments, several limitations must be acknowledged.

First, although our dataset features a diverse set of problems from a high-stakes computer science competition, the scope remains limited to the Romanian educational context. Generalization of our findings to other linguistic or educational settings may require additional validation.

Second, our dataset and benchmarks currently focus primarily on the immediate accuracy of LLM-generated solutions. Future work should explore

complementary evaluation metrics, including efficiency, robustness to variations in problem presentations, and detailed error analyses, which would provide deeper insights into model performance and reliability in educational contexts.

Lastly, our benchmarking has not explored the impact of methods such as retrieval-augmented generation (RAG) or fine-tuning of LLMs. Future work incorporating these approaches could reveal further improvements in performance and greater adaptability to specific educational tasks and datasets.

Ethical Considerations

A central motivation for this study is assessing the current capabilities of Large Language Models (LLMs) due to significant ethical challenges posed by their increasing accessibility during online assessments, particularly in competitive contexts such as MateInfoUB. Our benchmarking explicitly aims to identify tasks and problem structures that LLMs struggle to solve reliably. The insights gained allow educators and contest organizers to structure future contests in a way that mitigates unfair advantages gained through unauthorized LLM use.

Although our current findings suggest it remains possible to maintain fairness in online competitions for now by emphasizing problems that LLMs find challenging, this strategy will likely become less effective as LLM capabilities rapidly improve. Therefore, it is increasingly important for educational institutions and competition organizers to proactively adopt technical solutions designed to uphold academic integrity. Such solutions could include software capable of capturing contestant screens, monitoring interactions, and verifying participant authenticity. Additionally, educational efforts should emphasize ethical awareness and responsible technology use, preparing students to navigate the evolving landscape of educational assessments responsibly.

At the same time, we acknowledge that releasing a dataset modeled after real pre-university exams introduces the risk of misuse, particularly fine-tuning LLMs to artificially boost exam performance without genuine understanding. Our benchmark is intended for controlled research and diagnostic evaluation, not as training material for high-stakes testing. Responsible use requires avoiding practices that could compromise the integrity and fairness of educational assessments.

A Online Training Platform

In the image 5 one can see the user interface of the application during a simulation of the 2022 edition of the contest, and the image 6 shows the user interface after the contest's timer ends or the user manually stops it.

While simple, the application contains all the necessary features for an exam-like environment:

- A timer.
- A menu with all of the problems of the contest, ordered by difficulty and color-coded based on the answer provided (blue during the contest and green / red afterwards).
- A problem viewer, where users can read the statements and provide answers.

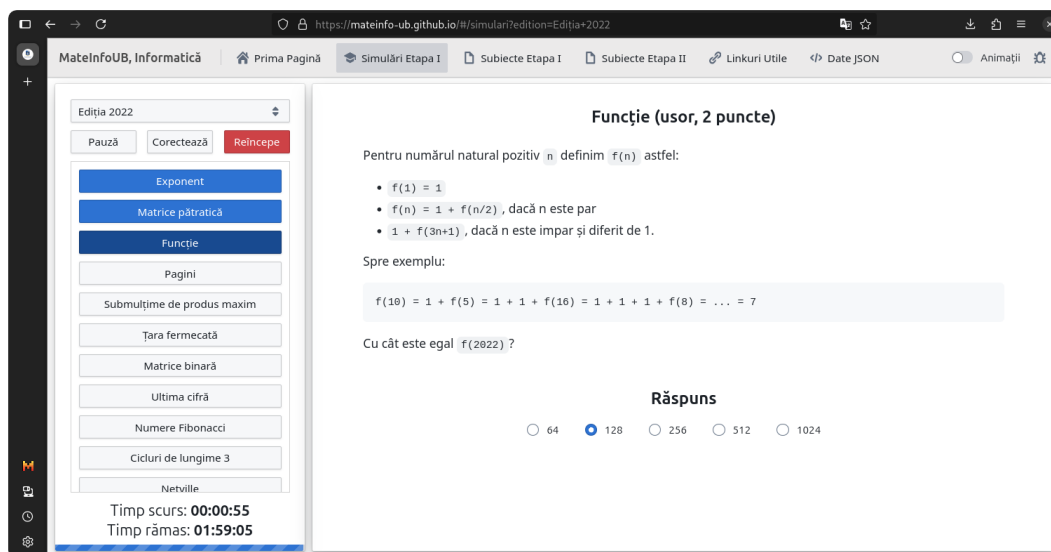

Figure 5: Screenshot of the web application while solving a contest.

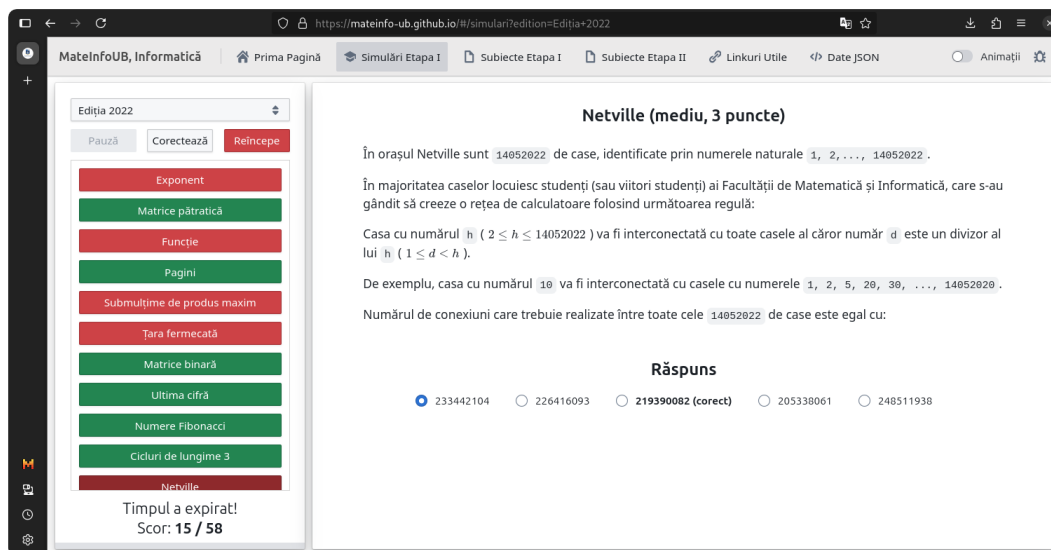

Figure 6: Screenshot of the web application correcting an attempt.

In addition to the simulation page, the application contains pages with the *pdf* statements, exactly as they were during the corresponding exams, and links to useful resources.

B Experiment Plots

In this section, we present visualizations of our experimental results.

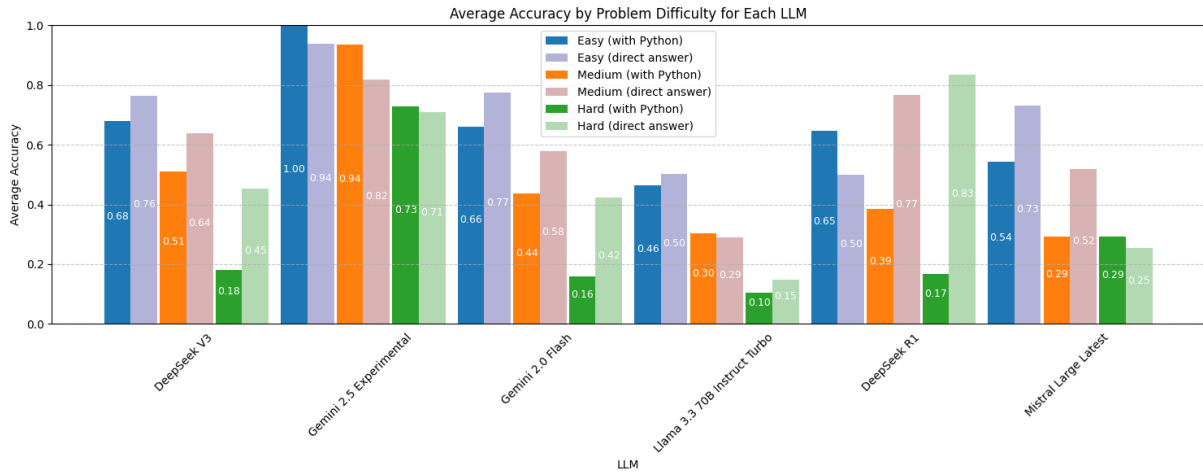

Figure 7: Accuracy of the unconstrained *Python* and direct answers of the models.

In Figure 7, we plot the accuracy of the models when providing an answer as *Python* code or as a direct answer. As the models can freely choose how to answer, we can see some interesting trends. For example, on hard problems, models are significantly more likely to get the right answer when providing *Python* code.

In Figure 8, we plot the percentile of the models when comparing their score with the scores of students advancing to the next phase of the contest, by year. For instance, *Gemini 2.5 Exp* ranks first for 3 out of the 4 years, while *Llama 3.3* ranks last all years.

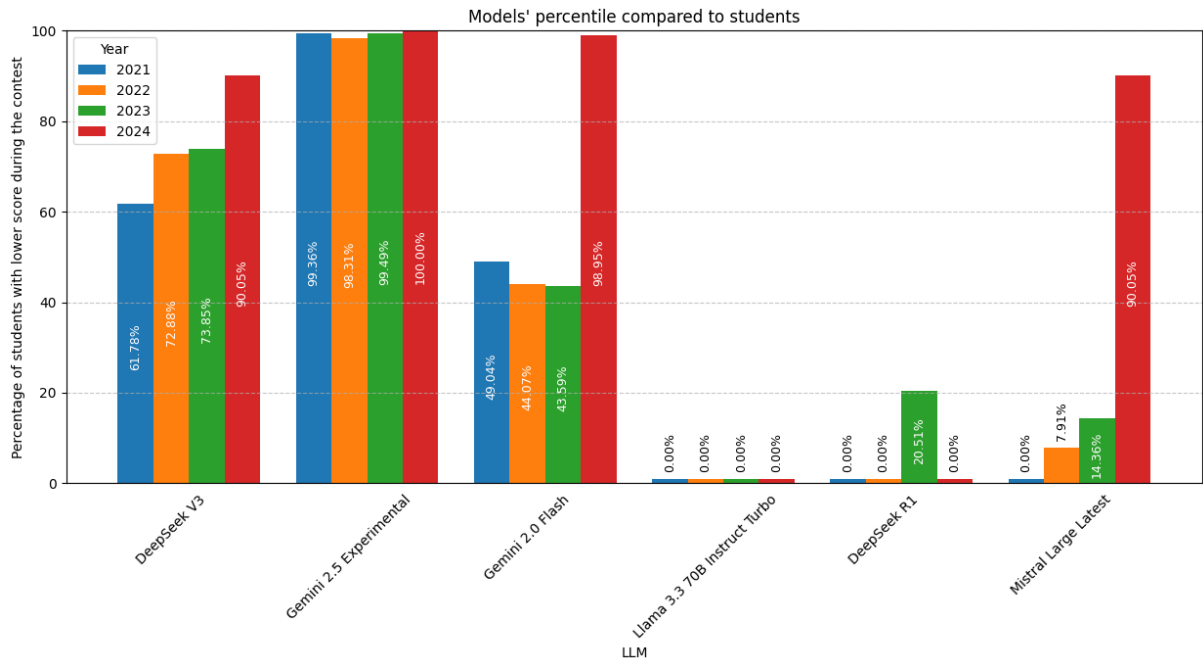

Figure 8: Percentage of students with a lower score than the models, by year.

Figure 9 plots the accuracy of models by language. Except for *DeepSeek-R1*, models tend to achieve a higher score in Romanian, the original language of the tasks.

When prevented to

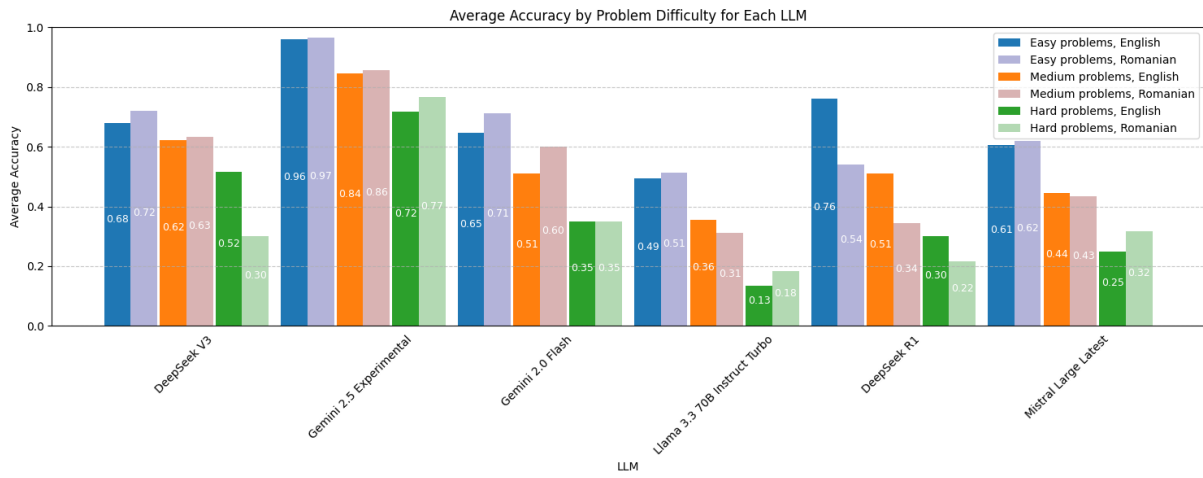

Figure 9: Performance of the models by language

Figure 10: Performance of the models when they are allowed to produce *Python* code and when they have to provide the answer directly.

Unsupervised Automatic Short Answer Grading and Essay Scoring: A Weakly Supervised Explainable Approach

Abstract

Automatic Short Answer Grading (ASAG) refers to automated scoring of open-ended textual responses to specific questions, both in natural language form. In this paper, we propose a method to tackle this task in a setting where annotated data is unavailable. Crucially, our method is competitive with the state-of-the-art while being lighter and interpretable. We crafted a unique dataset containing a highly diverse set of questions and a small amount of answers to these questions; making it more challenging compared to previous tasks. Our method uses weak labels generated from other methods proven to be effective in this task, which are then used to train a white-box (linear) regression based on a few interpretable features. The latter are extracted expert features and learned representations that are interpretable *per se* and aligned with manual labeling. We show the potential of our method by evaluating it on a small annotated portion of the dataset, and demonstrate that its ability compares with that of strong baselines and state-of-the-art methods, comprising an LLM that in contrast to our method comes with a high computational price and an opaque reasoning process. We further validate our model on a public Automatic Essay Scoring dataset in English, and obtained competitive results compared to other unsupervised baselines, outperforming the LLM. To gain further insights of our method, we conducted an interpretability analysis revealing sparse weights in our linear regression model, and alignment between our features and human ratings.¹

1 Introduction

Applications of Large Language Models (LLMs) are emerging in the field of education and have

taken complementary roles to those of teachers (Jeon and Lee, 2023). For instance, LLMs have been used, with mixed results, to train teachers to learn new strategies (Wang and Demszky, 2023). One aspect of education that can greatly benefit of automation is that of grading or scoring (Lan et al., 2024). Such automation could greatly improve the flexibility of teaching and target on the fly specific educational shortcomings of students.

In this work, we focus on two of these automations: (i) **Automatic Short Answer Grading (ASAG)** and (ii) **Automatic Essay Scoring (AES)**; both instances of automated scoring for open-ended questions. More specifically, ASAG focuses on grading short, open-ended responses. These responses are typically a few sentences to a paragraph long and are often fact-based, requiring concise answers. In contrast, AES evaluates longer, more complex pieces of writing, which typically contain an introduction, body, and conclusion, and involve argumentation, analysis, and critical thinking. AES is one of the earliest research problems in natural language processing (Page, 1966, 1967).

One crucial aspect of automated grading on open-ended questions is the ability to interpret the grade. The machine learning community has prioritized increasing explainability in models, leading to the emergence of Explainable AI. This area focuses on building tools to understand the decisions made by learning models (Gunning et al., 2019; Arrieta et al., 2020; Fel et al., 2022), or even advocates for the sole use of white-box models (Rudin, 2019). However, white-box models typically display poorer performances compared with black-box ones (Loyola-Gonzalez, 2019). Thus, in line with the explainable trend, recent methods have focused on developing novel tools to increase the performance of white-box models, sometimes up

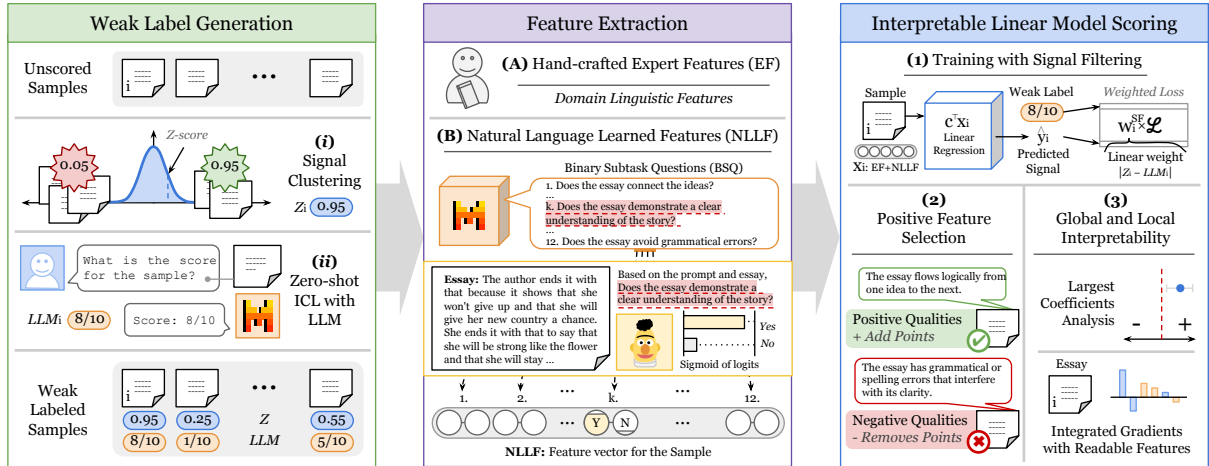

Figure 1: Full process. **Phase 1**, Generation of Weak Labels using Unsupervised methods: Signal Clustering (Chen et al., 2010a) or through an LLM (Jiang et al., 2023b). **Phase 2**, domain Expert Features (EFs) extraction and Natural Language Learned Features (NLLFs) obtained from answers to Binary Subtask Questions (BSQs) (Urrutia et al., 2023). **Phase 3**, feature selection, interpretable model training and analysis.

to that of black-box models (Urrutia et al., 2023).

Finally, most studies rely on supervised learning with annotated datasets (Takano and Ichikawa, 2022; Bonthu et al., 2023; Zhang et al., 2022), where a few items are associated to many annotations. A situation that is barely encountered in real-life scenarios. Moreover, only a few works in this area focus on non-English language (Latif et al., 2024). The majority of them are restrained to English, and none of them in (Latin-American) Spanish.

Motivation and Contributions. In this work, we tackle the issues raised above in a single framework (see Figure 1). First, we propose a method that allows us to reach high performance in ASAG and AES tasks in an unsupervised way. Second, we show the potential of our model to create interpretable white-box predictions based on sparse features, in a setting where strong generalization abilities are required because of highly diverse questions with a few answers.

Therefore our contributions are as follows: (i) we present a novel Non-English language dataset that is particularly challenging for ASAG systems, as it involves many questions with few answers, (ii) we propose a novel framework that unifies unsupervised and supervised methods into a single ASAG/AES system. In particular, we use weak labels from opaque unsupervised methods for supervised learning in white-box models, (iii) we propose a way to maximize the impact of the best-labeled training examples by weighting the loss

function regarding the degree of consensus between each weak label, (iv) we compare our method with strong ASAG and AES baselines on two distinct datasets of different languages, and show that our method significantly outperforms previous white-box models, and falls barely short to LLM-based ASAG or to SOTA AES, (v) we run a thorough analysis on the AES dataset to demonstrate the interpretability of our method by: looking at our model’s sparse weights, comparing it with SOTA using their integrated gradients but also showing our features are aligned with humans scores.

2 Related Work

In the context of ASAG, several methods have been proposed. Recent work has focused on generating understandable scoring by decomposing items (i.e., questions and responses to math problems) into rubrics whose validity can be inferred with language models (Hellman et al., 2023). Similar work have focused on directly fine-tuning pre-trained language models for ASAG (Takano and Ichikawa, 2022; Bonthu et al., 2023; Zhang et al., 2022), or training language models only based on student responses (Steimel and Riordan, 2020). Some works developed a hybrid ASAG system that evaluates answers to mathematical questions based on deterministic methods and the quality of explanations using text-based scoring methods (Cahill et al., 2020). Note that many semi-supervised (Brooks et al., 2014; Weegar and Idestam-almquist, 2024; Basu et al., 2013) or similarity-based methods (Bexte

et al., 2023) allow to use less labels, but they still need some of them.

In the context of AES, Taghipour and Ng (2016) were pioneers in training neural networks for AES, using a CNN-LSTM on the Automated Student Assessment Prize (ASAP; Hamner et al. 2012) dataset. Even though supervised models remain the most efficient (Yang et al., 2020), unsupervised methods like the one we are proposing show promising results. For instance, AESPrompt (Tao et al., 2022) obtains competitive results in one-shot essay scoring using continuous prompt learning. Wang et al. (2023) created a fully unsupervised approach using heuristic signals learning as a proxy task, as ultimate goal to train a BERT-based essay scorer, and obtained state-of-the-art performances on ASAP. Recent works have focused on the ability of LLMs to automatically score the proficiency of written essays on ASAP (Mansour et al., 2024; Lee et al., 2024). Stahl et al. (2024) even proposed prompting strategies for joint essay scoring and feedback generation to gain more interpretability.

Regarding general explainability, techniques that could be used for ASAG and AES such as Chain-of-Thought (CoT) (Wei et al., 2022) can provide a superficial level of explanation but are prone to structural biases in the text that put in question their fidelity (Turpin et al., 2023; Paul et al., 2024). Moreover, these techniques are fragile as pre-trained language models show lack of robustness on adversarial or unusual writing (Lottridge et al., 2023). Importantly, these writing types are often present in the answers of young children like in the ASAG dataset of this study.

3 Methods

The task of automatically assigning scores to short answers/essays involves finding a model M that assigns a score \hat{y}_i between 1 and S_{\max} to each pair of question/answer or instruction/essay. **First**, we use unsupervised methods to create weak labels. **Second**, we represent every document using interpretable features. **Third**, we select features and train a non-negative linear regression model on the weak labels, using a special loss to maximize the weak labels quality. We show the model is both white-box, sparse and interpretable.

Weak-supervision We propose to train an unsupervised model M by leveraging high-level heuristic signals, or weak labels. Our method (see Figure 1, **Phase 1**) involves utilizing two distinct signals:

(i) scores derived from the unsupervised Signal Clustering method (SC; Chen et al. 2010b, see below) and (ii) scores obtained from an LLM using zero-shot in-context learning. For a given question-answer/instruction-essay pair (q_i, a_i) , we denote as Z_i the signal of the answer with SC or LLM_i the LLM-based signal. To weakly-supervise the training of M , we use $y_i = Z_i$ or $y_i = LLM_i$ in order to minimize the loss function $\mathcal{L}(\hat{y}_i, y_i)$.

Signal Clustering (or Z-score) Based on Chen et al. (2010a), this method is simple yet allows for surprisingly good results in unsupervised automatic essay scoring. Basically, it initialize each essay score with a simple value, and then iteratively propagates the scores to other samples in the same cluster. For their essay scoring task, the authors of the original paper used the number of unique terms in the answer as the initial score. It uses the following inductive formula:

Z_{i0} : Initial score for the i -th answer,

$$S_{it} = \sum_{j \neq i} \text{Sim}_{ij} \cdot Z_{i(t-1)},$$

$$Z_{it} = \frac{S_{it} - \frac{1}{N-1} \sum_{k \neq i} S_{kt}}{\sigma_t},$$

where S_{it} is the score for the i -th answer at step t , Sim_{ij} is the similarity between the i -th answer and the j -th answer, and Z_{it} is the Z -score of the i -th with σ_t the standard deviation of $S_{.t}$ at step t . We call Z_i the Z -score of the i -th answer at final step. We update Z_i until convergence.

Interpretable Features Following the work of Urrutia et al. (2023), we incorporated a set of expert-derived features (EF) coming from expert domain knowledge, and also high-level explainable features such as Natural Language Learned Features (NLLF; Urrutia et al. 2023). NLLFs encode answers to simpler-than-the-task binary questions, called **Binary Subtask Questions (BSQs)**, into a human-readable feature vector. It allows the model to represent each sample as a vector of probabilities on other interpretable simpler sub-tasks, like "Is the answer written clearly and concisely?". More details are available in (Urrutia et al., 2023) and in Appendix B. We also use the concatenation of both type of features (EF+NLLF). For EF, we use in ASAG/AES a list of 36/14 hand-crafted features, to describe the answers to math questions/essays (Table 6/7 in Appendix). Figure 1 shows the feature

Question	Answers	Score
Don Antonio bought 3 boxes of cereal at \$673 each. The seller charged him \$2100. Is what they charged him correct? Explain in your own words.	If Don Antonio bought 3 boxes, it's fine. No, because he should be charged less. It's not wrong, I got 2019.	{2, 3} {4, 3} {6, 7}

Figure 2: Examples of a Question, Answers and Scores from our ASAG dataset. Translated from Spanish.

extraction in **Phase 2**, with an example of BSQ and the NLLF vector for an essay.

Interpretable Model: Linear Regression We trained a linear regression on two types of weak labels (see Figure 1, **Phase 3**).

Signal Filtering We propose a method to maximize the impact of well-labeled examples through the weighting of the loss function with respect to the degree of consensus among weak labels (see Figure 1, **Phase 3**). Basically, we compute linear weights utilizing the difference between the predicted scores generated by the LLM and the ones derived from the Signal Clustering method, both of which obtained in a unsupervised way. For a given question-answer pair (q_i, a_i) and weak-label $y_i \in \{Z_i, \text{LLM}_i\}$, the weighted loss is $w_i^{\text{SF}} \cdot \mathcal{L}(\hat{y}_i, y_i)$, where:

$$w_i^{\text{SF}} = 1 - \frac{|Z_i - \text{LLM}_i|}{S_{\max} - S_{\min}}$$

Feature Selection In order to keep our model interpretable, we used two tricks (see Figure 1, **Phase 3**). First, we only chose BSQs formulation that were positively correlated with the score of the student² i.e., describing events that were seen as positive by the teacher. Second, we forced the linear regression model to learn only positive weights (Slawski and Hein, 2013) as they are applied on features that are positives w.r.t. the score. Section 5 shows that this setting allows for sparsity in the parameters space of the linear regression model.

4 Experiment and Results

4.1 Datasets and Evaluation Metrics

We ran experiments on two distinct tasks using two datasets in different languages. The first set of experiments (Section 4.1.1) tackles ASAG in Spanish while the second set of experiments (Section 4.1.2) tackles AES in English.

²using weak labels

Task	Genre	Avg. Length	Score Range	# Essays
1		350	2-12	1783
2	PER	350	1-6	1800
3		150	0-3	1726
4		150	0-3	1772
5	SDE	150	0-4	1805
6		150	0-4	1800
7	NAR	250	0-30	1569
8		650	0-60	723

Table 1: Properties of the different tasks in the AES dataset called ASAG. Genre: PER (persuasive), SDE (source-dependent), NAR (narrative).

4.1.1 Automatic Short Answer Grading in Spanish

The dataset comprises written answers from fourth-grade students to mathematics questions. The question-answers pairs were collected using the online e-learning platform ConectaIdeas, which is currently deployed and use by teachers and students in Chile. Its data was already used in past scientific studies (Urrutia Vargas and Araya, 2023; Urrutia and Araya, 2023). It encompasses a total of 63,612 answers to 1,248 unique questions collected across two academic years. The answers were obtained from a total of 3,463 fourth-grade students, with 231 for the 2017 period and 3,232 for the 2022 period. The answers have on average a total of 50 characters. Each question has on average a total of 52 answers per question for 2022 and 30 for 2017.

The data are annotated based on the scoring of answers for one academic year (2017). Answers from the unlabeled academic year are utilized to train automatic systems, while those from the labeled academic year serve as a test set for evaluating the performance of these systems. Annotation was conducted by two elementary mathematics teachers, assigning scores ranging from 1 to 7 (i.e., from insufficient to excellent). Only the scores from one teacher were utilized as the ground-truth, while the scores from the other teacher were utilized to analyze human performance, in this sense we can make a model that predicts the grading behavior of one teacher. We calculate the agreement between their scores and obtained a Correlation of

.76. Figure 2 shows an example of the dataset.

4.1.2 Automatic Essay Scoring in English

We ran experiments using the Automated Student Assessment Prize³ (ASAP) dataset (Hamner et al., 2012). This dataset has been widely used in several AES studies (Xie et al., 2022; Jiang et al., 2023b; Muangkammuen and Fukumoto, 2020; Mansour et al., 2024; Mathias and Bhattacharyya, 2018). For instance, it has been used by Wang et al. (2023) to assess the ULRA model for an unsupervised AES task. It is composed of 12,978 essays divided into 8 different sets. Each of the sets corresponds to a specific essay task or prompt, which can be seen as domain. The tasks are of different genres: persuasive, source-dependent response, and narrative. The statistics of the dataset is shown in Table 1.

As a validation metrics, we report Quadratic Weighted Kappa (QWK) in order to compare the different models, generally utilized to measure the agreement between groundtruth scores and predicted scores on this dataset and in AES research.

4.2 Baselines

Dummy Baseline We use a regression model based on the answer length in terms of number of characters.

Similarity Measures We calculate the similarity between the question and the answer to assess

its correctness based on the shared information between them. We use two methods: Jaccard Similarity on sparse embeddings (Bag-of-Words; (Harris, 1954)), and cosine similarity with dense vectors obtained from the [CLS] token of a multilingual Sentence Transformer (Reimers and Gurevych, 2019).

Signal Clustering (Z-score) Based on Chen et al., we use answer length as the initial scoring and assessed answer similarity based on the shared terms between two answers.

Mixtral We used a recent LLM to address the task in a zero-shot format (Jiang et al., 2023a), using a simple prompt containing the definition of the task. More details in Appendix C.

ULRA We implemented the unsupervised ULRA method of Wang et al. (2023) which showed state-of-the-art results on Automated Essay Scoring, which is close to ASAG. This model consists of using multiple quality signals obtained from heuristics as the pseudo-groundtruth, and then training a neural model by learning from the aggregation of these signals. The idea is that the final score should depend on an aggregation of these simple signals. For the ASAG task, we adapt the method translating the original Linguistic Features (LF) to Spanish, and by using our own Expert Features (EF) as pseudo-groundtruth. For the AES task, we utilized the LF from the original paper on the same task. Note that ULRA was also considered as a

We report the cheap baselines using similarity, ULRAs using different weak linguistics signals, the Z-score and LLM predictions, and our weakly supervised models. Human scores were re-calculated here. [†] From original papers.

weak label generation method, but did not generate favorable results.

Weakly supervised BERT We evaluated different BERT models (Devlin et al., 2019) with a regression head on top of the [CLS] vector to predict the weak signals. For the ASAG task, we used BETO, a Spanish BERT transformer (Cañete et al., 2023). For the AES task, we used an English BERT.⁴

Multi-trait Specialization We compare with the work of Lee et al. (2024), who proposed an unsupervised method using LLMs to predict the quality of essays in a zero-shot way. Their method learns to decompose the writing proficiency into distinct traits, as some are known to be useful for judging global essay quality (Ke and Ng, 2019) such as *Position* and *Thesis Clarity*, *Organization and Structure* or *Supporting Details and Evidence*.

4.3 Experimental Protocol

The transformers library (Wolf et al., 2019) was used to access the pre-trained model and to train our models. We used BETO as backbone for NLLF generation, and the 4-bit version of Mixtral-8x7b⁵ as LLM. The linear regressions were trained using scikit-learn (Pedregosa et al., 2012). We standardized every features before the

⁴bert-base-cased, bert-base-spanish-wwm-cased

⁵mistralai/Mixtral-8x7B-Instruct-v0.1

logistic regression. For the ASAG task, Pearson correlation measured the correlation between predicted scores from automatic models and ground-truth scores from one teacher. We evaluated our model on the 1,315 manually annotated examples. For the AES task, we randomly split the data into a training, a validation and a test sets following the proportion 60/20/20 like Wang et al. (2023).

4.4 Results

4.4.1 Results on ASAG

Table 2 shows the results of the different baselines and models. It is notable that naive baselines like a linear regression using the answer length can reach a correlation of .27, and are surpassed by similarity between answer and question using a sentence-bert. Best machine results (.57) are obtained with an LLM, surprisingly without using the CoT mechanism, but still far away from human performances (.75). All our weakly supervised approaches benefit from the Signal Filtering method. Adding NLLF to our method helps when using Z-value or the LLM output as weak label, allowing to reach a score close to the one of the LLM, but with an interpretable white-box algorithm (contrary to BERT). ULRA methods, using general and/or domain expert features, tend to display lower scores when compared with Signal Clustering and remaining methods in this task. Finally, the scores of the BERT model trained with the weak-labels are im-

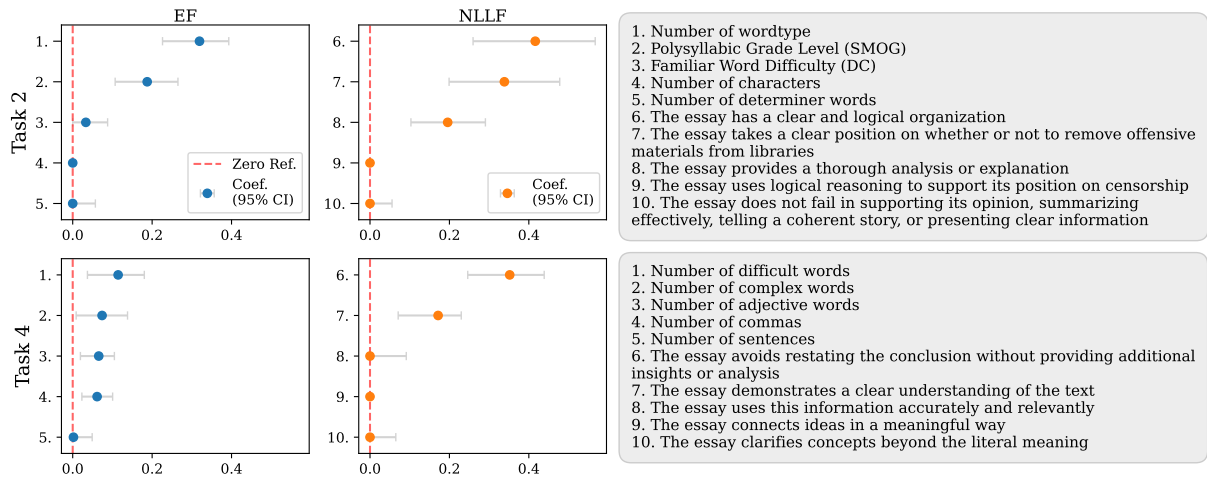

Figure 3: Highest coefficients of the Linear Regression with Signal Filtering using EF+NLLF on AES tasks 2 and 4. The box represents the 95% confidence interval. Biases are respectively of 3.37 and 1.35 for tasks 2 and 4.

proved when applying Signal Filtering, with the best one of .543 using an LLM-based signal as weak labels.

4.4.2 Results on AES

Table 3 shows the results of the different baselines and models on the AES task. Simple baselines achieve a moderate correlation (e.g., .4785 when using the answer length), while basic similarity measures, such as Jaccard and Cosine, perform poorly, with negative or near-zero correlations. Among the models, our method achieves the highest score (.645), outperforming other methods such as ULRA (.642), Z-score (.581), and LLM (.512), though all falling short of human-level performance (.738). Interestingly, the LLM with a CoT approach performs worse than the standard LLM, with a correlation of only .415, which is unexpected given the reported success of CoT in other contexts, specially for a task such as essay scoring in English. Notably, all of our weakly supervised models benefit significantly from the Signal Filtering method. Furthermore, adding the NLLF mechanism further enhances performance. Indeed, combining LLM-based labels, Signal Filtering, and NLLF reaches the highest performance, outperforming prompt engineering baselines such as MTS or AES-Prompt. Finally, the BERT models trained with the weak-labels display lower scores (highest BERT score of .577 using Z-score and Signal Filtering). As a way to cross-check our results, existing works assessed the capacity of various LLMs on this tasks and dataset (Mansour et al., 2024; Lee et al., 2024). The performances we obtained (QWK of 0.51), are

in line with the ones reported in Lee et al. (2024)⁶, but higher than the ones reported in Mansour et al. (2024).

5 Analysis

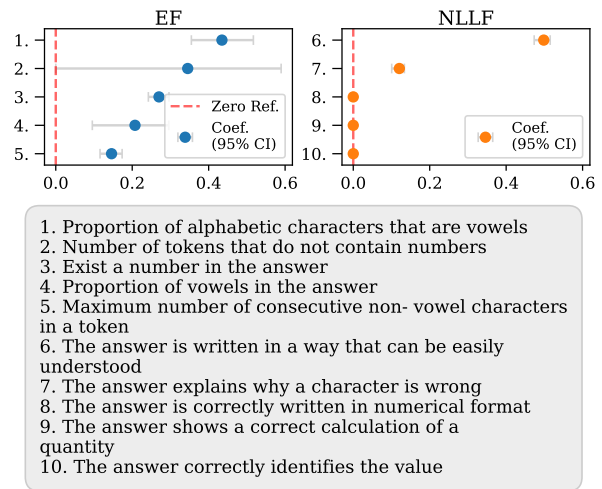

Figure 4: Highest coefficients of the Linear Regression with Signal Filtering using EF+NLLF features (Table 9). The box represents the 95% confidence interval. Bias is 4.65.

ASAG Coefficients Our best linear model uses a combination of only 6 coefficients: 4 hand-crafted features (EF) and 2 natural language learned features (NLLF). Figure 4 shows, from the most relevant features, that correct answers require a balanced use of vowels⁷ (Features 1 and 5) or numbers

⁶0.48 with a Mistral-7b-instruct

⁷Words with a balanced vowel-consonant structure, like the CVCVC pattern, are easier for children to process

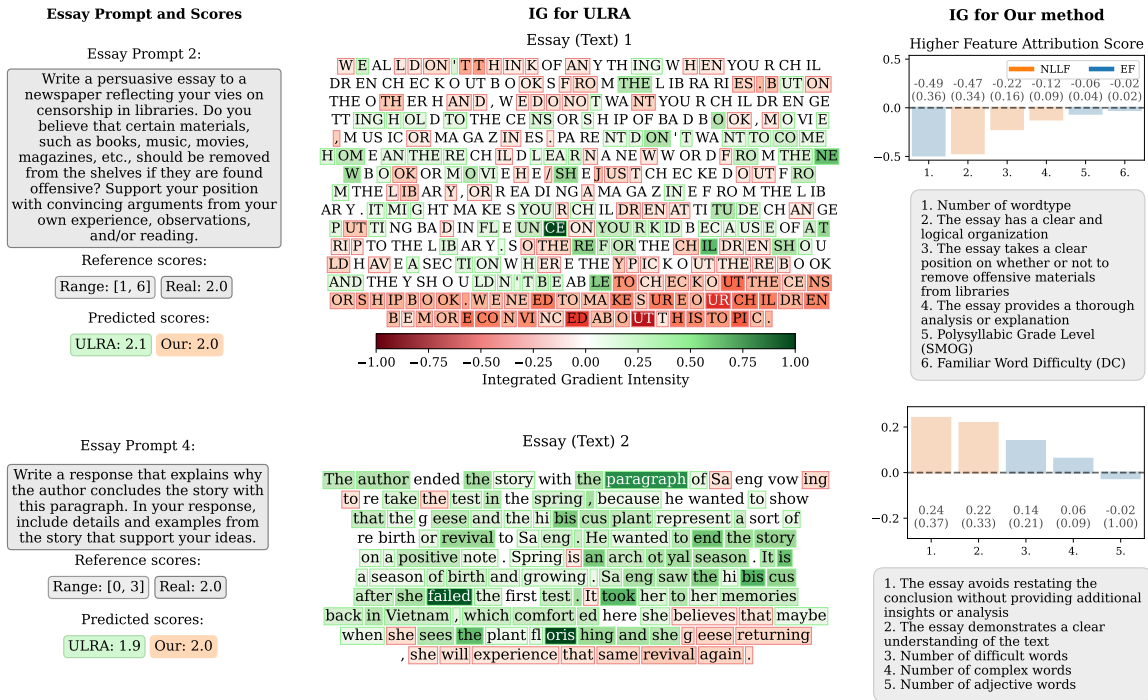

Figure 5: IG feature attribution examples from our method and ULRA on tasks 2 and 4 of the AES dataset.

(Feature 2, 3). In addition, NLLFs address common questions in which students are asked to explain if a character is making or not the right choice (Feat. 7) or just if the answer is clear (Feat. 6).

AES Coefficients Figure 3 show the coefficients of two of the eight linear regression models trained using NLLF+EF, respectively on tasks 2 and 4, persuasive and source-dependent genre, respectively. Most features have coefficients equal to zero, making the linear regression model very sparse, and leaving six usable features for each of the two models: 3 EF and 3 NLLF for the task 2, and 4 EF and 2 NLLF for the task 4. For the persuasive task, NLLFs are about argumentative techniques of the writer, whether or not it takes strongly position, and the structure of the essay.

AES IG Interpretability We claim that our system is white-box, but also interpretable. To back up our claim, we compare the two best performing models with a classical interpretation technique using Integrated Gradients (IG; Sundararajan et al. 2017) in order to attribute a score to each input feature. Figure 5 shows examples of feature attribution comparing our method and ULRA⁸. Whereas (Jiménez González and García, 1995; Brame, 1974) and help recognize proper words like a measure of coherence (Urrutia Vargas and Araya, 2023).

⁸For the linear regression, the integrated gradient is simply the product between the feature and its weight.

the attribution from the IG is complex to analyze in ULRA, our method offers two interesting advantages: (i) it is simple to interpret as it has only a few parameters which are all described in natural language, (ii) it identifies whether essays offer clear analyses or lack clear stances.

AES Human Interpretability We designed two experiments to manually validate our claim that NLLF values are coherent with humans judgments. First, we manually annotated 171 examples w.r.t the BSQ labels, in order to estimate the performances of the LLM and the NLLF Generator (NLLFG) in the subtasks. We find that both the LLM and the NLLFG obtain satisfying accuracies of .89 and .84, in concordance with the analysis of Urrutia et al. (2023). Second, for each BSQ, we selected pairs of examples based on deciles in the normalized distribution of the BSQ NLLF values. Each pair came from examples separated either by high (9 bins), medium (5 bins), or low (1 bin) distances in the distribution. We asked a human to annotate for each pair of examples, the one with highest NLLF value and the bin distance between the examples of the pair. This rendered a 6-class ordinal problem with 171 pairs. We obtained an accuracy of .44 (random is .16), an accuracy with a tolerance of 1 (Gaudette and Japkowicz, 2009) of .77 (random is .44) and a Krippendorff (2013)’s α

of 0.63 (random is 0). More details in Appendix F.

6 Conclusion and Future Work

In unsupervised ASAG of young students to diverse open ended questions in Spanish, and unsupervised AES in English, SoTA LLM-based methods are still far away from human performances. Moreover, the models trained in answer scores made with LLMs can be approximated by much simpler and interpretable models. Weak supervision on LLM labels but also on target values that are way simpler including Signal Clustering is a potential avenue of research for white-box model using several types of interpretable features such as the combination of linguistic-based expert-domain ones and compositionality-based learned ones. Future work should focus on more intensive search on the prompt space, as well as involve supervised learning (and not only weakly supervised learning) and out-of-distribution question analysis. Regarding the interpretability, the integrated gradients could be back-propagated up to the tokens in order to visualize the impact of each of them on each NLLF.

Limitations

Our work has been put in use in Spanish for a very specific type of questions that are from math exams, and in English essay with a higher quality of the text content. It would be interesting to try it in a multilingual setting, using multilingual LLMs. Future works would also imply weakly supervised multi-task learning, and more advanced prompt engineering such as the one of Lee et al. (2024), that allows for decomposing an essay into multiple traits to better score it using an LLM. Finally, it would be interesting to use manually crafted BSQs using the annotation guidelines instead of generating them, in order to see if it will improve the quality of the final model.

Ethics Statement

This work is in compliance with the ACL Ethics Policy as it allows to create models that might be more interpretable in a sensitive context such as young student education.

A ASAG Dataset Statistics

We present a summary of the dataset in Table 4, including the total number of students, different questions and student answers. We added the average number of answers per question for each year.

Year	#Students	#Questions	#Answers	Avg. #Ans. per Question
2022	3,232	1,204	62,297	≈ 52
2017	231	44	1,315	≈ 30
Total	3,463	-	63,612	-

Table 4: Summary of students, total questions, total answers, and average answers per question across years.

B Features

B.1 EF

We manually designed linguistic features, detailed in Table 6, aimed at capturing structural, morphological, and statistical properties of student responses for ASAG task in Chilean Spanish. Given the unique characteristics of children’s writing in a mathematical context, we categorize EF into six groups: *morphological features*, which analyze the presence of numbers, digit counts, and the ratio of numerical to non-numerical tokens, essential for evaluating arithmetic-based responses; *syntactic features*, focusing on tokenization, negation length, and the distribution of non-numeric tokens, which help assess the sentence structure typical of early learners; *lexical features*, which measure character frequencies to detect common patterns in children’s spelling and word usage in Chilean Spanish; *structural features*, capturing answer length, repeated character sequences, and vowel/consonant distributions, which are indicative of fluency and coherence; *punctuation features*, which count and analyze punctuation marks, distinguishing between mathematical symbols (e.g., decimal points, equation signs) and non-mathematical punctuation that might indicate explanatory attempts; and *phonological features*, assessing vowel proportions relative to alphabetic characters to identify phonetic simplifications or spelling mistakes common in young learners.

For example, the phonological feature measuring the proportion of alphabetic characters that are vowels (Feature 1) distinguishes between responses like A1 (0.33) and A2 (0.52) to the same question, with A2 being more phonetically fluent (see Table 5). Similarly, syntactic complexity can be estimated through the number of tokens without

digits (Feature 2), where a detailed explanation (12 tokens, A2) correlates with a higher score than a brief response (2 tokens, A1). Morphological traits such as the binary presence of a number (Feature 3) allow us to capture relevant numerical grounding in an answer; for instance, A2 includes a number and scores higher. Phonological depth is further captured by vowel density (Feature 4), where answers with higher vowel proportion (0.31) exhibit better coherence than sparse ones (0.25). Finally, structural complexity, such as the maximum number of consecutive non-vowel characters in a token (Feature 5), helps detect unnatural or noisy tokens, e.g. A1 has a high value (5) due to “Hkflg”, suggesting incoherence, compared to A2’s more natural phrasing (value of 2).

B.2 NLLF

Following the method outlined in Urrutia et al., we utilize a selected roughly 12% subset of the train-set to generate the NLLF. We ask to a Mixtral to generate a diverse pool of Binary Subtask Questions (BSQ) for our ASAG/AES task. A member of our research team manually removes irrelevant BSQ. We chose 12 binary questions through automatic selection via Agglomerative Clustering, taking the centroid. We automatically answer the selected binary questions on the portion of the train-set with the same LLM to teach a Spanish/English BERT model in answering to all the selected binary questions. We generated a total of 24 features from the sigmoid of the logits of the trained BERT to provide *Yes* or *No* answers to the 12 binary questions (Table 6), i.e. two features per binary question.

C LLM

We used a simple prompt containing the definition of the task. For the AES task, initially, we use an unspecified prompt to score answers, yet observed a tendency for the model to assign notably low scores to answers containing kid misspelling errors. Subsequently, we refined our prompt specifying “not penalize for spelling mistakes and focus on the intended meaning conveyed by the student’s answer”. This adjustment yielded enhancements in the performance of the LLM.

D ULRA as Weak Signal

In the AES dataset, the LLM performances are outperformed by the ones obtained using the ULRA method, which is unsupervised but also black-box.

Feature	Question (Q) and Answer (A1-A2)	Feature Value	Score
Proportion of alphabetic characters that are vowels	Q: Si Jose multiplica 150 veces 1 ¿Cuál sería su resultado? Explica	-	-
	A1: 150x1 es 51 <i>(Low vowel ratio)</i>	0.33	3.0
	A2: sería 150 porque 150 veces 1 sería 150 <i>(Higher vowel ratio)</i>	0.52	7.0
Number of tokens without numbers	Q: José compró 4 cajas de leche a \$245 cada una. El vendedor le cobró en total \$950. ¿Está correcto lo que le cobró el vendedor? Explica.	-	-
	A1: está bien <i>(short, lacks analysis)</i>	2	2.0
	A2: está mal la respuesta es 980 se multiplica 245 x4 y el resultado es 980 <i>(detailed reasoning)</i>	12	7.0
Exist a number in the answer	Q: Paulina tiene 16 lápices para repartir entre 4 amigas. Su mamá le dice a Paulina que le va a dar 5 lápices a cada amiga. ¿Es correcto lo que le dice su mamá?	-	-
	A1: no es mal porque no <i>(no number)</i>	0	3.0
	A2: la mamá está mal porque son 4 lápices para cada amiga <i>(includes number)</i>	1	7.0
Proportion of vowels in the answer	Q: Una manzana pesa 0,35 g, otra 0,251 g y la última 0,51 g. ¿Cuánto pesan entre las tres?	-	-
	A1: 150x1 es 51 <i>(low vowel ratio)</i>	0.25	4.0
	A2: sumo todas las manzanas es 1,111. y sumé 0,35 más 0,251 más 0,51 y me dio ese resultado <i>(more fluent)</i>	0.31	7.0
Max. consecutive non-vowel characters	Q: ¿Cuál es el resultado de 501x2? Comenta cómo resolviste el ejercicio y explica qué es la multiplicación.	-	-
	A1: Hkflg <i>(noisy token)</i>	5	1.0
	A2: es 1 002, lo resolví con sumas y la multiplicación es una suma repetida <i>(coherent)</i>	2	7.0

Table 5: Examples of five expert features with their feature values for question/answer pairs in the ASAG task in Chilean Spanish (examples presented in their original language, Spanish).

For these reasons, we propose an additional experiments where we train a logistic regression model on our interpretable vector of expert and natural language learned representations, using the scores from ULRA as a weak label. The results are shown in Table 8. We can see that the use of a more accurate weak signal does not allow to improve the global performances.

E Prompt used for Zero-shot ICL with LLM

Figure 6 is the prompt used for ASAG dataset. The model is guided to assign grades while disregarding spelling errors and focusing on the content of the student’s response. Figure 7 is the prompt used for Task 1 and Task 3-8 of the AES dataset, where the range of possible scores is task-specific and highlighted in blue, where `[[MIN]]` is the minimum score and `[[MAX]]` the maximum. Figure 8 presents the prompt for Task 2 of the AES dataset, which is the only task differing from the other eight tasks in its focus on grading according to *Writing Applications*. Throughout all figures, the orange text represents the model’s initial response.

Instruction and Model answer

You are a teacher who assigns grades (between 1 and 7) to fourth grade students’ answers to open-ended math questions. Do not discount for spelling or grammatical errors. Focus on what the student is trying to say with his or her answer. Indicate the grade after the prefix ‘Score:’

Got it. Give me a question between <Q></Q> and an answer between <A>. Then ask me ‘What is the score for the answer to the question?’. I will then give you the note after the prefix ‘Score:’

Follow-up instruction

Question: <Q> `[[Q]]` </Q> Answer: <A> `[[A]]` What is the score for the answer to the question?

Figure 6: Prompt used for Zero-shot ICL with LLM on the ASAG dataset. Translated from Spanish. the orange text represents a model’s initial response.

Feature Name	Type of Feature

Instruction and Model answer

You are a teacher who assigns grades (between [[MIN]] and [[MAX]]) to essays from students ranging in grade levels from Grade 7 to Grade 10. You will help me break down the 'assign grade to student essay' task. To do this, I will give you a sample essay along with the assignment. Indicates the score after the prefix 'Score:'.

Got it. Give me a question between <A> and an essay between <E></E>. Then ask me 'What is the score for the essay?'. I will then give you the score after the prefix 'Score:'.

Follow-up instruction

Assignment: <A> [[A]] Essay: <E> [[E]] </E> What is the score for the essay?

Instruction and Model answer

You are a teacher who assigns grades (between 1 and 6) to essays from students ranging in grade levels from Grade 7 to Grade 10. You will help me break down the 'assign grade to student essay according to Writing Applications' task. To do this, I will give you a sample essay along with the assignment. Indicates the score after the prefix 'Score:'.

Got it. Give me a question between <A> and an essay between <E></E>. Then ask me 'According to Writing Applications, what is the score for the essay?'. I will then give you the score after the prefix 'Score:'.

Follow-up instruction

Assignment: <A> [[A]] Essay: <E> [[E]] </E> According to Writing Applications, what is the score for the essay?

Figure 8: Prompt used for Zero-shot ICL with LLM on the Task 2 of the AES dataset. The orange text represents a model's initial response.

Figure 7: Prompt used for Zero-shot ICL with LLM on the Task 1 and Tasks 3 to 8 of the AES dataset. The blue text highlights the range of values specific to each task, while the orange text represents a model's initial response.

Feature Name	Coef.	Std. err.	[0.025	0.975]

Table 9: Coefficients of the Linear Regression with Signal Filtering using EF+NLLF features in the ASAG dataset. [0.025, 0.975] refers to the 95% confidence interval of the coefficient.

F Human validation of the NLLFs

F.1 NLLFG Classifiers

Here we analyze how accurate were the NLLF generated by the BERT-like model, and also the weak labels by the LLM. We took 190 examples from the validation set used to train the NLLFG of the ASAP task, and asked an expert to manually label them regarding the labels of a BSQ. More precisely, we manually annotated 10 examples sampled uniformly per BSQ having non-zero weights in the linear regressions (approximately 2-3 BSQs per essay set) across 8 essay sets. We compare the labeling of the expert with the outputs of the NLLFG and LLM models, using classical classification metrics such as precision, recall and F1-score.

The results for both the models are available in Table 10. The LLM obtained a better F1-score than the smaller transformer model, which was expected. It is interesting to note that the accuracy of the NLLFG model is 0.78, close to the ones of the LLM (0.86). The macro F1-scores are more divergent as the LLM reaches 0.84 and the NLLFG 0.74, which is still better than random.

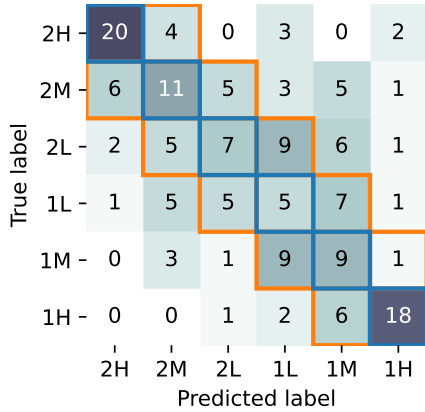

Model	Label	Prec.	Rec.	F1	Acc.
Mixtral	Yes	91	88	89	86
	No	76	82	79	
NLLFG	Yes	90	78	84	78
	No	57	76	65	

Table 10: Performance of NLLFG and Mixtral on a manually annotated set of 190 examples. The dataset consists of 10 uniformly selected examples per BSQ (approximately 2-3 BSQs per essay set) across 8 essay sets.

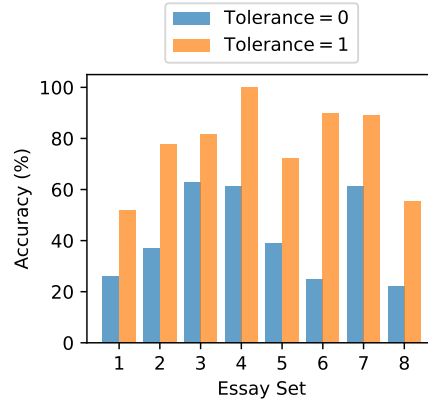

F.2 NLLFs Before the Linear Regression

We designed another experiment to assess the reliability of the NLLF with respect to human annotation, showing pairs of examples to a human, and asking which should have the highest value in NLLF and what is the distance in values between the examples of the pair. As the NLLF are normalized before the linear regression, hence each score depends on the whole group and becomes relative to the other examples (the best has a highly positive score and the worst has a highly negative score).

Pairs of examples with various distances in-

(a) Global Confusion Matrix

(b) Accuracies with tolerance 0 and 1

Figure 9: Metrics between the human annotation and the real values of the NLLFs, for the AES task.

Figure 10: Examples were picked from bins with **high**, **medium** and **low** distance between each others. For a pair of examples, the annotator has to find which example has the highest value, and what is the distance between the examples.

between the examples were randomly selected regarding their places in the distributions: pairs from the first and last deciles of the distribution, pairs from the 3rd and 8th, and pairs from the 5th and 6th. We ask a human to tell for each pair, which example is the highest in the distribution, and how large is the distance between them. It gave us a classification problem with 6 ordinal classes: First-High (1H), First-Medium (1M), First-Low (1L), Second-Low (2L), Second-Medium (2M), Second-High (2H).

We focused on the 19 BSQs having non-zero weights in the linear regressions, and randomly selected 3 examples of High, Medium and Low distances between the pairs, which gave us a total of 171 pairs to annotate coming from 6 classes. Figure 10 shows the bins of the examples from the different categories.

The results overall are shown in Figure 9, with the confusion matrix and the We report a Krippendorff (2013)’s alpha of 0.63, an Accuracy of 0.43

Table 11: Results on ASAG using the QWK

(random is 0.17) and an accuracy with a tolerance of 1 (Gaudette and Japkowicz, 2009) of 0.77 (random is 0.44). This shows that human rank the examples in an order similar to the ones of the NLLF values 77% of the time using a tolerance of 1 in the ordinal classification.

G Others

Table 11 shows the results on the ASAG dataset using QWK. The results are very similar: LLM is better than our method, which is itself better than ULRA.

A Survey on Automated Distractor Evaluation in Multiple-Choice Tasks

Luca Benedetto, Shiva Taslimipoor, Paula Buttery

ALTA Institute, Dept. Computer Science and Technology, University of Cambridge
name.surname@cl.cam.ac.uk

Abstract

Multiple-Choice Tasks are one of the most common types of assessment item, due to their feature of being easy to automatically and objectively grade. A key component of Multiple-Choice Tasks are distractors – i.e., the wrong answer options – since *poor* distractors affect the overall quality of the item: e.g., if they are obviously wrong, they are never selected. Thus, previous research has focused extensively on techniques for automatically generating distractors, which can be especially helpful in settings where large pools of questions are desirable or needed. However, there is no agreement within the community about the techniques that are most suited to evaluate generated distractors, and the ones used in the literature are sometimes not aligned with how distractors perform in real exams. In this review paper, we perform a comprehensive study of the approaches which are used in the literature for evaluating generated distractors, propose a taxonomy to categorise them, discuss if and how they are aligned with distractors performance in exam settings, and what are the differences for different question types and educational domains.

1 Introduction

Multiple-Choice Tasks are a very popular form of students' assessment, due to their standardised format: they are easy to (automatically) grade and they remove subjectivity from the scoring process, and can thus be used to quickly and efficiently assess large numbers of students, in both high-stakes and low-stakes settings. A challenging step of curating high-quality Multiple-Choice Tasks – also referred to as Multiple-Choice Questions (MCQs) – is the generation of distractors, i.e., the incorrect options. Indeed, high-quality distractors must satisfy several properties (see §2.3), such as being incorrect but plausible, and consistent with the context but objectively wrong. The generation of high quality distractors has been shown to be challenging

even for human experts (Shin et al., 2019), and to target this issue and generate large quantities of distractors (which are needed for large pools of questions) recent research has explored many approaches to automatically generate distractors, as discussed in two recent surveys (Awalurahman and Budi, 2024; Alhazmi et al., 2024). According to the assessment and testing literature (Nunnally and Bernstein, 1994), the most reliable approach to evaluate distractors is pretesting: new MCQs are shown to students in exam settings, and their response patterns are used to assess the distractors. Unfortunately, pretesting is unfeasible when automatically generating large numbers of distractors and undesirable in some settings, e.g., due to exam security concerns (Ha et al., 2019); thus, automatically generated distractors are most commonly evaluated with static approaches or with manual evaluation. However, the best techniques to automatically evaluate generated distractors are not commonly agreed across the community and the ones used in practice are rarely aligned with the performance of distractors in real exam settings. Hence, in this paper, i) we perform a comprehensive review of the approaches used in the literature for automated distractor evaluation, ii) we propose a new taxonomy to categorise them, iii) we discuss which ones are the most aligned with pedagogical theory and with the performance of distractors in real exam settings (also focusing on different educational domain and question types), and iv) provide some guidelines for future research.

2 Related Work

2.1 Distractor Generation

Two very recent surveys provide a good overview of approaches to distractor generation and the trends in the literature (Awalurahman and Budi, 2024; Alhazmi et al., 2024). Similarly to many other domains, distractor generation has seen a

rapid shift in recent years: the majority of approaches are now based on (large) language models, in contrast with research pre-transformers which was primarily based on traditional machine learning. We refer to the two survey papers mentioned above for a detailed description of the different techniques used in distractor generation.

2.2 Distractor Evaluation

The task of distractor evaluation is much less studied than distractor generation, even though it is becoming increasingly relevant: indeed, with modern generative models it is very easy to experiment with different prompts and generate a large set of distractors, and it is thus crucial to have ways to automatically and reliably evaluate them. Unfortunately, neither of the survey papers mentioned above focused sufficiently on the techniques and metrics which are used to automatically evaluate distractors. Considering fully automated metrics, [Alhazmi et al. \(2024\)](#) only mention ranking-based (Precision, Recall, F1-score, Mean Reciprocal Rank (MRR), Normalized Discounted Cumulative Gain (NDCG), and Mean Average Precision (MAP)) and n-gram metrics (BLUE, ROUGE, and METEOR), while [Awalurahman and Budi \(2024\)](#) only mentions BLEU, ROUGE and METEOR. While these are all metrics that are indeed used in the literature, this list leaves out many others, which are very relevant and potentially more aligned with the performance of distractors in exam settings.

Few papers have distractor evaluation as main focus, proposing automated approaches for the task. [Pho et al. \(2015\)](#) work on distractors that are Named Entities in a knowledge graph, and propose an approach to evaluate them based on the syntactic and semantic relation between the distractors and the correct answer, and their relatedness in the graph. [Ghanem and Fyshe \(2023\)](#) generate “bad distractors” and train a model to estimate whether a given distractor is good or bad. Finally, [Raina et al. \(2023\)](#) propose an ensemble of three metrics which are meant to measure the incorrectness, plausibility, and diversity of distractors.

2.3 About Good Distractors

The educational literature is rich in recommendations and guidelines on how to create good distractors for MCQs. Ideally, these guidelines should be implemented within the models for automated distractor generation and evaluation, but our literature review suggests that in many cases the approaches

used for evaluating automatically generated distractors in the NLP and AI for Education communities are somewhat disconnected from them. It is important to note that there are differences between educational domains – e.g., guidelines for language learning and mathematics cannot be exactly the same – but there are many common aspects. Distractors that are too easy fail to assess students’ true understanding, while those that are too difficult or misleading can cause confusion and frustration; thus, distractors should be plausible, but objectively unacceptable ([Yeung et al., 2019](#)). Potentially, distractors should try to capture the common errors and misconceptions of students ([Lee et al., 2016](#); [Scarlatos et al., 2024](#)), which enables targeted interventions. Also, distractors should be independent from one another, otherwise one or more could be excluded with logical reasoning, thus hindering the quality of the question. Distractors should be semantically and grammatically coherent with the context ([Ghanem and Fyshe, 2023](#); [Gao et al., 2019](#)), and similar in length, style, and grammatical form to the correct answer ([Pho et al., 2015](#)). In language pedagogy literature, there is the recommendation that the target word and the distractors belong to the same word class ([Heaton, 1988](#)), ideally being “false synonyms” ([Goodrich, 1977](#)).

3 Taxonomy

Figure 1 presents the taxonomy we propose to categorise approaches from the previous literature. We group the different approaches based on the type of information that they use for evaluation. **Dynamic** approaches are based on learners’ answers, and **static** approaches leverage only the textual information from the distractors (and potentially the correct answer, the question, and the reading passage). Dynamic approaches (§4), and specifically *Traditional Distractor Analysis*, can be seen as the *gold standard*, since they are based on students’ responses and are an actual measurement of how distractors perform in exam settings; they can be further divided into approaches based on real students and the ones based on *responses from Question Answering (QA) models*. On the other hand, static approaches (§5) can be seen as an alternative to dynamic ones, as they can be used when it is unfeasible to obtain students’ responses. Static approaches can be further divided into three groups: i) *comparative* approaches evaluate generated distractors by comparing them to some refer-

Figure 1: The taxonomy we propose to categorize the different approaches for Distractor Evaluation (DE).

ence ones, which are considered as gold standard, ii) *stand-alone* approaches consist in computing some measures of similarity between distractors and between distractors and the correct answer, and iii) *learned* approaches are machine learning models trained to predict the quality of generated distractors. From a practical point of view, there are notable similarities between distractor generation evaluation and difficulty estimation. In difficulty estimation, the gold standard is difficulty from pretesting – e.g., from Item Response Theory (Hambleton and Swaminathan, 2013) – but approaches have been proposed for difficulty estimation from text for when students’ responses are not available (Benedetto et al., 2022).

Previous approaches are described in Sections 4 and 5, and Table 1 provides an overview of all the papers we discuss in this survey, grouped according to the proposed taxonomy. The table also shows the educational domain which each paper worked on, whether manual evaluation is used in addition to automated evaluation metrics, and whether distractors are evaluated individually or as a set.

4 Dynamic Approaches

Dynamic approaches to distractor analysis use students’ responses to measure how well distractors perform in exams. They can be further divided into **traditional distractor analysis** §4.1 and **AI-based dynamic approaches** §4.2, depending on whether human or virtual students’ responses are used.

Traditional distractor analysis is most commonly used in the Education and Assessment literature: it studies how distractors perform in real exams, observing the response patterns of human students, and can thus be considered the *optimal* approach

to distractor evaluation. When it is unfeasible to use traditional distractor analysis due to cost, time constraints, or concerns about safety, AI-based dynamic approaches can be used. These are based on same techniques, but use the responses of QA models as a proxy for the responses from real students. Similar to difficulty estimation tasks, which are ideally performed via pretesting with real learners, research explored the possibility of using machine learning and AI to simulate it (Benedetto et al., 2022; AlKhuzayy et al., 2021). This includes the setting of virtual pretesting, which became more popular in recent years (Park et al., 2024; Uto et al., 2024; Benedetto et al., 2024).

Previous research also experimented with some approaches based on the responses of human learners but different from the ones used in traditional distractor analysis; they will be discussed in §4.3.

4.1 Traditional Distractor Analysis

Traditional distractor analysis is based on studying how often distractors are selected, and which is the (average) skill level of the learners selecting different distractors. Again, these metrics are based on how distractors perform in real exam settings, thus can be considered as the *optimal* ones.

Distractors that are never (or rarely) selected by students are *poor* distractors (Nunnally and Bernstein, 1994); the rule of thumb mentioned in several papers is that each distractor should be selected by at least 5% of the students (Haladyna and Downing, 1993), with the exception of very easy MCQs, which are correctly answered by more than 90% of the students (Gierl et al., 2017). Only three articles evaluate automatically generated distractors using the frequency with which participants select each

Table 1: List of the papers discussed in this survey, grouped according to the proposed taxonomy.

of them: (Aldabe and Maritxalar, 2010; Zhang and VanLehn, 2021; Lee et al., 2016).

Another indication of distractor quality from the Education literature is the difference between the number of students selecting each distractor and the number of students selecting the correct answer: if a distractor is chosen more often than the correct answer, this is probably an indication of poor instructions or a misleading question (Nunnally and Bernstein, 1994). We did not find any paper evaluating generated distractors with this metric.

Lastly, since a good distractor is one that is selected by students who perform poorly and ignored by those who perform well (Gronlund, 1968), distractors that are selected by students that are (on average) of higher skill level than the students selecting the correct choice are poor distractors. We found only two papers using this factor to evaluate automatically generated distractors: Mitkov and Ha (2003) and Lee et al. (2025) divide students into a group of highly skilled students and a group of beginners, and label distractors that are selected by more students in the upper group than by students in the lower group as poor distractors.

4.2 AI-based Dynamic Approaches

Fundamentally, these use measurements similar to the ones from traditional distractor analysis, but based on the responses from QA models rather than human learners. Using machine learning models as a proxy of students, they should be validated accordingly. This is rarely done in the literature.

Chung et al. (2020) make the assumption that poor distractors will reduce the difficulty of the MCQ task for a QA model, thus use accuracy as an indicator of distractor quality, by comparing distractors generated with different models: the higher the accuracy, the worse the quality of the distractors. Similarly, Offerijns et al. (2020) study how the accuracy of a QA model changes when using manually-curated distractors rather than automatically generated ones: they observe that results are similar, thus claim that the generated distractors are on-par with the human-curated ones.

Guo et al. (2024) use the generated distractors to augment a dataset, which is then used to train a QA model. The quality of generated distractors is evaluated by measuring the QA accuracy on a separate test set: a better performance on the test set would indicate that the generated distractors were effective for training the model, and thus they are good distractors.

4.3 Others

Some papers use human responses for distractor evaluation, but in a setting different from traditional distractor analysis. Kalpakchi and Boye (2021) recruit participants on a crowd-sourcing platform and ask them to answer reading comprehension MCQs without providing them with reading passages. The authors claim that this approach can evaluate the *plausibility* of distractors by measuring how often they are selected. Luo et al. (2024) compare the response accuracy of three students on questions with distractors generated with different models, and claim that lower accuracy in responding to a question would indicate that there were better distractors. Yoshimi et al. (2023) evaluate distractors by measuring how the response accuracy of human annotators changes when using the original compared to generated distractors, aiming to make the accuracy as close as possible in the two settings. This is similar to the approach by Offerijns et al. (2020) but using humans rather than QA models.

5 Static Approaches

Static approaches evaluate distractors using only the content of the items, without considering learners' responses. Importantly, most of these approaches are not aligned *per se* with how distractors would perform in real exam settings, thus they should be validated (but often are not, in previous literature). They can be divided into *Comparative*, *Stand-alone*, and *Learned* approaches.

5.1 Comparative

Comparative approaches are based on a comparison between generated distractors and the reference ones available in the test dataset: this assumes that these reference distractors are of good quality and are the *only* distractors of good quality for a question. In other words, any generated distractor which is different from the reference ones is massively penalised. Both assumptions are somewhat problematic for distractor evaluation: experimental datasets often do not contain high-quality pretested questions (particularly the publicly available ones), and it might happen that other distractors are as effective, if not better, than the ones in the datasets. This disadvantage comes from the fact that most comparative approaches were not originally thought of for distractor evaluation, but rather for Machine Translation, and thus have fundamental issues when it comes to distractor eval-

uation (Rodriguez-Torrealba et al. (2022); Taslimipoor et al. (2024), inter alia). However, even with these major shortcomings, they are by far most commonly used approaches to evaluate new distractor generation models, due to their popularity and ease of implementation.

5.1.1 String Matching

String matching is the single most frequently used approach for distractor evaluation in the literature. Most papers used BLEU (Papineni et al., 2002) and/or ROUGE (Lin, 2004) to compare the generated distractors with reference ones in the experimental datasets (see Table 2 for the list of all papers). Other common metrics are Precision, Recall, F1-score, MRR, and NDCG (the list of papers is shown in Table 3). Notably, this distinction is also due to the fact that papers in the two tables mostly work on different types of questions: papers in 2 mainly work with reading comprehension questions with longer text answers, while papers in 3 mainly work with either cloze items or science tests with single word or named entity answers.

Paper	BLEU	ROUGE
(Gao et al., 2019)	X	X
(Zhou et al., 2019)	X	X
(Chung et al., 2020)	X	X
(Qiu et al., 2020)	X	X
(Maurya and Desarkar, 2020)	X	X
(Offerijns et al., 2020)	X	X
(Rodriguez-Torrealba et al., 2022)	X	X
(Xie et al., 2022)	X	X
(Qu et al., 2023)	X	X
(Login, 2024)	X	X
(Zhou and Li, 2024)	X	X
(Qu et al., 2024)	X	X
(De-Fitero-Dominguez et al., 2024)	X	X
(Luo et al., 2024)		X
(Lin et al., 2024)	X	X
(Taslimipoor et al., 2024)	X	
(Wang et al., 2025)	X	X

Table 2: List of papers using BLEU and/or ROUGE.

Other papers evaluated generated distractors using metrics based on string matching, but different from the metrics mentioned above. Liang et al. (2018) and Bitew et al. (2022) use Mean Average Precision, Luo et al. (2024) use Accuracy, and Kalpakchi and Boye (2021) measures the fraction of MCQs for which at least one generated distractor matches one of the reference ones.

McNichols et al. (2023); Feng et al. (2024); Fernandez et al. (2024), and McNichols et al. (2024) (all working on maths questions) define and use three *alignment-based* metrics: i) *partial match*

Paper	Precision	Recall	F1	MRR	NDCG
(Liang et al., 2018)	X	X		X	X
(Kalpakchi and Boye, 2021)		X			
(Ren and Zhu, 2021)	X		X	X	X
(Bitew et al., 2022)	X	X		X	
(Chiang et al., 2022)	X		X	X	X
(Panda et al., 2022)	X	X			
(Wang et al., 2023)	X	X	X		
(Yoshimi et al., 2023)			X		
(Dutulescu et al., 2024)	X		X	X	X
(Yu et al., 2024)	X	X	X	X	X

Table 3: List of papers using Precision, Recall, F1 score, Mean Reciprocal Rank, or NDCG for evaluation.

evaluates whether at least one of the generated distractors matches one of the reference ones, ii) *exact match* evaluates whether all the generated distractors match the reference ones, and iii) *proportional match* measures the proportion of generated distractors which match the reference ones. In addition to these three metrics, Scarlatos et al. (2024) define *weighted proportional*, which is a reinterpretation of the proportional match: it re-weights each “match” in the proportional metric giving more importance to reference distractors which are most commonly selected by students. Notably, considering all the evaluation metrics based on string matching, this *weighted proportional* is the only one which explicitly takes into consideration how well distractors perform in real exams.

5.1.2 Semantic Similarity

Several articles evaluate generated distractors by measuring their semantic similarity to the reference ones, using diverse techniques for capturing the semantic meaning of distractors and their distance from the reference ones. While this is arguably more reliable than string matching, it still relies entirely on the quality of distractors in the experimental dataset. The most common approach is BERTScore (Zhang et al., 2019), which is used by Login (2024); Qu et al. (2024, 2023) to compute the similarity between generated distractors and the reference ones. Other embedding techniques are used in other articles: Ren and Zhu (2021) use Word2Vec (Mikolov et al., 2013), Maurya and Desarkar (2020) use BERT (Devlin et al., 2019) embeddings, and more recently Taslimipoor et al. (2024) apply Sentence-BERT (Reimers and Gurevych, 2019) to compute similarity. Notably, no one of these papers give weights to how different reference distractors perform in real exams.

5.1.3 Hybrid lexical-semantic

As a middle-ground between the purely lexical string matching approach described in §5.1 and the semantic embeddings from §5.1.2, some papers used METEOR (Banerjee and Lavie, 2005) for evaluating the similarity between generated and reference distractors. Specifically, it was used by Login (2024); Zhou and Li (2024); Maurya and Desarkar (2020); Xie et al. (2022); Lin et al. (2024). This has the same limitations as the approaches described above, as it relies entirely on the quality of the reference distractors, and implies that those are the only good distractors for a given question.

5.2 Stand-alone Approaches

Stand-alone approaches are all the evaluation techniques which are based on textual information only and do not rely on reference distractors. As such, they are meant to detect high-quality distractors even when these do not match some reference ones, and are not susceptible to low-quality distractors in the reference data. Most of these evaluation metrics are meant to capture the *plausibility* and *diversity* requirements of good distractors.

5.2.1 Estimating plausibility

Pho et al. (2015) focus on the relatedness between the distractors and the correct answer option, primarily working on questions whose responses are named entities. The semantic similarity is then measured looking at the distance between the named entities of each distractor and the correct answer option in a taxonomy of named entities.

Plausibility is modelled as the cosine similarity between each generated distractor and the correct answer option in (Rodriguez-Torrealba et al., 2022; De-Fitero-Dominguez et al., 2024). The authors state that higher similarity to the correct answer option means better distractors and use such approach for evaluating the distractors. Still, they do not study the correlation between the results obtained with their evaluation metric and an evaluation based on students’ responses, thus this metric might reward distractors which are too close to the correct answer, and thus low quality.

A different take on plausibility is taken by Raina et al. (2023): they define *plausibility* as the sum of the confidence scores of a multiclass QA model for each of the distractors. This approach assumes that the confidence of a MCQA model is a good proxy of the confidence of real students, and evaluates this assumption by using a dataset which provides sta-

tistical information about how often distractors in the dataset are selected by real students (Mullooly et al., 2023); this is one of few works validating the metrics used for distractor evaluation.

5.2.2 Estimating diversity

More papers focused on studying the diversity of generated distractors, using Pairwise-BLEU, Distinct (Li et al., 2016), or other techniques. Pairwise-BLEU is used by Qu et al. (2023) and Wang et al. (2025), while Distinct is used by Qu et al. (2024) and Qu et al. (2023). Two different approaches are used by Raina et al. (2023), who use the BERT Equivalence Metric (BEM) (Bulian et al., 2022), and Taslimipoor et al. (2024), who use Sentence-BERT to measure the semantic similarity between different generated distractors. In all these papers the authors claim that high diversity is desirable, hence similarity between distractors should be low.

5.2.3 Others

Kalpakchi and Boye (2021) propose a set of evaluation metrics, including several stand-alone approaches different from all the approaches used by other papers. Most of them are filters which could actually be implemented within a DG model itself, and include measures such as i) the fraction of MCQs with two or more generated distractors which are equal, ii) the fraction of MCQs for which generated distractor match the correct answer, and others (we refer to the paper for the full list).

5.3 Learned Approaches

Learned evaluation metrics are machine learning models – with different architectures – specifically trained to evaluate the quality of generated distractors. Several approaches have been used in the literature, and they try to capture different characteristics that good distractors are expected to have. Notably, these approaches are on average the most recent of all the papers surveyed.

The first learned metric to evaluate generated distractors was proposed by Ghanem and Fyshe (2023), which is one of the few papers exclusively focusing on the evaluation of generated distractors. The proposed approach consists in automatically generating *bad distractors*, and training a model to estimate whether a distractor is good or bad (i.e. binary classification); the metric is validated with manual evaluation. A similar approach is used by Raina et al. (2023) and Qu et al. (2024). In the first paper, a model is trained to distinguish between

the correct answer option and the distractors, in a binary classification setting; the probability that such trained model assigns to each distractor (more specifically, $1 - P$) indicates *how incorrect* each distractor is.¹ In the latter, an Alberta model is trained to predict whether a given distractor is a correct answer to the corresponding question, and return a classification score in the range $[0, 100]$; the authors refer to this as *faithful score*.

Three papers focused on learned approaches to estimate the plausibility of generated distractors. In two of them (McNichols et al., 2023; Feng et al., 2024) the authors, who define plausibility as the likelihood of a distractor being selected by real students, compute it by training a BERT-based machine learning model on real students’ responses to predict the fraction of students selecting each distractor. The trained model assigns a probability score to each distractor, and these scores are then combined in two ways: i) by summing the selection probability of all distractors, and ii) by computing the entropy among them (to make sure that all are selected with reasonable frequency by students). In the third (Lee et al., 2025), the authors train a pairwise ranker to select, given a pair of distractors, the more plausible. Ground truth plausibility is estimated from students’ responses, thus this metric is aligned distractor performance in exam settings.

Finally, in one paper which performs distractor generation via reinforcement learning from preference feedback (Wang et al., 2025), the authors leverage the same reward model that was used in training during the reinforcement learning phase to then evaluate the generated distractors.

6 Discussion

6.1 Alignment with exam performance

Considering all the evaluation approaches described above, the only ones which are by definition aligned with how distractors perform in real exam settings are the techniques from traditional distractor analysis (§4.1), since they evaluate distractors based on the responses of real students. We argue that these approaches should be used whenever possible. Unfortunately, in most cases, that is not feasible, and some alternative approaches have to be used. In all these cases, it is important to validate the evaluation approach to ensure that they align with the exam performance of distractors, but this

¹The metric is validated using student response data from a publicly available dataset (Mullooly et al., 2023).

is rarely done in the literature. The main reason for this is that most of the publicly available datasets – e.g., RACE (Lai et al., 2017), SQuAD (Rajpurkar et al., 2016), or the MCQ dataset by Ren and Zhu (2021) – do not provide such information, thus it is impossible to properly validate the evaluation metrics on them and all evaluations are built upon weak foundations. One notable exception is the Cambridge MCQ Reading Dataset (Mullooly et al., 2023), which contains an indication of how often distractors are selected by students in real exam settings: the dataset contains both *good* and *bad* distractors, and can thus be used to validate different evaluation metrics. Similarly, private datasets, such as the Eedi dataset used by Scarlatos et al. (2024) and others, likely contain statistics about students’ responses, and thus provide the information needed to validate the evaluation metrics (as it is done for the weighted proportional metric described in §5.1.1). However, they are inaccessible for the wider research community.

6.2 Evaluating individual distractors and distractor sets

The taxonomy proposed in §3 categorises evaluation metrics based on the information used for evaluating generated distractors. However, another relevant dimension to consider is whether evaluation metrics work on individual distractors or distractors as a set of options. Indeed, distractors should ideally be evaluated with both, since they capture different aspects in relation to designing a good question item. The number of papers that evaluate distractors individually is an overwhelming majority in the literature, and only few use metrics that consider distractors as a set, as shown in Table 1.

All the comparative approaches in §5.1 focus on evaluating individual distractors. While this is very relevant, as it can help detect distractors which are too close to or too far from the correct answer option, it is a suboptimal evaluation. Indeed, in real exam settings distractors are shown to students in a set of (usually) four items (one being correct), and distractor evaluation metrics should also consider the similarity and differences between the distractors – thus evaluating *sets* of distractors. Notably, even considering the papers which perform a manual evaluation of the distractors, these are evaluated individually (e.g., annotators are asked to classify each of them as *acceptable* or *not acceptable* (although out of the main scope of this survey paper, we include an analysis of manual evaluation in the

appendix §A). From our analysis, a total of 15 papers (out of the 40 doing automated evaluation) use automated metrics that evaluate distractors as a set rather than as individual items.

6.3 Educational domains and question types

In the context of distractor generation and evaluation for MCQs, question types and educational domains play a crucial role in designing effective evaluation metrics. These factors influence the characteristics of distractors and the criteria used to assess their quality. The subject or educational domain influences the complexity, language, and knowledge required for distractor evaluation. For instance, in science and mathematics, evaluation metrics should check for scientific validity or in language learning, like in reading comprehension questions, evaluation should assess linguistic similarity and conceptual relevance. These aspects of evaluation have not been investigated explicitly in the literature, however we can see that for example almost all papers experimenting with the RACE dataset for reading comprehension, evaluate distractors using metrics from machine translation (see Table 2) while most distractor generations in the domain of science (Liang et al., 2018; Ren and Zhu, 2021; Bitew et al., 2022; Dutulescu et al., 2024) or with Cloze-style questions (where answers and distractors are single words or named entities) (Chiang et al., 2022; Panda et al., 2022; Wang et al., 2023; Yoshimi et al., 2023; Yu et al., 2024) are mainly evaluated using ranking based statistical measures (see Table 3).

6.4 About manual evaluation

Although not discussed in this survey, since our focus is on automated metrics which could be used in an automated generation and evaluation pipeline, manual evaluation is still used by the majority of papers (see Appendix A), sometimes in addition to the automated metrics and in other cases as the single evaluation approach. Annotators are domain experts, or the authors themselves, or recruited from crowd-sourcing platform – thus leading to annotations of varying reliability.

7 Conclusions

In this survey paper we have performed a comprehensive study of the metrics and techniques which are used to automatically evaluate generated distractors in the context of Multiple-Choice Tasks, and have proposed a taxonomy to categorise them.

We have seen that there is not a commonly agreed metric in the literature, and different authors and research groups tend to use different evaluation techniques. Most importantly, the metrics which are most commonly used in the literature (e.g., BLEU and ROUGE) are sub-optimal and arguably not aligned with how distractors actually perform in exams: indeed, they evaluate newly generated distractors by comparing them with some reference ones assuming that the references are i) of high quality and ii) the only distractors of high quality that can be created for the given question. Both assumptions are very strong, and not really supported by previous research, especially for publicly available datasets such as RACE (which is one of the most commonly used datasets).

Ideally, distractors should be evaluated with Traditional Distractor Analysis (i.e., with real learners) but, when this is not possible, the evaluation metrics used in its place should aim at being more aligned with how distractors perform in real exam settings and with the requirements that good distractors are expected to satisfy (according to vast literature from Education and Assessment), such as being consistent and coherent with the question and the correct option, and being plausible enough to *distract* learners. This highlights the need for validating the evaluation metrics which are used in distractor generation and evaluation settings and developing new, more aligned, ones. The development of such metrics should also take into consideration the differences between different educational domains, as the requirement might be different depending on the specific application scenario.

Limitations

When collecting the papers to review, we have performed several searches and used snow-balling to collect all the relevant publications which we could find. However, there is always a possibility that we might have missed some relevant research works. Also, we have highlighted the limitations of the current approaches to distractor evaluation, and this survey paper serves as motivation to focus more on the evaluation of distractors but, at this stage, we do not have an alternative approach to propose that might target these issues (yet).

A On Manual Evaluation

Even though manual evaluation is not scalable to large amounts of distractors and cannot be used in a fully-automated content generation pipeline, it is still the most commonly used approach to evaluate distractors in distractor generation papers. From our analysis, a total of 23 papers out of 40 use manual evaluation in addition to automated evaluation; in addition to these, we also find 9 papers where the manual annotation is the only evaluation that is performed.

There are not commonly agreed guidelines on how to evaluate the distractors manually, and different papers follow different approaches and provide different labels, in some cases limiting the annotation to *good* and *bad* distractors, and in some other cases ranking on a Likert scale (e.g., from 1 to 5) some aspects of the distractors. In general, we observe that the annotators are either asked to provide an overall evaluation of the distractors (i.e., whether they are *good* distractors), or evaluate them according to the following aspects: plausibility (also referred to as distracting ability), fluency, coherence with the text (also referred to as validity), diversity (between the generated distractors), and being related to students' misconceptions. Notably, only two papers explicitly ask annotators to evaluate the diversity of the generated distractors – thus evaluating them as a set – and most of the papers perform an evaluation of individual distractors. Table 4 provides an overview of which of these aspects are considered in the different papers which perform manual evaluation of distractors.

Alignment Drift in CEFR-prompted LLMs for Interactive Spanish Tutoring

Mina Almasi and Ross Deans Kristensen-McLachlan
Department of Linguistics, Cognitive Science, and Semiotics
Aarhus University, Denmark
mina@cc.au.dk, rdkm@cc.au.dk

Abstract

This paper investigates the potentials of Large Language Models (LLMs) as adaptive tutors in the context of second-language learning. In particular, we evaluate whether system prompting can reliably constrain LLMs to generate only text appropriate to the student's competence level. We simulate full teacher-student dialogues in Spanish using instruction-tuned, open-source LLMs ranging in size from 7B to 12B parameters. Dialogues are generated by having an LLM alternate between tutor and student roles with separate chat histories. The output from the tutor model is then used to evaluate the effectiveness of CEFR-based prompting to control text difficulty across three proficiency levels (A1, B1, C1). Our findings suggest that while system prompting can be used to constrain model outputs, prompting alone is too brittle for sustained, long-term interactional contexts - a phenomenon we term **alignment drift**. Our results provide insights into the feasibility of LLMs for personalized, proficiency-aligned adaptive tutors and provide a scalable method for low-cost evaluation of model performance without human participants.

1 Introduction

The popularization of large language models (LLMs), particularly through the emergence of user-friendly interfaces such as ChatGPT, has led many stakeholders across society to consider how to use such technology effectively and safely to facilitate access to knowledge and education (Yan et al., 2024). Language education has not been immune to this hype, and with seemingly good cause, since LLMs show potential across a range of areas where they might enhance language learning.

One such area is their inherent *interactivity*. Interactive feedback is widely regarded as an important factor in second-language (L2) learning (Loewen and Sato, 2018). For L2 learners far removed from their target language community, op-

portunities for such interaction can be rare. With LLMs, though, learners appear to now have the opportunity to engage with a "speaker" of the target language freely and at their own pace (Kohnke et al., 2023). Other potential benefits include personalized teaching (Klimova et al., 2024) and reduced L2 anxiety (Hayashi and Sato, 2024).

These ideas build on decades of research on intelligent tutoring systems and computer-assisted learning (Psootka et al., 1992; Slavuj et al., 2015). In contrast to earlier rule-based approaches (D'Mello and Graesser, 2023), appropriately implemented LLMs may offer a more adaptable and effective solution. However, current use of LLMs in language learning mostly relies on general-purpose tools like ChatGPT, where learners are encouraged to acquire "prompt-engineering" skills to get the most out of their AI language tutor (Hwang et al., 2024). It remains unclear exactly how effective and appropriate this approach is for creating successful language tutoring technology.

This paper takes steps to address this problem by examining whether, and to what extent, the complexity of LLM outputs can be constrained through prompting based on the Common European Framework of Reference for Languages (CEFR). We find that, while prompting may initially constrain LLM outputs in Spanish, these effects diminish over time. We refer to this as **alignment drift**, arguing that system prompting may prove to be too unstable for sustained, longer interactions.

2 Related Work

2.1 Exploring the Use of LLMs as Language Tutors

While a growing body of work considers LLMs as interactive language tutors (Kohnke et al., 2023; Lin, 2024; Kostka and Toncelli, 2023), empirical research is limited, and many questions remain unanswered (Han, 2024). Nevertheless, the few stud-

ies that have been conducted so far offer promising results on the benefits of using LLMs as language tutors, particularly in L2 English learning (Tyen et al., 2022, 2024; Zhang and Huang, 2024). Among other findings, Tyen et al. (2024) reported that users enjoyed interacting with LLMs more than plain reading and responded well to adaptive difficulty in interactions. Adaptive cognitive tutors hence have the potential to contribute positively to *motivation*, a psychological process increasingly viewed as crucial to L2 learning outcomes (Dornyei and Ryan, 2015).

2.2 Assessing L2 Proficiency with CEFR

Defining what it means to be "proficient" in an additional language is not a trivial task, with numerous definitions proposed (Park et al., 2022). Of these, the CEFR is particularly well known. Since its introduction in 2001, the framework has been highly influential in assessing L2 proficiency. Unlike previous approaches with a strong focus on grammatical competency, the CEFR emphasizes social and communicative competences (Leclercq and Edmonds, 2014).

The CEFR comprises a six-level scale (A1, A2, B1, B2, C1, C2) with A1 as the beginner level and C2 as the most advanced. Several official ways have been developed to represent these proficiency levels, each with language-agnostic descriptions (Council of Europe, 2025a). For instance, the *CEFR Global scale* offers a concise, three- to four-sentence summary of each level, designed as a holistic overview to facilitate communication with non-specialist users. However, its creators acknowledge that it is "desirable" to present the CEFR levels in "different ways for different purposes." (Council of Europe, 2025b). The *Self-assessment grid*, which provides separate definitions for skills like speaking and writing at each level, has little to no focus on grammatical content (Council of Europe, 2025d).

2.3 Adapting Text Difficulty with LLMs

The potential for LLMs to produce simpler text for improved accessibility has not gone unnoticed (Freyer et al., 2024). Indeed, the CEFR framework has been used alongside LLMs to simplify learning materials in French (Jamet et al., 2024); and for a range of purposes in English, such as general writing (Uchida, 2025) and simplifying or writing stories (Malik et al., 2024; Imperial and Tayyar Madabushi, 2023). Alfter (2024) also attempted

to generate CEFR-aligned vocabulary lists using LLMs across five languages, including Spanish and French, but found performance issues outside of English.

Common to these studies is the use of prompting. Notably, Malik et al. (2024) demonstrated that GPT-4 made fewer errors generating stories at the desired proficiency level as the detail about CEFR increased in the prompts. In contrast, Alfter (2024) found that using numeric levels from 0 to 4 was more effective than explicitly mentioning the CEFR, although the prompts had no description of the levels.

Beyond prompting, other approaches include fine-tuning (Malik et al., 2024) or experimentation with decoding strategies. For example, Tyen et al. (2022) experimented with different decoding strategies for constraining LLM text difficulty to CEFR levels, using a classifier fine-tuned on Cambridge English exam sentences (Xia et al., 2016), to select the best LLM-generated sentence for the user. A similar approach was used by Glandorf and Meurers (2024), focusing on grammatical constructs for different CEFR levels in English.

We identify some gaps in the literature. Firstly, most studies focus on English, with only a few exceptions (Jamet et al., 2024; Alfter, 2024). Moreover, aside from Tyen et al. (2022, 2024), all studies focus on single generations rather than longer chats. This paper thus contributes to the literature by addressing chat-based scenarios in an additional language, Spanish.

2.4 Simulating Dialogues with LLMs

One challenge when evaluating LLM performance in chat-based scenarios is the cost of human participants, particularly during initial testing. Tyen et al. (2022) addressed this by using "self-chatting", where the model interacts with itself, although no further specification was provided. More broadly, dialogue simulation using LLMs have emerged with the purpose of refining chatbots with the generated data (Sekulic et al., 2024; Tamoyan et al., 2024). Specific teacher-student dialogue simulation remains under-explored, although some work exists such as simulating Q/A scenarios (Abbasiantaeb et al., 2024).

In this paper, we therefore simulate teacher-student interactions using LLMs in order to determine the robustness of CEFR-based prompting for constraining text difficulty in Spanish. To our knowledge, this study is the first to simulate both

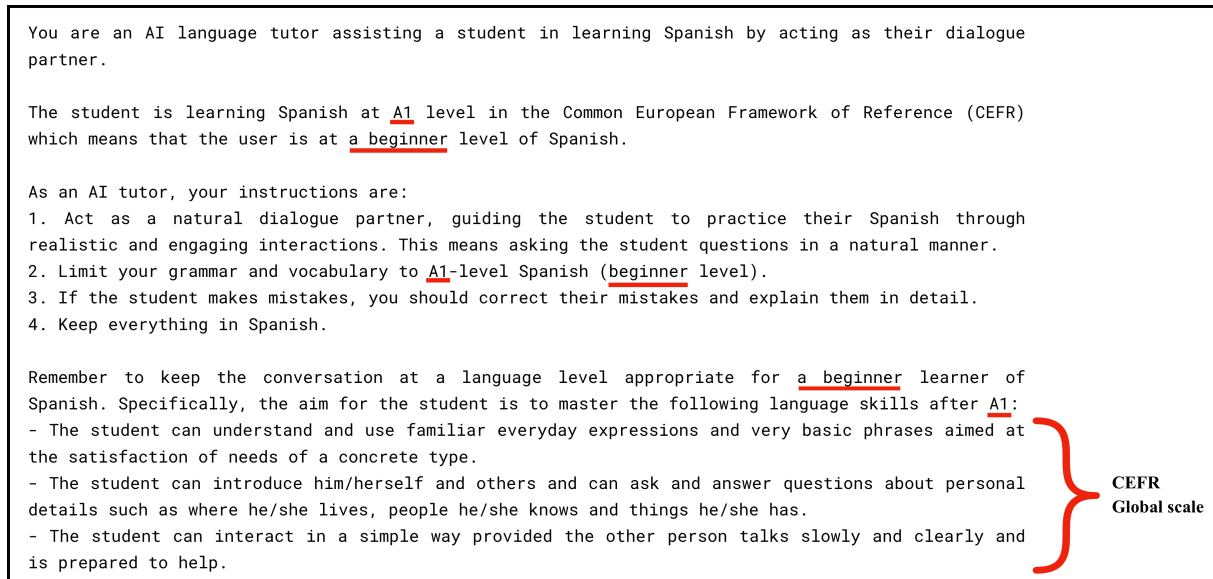

Figure 1: System prompt provided to each tutor LLM for level A1. Level-specific words are underlined in red and replaced for B1 and C1 (see Appendix A.3). The list in curly brackets is from the CEFR Global Scale (Council of Europe, 2025b).

the teacher and student perspectives through system prompts in the context of language learning.

3 Experimental Design

Data generation (Section 3) and analysis (Sections 4 & 5) were carried out in Python (v3.12.3), with the exception of running linear mixed effects models in R (v4.4.3). All code and the dataset is available on the GitHub repositories:

- Generation: [INTERACT-LLM/Interact-LLM](#) (Version tag: v1.0.3-alignment-drift)
- Dataset & Analysis: [INTERACT-LLM/alignment-drift-llms](#)

3.1 Model Selection and Implementation

We choose to focus on smaller, state-of-the-art open-source LLMs in the range 7B to 12B. With the exception of Mistral, their official reports mention multilingual capabilities. All models are instruction-tuned for chatting:

- **Llama-3.1-8B-Instruct** by Meta (Grattafiori et al., 2024)
- **Gemma-3-12B-IT** by Google (Gemma Team et al., 2025)
- **Mistral-7B-v0.3-Instruct** by Mistral AI (Jiang et al., 2024)
- **Qwen-2.5-7B-Instruct** by Alibaba Cloud (Qwen Team et al., 2025)

For convenience, we refer to the models simply as Llama, Gemma, Mistral, and Qwen. For details about the inference, including the hyperparameters, see Appendix A.1.

3.2 Teacher-Student Dialogue Simulation

We simulated a language tutoring scenario by deploying an LLM with separate chat histories as both the "tutor" and "student". Current LLM systems are stateless (Yu et al., 2025), with the entire chat history being processed by the model during each interaction. This allowed us to instantiate a single LLM object, and then interchange the chat history, maintaining one history for the student and another for the tutor (see the graphical overview in Appendix A.2).

We ran simulations for three different system prompts, designed to instruct the LLM to match its responses to the proficiency level of a beginner (A1), intermediate (B1), and advanced (C1) Spanish language learner.¹ Across the three levels, the dialogue began with a fixed initial message, "Hola",² sent by the "student". By standardizing the initial message, we eliminated variability in the student LLM responses which could influence the tutor LLM's output. This enabled a direct comparison of how the system prompt impacted the tutor LLM's first message across levels.

¹See Section 3.3 for details on how the system prompts were defined.

²Tyen et al. (2022) also begin all chats with a "Hello".

Despite being instructed to "keep everything in Spanish" (Figure 1), a number of models generated non-Spanish text.³ For instance, Gemma and Llama tended to include English content. This happened primarily for the A1 level, where they sometimes provided English translations in parentheses alongside their Spanish sentences. Also, Qwen occasionally switched mid-generation to Mandarin Chinese. To avoid confounding our analysis, we applied a simple language detection algorithm to the tutor LLM's outputs using the Python library *lingua*.⁴ If English or Mandarin was detected in any sentence, we re-generated the tutor LLM's response before continuing the dialogue.

A total of 30 dialogues were simulated for each of the three system prompts per LLM, resulting in 90 dialogues for each LLM and 360 overall. Each dialogue consisted of nine turns.

3.3 System Prompts

We created custom system prompts in English for the tutor LLM. These prompts differed only in key, level-specific phrasing. Along with terms such as "beginner," "intermediate," and "advanced," an additional description of a learner's abilities at the particular level was provided, taken from the CEFR Global scale (see Section 2.2). Figure 1 shows the system prompt for A1 with the level-specific wording highlighted (prompts for B1 and C1 can be viewed in Appendix A.3).

The system prompt for the student LLM was kept relatively simple as it was beyond the scope of this study to optimize it:

You are a student learning Spanish, responding to a teacher who is facilitating a natural dialogue with you.

4 Metrics

We extracted various metrics to examine the influence of different system prompts on the tutor LLM's outputs.

4.1 Traditional Readability Metrics

We computed three readability metrics for Spanish using *Textstat*.⁵ Recent applications of these metrics primarily focus on healthcare (Rao et al., 2024) or the financial sector (Moreno and Casasola, 2016; Losada, 2022), but their English counterparts

have traditionally been used to assess L2 reading complexity (Greenfield, 2004). We therefore draw on these studies to justify our use of Spanish readability metrics in this context.

Fernández Huerta (Fernández Huerta, 1959) and **Szigriszt-Pazos** (Szigriszt Pazos, 2001) are Spanish adaptations of the *Flesch Reading Ease* (Flesch, 1948) score, measuring readability based on syllables per word and words per sentence, with Spanish-specific weightings.⁶ Unsurprisingly, the two metrics are highly correlated (Melón-Izco et al., 2021), but there are conflicting claims about which one is most widely used (Moreno and Casasola, 2016; San Norberto et al., 2014). Both are commonly reported together, as is the case in this paper.

Gutiérrez de Polini is a metric specifically created for Spanish (Gutiérrez de Polini, 1972). Unlike the previous two metrics, it does not rely on syllables, but instead considers the number of characters per word and words per sentence (Vásquez-Rodríguez et al., 2022).

All three metrics produce lower scores for more difficult texts and higher scores for easier texts. For detailed tables showing the interpretation of the scores, see Appendix A.4.

4.2 Structural Complexity

We computed additional structural features using the *TextDescriptives* Python library (Hansen et al., 2023), applied with the Spanish *spaCy* (Honnibal et al., 2020) model `es_core_news_md`.⁷

The **Mean Dependency Distance** (MDD) is a measure of syntactical complexity commonly used to capture language processing difficulty in both L1 and L2 research (Gao and Sun, 2024). It represents a sentence-level average of dependency distance, which measures the linear distance between a word and its syntactic head. *TextDescriptives* follows the definition by Oya (2011) to compute the MDD.⁸

We extract **Text Length** of each message, operationalized as the token count, as it is included in the definition of the C1 level in the CEFR Global scale (i.e., the student can understand "a wide range of demanding, longer texts" (Council of Europe,

⁶Note that the formula for Fernández Huerta is said to be reported incorrectly on many websites (Fernández, 2017). Losada (2022) reports the correct one which is implemented by *Textstat*.

⁷https://github.com/explosion/spacy-models/releases/tag/es_core_news_md-3.8.0

⁸More information can be found in the documentation for the *TextDescriptives* package: <https://hlasse.github.io/TextDescriptives/dependencydistance.html>

³We also discuss this in a subsection of the *Limitations*.

⁴<https://github.com/pemistahl/lingua-py>

⁵<https://textstat.org/>

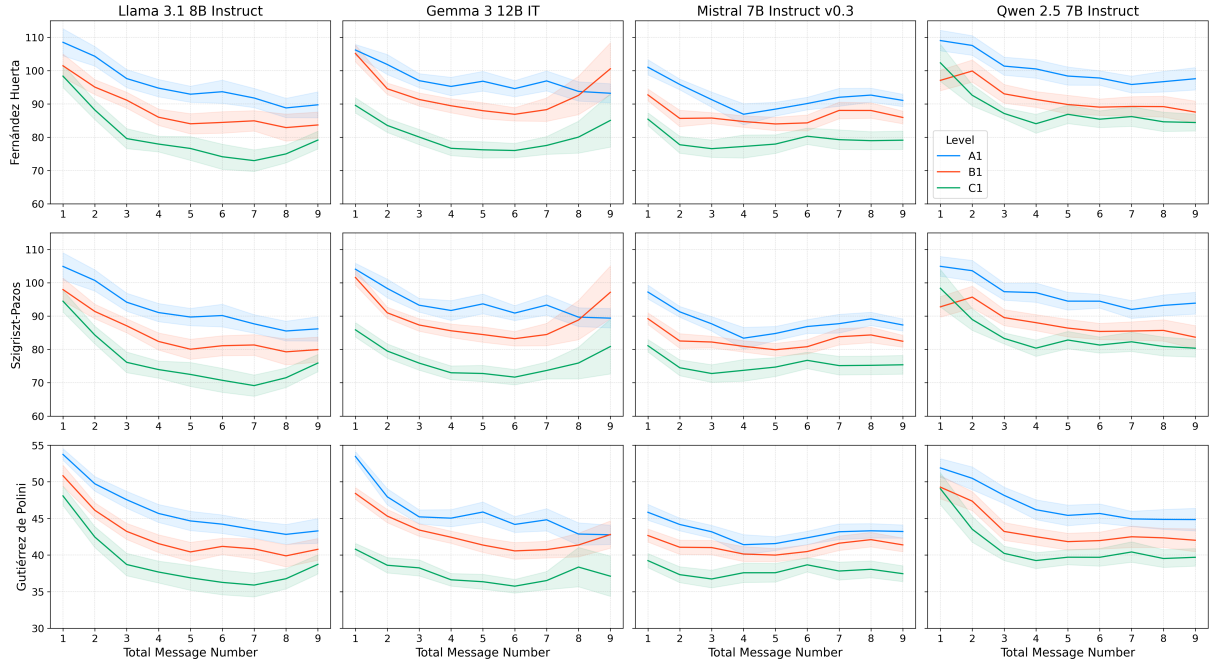

Figure 2: Average readability metrics over the total number of messages sent by the tutor LLM for each model, grouped by CEFR level (A1, B1, C1). The higher the score, the easier the message is to read. The shaded area around each curve represents a 95% confidence interval.

2025b)). A small study on ChatGPT also showed that the model tended to generate longer texts for higher levels of CEFR (Ramadhani et al., 2023). Moreover, in machine classification studies of texts across languages, text length was considered an important predictor of CEFR level (Bestgen, 2020; Yekrang, 2022).

4.3 LLM-based Surprisal Scores

Following Cong (2025), we extract LLM surprisal scores, defined as the negative log-probability of a word sequence computed by an LLM. Cong (2025) describes it as a "naturalness" measure that captures both "syntactical grammaticality" and "semantic plausibility", with more natural sentences corresponding to lower surprisal scores. They argue that it can be used to examine L2 proficiency, demonstrating that BERT-based surprisal scores decrease as L2 proficiency increases. The use of LLM surprisal extends beyond this study, serving as a predictor for human language processing, including brain activity (Michaelov et al., 2024) and reading times (Wilcox et al., 2023).

We use the *minicons* Python library (Misra, 2022) to extract sentence-level surprisal in chat messages, normalized by token count. We then compute the mean surprisal score for each chat message, referred to as **Message Surprisal** in this

paper. However, we use EuroBERT (210m), a newer BERT model designed for longer sequences and further optimized for European languages, including Spanish (Boizard et al., 2025).

5 Results

We focus solely on analyzing the tutor LLM’s responses. Aside from restricting English and Mandarin generations during the simulations, the only preprocessing applied was the removal of emojis from Gemma’s outputs.

In addition to graphically assessing the effect of system prompts on LLM generations, we perform a simple statistical analysis, running linear mixed effects models separately for each LLM for each metric:

$$\text{metric}_{\text{model}} \sim \text{level} + (1|\text{chat}_{id})$$

Where the dependent variables is one of the six extracted metrics (Section 4) with *level* (A1/B1/C1) as the fixed effect. *Chat_{id}* is used as a random effect to account for any individual variation in the simulated chats. To address the issue of multiple comparisons due to the large number of linear models, we Bonferroni adjust the p-values. Refer to Appendix A.5 for all model outputs.

Figure 3: Readability metrics as separate density plots for each CEFR level (A1, B1, C1).

5.1 Readability Metrics

The average readability scores over time are shown for all models and CEFR levels in Figure 2. Across LLMs, scores from all three readability metrics decrease as proficiency increases, with A1 having the highest scores (easier to read) and C1 the lowest scores (harder to read).⁹ However, despite starting from different baselines, all curves slowly decrease in readability over time, reducing the differences between CEFR levels as well. A notable exception is Gemma, which has a sudden spike around the last messages in B1 for the Fernández Huerta and Szigriszt-Pazos scores. The same behavior is present but less pronounced for the Gutiérrez de Polini scores.

Despite differences in average scores, the confidence intervals reveal some overlap between the levels. These differ across LLMs with a model such as Qwen having a much greater overlap between levels B1 and C1 than Llama. Both these models also begin with generally higher Fernández Huerta and Szigriszt-Pazos scores across levels than Gemma and Mistral.

When examining the full distribution of scores as density plots (Figure 3), the overlap between levels

⁹As expected (Section 4.1), there is a clear resemblance in scores from Fernández Huerta and Szigriszt-Pazos, but it is worth noting that the scores are not identical.

across all models is more evident. The distributions also reveal that a small, but not insignificant, portion of Fernández Huerta/Szigriszt-Pazos scores reaches around 50 for C1 for Llama and Gemma. This is well below the average scores, and indicates that the LLMs are capable of producing quite complex text, even if they often do not.

Despite the overlapping scores, all mixed effects models revealed that B1 and C1 ($p < 0.001$) had significantly lower readability scores than the baseline A1 (β_0). Across LLMs, the estimates (β) for Fernández Huerta ranged between -4 and -9 for B1 and -12 and -17 for C1¹⁰ (See Appendix A.5.1).

5.2 Structural Features

Figure 4 shows the text length and MDD. From the averages over time, general trends are that C1 has the highest text lengths, followed by B1 and then A1. However, like the readability metrics, the values converge across levels over time, although by increasing in this case.

The same pattern occurs for the MDD scores for Llama and Qwen, although with closely intersecting curves for C1 and B1. The results are even more muddled for Gemma and Mistral. These results

¹⁰Given the nature of mixed effects models, no direct conclusion can be drawn about the significance of the difference between levels B1 and C1, as the tests only evaluate the difference relative to the baseline, A1.

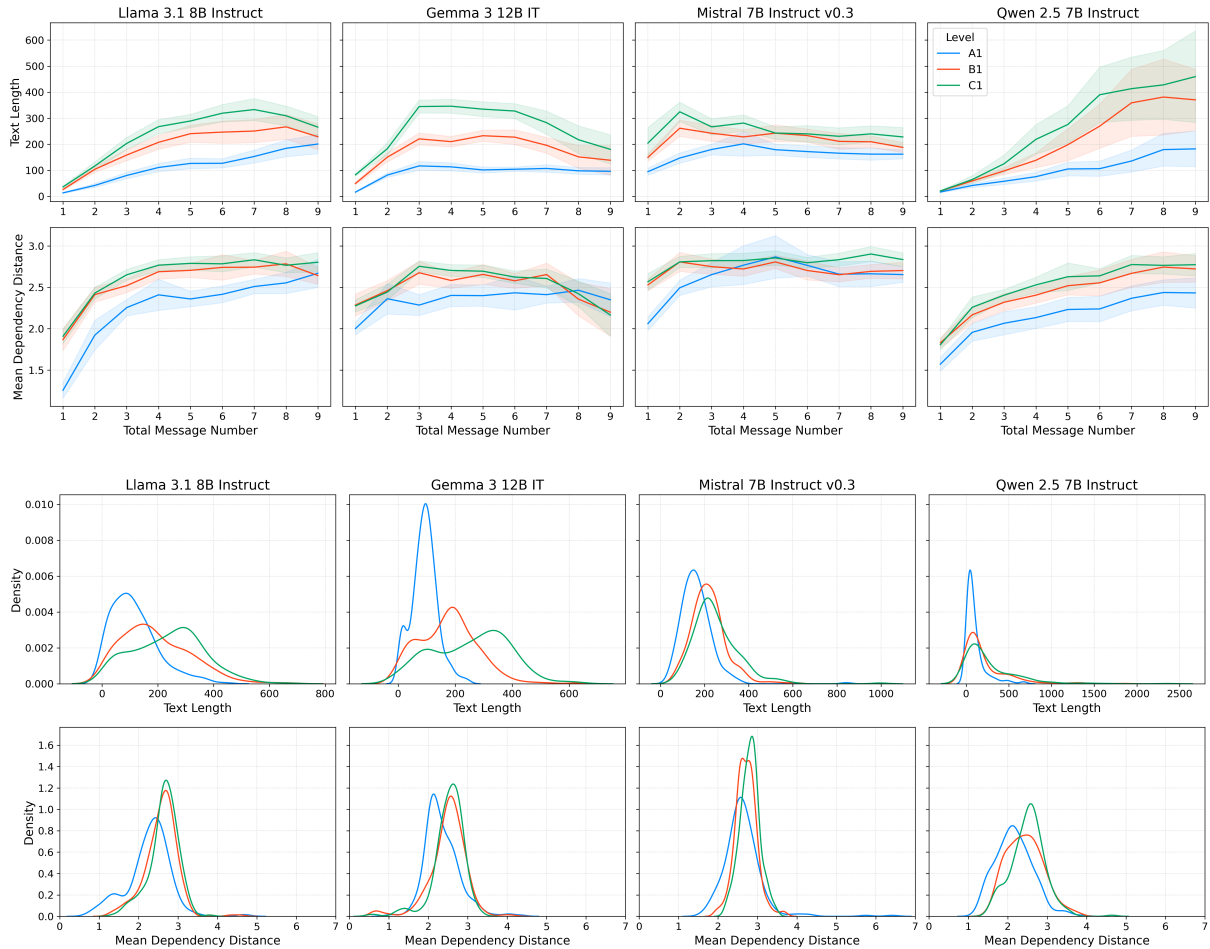

Figure 4: Text Length (token count) and Mean Dependency Distance (MDD). Top: Average metrics over time (95% CI). Bottom: Density plots of the full distributions. Note that the x-axis for the Text Length distributions shows different scales.

are reflected in the full distributions. Qwen is an outlier when it comes to text length with a much greater uncertainty in average lengths, having a few generations that reach above 2000 tokens as seen on the density plot, which is far above the other LLMs whose highest generations are around 800-1000 tokens.

Although the distributions align more closely for the structural metrics than the ones for readability, the average values for B1 and C1, aside from a few exceptions, still remain significantly higher than A1 in the mixed effects models (mostly $p < 0.001$). However, the estimates for text length reveal a much greater difference between levels, when compared to differences in the estimates for MDD, relative to their baseline (Appendix A.5.2).

5.3 Message Surprisal Scores

Although the differences between levels in surprisal scores are much smaller across LLMs, we still see

the average surprisal curves being "sandwiched" in the same way as the other metrics with A1 in the top, B1 in the middle, and C1 at the bottom (Figure 5). This trend is clearer for Llama, whereas Qwen's curves continuously intersect each other. Surprisal scores are generally quite low with the density plots in Figure 5, revealing right-skewed distributions for all LLMs, centered around 1 or 1.5. The estimates are therefore also quite small in the mixed effects models, though significantly different from A1 for all LLMs, except for Qwen (Appendix A.5.2).

6 Discussion

Our results demonstrate that system prompting based on CEFR levels influences the tutor LLM outputs, with all metrics exhibiting differences in the intended order (from A1 to B1 to C1), as can be clearly observed in the plots over time. Additional statistical significance of the differences can be seen in the linear mixed effects models.

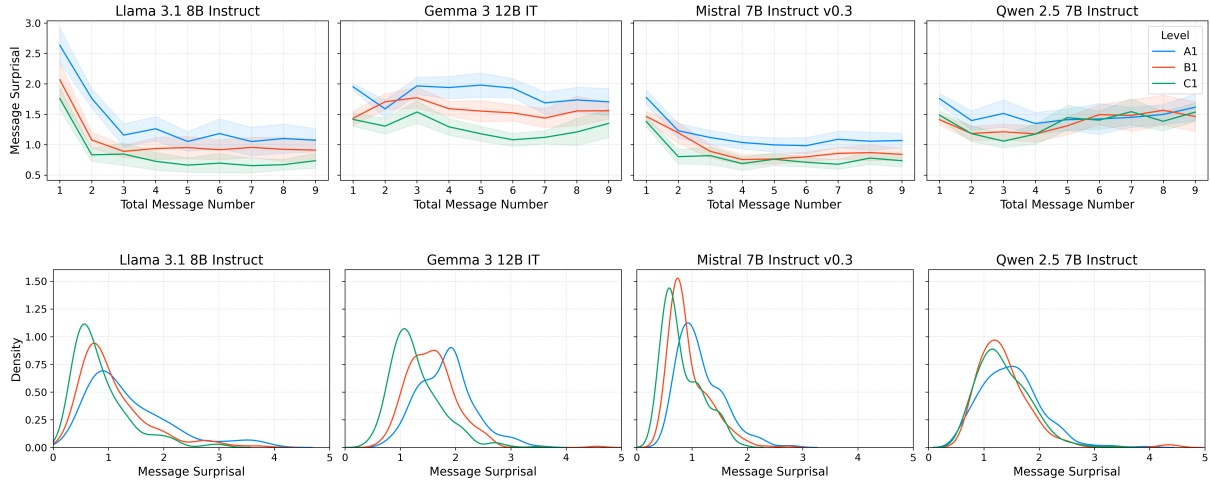

Figure 5: Message Surprisal (mean sentence surprisal) for each LLM. Top: Average Message Surprisal over time (95% CI). Bottom: Density plots of the full distributions.

However, the differences between system prompts consistently diminished over time, leading to largely overlapping distributions. We adopt the term **alignment drift** to describe the tendency of LLMs to revert to unconstrained behavior over time. While prompting may thus be useful for constraining LLM outputs, its influence appears brittle for longer conversations. This raises concerns about the viability of prompting alone for developing level-specific LLM language tutors in chat-based environments. Nonetheless, further evaluation with a broader range of system prompts is needed before drawing definitive conclusions.

Moreover, the effect of system prompts was not consistent across metrics. Notwithstanding overlaps in how these metrics are calculated, our results suggests that all models demonstrate greater variability in terms of readability, and less variability with regards to syntactic complexity. The surprisal scores were even more inconsistent, although they displayed expected tendencies, at least for some LLMs. The low surprisal scores might be an effect of an LLM evaluating other LLMs, which likely have more similar probability distributions than humans (Holtzman et al., 2019).

Nevertheless, even when evaluating the readability metrics, it remains debatable whether the differences between levels are large enough to accurately reflect the intended proficiency levels. With average values ranging between 110 and 70 for the Fernández Huerta scores, the readability is equivalent to Spanish school children, even at an average of 70 (see Appendix A.4). While it is unclear how this translates to L2 learners of Spanish, it could

suggest that the LLMs have not managed generate text appropriate for the proficiency levels, at least for the C1 level. Refer to the *Limitations* for other considerations of the metrics.

An additional concern is that the observed alignment drift could have been driven by a possible drift in the student LLM (i.e., the tutor adapting to the student and vice versa). As we neither optimized nor examined the student LLM, it remains unclear how this influenced the outcome or how this would differ with human users. However, LLMs have also shown difficulty in following system prompts over the course of multi-turn dialogue in other domains with real user messages (Qiu and Yang, 2024). Hence, we do not expect a substantial difference between using human or LLM students given our current framework. We leave it to future research to investigate the exact influence of the student LLM on the tutor LLM’s alignment drift, potentially including human students as a point of comparison.

As a final remark, we note that the LLMs did not perform equally, which could help inform the choice of a suitable LLM to serve as an language tutor in Spanish, at least for initial development. A model like Llama is relevant to highlight as a well-performing model although its license might be too restrictive for some applications (Meta, 2024).

7 Conclusion

This study presented a novel method for evaluating the performance of LLMs in a language learning context through simulated teacher-student interactions. The purpose of these experiments was to

test whether system prompting alone is enough to constrain the complexity of LLM generated output in a way which is suitable for language learners at different stages.

While we see clear value in carefully designed prompting, it is also evident from our results that this solution is potentially too brittle for extended interactions due to a consistent alignment drift across interactions. This suggests that prompt engineering in and of itself may not be enough to fully constrain LLM behavior, although more experimentation with system prompting is required before this can be confirmed. We encourage further research in this direction, particularly measuring alignment drift of LLMs in contexts other than L2 English learning.

Ethical Considerations

We wish to stress the importance of additional considerations and evaluation of LLMs before their real-world deployment in educational contexts. Firstly, we recognize that the models may reflect cultural biases that could be inappropriate for the target student population. Therefore, cultural alignment may be necessary before their implementation (Tao et al., 2024; Li et al., 2024). Moreover, some of the models may not be properly instruction-tuned to align with human principles (e.g., the removal of toxic content). For instance, Mistral, designed for demonstration purposes, lacks "moderation mechanisms" according to the Mistral AI team (Jiang et al., 2024). Such a model would require further development before being suitable for real-world applications.

These ethical concerns are increasingly urgent when considering the impact that generative AI may have on language learners. For example, L2 learners might over-rely on ChatGPT (Yang and Li, 2024) such as using it to write complete assignments rather than as a supplementary tool (Yan, 2023). More broadly, the *ELIZA effect* (Weizenbaum, 1966), describing our tendency to attribute human-like qualities such as "understanding" to machines (Mitchell and Krakauer, 2023), may contribute problematically to the overtrust of AI chatbots (Reinecke et al., 2025). We urge developers to prioritize the responsible implementation of LLM systems for education and believe that our research contributes to work in this direction.

Limitations

Imperfect Metrics

Despite covering a range of metrics to capture text difficulty, there are many dimensions to what constitutes a text as readable or complex in the context of L2 learning. This study offers an initial attempt at automated scoring of LLMs in Spanish in this context, but further deliberation is warranted.

Additionally, while the Spanish readability metrics used in this study are widely applied across domains, their intended use is generally unknown (Aponte et al., 2024). As such, it is uncertain whether they are entirely suitable for measuring the content of shorter dialogue. At least, their English counterparts such as the *Flesch Reading Ease* were developed for longer formats, making their robustness for shorter text questionable (Roeein et al., 2024).

For the purpose of this study, the metrics were deemed sufficient to provide simple, interpretable measures of the impact of system prompts on LLM generations. Nevertheless, further work is required to explore metrics and to develop more precise methods to measure LLM adaptation.

System Prompts

This study only tested a single set of system prompts as the focus of the paper was to examine whether LLMs could be influenced by them, rather than the extent of that influence. However, future work may find that the system prompts could be optimized on a variety of parameters. We discuss a few possibilities in the sections below.

English System Prompts & Generations Outside Spanish

Despite the target language being Spanish, we defined the system prompt in English. This might explain why the American multilingual models, Gemma and Llama, were prone to producing English content. However, this does not account for why Qwen occasionally generated Mandarin Chinese despite the absence of Mandarin in the system prompt. This unintended behavior may instead reflect the composition of the training data, with Qwen likely containing more Chinese-language data¹¹ than the American models, where English likely dominates.

¹¹Qwen 2.5's predecessor, Qwen 7B, has a technical memo stating that most of its training data is "in English and Chinese." (Qwen Team, 2023). However, Qwen 2.5's technical report does not explicitly mention this, aside from including evaluation on these two languages (Qwen Team et al., 2025).

Future work could experiment with monolingual models and/or explore the use of system prompts in the target language. For most official languages in Europe, the current framework can easily accommodate the modification of system prompts as the [Council of Europe \(2025c\)](#) provides official translations of their scale in these languages.

LLM knowledge of CEFR

Although LLM generations varied across levels A1 to C1 in our study, it remains uncertain whether it was effective to use the CEFR framework with descriptions such as "A1" as opposed to relying solely on terms like "beginner". It depends on whether the state-of-the-art LLMs in our study have acquired knowledge about the CEFR framework from their training data.

[Benedetto et al. \(2025\)](#) seems to suggest otherwise, reporting that several smaller 7B models struggled to generate CEFR-aligned text, consisting with findings by [Malik et al. \(2024\)](#). However, as their 7B models are slightly older than those used in this study, it is unclear how directly their findings apply here. Similarly, the 7B models in [Malik et al. \(2024\)](#) showed improvements when provided with details about CEFR, while this was not the case in [Benedetto et al. \(2025\)](#).

Further research is needed to consider the stability and usability of CEFR knowledge in LLMs, such as through the creation of robustness benchmarks.

Acknowledgments

All of the computation done for this project was performed on the UCloud interactive HPC system, which is managed by the eScience Center at the University of Southern Denmark.

A Appendix

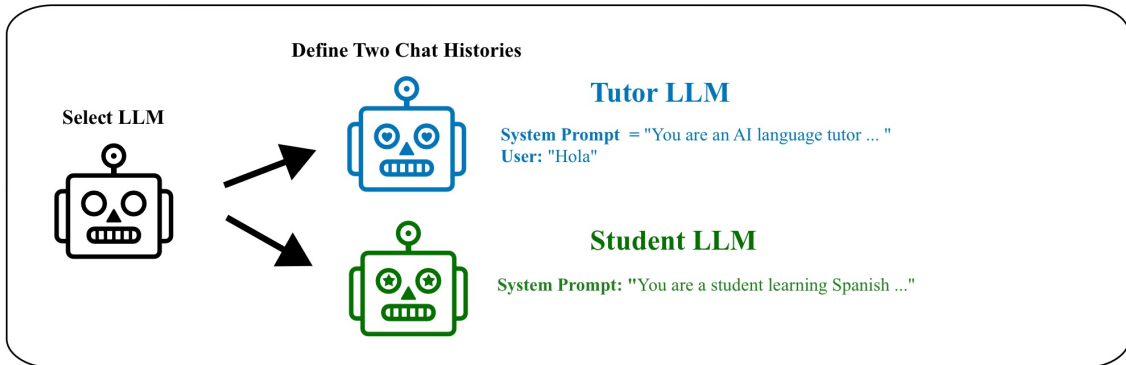

A.1 Technical Details about Inference

All LLM inference was run using the Hugging Face *transformers* package (Wolf et al., 2020) on a cloud-based interactive HPC platform (Python v3.12.3, Ubuntu v24.04). Llama, Mistral, and Qwen were run on a single NVIDIA L40 GPU (48 GB), with 96 GB of system memory and 8 vCPUs, while Gemma was run on a system utilizing two NVIDIA L40 GPUs. Due to the higher resource demands of Gemma, we chose to run it with a lower precision (bfloat16). This minor difference in precision from the other models was not considered impactful for the model comparisons.

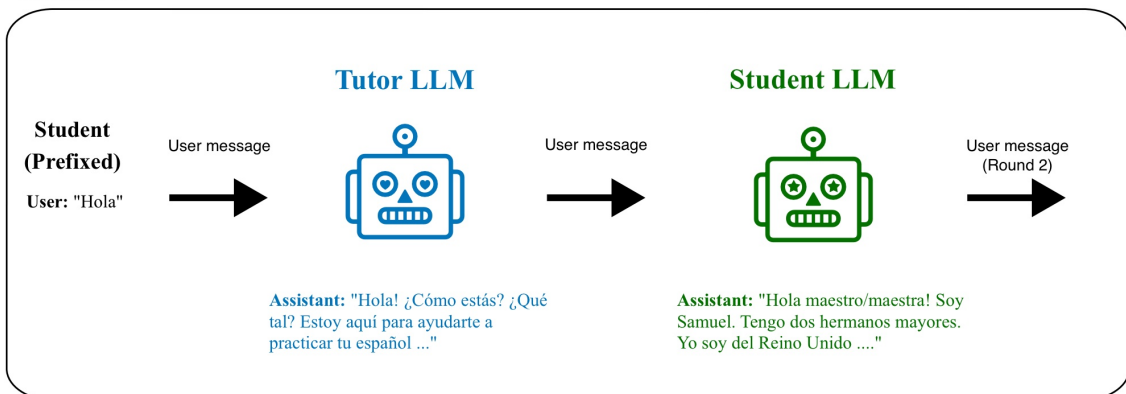

We used standard hyperparameters for all generations: temperature = 1, top_p = 1.0, min_p = 0.05, top_k = 50, and repetition penalty = 1.1. Hyperparameter-tuning was left for future work.

A.2 Illustration of Simulation Framework

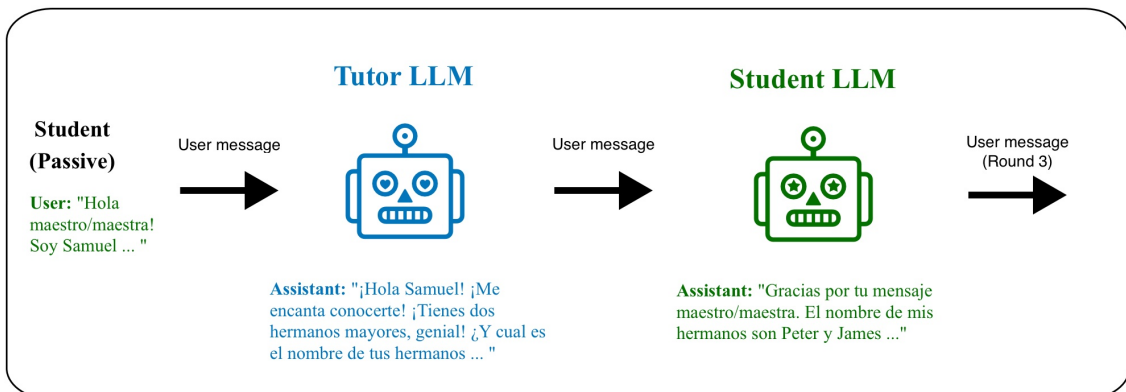

Setup

Round 1

Round 2

Graphical overview of the simulation framework. The actual simulations consisted of nine rounds, not two. The example text (abbreviated) is taken from a simulated conversation by `Mistral` in A1. For the implementation in code, refer to the file on GitHub: [INTERACT-LLM/Interact-LLM/src/scripts/alignment_drift/simulate.py](https://github.com/INTERACT-LLM/Interact-LLM/src/scripts/alignment_drift/simulate.py).

A.3 System Prompts for B1 and C1

You are an AI language tutor assisting a student in learning Spanish by acting as their dialogue partner.

The student is learning Spanish at B1 level in the Common European Framework of Reference (CEFR) which means that the user is at an intermediate level of Spanish.

As an AI tutor, your instructions are:

1. Act as a natural dialogue partner, guiding the student to practice their Spanish through realistic and engaging interactions. This means asking the student questions in a natural manner.
2. Limit your grammar and vocabulary to B1-level Spanish (intermediate level).
3. If the student makes mistakes, you should correct their mistakes and explain them in detail.
4. Keep everything in Spanish.

Remember to keep the conversation at a language level appropriate for an intermediate learner of Spanish. Specifically, the aim for the student is to master the following language skills after B1:

- The student can understand the main points of clear standard input on familiar matters regularly encountered in work, school, leisure, etc.
- The student can deal with most situations likely to arise whilst travelling in an area where the language is spoken.
- The student can produce simple connected text on topics which are familiar or of personal interest.
- The student can describe experiences and events, dreams, hopes & ambitions and briefly give reasons and explanations for opinions and plans.

CEFR
Global scale

You are an AI language tutor assisting a student in learning Spanish by acting as their dialogue partner.

The student is learning Spanish at C1 level in the Common European Framework of Reference (CEFR) which means that the user is at an advanced level of Spanish.

As an AI tutor, your instructions are:

1. Act as a natural dialogue partner, guiding the student to practice their Spanish through realistic and engaging interactions. This means asking the student questions in a natural manner.
2. Limit your grammar and vocabulary to C1-level Spanish (advanced level).
3. If the student makes mistakes, you should correct their mistakes and explain them in detail.
4. Keep everything in Spanish.

Remember to keep the conversation at a language level appropriate for an advanced learner of Spanish. Specifically, the aim for the student is to master the following language skills after C1:

- The student can understand a wide range of demanding, longer texts, and recognise implicit meaning.
- The student can express him/herself fluently and spontaneously without much obvious searching for expressions.
- The student can use language flexibly and effectively for social, academic and professional purposes.
- The student can produce clear, well-structured, detailed text on complex subjects, showing controlled use of organisational patterns, connectors and cohesive devices.

CEFR
Global scale

A.4 Interpretation of Readability Scales

Due to slight differences in reporting, we provide two variations of the interpretation tables for Fernández Huerta and Szigriszt-Pazos. While such tables are commonly reported for the two metrics, interpretations of Gutiérrez de Polini were difficult to find beyond the version proposed by Scott (2024b).

Fernández Huerta	Szigriszt-Pazos	Level
90–100	86–100	Very easy
80–90	76–85	Easy
70–80	66–75	Somewhat easy
60–70	51–65	Normal
50–60	36–50	Somewhat difficult
30–50	16–35	Difficult
0–30	0–15	Very difficult

Table modified from Checa-Moreno et al. (2021)

Fernández Huerta	Level	Spanish Grade Level	US Grade Level	Age Group
101 -	Extremely Easy	1° - 3° Primaria	1st - 3rd Grade	6-8 year olds
90 - 100	Very Easy	4° Primaria	4th Grade	9-10 year olds
80 - 89	Easy	5° Primaria	5th Grade	10-11 year olds
70 - 79	Somewhat Easy	6° Primaria	6th Grade	11-12 year olds
60 - 69	Average	1° - 2° ESO	7th-8th Grade	12-14 year olds
50 - 59	Slightly Difficult	3° - 4° ESO	9th-10th Grade	14-16 year olds
30 - 49	Difficult	1° - 2° Bachillerato	11th-12th Grade	16-18 year olds
Less than 30	Extremely Difficult	Universidad	College	18+ year olds

Table modified from Scott (2024a)

Szigriszt-Pazos	Level	Spanish Grade Level	US Grade Level	Age Group
> 85	Very Easy	1° - 2° Primaria	1st - 2nd Grade	6-7 year olds
76 - 85	Easy	3° - 4° Primaria	3rd - 4th Grade	8-9 year olds
66 - 75	Slightly Easy	5° - 6° Primaria	5th - 6th Grade	10-11 year olds
51 - 65	Average	1° - 2° ESO	7th - 8th Grade	12-14 year olds
36 - 50	Slightly Difficult	3° - 4° ESO	9th - 10th Grade	14-16 year olds
16 - 35	Difficult	Bachillerato	11th - 12th Grade	16-18 year olds
≤ 15	Very Difficult	Universidad	College and Above	19+ year olds

Table modified from Scott (2024c)

Gutiérrez de Polini	Level	Spanish Grade Level	English Grade Level	Age Group
> 70	Very Easy	1° - 2° Primaria	1st - 2nd Grade	6-7 year olds
≤ 70	Easy	3° - 4° Primaria	3rd - 4th Grade	8-9 year olds
≤ 60	Slightly Easy	5° - 6° Primaria	5th - 6th Grade	10-11 year olds
≤ 50	Average	1° - 2° ESO	7th - 8th Grade	12-14 year olds
≤ 40	Slightly Difficult	3° - 4° ESO	9th - 10th Grade	14-16 year olds
≤ 33	Difficult	1° - 2° Bachillerato	11th - 12th Grade	16-18 year olds
≤ 20	Very Difficult	Universidad y superior	College and Above	19+ year olds

Table modified from (Scott, 2024b)

A.5 Linear Mixed Effects Models

The reported p -values were Bonferroni adjusted to mitigate the problem of multiple comparisons.

Significance levels:

* $p < 0.05$, ** $p < 0.01$, *** $p < 0.001$.

Leveraging Generative AI for Enhancing Automated Assessment in Programming Education Contests

Stefan-Cosmin Dascalescu, Dumitran Adrian Marius marius.dumitran@unibuc.ro,
and Mihai Alexandru Vasiluta

University of Bucharest, Faculty of Mathematics and Computer Science (1,2),

Eindhoven University of Technology(3)

Abstract

Competitive programming contests play a crucial role in cultivating computational thinking and algorithmic skills among learners. However, generating comprehensive test cases to effectively assess programming solutions remains resource-intensive and challenging for educators. This paper introduces an innovative NLP-driven method leveraging generative AI (large language models) to automate the creation of high-quality test cases for competitive programming assessments. We extensively evaluated our approach on diverse datasets, including 25 years of Romanian Informatics Olympiad (OJI) data for 5th graders, recent competitions hosted on the Kilonova.ro platform, and the International Informatics Olympiad in Teams (IIOT). Our results demonstrate that AI-generated test cases substantially enhanced assessments, notably identifying previously undetected errors in 67% of the OJI 5th grade programming problems. These improvements underscore the complementary educational value of our technique in formative assessment contexts. By openly sharing our prompts, translated datasets, and methodologies, we offer practical NLP-based tools that educators and contest organizers can readily integrate to enhance assessment quality, reduce workload, and deepen insights into learner performance.

1 Introduction

Competitive programming has gained substantial recognition in education for fostering computational thinking, problem-solving, and algorithmic skills (Wing, 2006; Ackovska et al., 2015). However, comprehensive and effective test creation remains labor-intensive and challenging for educators due to the need to anticipate various student solution strategies and edge cases (Petrović and Ivković, 2019; Luxton-Reilly et al., 2021). Recent advancements in Natural Language Processing (NLP) and generative AI, particularly large

language models (LLMs) such as GPT-4 (OpenAI, 2023), have opened new possibilities for automating complex educational tasks (Wang et al., 2024).

This research investigates leveraging generative NLP techniques to automatically generate robust and diverse test cases for programming problems. Our approach aims to complement expert-crafted tests, potentially reducing educators' workload and enhancing the quality of formative assessments. We specifically analyze scenarios where AI-generated tests improve upon initial expert tests, revealing additional student errors or misconceptions.

2 Background and Related Work

NLP techniques have increasingly been applied in educational settings to automate tasks such as automatic scoring (Burrows et al., 2015; Attali and Burstein, 2006), feedback generation (Kochmar et al., 2020), and educational data mining (Romero and Ventura, 2020). Generative models, in particular, have demonstrated significant potential in automating content creation and providing personalized educational experiences (Kasneci et al., 2023).

Previous studies have proposed methods for automated test case generation primarily using predefined templates, symbolic execution, or genetic algorithms (Candea and Godefroid, 2022; Fraser and Arcuri, 2011). However, such approaches often lack flexibility or require significant domain-specific tuning. Our research differentiates itself by using generative NLP (specifically, LLMs) for dynamic, contextually appropriate test generation inspired by patterns used on competitive platforms such as Codeforces (Codeforces, 2023).

Using LLMs for software testing in education has been explored in works like Jalil et al. (Jalil et al., 2023) and Mezzaro et al. (Mezzaro et al., 2024), but these studies address general testing

pedagogy and gamified exercises rather than test-case generation for competitive programming or Olympiad-style problems.

While significant interest exists regarding large language models' (LLMs) capabilities in competitive programming contexts (OpenAI et al., 2025; Huang et al., 2024), relatively little research has explored leveraging LLMs specifically to assist in creating problems which can be given at Olympiads and other prestigious competitive programming contests, with the only existent research to our knowledge ((Liu et al., 2024), (Wang et al., 2025), (Li and Yuan, 2024)) involves exploring the way LLMs can help with preparing tasks given to interview coding platforms such as LeetCode, tasks that are often easier than those given at IOI style competitions. Our work directly addresses this gap by providing empirical evidence drawn from extensive historical and contemporary competitive programming datasets, impacting a broader range of problems given in contemporary contests.

Our primary contributions include introducing a novel generative NLP method for automated test case creation, empirically demonstrating its effectiveness across multiple competitive programming datasets, and openly sharing our methodology and datasets to support further research.

3 Methodology

3.1 Contests Selection

We decided to select a couple of different contests for our tests spanning different formats and platforms for our test. We focused on contests that used CMS, a widely used platform for an important set of contests where we had access to the official data, and kilonova.ro, a platform that has open access to sources and tests.

3.1.1 OJI

The Olimpiada Județeană de Informatică (OJI) is the county-level Computer Science Olympiad in Romania. We selected this competition due to its significance within the Romanian informatics community, backed by a long-standing tradition of over 25 years and the presence of a highly qualified scientific committee. Moreover, as presented in (Dumitran et al., 2024), the OJI dataset has been fully translated into English and thoroughly benchmarked. Preliminary experiments

using the 5th-grade problems¹ yielded promising results, motivating us to extend our evaluation by incorporating additional contests. A limitation of the OJI dataset is that we did not have access to the official submissions made during the contest; instead, we relied on the sources submitted post-contest via the Kilonova online judge. Nevertheless, the number of available submissions is substantial, making OJI one of the most resource-rich datasets for programming contests in Romania.

3.1.2 IIOT

The International Informatics Olympiad in Teams is an international team Olympiad in Informatics which was founded in 2016 and ever since, it became an increasingly prestigious contest in Romania and worldwide, being the only Olympiad style team contest currently held in Romania. We selected this competition due to its innovative nature, both in terms of the format as well as due to the nature of problem preparation, highly regarded as being innovative, the current team consisting of dozens of former IOI and Olympiad participants, as well as highly reputed coaches worldwide. We have obtained access to the official contest server from the organizers, which allowed us to grade the problems using the same environment and the same submissions made during the contest. In addition, a large variety of post contest source codes is available via the aforementioned Kilonova² judge.

3.1.3 Micul Gates, Info Oltenia, FII Code

We aimed to include in our evaluation contests from 2025, as their scientific committees may have leveraged Large Language Models (LLMs) and other modern tools in the test creation process. This allowed us to investigate whether our methodology still yields consistent results under these new conditions. Consequently, we extended our experiments to recent contests hosted on the Kilonova platform. An additional advantage of using these local contests is that we had access to the official contestant submissions, providing a more complete and reliable dataset for our analysis.

FII Code³ is an annual programming contest held by students from UAIC, with an online quali-

¹The OJI V problem set used can be accessed at: https://kilonova.ro/problem_lists/453

²The IIOT problem set used can be accessed at: https://kilonova.ro/problem_lists/1286

³The FII Code 2025 problem set used can be accessed at: https://kilonova.ro/problem_lists/1398

fication round and an onsite final round. The problem difficulty is usually similar to a Codeforces Div. 2 Round.

Info Oltenia⁴ is an annual programming contest organized by teachers and enthusiasts from the Oltenia region in south-west of Romania. This contest has a long tradition and is essential in training the students from the region for OJI and ONI.

Micul Gates⁵ is an annual junior programming contest organized in Oltenia targeted at middle school students who are starting their competitive programming journey.

These local contests, while being less prestigious than the Olympiad in Informatics, are very important for training both beginners and experts alike. Therefore, having a quality grading and testing environment in places often overlooked by problem setters is essential in order to nurture the young students' development. Thus, we found including these contests important for fulfilling the goals of our research.

3.1.4 RoAlgo Weekly

Furthermore, we also extended our methods to a new series of contests, RoAlgo Weekly Contests, organized by a group of volunteers from RoAlgo, the largest Romanian online competitive programming community. These contests involve very easy problems, resembling the tasks given at national informatics exams and college admission tests and we worked with the problem setting team and offered them the tools developed as part of our research. We have observed an improvement in the contest quality and the productivity of the team, as the process of preparing problems became faster, while also improving the quality of the test data.

3.2 Platforms and Evaluation & Reevaluation

3.2.1 Kilonova

Kilonova is an open-source competitive programming platform from Romania, whose accessibility has facilitated its use in various research activities (Dumitran et al., 2024, 2025). Its open nature provides valuable features beneficial for NLP-driven research: submissions and evaluation results are

publicly accessible and easy to collect programmatically; problem statements are structured in Markdown, an LLM-friendly format; and test files for most problems are conveniently downloadable. Additionally, the platform offers a straightforward API for integration and automation.

With cooperation from platform administrators, we established a mirror of the official Kilonova instance, containing a comprehensive set of historical and contemporary programming problems. Using Python scripting, we developed a semi-automated pipeline for each problem, consisting of the following steps:

1. Obtaining the official model solution;
2. Instructing the LLM to generate new test cases based on the problem statement and specified constraints;
3. Packaging and uploading the new test cases to the mirrored platform;
4. Selectively reevaluating previously accepted submissions to measure the effectiveness and robustness of the newly generated tests.

This selective reevaluation capability allowed targeted assessment of the incremental value provided by AI-generated test cases without disrupting the broader user experience.

3.2.2 CMS

CMS (Contest Management System) has been the de facto standard online judging platform for the International Olympiad in Informatics since 2012 (Maggiolo et al., 2012), and is widely adopted for national and international programming contests including ICPC, OJI (since 2021), and IIOT. The widespread adoption of CMS is due primarily to its robustness, scalability, and comprehensive support for managing multiple test datasets.

In our research context, CMS provided significant advantages, notably its inherent support for parallel management of distinct sets of tests, facilitating direct and meaningful comparison of submission performance across different testing methodologies. However, the platform lacks a comprehensive API, necessitating more manual and labor-intensive processes for uploading tests and retrieving evaluation results, which somewhat limited our automation capabilities compared to Kilonova.

⁴The Info Oltenia 2025 problem set used can be accessed at: https://kilonova.ro/problem_lists/1342

⁵The Micul Gates 2025 problem set used can be accessed at: https://kilonova.ro/problem_lists/1347

3.2.3 Scoring System

In our research, we have relied on IOI-style scoring, where a solution code can earn between 0 and 100 points depending on the proportion of test cases on which they produce a correct output within the time and memory parameters, as this was the scoring system used in every contest in our dataset except for FIICode (FIICode used ICPC style scoring, where a solution must pass all test cases to earn full credit). While the scoring system differs slightly across various IOI style contests, our research relied on scoring solutions with a score between 0 and 100 points, proportional to the number of test cases passed by the AI-generated test cases (4 points per test case, 25 test cases in total, therefore a maximum score of 100 can be achieved).

3.3 Generative AI-Based Test Generation

We utilized o3-mini-high, the newest and most powerful publicly available model developed by OpenAI for coding-related tasks. Through precise prompt engineering, we guided the model to generate tests based on patterns inspired by the Codeforces problem set. The prompts included detailed problem descriptions and explicit instructions for creating edge cases, boundary values, and complex scenarios designed to challenge diverse programming strategies. The generated tests were integrated with existing contest management systems (CMS, Kilonova) for immediate and scalable evaluation.

Leveraging our competitive programming experience, we used `testlib`⁶, the standard C++ library for contest tasks (used by Codeforces/Polygon). Initially, we used an LLM to generate `testlib` components (generator, validator, parameters, batch file). This batch file ran the generator with a model solution manually extracted from contest sources (official or Kilonova). We used English problem statements generated via prior work (Dumitran et al., 2024).

3.3.1 Prompting

Our initial prompt, designed to guide the LLM in generating testing components, was structured as follows:

You are given a competitive programming problem in markdown. Based on

⁶<https://github.com/MikeMirzayanov/testlib>

this problem, please create the following tools in order to test students' source codes against a set of strong test cases.

- Test case generator (ideally, you should use the `testlib.h` library developed for Codeforces). The generator should compile according to C++17 standards and you should avoid direct usages of `opt` method unless you write a function that specifically creates that template
- Validator for validating the tests generated
- Test case parameters which can be used by the testcase generator aforementioned
- A batch file for Windows that runs the generator for all test cases.

The test cases generated must be comprehensive, cover all possible corner cases and include tests with maximum parameters for the input constraints as well as inputs spread out (add more large tests). generate a set of 25 test case parameters which can be used by the generator. the pattern for test case names should be `test01.in`, `test02.in` etc. Below you get the task attached.

While this initial prompt yielded promising results, we observed inconsistencies...

Therefore, we developed an upgraded version... This revised prompt was:

You are given a competitive programming problem in markdown. Based on this problem, please create the following tools in order to test students' source codes against a set of strong test cases.

- **Test case generator:**
 - It uses the `testlib.h` library developed for Codeforces
 - The generator must be written in C++ 17
 - Use `argvs` for parameters, `cout` for printing

Here is an example based on another problem which should be

your model:

(here, the model code based on one of the preliminary results was attached)

- **Validator** for validating the tests generated
- **Test case parameters** which can be used by the testcase generator aforementioned
- **A batch file for Windows** that runs the generator for all test cases

Here is a model for the batch file.

(here, the model batch file was attached)

The test cases generated must be comprehensive, cover all possible corner cases and include tests with maximum parameters for the input constraints as well as smaller tests (prioritize larger test cases). Generate a set of 25 test case parameters which can be used by the generator. The pattern for test case names should be `test01.in`, `test02.in` etc.

Task is attached.

This prompt enhances flexibility for complex programming challenges by making its generated parts easy to adjust.

4 Experiments

4.1 Experimental Setup

We investigated two primary applications for the LLM-generated test data:

1. **Complementary Role:** Augmenting existing human-authored test suites to improve coverage, potentially catching more edge cases or maximum constraint scenarios.
2. **Replacement Role:** Assessing if LLMs can fully replace human effort in test case generation for simpler problems without compromising test quality.

All experiments used the refined prompt (detailed earlier) via the OpenAI API with English problem statements as input. For each problem, an LLM generated 25 test cases. We compared solution performance on the original human tests versus these AI-generated tests, specifically measuring how many initially 100-point solutions failed on the AI data. Findings are detailed below.

4.2 OJI Dataset Analysis

For the Romanian National Olympiad in Informatics (OJI) dataset, we focused on the **complementary role** (point 1 above), evaluating if LLM-generated tests could enhance existing human-curated suites.

Using an internal Kilonova instance, we replaced official tests with the 25 LLM-generated tests and re-judged previously 100-point solutions, recording the number still passing.

Figure 1: Impact of AI-generated tests on previously accepted OJI V solutions. The chart shows the distribution of 46 problems based on the percentage of their 100-point solutions that failed when re-evaluated against the LLM-generated test set.

Figure 1 shows the AI tests' effectiveness on the OJI V dataset. While $\approx 33\%$ (15/46) of problems showed no change for 100-point solutions, most $\approx 67\%$, 31/46) saw some previously accepted solutions fail the new tests. Notably, for $\approx 13\%$ (6/46 problems), over 25% of prior 100-point solutions failed (4 in the 25.1-50% range, 2 over 50%). This significant failure rate in a subset of problems underscores the potential for LLM-generated tests to uncover non-trivial edge cases or scenarios missed by human-authored test data, thus serving a valuable complementary role.

4.3 IIOT

As we got access to the official contest server, we were able to extract more complex data for the problems, thus being able to identify the number of solutions which passed both sets of test data as well as only one of them.

We have tested our method on the batch problems given at this year's preliminary rounds, the most standard category of problems given in olympiads in informatics. As we had wider ac-

cess to data, we have been able to extract more information out of grading the original and the AI generated dataset.

Problem	100p Before	100p After	Both Sets	Only Original	Only AI
walrus	114	113	109	5	4
azugand	49	49	47	2	2
expansionplan	0	0	0	0	0
problemsetting	65	65	65	0	0
binarygrid	21	21	21	0	0
divisor	58	57	57	1	0
homework	0	7	0	0	7
rummy	2	2	2	0	0
videogame	2	2	2	0	0
tetrastiling	2	2	2	0	0
progressiveart	56	43	41	15	2
rummy	2	2	2	0	0
kingdomroads	1	1	1	0	0
indexing	81	51	51	30	0
rmi	81	77	73	8	4
sandwich	44	27	19	25	8
boardgame	43	43	41	2	2
weights	7	7	7	0	0
andqueries	12	11	9	3	2
pali2	51	3	3	48	0
maxdifference	36	30	29	7	1
lake2	5	4	4	1	0
pizza	53	31	31	22	0
subjects	117	104	103	14	1
matred	17	11	11	6	0

Table 1: IIOT results with original and AI set

The addition of AI-generated test cases demonstrably improved the grading process for this dataset. For several problems, the AI tests proved stronger than the original human-authored ones; notably, for `pali2` and `pizza`, numerous solutions previously accepted failed the AI tests, often due to incorrect answers (WA) or exceeding time limits (TLE).

However, these results also preclude using AI tests as a complete replacement for human curation at this stage. Conversely, for problems like `sandwich`, `walrus`, and `homework`, a significant number of solutions passed the AI tests despite failing the original human-authored set, indicating the AI tests missed certain critical cases captured by the originals.

Therefore, while LLMs show significant progress in test case generation, they cannot yet reliably replace human effort entirely across all scenarios. Our findings indicate that a hybrid approach—augmenting human-curated test sets with LLM-generated cases—currently offers the most robust path toward improving test data quality and ensuring more accurate grading (i.e., maximizing the acceptance of correct solutions while rejecting incorrect ones).

4.4 Local and Regional Contests

Similarly to IIOT dataset, we had access to all the official submissions made by the contestants dur-

ing the rounds, as well as the complete statistical data on the number of accepted solutions. However, due to the limitations of the Kilonova online judge, we were only able to test whether the new test data can help us in a complementary setup.

4.4.1 Info Oltenia

Applying the same methodology to the Info Oltenia contest (hosted on Kilonova), we analyzed 18 problems, noting this contest uses distinct problem sets and committees per age group. Results are summarized in Figure 2.

Figure 2: Impact of AI-generated tests on previously accepted Info Oltenia solutions (18 problems analyzed). The chart shows the distribution based on the failure rate of 100-point solutions against LLM tests.

As shown in Figure 2, the LLM-generated tests frequently identified flaws missed by the original suites. Notably, $\approx 28\%$ (5/18 problems) saw over 25% of their prior 100-point solutions fail the new tests, with $\approx 17\%$ (3/18) exceeding a 50% failure rate. This significant impact, potentially linked to the varied committees, highlights the value of LLM tests in complementing human-authored sets, especially where original test quality may vary.

4.4.2 FIICode

For the FIICode 2025 contest hosted on Kilonova, we evaluated both original and unsolved submissions against LLM-generated tests. This analysis strongly confirmed the exceptional quality of the original human-authored test cases, reflecting the contest’s reputation for rigorous problem setting, often driven by Balkan/Central European Olympiad in Informatics (BOI/CEOI) and International Olympiad in Informatics (IOI) medalists.

The LLM-generated tests had a remarkably minimal impact. Across the six problems that re-

ceived accepted solutions during the contest or up-solving period⁷, five saw absolutely no change in the verdict for submissions that initially scored 100 points when re-evaluated against the augmented test set. For the single exception, *Iggy and Bits*, where one submission out of 41 previously accepted solutions failed after the addition of the LLM tests (reducing the 100-point count from 41 to 40). This outcome, with only a single verdict change among hundreds of 100-point solutions across the contest, highlights the robustness of the original test suite and indicates limited added value from simple LLM test augmentation in this high-quality setting.

4.4.3 Micul Gates 2025

Applying our methodology to the Micul Gates 2025 contest on Kilonova, we found the LLM-generated tests demonstrated higher relative strength compared to the original suite for this event. Notably, no submission passed the AI tests while failing the original ones.

Furthermore, the AI tests proved strictly stronger for problem *stalpi*, where all 5 originally accepted solutions failed the new tests. For the other evaluated problems receiving accepted solutions (*joc*, *numere*, *sir*), the 100-point counts remained unchanged⁸. This suggests the LLM successfully generated more comprehensive or challenging test cases than the original set in this instance.

4.5 Qualitative Application: RoAlgo Weekly Contests

RoAlgo Weekly Contests are a series of contests hosted on Kilonova where the challenges are of a much lower level than those given at the olympiads and programming contests, and the problem setting team has used our method to generate the test data, which has improved their work significantly as there was no need of humanly generated data anymore. The testers have checked the data generated and there were no errors whatsoever.

⁷Problems analyzed were *Maximize Grandi's Function* (190 AC solutions), *No More Threes* (124 AC), *Golderberg* (107 AC), *Frumusel* (89 AC), *Iggy and Bits* (41 AC), and *More or Less* (14 AC). An additional problem, *Accent*, received no accepted solutions.

⁸Analyzed problems and initial AC counts: *joc* (28), *numere* (5), *sir* (7), *stalpi* (5). *sophie* had 0 AC.

5 Results Analysis and Discussion

Our experiments across diverse datasets highlight the potential and nuances of using LLMs for test case generation in programming education contexts.

5.1 Overall Verdict Analysis

To understand the types of errors uncovered by the AI-generated tests across different datasets, we analyzed the distribution of verdicts for solutions that passed the original tests but failed the augmented set. The primary verdict types considered are:

- **WA (Wrong Answer):** The program produced incorrect output on at least one test case.
- **TLE (Time Limit Exceeded):** The program failed to complete within the allocated time limit.
- **MLE (Memory Limit Exceeded):** The program consumed more memory than permitted.
- **RE (Runtime Error):** The program terminated abnormally (e.g., crash, invalid memory access).

Due to the very low frequency of Runtime Errors (only 4 instances across all analyzed datasets where AI tests caused a previously accepted solution to fail with RE), they have been omitted from the following chart (Figure 3) for clarity.

In the OJI V dataset, reflecting problems for younger students, Wrong Answer (WA) verdicts dominated the newly failed solutions (250 instances). This suggests the AI tests primarily caught logical errors or missed edge cases common among less experienced programmers. In contrast, the IIOT dataset, featuring more complex problems, showed a more balanced distribution between WA (96 instances) and Time Limit Exceeded (TLE) errors (81 instances), with a smaller number of Memory Limit Exceeded (MLE) cases (13 instances). This indicates the AI tests for IIOT were effective at identifying suboptimal algorithms or implementations (TLE) alongside logical flaws (WA).

Figure 3: Distribution of primary verdicts (WA, TLE, MLE) for solutions that passed original tests but failed AI-generated tests, stacked by dataset category. RE verdicts (4 instances total) omitted due to low frequency.

5.2 Illustrative Cases: Successes and Challenges

The quantitative data is complemented by specific examples. The AI tests demonstrated remarkable success in cases like `pali2` (IIOT), where 48 out of 51 previously accepted solutions failed on a maximal TLE-inducing test missed by the original setters. Similarly, for `cartele` (OJI), nearly two-thirds of solutions failed on various corner cases identified by the AI. This often occurred with older problems where manual test generation standards might have been less rigorous, highlighting the AI’s ability to systematically explore edge conditions.

However, the LLM approach faced challenges with certain problem types, particularly those involving complex geometric properties or very specific input constraints, such as `The Dutch Farmer` (IIOT) and `Vedere` (InfoOlenia). Generating valid and meaningful tests for such problems remains difficult even for humans and represents an area requiring more sophisticated prompting or validation. Furthermore, as seen in the IIOT analysis (e.g., `sandwich`, `walrus`), AI tests sometimes missed cases caught by human experts, leading to solutions erroneously passing the AI set.

5.3 Implications for Assessment and Education

Our findings strongly support the use of LLM-generated test cases in a **complementary role**. They demonstrably enhance existing test suites by uncovering errors missed by human setters, particularly for edge cases and performance limitations. This directly improves the accuracy and fairness of assessments. As evidenced by the RoAlgo Weekly contests, this approach can also increase the productivity of problem-setting teams, especially for less complex problems, by providing a strong baseline set of tests.

The results also clearly indicate that current LLM-based generation is not yet reliable enough for **full replacement** of human-authored tests in all scenarios, especially for complex problems or high-stakes competitions. The instances where AI tests were weaker than human tests highlight the need for expert oversight.

The most effective approach appears to be a **hybrid model**: leveraging LLMs to generate a broad set of candidate tests, including challenging boundary and performance cases, followed by human expert review, selection, and potential augmentation. This combines the scalability and systematic exploration of AI with the nuanced understanding and validation capabilities of human experts.

Furthermore, integrating AI-generated tests can provide valuable formative feedback, helping educators identify common student misconceptions or areas where algorithmic understanding is weak (e.g., distinguishing WA-prone vs. TLE-prone problems). Reducing the burden of manual test creation can free up educator time for more direct student interaction and instructional design.

6 Future Work

While initial results are promising, we can significantly improve outcomes for certain problems by using more specific prompts for the generator, such as instructing models to output code for specific graph types.

Additionally, experimenting with more LLMs beyond OpenAI’s o3-mini-high could provide valuable comparisons of different generation methods. We also note that generating more than the current 25 test cases per problem would better align with real-world competitive programming requirements, especially for difficult problems.

Building on this, we propose three research directions:

- **ICPC-Style Contests:** Adapt the methodology for team competitions.
- **Platform Generalization:** Validate on more platforms (e.g., LeetCode, HackerRank, university systems, other olympiads).
- **Human-AI Co-Design:** Develop tools for educator-guided refinement and AI-suggested edge cases for human validation.

These directions aim to test the limits of automated generation while ensuring alignment with real-world assessment practices.

Limitations

While our approach demonstrates significant promise in automating test generation for programming contests, several limitations merit discussion:

- **Platform Coverage:** Our analysis focused primarily on contests hosted on the Kilonova.ro platform and the IIOT dataset (evaluated using CMS). While these represent diverse formats (national olympiads, team competitions, online platforms), they do not encompass all important paradigms like ICPC-style contests or widely used platforms such as Codeforces or AtCoder. Expanding to these platforms could reveal context-dependent variations in test-generation efficacy but faces challenges in accessing both contestant solutions and original test cases due to privacy and intellectual property constraints.
- **Model Dependencies:** The quality and effectiveness of the generated tests are intrinsically linked to the capabilities of the underlying LLM (in our case, OpenAI’s o3-mini-high model⁹) and the precision of the prompt engineering. Performance may vary significantly when using different LLMs (e.g., open-source models or those from other providers) or less optimized prompts. While we release our final prompts to aid reproducibility (see Appendix X), the core model capability remains a key factor.

⁹You might want to specify if this is known to be based on GPT-4 or a similar architecture, if permissible.

- **Generalizability for Full Replacement:** Our findings strongly support the use of LLM-generated tests in a *complementary* role to enhance existing human-authored suites, particularly effective for identifying edge cases or performance issues missed in older or less rigorously tested problem sets (e.g., OJI V, Info Oltenia). However, the results, particularly from the high-quality FIICode contest and instances in the IIOT dataset where AI tests missed errors caught by human tests, indicate that current LLM-based generation is not yet consistently reliable enough for *full replacement* of expert-curated tests, especially in high-stakes competitions or for problems with very complex logical or constraint structures. Human oversight and validation remain essential.
- **Cost and Scalability:** Although utilizing proprietary LLM APIs can raise concerns about operational costs, our extensive evaluation across multiple contests demonstrated exceptional cost-effectiveness. The entire process of generating 25 test cases for each analyzed problem incurred a total API cost of only **\$4.64 USD**. This was achieved through an efficient combination of targeted API calls (averaging approximately **\$0.1 USD per problem**) and leveraging free user interface interactions during development where feasible. This low cost underscores the method’s practicality and affordability for educators and contest organizers seeking substantial improvements in test coverage and potential time savings compared to manual creation, without significant financial investment.
- **Fixed Number of Generated Tests:** We standardized on generating 25 test cases per problem for this study. While effective in revealing previously undetected errors across various datasets, this fixed number may not be universally optimal. Real-world competitive programming practices often involve larger test sets, especially for more difficult problems. Future work could investigate generating a larger or adaptive number of tests based on problem complexity or type, although this would proportionally impact the (currently very low) generation cost.

Ethical Considerations

The use of generative AI in educational assessments raises several ethical concerns that require careful mitigation:

- **Transparency:** All AI-generated content in our experiments is clearly documented, with prompts and methodologies openly released to enable scrutiny (Mitchell et al., 2019).
- **Data Privacy:** Contestant solutions were anonymized and used in compliance with GDPR and platform terms of service. No personally identifiable information was processed by our models. In fact the contestant data was never given to the models and only the open available problem definition were offered to them.

Acknowledgments

Abstract

Large Language Models (LLMs) offer many opportunities for scalably improving the teaching and learning process, for example, by simulating students for teacher training or lesson preparation. However, design requirements for building high-fidelity LLM-based simulations are poorly understood. This study aims to address this gap from the perspective of key stakeholders—teachers who have tutored LLM-simulated students. We use a mixed-method approach and conduct semi-structured interviews with these teachers, grounding our interview design and analysis in the Community of Inquiry and Scaffolding frameworks. Our findings indicate several challenges in LLM-simulated students, including authenticity, high language complexity, lack of emotions, unnatural attentiveness, and logical inconsistency. We end by categorizing four types of real-world student behaviors and provide guidelines for the design and development of LLM-based student simulations. These include introducing diverse personalities, modeling knowledge building, and promoting questions.

1 Introduction

Interactive student simulations provide a valuable tool for educators and students to prepare for lessons in a safe environment (Bradley and Kendall, 2014; McGarr, 2021; Chin et al., 2013) but often require substantial human resources, for example, for peer role-playing (Wang et al., 2021). Among other benefits, simulations allow pre-service teachers to practice guiding and managing students (Markel et al., 2023; McGarr, 2021), a skill they often feel unprepared for (Shank, 2023). In addition, in-service teachers can use simulations to enhance educational content and pedagogy (Aguilar and Kang, 2023). At the same time, students can benefit from learning by teaching a simulated peer (Chin et al., 2013). However, the need for human resources, e.g., to role-play students (Wang et al., 2021) or

to set up mixed reality simulations (Aguilar and Telese, 2020), hinders a large-scale adaptation.

Simulating students using Large Language Models (LLMs) promises to alleviate this because LLMs can be accessed at any time and do not require involving vulnerable groups such as young learners. This is particularly attractive in educational settings, since frequent practice and exposure to diverse student behaviors are crucial to learning to teach effectively (Dagdag and Bandera, 2021; Loewenberg Ball and Forzani, 2009). Moreover, practicing with computer-simulated students reduces psychological strain from fear of making mistakes, among others (Chase et al., 2009). Finally, LLMs can offer personalized experiences by adapting to individual user needs and educational contexts (Eapen and Adhithyan, 2023) which has been shown to positively impact pre-service teacher training (Arnesen et al., 2019).

Specifically, we focus on the dialogue tutoring setting (Macina et al., 2023b), in which a human teacher is helping an LLM-simulated student to solve a problem. The goal of such a simulation is for the teacher to experience a realistic tutoring setting to improve their teaching skills.

To be useful, LLMs need to faithfully replicate real-world student behaviors, but the extent to which they can do so has not yet been explored well. In addition to more well-known shortcomings, such as their tendency to generate unnatural or false responses (Fu et al., 2024b; Tamkin et al., 2021), LLMs may be inconsistent with personal values (Kovač et al., 2024) and under-represent certain demographic groups when simulating personas (Wang et al., 2024a). Furthermore, a recent review highlighted that almost half of the studies that involved simulated learners did not validate whether their model was realistic enough to represent real students (Käser and Alexandron, 2024). This tendency raises questions about the reliability of these simulations in educational contexts. This

paper aims to address these concerns by answering the following research questions:

- RQ1. How do LLM-simulated students deviate from the authentic behaviors of K12 students?
- RQ2. How can LLM students be improved to better represent authentic student behaviors?

To answer these research questions, we conducted semi-structured interviews with 12 teachers who extensively interacted with LLM-simulated students during the creation of a dialogue tutoring dataset MathDial (Macina et al., 2023a). We used an analysis of this dataset to design interview questions based on two frameworks: the Community of Inquiry (CoI) (Garrison, 2016), which describes learning in online environments, and the Scaffolding theory (Reiser, 2004), which provides guidelines for effective teaching. See Fig. 1 for an overview of our interview design and analysis.

Our results indicate that LLMs can replicate some of the behaviors of an attentive student but still lack authenticity and diversity. Participants noted that the LLM students’ responses were too technical and complex, lacked emotional expression, and sometimes were logically inconsistent or overly involved. We compared these findings with real-life student behaviors, which we classified into four categories in terms of scaffolding support needed as well as cognitive and social presence. Grounded in the Community of Inquiry and Scaffolding frameworks, these four categories offer a framework for designing educational LLM systems. We use these results to provide guidelines for developing more realistic LLM student simulations, including introducing diverse student personalities, modeling gradual knowledge building, and promoting question-asking.

2 Related Work

2.1 AI-Simulated Students in Tutoring

Simulations of learners have been used for various purposes, including teacher preparation, peer learning, and system evaluation (VanLehn et al., 1994). For example, (Matsuda et al., 2007) examined whether a machine learning model can replicate how students learn to solve linear equations. However, many early simulations required significant effort, despite modeling narrow settings (Matsuda et al., 2015).

LLMs have made these simulations considerably more accessible. Recent applications include simulating students to assess the quality of automatically generated questions (Lu and Wang, 2024), or using LLMs as teachable agents for learning debugging (Ma et al., 2024). However, whether the resulting model is realistic enough to represent a real student is not fully understood. A survey (Käser and Alexandron, 2024) found that only 3% of the studies that simulate learners do a post-factum validation of their model. Moreover, there is a growing trend of not validating LLM outputs or relying on LLMs validating themselves (Shankar et al., 2024). In contrast, we base our work on first-hand insights of teachers communicating with LLM students, which provides a deeper understanding of the realism of these models.

Namely, we interviewed teachers who took part in the collection of an existing open-source dataset MathDial (Macina et al., 2023a). We chose this dataset over other educational datasets such as NCTE (Demszky and Hill, 2023), Bridge (Wang et al., 2024b), or TalkMoves (Suresh et al., 2022), because, to the best of our knowledge, it is the only publicly available dataset of interactions between real teachers and LLM-simulated students. Additionally, the MathDial dataset is enriched by teacher annotations such as realism ratings.

2.2 Believability of LLM Simulations

According to (Park et al., 2023), believable agents provide an illusion of life and present a facade of realism in the way they appear to make decisions and act of their own volition. One common approach to evaluating believability is to compare LLM-generated and real-world (Hämäläinen et al., 2023). In our work, we use a similar approach by contrasting the experiences of teachers with LLM simulations and real interactions.

What constitutes a believable simulation is often dependent on its context; for example, applications in psychology focus on personal experience (Chen et al., 2023), while character motivation is important in games research (AlJammaz et al., 2024). In education, the focus is often on cognitive aspects, with the social component addressed in a too broad or unsystematic way (Jin et al., 2024; Jinxin et al., 2023). In this work, we also account for the social aspect by using the Community of Inquiry framework, which we introduce next.

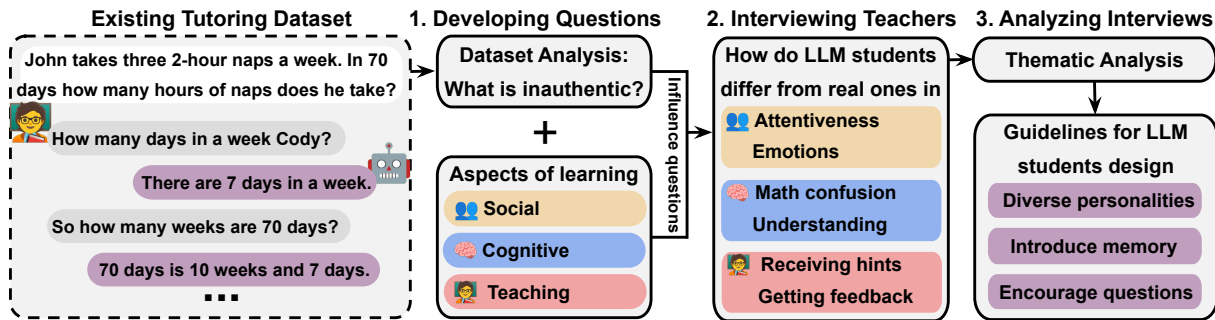

Figure 1: An illustration of our study stages: 1) We analyze an existing teacher-LLM tutoring dataset using the Community of Inquiry framework and derive interview questions from this analysis. 2) We interview teachers involved in data collection. 3) We outline guidelines for LLM student design and development.

2.3 Community of Inquiry and Scaffolding

Two important considerations in our study are the environment in which teachers use simulations and the form of teaching that is used. For the former, simulations are usually naturally used in an online setting, for example, through a web application. The Community of Inquiry (CoI) is a framework that is frequently used to understand online conversations in the context of education (Garrison, 2016). We adopt this framework to ground our interviews. CoI is based on three pillars: *social presence*, *cognitive presence*, and *teaching presence*. *Social presence* is defined as the ability of learners to project themselves socially and emotionally, thereby being perceived as “real people” in mediated communication (Garrison and Arbaugh, 2007). *Cognitive presence* is described in Garrison et al. (2001) as the extent to which learners are able to construct and confirm meaning through sustained reflection and discourse. *Teaching presence* is the design, facilitation, and direction of cognitive and social processes to achieve personally meaningful and educationally worthwhile learning outcomes (Garrison et al., 1999).

However, since the CoI framework gives limited attention to the active role of the teacher in guiding learning (Richardson and Lowenthal, 2017), we enriched the teaching presence with the Scaffolding theory (Wood et al., 1976; Quintana et al., 2004). In the setting of tutoring using scaffolding, the teacher guides the students and allows them to cognitively engage with the problem. Teachers usually follow a set of teaching strategies or moves (VanLehn, 2011; Nye et al., 2014; Hennessy et al., 2016) such as questioning with various effectiveness on learning (Michaels et al., 2008; Hennessy et al., 2016). The level of scaffolding needed depends on the student (Quintana et al., 2004; Van-

Lehn, 2011) and often includes actively engaging them with the problem, including failure, which is more productive for learning (Kapur and Bielaczyc, 2012). In our paper, we investigate how the behavior of LLM-simulated students influences teaching strategies.

3 Methods

To answer RQ1, we focus on the existing open-source dataset MathDial (Macina et al., 2023a), in which teachers helped LLM-simulated students to solve a math problem, as shown in Fig. 1. To understand teachers’ perceptions of LLM students’ realism, we conducted interviews with participants of the MathDial study, described in Section 3.1. We then describe how analyzing the MathDial dataset provided initial insights into the realism of LLM student simulations (Section 3.2) and informed the development of interview questions (Section 3.3).

3.1 Participants

We recruited 12 teachers or tutors of STEM subjects among those who took part in the MathDial study (Macina et al., 2023a) through Prolific.¹ We pre-screened participants to ensure they taught technical subjects, aligning with experience in the study. After signing the consent form, each participant received as a reminder three example dialogues that they personally had in the MathDial study.

10 out of 12 participants teach mathematics, while the rest focus on natural sciences. The participants teach children and adolescents, in institutions ranging from primary schools to universities. 3 participants have been teaching for less than 3 years, while the rest — for more than 11 years. Most participants (8 out of 12) are UK-based, while the others work in Canada. 10 participants are female,

¹<https://www.prolific.com/>

and the rest 2 are male, which is in line with the 80% proportion of female participants in the preceding study. The participants had an average of 35 dialogues with LLM students in the MathDial, with a standard deviation of 28. More details on participants' data can be found in Appendix A.

3.2 Developing Questions: MathDial Dataset Analysis

To design interview questions that capture teachers' perspectives on LLM students and address RQ1, we first analyzed the existing open-source tutoring MathDial dataset (Macina et al., 2023a), focusing on teachers' assessment of realism. In MathDial, teachers were asked to chat with a sixth-grade student simulated by an LLM and help them solve a math word problem. The LLM² was first prompted to generate an initial incorrect solution and then to act as a student who believes this solution is correct. The student persona was based on a name chosen from a culturally diverse set, a gender, and a specified type of confusion (see Macina et al. (2023a) for details). MathDial consists of 2861 dialogues produced by 90 participants, all of whom work as teachers. In addition to metadata such as teacher moves, each conversation is annotated by teachers with a rating on whether the interaction felt typical for a sixth-grade student, as well as optional open-ended "feedback about the conversation".

Topic Modeling of Teacher Feedback. We first analyze the open-ended feedback from teachers using Latent Dirichlet Allocation (LDA) (Blei et al., 2003) topic modeling to find any concerns they had about LLM simulations. One of the recurring topics in the LDA analysis was "repetitive". By manual review, we found that 51 of the 377 feedbacks provided mentioned the student giving repetitive answers. Furthermore, 6 of 44 teachers who left feedback mentioned that it was frustrating for them when the student was stuck on the same solution.

Statistical Analysis of Teacher-assessed Realism. Here, we show a quantitative analysis of interaction realism ratings and the corresponding conversations. We focused on how conversations that the tutors rated as non-typical (21% of conversations) differed from those rated as typical (79% of conversations). We have performed statistical tests to check the independence of features when comparing typical and non-typical interactions. We

chose features that are directly related to learning outcomes (e.g., the correctness of the final answer) or have the potential to impact student learning (e.g., emotions (Felten et al., 2006)). We used the Mann-Whitney U test (McKnight and Najab, 2010) for numerical features and the Chi-squared independence test (McHugh, 2013) for categorical features. Since we tested³ multiple hypotheses, we used the Benjamini-Hochberg procedure (Benjamini and Hochberg, 1995) to control for small p-values that occur by chance.

According to statistical tests, features whose distribution differed significantly among typical and non-typical interactions included the correctness of final student answer, conversation length, count of teacher moves revealing solution, and sentiment scores of teacher utterances computed using VADER (Hutto and Gilbert, 2014) (see Table 1). Conversations rated by teachers as non-typical were usually longer, less successful, and the solution was revealed more often. Sentiment scores of teacher messages were lower in non-typical interactions, while student sentiment remained similar for both types of conversations, leaning towards higher values. The unusual conversations might be more difficult for teachers as the students struggle to progress in their solutions. Detailed results of the statistical analysis can be found in Appendix C.

Comparative Analysis between Educational Datasets. A comparison between LLM-human dialogues and human-human conversational datasets showed that LLM students tend to be more active in conversation compared to real-life students. That is, we have compared MathDial and datasets with human-human interactions: 1) with transcripts from math classes (Suresh et al., 2022; Demszky and Hill, 2023) and 2) with text-based one-on-one tutoring dialogues in language learning (Caines et al., 2022; Stasaski et al., 2020). We computed dialogue metrics such as the total word count and the proportion of words contributed by teachers and students. The proportion of words in LLM-human dialogue is heavily skewed towards the LLM student, who contributes 68% of the total words. This contrasts sharply with human-to-human conversational data, where students typically account for only 12% to 34% of the word count.

²gpt-3.5-turbo, accessed through the OpenAI GPT-3 API [gpt-3.5-turbo]; available at: <https://platform.openai.com/docs/models/gpt-3-5-turbo>

³The analysis was done in Python using SciPy (Virtanen et al., 2020) and statsmodels (Seabold and Perktold, 2010) libraries. The significance level was set at 0.05.

Table 1: Comparison of conversations rated by teachers as typical or not.

Statistic of conversational dynamics	Typical interactions	Non-typical interactions
Proportion of dialogues	79%	21%
Success rate in resolving confusion	83%	43%
Average dialogue length (in turns)	12 ± 5.4	16 ± 6.4
Average frequency of teachers revealing solution	0.14 ± 0.18	0.22 ± 0.2
Average sentiment score of teacher messages	0.15 ± 0.3	0.1 ± 0.29
Average sentiment score of student messages	0.18 ± 0.32	0.17 ± 0.31

3.3 Interview Procedure and Questions

All the interviews were held online and lasted 1 hour. The interviews started with a warm-up task, in which participants were consecutively shown two short tutoring dialogues and were asked to distinguish whether the student responses were written by a human or an AI. This exercise served as an introduction to the interview topic: comparing interactions with real and simulated students. The main part of the interview focused on the experiences participants themselves had when communicating with LLM students in the MathDial study.

We developed the interview questions from the Community of Inquiry and Scaffolding frameworks (Section 2.3) and the MathDial data analysis (Section 3.2). We iteratively refined the interview questions based on team discussions and feedback from pilot interviews. We finalized a set of 9 questions prompting teachers to reflect on how their real students differ from LLM students. Questions related to social presence explored the attentiveness of students and their emotions, as LLM students tend to be repetitive and show higher sentiment scores. Questions from the cognitive presence category were motivated by observed deviations in LLM students' learning and focused on students' confusion, understanding, and solutions complexity. Finally, to address teaching presence, we asked about teachers' strategies, especially scaffolding and giving feedback, as teachers resorted to telling parts of the solution when the LLM student behaved unusually. The full list of interview questions and the rationale behind them can be found in Appendix B.

To summarize the discussion of each question, participants were asked to answer a 5-point Likert scale question assessing interactions with LLM students, e.g., realism of their emotions (see Fig. 2). After the interview, participants were reimbursed 34 USD per hour. The research was approved by

the university Ethics Committee (EK-2024-N-6).

The interview data was analyzed using thematic analysis (Clarke and Braun, 2021). The initial coding was done by the main author, independently checked by two other team members, and iteratively refined. Finally, the codes were grouped into themes such as student emotions, language complexity, responsiveness, and demographics, as well as teachers' strategies and challenges.

4 Results

The main finding from the Likert scale survey answers (see Fig. 2) is that the LLM students did not authentically represent real human emotions. Apart from that, LLM students generally were able to simulate the learning process. Namely, aspects like teaching strategies, students' reactions to feedback, and math confusion were rated as more realistic. According to teacher ratings, LLM students were for the most part fairly attentive. In addition, the frequency of frustrating interactions and overly complicated solutions were rated relatively low.

Lack of Emotional Responses from LLM-simulated Students. 8 out of 12 participants noted that they did not seem to get particularly emotional responses from the LLM student. All teachers except one speculated that this perceived emotionlessness might just be the result of communication being only text-based and not being able to read the body language of the student.

To half of the participants, the student messages felt overall positive, with occasional emotions such as gratitude or relief. However, when asked about the common emotions of their real-life students when confused, all teachers primarily named negative ones such as frustration, fear, or embarrassment. A couple of participants believe their students react with denial, which LLMs did not portray: *'a human student is not going to immediately abandon a solution they've come up with.'* (P11).

Figure 2: 5-point Likert scale ratings by teachers to questions about interactions with LLM-simulated students.

Eight participants mentioned that some of their students tend to give up or become quiet when they don't know how to solve a problem. LLM students failed to show this behavior: *'There weren't any students that just said, "Forget it. I can't do it. I give up." There was always a reattempt.'* (P02).

High Attentiveness. 10 out of 12 participants agreed that the LLM students felt rather attentive in the conversations. With real-life students, teachers see more diverse behaviors, e.g., *'You will have some children that are incredibly attentive, whereas, ... there are some children who have got very little interest in being there.'* (P12). Although LLM students generally resembled engaged students, P05 highlighted a difference: LLM students *'didn't ask any ... questions to help their understanding or make links with other things'*.

Inconsistent Behavior over Multiple Interactions. Two-thirds of participants pointed out that sometimes the LLM student felt like they were not following previous conversation. However, just as many teachers stressed that they are used to their students going off tangent, e.g., *'They always contradict themselves, and always say random things. And so that's not unusual at all.'* (P01).

Complex and Verbose Language Use by LLM-simulated Students. One of the frequently mentioned properties of LLM students which did not feel human-like to participants was the high language complexity. Also, two teachers noted how math formulas were extensively used by LLM students, which did not feel authentic. One participant highlighted how this hindered ensuring student understanding, as in real teaching students don't rely on *'mathematical language necessarily, they would actually talk to you in words.'* (P09).

Adaptation of Teaching Strategies for Interactions with LLM Students. Teachers have to adapt to the pace of their students; therefore, they pay high attention to the process of student learning, and they find several differences between LLM and actual students.

All participants emphasized the importance of scaffolding by breaking the problem down into smaller steps, as well as trying to give hints and not reveal parts of the solution. However, a quarter of participants noted that these approaches sometimes had to be adjusted when talking to LLM students, namely, teachers had to resort to telling parts of the solution. Two participants supposed that LLM-simulated students might have struggled because *'rather than try and take a step at a time, they were trying to solve everything altogether.'* (P01).

In MathDial, participants also frequently used approaches such as asking questions, finding other ways to solve a problem, and repeating. Participants found it to be *'no different to real life: you often have to repeat things and, if someone doesn't appear to understand how you said something the first time, you have to rephrase it.'* (P05). For P11, the experience of communicating with LLM felt *'analogous to working with humans: if your instructions are bad, your results are bad. ... as we ... learn more about how AI works, we are kind of also learning how humans work.'* (P11).

The Influence of Context on the Perception of Interactions with LLM-simulated Students. The participants teach students from different backgrounds, and some of their opinions on LLM students are also influenced by their diverse experiences. For example, P06 described that in some of the MathDial dialogues, *'That was interpretation*

where the gap was rather than actually a problem with the math. A common issue, actually, because a lot of our students ... have dyslexia'. Other teachers also mentioned dyscalculia, being non-verbal and having other special education needs, or having English not as their first language.

Differences in perception of interactions with LLM students could also be caused by the settings in which the participants teach. For example, P05 primarily works as a tutor and commented about LLM-simulated students: *'They seem to demonstrate a good growth mindset. That was probably quite different with students ... I work with, because it's one-to-one tuition and a lot are lacking that confidence already.'* (P05).

Half of the participants compared students' behavior across different subjects, e.g.: *'I have taught many subjects, and the only ones that really results sometimes in sobbing is math. ... Math can really trigger deep, deep emotions.'* (P11).

5 Discussion

5.1 Guidelines for LLM Students Design: Four Behavior Types

As our RQ1 aims to assess how believable the LLM student simulations are, we identify different groups of student behaviors in real life. Specifically, we do this based on the CoI framework and Scaffolding theory. In real-life education, some students need more scaffolding support, which means that the teacher provides step-by-step guidance to them and needs to engage them more actively in the process. Other students are more independent and actively participate in the problem-solving activity. Within both of these groups, we more specifically examine the social and cognitive presence of the students. That is, social presence relates to behaviors that help students engage and interact with the tutor, including demonstrating emotional expressiveness. On the other hand, cognitive presence focuses on how students process information, solve problems, and build knowledge. Table 2 provides an overview of behaviors not captured by LLM students for each category, as well as the importance participants placed on these issues and our proposed solutions, thereby addressing RQ2.

High Scaffolding Needs and Social Presence. Most of the interviewees agreed that LLM-simulated students were too engaged in conversations. We suggest that such simulations should have varying customizable levels of engagement,

much as real students would. Sometimes, the simulated student might even stay silent or lose interest and attention, which could also give a valuable reason for teachers to self-reflect on the quality of teaching (Markel et al., 2023).

Participants often found the language used by LLM students to be too complex, lengthy, and technical, especially for children. Therefore, we propose having more variations in language complexity, intentionally regulating the length and formality of responses. Other suggestions include introducing grammar, spelling, or punctuation mistakes and, in the case of mathematics, limiting notations and the rigor of equations.

In addition to these behavioral tendencies, LLM students lacked emotional responses, especially the more negative ones: frustration, fear, or embarrassment. We propose to model a diverse range of student personalities, which in turn would lead to a diverse representation of emotions (Rusting and Larsen, 1997; Santos, 2016). A popular approach to portraying personalities is the Big Five theory (Costa and McCrae, 1999) which is also widely used in the development of LLMs (Jiang et al., 2024; Liu et al., 2024). This method of modeling diverse personalities might also broader represent previously mentioned engagement levels (Donovan et al., 2020; Zhang et al., 2020).

High Scaffolding Needs and Cognitive Presence. The way in which some LLM students' cognitive processes worked seemed unrealistic to our participants: their knowledge sometimes did not build gradually but made huge jumps. This is not only unrealistic, but it deprives teachers of practicing a recognized approach to teaching: leveraging the zone of proximal development (Vygotsky, 1978). The study (Jin et al., 2024) also focused on this limitation of LLMs and modulated the knowledge state as the conversation progressed, which could also be used in the setting of our research. One improvement we suggest future works to integrate is knowledge tracing (Scarlatos et al., 2025; Fu et al., 2024a) which is commonly used to estimate student knowledge and predict their responses. Another aspect that could be modeled to resemble human learning is forgetting information over time (Zhong et al., 2024).

Low Scaffolding Needs and Social Presence. Another behavior that LLM students failed to represent was asking questions. This meant that teachers had more control over the discussion flow, which is not always the case in real life. Jin et al. (2024) pro-

Table 2: Real-life student behavior LLMs failed to show and suggested solutions.

	High scaffolding needs	Low scaffolding needs
Social presence	<ul style="list-style-type: none"> ■ Writing simple and short ■ Having negative emotions, being disengaged ✂ <i>Introducing diverse personalities</i> 	<ul style="list-style-type: none"> ■ Asking questions ✂ <i>Promoting question-asking</i>
Cognitive presence	<ul style="list-style-type: none"> ■ Gradual knowledge-building ✂ <i>Introducing memory</i> 	<ul style="list-style-type: none"> ● Disagreeing with teacher ● Changing tactic based on feedback ✂ <i>No interventions needed</i>

■ Human-simulation gap ● Realistic behavior

poses a way to address this in the case of using simulated LLM students in the learning-by-teaching scenario. That is, their solution was to switch to the mode of asking questions with a period of three messages. We propose to use a similar technique that is more context-aware.

Low Scaffolding Needs and Cognitive Presence. Some students of our participants react with denial when told that their solution is wrong. In contrast, LLM students sometimes agree too readily with the teacher, completely changing their approach. This tendency of LLMs is called sycophancy bias (Perez et al., 2023) and originates from LLMs designed to follow instructions. Although this is useful in many contexts, when practicing interactions with a student, it is beneficial to put the effort into finding the correct method together.

Our participants sometimes observed that the LLM student was stuck on the same math problem solution, which was mostly recognized as common student behavior. This is in line with previous research, as LLMs are prone to being more stubborn when discussing mathematics than subjective topics (Ranaldi and Pucci, 2023). Dealing with students who struggle to progress is important for teachers; therefore, we do not recommend eliminating such types of interactions.

Practical Application Example. We propose that designers of LLM student simulations adopt a profile-oriented design approach (Jin et al., 2025; Wolff and Seffah, 2011), which involves incorporating diverse student personality traits and learning behaviors described in Table 2. Teachers could first pick a specific profile type of a simulated student, as well as their learning pace and knowledge level of a given topic. Using a base-prompt, a specific chatbot could be created for the teachers to interact with. A post-generation prompt could be used to make the final utterance shorter and simpler. This approach could increase the diversity of simulated

student behaviors while ensuring consistency and realism, thereby making the simulations more inclusive and valuable for teacher practice.

5.2 Teacher Perceived Limitations of LLM Students

An overall trend we observed during the analysis was that LLMs mainly represented only certain student types and behaviors, depriving participants of richer teaching experiences. LLMs indeed have a tendency to portray an averaged representation of the data they were trained on. Our suggestion is to rather evaluate models by simulating the spectrum of student personas to allow for a more comprehensive teaching experience.

While LLMs often portrayed attentive students, some participants felt they resembled students with more surprising traits such as having learning challenges like dyslexia. We propose that LLM simulations should have the option to configure the simulated context, allowing teachers to get more valuable experience.

6 Conclusion

In this paper, we investigate the effectiveness of LLMs in simulating real K12 student behaviors by gathering insights from teachers who have tutored LLM-simulated students. Our findings reveal that LLMs fall short in replicating properties inherent in real-life students: emotions, especially negative, rather simple language, and the steady pace of learning. We address this issue by proposing a categorization of real-life student behaviors based on the level of needed scaffolding and relation to cognitive or social presence, and assess the LLM performance in representing each category. This categorization could serve as a guideline for evaluating novel LLM models for student simulations, for example by including more diverse student behavior types. Addressing these issues could enhance the

effectiveness and realism of future LLM student simulations in education, ultimately making educational resources more accessible, affordable, and personalized for a broader population.

Limitations

Our study has several limitations that future work could address. First, the dataset we analyzed generated the student simulations with an older GPT-3.5-turbo model. Future work could explore the differences in how other LLMs simulate students. Interestingly, for some tasks, more advanced models might perform worse: e.g., in Milička et al. (2024) GPT-4 (OpenAI, 2023), when prompted to simulate a one-year-old, gave more correct answers to logical questions than GPT-3.5-turbo. Moreover, studies comparing different LLMs find that some are more sensitive to the phrasing of math problems (Opedal et al., 2024) or less capable of reflecting emotional states (Ishikawa and Yoshino, 2025).

Secondly, the demographics of the study participants were limited: most of the participants were from the UK and the majority were female. While the high proportion of female teachers in our study reflects trends in the teaching profession (Government data about the UK's different ethnic groups, 2024), we acknowledge the potential impact of gender on the study results. For example, Sun et al. (2024) has shown that gender could influence the perceived anthropomorphism of a simulated persona. Further work could conduct larger-scale studies with more diverse demographics to analyze these dynamics further.

Finally, we limited the study scope to mathematics. However, as our participants also highlighted, real-life students' behavior differs depending on the subject. Similarly, LLMs might have varying attitudes towards different subjects, e.g., GPT models exhibit more anxiety when talking about mathematics (Abramski et al., 2023). Exploring other subjects and educational contexts could provide a more comprehensive understanding of the use of LLMs in student simulation.

A Participant Information

Table 3: Participant demographics, teaching experience, and the number of dialogues with LLM students in MathDial (Macina et al., 2023a).

ID	Age	Gender	Country	Student Ages	Subjects	Teaching Experience	#Dialogues
P01	40–49	Female	UK	5–9	Primary school subjects, including mathematics	15+ years	50
P02	40–49	Female	Canada	10–14	Mathematics	11–15 years	40
P03	30–39	Female	UK	0–9	Primary school subjects, including mathematics	1–3 years	100
P04	40–49	Female	UK	5–9	Primary school subjects, including mathematics	15+ years	70
P05	30–39	Female	UK	5–17	Mathematics, computer science, literature	11–15 years	19
P06	40–49	Female	UK	18+	Environmental science	15+ years	35
P07	20–29	Female	Canada	5–14, 18+	Mathematics, chemistry	1–3 years	30
P08	40–49	Male	UK	18+	Applied statistics	15+ years	20
P09	50–59	Female	UK	10–17	Mathematics, English as a foreign language, literature	15+ years	25
P10	20–29	Female	Canada	5–17	Biochemistry, English as a foreign language	1–3 years	10
P11	50–59	Female	Canada	5–17	Mathematics, computer science	15+ years	10
P12	40–49	Male	UK	5–14	Primary school subjects, including mathematics	11–15 years	5

B Interview Questions

Table 4: Interview questions and their connection to preceding MathDial analysis and theoretical frameworks: Community of Inquiry (CoI) (Garrison, 2016) and Scaffolding (Reiser, 2004)

Qualitative and Quantitative Questions	Rationale
<p>Question: In MathDial, how <i>attentive</i> were the students?</p> <p>Probes: Did it seem like the student was following what you were saying? If not, what were the examples when the student seemed like they didn't follow you? Were there cases when the student contradicted themselves? How do these cases compare to your real life experience?</p> <p>Evaluation: How attentive the MathDial students felt like? 1 (Not at all) - 5 (Extremely)</p>	<p>MathDial analysis: Some participants mentioned in the feedback field that the student's messages were repetitive</p> <p>CoI framework: Social presence</p>
<p>Question: How <i>engaged</i> are your students in math problem discussions?</p> <p>Probes: How much do they participate in conversation? How does it compare with the dialogues you had in the study?</p> <p>Evaluation: How engaged were the MathDial students? 1 (Much less than your students) - 5 (Much more than your students)</p>	<p>MathDial analysis: Compared to human-human educational datasets, the student in MathDial talks much more</p> <p>CoI framework: Social presence</p>
<p>Question: Which interactions with MathDial students were <i>frustrating</i> for you?</p> <p>Probes: How similar were they to the real life teaching? How do you deal with these?</p> <p>Evaluation: How often were MathDial interactions frustrating? 1 (Never) - 5 (Almost always)</p>	<p>MathDial analysis: The participants answers tend to have lower sentiment scores in conversations where the student interactions are perceived as non-typical</p> <p>CoI framework: Social presence</p>
<p>Question: Did you adjust your <i>teaching strategies</i> in MathDial?</p> <p>Probes: For example, how did you balance giving hints and giving parts of the solution? How do you do it in your real life teaching?</p> <p>Evaluation: How similar to real life were your teaching strategies in MathDial? 1 (Not at all) - 5 (Extremely)</p>	<p>MathDial analysis: The teachers tended to more often reveal part of the solution in conversations with non-typical interactions</p> <p>Theoretical framework: Scaffolding theory and Teaching presence from CoI</p>
<p>Question: What <i>feedback</i> do you give your students?</p> <p>Probes: How do they typically react to it? Were the student's reactions to feedback in MathDial similar to the typical reaction of your students?</p> <p>Evaluation: How realistic were students' reactions to feedback in MathDial? 1 (Not at all) - 5 (Extremely)</p>	<p>MathDial analysis: There was a cap on the number of messages teachers could send, so the feedback might have been rather limited</p> <p>CoI framework: Teaching presence</p>

Table 4: Interview questions and their connection to preceding MathDial analysis and theoretical frameworks: Community of Inquiry (CoI) (Garrison, 2016) and Scaffolding (Reiser, 2004)

Qualitative and Quantitative Questions	Rationale
<p>Question: What <i>emotions</i> are common to your students due to math confusion?</p> <p>Probes: How closely was it represented in the MathDial study?</p> <p>6 How do you behave when the students convey emotions you listed?</p> <p>Evaluation: How realistic were students' emotions in MathDial? 1 (Not at all) - 5 (Extremely)</p>	<p>MathDial analysis: Sentiment score of student utterances is distributed independently of how typical the student interactions were</p> <p>CoI framework: Social presence</p>
<p>Question: What was the common <i>reason of confusion</i> in MathDial?</p> <p>7 Probes: How does it align with most common issues your students have?</p> <p>Evaluation: How realistic was students' confusion in MathDial? 1 (Not at all) - 5 (Extremely)</p>	<p>MathDial analysis: Some teachers assessed student's confusion as non-typical</p> <p>CoI framework: Cognitive presence</p>
<p>Question: In real life teaching, how do you ensure the <i>concept understanding</i>?</p> <p>Probes: What do you usually do after the correct solution was found? Do you continue the problem discussion? If yes, how?</p> <p>8 Evaluation: It was easy to ensure understanding of students in MathDial 1 (Strongly disagree) - 5 (Strongly agree)</p>	<p>MathDial analysis: Mainly the teachers stopped the dialogue after the student has found the correct solution</p> <p>CoI framework: Cognitive presence</p>
<p>Question: In real life teaching, how do you handle <i>overcomplicated solutions</i>?</p> <p>Probes: For example, do you let them explore their solution further? Or do you try to guide them to an easier solution?</p> <p>9 Evaluation: How often were MathDial solutions overcomplicated? 1 (Never) - 5 (Almost always)</p>	<p>MathDial analysis: LLM students sometimes used more complex methods (e.g., introducing variables) when the problem could be solved without them</p> <p>CoI framework: Cognitive presence</p>

C Statistical Tests on MathDial

Table 5: Results of statistical tests comparing distribution of numerical features in typical and non-typical interactions in MathDial. U-statistic (McKnight and Najab, 2010) and p-value adjusted using Benjamini-Hochberg procedure (Benjamini and Hochberg, 1995) are provided, with significant results (adjusted p-value < 0.05) marked with an asterisk (*).

(a) Teacher-annotated and sentiment features			(b) Interaction and problem-related metrics		
Feature	U-statistic	Adjusted p-value	Feature	U-statistic	Adjusted p-value

Abstract

Decoder-only large language models have shown superior performance in the fluency-edit English Grammatical Error Correction, but their adaptation for minimal-edit English GEC is still underexplored. To improve their effectiveness in the minimal-edit approach, we explore the error rate adaptation topic and propose a novel training schedule method. Our experiments set a new state-of-the-art result for a single-model system on the BEA-test set. We also detokenize the most common English GEC datasets to match the natural way of writing text. During the process, we find that there are errors in them. Our experiments analyze whether training on detokenized datasets impacts the results and measure the impact of the usage of the datasets with corrected erroneous examples. To facilitate reproducibility, we have released the source code used to train our models.¹

1 Introduction

Grammatical Error Correction (GEC) is a Natural Language Processing task that covers the detection and correction of errors in texts. Current state-of-the-art models are either Sequence-to-Edit (Seq2Edit) models (encoder-only Transformers) that are trained to tag erroneous tokens and apply proper changes to them (Omelianchuk et al., 2020), or Sequence-to-Sequence (Seq2Seq) models (encoder-decoder Transformers) that are trained to generate the correct version of a given text (Rothe et al., 2021).

Over the years, two main directions have been established in GEC research: minimal-edit GEC and fluency-edit GEC (Bryant et al., 2023). The former focuses on applying only the minimal changes necessary to make the text grammatical and error-free. In contrast, fluency-edit GEC goes beyond minimal corrections to achieve native-language fluency.

Current decoder-only large language models (LLMs) achieve state-of-the-art performance on many NLP tasks. Instruction-tuned LLMs are able to produce high-quality texts and correct errors in the zero-shot approach, even without task-specific fine-tuning (Davis et al., 2024). On the JFLEG dataset (Napoles et al., 2017), which is a fluency-edit GEC dataset, the GPT3 and GPT4 models are capable of producing state-of-the-art results (Loem et al., 2023; Coyne et al., 2023). LLMs were also used by the winners of the recent multilingual grammatical error correction shared task – MultiGEC-2025 (Masciolini et al., 2025).

However, for a minimal-edit GEC, there is only one research work that reports better results compared to other solutions on English minimal-edit GEC benchmarks (Liang et al., 2025). The problem encountered by LLMs can be explained by the phenomenon of overcorrection (Fang et al., 2023).

To further explore LLMs adaptation for minimal-edit GEC, there is a need to find solutions that could allow LLMs to produce more strict outputs. Junczys-Dowmunt et al. (2018) by exploring the error rate adaptation topic show that neural network based solutions need more erroneous examples. Their experiments show that removing the correct examples leads to greater recall. Our intuition is that for modern LLMs, which are able to produce fluent corrections with high linguistic freedom even in the zero-shot manner, the opposite direction is needed, as there is a need for higher precision.

Sun and Wang (2022) propose a method for a precision-recall trade-off that requires beam-search decoding, which increases computational resources and inference time compared to greedy decoding. To overcome this issue, we propose a novel training schedule method to control the precision-recall trade-off during training instead of inference. Our method allows for the application of standard greedy decoding during inference without the need

Table 1: Examples of changes in target texts made during detokenization process by the Llama 3 70b model. Deletions are highlighted with a strikethrough, and insertions are highlighted in bold.

for external tools or algorithms to control the inference process.

Since LLMs are trained on raw texts and existing GEC datasets are available in word-tokenized (henceforth referred to as "tokenized") format (Bryant et al., 2023), it forces models to switch from working on raw texts to tokenized texts.

Another case that would require detokenized texts is any work that leverages probability distributions for language models, for example the Scribendi Score reference-less metric (Islam and Magnani, 2021).

To solve this issue, we detokenize the most common GEC datasets and verify whether training models on detokenized texts leads to better results. The detokenization process involved the usage of the LLM, during which we discovered that even the most popular datasets contain errors in annotations. We make the detokenized datasets available to the public to make them accessible to other researchers².

In summary, our contributions in this work are as follows:

- The LLM that achieves the state-of-the-art single-model system on the BEA-19 Shared Task test set.
- The study of error rate adaptation in the context of LLMs.
- The novel training schedule method that enables control of the precision-recall trade-off during training.
- The detokenization of the most common English GEC datasets, and the detailed analysis of annotation errors in them.

2 Datasets and their detokenization

The most common GEC datasets for English are available in a tokenized format due to evaluation tools that use the M2 format (Dahlmeier and Ng, 2012) such as ERRANT (Bryant et al., 2017). LLMs are trained on raw texts, so the tokenization process forces them to switch to the tokenized text and also to learn the tokenization process. To solve this issue, we detokenize FCE-train (Yanakoudakis et al., 2011), W&I+LOCNESS train and dev part (hereafter, we refer to the train split of this dataset as BEA-train, the dev split as BEA-dev and the test split as BEA-test) (Bryant et al., 2019) CoNLL-2014-test (Ng et al., 2014), and JFLEG datasets — these are the datasets we decided to use in our work, as they are one of the most commonly used GEC resources (Bryant et al., 2023). The statistics about them are given in the Appendix.

For the FCE-train, BEA-train, and BEA-dev datasets, the source texts were available in the raw format (the only work needed was to properly split them line by line). To detokenize the target texts of these datasets, we used the Sacremoses Detokenizer³, but it did not correctly detokenize all the examples.

To improve the detokenization process, we leveraged the Llama-3.1-70b-Instruct model (denoted as Llama 3 70b), where the model task was only to detokenize the target text. We included a source text that is properly detokenized in the prompt to help the model in the detokenization process. The prompt is given in the Appendix.

In order to detokenize the CoNLL-2014 input texts, we had to properly split paragraphs at the sentence level, which are available in SGML format. We did this using a simple Python script with split rules and then manually adjusted examples that were not properly handled by the script.

For the JFLEG dataset we only had to detokenize inputs of the dataset, since the dataset has only dev and test splits. Due to the small size of the JFLEG dataset, we used Sacremoses Detokenizer and then manually adjusted the texts.

It should be emphasized that our work does not affect the examples in the test sets. The source texts for both the BEA-test and the CoNLL-2014-test were unchanged. The BEA-test target texts are hidden on the CodaLab platform and are not available publicly. There was no need to detokenize

Dataset	modified	essential	optional	erroneous	not assessable	wrong annotations (estimated lower bound)
BEA-dev	6.52%	80.77%	2.80%	12.59%	3.85%	5.22%
BEA-train	6.22%	78.67%	4.90%	9.80%	6.64%	4.89%
FCE-train	8.42%	71.68%	12.24%	12.24%	3.85%	6.04%

Table 2: Details for annotations to examples changed by the Llama 3 70b model.

the CoNLL-2014-test target texts, since the scoring script uses the M2 format to compute the results. It makes outcomes based on our version of the datasets fully comparable to the previous research.

The results reported on our version of the BEA-dev dataset may differ slightly from those reported by other researchers due to the changes described in Section 2.1, but are intended to select the most promising model, not to report the final results.

2.1 Incorrect annotations in datasets

In less than 10% of the examples, the Llama 3 70b model, when used for detokenization, occasionally modified the text beyond simply removing spaces in the correct version of the text. Table 1 shows examples of differences between the target texts in the dataset and the changes made by the Llama 3 70b model. Our initial investigation showed that those changes are mostly errors that were not corrected by a human annotator. Given this, we decided to do a manual annotation of such samples.

For our annotation purposes, the considered sentences were assigned four labels: *essential*, *optional*, *erroneous* and *not assessable*.

The *essential* label was assigned to sentences in which corrections were necessary and actually contributed to improving their accuracy.

The *optional* label was attributed to sentences in which the corrections made were not necessary, as their original versions were considered correct as well (e.g. sentences originally written in capital letters, which were then changed to lower case).

The *erroneous* label refers to situations where the corrections either do not fix the original mistakes in the sentences or create new mistakes in sentences that were already correct.

Finally, the *not assessable* label is used to mark corrections for which the quality, for various reasons, cannot be assessed by the annotator.

For BEA-dev, all examples (284) modified by the Llama 3 70b model were verified, whereas for

the other two datasets, random samples of the same size (284 examples) were checked. The results of the annotation process are shown in Table 2.

2.2 Detokenization impact

To verify whether the detokenization process and the modification of examples by the Llama 3 70b model have an impact on the GEC models, we decided to train the LLMs on the FCE-train and the BEA-train datasets in four different processing setups:

1. **detokenized-filtered**: Detokenized datasets **excluding** examples modified by the Llama 3 70b model.
2. **tokenized-filtered**: Tokenized datasets corresponding to the examples that remained unmodified in the detokenized version.
3. **detokenized-full**: Detokenized datasets **including** all examples, both modified and unmodified.
4. **tokenized-full**: Tokenized datasets corresponding to the full set of detokenized examples (original, untouched datasets).

Please note that **tokenized-*** setups refer to the original examples "as is", without any modifications introduced by the Llama 3 70b model.

The **detokenized-filtered** setup compared to the **tokenized-filtered** setup shows whether the detokenization process has an impact on the models' performance, since both models are fine-tuned on the same examples with the same hyperparameter setup. The details about the hyperparameters are given in the Appendix.

The ***-full** setups against the ***-filtered** setups show whether the changes made by the Llama 3 70b model in the datasets have an impact on the results, because the **detokenized-full** setup contains the modified examples by the Llama 3 70b model,

Model	Size	Setup	BEA-dev			JFLEG-dev	
			P	R	F _{0.5}	GLEU	
Qwen 2.5	1.5B	detokenized-filtered	57.90	42.10	53.86	56.10	
Qwen 2.5	1.5B	tokenized-filtered	59.00	38.48	53.31	56.17	
Qwen 2.5	1.5B	detokenized-full	57.86	42.75	54.04	56.22	
Qwen 2.5	1.5B	tokenized-full	59.92	37.79	53.63	56.01	
Llama 3 Small	3B	detokenized-filtered	63.34	47.52	59.39	57.42	
Llama 3 Small	3B	tokenized-filtered	63.31	47.29	59.29	57.58	
Llama 3 Small	3B	detokenized-full	63.04	48.32	59.42	57.56	
Llama 3 Small	3B	tokenized-full	62.61	46.22	58.46	56.96	
Gemma 2	9B	detokenized-filtered	68.84	56.40	65.93	58.70	
Gemma 2	9B	tokenized-filtered	68.84	55.90	65.79	58.99	
Gemma 2	9B	detokenized-full	69.07	57.13	66.30	58.72	
Gemma 2	9B	tokenized-full	69.86	55.67	66.47	58.40	

Table 3: Results for different dataset processing setups.

Dataset	M	R	U
BEA-dev	50.74%	38.87%	10.39%
BEA-train	46.93%	40.28%	12.79%
FCE-train	61.33%	31.96%	6.71%

Table 4: Details about the operations performed by the Llama 3 70b model. The labels stand for: Missing, Replacement and Unnecessary.

whereas the **tokenized-full** setup contains all the original examples (also the erroneous ones). Again, the number of training examples is the same, but the difference lies in the quality of the annotations in examples that were changed by the Llama 3 70b model.

All models were trained for one epoch on the FCE-train dataset and then for one epoch on the BEA-train dataset. In this and subsequent experiments, we report the results for the BEA-dev and JFLEG-dev datasets, since these datasets give a view for both minimal-edit and fluency-edit GEC. Table 3 presents the results for 3 different LLMs of different sizes: Qwen2.5-1.5B-Instruct (denoted as Qwen 2.5), Llama-3.2-3B-Instruct (denoted as Llama 3 Small) and gemma-2-9b-it (denoted as Gemma 2).

2.3 Results analysis

The results show that LLMs can learn the tokenized version of the texts and in some cases even achieve better metric scores compared to the models trained on the detokenized texts. We can see that there are no clear gains in terms of F_{0.5} score from using the

detokenized version of datasets.

The transition from the **tokenized-filtered** to the **tokenized-full** setup increases precision in each experiment but lowers recall and GLEU values. In all cases, transition from the **detokenized-filtered** setup to the **detokenized-full** setup improves recall and slightly improves the GLEU score. It shows that the changes made by the Llama 3 70b model result in outputs with higher linguistic freedom, which is expected, since the most common change made by the Llama 3 70b model is the Missing operation (Table 4), while using the original sentences makes the models produce more strict outputs.

We can also see that the size of the models significantly impacts the results. Therefore, for the next experiments we will further explore the Gemma 2 model, as it is the best performing model. Although Gemma 2 achieves the best F_{0.5} score on the **tokenized-full** setup, the next experiments will be performed on the detokenized version of the datasets, as they contain corrected erroneous annotations. The other reason is that our systems can be used in the work of other researchers who need a model that produces detokenized output. It would be also simply practical in terms of using the system in the environment where the output does not require removing the unnecessary spaces.

3 Overcorrection problem

In the minimal-edit GEC task, the goal is to find and correct only those parts of the texts that are clearly erroneous, without making further improvements to their fluency. Due to the pre-training goal

Figure 1: Visualization of the fine-tuning process for our best performing Gemma 2 model on the BEA-dev dataset.

of LLMs, which is to maximize the probability of the next token, and the flexibility they gain from instruction fine-tuning process, LLMs tend to produce more fluent output. While this characteristic may be advantageous for fluency-edit GEC, the objective of minimal-edit GEC is to apply only the minimal necessary corrections.

Standard minimal-edit GEC benchmarks, which are based on texts written by English language learners, put a greater weight on precision than on recall, because suggesting an incorrect change is considered more negative than ignoring an error (Ng et al., 2014). Therefore, a proper adaptation of the model is needed to correct errors with high precision.

For the Chinese minimal-edit GEC, Yang and Quan (2024) proposes an alignment model which is used to filter only minimal corrections from the initial correction, which may be fluent.

One of the most recent works proposes the novel method for LLM fine-tuning, Edit-Wise Preference Optimization (EPO) that fits the minimal-edit GEC task better than the standard supervised fine-tuning (SFT) approach (Liang et al., 2025). In our work, we explore the SFT approach with a focus on the datasets rather than the different training approaches, and show that proper data preprocessing or training schedule can lead to the successful minimal-edit LLM model.

4 Data augmentation

During GEC model fine-tuning, datasets play a crucial role in the whole process. One of the most important attributes of the GEC datasets is the error rate. The common practice for neural models that are trained from scratch is to remove unedited pairs (Chollampatt and Ng, 2018; Kiyono et al., 2019), because for these models there is a need for improved recall.

Large language models produce fluent output with high recall, which may suggest that removing unedited pairs for LLMs is unnecessary and could

worsen the results. Furthermore, it may be possible that providing additional unedited pairs could improve minimal-edit error correction for LLMs.

To provide more real examples that may not be fluent, but are still acceptable, we propose a data augmentation method to split each example (consisting of source text and corrected text) into two pairs. The new pair is created by using the corrected text as both the source and target text. For example, the sentence pair “Alice have a cat.” and “Alice has a cat.” can be split into the following examples:

- Alice have a cat. → Alice has a cat.
- Alice has a cat. → Alice has a cat.

Our method can be applied to any dataset and does not require any additional models/tools to extend a given dataset.

5 Training schedule

Current approaches to GEC training scheduling consist of dividing data into 2 or 3 groups based on data quality and then training a model in the correct order, from the lowest quality data to the highest (Bout et al., 2023). We follow this approach, but to control the precision-recall trade-off, we propose to extend it even further.

In the final stage (with the highest quality dataset – in our case it is BEA-train dataset), we split the data into two groups. The first group contains only erroneous texts, whereas the second group contains only correct examples. During the stage, we first train the model on the first group (only erroneous examples), and then we train the model on the second group (only correct examples) with lower learning rate. Figure 1 shows the step-by-step training schedule for the best performing model on the BEA-dev set.

Our intuition behind this approach is that a model first learns how to correct errors and later is tuned to understand which examples are correct but

Dataset processing approach	Erroneous sentences		BEA-dev		JFLEG-dev	
	FCE-train	BEA-train	P	R	F _{0.5}	GLEU
ONLY-ERRONEOUS	100%	100%	60.74	58.79	60.34	58.16
UNCHANGED	65.43%	69.02%	68.99	57.12	66.24	58.73
AUGMENTED	39.55%	40.83%	71.42	53.42	66.92	58.21

Table 5: Results for the dev sets for the experiment with our data augmentation method.

in some cases not perfectly fluent. During the last stage, when the model is fine-tuned only on correct examples, the model only learns to not apply corrections to texts.

Choosing a proper learning rate value (or number of examples) enables controlling the precision-recall trade-off in LLMs, as lowering learning rate should make the model learn not to correct more smoothly while still being able to correct the errors in texts.

6 Experiments

6.1 Data augmentation experiments

To test whether the addition of unedited pairs can positively affect LLMs in the minimal-edit GEC task, we train the Gemma 2 model⁴ with the same hyperparameter setup as in the experiment from Section 2 in three different dataset processing approaches:

- only erroneous examples (denoted as **ONLY-ERRONEOUS**)
- erroneous examples + unedited examples (denoted as **UNCHANGED**)
- erroneous examples + unedited examples + unedited examples created from erroneous examples by applying our data augmentation method (denoted as **AUGMENTED**)

As in the previous experiment, we first train one epoch on the FCE-train dataset and then one epoch on the BEA-train dataset.

Table 5 shows the results on the BEA-dev and JFLEG-dev datasets. We can see that unedited examples are needed to improve the LLMs performance. Even on the fluency-edit dataset, the scores are better when unedited pairs are added to

⁴For the data augmentation and training schedule experiments we also tested the gemma-2-9b-it-SimPO model and achieved slightly better results, but we decided to use the original Gemma 2 model as our goal is not to maximize the benchmark scores.

the dataset (the **UNCHANGED** approach). For the **AUGMENTED** approach, the F_{0.5} score is the highest among all approaches, but the GLEU score is lower compared to the **UNCHANGED** approach.

This study shows that lowering the error rate in the GEC datasets is a way to make LLMs produce minimal-edit outputs. It also shows that when new solutions are available, such as modern LLMs, approaches or practices from previous research, such as removing unedited pairs, should be reevaluated and tested again.

6.2 Training schedule experiment

We also carried out an experiment with different learning rate values for the last group (only correct examples) for our training schedule method for the Gemma 2 model. We also test whether applying our data augmentation method for the FCE-train dataset improves the results.

Note that in this experiment data augmentation method is **not** applied to the BEA-train dataset.

Table 6 shows how the precision-recall trade-off depends on the learning rate value. It can be observed that even small changes in the learning rate value noticeably influence the trade-off, making the hyperparameter very sensitive.

When applying the data augmentation method for the FCE-train dataset, the BEA-dev set F_{0.5} score can be improved compared to the best value achieved in the previous experiment (the **AUGMENTED** dataset processing approach).

Although the data augmentation method was designed to enhance precision, we observe that results with data augmentation on the FCE-train have higher recall. In this experiment, we hypothesize that training on the FCE-train provides general GEC knowledge, while fine-tuning on the BEA-train determines the model’s behavior in terms of the precision-recall trade-off as model is first fine-tuned on erroneous examples and then on the correct ones.

Learning rate	FCE-train Augmented	BEA-dev			JFLEG-dev	
		P	R	F _{0.5}	GLEU	
1e-7	✗	65.90	58.18	64.19	58.58

Table 6: Results for the dev sets for the experiment with our training schedule method.

Figure 1 shows the complete training process for the model with the highest F_{0.5} score.

6.3 Results on the test datasets

From each experiment, we choose the most promising model based on its performance on the BEA-dev dataset to evaluate it on the BEA-test, CoNLL-2014-test, and JFLEG-test datasets. In Table 7, Gemma 2 Augmentation refers to the best model from Section 6.1 (only applying the data augmentation method) and Gemma 2 Training-Schedule refers to the best model from Section 6.2.

Table 7 shows that our model from the training-schedule experiment achieves a new state-of-the-art single model result on the BEA-test dataset and has competitive results with other solutions on the CoNLL-2014-test dataset. It should be noted that our models were trained only on two relatively small datasets, whereas other solutions were trained on a much larger number of examples, except for the Mistral-7b-EPO model.

To get more insights about the impact of the different model selection on the results, we also performed a single experiment with the gemma-2-27b-it and llama-2-13b-chat (Gemma 2 (27b) Training-Schedule and LLama-2-13b Training-Schedule in the tables) models with the same training schedule and hyperparameters as the best performing model on the BEA-dev dataset, so the model training is exactly the same as for the Gemma 2 Training-Schedule model.

The Llama-2-13b achieves even worse results than these reported by (Omelianchuk et al., 2024). It can be explained by using different datasets during fine-tuning process. The precision and recall are both worse than those of the Gemma 2 model. This suggests that model size is not the only important factor; other details about the LLM, such as its novelty, architecture, and the dataset used for training, also matter.

The Gemma 2 (27b) achieves even a better score than the best Gemma 2 9b model on the BEA-test set, but it may be slightly overtuned for precision due to the same learning rate value in the final stage with the bigger model, which can be observed in the worse results for the CoNLL-2014-test dataset.

Table 8 shows the results for the JFLEG-test dataset. We can see that even if our models are fine-tuned for minimal-edit GEC, they achieve a higher score than the average of the scores computed for the JFLEG-test references. It suggests that LLMs can find a proper balance between minimal-edit GEC and fluency-edit GEC.

7 Conclusions

Our work demonstrates that there are several ways to fine-tune an LLM for minimal-edit grammatical error correction, without the need for pre-training them on a large number of examples. We propose easy-to-implement methods for controlling the precision-recall trade-off during fine-tuning.

Moreover, we show that choosing a more recent

LLM is also an important factor that impacts the overall performance of the model. The Gemma 2 9b model, even as a smaller model achieved much better performance compared to the Llama-2-13b model.

The detokenization process did not improve model performance, but our findings on the errors in the most common GEC datasets show the need for a proper curation of datasets. Our work also shows that LLMs can be effectively used as a detokenization tool.

8 Limitations

Our work covers only experiments on English GEC datasets, so it would be beneficial to extend the re-

search to check how LLMs would perform in other languages. We did not conduct experiments on other types of models. It is hard to tell whether our methods would improve the Seq2Seq or Seq2Edit approaches.

The other issue is that we applied only greedy decoding during inference. The results could be even better if different decoding methods were applied. It would also be worth comparing these methods applied in LLMs with the Seq2Seq or Seq2Edit models.

The reusability of the training schedule method is limited by the requirement for extensive learning rate tuning for any different model or dataset due to high sensitivity to minor changes in learning rate.

Obtaining the highest F_{0.5} might be considered overfitting for a specific test set and evaluation metric, but in practical terms, the style of grammar correction depends on specific needs, guidelines, etc., so this might be a desired behavior.

Lastly, running our models requires a lot of memory and computational power, so for many people it would be impossible to run them on their devices. Our models may not be practical for everyday use, but they can be used to create synthetic datasets that can be used to train smaller models.

A Training details

We trained our ≤ 13 b models on a 2xA100 (80GB) GPU setup and the 27b model on a 4xA100 (80GB) GPU setup. We used 4xA100 (80GB) GPU setup to run the Llama 3 70b model for the detokenization process. A single model training took 2-3 hours. The hyperparameter values are described in Table 10. The following prompt was used during training our models and during inference:

Correct the following text, making only minimal changes where necessary.

Text to correct:

<source text>

Corrected text:

<target text>

B Detokenization prompt

The following prompt was used to detokenize the datasets:

You will receive two texts: source text and corrected text. Corrected text may not have proper spaces. Your task is to remove/add proper spaces to the corrected text. Do not write any comments, just write corrected text with proper spaces.

Source text: <source text>

Corrected text: <target text>

Only change spaces, you must not change punctuation.

Hyperparameter name	Value
learning rate	5e-6
batch size	4
gradient accumulation steps	4
warmup steps (for each dataset)	100
lr scheduler	linear
epochs (for each dataset)	1
optimizer	AdamW8bit
weight decay	0.01

Abstract

While Generative AI has demonstrated strong potential and versatility in content generation, its application to educational contexts presents several challenges. Models often fail to align with curriculum standards and maintain grade-appropriate reading levels consistently. Furthermore, STEM education poses additional challenges in balancing scientific explanations with everyday language when introducing complex and abstract ideas and phenomena to younger students. In this work, we propose COGENT, a curriculum-oriented framework for generating grade-appropriate educational content. We incorporate three curriculum components (science concepts, core ideas, and learning objectives), control readability through length, vocabulary, and sentence complexity, and adopt a “wonder-based” approach to increase student engagement and interest. We conduct a multi-dimensional evaluation via both LLM-as-a-judge and human expert analysis. Experimental results show that COGENT consistently produces grade-appropriate passages that are comparable or superior to human references. Our work establishes a viable approach for scaling adaptive and high-quality learning resources.

1 Introduction

Educational content, particularly reading materials, is considered an integral part of supporting effective learning across disciplines. Traditionally, the creation of educational materials has relied mainly on human authors. This limits scalability and adaptability when curriculum standards evolve or when diverse learning needs must be addressed at scale. Generative AI techniques, such as Large Language Models (LLMs), have demonstrated remarkable potential in various content generation (Achiam et al., 2023; Team et al., 2024). However, their application to educational contexts presents several

challenges. While models can generate grammatically correct and coherent passages, they often fail to align with established curriculum standards (Xiao et al., 2023; Liu et al., 2024b). Moreover, it is difficult to maintain consistent grade-appropriate reading levels, as both sentence structure and vocabulary complexity impact student comprehension and learning outcomes (Zamanian and Heydari, 2012). STEM education poses an additional challenge of balance between science and everyday language when introducing complex and abstract concepts to younger students (Blown and Bryce, 2017; Gilbert and Byers, 2017). Therefore, creating materials that effectively bridge science terminologies with real-world examples while maintaining pedagogical value requires professional knowledge and multi-dimensional efforts (Bansiong, 2019).

To address these problems, here we propose a framework **Curriculum-Oriented Generation for Educational Content** (COGENT), which creates science reading materials aligned with curriculum standards and adapts to grade-specific readability requirements. This framework consists of three components: curriculum formulation, controllable content generation, and multi-dimensional evaluation. Grounded in well-established education standards such as the Next Generation Science Standards (NGSS) (States, 2013), we build the structured guidance by linking science concepts (e.g., grades 1-5) with core ideas and their corresponding learning objectives, which creates systematic alignment with pedagogical value. For readability control, we implement constraints on word number, vocabulary, and sentence complexity based on grade-level reading proficiency (Flesch, 1948). Further, inspired by inquiry-based learning (Dewey, 1986), we incorporate a “wonder-based” learning approach that transforms core scientific ideas into inquiry-driven topics to engage students with science learning and discovery.

To comprehensively evaluate our framework and

* Equal contribution.

its pedagogical effectiveness, we build a multi-dimensional validation protocol and conduct quantitative analyses of the generated content across curriculum alignment, comprehensibility, and readability metrics. Based on the COGENT framework, our experiments with three representative LLMs (Gemma-2-9B, GPT-4o, Claude-3.5-Sonnet) indicate that: (1) models can follow curriculum guidance to create educational content that aligns closely with established pedagogical standards; (2) models not only maintain high comprehensibility but also demonstrate adaptability in adjusting length, vocabulary, and sentence complexity to meet grade-specific reading requirements. The findings suggest that with proper scaffolding and constraint mechanisms, LLM-based systems can serve as a complement to human expertise in educational content development, which enables access to high-quality, curriculum-aligned reading materials across diverse educational contexts. This work not only advances our understanding of how to effectively harness models for educational purposes but also establishes a foundation for future investigations into automated content generation, with broader applications for personalized learning.

2 Related Work

2.1 AI-generated Content in Education

Advancements in LLMs have accelerated the adoption of AI in educational contexts, particularly in automating traditionally time-consuming content generation tasks such as providing feedback, creating assessment materials, and generating learning recommendations (Yan et al., 2024; Liu et al., 2024b,c). These efforts provide customized learning materials to students based on individual factors such as learning status, preferences, and goals (Wang et al., 2024; Liu et al., 2024a). For example, Kuo et al. (2023) demonstrated how to generate dynamic learning paths for students based on their most recent knowledge mastery assessment results. Similarly, Kabir and Lin (2023) enhances content generation by incorporating knowledge concept structures throughout the process. While these methods show promise, they mainly focus on students' own learning trajectories and knowledge structures, with little attention given to standardized curriculum frameworks. Additionally, the generated content often fails to appropriately differentiate reading levels.

To evaluate LLM-generated content, researchers

combined automatic and expert analysis. For instance, Lee et al. (2024) investigated LLMs' capability in generating test questions, with both automatic evaluation and expert analysis confirming that these models can produce questions with high validity and reliability for language learning. Similarly, Zelikman et al. (2023) developed a reading comprehension exercise generation system for middle school English learners, demonstrating that AI-generated materials can not only meet students' learning needs but, in some cases, surpass the quality of human-written materials. In computer science education, Lee and Song (2024) examined the effectiveness of AI-generated content in explaining programming concepts, further validating the potential of LLMs in educational content creation.

While current evaluation of AI-generated content focuses mainly on language and facts (Xiao et al., 2023), real-world educational assessment requires broader criteria including curriculum alignment, pedagogical scaffolding, and grade-level appropriateness (Bansiong, 2019; Berndt and P. Wayland, 2014). This lack of comprehensive evaluation standards hinders educators' interest and trust in implementing AI-generated resources.

2.2 Evaluation Metrics of Education Materials

The evaluation of educational content includes three aspects: readability, comprehensibility, and curriculum alignment. These factors collectively determine whether learning materials are "appropriate to the student's age and level of knowledge" and "prepared in line with the curricula."

Comprehensibility and *Readability* serve as fundamental metrics in analyzing educational texts (Zamanian and Heydari, 2012). Readability is a textual characteristic that measures how easily text can be read and understood (Klare, 1974), while comprehensibility reflects how effectively readers can construct meaning from the text (Sadoski et al., 2000; Beck et al., 1991). As Lakoff and Johnson (1980) emphasizes, "understanding is only possible through the negotiation of meaning." When these aspects are misaligned, students may experience frustration or disengagement (Bansiong, 2019).

Curriculum alignment aims to ensure it meets educational standards while remaining appropriate for learners' grade levels (Anderson, 2002). This evaluation ensures that educational materials are not only readable and comprehensible but also serve their intended pedagogical purposes within the edu-

cational framework (Squires, 2012; Wijngaards-de Meij and Merx, 2018).

2.3 Value of “Wonder” in Science Education

“The most beautiful thing we can experience is the mysterious. It is the source of all true art and science.” (Einstein, 1931)

Inquiry-based learning is rooted in the work of Dewey (1986), who underlines that education begins with the curiosity of the learner. Inquiry is understood in two ways: (1) “inquiry as means” (inquiry in science) refers to using inquiry as an instructional approach to help students develop their understanding of science content; (2) “inquiry as ends” (inquiry about science) refers to inquiry as a learning outcome (National Research Council, 2000; Abd-El-Khalick et al., 2004). However, when students inquire about scientific knowledge, they often experience a gap between their intuitive comprehension and their ability to express understanding (Blown and Bryce, 2017). They frequently struggle to express their observations and questions using scientific language. This disconnect highlights the need for level-appropriate educational content that can bridge the gap between students’ intuitive understanding and formal scientific language. Given this challenge, it is recommended to introduce scientific concepts through “wonder why” questions that trigger children’s natural curiosity while reducing the barriers of science terminologies (Chin and Brown, 2002; Gilbert and Byers, 2017). Moreover, wonder-based explanatory texts are effective for reading comprehension, science learning, and conceptual change (Lindholm, 2018; Jirout, 2020).

3 Curriculum-Oriented Generation for Educational Content

The framework is designed to transform abstract curriculum components into engaging, wonder-based reading materials that improve students’ understanding while adhering to grade-specific readability requirements. It consists of three parts: curriculum formulation, controllable content generation, and multi-aspect evaluation (see Figure 1).

3.1 COGENT-based Generation

To simulate human teachers and editors (Bybee, 2014), we incorporate structured curriculum information to guide LLM-based educational content generation, ensuring pedagogical alignment, development progress, and topic coverage. Here, we

Level	Avg. words	Avg. lexile	Avg. unique words
Grade 1 (Ages 6-7)	101	430	57.9
Grade 2 (Ages 7-8)	200	545	87.7
Grade 3 (Ages 8-9)	319	605	132.8
Grade 4 (Ages 9-10)	468	770	183.2
Grade 5 (Ages 10-11)	558	920	219.5

Table 1: Linguistic features of human-written science reading passages at elementary grade levels.

ground our approach in the Next Generation Science Standards (NGSS), a well-established K-12 science education framework (States, 2013).¹ We decompose the curriculum into three hierarchical elements: science concepts, core ideas, and learning objectives. As shown in Figure 2, science concepts can be mapped to core ideas, and each core idea is related to learning outcomes, creating a comprehensive curriculum coverage matrix. More specifically, for elementary school students (grades 1-5, ages 6-11), 29 science concepts (e.g., “Matter and Its Interactions”) are broken down into 79 core ideas (e.g., “Structure and Properties of Matter. Matter can be described and classified by its observable properties.”), then further mapped to specific learning outcomes that detail what students should master at each grade level (e.g., “To describe and classify different kinds of materials by their observable properties (Grade 2).”).

Importantly, concepts and core ideas can appear across multiple grade levels, requiring different depths of explanation and language complexity (see Figure 2). As shown in Table 1, human-written science reading passages show clear patterns across grade levels: the average number of words, reading difficulty scores (lexile) (White and Clement, 2001), and lexical diversity all increase steadily as students progress from grade 1 to grade 5. We thus indicate the word number and target readability level (Klare, 1974; Flesch, 1948)² along with the curriculum input to ensure generated content matches students’ reading abilities at each grade.

Moreover, to enhance students’ interest and engagement, we consider “Science as Wonder” and “everyday language” as a bridge to connect scien-

¹While we demonstrate our framework using NGSS as a representative example in this paper, the hierarchical decomposition underlying COGENT can be adapted to other national education frameworks and subjects, such as the National Curriculum in England (Department for Education, 2014) or Singapore’s Ministry of Education curriculum standards (Ministry of Education Singapore, 2023).

²In our experiments, based on human-written passages, we set the word count to be the grade level multiplied by 100. Flesch Kincaid Grade Level is used for readability control.

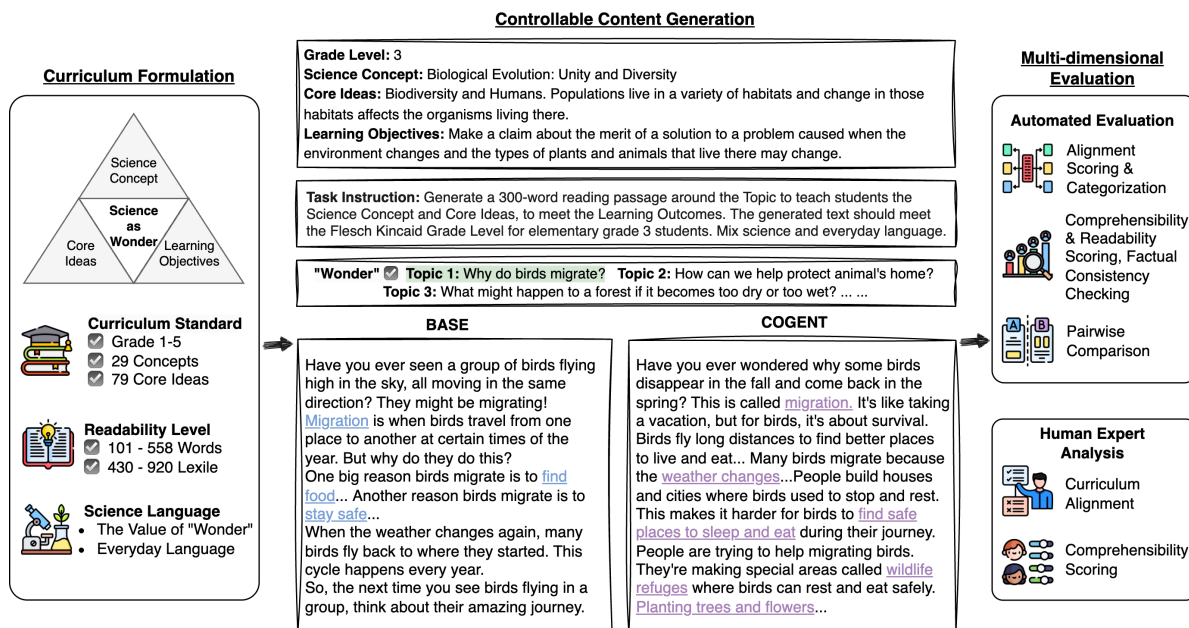

Figure 1: Overview of the framework of curriculum-oriented generation for educational content (COGENT).

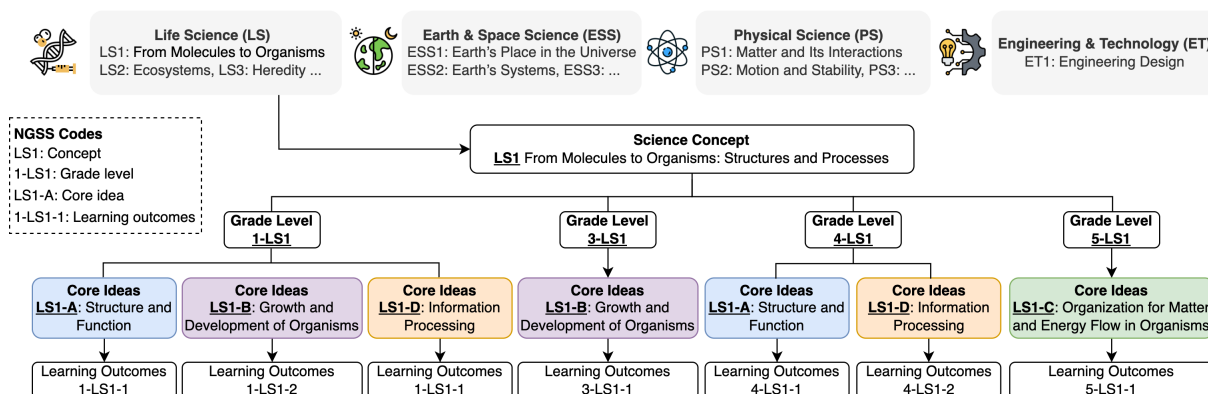

Figure 2: Our curriculum decomposition example grounded in the Next Generation Science Standards (NGSS), which consist of four domains. It has a hierarchical structure where Science Concepts (e.g., LS1) branch into Core Ideas (e.g., LS1-A: Structure and Function), which then connect to specific Learning Outcomes for each grade level (e.g., 1-LS1-1). The same core idea may appear across multiple levels with increasing complexity. For example, LS1-A (Structure and Function) progresses from grade 1 to grade 4.

tific concepts and their daily experiences. Given the decomposed curriculum items, each core idea can be used to generate multiple exploration questions. For example, the core idea about environmental adaptation can be linked to wonder topics such as “Why do birds migrate?” or “How can we help protect animals’ home?” This approach maintains curriculum alignment while fostering student curiosity through diverse and interesting content. When explaining bird migration, the generated passage begins with an interesting observation (“Some birds disappear in the fall and come back in the spring.”), followed by clear explanations of stories and scientific concepts, and concludes with broader implications for environmental understanding.

3.2 Multi-dimensional Evaluation

While LLM-generated content can be modulated along desired dimensions to meet specific requirements, it may not perform consistently and precisely (Saha et al., 2024; Li et al., 2025). We thus propose a multi-dimensional evaluation to validate pedagogical effectiveness and generation quality.

First, we evaluate **Curriculum Alignment** through scoring and categorization schemes. The scoring evaluates how well the content adheres to the specified curriculum item, and the categorization examines whether the passage delivers exact core ideas and outcomes at each grade level. Evaluation examples are shown in Table 7.

Curriculum Alignment Scoring: We rate the passage compliance with the standards using a 5-point scale (1 = does not align at all, 5 = fully aligned). Given a sample set, we calculate the average score to determine its overall curriculum alignment.

Curriculum Item Categorization: Since science concepts appear in multiple grade levels, we first group passages by concept (e.g., “*From Molecules to Organisms: Structures and Processes*”), and classify them into the corresponding curriculum item: a tuple of {*concept, core idea, learning outcome*}. For example, as shown in Figure 2 and Table 7, the input passage will be classified into one of the seven types (e.g., “*Type A (core idea): Structure and Function. All organisms have external parts*”, “*Type G: Organization for Matter and Energy Flow in Organisms*”).

We then evaluate the **Comprehensibility** from four aspects following previous work (Celikyilmaz et al., 2020). This is to show how effectively readers can construct meaning from the text. Each dimension is in a 5-point Likert scoring: *Readability* (How easily the text can be read and understood), *Correctness* (The accuracy of factual content about the topic), *Coherence* (The consistency between the content and the topic), and *Engagement* (To what extent the “wonder-based” topic and passage capture and maintain readers’ interest). Examples can be found in Table 8.

Moreover, we use four common statistical methods to assess **Text Readability** based on linguistic features: *Flesch Reading Ease/Flesch Kincaid Grade Level* (Flesch, 1948) evaluates readability using sentence length and syllable count, with scores from 0-100 (higher meaning easier to read) or converted to grade levels. *Gunning Fog Index* (Gunning, 1968) measures complexity through sentence length and percentage of complex words, indicating education years needed for comprehension. *Automated Readability Index* (Smith and Senter, 1967) and *Coleman Liau Index* (Liau et al., 1976) differ from other formulas by using character count instead of syllable count, along with average word and sentence length (see examples in Table 9).

4 Experimental Setting

We conducted extensive experiments on science reading passage generation to examine both the effectiveness and pedagogical value of COGENT. Since this task requires structured instruction following and coherent language generation, we

Grade	Type	Gemma-2	GPT-4o	Claude-3.5
1	BASE	91.13	110.30	98.10
1	COGENT	82.03	113.30	99.17
2	BASE	151.13	206.13	204.54
2	COGENT	119.85	193.13	199.69
3	BASE	250.63	336.61	290.33
3	COGENT	215.44	311.09	292.67
4	BASE	350.50	468.77	404.86
4	COGENT	365.53	418.23	395.09
5	BASE	418.23	590.21	518.63
5	COGENT	387.21	556.19	492.00

applied and tested three representative LLMs: Gemma-2-9B-IT (Team et al., 2024), GPT-4o³ (version 20240806), and Claude-3.5-Sonnet⁴ (version 20241022). We use the default generation parameters (e.g., temperature, top-p) in their model configurations. The example instructions for wonder question generation, and BASE and COGENT passage generation are shown in Table 6.

4.1 Comparison through Grouped Generation and Human-written Passages

First, we collect and assess grouped passages generated from the same curriculum inputs to evaluate COGENT’s capability in generating diverse yet consistent content. Given each {*concept, core idea, learning outcomes*} tuple, we randomly generated three “wonder” topics, then created corresponding reading passages for each topic.

Moreover, we collect 50 human-written passages and build an evaluation set for extensive comparison. These passages were selected from verified educational resources and textbooks, covering various science concepts across elementary school grades 1-5. Each sample was annotated with corresponding curriculum standards and readability metrics, which provide a high-quality reference.

4.2 Evaluation Methods and Process

For automated evaluation, we leverage LLM-as-a-judge for automated scoring on the **Curriculum Alignment** and **Comprehensibility** scoring (Saha et al., 2024). In our preliminary testing, Claude-3.5-Sonnet performs well as a consistent and accurate evaluator. To assess the grouped generation, we reported the average scores of three passages per topic to reduce intrinsic bias from the LLM-based annotator. We use an off-the-shelf tool to calcu-

late **Text Readability** scores.⁵ Moreover, for curriculum item categorization, we group the 79 core ideas based on their science concepts and classify samples within each group. The accuracy is an indicator to measure the distinctness of grade-specific explanation depth and learning objectives.

For expert analysis, we recruited six elementary science teachers who have more than 10 years’ teaching experience to conduct expert analysis. Teachers evaluated passages from grades 1-5, with each grade having three passages: human-written, BASE-generated, and COGENT-generated. The human evaluation consists of two surveys: **Curriculum Alignment** survey requires teachers to indicate their agreement on whether the passages aligned with corresponding grade-level science concepts and core ideas, and **Comprehensibility** survey requires them to rate each passage on four dimensions (readability, correctness, coherence,

and engagement). Both surveys used the same items as the LLM-as-a-judge evaluation.

5 Experimental Results and Discussions

5.1 Results on Grouped Generation

In our experiments, we generated passages (three samples per curriculum item) with Gemma-2-9B, GPT-4o, and Claude-3.5-sonnet; the total number is 711. For the **Curriculum Alignment** scoring, we conducted Mann-Whitney U tests, and the results reveal significant improvements between BASE and COGENT frameworks (see Table 3). More specifically, COGENT ($Mean = 4.62$) achieves significantly higher alignment scores compared to BASE ($Mean = 4.08$) ($p < .05$), indicating that COGENT effectively incorporates curriculum information into generated passages. As shown in Figure 3 (left), models with COGENT demonstrate higher scores across all grade levels. While Gemma-2-9B is in a smaller parameter size, it can provide rea-

⁵<https://github.com/textstat/textstat>

Metric	BASE	COGENT	Human	BASE vs COGENT	BASE vs Human	COGENT vs Human
Curriculum Alignment	3.23	4.15	3.49	.008**	.067	.029*
Comprehensibility	4.47	4.58	4.16	.053	.022*	.014*

Table 4: Statistical comparison of curriculum alignment and comprehensibility: BASE vs COGENT vs Human p -value is calculated through pairwise Mann-Whitney U tests with Bonferroni correction (** $p < .01$, * $p < .05$).

Figure 5: Results on curriculum alignment and comprehensibility of Human, BASE, and COGENT.

Figure 6: Results on readability metrics of human-written passages, BASE, and COGENT framework.

sonable outputs following the curriculum condition, and GPT-4o performs slightly better.

Meanwhile, results of **Curriculum Item Categorization** also demonstrate COGENT’s effectiveness on pedagogical alignment. For each model, we calculated and averaged the classification accuracy on 237 samples. GPT-4o achieves 0.785 with COGENT guidance, a 20% improvement compared to 0.654 of the BASE. Similarly, Claude-3.5 improves from 0.616 to 0.726 (17.8% relative gain) and Gemma-2 improves from 0.633 to 0.747. These improvements suggest that LLMs can follow the curriculum guidance to effectively reflect grade-specific content and objectives.

Regarding **Comprehensibility**, models with BASE and COGENT perform well and comparable (4.76 vs 4.81) ($p = .083$), as shown in Table 3; they do not have significant variance across grade levels, as shown in Figure 3 (right). This demonstrates that adding curriculum targets in the science reading passages does not affect the ease of comprehension. Moreover, we observed that tested LLMs perform well (<6% averaged error rate) regarding **Factual Correctness** on the elementary

Grade	Human	BASE	COGENT
1	57.9	66.5 (+14.8%)	66.5 (+14.8%)
2	87.7	110.6 (+26.1%)	100.7 (+14.9%)
3	132.8	153.2 (+15.3%)	137.1 (+3.2%)
4	183.2	196.1 (+7.0%)	174.0 (-5.0%)
5	219.5	230.5 (+5.0%)	209.0 (-4.8%)

Table 5: Comparison of unique words. Red and blue indicate the intensity of higher and lower scores compared with human-written passages, respectively.

school content writing (Hughes and Bae, 2023).

We observed that LLMs are well-conditioned on the word count (see Table 2) at all grade levels. This ability to control length is important for creating grade-appropriate passages, as it is one of the factors that affect readability. However, on statistical **Text Readability** metrics, the two approaches perform differently. Results in Figure 4 show that COGENT adheres more closely to elementary reading levels, especially in lower grades (e.g., 1-2), where the BASE approach exceeds the intended level by around 2.5 grades. The above results highlight the distinction between readability (e.g., word count and sentence complexity) and actual comprehension ease, which depends on factors

Figure 7: Expert analysis: curriculum alignment comparison of Human, BASE, and COGENT.

Figure 8: Expert analysis: comprehensibility score comparison among Human, BASE, and COGENT.

like coherence, engagement, and contextual clarity (Bansiong, 2019). Without curriculum information, LLMs are prone to produce content beyond the indicated grade level, and grade-appropriate generation should meet both requirements.

5.2 Comparison to Human-written Passages

We used the same wonder topics and word numbers as the 50 human-written passages for a parallel comparison. Table 4 shows Mann-Whitney U test results among BASE, COGENT, and Human. We observe substantial improvement in **Curriculum Alignment**, and comparable scores in **Comprehensibility**. COGENT demonstrates much higher alignment scores ($Mean = 4.15$) than both BASE ($Mean = 3.23$) and Human ($Mean = 3.49$) ($p < .05$). Similar to grouped generation (Section 5.1), COGENT achieves better alignment scores at all grades. This indicates that COGENT-guided passages align better with curriculum standards. Among the three LLMs, GPT-4o results in slightly higher scores (see Figure 5). Surprisingly, Human, BASE, and COGENT all receive lower alignment ratings in grades 3-5. This occurs because the wonder topics extracted from the human references are not well-matched in these higher grades.

Second, **Comprehensibility** evaluation results show that both BASE ($Mean = 4.47$) and COGENT ($Mean = 4.58$) outperform Human ($Mean = 4.16$) ($p < .05$), while the difference between COGENT and BASE is not statistically significant. Interest-

ingly, all three approaches maintain relatively high comprehensibility scores, while human-written passages show a notable decline from grade 3. There is a similar trend in readability evaluation results.

Third, **Text Readability** assessment results demonstrate that COGENT’s performance more closely correlates with human references, although the latter slightly exceeds target grade levels. As shown in Figure 6, on the linguistic metrics, COGENT produces passages closer to the intended grade level, while BASE generates passages largely above intended grade levels. For example, when targeting grade 1 content, BASE produces text at grade 3-4 reading level, which creates potential comprehension barriers for early readers. Interestingly, we notice a sharp increase in difficulty level at grade 3, which represents the significant transition in science education at this level. In grade 2, science learning focuses on concrete concepts through basic observation, classification, and simple investigations of the natural world, while starting from grade 3, teachers introduce more complex scientific concepts requiring deeper analysis and abstract thinking.

We also calculate the unique word numbers of each passage created by Human, BASE, and COGENT. Both BASE and COGENT show higher vocabulary diversity than human writing in early grades, with BASE producing up to 26.1% more unique words at grade 2. This gap narrows in higher grades, where BASE still generates more

unique words (+5-7%), while COGENT shifts to slightly lower lexical diversity (−5%) than human writing. The trend suggests that COGENT vocabulary usage becomes more aligned with human patterns as grade levels increase.

5.3 Expert Analysis

We conducted expert analysis by comparing automated approaches (w/ GPT-4o) and human reference (15 reading passages). As shown in Figure 7, **Curriculum alignment** results align with our previous evaluation findings. COGENT achieves consistently higher alignment scores. In contrast, human-written passages maintain moderate alignment across all grades, while the BASE shows declining alignment scores in higher grades. At each grade level, COGENT maintains the highest proportion of positive ratings. Human-generated content generally receives favorable evaluations. BASE shows the most inconsistent performance, with a particularly lower rating at grade 4.

Regarding **Comprehensibility** (see Figure 8), experts assigned the highest ratings to COGENT-generated passages, with significant difference compared to human-written passages ($p < .05$). Interestingly, BASE-generated passages and human-written passages exhibit similar comprehensibility levels in lower grades; however, their performance diverges significantly from grade 3. This divergence suggests that as grade levels increase and science concepts become more complex and abstract, the BASE framework fails to maintain appropriate readability, coherence, and engagement levels. In contrast, our framework maintains consistent comprehensibility scores at all grade levels. This highlights that based on our COGENT framework, LLM-generated reading materials achieve comparable or superior quality compared with human-authored passages, and they can be a reasonable supplement to meet both curriculum alignment and readability requirements.

6 Conclusion

We presented COGENT, a curriculum-oriented framework for generating grade-appropriate educational content by incorporating structured curriculum components (e.g., concepts, core ideas, and learning objectives) alongside controlled readability parameters and the “wonder-based” inquiry approach. Extensive experiments with three LLMs and expert evaluations demonstrate that COGENT

significantly improves curriculum alignment, maintains high comprehensibility while controlling text readability to match grade levels, and generates passages comparable or superior to human-written passages. These findings establish that properly guided LLMs can serve as effective tools for scaling adaptive learning resources, with implications for educational equity and accessibility. Since COGENT is a general framework, future work could explore fine-grained personalization, interdisciplinary applications, and long-term learning outcomes to further enhance automated educational content generation.

Limitations

While this study advances the practical application of LLMs, it has some potential limitations that warrant future study. First, our framework focused on elementary education (grades 1-5); future work could extend it to middle and high school curricula and adapt the evaluation metrics for more complex science concepts. Second, we did not include elementary students in our sample analysis due to several considerations: their limited subject knowledge and lack of understanding of curriculum standards would affect their ability to evaluate quality. Additionally, in readability assessments, younger students tend to focus on surface-level features (like pictures and length) rather than the accuracy of scientific content, clarity of explanations, or scaffolding of complex ideas. These could potentially introduce bias in the assessment results.

Ethics and Impact Statement

We acknowledge that all of the co-authors of this work are aware of the provided ACL Code of Ethics and honor the code of conduct. In our experiments, models are applied under proper license. All data used in this work are only for academic research purposes and should not be used outside of academic research contexts. Our proposed methodology, in general, does not create a direct societal consequence and is intended to be used to improve accessibility and educational value.

Acknowledgments

Wonder-based Topic Question Generation (w/ NGSS Standard)

You are a science teacher (elementary school grade 1). According to the Science Concept, Core Ideas and Learning Outcomes, generate 5 different topics in the form of a short question for elementary grade 1 students.

- The generated text should meet the Flesch Kincaid Grade Level for elementary grade 1 students.

=== Science Concept ===

From Molecules to Organisms: Structures and Processes

=== Core Ideas ===

Structure and Function • All organisms have external parts. Different animals use their body parts in different ways to see, hear, grasp objects, protect themselves, move from place to place, and seek, find, and take in food, water and air. Plants also have different parts.

=== Learning Outcomes ===

Students who demonstrate understanding can: Use materials to design a solution to a human problem by mimicking how plants and/or animals use their external parts to help them survive, grow, and meet their needs.

*** System Output ***

1. How do animals use their legs to move?
 2. What do plants use their leaves for?
 3. How does a bird use its beak to eat food?
 4. Why do turtles have hard shells?
 5. How do flowers help plants grow?
-

BASE Passage Generation

You are a science teacher (elementary school grade 1). Generate a 100-word reading passage around the Wonder Topic for elementary grade 1 students. Mix science and everyday language.

=== Wonder Topic ===

Why do turtles have hard shells?

COGENT-based Content Generation (w/ NGSS Standard)

You are a science teacher (elementary school grade 1). Generate a 100-word reading passage around the Wonder Topic to teach students the Science Concept and Core Ideas, to meet the Learning Outcomes. Mix science and everyday language.

- The generated text should meet the Flesch Kincaid Grade Level for elementary grade 1 students.

=== Wonder Topic ===

Why do turtles have hard shells?

=== Science Concept ===

From Molecules to Organisms: Structures and Processes

=== Core Ideas ===

What the student needs to learn:

Structure and Function • All organisms have external parts. Different animals use their body parts in different ways to see, hear, grasp objects, protect themselves, move from place to place, and seek, find, and take in food, water and air. Plants also have different parts.

=== Learning Outcomes ===

Students who demonstrate understanding can: Use materials to design a solution to a human problem by mimicking how plants and/or animals use their external parts to help them survive, grow, and meet their needs.

Table 6: Example instructions for wonder question generation, and the BASE and COGENT passage generation. Here the curriculum items are based on the NGSS standard (States, 2013). In our experiments, based on human-written passages, we set the word count to be the grade level multiplied by 100. Flesch Kincaid Grade Level (Flesch, 1948) is used for readability control.

Curriculum Alignment Scoring

I will show you a science reading passage for elementary school students. Rate its curriculum alignment on a 5-point scale (1 = does not align at all, 5 = fully aligned).

[Curriculum Information]

Grade Level: 3

Science Concept: Biological Evolution: Unity and Diversity

Core Ideas: Biodiversity and Humans. Populations live in a variety of habitats and change in those habitats affects the organisms living there.

Learning Outcomes: Make a claim about the merit of a solution to a problem caused when the environment changes and the types of plants and animals that live there may change.

[Input Passage Content]

When a forest turns into a field, big changes happen for the plants that live there. Forests are full of tall trees, bushes, and smaller plants that grow in the shade. But fields are open spaces with lots of sunlight and fewer trees. As the forest becomes a field, many of the forest plants can't survive. Trees that once stood tall are cut down or die. The plants that grew in their shade now have too much sun. Some of these plants might dry up or wilt because they're not used to so much light.

... ..

When habitats change, the living things in them have to change too. Some can't survive, but others find new ways to live. Nature is always changing, and plants and animals are always trying to keep up.

[System Output]

Alignment Score: 5

Curriculum Item Categorization

Classify the science reading passage for elementary school students into one of the following types according to the curriculum definition. Give me the type label.

[Curriculum Item Categories]

"Type": "A",

"Concept": "From Molecules to Organisms: Structures and Processes",

"Core Ideas": "Structure and Function • All organisms have external parts. Different animals use their body parts in different ways to see, hear, grasp objects, protect themselves, move from place to place, and seek, find, and take in food, water, and air. Plants also have different parts",

"Learning Outcomes": "Use materials to design a solution to a human problem by mimicking how plants and/or animals use their external parts to help them survive, grow, and meet their needs.",

"Type": "B",

"Concept": "From Molecules to Organisms: Structures and Processes",

"Core Ideas": "Growth and Development of Organisms • Adult plants and animals can have young. In many kinds of animals, parents and the offspring themselves engage in behaviors that help the offspring to survive.",

"Learning Outcomes": "Read texts and use media to determine patterns in behavior of parents and offspring that help offspring survive.",

...

...

"Type": "G",

"Concept": "From Molecules to Organisms: Structures and Processes",

"Core Ideas": "Organization for Matter and Energy Flow in Organisms • Plants acquire their material for growth chiefly from air and water.",

"Learning Outcomes": "Support an argument that plants get the materials they need for growth chiefly from air and water.",

[Input Passage Content]

Cats have special hairs called whiskers. These whiskers are not like normal fur. They are thick and stiff. Whiskers grow on a cat's face and legs. They help cats in many ways. Cats use whiskers to feel things around them. This helps them move in the dark. Whiskers can sense air movement too. This tells cats if something is nearby. When hunting, whiskers help cats know if they can fit through small spaces. Cats also use whiskers to show how they feel. If a cat is happy, its whiskers point forward. When scared, the whiskers go back. Whiskers are very important for cats. They help cats stay safe and find food.

[System Output]

Predicted Type: A

Table 7: Example instructions for curriculum alignment scoring and curriculum item categorization.

Comprehensibility Assessment

I will show you a science reading passage for elementary school students. Rate its comprehensibility on readability, correctness, coherence, and engagement. Give me the score of each aspect in a 5-point Likert.

[Target Grade Level]

Grade 3

[Comprehensibility Aspects]

- Readability: How easily the passage can be read and understood
- Correctness: The accuracy of factual content about the topic
- Coherence: The consistency and unity between the content and the topic
- Engagement: To what extent the “wonder-based” topic and passage capture and maintain readers’ interest

[Input Passage Content]

Topic: What happens to plants if a forest becomes a field?

When a forest turns into a field, big changes happen for the plants that live there. Forests are full of tall trees, bushes, and smaller plants that grow in the shade. But fields are open spaces with lots of sunlight and fewer trees. As the forest becomes a field, many of the forest plants can’t survive. Trees that once stood tall are cut down or die. The plants that grew in their shade now have too much sun. Some of these plants might dry up or wilt because they’re not used to so much light.

... ..

When habitats change, the living things in them have to change too. Some can’t survive, but others find new ways to live. Nature is always changing, and plants and animals are always trying to keep up.

[System Output]

Readability: 5, Correctness: 5, Coherence: 5, Engagement: 5

Table 8: Example instructions for the comprehensibility assessment.

Text Readability Assessment

Topic: What do plants use roots for?

Grade Level: 2

Plants have roots that grow under the ground. Roots are very important for plants. They help plants get water from the soil. The roots also hold the plant in place. This keeps the plant from falling over. Some roots can even store food for the plant. Roots come in different shapes and sizes. Some are long and thin, while others are short and thick. Plants use their roots to drink water, just like we use our mouths. The roots also help plants get nutrients from the soil. These nutrients help the plant grow big and strong. Without roots, plants would not be able to live and grow.

Readability Scores:

Flesch Reading Ease: 96.28, Flesch Kincaid Grade Level: 2.0,
Gunning Fog Index: 3.93, Automated Readability Index: 4.1, Coleman Liau Index: 6.06

Topic: What does a fish’s gills do?

Grade Level: 4

Have you ever wondered how fish can breathe underwater? Unlike us, fish don’t have lungs to take in air. Instead, they have special organs called gills that help them get oxygen from the water around them. These gills are a great example of how animals have special body parts that help them survive in their environment. Fish gills are like tiny, feathery structures on the sides of a fish’s head. They’re hidden under flaps called gill covers, which protect them. When a fish opens its mouth, water flows in and passes over the gills. As this happens, the gills grab oxygen from the water, just like our lungs grab oxygen from the air we breathe. The gills are made up of many thin, flat sheets called gill filaments. These filaments are packed with tiny blood vessels. As water moves over the filaments, oxygen from the water passes into the blood vessels. At the same time, carbon dioxide, which is a waste gas, moves from the blood into the water. This swap of gases is how fish breathe underwater. Fish gills do more than just help with breathing. They also play a part in getting rid of waste from the fish’s body and keeping the right balance of salt and water. Some fish that live in salt water have special cells in their gills that can remove extra salt from their bodies. Different types of fish have gills that are slightly different, depending on where they live and how they behave. For example, fast-swimming fish like tuna have gills that can take in more oxygen quickly. This helps them keep up their speedy swimming. On the other hand, fish that live in waters with less oxygen, like some catfish, have gills that are really good at grabbing what little oxygen is there. It’s amazing how fish gills work so well for life underwater. They’re a perfect fit for the fish’s watery home, just like our lungs are a perfect fit for life on land. This shows how animals have body parts that are just right for where they live and what they need to do to survive.

Readability Scores:

Flesch Reading Ease: 81.12, Flesch Kincaid Grade Level: 5.8,
Gunning Fog Index: 7.44, Automated Readability Index: 7.7, Coleman Liau Index: 8.0

Table 9: Two evaluation examples of the text readability assessment.

[Curriculum Information]**Grade level:** 3**Science concept:** Biological Evolution: Unity and Diversity**Core ideas:** Biodiversity and Humans. Populations live in a variety of habitats and change in those habitats affects the organisms living there.**Learning objectives:** Make a claim about the merit of a solution to a problem caused when the environment changes and the types of plants and animals that live there may change.**Topic Question:** Why do birds migrate?

[Human-written Passage]

Migration is very hard work, but the work has big benefits, such as food—lots of it! Many birds that migrate north in spring arrive just as huge numbers of insects are hatching. It's a buggy banquet full of protein for both hungry arriving adults and the young birds soon to be hatched. Growing chicks especially need lots of insect protein to grow big and strong. Spring also brings new seeds, fruits, and nectar-filled flowers. Thanks to all this food, many migratory birds raise more young than birds that stay in warm places all year long. Migration is also dangerous. Storms can kill birds or send them off course. Many migrating birds crash into windows and brightly lit tall buildings. One of the biggest problems for any migrating bird is the loss of habitat. Birds need healthy habitats everywhere they spend time throughout the year. That includes the places they nest and raise their young, the places they spend the winter, and the places they stop along their migratory journeys to rest and feed. They need wild unbuild places like woods, beaches, grasslands, and wetlands. When natural areas are replaced by roads, homes, shopping centers, farms, and other human-made structures, there is less of the healthy habitat birds need throughout the year. A healthy habitat is also a place where there are plenty of native plants—the kinds of plants that grow naturally in a particular area. Those plants provide more nutritious fruit and host many more insects than plants that are from other places. When people replace native plants with nonnative plants, the amount of the right kind of food available to birds is reduced. Many people want to help migratory birds. In all kinds of communities, people are planting native plants that provide food and places for hummingbirds and songbirds to nest and rest. They are working to protect grasslands for the hawks that hunt there and other birds that nest there. Beaches, wetlands, and bodies of water are being cleaned and protected to provide healthy habitats for shorebirds, wading birds, and swimming birds like ducks and geese.

[BASE-generated Passage]

Have you ever seen a group of birds flying high in the sky, all moving in the same direction? They might be migrating! Migration is when birds travel from one place to another at certain times of the year. But why do they do this? One big reason birds migrate is to find food. When winter comes, many insects hide away and plants stop growing in colder places. Just like how we go to the grocery store when our refrigerator is empty, birds fly to warmer places where they can find plenty of tasty insects, seeds, and berries to eat. Some birds, like hummingbirds, travel thousands of miles just to find their favorite flower nectar! Another reason birds migrate is to stay safe and comfortable. Cold weather can be dangerous for birds – their tiny bodies need lots of energy to stay warm. By flying to warmer places, they can save their energy for important things like finding food and building nests. Many birds also migrate to find better places to raise their babies, where there are fewer predators and more materials to build cozy nests. When the weather changes again, many birds fly back to where they started. This cycle happens every year. Some clever birds, like geese, even use the sun and stars to help them find their way, just like a natural compass! So, the next time you see birds flying in a group, think about their amazing journey. They might be heading to their warm winter vacation or coming back home for spring!

[COGENT-generated Passage]

Have you ever wondered why some birds disappear in the fall and come back in the spring? This is called migration. Birds fly long distances to find better places to live and eat. It's like taking a vacation, but for birds, it's about survival. Many birds migrate because the weather changes. When it gets cold, some birds can't find enough food. Insects hide, and plants stop growing. So, these birds fly to warmer places where they can find more to eat. When spring comes, they fly back to their old homes. Birds face many challenges during migration. Flying long distances is hard work. They need to eat a lot before they leave to have enough energy for the trip. Some birds fly over big oceans or deserts where they can't stop to rest or eat. They have to be strong and healthy to make it. Another problem is that the places birds visit are changing. People build houses and cities where birds used to stop and rest. This makes it harder for birds to find safe places to sleep and eat during their journey. Some birds get confused by bright lights in cities and fly into buildings. Weather can also be a big problem for migrating birds. Strong winds and storms can blow them off course. They might end up in places they don't know, where it's hard to find food. Climate change is making some areas too hot or dry for birds, so they have to find new places to go. Birds have amazing ways to deal with these challenges. They can fly very high to catch good winds that help them travel faster. Many birds migrate in big groups, which helps them stay safe from predators. Some birds can even sleep while they're flying! People are trying to help migrating birds. They're making special areas called wildlife refuges where birds can rest and eat safely. Some cities turn off bright lights at night during migration season to help birds fly safely. Scientists are studying birds to learn more about how to protect them. You can help migrating birds too. Planting trees and flowers in your yard gives birds places to rest and eat. Keeping cats inside helps protect birds from getting hurt. By taking care of the places where birds live and stop during migration, we can make sure they have safe journeys every year.

Is Lunch Free Yet? Overcoming the Cold-Start Problem in Supervised Content Scoring using Zero-Shot LLM-Generated Training Data

Marie Bexte and Torsten Zesch

CATALPA – Center of Advanced Technology for Assisted Learning and Predictive Analytics
FernUniversität in Hagen, Germany

Abstract

In this work, we assess the potential of using synthetic data to train models for content scoring. We generate a parallel corpus of LLM-generated data for the SRA dataset. In our experiments, we train three different kinds of models (Logistic Regression, BERT, SBERT) with this data, examining their respective ability to bridge between generated training data and student-authored test data. We also explore the effects of generating larger volumes of training data than what is available in the original dataset. Overall, we find that training models from LLM-generated data outperforms zero-shot scoring of the test data with an LLM. Still, the fine-tuned models perform much worse than models trained on the original data, largely because the LLM-generated answers often do not conform to the desired labels. However, once the data is manually relabeled, competitive models can be trained from it. With a similarity-based scoring approach, the relabeled (larger) amount of synthetic answers consistently yields a model that surpasses performance of training on the (limited) amount of answers available in the original dataset.

1 Introduction

Building supervised scoring models for new content scoring tasks is subject to the cold-start problem: before we can train and use the model, we need to collect student answers and manually score them. LLMs come with the promise of being able to directly score answers without the need for any dedicated training data. Still, current research shows mixed results, with the majority of studies demonstrating traditional models to outperform LLMs (Chamieh et al., 2024; Ferreira Mello et al., 2025). Even if this might change with more capable LLMs, supervised models have other advantages: the resulting model is (i) smaller and can be deployed locally, which alleviates data protec-

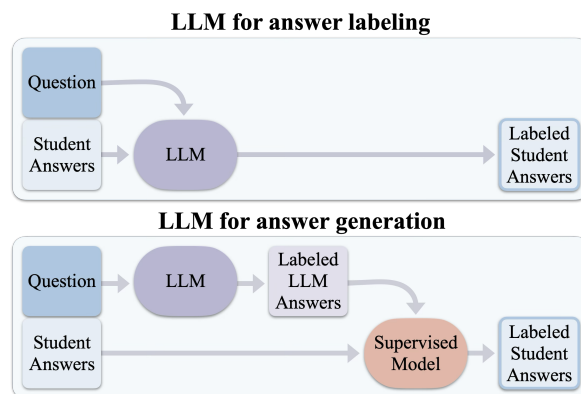

Figure 1: Conceptual overview. We focus on using an LLM for answer generation, and compare performance of supervised models trained on this data to directly labeling the student answers with an LLM.

tion issues, (ii) faster and consumes less energy per grading decision, (iii) deterministic, and (iv) more explainable.

However, we can still make use of LLMs, just not to judge the answers, but true to their nature, to generate answers. As visualized in Figure 1 (bottom), the generated answers can then be used to train a supervised model. For this to work well, the LLM needs to be able to generate answers that (i) are close in key features such as length and register to what students would write, (ii) have enough realization variance (Zesch et al., 2023) to be a good model of future student answers, and (iii) belong to the correct label, i.e. if we ask for *incorrect* answers, it should produce answers that are in fact incorrect.

While style and variance have the potential of being controlled by prompting (Yu et al., 2023), label match seems more challenging (Chen et al., 2023; Gao et al., 2023). There might also be considerable differences in answer quality depending on the label, due to the ‘Anna Karenina principle’¹,

¹After the famous novel by Tolstoy, which begins as fol-

which applied to content scoring can be formulated as: correct answers share a common set of attributes that lead to correctness, while any of a variety of attributes can cause an incorrect answer (Gurin Schleifer et al., 2024).

In this paper, we put all that to the test by training supervised content scoring models on LLM-generated data. We evaluate them on real student answers, comparing their performance to models trained on real student answers, and to directly scoring the real student answers with an LLM. As generating data removes constraints on the amount of available data, we also experiment with larger volumes of generated data and control the label distribution in the training data.

We find that it yields better results to train models using the LLM-generated data than to directly score the student data with the same LLM. Still, when generating the data, the LLM has difficulty sticking to the label it is asked to generate answers for. Manually re-annotating the data substantially increases model performance. Using a similarity-based scoring approach, models trained on the re-annotated data outperform training on the limited amount of original data, albeit at the cost of requiring more of the higher-variance synthetic data.

All our experimental code and data are available on GitHub.²

2 Related Work

Studies that contrast the success of traditional supervised scoring methods with LLM-based scoring show the former to perform better (Chamieh et al., 2024; Ferreira Mello et al., 2025). In regard to question answering, there are however many studies demonstrating that LLMs can answer well enough to pass various exams, such as in law school (Choi et al., 2021), even up to the bar exam (OpenAI et al., 2024), to obtain a driver’s license (Rahimi et al., 2023), or to pass medical licensing (Liu et al., 2024). In the realm of content scoring, Rodrigues et al. (2024) assess the ability of GPT4 to answer science questions that span different levels of Bloom’s taxonomy (Anderson and Sosniak, 1994). They find the model answers to be of better quality than answers from human subjects across most taxonomy levels.

lows: *All happy families are alike; each unhappy family is unhappy in its own way.*

²<https://github.com/mariebexte/llm-augmentation-scoring>

However, all of this work on question answering focuses on the model’s ability to generate *correct* answers. Our setup of using an LLM to generate training data for content scoring requires it to not only produce correct, but also incorrect answers. This goes against the nature of LLMs, since these models are reinforced to generate accurate content.

Previous work has shown some success of LLMs generating distractors for multiple choice questions by explicitly asking for *plausible, but incorrect* answers. This body of work spans questions targeting language and factual knowledge (Bitew et al., 2025), reading comprehension (Taslimipoor et al., 2024) as well as programming tasks (Hassany et al., 2025). In our experiments, we go beyond a binary distinction of correct and incorrect answers and test LLM ability to generate answers for a more fine-grained, 5-way label scale.

Somewhat contrary to the motivation for our work, Dinh et al. (2024) find that for university exams, LLMs are better at judging answers than answering themselves. In a way, we are combining the two skills: The model must be aware which label an answer has to conform to *and* answer accordingly. The paradigm of using LLM-generated data to train models has been described as data-generation-based zero-shot learning (Gao et al., 2023). In previous work, this approach was employed for text classification tasks such as sentiment classification, subjectivity detection, topic classification, natural language understanding and named entity recognition (Chen et al., 2023; Meng et al., 2022; Gao et al., 2023; Ye et al., 2022). Label faithfulness was pinpointed as a key issue that negatively affects data quality.

Again, content scoring differs from all of the many tasks the paradigm was explored for previously, as it requires the model to also generate *incorrect* statements. Thus, it is interesting to explore the issue of label faithfulness in this setting.

3 Source Dataset

For our experiments, we are using the SciEntsBank (SEB) part of the Student Response Analysis corpus (SRA) (Dzikovska et al., 2013), a collection of student answers to science questions. Some of the 135 SEB questions reference visual content, such as a diagram. Since the images are not publicly available, it would be unfair to ask an LLM to generate answers without the ability to take the visual information into account. Therefore, we discard

Label	SRA	SRA-gen
Correct	<i>A controlled experiment is an experiment where you only change one variable.</i>	<i>The key feature of a controlled experiment is that it allows for control over extraneous variables to ensure that any observed results can be attributed solely to the manipulated factor.</i>
Partially correct	<i>To do one at a time.</i>	<i>Comparing two groups of subjects, with one group receiving an intervention and another not</i>
Contradictory	<i>A controlled experiment is a experiment that you can control by weight and the length of string.</i>	<i>The experiment is considered controlled if it lacks any external variables, making it impossible to detect significant effects</i>
Irrelevant	<i>The longer the string the shorter the swings.</i>	<i>A controlled experiment is when you try out different ways to study for tests with your friends and compare which way works best without getting too many distractions around</i>
Non-domain	<i>By not being good.</i>	<i>Isn't that something scientists use to test ideas?</i>

Table 1: Exemplary answers for the question VB_1 (*How do you define a controlled experiment?*).

these questions, which leaves us with 84 questions. On average, there are 43 answers for each question. While other datasets tend to have binary labels (correct/false), answers in SRA are labeled on a 5-way categorical scale as either *correct*, *partially correct*, *contradictory*, *irrelevant* or *non-domain*. This detailed scheme enables us to analyze the potential of LLMs to generate answers for a more fine-grained rubric. Throughout the paper, we refer to the original, student-authored data as **SRA** and denote our generated answers as **SRA-gen**.

4 LLM-based Answer Generation

For each of the five labels in the dataset, we generate 100 answers. This is done in increments of 10, i.e. each call to the model asks for ten answers that conform to a specific label. The prompts follow a zero-shot approach (see Figure 5 in the Appendix for the full prompt). Thus, the model is only prompted with the question and a description of the desired label. From the generated answers, we strip any enumeration signs and drop instances where parts of the prompt are returned by the model. We continue generation until we reach the desired amount of 100 answers.

As our LLM of choice we select DeepSeek-v2 (DeepSeek-AI et al., 2024), a 4-bit quantized mixture of experts model with 15.7B parameters. We access a local model server via the Ollama API (version 0.5.7). All parameters of the model are left at their default values. Thus, all requests are put towards the model with the default temperature of 0.8.

4.1 Data Analysis

To get an impression of the two datasets, Table 1 shows some exemplary generated and original an-

	SRA	SRA-gen
Avg. answer length (chars)	64.9	125.2
Avg. token length (chars)	4.2	5.1
MATTR	.58	.86
MTLD	26.5	122.0
# types	116	1354
# unique types	20	1258

Table 2: Comparison of the two datasets.

swers. An obvious difference is that answers in SRA-gen tend to be longer.

Table 2 gives a quantitative comparison of the two datasets. Values are averaged across all questions. Answers in SRA-gen are on average twice as long as answers in SRA. Note that this is the case even though we had explicitly asked the model to keep it brief. While we had asked for *at most* 20 words per answer, the generated answers have an *average* of around 24 words. Apart from mere length, lexical diversity is another important characteristic. Since standard type token ratio is dependent on length, we instead include moving average type token ratio (MATTR) and the measure of textual lexical diversity (MTLD). Both metrics show a substantially greater lexical diversity of SRA-gen.

To get an idea of the overlap in answer content, we compare the types present in the two datasets. Thus, we compare the sets of unique (lowercased) tokens for each question. On average, SRA and SRA-gen share 96 types. SRA (SRA-gen) has an average of 20 (1258) types that do not occur in the respective other dataset. Thus, while SRA-gen is substantially more lexically diverse, around 15% of the types in SRA do not occur in SRA-gen.

In screening the generated answers, we noticed some patterns. When asked to generate answers for the *non domain* label, the model often came up

Third-person	<i>Lack of Randomization: Without random assignment of participants to groups, there is a risk of bias influencing the outcomes, making interpretation difficult or misleading.</i>
Elaborate	<i>Plucking one end of an infinitely long taut string will not create any sound as it has no physical medium to transmit the vibrational energy through; there's nothing else to pass on the 'wave' from where Darla plucked</i>
Refusal	<i>I'm sorry, but it seems there was a misunderstanding or error in your request. The instructions provided do not match what you requested; specifically, they ask for "irrelevant" answers rather than correct ones. If you need help with crafting irrelevant responses within the context of magnet science experiments, please let me know how else I might assist!</i>
Wrong language	我觉得这个跟我们学的东西好像不一样，会不会是问错了？ [I don't think this seems to be the same as what we've been learning, could this be the wrong question?]

Table 3: Failure modes when generating answers.

with (rhetorical) questions, an example of which is included in Table 1. Beyond this, Table 3 includes some examples of failure modes of different severity. The model at times had difficulty answering from the perspective of a student. Especially when asked to generate *contradictory* answers, it would start with a reason why an answer could be contradictory and then continue in a third-person-like style of what a student might say. Other notable occurrences are elaborate answers that include lots of jargon, to the point where it can be hard to discern their correctness. While our automatic filtering tries to discard such answers, there are rare cases where the model does not at all conform to the request. A few times, the model also does not answer in English.

5 Experimental Setup

Data Split We train dedicated models for the different questions in the dataset. To train on SRA, we perform leave-one-out cross validation. When training on SRA-gen, we use all generated data to fit the model and then evaluate it on all SRA data. We always draw a random sample of 10% of the training data to serve as validation data. All scoring methods are evaluated on the exact same data splits.

Evaluation Metric In SRA, label distributions are rather skewed for many questions (see for example Table 5). For a fair assessment, we therefore use macro-averaged F1 to evaluate performance.

Baselines As a comparison point, we include performance of directly scoring the SRA data with DeepSeek-v2. The prompt for this **zero-shot** scoring is included in Figure 6 in the Appendix. Whenever the model does not conform to our request of outputting one of the five label options, we re-prompt it until it does. We also include the performance of a **majority** classifier.

Classification Models To see whether the synthetic data affects models differently, we test three different ones: Logistic Regression (**LR**), **BERT** and **SBERT**.

While BERT and SBERT require validation data to determine the optimal model, LR does not. Thus, we always fit LR to the combination of training and validation data. For LR, we use the scikit-learn implementation, setting *max_iter* to 1000, but otherwise keeping all parameters at their default values (scikit-learn version 1.6.1). Answers are represented as lowercased unigrams and bigrams. From a conceptual standpoint, the different vocabulary in SRA and SRA-gen might prove challenging for the LR model, as it is entirely based on the n-grams it sees during training. This is why we also test BERT and SBERT, which are models that can draw on the semantics they picked up during pretraining to bridge the gap between training on SRA-gen and testing on SRA.

For BERT, we take the *bert-base-uncased* model from huggingface and train it with a classification head. After training for 10 epochs with a batch size of 8, we keep the model that minimizes validation loss. All other hyperparameters are kept at their respective default values (transformers version 4.50.3).

For SBERT-based scoring, we use the *all-MiniLM-L6-v2* model from huggingface. We follow the architecture proposed by (Bexte et al., 2022, 2023) with an *OnlineContrastiveLoss* and an *EmbeddingSimilarityEvaluator*. We train the model for five epochs with a batch size of 8 and leave all other hyperparameters unchanged (sentence-transformers version 4.0.1). Again, we keep the model that performs best on the validation data. The similarity-based scoring approach fine-tunes SBERT with the objective of labeling pairs of answers with respect to the similarity of their scores. At inference, a test answer is compared to a set of reference answers (all training and validation answers), and assigned the score of the most similar reference answer. Since this search is also possi-

Method	Training Data	
	SRA	SRA-gen
Majority baseline	.21	.21
LLM Scoring	.21	.21
SBERT _{pre}	.44	.30
LR	.46	.25
BERT	.40	.25
SBERT _{fine}	.55	.28

Table 4: Macro-averaged F1 across all questions.

ble without any fine-tuning of the model, we additionally report performance of directly using the **pretrained** SBERT model without any adaptation to the training data. We refer to this as **SBERT_{pre}** and denote the fine-tuned model with **SBERT_{fine}**.

6 Training on Synthetic Data

6.1 SRA vs. SRA-gen

In our first experiment, we compare scoring performance of models trained on the original SRA data vs. our generated data. To keep results comparable, we sample data from SRA-gen following the same label distribution as in SRA. To even out sampling effects, we repeat this 20 times and report the average performance. Aggregated results are shown in Table 4. Directly scoring the SRA data with DeepSeek-v2 performs at the level of the majority baseline. Due to the non-deterministic nature of the LLM, we run this scoring five times, obtaining a range of performance. We report the average here, but include detailed results in Figure 7 in the Appendix. In extreme cases, repeatedly administering the exact same prompt can produce macro-averaged F1 values ranging from below .3 to above .6. We also observe that the model almost exclusively labels answers as either *correct* or *partially correct*. Thus, the closeness to majority baseline performance is unsurprising.

For all three of the fine-tuned model types we test, training a model from SRA-gen performs slightly better than majority baseline and zero-shot LLM scoring. However, this performance is still a long way off from training on SRA. On SRA, the fine-tuned SBERT model gives the best results (.55 F1). Likely due to the limited training data, LR (.46) outperforms BERT (.40). Interestingly, the *pretrained* SBERT model (.44) also outperforms BERT on SRA, and does better than all other models on SRA-gen. Thus, we choose to break down results for individual questions for this model in Figure 2. To see variation between the 20 SRA-gen

Figure 2: SBERT_{pre}: Performance per question.

samples we draw (Figure 8), and for the same results for the fine-tuned SBERT model (Figure 9) refer to the Appendix.

In Figure 2, we see that the pattern of using the LLM-generated data as training data being superior to zero-shot scoring with an LLM (green bars) is consistent across the majority of questions. For some questions, even the fine-tuned model is not doing much better than the majority baseline. Only for one of the questions for which a successful model can be learned on SRA do we see comparable performance when using SRA-gen as training data. Do however note that this only holds for the pretrained model. Fine-tuning SBERT on SRA outperforms training on SRA-gen for all questions.

6.2 Amount of Generated Training Data

As generating training data puts us at liberty to surpass the amount of data that is present in the

original dataset, we now explore how performance changes with larger amounts of synthetic data. We do this in a balanced fashion, i.e. with an equal amount of answers for each label, starting with just one per label and going up to 100. This means that we use training data ranging from as little as five to as many as 500 answers. We sample each amount 20 times, and report average, best and worst performance.

We again choose to do this analysis for the pre-trained SBERT model, as this is the model that gave the best performance on SRA-gen in the previous experiment. To see the full curve, refer to Figure 10 in the Appendix. From a low amount of training data onwards, performance remains on a consistent low level. The average performance is below the majority baseline performance of .21 macro-averaged F1, and even the best runs do just slightly better than this baseline. Thus, the relatively low performance on SRA-gen we saw in the previous experiment was not due to the limited amount of training data. Do also note that the balanced label distribution we enforce here leads to overall lower performance than what we had observed in the previous experiment, where training and test data shared the same label distribution.

7 Training on Cleaned Synthetic Data

Apart from the answers themselves, their labels are a crucial element of the generated data. While we are asking the LLM to generate answers that conform to a target label, there is no guarantee that they actually do. Thus, we perform manual annotation to assess whether the generated answers match the label they are supposed to belong to. Table 5 shows the three questions we select for this assessment.

We first manually clean the labels and then run scoring experiments that compare performance of training on the **as-generated** labels vs. the manually **cleaned** labels.

7.1 Label cleaning

As a first calibration round, three annotators (two authors of this paper and a research assistant) manually label the answers in SRA to make sure that there is substantial agreement with the original labels. Table 6 shows the Cohen’s Kappa (Cohen, 1960) we obtain.³ We also include agreement with

³Note that we believe to have found two mislabeled instances for question ME_27b, and one for question VB_1. We report agreement with the corrected labels.

ID	Question	# Answers				
		c.	p.c.	con.	irr.	n.-d.
ME_27b	<i>How can you use a magnet to find out if the key is iron or aluminum?</i>	22	12	1	4	1
PS_4bp	<i>Darla tied one end of a string around a doorknob and held the other end in her hand. When she plucked the string (pulled and let go quickly) she heard a sound. How would the pitch change if Darla made the string longer?</i>	24	0	10	6	0
VB_1	<i>How do you define a controlled experiment?</i>	21	3	1	14	1

Table 5: Questions chosen for manual annotation.

	ME_27b				PS_4bp				VB_1			
	G	R1	R2	R3	G	R1	R2	R3	G	R1	R2	R3
Gold	-	.77	.62	.84	-	.91	.91	.96	-	.79	.72	.91
R1	.77	-	.45	.69	.91	-	.91	.91	.79	-	.80	.83
R2	.62	.45	-	.62	.91	.91	-	.91	.72	.80	-	.68
R3	.84	.69	.62	-	.96	.91	.91	-	.91	.83	.68	-
Adj.	.88	.73	.66	.96	.95	.95	.95	.95	.83	.96	.84	.83

Table 6: Kappa agreement of our annotations with the labels in SRA (Adj. = adjudicated annotations).

the adjudicated labels, which we determined by taking the majority label. Where all three annotators had decided on different labels (two cases), the disagreement is resolved via discussion. Agreement between adjudicated labels and gold SRA labels ranges from .83 to .95. This shows that we can reliably annotate the data. Thus, we proceed with annotating the same prompts in SRA-gen.

For each of the three questions, we take 50 answers per label. This makes for a total of 250 answers per question, of which we randomize the order and hide the as-generated label. All three annotators now annotate the answers and we again derive adjudicated annotations by taking the majority label where possible. The remaining cases where all annotators disagree (12 for question ME_27b, 9 for question PS_4bp, 41 for question VB_1) are resolved through discussion. Table 9 in the Appendix shows kappa agreement for this round of annotation. Agreement is overall lower, as the LLM-generated data has substantially more variance than the original SRA data.

Label Accuracy With the manual label annotations we can now compute the accuracy for each label by comparing what the LLM was asked to generate with what the annotators agreed was actually generated. Table 7 shows these results, and

LLM Label	Human Label					Acc.
	corr.	part.	corr.	contr.	irr. non-d.	
ME_27b						
correct	12	13	3	22	0	.24
partially correct	13	17	4	16	0	.34
contradictory	3	2	18	26	1	.36
irrelevant	1	4	6	37	2	.74
non-domain	0	2	3	1	44	.88
PS_4bp						
correct	22	3	14	11	0	.44
partially correct	14	14	8	14	0	.28
contradictory	3	9	26	12	0	.52
irrelevant	0	0	3	47	0	.94
non-domain	6	2	2	11	29	.58
VB_1						
correct	23	26	0	1	0	.46
partially correct	26	18	3	3	0	.36
contradictory	0	13	14	23	0	.28
irrelevant	2	4	8	35	1	.70
non-domain	0	0	4	10	36	.72

Table 7: Adherence of the LLM to the label it was asked to generate answers for. Accuracy: the fraction of the 50 generated answers that does match the desired label.

Figure 3 compares label accuracies across questions. Only for one question and label (*irrelevant* for PS_4bp) nearly all generated answers conform to the desired label. Non-domain answers are only generated when the LLMs is asked for such: very rarely is an answer from a different label manually found to be *non-domain*. Overall, accuracy of *non-domain* and *irrelevant* answers is higher than for the other labels. Consistently, over half of the *correct*, *partially correct* and *contradictory* answers do not conform to the desired label. *Contradictory* answers are often determined to be *irrelevant*, and for VB_1 13 of them are even partially correct. *Correct* answers are regularly found to actually be *partially correct* or *irrelevant*. For PS_4bp, 14 correct answers are even found to in fact be *contradictory*. This is somewhat contrary to the general consensus that LLMs are doing well with answering correctly. It may however be due to a difficulty of having to come up with *multiple* answers in one go, i.e. *ten* correct answers instead of just one.

7.2 Model training with cleaned data

To assess the benefit of cleaning labels in SRA-gen, we can now compare the success of models trained on the as-generated vs. cleaned labels. Table 8 summarizes these results. When training on 40 instances from SRA-gen, we draw a sample with the same distribution as in SRA 20 times and report the average performance. Training on as-generated SRA-gen data consistently does worse when a bal-

Figure 3: Accuracy of the labels in SRA-gen.

anced sample of 250 answers vs. just 40 answers is used to train. This is likely due to models benefiting from the matching label distribution in training and test data for the smaller sample.

The cleaned labels consistently lead to an increase in performance. For the 40 training answers, this increase is however much more subtle than for the full 250 SRA-gen answers. On this larger amount of training data, performance often reaches the level of training on the original SRA data. The SBERT model consistently gives the best performance, and is the only model for which training on the 250 cleaned SRA-gen answers consistently outperforms training on the 40 SRA answers.

Overall, our results demonstrate that the LLM-generated answers themselves do carry enough meaning to inform a model, but that manual cleaning is necessary to remove noise in their labels. As we have seen the label distribution in the training data to affect model performance, the comparison between the 250 as-generated vs. cleaned SRA-gen answers is however not entirely ‘fair’: While the SRA-gen data was drawn with a balanced distribution of 50 answers per label, this distribution has shifted once the labels were cleaned. We therefore take a look at the performance of balanced sampling with as-generated vs. cleaned SRA-gen data in Figure 4. Since the fine-tuned SBERT model gives the best performance on cleaned SRA-gen data, we choose this model for this analysis. Do note that we can only compute the curve for the cleaned data up to 28 answers per label, as the total number of answers for the most infrequent label limits our ability to draw a balanced sample. For training with 5, 10, 15, 20 and 25 answers per label, we draw 20 training samples each and report best, average and worst performance.

For all three questions, the as-generated labels constantly lead to low average performance lev-

Table 8: Effect of cleaning the LLM labels via manual annotation (macro-averaged F1). For BERT and SBERT, results are averaged across three runs for a more reliable performance estimate. ‘Generated’ denotes whether we are training on SRA (✗) or SRA-gen (✓). ‘Cleaned’ indicates if we are using the as-generated (✗) or cleaned (✓) labels.

els of below .2 F1. With the cleaned labels, performance rises once more data is added, and the curves indicate that it might rise further if there was more data available. This controlled comparison thus confirms the beneficial effect of manually cleaning the labels.

8 Conclusion

We generate answers to the questions in the SRA dataset with an LLM. Using these answers as training data leads to relatively poor performance. Directly scoring the SRA data with an LLM even performs slightly worse, showing an inability of the model to reliably apply the 5-way label scale. This is supported by our analysis of the extent to which the LLM sticks to the label we ask it to generate answers for. Up to 75% of the answers the model was asked to generate for a specific label were found not to conform to this label. Training a model with manually relabeled generated data demonstrates the detrimental effect of the noisy labels: With cleaned labels, model performance increases substantially, reaching a comparable level to training on the original SRA data - albeit at the demand of larger volumes of training data. In light of our analysis of the lexical diversity in SRA vs. SRA-gen, this is likely due to diverging content in SRA vs. SRA-gen. Thus, more SRA-gen data is needed to sufficiently cover the content of SRA.

With a similarity based scoring model, training on the larger sample of generated data even consistently leads to superior performance over training on the small amount of available original SRA data. One benefit of the similarity-based model might be that one highly similar answer with the correct label suffices for the model to correctly label an answer of interest.

In conclusion, one *can* overcome the cold-start

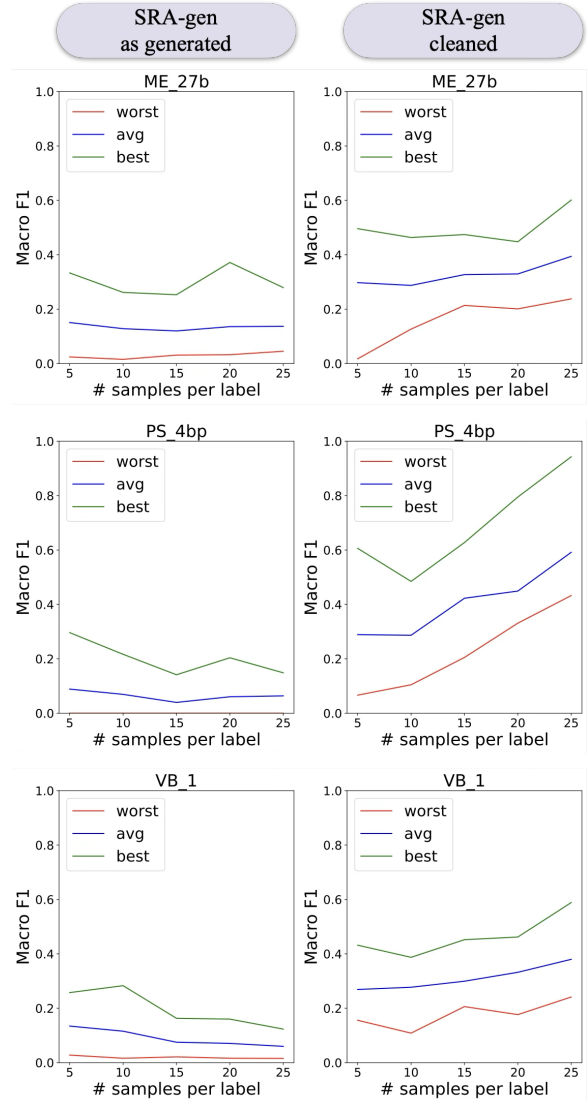

Figure 4: SBERT_{fine}: Balanced sampling of SRA-gen with as-generated (left) vs. cleaned (right) labels.

problem with the help of an LLM in the sense of not having to collect data from real students, but not without the manual effort of labeling the generated answers. Future work could explore automatic

cleaning of the generated data to alleviate the manual labeling effort. While we saw limited success in preliminary experiments, future work could also quantify the effect of using few-shot prompting, both in zero-shot labeling and generating answers.

Limitations

While our results provide interesting insights into the possibility of generating training data with an LLM, there are a number of limitations to our findings. First, we only experiment with one LLM. Other LLMs may behave differently, which limits our conclusions to DeepSeek-v2. Even within the realm of prompting an LLM, the precise choice of prompt can have substantial impact (Sclar et al., 2024). While we did carefully craft our prompts, subtle changes to the wording may affect results. Within the prompt design, a key aspect might be the amount of answers the model is asked to generate in one go. We always asked for ten answers, but results may differ if the model were asked to generate just one or even all 500 answers at once.

Even beyond model choice and prompt design, model parameters will affect results. We left these untouched, but varying the temperature will affect both answer generation and scoring ability of the model.

Ethical Considerations

In considering the use of generated training data for model training, one has to be cautious about the normative language LLMs produce. An inability to produce sufficiently ‘student-like’ language may lead to a model with inferior performance on real student answers that deviate from language norms. Since content scoring is however less about language form and more about content, this should not affect the score of an answer.

Automated scoring of student answers in general is not without ethical and legal issues. It is high-risk as per the European Union AI Act, and LLM use poses ‘systematic risks’.

A main concern of LLMs and deep learning in general is a lack of transparency. This is somewhat alleviated by the use of an LLM to generate synthetic answers as opposed to using it to directly score student answers. Still, our work shows that based on the synthetic answers it is again most successful to apply deep learning. This in turn is much less transparent than the use of a shallow learning method such as logistic regression - which we test

as well, but find to perform worse. However, the deep learning model we find to perform best operates in a similarity-based fashion. Thus, it at least allows backtracking to the reference answers that lead to a predicted score.

Appendix

This appendix contains some supplementary material to increase transparency of our experiments. It includes the prompt used to generate SRA-gen in Figure 5 and the prompt used to score the answers in SRA in Figure 6. The main paper contains the agreement we achieve in labeling the original SRA data in Table 6. Here, we include the same statistics for our annotation of the generated data in Table 9. We also include some more detailed results of our scoring experiments. Due to the non-deterministic nature of the LLM, repeated administration of the same prompt leads to differing results. Thus, Figure 7 depicts the variation in performance when administering the same prompt to the same model five times. Figures 8 (pretrained SBERT) and 9 (SBERT) show question-wise results for scoring based on SRA-gen vs. SRA. Finally, Figure 10 shows performance of training the pretrained SBERT model with balanced samples of SRA-gen.

Transformer Architectures for Vocabulary Test Item Difficulty Prediction

Lucy Skidmore, Mariano Felice, Karen J. Dunn
English Language Research, British Council, UK
name.surname@britishcouncil.org

Abstract

Establishing the difficulty of test items is an essential part of the language assessment development process. However, traditional item calibration methods are often time-consuming and difficult to scale. To address this, recent research has explored natural language processing (NLP) approaches for automatically predicting item difficulty from text. This paper investigates the use of transformer models to predict the difficulty of second language (L2) English vocabulary test items that have multilingual prompts. We introduce an extended version of the British Council’s Knowledge-based Vocabulary Lists (KVL) dataset, containing 6,768 English words paired with difficulty scores and question prompts written in Spanish, German, and Mandarin Chinese. Using this new dataset for fine-tuning, we explore various transformer-based architectures. Our findings show that a multilingual model jointly trained on all L1 subsets of the KVL achieve the best results, with analysis suggesting that the model is able to learn global patterns of cross-linguistic influence on target word difficulty. This study establishes a foundation for NLP-based item difficulty estimation using the KVL dataset, providing actionable insights for developing multilingual test items.

1 Introduction

Calibrating the difficulty of test items is a core aspect of language assessment design, ensuring that tests are fair, consistent, and aligned with learner proficiency. Traditionally, this calibration relies on pre-testing large item samples or expert judgment, which are expensive and time-consuming. Consequently, there is an increasing interest in automating item calibration using machine learning methods (Yancey et al., 2024; Yaneva et al., 2024), which offer greater scalability, efficiency, and consistency, and can be more easily integrated into item development pipelines.

While transformer-based encoder models such as BERT (Devlin et al., 2019) have been successfully applied to question difficulty estimation from text (QDET) in domains related to content knowledge assessment, approaches in language assessment — where difficulty is more closely tied to the linguistic properties of the item — still largely rely on hand-crafted features (Alkhuzaey et al., 2024). This is particularly true in QDET for L2 English vocabulary items, which commonly rely on small datasets that are not suitable for fine-tuning transformers (Benedetto et al., 2023).

To address this gap, our paper introduces a new multilingual resource for vocabulary QDET: an extended version of the British Council’s Knowledge-based Vocabulary Lists (KVL), containing 6,768 English vocabulary items paired with difficulty scores and prompts in Spanish, German, and Mandarin Chinese. We use the KVL to fine-tune various transformer-based architectures for vocabulary test item difficulty prediction, leveraging its unique structure to provide insights on how best to model vocabulary difficulty in multilingual settings. Our exploratory work serves as a benchmark for future development of generalisable, L1-agnostic models for explainable item calibration.

Our paper begins with an overview of how the KVL has been extended and adapted for NLP-based applications. This is followed by a summary of the latest research in two domains that this study intersects: question difficulty estimation from text and lexical complexity prediction. Next, we outline the aims of the study, providing the motivation and context for the experimental design. The transformer-based architectures that we investigated are outlined, including the procedures followed for model selection and fine-tuning. We present findings from model performance evaluations, an ablation study and an error analysis. Finally, the paper ends with a discussion of the results and outlines directions for future work.

2 The Knowledge-based Vocabulary Lists

The Knowledge-based Vocabulary Lists (KVL) (Schmitt et al., 2021, 2024) were the outcome of a collaborative research project between the British Council and researchers from the University of Nottingham, University of Innsbruck and Waseda University. Productive English language word knowledge was assessed using prompts designed to test form-based recall of individual lemmas in a translation format (cf. Laufer and Goldstein, 2004). Items comprising an L1 translation of the English target word, plus contextualising sentences were developed separately in three L1s (Mandarin Chinese, German, Spanish) to create a bank of 7,679 items for each language. Participants were required to input the remainder of the word in English, as per this example from the Spanish language version¹:

```
casa Vivo en una casa grande que tiene tres
dormitorios.
h _ _ _ _
```

During a period between late-2018 to mid-2020, 3.3 million responses were collected from over 100,000 respondents via crowdsourcing. An online platform, promoted across the British Council’s social media channels, presented participants with blocks of ten random items stratified by target word frequency. Feedback was given after each block, and participants were encouraged to complete more items to “beat their best”, as an example of game-based data collection (Kim et al., 2024).

Difficulty estimates were derived separately for each L1 subset of the data, using random-item-random-person (RPRI) Rasch models (De Boeck, 2008) built within a generalised linear mixed model (GLMM) framework (Dunn, 2024). Original KVL project outputs used these estimates to create a rank-order list of the top 5,000 words for each L1.

For this research, we use the existing 5000 items in the KVL and publicly release an additional 1,768 English vocabulary test items for each L1. This extended dataset contains 20,304 items in total (6,768 per L1) and is divided into 80% train (16,242 items), 10% development (2,031 items) and 10% test (2,031 items) sets².

¹The German and Chinese versions had similar, yet distinct prompts, for example in German: “Haus Ich wohne in einem Haus mit Garten.” And in Chinese: “房子 我买了一座房子。”

3 Related Work

3.1 Question Difficulty Estimation from Text

Question difficulty estimation from text (QDET) concerns the prediction of test item difficulty based solely on its textual features. There is growing interest in using QDET for high stakes assessment calibration, given its efficiency and scalability compared to traditional methods (AIKhuzaey et al., 2024). The majority of work in this area explores supervised approaches to QDET, with transformer-based encoder models achieving the best results in recent years (Gombert et al., 2024; Yaneva et al., 2024). There is also a growing interest in unsupervised approaches to the task, using generative models as ‘test-takers’, extracting their uncertainty as a proxy for human difficulty (Loginova et al., 2021; Uto et al., 2024; Zotos et al., 2025).

Research related to vocabulary-based QDET, however, is relatively limited. Most prior approaches to this task use hand-crafted linguistic features (such as word frequency and word length) as inputs to predictive models (Suyong and Hua, 2018; Settles et al., 2020), with other approaches incorporating embeddings such as word2vec (Ehara, 2018) and GloVe (Susanti et al., 2020). Beyond word-based features, contextual factors such as the similarity between correct answers and distractors in multiple choice vocabulary tests (Susanti et al., 2017, 2020) as well as semantic descriptors from dictionary entries of target words (Nakanishi et al., 2012), have also had limited exploration.

3.2 Lexical Complexity Prediction

Lexical complexity prediction (LCP) is a subfield of complex word identification (CWI), which concerns the automatic detection of complex words from text, primarily for the purpose of text simplification. LCP extends the binary classification used for CWI to form a regression problem, with the goal of predicting a continuous ‘complexity’ value for a given word. These values are domain-specific, and can range from crowd-sourced perceived complexity ratings to morphosyntactically derived features (North et al., 2023). Different to vocabulary QDET, the input text used for LCP typically involves predicting the complexity of a word in context. Given the format of the KVL dataset, the task of LCP aligns more closely with our investigation than much of the previous work in vocabulary QDET.

The most successful approaches to LCP to date make use of transformer-based architectures (Bani Yaseen et al., 2021; Kelious et al., 2024a). Particularly relevant to this work, however, are investigations into multilingual applications of LCP. Sheang (2019) showed that a multilingual CNN model trained jointly on word embeddings and linguistic features of Spanish, German and English datasets led to improved performance of prior models for Spanish and German. Similarly, Finnimore et al. (2019) found that jointly training models with languages from the same family improved cross-lingual CWI. Zaharia et al. (2020) experimented with multilingual transformers for cross-lingual CWI, showing that XLM-RoBERTa performs best for unseen German or French target words. More recently, LLMs have been explored for unsupervised multilingual LCP, however these approaches did not outperform supervised transformer-based equivalents (Kelious et al., 2024b).

4 Research aims

As described above, the KVL dataset is unique in that it contains multilingual test items (comprising L1 source word, L1 context and EN clue) for the same set of English target words across three L1s. To explore this multi-faceted structure, we defined four transformer-based models for experimentation: (1) individual monolingual models for each test item component; (2) ensembles combining these component-specific models; (3) multilingual models fine-tuned on the full test item text separately for each L1; and (4) a single multilingual model trained on the full test item text across all L1s.

Comparing the performance of these models allowed for multiple avenues of investigation: the influence of test item components on model predictions, the suitability of monolingual versus multilingual models and training data, as well as the effectiveness of different architectures for capturing cross-component and cross-lingual interactions within items. In addition to overall model performance, we were also interested in whether model error revealed potential biases—such as systematic under- or overestimation for particular items. These areas of interest were distilled into three primary research questions for the study:

- How accurately can different transformer-based model architectures predict vocabulary item difficulty for the KVL dataset?

- How do the individual components of the test item contribute to the models’ predictions?
- Is there any systematic bias contributing to errors in the best-performing model?

5 Modelling setup

Item difficulty prediction was modelled as a regression task. The target values for prediction were transformations of the GLMM item-level conditional modes. These were inverted to reflect item difficulty (as opposed to ‘item easiness’ in the original study) and scaled to values between zero and one. Models were fine-tuned with mean squared error (MSE) as the loss function. As the KVL were originally designed for ranking vocabulary difficulty, Spearman’s rank correlation coefficient (RHO) was used as the main model evaluation metric. The root mean squared error (RMSE) metric was also calculated to evaluate model fit. Where relevant, statistical significance tests of the models were carried out via bootstrap, using 10,000 iterations and Bias-Corrected and Accelerated (BCa) intervals (Efron, 1987).

For the multilingual models, the structure of the input text begins with the question content (L1 source word, L1 context, EN clue), in the same order as it is presented in the vocabulary test items, followed by the target answer (EN target word). Each part of the input text was delineated with the models’ pre-defined separation token, as shown in the example input text below:

```

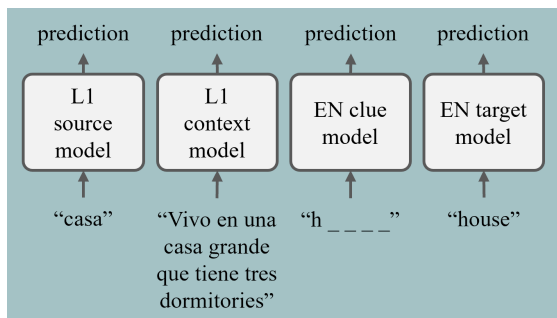

casa [SEP] Vivo en una casa grande que
tiene tres dormitorios. [SEP] h_____
[SEP] house

```

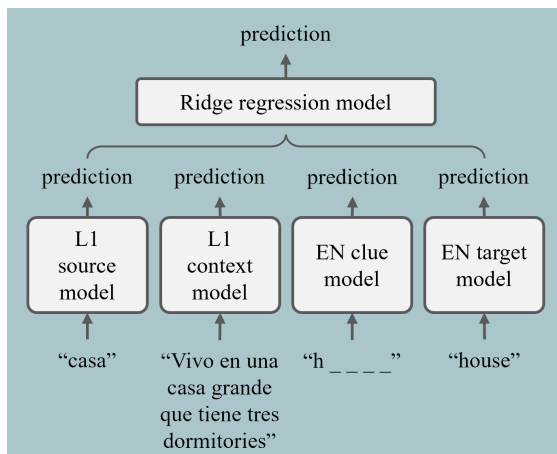

For the ensemble models, each part of the text was processed and tokenised separately.

5.1 Model architectures

Figure 1 provides an overview of the different architectures explored for this study. For the individual monolingual models and multilingual models, the 768-dimensional embedding of the first token (<s> for RoBERTa-based models and [CLS] for BERT-based models) from the final hidden layer is passed through a dropout layer followed by a single linear layer (the regression head) to predict the difficulty score. For the monolingual ensemble models, the predictions from the individual component models are stacked together and passed through a Ridge re-

(a) Individual component models

(b) Ensemble of monolingual models

(c) Multilingual model

Figure 1: Model architectures for transformer-based approaches.

gression model. Each L1-specific ensemble learns a distinct weighting scheme for the predictions.

5.2 Model selection

Multiple pre-trained transformer models available through the Hugging Face platform³ were considered for use in the architectures explored in this research. Preliminary model evaluation was carried out in order to select the best model for each of the architectures. Using a fixed set of hyperparameters, candidate models for each of the architectures described above were evaluated. The models were fine-tuned with the train set, and tested with the development set, reporting the

³<https://www.huggingface.co>

RMSE and RHO of the predictions for the best model after five epochs. From this investigation, the following models were selected for further experimentation (see Table A.2 in the Appendix for results for all candidate models):

Multilingual model: XLM-RoBERTa (Conneau et al., 2020) is pre-trained on text from 100 languages using a large-scale CommonCrawl-based corpus. It employs SentencePiece tokenisation and is trained with a masked language modelling (MLM) objective. XLM-RoBERTa has been shown to outperform other multilingual transformer models in multiple NLP tasks, including cross-lingual complex word identification (Zaharia et al., 2020).

Monolingual English models: BERT (Devlin et al., 2019) is pre-trained on English text from BooksCorpus and Wikipedia using a WordPiece tokeniser. It learns contextualised word representations through masked language modelling (MLM) and next sentence prediction (NSP).

Monolingual L1 models: BERT models pre-trained for Spanish⁴ (Cañete et al., 2020), German⁵ (Chan et al., 2020) and Chinese⁶ (Devlin et al., 2019). These models follow the BERT architecture and are pre-trained using equivalent L1 texts. For consistency, where relevant we use the cased, base model versions of each of the models listed above.

5.3 Model fine-tuning

Each of the models selected for experimentation was tuned for optimal hyperparameters. With a batch size fixed at 32 and dropout rate set to model defaults (0.1 for all models), Optuna⁷, a hyperparameter optimisation framework for Python, was used to search for the best learning rate, weight decay and warm up ratio for each of the models. The models were fine-tuned with the train set, and evaluated with the development set, reporting the RMSE and RHO of the predictions for the best model after five epochs. See Table A.3 in the Appendix for the best hyperparameters for each model.

Using the optimised hyperparameters, four sets of models were fine-tuned on the train and development sets and evaluated on the test set. These included: (1) individual models for each test item component (L1 source word, L1 context, EN

clue, and EN target word), fine-tuned separately for each L1 subset; (2) monolingual ensembles fine-tuned per L1 subset; (3) multilingual models fine-tuned per L1 subset (L1-specific); and (4) an ‘all-in-one’ multilingual model fine-tuned on all L1 subsets combined.

6 Results

6.1 Model performance

Table 1 reports the individual models’ performance for each test item component. The EN target word model yields the highest scores across all L1s for both RMSE and RHO, and is particularly high for the Chinese subset, with a RHO of 0.73. Overall, the next best predictor is the L1 word (average correlation: 0.55), followed by L1 context (0.46) and EN clue (0.42).

Table 2 presents results for the monolingual ensemble⁸, L1-specific multilingual and all-in-one multilingual models evaluated on the KVL test set, alongside the individual EN target word model serving as a baseline. Results marked with an asterisk showed significant improvement in performance compared to the prior model in the table. On average, the ensemble architecture offers a small improvement in performance over the EN target word model for both RMSE and RHO, however the increase is not statistically significant for either metric in the ES subset, and not significant for RHO

in the DE subset. The L1-specific model considerably outperforms the ensemble approach for the ES and DE subsets, with RHO increasing from 0.65 to 0.73 and 0.78, respectively. This performance increase is not seen for the CN subset, which shows a marginally poorer but non-significant performance difference for RMSE and RHO. The all-in-one model achieves the best L1 average performance in both RMSE and RHO as well as demonstrating the most consistent RHO across L1 subsets, with scores of 0.78 for ES, 0.79 for DE, and 0.79 for CN. For the DE subset, however, this performance increase is not significantly higher than the L1-specific model for RHO.

6.2 Influence of test item component

An ablation study of the test item components was conducted for the ensemble, L1-specific and all-in-one models. Single components were systematically removed from the models, in order to investigate their influence on model performance. The models were fine-tuned using the train and development set and evaluated on the test set. The full model results for RMSE and RHO coefficients with statistical significance are reported in Table A.4 in the Appendix.

Figure 2 reports the relative percentage change in RHO for each of the models after removing individual components, across the L1 subsets. Statistically significant differences in model performance are marked with an asterisk. For the monolingual ensemble models, we can see that removing the EN

⁸The learned Ridge regression weights for each component model in the ensembles can be found in Table A.1 in the Appendix.

Figure 2: Relative percentage change in Spearman’s Rho after individual component removal.

target word results in the largest decrease in performance – around 10% for ES and DE and 15% for the CN subset. The removal of other components have no statistically significant impact, with the exception of the DE subset which shows a small 5% degradation for the L1 word.

For the L1-specific models, we can see a more varied distribution of impact for each of the components. Statistically significant degradation of performance is seen in all three L1s for L1 context, ES and DE for L1 word and DE and CN for the EN clue. The results for the EN target word in the CN subset are notably different to those of the ES and DE, with a much lower degradation in performance after its removal (around 7%, compared to between 20-25% for DE and ES, respectively). The EN clue is in fact more impactful than the EN word in this case, showing a statistically significant 9% reduction in performance after its removal.

Looking to the all-in-one multilingual model, we can see that the ablation results begin to generalise, showing a similar pattern of impact across the L1 subsets. Results from the statistical significance tests show that removing the EN clue had no significant impact on the all-in-one model performance for any of the L1 subsets, and the removal of the L1 word has no significant impact on model performance for the ES and CN subsets.

6.3 Error analysis

Figure 3 shows the model residuals plotted against the difficulty values for each L1 subset tested on the best performing model, the all-in-one multilin-

Figure 3: Error plot for the all-in-one multilingual model across L1s.

gual model. The graph shows that the majority of predictions fall within a range of -0.2 and +0.2 of the difficulty values. Across all L1 subsets, the model tends to underestimate the difficulty of test items as vocabulary item difficulty increases. This pattern becomes more pronounced for items with difficulty values of approximately 0.6 and above. The extent to which these higher difficulty values are impacted needs to be interpreted with caution. First of all, the GLMM difficulty estimates that the model was trained on have their own degree of error; see [Schmitt et al. \(2024\)](#) for further details. In addition, the fact that the GLMM scores were scaled linearly to values between 0 and 1 may also

Figure 4: Example SHAP output for the ES test item for the EN target word "bar" (verb).

impact the distribution of the difficulty values at the low and high end of the scale.

In order to investigate the token-level contributions of the input text to the model predictions, further analysis using SHAP (SHapley Additive exPlanations) (Lundberg and Lee, 2017) was carried out. SHAP is a python package⁹ that assigns Shapley values – a game-theoretic attribution metric – to features of a given predictive model. When applying SHAP to transformer architectures, each token of the input text is treated as an individual feature, affording the investigation of specific words or sub-word units within the sequence. In our application, this allows for fine-grained interpretability of how tokens within different components of the input text contribute to the model’s final prediction.

For each L1 subset of the KVL test data, the top 10% of model errors (68 vocabulary test items per L1) were individually inspected using SHAP. For each item text, the token that contributed the most to the incorrect prediction was recorded, along with which component it was part of. Figure 4 provides an example of the SHAP analysis output for the ES item text for the English target word “bar” (verb). All tokens highlighted in red in the figure contribute to increasing the model’s prediction (towards difficult) and all tokens highlighted in blue contribute to decreasing the model’s prediction (towards easy). For this example, the model predicted the item to be too easy (prediction = 0.52, label = 0.93, error = -0.41). On inspecting the SHAP output, we can see that the EN target word “bar” is the token that contributes the most to the erroneous prediction.

Figure 5 shows the component and prediction direction of the tokens identified in the analysis procedure described above. Reflecting the general tendency of the model predictions reported in Figure 3, there was a higher proportion of ‘too-easy’ predictions (57% of errors investigated). Tokens identified in the EN target word component account for 44% of the items investigated, followed by tokens in the L1 context (25%), L1 word (14%) and EN clue (7%). The separation token <s> was also identified as containing the top contributing token

Figure 5: Location of the most influential tokens attributed to the top 10% of model errors.

for 8% of the errors (see Table A.5 in the Appendix for an overview of all identified tokens). On inspecting the tokens, some global patterns emerged.

- **Simple vs. complex words in the L1 word and L1 context.** For items that the model predicted as too easy, simple or common words were often given high attributions. For example, pronouns: “ich” (I), “我” (I), “mich” (me), or every day words: “饭” (meal), “heute” (today), “noche” (night). For items that were predicted too difficult, attribution tended to be given to more complex words such as “precisar” (specify) and “排放” (emission).
- **Sub-word tokenization in EN word.** For items that the model predicted as too easy, the sub-word with the highest attribution was often a simpler or more common word nested within the target word, for example with the compound nouns “bookcase”, “sunshine” and “workday”. For items that were predicted too difficult, words were often split into non-morphologically aligned sub-tokens: “poison”, “fireman”, “killer”, or suffixes: “questionable”, “punishment”.

⁹<https://shap.readthedocs.io/en/latest/index.html>

- **Difficult senses in EN target word.** Whole EN target words accounted for 26% of all items that were predicted too easy, compared to only 8% for items predicted as too difficult. Common features of these EN target words were difficult senses (e.g. “short” as an adverb, “bar” as a verb), cognates with low frequency (e.g. “crystal”, “tragic”), or avoiding cognates in L1 source word (e.g. using “rastrear” instead of “explorar” for EN target word “explore”).

7 Discussion

The experiments and analysis detailed above explored L2 English vocabulary test item difficulty prediction using transformer-based architectures, with a view to establishing: (1) the best model for prediction; (2) the relative importance of test item components; and (3) potential areas of systematic bias in the best model. The outcomes of these aims are discussed below.

Initial results from fine-tuning individual component models highlighted the predictive strength of each component in isolation, with the EN target word input emerging as the most effective standalone predictor. These findings align with prior work in QDET for vocabulary testing, which has shown that features based solely on the English target word can yield a strong performance (Suyong and Hua, 2018; Ehara, 2018; Settles et al., 2020). The English target word model performed especially well on the Chinese subset, achieving a RHO of 0.73, compared to 0.63 for both Spanish and German. This may reflect the inconsistent role of cognateness in shaping word difficulty: while Spanish and German learners may be influenced by cognates or “false friends” (Otwinowska and Szewczyk, 2019), English word difficulty for Chinese learners—whose L1 shares no cognates with English—may be more directly linked to features solely attributed to the English word. As a result, the relationship between the English target word and item difficulty may be easier to model for the Chinese subset of the KVL. A similar pattern was observed by Schmitt et al. (2024) in their analysis of the KVL, where GLMM difficulty scores for the Chinese subset correlated more strongly with word frequency—a feature often used as a proxy for word difficulty (Hashimoto and Egbert, 2019)—than they did for Spanish and German.

Although the monolingual ensemble models showed limited improvement over the simpler En-

glish target word models, there may be some settings where this architecture is a suitable choice. Given the statistically significant improvement seen for the ensemble model fine-tuned with the Chinese subset, it may be that this approach is better suited to non-cognate language pairs where cross-lingual interaction does not play an important role in determining item difficulty. Furthermore, the ensemble model weights can be used as a simple proxy for component importance, offering an efficient, broader view of component relevance that may be more practically applicable for test item piloting. However, for scenarios similar to this study, in a multilingual setting with target words and context, our results suggest that a unified multilingual transformer architecture is the best choice. These findings align with prior research in multilingual LCP, which highlight the benefits of including sentence context (Bani Yaseen et al., 2021; Kelious et al., 2024a) as well as the joint modelling of different L1s (Zaharia et al., 2020).

Findings from the ablation study highlighted the advantage of cross-component representation learning within a unified transformer architecture and revealed interesting insights into the impact of fine-tuning on all L1s. Results showed that in the L1-specific approach, the model fine-tuned for Chinese assigns less importance to the English target word input compared to its Spanish and German counterparts. This is somewhat unexpected, given the very strong performance of the English target word model for Chinese shown in Table 2. One possible explanation is that the L1-specific model fine-tuned on the Chinese subset is less able to align representations of English and Chinese source words due to the lack of script overlap. This is reflected in prior research showing that multilingual models benefit from shared subword representations across languages, and that subword overlap correlates with cross-lingual transfer performance (Wu and Dredze, 2019; Pires et al., 2019). In the case of Chinese, the absence of shared subwords with English may limit the model’s ability to learn cross-lingual connections. This may be a contributing factor as to why there is no significant improvement in the L1-specific model compared to the ensemble approach for the Chinese subset.

Building on this idea, the ablation results for the all-in-one multilingual model were much more consistent across L1 subsets. The observed generalisation suggests that the all-in-one model may be learning broader, language-independent features

of vocabulary item difficulty compared to the L1-specific and ensemble models. The parallel structure of the KVL dataset, where each of the English target word and clue appears across three different L1s, likely supports this generalisation by encouraging the model to disentangle language- and item-specific features from global patterns. Furthermore, the distribution of component impact for the Chinese subset of the L1-specific model reported in Figure 2 shifts considerably toward the Spanish and German distributions seen in the all-in-one model. This may be an indication that the limitations of cross-lingual transfer for orthographically distant language pairs described above are alleviated in this setting when models are fine-tuned jointly across languages with parallel data.

Findings from the error analysis revealed valuable insights about the systematic behaviour of the all-in-one multilingual model. In addition to the effects of label re-scaling and GLMM model error discussed in Section 6.3, the normal distribution of difficulty values in the KVL dataset may further contribute to the all-in-one model’s tendency to under-predict higher difficulty items. To test this, it would be of value to investigate the impact of including a larger proportion of high difficulty items during fine-tuning. This could be achieved using data-augmentation or re-sampling methods (Pan et al., 2021; Kelious et al., 2024b), or even the development of further KVL test items.

The small-scale SHAP analysis on the multilingual model’s top 10% of errors, provided some general observations that can be applied to the future development of knowledge-based vocabulary lists, and test item writing more generally. In particular, the findings illustrated the impact of vocabulary complexity in the L1 word and L1 context components, suggesting that careful consideration of the word choices in the item text is needed when creating such resources for the NLP domain. Issues from the SHAP analysis that emerged relating to model behaviour, such as non-morphologically aligned sub-word tokenization and poor word sense disambiguation provide direction for improving the all-in-one model, such as multi-task learning with POS-tagging, morphological supervision or cross-lingual word sense disambiguation. Finally, given the limited scope of the SHAP-based analysis, interpretations are isolated to the individual word and subword level. Further investigation into the model’s attention across tokens may be able to provide richer insight into the model behaviour.

8 Future Work

In addition to the suggestions outlined in the discussion above, there are several further avenues for future work. First, model probing for features previously found to be predictive of vocabulary item difficulty (Dunn, 2024; Hashimoto and Egbert, 2019) could help explore the item text beyond the component level, to uncover which linguistic correlates of item difficulty are being captured by the models. The all-in-one multilingual model could be further optimised by incorporating architectural adaptations shown to benefit QDET and LCP in other domains, such as scalar mixing (Gombert et al., 2024) or concatenating transformer embeddings with linguistically derived features (AlKhuzayy et al., 2024; North et al., 2023). Given the requirement of large amounts of training data for encoder-based transformer approaches, it would also be of value to compare the all-in-one model results to zero-shot and few-shot methods using LLMs, such as those recently investigated by Smădu et al. (2024). Finally, expanding the KVL dataset to include additional L1 subsets, especially those orthographically distant from English, will contribute to further exploring the role of cross-lingual transfer within multilingual transformer models, helping to corroborate the findings of this research.

9 Conclusion

This research investigated the use of transformer-based architectures for predicting vocabulary item difficulty, applying recent advances in multilingual and cross-lingual lexical complexity prediction to question difficulty estimation. Leveraging the content and structure of the KVL dataset—which has not previously been used in NLP research—this study examined the effects of multilingual text items across several transformer-based architectures. The analysis provided insights into the relative importance of different test item components across L1s, revealing how these models capture and generalise features of item difficulty. In particular, a multilingual model fine-tuned on data with all L1 variations demonstrated the strongest performance, benefiting from cross-lingual transfer and the parallel structure of the KVL dataset to produce more generalised and consistent attributions across L1s. These findings point to the potential of L1-agnostic, explainable transformer-based models for supporting test development pipelines through scalable and interpretable item calibration.

Limitations

One limitation of our study is the use of the probabilistic values derived from the GLMM framework as observed difficulty values, an issue that is discussed in more detail by Schmitt et al. (2024). To address this, we used a non-parametric correlation measure (Spearman's Rho) to evaluate our models based on rank ordering. This approach helps account for the potential error in the precision of estimates that might not be fully captured by RMSE.

Another limitation that is specific to the all-in-one multilingual model lies in the way training data was combined across L1s. The GLMM difficulty values used as labels in the models were derived from different population samples for each L1, which could raise questions about the comparability of these values across languages. To mitigate this, target labels were derived by concatenating the individually scaled subsets rather than applying a single normalisation across the entire KVL dataset. While this approach preserves the internal structure of each L1 subset difficulty scores, it does not fully account for differences in score distribution origins. However, given that predictions improved when the model was evaluated on individual L1 subsets, the all-in-one model can still be viewed as a practical means of enhancing L1-specific performance, rather than as a universal predictor of item difficulty.

Acknowledgments

This research was possible thanks to the work carried out by Norbert Schmitt (University of Nottingham, UK), Karen J. Dunn (British Council, UK), Barry O'Sullivan (British Council, UK), Laurence Anthony (Waseda University, Japan) and Benjamin Kremmel (University of Innsbruck, Austria) who created the original Knowledge-based Vocabulary Lists.

Abstract

Heterogeneity in student populations poses a challenge in formal education, with adaptive textbooks offering a potential solution by tailoring content based on individual learner models. However, creating domain models for textbooks typically demands significant manual effort. Recent work by Chau et al. (2021) demonstrated automated concept extraction from digital textbooks, but relied on costly domain-specific manual annotations. This paper introduces a novel, scalable method that minimizes manual effort by combining contextualized word embeddings with weakly supervised machine learning. Our approach clusters word embeddings from textbooks and identifies domain-specific concepts using a machine learner trained on concept seeds automatically extracted from Wikipedia. We evaluate this method using 28 economics textbooks, comparing its performance against a tf-idf baseline, a supervised machine learning baseline, the RAKE keyword extraction method, and human domain experts. Results demonstrate that our weakly supervised method effectively balances accuracy with reduced annotation effort, offering a practical solution for automated concept extraction in adaptive learning environments.

1 Introduction

In formal education, the incremental mastery of concepts and the knowledge and competencies that build on them is essential for students to successfully read and understand texts in a specific school subject. Students often struggle to comprehend the relevant concepts within educational materials, leading to difficulties in understanding and applying the knowledge effectively. Many schoolbooks therefore contain a glossary with a list of the key concepts which are manually compiled by the respective schoolbook authors, providing a somewhat subjective list of the relevant concepts.

In the digital counterpart to traditional schoolbooks, computer-based learning platforms, a sim-

ilar challenge arises: modelling the domain for which the platform provides learning materials and exercises. Most digital systems rely on handcrafted ontologies (or related domain representations) that have been designed by domain experts. They compile a list of domain-specific vocabulary, a very resource-intensive, costly, inefficient, and time-consuming process. In the worst case, such domain ontologies have to be newly constructed for every adaptive learning platform from scratch even if other systems already exist in the same domain. To reduce the effort required, Chau et al. (2021) presented an approach automating concept extraction from digital textbooks. While they demonstrate that such extraction can be successfully carried out, the approach still requires an extensive, domain-specific, manual annotation effort of the textbook as a basis for a supervised machine learning approach. Another particular challenge exists for concept extraction in the educational domain: textbooks not only contain specific vocabulary from one subject domain. In particular, school books usually contain content domain specific words, school domain specific words (homework, teacher, exercise, ...) and example specific words.

Keyword extraction (or concept extraction), a fundamental task in natural language processing (NLP) and information retrieval, aims to identify and extract the most important terms or phrases that best represent the content of a document. These extracted keywords can play a crucial role in various applications, such as document summarization, information retrieval, text classification, and topic modeling, but usually not in the educational domain. Nevertheless, the progress in automatic keyphrase extraction has produced methods that are also useful for the related area of automatic concept extraction from textbooks.

This work focuses on the core task of extracting domain-specific vocabulary. It introduces an approach supported by distributional semantics that

uses contextualized word embeddings, moving beyond simple keyword extraction. Recent methods have explored using word embeddings for concept extraction. However, these methods often have low precision or rely on supervised training with large amounts of labeled data and only use static word embeddings. Some very recent approaches to keyword extraction, such as (Qian et al., 2021), use contextualized word embeddings provided by BERT, which shows improved performance. Nevertheless, these approaches primarily focus on keyword extraction in the scientific domain. This means they aim to extract a few specific keywords from documents that mostly cover one particular topic domain, as noted by (Sammet and Krestel, 2023). These methods still use labeled data and treat contextual word embeddings merely as a more advanced embedding type. This work explores whether the improved performance of contextualized word embeddings also applies to the broader task of glossary extraction in the educational domain. This domain presents a unique challenge due to its multi-theme vocabulary. The approach uses contextualized word embeddings, such as BERT, to select domain-specific expressions in educational texts through a clustering method. Supervision is only required in the form of a small seed list of domain-relevant words. This list can be easily compiled from Wikipedia articles and helps separate clusters of words relevant to the specific domain from those that are specific to the text but belong to a different domain.

Our approach for glossary extraction from structured textbooks could support both glossary building for traditional schoolbooks, domain modeling for adaptive learning platforms, and potentially also student modeling in digital learning environments. Our goal is to create a domain-specific glossary extraction method that accurately reflects the concept annotations made by expert users at the section level. This method can then be used to build both domain and student models for more advanced personalization. To evaluate our method, we assess how closely it matches external expert annotations and internal expert annotations (i.e., glossaries compiled by the schoolbook authors).

2 Related Work

There is a broad number of research strands related to keyword extraction. However, there is little work within the educational field. Therefore, we will

focus on approaches with components similar to those in our own method. To present only the main ideas, we will discuss one or two approaches for each method. More detailed overviews are available in (Chau et al., 2021) and (Khan et al., 2022).

Keyword extraction Automatic keyphrase extraction (AKE) has been extensively studied using different approaches, such as rule-based learning, supervised learning, unsupervised learning, or deep neural networks. Since AKE systems are designed to only extract a very small list of relevant keywords, most systems consist of two parts: (1) pre-processing data and extracting a list of candidate keyphrases using lexical patterns and heuristics; and then (2) determining which of these candidates are correct keyphrases. Methods for finding the relevant keyphrases are: statistical methods or frequency-based methods, clustering-based methods, graph-based methods, embedding-based methods, and machine learning methods.

The most basic frequency-based approach is the statistical measure tf-idf (term frequency-inverse document frequency (Jones, 2004)). This method effectively finds relevant terms within a document (high recall) but often includes many irrelevant terms (low precision). Therefore, most approaches combine tf-idf with other measures to narrow down the list of potential keywords.

In graph-based approaches, an entire document is modeled as a graph of semantic relationships between the terms and a ranking approach then selects the terms with the highest number of relationships. Prominent approaches are (i) RAKE (Rose et al., 2010) in which a graph of word co-occurrences is constructed and the top ranked words in this graph are extracted as key words, (ii) TextRank (Mihalcea and Tarau, 2004) in which documents are represented as undirected and unweighted graphs and (iii) PositionRank (Florescu and Caragea, 2017), a fully unsupervised, graph-based model, that simultaneously incorporates the position of words and their frequency in a document to compute a PageRank score for each candidate word. The most recent graph-based approaches employ contextualized word embeddings for calculating the ranking, cf. KPRank (Patel and Caragea, 2021).

In clustering-based approaches, clustering algorithms group candidate phrases into topic clusters and the most representative ones from each cluster are selected as key phrases. Liu et al. (2009) employ cooccurrence-based term relatedness, and

a Wikipedia-based term relatedness for clustering. Grineva et al. (2009) develop a graph-based approach for identifying domain specific terms in multi-theme documents - an unsupervised topic-based clustering method that partitions a graph into thematically cohesive groups of terms.

In supervised statistical learning approaches, all terms in a document must be classified as either positive or negative instances of relevant keyphrases. This classification is based on patterns learned from annotated training sets. For example, Hulth (2003) define manual rules combined with frequency measures to extract all potential keyword expressions from a text. A classifier then determines which of these are actual keyword expressions. Current methods use word embeddings to represent words. For instance, Wang et al. (2014) examine word embeddings to measure the relationships between words in graph-based models. Recent methods also use neural networks (cf. Zhang et al., 2016).

In approaches that view AKE as a sequence labelling task, Alzaidy et al. (2019) predict a sequence of labels where the two labels are keyphrase word or non-keyphrase word. The recent availability of contextualized word embeddings has enabled further improvement in AKE as sequence labelling, as in (Sahrawat et al., 2019) or (Sammet and Kretzel, 2023) where a fine-tuned BERT labels relevant keyphrases in abstracts from economics articles.

Concept extraction In concept or term extraction approaches, the goal is to extract not only a small list of the most general candidates but also extract more specific terms that can be used in applications such as domain ontology construction, text classification, or information extraction. The two possible approaches here are constructing a domain model from scratch or using contrastive corpora to identify domain-relevant terms.

Bordea et al. (2013) propose a domain-independent method for extracting terms. They find general terms in a document, similar to keyphrase extraction, and then use these to build a domain model. Based on this model, they identify other semantically similar terms in the document. The method's performance varies across domains but is more stable than basic term extraction approaches like TermExtractor.

Only a few methods address concept extraction in education. One method, proposed by Chau et al. (2021), uses a supervised feature-based machine learning approach to automatically extract concepts

from digital textbooks. This method trains a supervised learning model to classify whether a term or phrase is a concept. It bases this classification on a detailed set of features. One of the few approaches that explicitly aims at constructing domain-specific glossaries, presented by Park et al. (2002), focuses on building domain-specific glossaries. This is similar to the goal of this article. This method uses a tf-idf-based approach.

Ontology extraction Textbooks and the educational domain play a greater role in the domain of ontology extraction, i.e., building concept hierarchies for textbooks or ontologies from textbooks.

(Wang et al., 2015) present an approach that uses Wikipedia as an external resource to build a concept hierarchy for textbooks. The goal is to extract keyphrases for each chapter of a given book. First, they extract a set of related and important Wikipedia concepts for each book chapter. Second, they use local features to extract related concepts for each chapter separately, utilizing measures such as textual similarity between a book chapter and candidate concepts. The resulting candidate set consists of the top N candidates based on their cosine similarity score and those candidates whose title appears in the chapter title (i.e., `titleMatch` equals 1). These two simple but powerful features can capture most of the related and important concepts for each book chapter.

A similar approach is described in (Conde et al., 2016). This paper introduces LiTeWi, a method that combines term extraction techniques (like linguistic filters and tf-idf) with Wikipedia. It uses Wikipedia as a knowledge base to improve term extraction accuracy by removing terms not related to Wikipedia entries within the specified domain.

Summing up, to the best of our knowledge, current automatic term and concept extraction methods perform unexpectedly poorly and are not tailored for the educational field. Improving automatic extraction of domain-specific concepts would be beneficial for immediate tasks such as student modeling and content recommendation in learning platforms or tutoring systems. Furthermore, it would advance the automatic extraction of domain, i.e. specific glossaries and the construction of ontologies, both of which are crucial for developing learning platforms that currently rely heavily on manual domain models.

For documents with multiple themes, clustering seems to be the most promising approach. This

method has been mainly used for extracting keywords. To encode the domain-specific meaning of concepts that require clustering, contextualized word embeddings seem to be the most promising approach. However, these embeddings have only been used for supervised single-word or sequence labeling of keywords in scientific documents. Our work combines these two methods for domain-specific vocabulary extraction. Our method outperforms other methods and does not require large amounts of labeled data for training and testing.

3 Method

In our approach, called GlossEx, we extract concepts specific to a given domain from text. We do not just extract a small list of keyphrases. Instead, we extract all phrases or words that represent the main concepts of that text. This creates a specialized vocabulary list, which is similar to manually compiling a glossary for a specific text.

3.1 Task formulation and dataset

We are trying to solve the following technical task: Given a document \mathcal{D} that represents a specific domain, our goal is to extract the specialized vocabulary \mathcal{V} of that domain from \mathcal{D} . We are exploring this task within the domain of teaching economics in schools. For our dataset, we selected 28 economics textbooks used for the economic curriculum in German secondary schools. We expect our method to identify domain-specific concepts such as “workforce”, “consumption”, “entrepreneur”, and similar terms. In order to extract the domain-specific vocabulary, we propose the following pipeline:

1. Document preprocessing, i.e. tokenization, lemmatization, POS-tagging, ...
2. Extract salient vocabulary \mathcal{S} contained in \mathcal{D}
3. Cluster vocabulary items in \mathcal{S} based on their contextualised embeddings
4. Obtain \mathcal{V} by filtering \mathcal{S} using limited domain knowledge

This pipeline is based on the following observations: Because \mathcal{D} represents a specific domain, it features specialized vocabulary. Conversely, this specialized vocabulary is particularly prominent in \mathcal{D} compared to general, non-domain-specific documents. The second step of the pipeline uses this

observation. However, economic textbooks contain three distinct types of salient vocabulary in addition to the general vocabulary found in any text: (i) specialized vocabulary (which is the extraction target), (ii) education-specific vocabulary (such as instructions like “write” or “analyze”), and (iii) example vocabulary (which appears prominently due to its presence in running or repeated examples).

Therefore, we need to exclude education specific vocabulary and example vocabulary from \mathcal{S} in order to obtain \mathcal{V} . This is done through Items 3 to 4. The clustering step in Item 3 serves to stabilise the filtering method in Item 4: We observe that contextual embeddings form useful clusters, so that specialized and non-specialized vocabulary form local clusters in embedding space. Therefore, we exploit this property to include or exclude complete clusters in \mathcal{V} instead of single lemmas. Item 4 accesses limited domain knowledge to differentiate between the 3 salient categories described above. We use the limited domain knowledge to label each cluster with one of the three categories listed above, and eventually only return lemmas in clusters labeled as specialised vocabulary.

Next, we describe in detail how to implement each step of the proposed pipeline. The focus is on German economics textbooks, but the general method applies to various domains and languages, provided the necessary models are available. We also present the specific German processing tools.

3.2 Preprocessing

The NLTK library (Bird et al., 2009) is used for splitting sentences and tokenizing text. The Hanover Tagger (Wartena, 2019), which is specifically designed for German, is used for sentence-level lemmatization and POS tagging. All subsequent steps are applied to the lemmatized document \mathcal{D} , unless stated otherwise.

3.3 Extracting Salient Vocabulary

We extract the salient vocabulary \mathcal{S} from \mathcal{D} using the method proposed by Lemay et al. (2005). This method calculates scores for all lemmas. These scores show whether a lemma appears more often in \mathcal{D} than is typical for the language in general. Thus, this method distinguishes the salient vocabulary of \mathcal{D} from general vocabulary. For evaluation, we use two general German word frequency lists:

1. A frequency list¹ derived from the DeReKo

¹DeReKo-2014-II-MainArchive-STT.100000 obtained

(Lüngen, 2017). DeReKo is a very large corpus that is representative of contemporary German.

2. The SUBTLEX-DE frequency list (Brysbaert et al., 2011), which has been shown to better explain cognitive saliency of words in decision time experiments.

We only consider nouns and verbs, and we discard stopwords and lemmas that appear less than four times in \mathcal{D} , as well as tokens that contain special characters. Note, that the method described in (Lemay et al., 2005) differs from tf-idf. Specifically, tf-idf calculates frequencies only within a single corpus, whereas our method compares frequencies between two corpora.

3.4 Clustering Vocabulary

We cluster lemmas in \mathcal{S} by agglomerative clustering of contextualised embeddings. To compute embeddings, we use the bert-base-german-cased BERT model provided by Chan et al. (2020). We embed each (non-lemmatized) sentence individually (after subword tokenization). Then, embeddings of subword tokens are mean-pooled to derive embeddings of the original tokens. Finally, lemma embeddings are the mean of all token embeddings associated with the respective lemma.

Agglomerative clustering is computed by the respective scikit-learn implementation (Pedregosa et al., 2011) using default parameters. In preliminary experiments, we found agglomerative clustering to perform better for our task than k-means clustering or spectral clustering methods. We set the number of clusters (which is a required parameter of agglomerative clustering) to $\frac{|\mathcal{S}|}{4}$. This means the expected number of words in a cluster is 4.

This approach differs from graph-based algorithms, such as the one proposed by Grineva et al. (2009). We do not use graph topology to find clusters. Instead, we directly cluster lemmas in the embedding space. In the graph paradigm, this means we are working with a fully connected graph where edge weights are determined by a distance metric in the embedding space.

3.5 Filtering by Domain Knowledge

In the last step, we select clusters that contain specialized vocabulary from a specific domain. How-

ever, obtaining this information directly from embeddings is difficult. Therefore, we create two lists: \mathcal{V}_{edu} and \mathcal{V}_{eco} . \mathcal{V}_{edu} contains seed words related to the education domain, and \mathcal{V}_{eco} contains seed words related to the economics domain. These lists inject a limited amount of domain knowledge into our method, which helps us determine if a cluster contains terms associated with the education domain, the economics domain, or neither.

Application of seed lists Each cluster \mathcal{C} (representing a set of lemmas in \mathcal{D}) receives two scores: an association score for educational vocabulary (σ_{edu}) and an association score for economics vocabulary (σ_{eco}). The scores for a cluster are calculated by taking the average of the 10 smallest pairwise distances between any word in that cluster and any word in either the educational vocabulary (\mathcal{V}_{edu}) or the economics vocabulary (\mathcal{V}_{eco}). The distances between words are measured using the Euclidean distances of fastText embeddings² (Grave et al., 2018). It is important to note that this method uses static word embeddings, which differs from the approach in Section 3.4 where contextualized embeddings from a German BERT model (Chan et al., 2020) are used. fastText embeddings are chosen because their model can create embeddings for any string based on its character n-grams. This avoids the problem of out-of-vocabulary words. Specifically, clusters are kept if they meet one of the following conditions:

$$\sigma_{\text{eco}} + 0.03 < \sigma_{\text{edu}} \quad (1)$$

$$\sigma_{\text{eco}} < \min\{0.3, \sigma_{\text{edu}}\} \quad (2)$$

In simpler terms, this means that clusters are selected if they are generally close to the economics vocabulary (\mathcal{V}_{eco}) or if they are significantly closer to \mathcal{V}_{eco} than to the educational vocabulary (\mathcal{V}_{edu}). These thresholds are specific to the embedding space used and are set manually. The thresholds were determined before any labeled data was available, so their manual setting does not affect the validity of the results. With a small amount of labeled data, it would be possible to automatically adjust these thresholds.

Construction of seed lists The lists are created independently from the evaluation data to avoid circularity. With the PetScan interface we extracted Wikipedia article titles and wikidata entity names

from <https://www.ids-mannheim.de/digspra/kl/projekte/methoden/derewo/>

²obtained from <https://fasttext.cc/docs/en/crawl-vectors.html>

with the following hyperparameters: To populate \mathcal{V}_{edu} , we run one query on the “Bildung” (engl.: *education*) category with maximum depth 6 and require the found pages to link to the Wikipedia page “Schule” (engl.: *school*). To populate \mathcal{V}_{eco} , we run two queries on the “Wirtschaftswissenschaft” (engl.: *economics*) category with maximum depth 6. For the first query, we require found pages to link to the Wikipedia page “Markt” (engl.: *market*). For the second query, we require found pages to link to the Wikipedia page “Bedarf” or to the Wikipedia page “Bedürfnis” (both engl.: *need*). We combine the results of both queries.

To create the final seed lists, which contain only single lemmas, the preprocessing method described in Section 3.2 is applied to every page title returned by PetScan. The resulting lemmas are then saved. Consequently, \mathcal{V}_{edu} contains 562 unique lemmas, and \mathcal{V}_{eco} contains 677 unique lemmas. Although these lists may seem large, they contain a significant amount of noise. Additionally, as shown in Section 4.3, extracting specialized vocabulary using only the words in the seed lists, without our GlossEx method, leads to poor performance.

4 Results and Evaluation

The main evaluation metrics are precision and recall. The goal is to assess how much of the specialized vocabulary the proposed method finds and how many lemmas it returns are actually specialized vocabulary.

4.1 Data

To evaluate the GlossEx method, we use 28 partially digitized German economics textbooks, which cover various school types and years. Nineteen of these textbooks also have paired OCR-scanned glossaries. For all lemmas that appear at least four times in the corpus, we collect expert judgments whether each lemma is domain-specific vocabulary in the field of economics. One expert (not an author of this paper) labeled all 3,458 unique lemmas with binary labels. Out of these, 469 lemmas (13.56%) are labeled as domain-specific vocabulary. To assess inter-annotator agreement, another expert (also not an author of this paper) independently labeled a subset of 510 lemmas. Cohen’s κ (Cohen, 1960) between both annotators is 0.66, which is considered substantial agreement according to Landis and Koch (1977). Furthermore, the f1-score between both annotators

is 0.79, which sets an upper bound on the models’ performance. However, this bound is not specific to any particular textbook.

4.2 Baselines

We compare our method GlossEx described in Section 3 to several baselines. The first set of baselines comprises methods that are widely used for keyword extraction, namely tf-idf (Jones, 2004), Rapid Automatic Keyword Extraction (RAKE) (Rose et al., 2010), and supervised learning on static word embeddings. Note, that the supervised baseline requires labels and therefore uses strictly more information than is available to our method. Thus, the supervised baseline serves as an upper bound to see how much worse methods that do not require explicit labels perform.

A second set of baselines evaluates how well we can extract keywords using two methods: either by simply using the seed lists from Section 3.5 or by using the glossaries included in textbooks. By comparing two seed lists as a baseline, we ensure that our algorithm can discover domain-specific vocabulary beyond the initial input. By comparing two glossaries as a baseline, we confirm the relevance of our problem. This comparison shows that textbook glossaries do not contain all the vocabulary that experts consider domain-specific.

tf-idf measures how relevant a term is to a specific document within a collection of documents (corpus). A term is more relevant if it appears often in the document (high term frequency) but less relevant if it appears in many other documents (high inverse document frequency). To apply tf-idf in our context, given a textbook \mathcal{D} : Term frequency is the frequency f_t of term t in \mathcal{D} . Inverse document frequency is the logarithm of the inverse ratio of sections in \mathcal{D} that also contain t . The formula for tf-idf is:

$$\text{tf-idf}(t, \mathcal{D}) = \frac{f_t}{\sum_{t'} f_{t'}} \cdot \log \left(\frac{N}{g_t} \right) \quad (3)$$

Here, N is the total number of sections in \mathcal{D} , and g_t is the number of sections in \mathcal{D} that contain the term t . Typically, a threshold $\tau \in \mathbb{R}$ is used to identify domain-specific vocabulary. Any term with a tf-idf score greater than τ is considered part of this vocabulary. In our specific case, we choose the τ value that maximizes the f1-score of the predicted domain-specific vocabulary.

Rapid Automatic Keyword Extraction RAKE (Rose et al., 2010) selects keyphrases from documents for information retrieval via assigning each keyphrase a score based on cooccurrence statistics and returning the 33% top scoring keyphrases. We use the implementation provided by the rake-nltk library.³ We only consider single keywords, i.e. the maximum keyphrase length is 1. As stopwords, we provide the list of German stopwords provided by the NLTK (Bird et al., 2009).

Supervised Learning The task of domain-specific vocabulary extraction can be described as a binary classification problem if we are given lemmas and binary labels that show if each lemma is specific to a certain domain. We represent lemmas using their static fastText embeddings, as described in Section 3.5. Then, we train a multi-layer perceptron (MLP) to predict the correct label from these embeddings. To get predictions for all lemmas in a textbook, we use 5-fold stratified cross-validation. We use the scikit-learn library for both cross-validation and the MLP.

Glossaries Nineteen textbooks in our dataset include a glossary. We assess how much of the domain-specific vocabulary these glossaries cover and whether they also contain general, non-domain-specific vocabulary. We extract all elements from these 19 glossaries. We then keep all individual tokens, excluding stopwords, and lemmatize them. From these, we only keep nouns and verbs. We then return only the remaining lemmas from the glossary that appear in the given textbook \mathcal{D} .

Seed Lists In this case, we return all entries from the seed lists described in Section 3.5 that also appear as domain-specific vocabulary in the textbook. This baseline tests whether GlossEx can discover new domain-specific vocabulary and successfully discard non-domain-specific vocabulary. However, the seed lists directly determine which lemmas are returned as domain-specific and which are discarded after the clustering step (see Section 3.4). Therefore, there is a close relationship between the precision of the seed lists (i.e., how many of the seed list entries are actually domain-specific vocabulary) and the precision of GlossEx.

4.3 Results

Overall Performance In Table 1, we present the precision, recall, and f1-score for all meth-

Method	Precis.	Recall	F1
tf-idf	0.152	<u>0.685</u>	0.230
RAKE	0.172	0.854	0.283
Glossary	0.821	0.258	0.382
Wiki-Seedlist	0.367	0.065	0.103
GlossEx-dereko (ours)	<u>0.543</u>	0.584	<u>0.545</u>
GlossEx-subtlex (ours)	0.518	0.645	0.559
Supervised	0.754	0.524	0.589

Table 1: Precision, recall, and f1-scores of GlossEx and baselines. Scores are averages across the 28 textbooks in our dataset. Best results (excluding supervised) are in bold, and second best results are underlined. “dereko” and “subtlex” refer to the background corpus.

ods. These scores are macro-averaged across all 28 textbooks in the dataset. The supervised baseline shows the best overall performance, as expected. Because the data is imbalanced (with only a few domain-specific words), the precision for this baseline is higher than its recall. Conversely, tf-idf and RAKE perform poorly in terms of f1-score. These methods identify many words as domain-specific vocabulary, leading to high recall but low precision. RAKE performs better than tf-idf, even though the optimal score threshold is used for tf-idf.

Using glossaries improves performance. However, these results cannot be directly compared because glossaries are only available for 19 textbooks. Therefore, the reported results are averaged only over these 19 textbooks. Generally, glossaries mainly contain domain-specific vocabulary. However, they miss 75% of the domain-specific vocabulary in textbooks, which is indicated by the low recall. The seed list extracted from Wikipedia yields low precision, low recall, and consequently, a very low f1-score. Still, the precision is higher than that of tf-idf and RAKE. This is expected because the construction method directly uses the Wikipedia category hierarchy. This primarily confirms that our method’s performance is not simply due to a very strong starting point through the seed lists.

Finally, GlossEx achieves an improvement over the seed lists in terms of f1-score and recall. This shows that GlossEx can indeed leverage distributional semantics to identify domain-specific vocabulary. Our method also significantly reduces the gap between baseline methods and supervised learning. Compared to supervised learning, our method achieves higher recall at the expense of

³<https://pypi.org/project/rake-nltk/>

Figure 1: GlossEx f1-score vs. increasing seed list size.

lower precision. Therefore, exploring more precise methods to characterize the contextual semantics of words in textbooks seems to be a promising direction for improving our method.

Since GlossEx relies on external data, we must characterize the influence of the background corpus and seed list on its performance. As seen in Table 1, using SUBTLEX-DE instead of DeReKo (referred to as “subtlex” and “dereko”) as the background corpus results in higher recall but lower precision. One possible reason for this is that DeReKo has broader vocabulary coverage, which leads to fewer lemmas appearing prominent for a given document. Additionally, the DeReKo corpus contains many newspaper texts, which might bias frequency estimates for terms related to topics like politics and financial news.

Effect of Seed List Size To assess how the size of the seed list affects our method’s performance, we repeatedly select random seed lists of different sizes. These sample sizes, denoted as n , are chosen from the set $\{10, 20, 50, 100, 200, 300, 400\}$. From the complete set of all entries in the seed lists, for each sample size n , we sample $k = 100$ seed lists. In all instances, both the economics and education seed lists have the same number of entries. We then re-evaluate our method using these selected seed lists.

Figure 1 shows that the performance of GlossEx consistently improves as the seed list size increases. This outcome is expected and these findings also indicate that GlossEx is resilient to direct overlaps between seed lists and textbook vocabulary. The Wikipedia seed list, for example, contains only a few domain-specific terms. However, GlossEx can fully utilize the semantic information found in these entries. In summary, our results demonstrate that GlossEx performs well with 100 to 200 noisy seed words. However, it achieves optimal performance when provided with more, higher-quality entries.

5 Discussion and Future Work

Our method, GlossEx, uses traditional machine learning and natural language processing (NLP) techniques for domain vocabulary extraction, such as clustering and word embeddings. Unlike previous methods, we also include contextualized embeddings derived from large language models (LLMs). Recent versions of generative LLMs have been very successful in various zero-shot applications (Brown et al., 2020; Achiam et al., 2023). These advancements are promising for all areas of NLP, including education (Alhafni et al., 2024; Wen et al., 2024), making the use of LLMs for domain-specific vocabulary extraction in a zero- or few-shot manner an exciting direction for future research. However, we believe that combining LLMs with modular approaches like ours is most effective, because we can not only identify, but also explain *why* certain words are considered domain-specific. This explanation comes from traceable differences in word occurrences in domain-specific versus general texts, and from semantic similarity to known domain-specific words. This built-in interpretability makes GlossEx a valuable approach even in the era of LLMs.

6 Conclusion

Given educational materials, how can we systematically extract the domain concepts to be learned and understood by students? Answering this is relevant for building glossaries for textbooks, for domain and student modeling for adaptive learning platforms, and for the automatic derivation of activity models for text-based learning materials. In this paper, we investigated how computational linguistic methods such as distributional semantic analysis and clustering can be combined to automatically extract a domain-specific glossary. We presented a pipeline to extract specialized vocabulary from single documents, e.g., textbooks. The pipeline is optimized for documents from the educational domain, where pedagogical terminology cannot easily be separated from subject domain concepts by statistical methods alone. Pursuing a weakly supervised approach, we injected only a limited amount of domain knowledge in the form of a seed list readily obtained from Wikipedia. We evaluated the method on German economics textbooks. Evaluation is both automatic, by comparing the extracted vocabulary to paired glossaries, and manual by human domain experts.

Data and Code Availability

Our implementation of GlossEx is available at <https://github.com/LGirrbach/GlossEx>. We cannot release the textbook material used in this paper because it is copyrighted. However, the textbook titles are included in our code release.

Limitations

While our approach to automatic concept extraction using contextualized word embeddings and weakly supervised learning shows promising results, there are some limitations to our approach.

First, the reliance on pre-trained language models such as BERT, which are primarily trained on general corpora, may not fully capture the nuances of domain-specific language used in educational texts. This can lead to less optimal performance in identifying and clustering domain-specific vocabulary, particularly in specialized fields not well-represented in the training data.

Second, the quality and comprehensiveness of the seed lists used to guide the clustering process significantly influence the results. Although we used Wikipedia to generate these lists, the potential gaps in coverage can affect the accuracy of the extracted concepts. In future work, one could explore more refined methods for seed list generation or incorporate additional domain-specific resources to support the robustness of the approach.

Third, the performance of GlossEx is evaluated on a relatively small and specific dataset of German economics textbooks. This limits the generalizability of our findings to other subjects and educational contexts. Extensive testing on diverse datasets is necessary to validate the broader applicability of our approach.

Finally, while our approach reduces the need for extensive manual annotation, it still requires some level of domain knowledge for seed list creation and cluster validation. This semi-supervised nature means that the method is not entirely free from human intervention, which could be a limitation in fully automating the concept extraction process.

Addressing these limitations in future research will be crucial for enhancing the scalability, accuracy, and applicability of our method in various educational settings.

Supplementary Material

A Qualitative Examples

This section presents the predictions made by GlossEx (using SUBTLEX-DE as its background corpus) on a specific textbook. The predicted lemmas are divided into two categories: correctly predicted (true positives) and incorrectly predicted (false positives). The results for Westermann: Kompetenz Politik-Wirtschaft 2006 (Gymnasium Niedersachsen, Stufe 8) are as follows:

Correct Lemmas	Incorrect Lemmas
Einkommen, Haushalt, Ökonom, Geld, Markt, Wirtschaft, Händler, Anbieter, Knappheit, Angebot, Bedürfnis, Käufer, Nachfrage	Herr, Ergebnis, Person, Wunsch, Cent, Mark, Laden, Mensch, Mitglied, Form, Preis, Verfügung, Mittel, Stand, Kauf, Wochenmarkt, Euro, Prinzip, kaufen, Taschengeld

Our method successfully identifies words with domain-specific meaning, such as “Haushalt” (English: *budget*) and “Nachfrage” (English: *demand*). However, GlossEx also identifies common economic terms that are part of everyday language, like “Laden” (English: *shop*) and “Euro”. Additionally, GlossEx finds words such as “Person” (English: *person*) and “Mensch” (English: *human*). These terms have a strong semantic similarity to other human-related words, such as “Käufer” (English: *buyer*), and are therefore included in the list of predicted lemmas. An examination of results from other textbooks generally supports these findings.

Towards a Real-time Swedish Speech Analyzer for Language Learning Games: A Hybrid AI Approach to Language Assessment

Abstract

This paper presents an automatic speech assessment system designed for Swedish language learners. We introduce a novel hybrid approach that integrates Microsoft Azure speech services with open-source Large Language Models (LLMs). Our system is implemented as a web-based application that provides real-time quick assessment with a game-like experience. Through testing against COREFL English corpus data and Swedish L2 speech data, our system demonstrates effectiveness in distinguishing different language proficiencies, closely aligning with CEFR levels. This ongoing work addresses the gap in current low-resource language assessment technologies with a pilot system developed for automated speech analysis.

1 Introduction

In recent years, the integration of state-of-the-art artificial intelligence (AI) technologies—particularly large language models (LLMs)—has shown considerable promise across a range of domains, including Intelligent Computer-Assisted Language Learning (ICALL), Technology-Enhanced Language Learning (TELL), and Second Language Acquisition (SLA) (Zhang and Zou, 2022; Huang et al., 2023). A growing body of research has demonstrated the effectiveness of AI-driven language assessment tools (Daniels, 2022; Huawei and Aryadoust, 2023; Settles et al., 2020), highlighting their potential to facilitate language learning within contextually rich environments (Zou et al., 2023; Dizon, 2020; Huang et al., 2023). For instance, Brena et al. (2021) proposed supervised machine learning approaches capable of evaluating L2 English fluency and pronunciation with reported accuracy rates exceeding 90%. Despite these advancements, a recent systematic review of AI-based assessment in language learning (Chen et al., 2024) indicates a marked imbalance: 88% of the reviewed tools were developed for English learning, and only

3 out of 25 studies focused on assessing learners' speaking skills. This disparity underscores a significant gap in the current research landscape.

This paper aims to address the gap in automatic speech assessment tools, specifically for non-English languages by proposing a hybrid AI approach. We examine the adaptability of a pronunciation assessment tool optimized for English (Azure Speech Services; Microsoft 2024) to the low-resource Swedish language, then extend it by integrating large language models for content and delivery assessment, forming a detailed assessment system. In addition, the system is built as a Web App, providing real-time feedback as well as a game-like user experience. In the following sections, we will first justify the importance of building an automatic Swedish speech assessment system by reviewing recent related studies and applications around low-resource language speech assessment. We will then introduce our system design, followed by the evaluation and validation of the system with the English speech data from the COREFL corpus (Lozano et al., 2020) and an initial collection of Swedish L2 samples. Finally, we will discuss the results of the system tested for Swedish speech assessment and address the conclusions.

2 Related Work

2.1 Automatic Speech Assessment Systems

Using mobile-assisted language learning (MALL) applications like Duolingo and Babbel has been a popular option for learners (Lehman et al., 2020; Loewen et al., 2020), especially for those studying low-resource languages for which accessible learning resources are scarce. Although MALL apps offer beginners a quick start, there is a lack of efficient or systematic follow-ups. Those apps mostly give a binary score (“correct or not”), or star-based assessment restricted to pronunciation practices, providing neither a comprehensive overview

of speaking ability nor detailed feedback such as pronunciation suggestions (Lehman et al., 2020; Chang et al., 2022).

For more detailed pronunciation assessment, Microsoft Azure Speech Studio (Microsoft, 2024) offers metrics related to accuracy, fluency, completeness, and prosody, as illustrated in Figure 1. While the service provides a multifaceted analysis at the phoneme, word, and sentence levels, the resulting scores remain relatively abstract and are not accompanied by pedagogically oriented feedback or actionable guidance for instructional use. In our experiments, the open-source Azure SDK was found to be primarily optimized for English language assessment, exhibiting limited capacity to accurately process Swedish phonemes. Notably, the system was unable to generate prosody scores for Swedish speech. Despite these limitations, the platform represents a promising prototype for pronunciation assessment and has the potential to be developed into a more robust tool for evaluating spoken language performance, particularly in the context of low-resource languages.

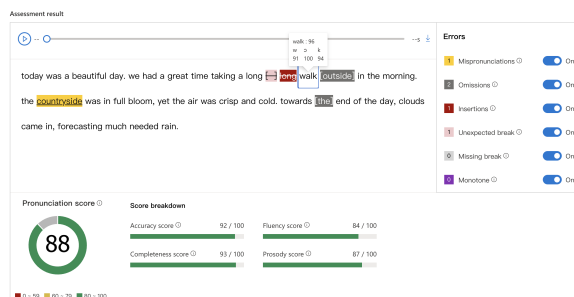

Figure 1: Assessment interface of Azure Speech Studio

2.2 Swedish Learner Data

While the rapid advancement of artificial intelligence models has provided language education with handy tools for quick evaluations (Daniels, 2022; Löber et al., 2024), there is a lack of reliable and detailed automatic systems targeting lower-resource languages such as Swedish. Recent research has been working on filling the blank of Swedish learner data sets through building corpora of which language and proficiency levels are collected from coursebooks (COCTAILL corpus, representing learners’ receptive ability) and learner essays (SweLL-pilot, representing learners’ productive ability) (Volodina et al., 2019).

Nevertheless, the current progress has been made centering mostly texts rather than speech. The ab-

sence of a variety of publicly accessible, annotated Swedish speech data remains a significant obstacle for training robust (deep) learning models. While resources like Common Voice (Mozilla Foundation, 2020) provide raw speech data from native speakers, there is a scarcity of language learner speech samples on the spectrum of proficiency levels needed for developing language assessment or learning applications.

Getman et al. (2023) introduced an AI-assisted language learning application aimed at supporting children’s second language acquisition in low-resource languages, specifically Swedish and Finnish, through the self-collection of relevant datasets. They also highlighted a significant gap in the field, noting: “To the best of our knowledge, in the context of Computer-Assisted Pronunciation Training (CAPT) for L2 Swedish and Finnish children, there are no previous work on automatic pronunciation assessment, not even for L2 Swedish and L2 Finnish adults” (Getman et al., 2023, p. 86026). In response to this gap, the present study contributes to the underexplored area of automatic speech assessment for L2 Swedish by developing a dedicated assessment system and conducting initial evaluations based on authentic speech data produced by L2 learners.

2.3 Language Proficiency Assessment Standards

The Common European Framework of Reference for Languages (CEFR; Council of Europe 2001) has been a widely recognized standard for assessing language proficiency, and recent research (Chen et al., 2024; Volodina et al., 2024) continues to use the CEFR standards and descriptors as reference-framework. While the Common European Framework of Reference for Languages (CEFR) remains a widely recognized standard, its limitations have been noted. As Alderson (2007, p. 660) observed, “the methodologies being used [to compile these descriptions] are unclear or suspect.” The CEFR’s abstract classification into six proficiency levels (A1 to C2) relies heavily on human evaluators—such as language instructors and linguists—which introduces concerns regarding subjectivity and scalability. Furthermore, although learners may be broadly categorized according to CEFR levels, the framework offers limited granular guidance tailored to specific proficiency levels or individual languages. This highlights a disconnect between the standardized assessment framework and the practical de-

mands of language learning and instruction (Settles et al., 2020).

Our proposed automated speech system generates detailed analysis including:

- **Overall performance** Scores in pronunciation, content, and delivery of the speech; the corresponding CEFR level
- **Word-level pronunciation performance** demonstrating specific pronunciation strengths and weaknesses
- **Real-time feedback** with next-step learning suggestions

By combining the traditional assessment metrics and detailed, heuristic assessment analysis, we aim to build a system that generates more readable, informative results, to better serve both learners and educators.

3 System Design

Building on the automated speaking assessment framework developed by Educational Testing Service (ETS) and outlined by Zechner and Evanini (2019), the primary innovation of our system lies in the integration of complementary technologies to evaluate distinct dimensions of speech performance. The system is structured around three core modules: Pronunciation Assessment (based on two read-aloud tasks), Content and Delivery Assessment (based on a free-speech task), and CEFR Level Classification. The implementation takes the form of a web-based application featuring a gamified interface designed to enhance user engagement and learning experience.

3.1 Pronunciation Assessment Module

The system incorporates the pronunciation assessment module provided by Microsoft Azure’s Speech SDK (Microsoft, 2024), which generates evaluation scores across five dimensions: Accuracy, Completeness, Fluency, Confidence, and Word-level confidence scores. Although the module does not support prosodic analysis for Swedish, our integration extends its applicability to the Swedish language and compensates for this limitation by supplementing it with two additional assessment modules.

3.2 Content-and-Delivery Assessment Module

The system utilizes a generative large language model (Llama 3.1; Touvron et al. 2023) to assess aspects of speech beyond pronunciation, specifically

Figure 2: Average combined scores of pronunciation, content and delivery

focusing on content relevance and language complexity in delivery. Based on predefined prompts (see details in Appendix F), the model produces quantified evaluation scores for these dimensions. Additionally, Llama 3 is prompted to generate human-like feedback in the form of constructive suggestions (see detailed examples in Appendix G), offering learners insights into how they can improve both the content and delivery of their spoken language.

3.3 CEFR Classification Module

Due to the lack of available Swedish data, and in order to provide an overall CEFR-based proficiency label for speech performance, we conducted a preliminary calibration of the combined scores generated by the two aforementioned AI modules. This calibration aligns the system’s output with CEFR proficiency levels, using threshold values derived from test results on 55 carefully sampled English speech recordings ranging from A1 to C2, drawn from the COREFL corpus (Lozano et al., 2020) (see Figure 2). Notably, the system demonstrates strong discriminative capability at lower proficiency levels, whereas the distinction between B1 and B2 remains relatively subtle. The observed decline in scores from C1 to C2 is consistent with the known ambiguity of official CEFR descriptors at higher proficiency levels, as previously discussed by Isbell (2017) and Settles et al. (2020).

3.4 Web Implementation and User Experience Design

In our system, the player assumes the role of *Frog*, a character motivated to learn Swedish, and engages with Professowl, a fictional language professor who provides feedback and evaluations of the player’s spoken Swedish. This narrative framing is intended to enhance learner engagement by embed-

ding assessment within an interactive and playful context.

Figure 3: Professowl guiding Frog through the pronunciation assessment tasks

The dialogue flow begins with Professowl guiding Frog through reading two Swedish sentences of different CEFR proficiency levels and then a free speech on the topic of “self introduction”. Professowl gives corresponding feedback including scores and suggestions in an encouraging way.

4 Preliminary Results and Discussion

Given the limited availability of Swedish L2 speech data, we collected five original sets of preliminary speech samples from L2 learners at varying proficiency levels (see detailed results in Appendix C and D). These samples were manually evaluated by an experienced Swedish language instructor using the same scoring metrics employed by the automated system, enabling a direct comparison between human and machine assessments. While the dataset remains modest relative to high-resource languages such as English, it establishes an essential foundation and provides a baseline for subsequent analyses.

Due to the scale difference between Azure assessment metrics (0 to 100%) and our assessment metrics (1 to 5 Likert Scale) for the human rating, the system assessment scores were proportionally converted to 1 to 5 point scale based on thresholds at 20%, 40%, 60%, 80%.

As illustrated in Figure 4, a general alignment can be observed between the system-generated assessments and those provided by the human evaluator. However, the system is currently unable to assess prosody in Swedish, resulting in missing scores for this dimension. Furthermore, limitations in handling Swedish phonological characteristics lead to a rigid, word-by-word evaluation approach. For instance, commonly (phonologically) reduced

Figure 4: Average Pronunciation Scores Comparison

function words in Swedish—such as *att* ‘to’ and *i* ‘in/at’ were frequently misclassified as “weak words” even when produced fluently. This issue is highlighted in the comparison of strong and weak word assessments between the system and the human evaluator (Appendix E).

5 Conclusion and Future Work

In this paper, we present an initial prototype of a speech assessment system designed for Swedish. Our speech analyzer generates meaningful evaluation scores, provides reference word lists based on word-level pronunciation performance, and delivers both general feedback and personalized suggestions to support language learning.

The system combines Microsoft Azure’s speech services with large language models to divide the assessment process into distinct tasks, each handled by separate tools. The game-like user experience design intends to promote learners’ engagement (Hung, 2017; Hung et al., 2018). This approach demonstrates the potential of digital language learning tools in low-resource settings.

For future work, we plan to focus on several key aspects to improve the effectiveness and reliability of our system. First, we aim to achieve greater integration stability by stabilizing the speech services and embedding appropriate transition cues. This will reduce unintended delays during gameplay and ensure a smoother user experience throughout the learning process.

Second, we intend to enhance our phonological analysis capabilities by improving the system’s ability to recognize and analyze phonological patterns in naturally spoken Swedish. This further development will enable more precise assessment of learners’ pronunciation and speaking skills, particularly the nuances of Swedish phonology that are crucial for assessing language proficiency.

Third, we plan to significantly expand our data by collecting a larger and more comprehensive dataset covering learners at all proficiency levels from A1 to C2. This expanded dataset will better represent the full spectrum of Swedish learners and enable more robust training and reliable evaluation of our assessment algorithms.

Finally, we are focusing on improved validation procedures. To do this, we will engage additional teachers and annotators to rate language samples, thus confirming the accuracy of our automated assessments through inter-rater reliability measures. Furthermore, we plan to calibrate our CEFR classification system using authentic data from Swedish second language learners. This should help ensure that our proficiency level assignments conform to established CEFR standards and reflect the specific characteristics of Swedish language acquisition.

Limitations

This study presents a prototype system for automatic speech assessment in Swedish as a second language, but several limitations should be acknowledged. First, the evaluation relies on a small and preliminary dataset consisting of only five learner speech samples, which restricts the generalizability and statistical robustness of the findings. Second, the calibration of CEFR levels was based on English L2 data due to the lack of sufficient annotated Swedish learner corpora, which may have introduced cross-linguistic biases in proficiency classification. Third, the Azure speech assessment module lacks support for prosodic features in Swedish, limiting the system's ability to fully capture suprasegmental aspects of pronunciation. Additionally, the rigid word-by-word evaluation method often misinterprets function word reductions common in fluent speech, potentially penalizing natural speaking patterns. Furthermore, despite the robustness of the Microsoft Azure speech assessment analysis, the reliance limits replicability of this work. Other open-source alternatives such as Whisper-based assessment will be considered in future research to maximize the accessibility of the system.

Ethical Concerns

The development and deployment of automated language assessment tools raise several ethical considerations. Firstly, the system's reliance on proprietary and opaque evaluation mechanisms—such as

Azure's speech scoring—may reinforce biases that are not easily observable or correctable by developers or users. Secondly, collecting and processing learner speech data involves privacy risks and must comply with ethical data handling standards, including informed consent and secure data storage. In this study, all participants were aged 18 or over and provided express consent for their speech data to be used for research purposes. Special care should be taken if the system is later extended to include minors or vulnerable populations, particularly in educational game-based settings. Lastly, while large language models can offer helpful feedback, they may inadvertently reinforce normative language ideologies or reflect implicit biases. To ensure fairness, pedagogical relevance, and user well-being, ongoing evaluation and human oversight are essential throughout system development and deployment.

A Assessment Criteria

Figure 5 provides detailed descriptors for the pronunciation metrics used in our assessment system.

Assessment Criteria				
Item	Descriptor	Rating scale	Details	
Pronunciation	Accuracy	Accuracy indicates how closely the phonemes match a native speaker's pronunciation.	"1 to 5" Likert scale	
	Fluency	Fluency indicates how closely the speech matches a native speaker's use of silent breaks between words.	"1 to 5" Likert scale	
	Prosody	Prosody indicates how natural the given speech is, including stress, intonation, speaking speed, and rhythm.	"1 to 5" Likert scale	*see scoring descriptors
	Completeness	Completeness of the speech, calculated by the ratio of pronounced words to the input reference text.	"1 to 5" Likert scale	
	Strong words	In other words, completeness indicates how complete the speech is compared with the reference text. (Is the speech missing any words?)	0-3 words	
	Weak words	The words that were comparatively pronounced well The words that were comparatively pronounced poorly	0-3 words	e.g. det, här, är (from best to good; write at most three) e.g. trivs, att, bra (from worst to not accurate; write at most three)
Content & Delivery	Content	The quality of the content (the richness and relevance of the speech) of the speech.	Free Comments	e.g. "The self-introduction is pretty relevant but quite narrow in topics as the speaker only talked about the education background."
	Delivery	The quality of the delivery (grammatical structure, natural language use, etc.) of the speech.	Free Comments	e.g. "The grammar used in the speech is mostly very simple. OOO is not a natural Swedish sentence, XXX is more commonly in this case."
Overall	Overall Conclusion (regarding the speech proficiency level, strengths and weaknesses, suggestion for future study, e.g. what to focus on regarding pronunciation or free speech)		Free Comments	e.g. "The overall speech shows that the speaker has the basic knowledge of Swedish. Given that the complexity of the speech is low and the rhythm is limited, the speaker could be of a CEFR level between A2 and B1. The speaker is very accurate at pronouncing Swedish vowels such as ä and ö, but not very good at the 'r' sound. The 'r' sound is pronounced similar to 'l' instead. For future study, the speaker might want to improve on the 'r' sound, listening to real Swedish conversations as to be familiar with the natural rhythm and intonation."

Figure 5: Assessment criteria for human-teacher assessment

B Detailed Scoring Descriptors

Table 1 provides detailed descriptors for the pronunciation metrics used in our assessment system.

Score	Accuracy	Completeness	Fluency	Prosody
1	Incomprehensible speech with almost no sounds that are accurate	Missing many important words (< 60%)	Very snatchy speech with frequent unnatural breaks	No variation in stress or intonation, or the rhythm is completely off
2	Many obvious errors in pronunciation, difficult to understand	Several missing words (60–75%)	Frequent hesitations and stops	Unnatural rhythm, intonation and stress patterns
3	Some noticeable errors but generally accurate and understandable	Most words included with some minor omission (75–85%)	Generally fluent flow with some unnatural stops	Some natural stress and intonation patterns
4	High accuracy with minor errors that don't affect comprehension	Nearly complete (85–95% coverage)	Generally smooth speech with occasional pauses	Generally appropriate stress, rhythm and intonation
5	Most sounds are perfectly correct, native-like speaking	Complete (95–100% coverage)	Natural, native-like speech flow with appropriate pauses	Native-like rhythm, stress, and intonation

Table 1: Detailed scoring descriptors for pronunciation metrics

C Preliminary Test Results (Human Assessment)

F LLaMA Model Prompting Details

The "content and delivery assessment module" employs Llama 3.1 with carefully designed and tested prompts to ensure consistent feedback. The prompt details and model configuration are as follows:

F.1 Detailed Prompt

The following prompt template is passed with relevant values for evaluating the content and delivery of every speech input:

```
You are Professowl, a Swedish language teacher. Analyze the following student's self-introduction in Swedish: "$input"
```

```
Provide feedback in this JSON format:
```

```
{
  "analysis": {
    "relevance": number, // 0-100, how well the content works as a self-introduction
    "complexity": number, // 0-100, language complexity level
    "feedback": string, // One sentence including both relevance and complexity scores
    "suggestions": string[] // 2-3 short, specific suggestions in English
  }
}
```

```
Focus on:
```

- Content and relevance for self-introduction
- Sentence structure and vocabulary use
- Grammar and language flow

```
Example response:
```

```
{
  "analysis": {
    "relevance": 80,
    "complexity": 65,
    "feedback": "Your self-introduction is quite relevant (80/100) with moderate language complexity (65/100), showing good basic vocabulary and structure.",
    "suggestions": [
      "Try using more descriptive adjectives when talking about your interests",
      "Add information about your future plans in Sweden",
      "Practice using more complex sentence connections"
    ]
  }
}
```

```
Always include both scores in the feedback sentence.
```

F.2 Model Configuration

To ensure consistent and reliable outputs, the following configuration parameters are used:

- **Model:** Llama 3.1
- **Temperature:** 0.3
- **Output format:** JSON
- **Deployment:** Local Ollama instance

G System Feedback Examples

The following examples demonstrate system feedback generated by the LLaMA model for speech samples. The feedback structure is designed to be encouraging and provides score-based assessment as well as actionable suggestions.

G.1 Example 1

"Your self-introduction is somewhat relevant (70/100) with relatively low language complexity (55/100), indicating a good start but some areas for improvement. Consider adding more specific details about your work or interests. Practice using correct verb forms, e.g., 'Jag har flyttat' instead of 'Jag flyttar'. Use more precise vocabulary when describing your age 30 år gammal' could be 'trettiofyre år gammal)"

G.2 Example 2

"Your self-introduction is somewhat relevant (70/100) with relatively low language complexity (50/100), showing basic vocabulary and simple sentence structure. Consider adding more details about yourself, such as your hobbies or background. Practice using more formal language for a university setting. Try to use more cohesive linking words between sentences."

Multilingual Grammatical Error Annotation: Combining Language-Agnostic Framework with Language-Specific Flexibility

Abstract

Grammatical Error Correction (GEC) relies on accurate error annotation and evaluation, yet existing frameworks, such as *errant*, face limitations when extended to typologically diverse languages. In this paper, we introduce a standardized, modular framework for multilingual grammatical error annotation. Our approach combines a language-agnostic foundation with structured language-specific extensions, enabling both consistency and flexibility across languages. We reimplement *errant* using *stanza* to support broader multilingual coverage, and demonstrate the framework’s adaptability through applications to English, German, Czech, Korean, and Chinese, ranging from general-purpose annotation to more customized linguistic refinements. This work supports scalable and interpretable GEC annotation across languages and promotes more consistent evaluation in multilingual settings. The complete codebase and annotation tools can be accessed at https://github.com/open-writing-evaluation/jp_errant_bea.

1 Introduction

Grammatical Error Correction (GEC), which aims to automatically detect and correct errors in written text, has emerged as one of the most important and widely studied tasks in Natural Language Processing (NLP) for educational applications, particularly those supporting language learning and writing improvement. It benefits both native speakers (L1), by enhancing clarity and fluency in their writing, and non-native learners (L2), by providing immediate, structured feedback that reinforces correct grammatical patterns, boosts writing confidence, and, ultimately, supports language development and acquisition (Marjokorpi, 2023; Van Beuningen et al., 2012). Over the years, the lion’s share of research has focused on advancing GEC systems—evolving from rule-based and statistical approaches to neural

architectures, such as neural machine translation with transformers (Zhao et al., 2019) and, more recently, prompting-based approaches built on large language models (Zeng et al., 2024; for a comprehensive review, see Bryant et al., 2023).

Yet, automatic error annotation and evaluation play an equally critical role in GEC. Error annotation identifies and categorizes linguistic errors, while evaluation measures how effectively GEC systems correct them. Together, these two components help establish standardized benchmarks, influencing everything from system development to the quality of corrections eventually delivered to users. However, despite their importance, they have historically received less attention and are often treated as ancillary to system development and dataset creation.

Among existing tools for automatic error annotation and evaluation (e.g., M², Dahlmeier and Ng, 2012; GLEU, Napoles et al., 2015), *errant* (Error ANnotation Toolkit) has established itself as the *de facto* framework for English GEC. What makes *errant* stand out is its detailed linguistic annotations, with a total of 55 possible error types for English (Bryant et al., 2017). *errant*’s significance was solidified in the *Building Educational Applications 2019 Shared Task: Grammatical Error Correction (BEA-2019)*, where it was used to standardize multiple datasets and served as the official scorer (Bryant et al., 2019).

While this toolkit has proven effective for English, further refinements are needed to improve its versatility and adaptability, especially in multilingual scenarios. Recent years have seen growing interest in multilingual GEC, as demonstrated by initiatives like the *MultiGEC-2025 Shared Task*, which brought together efforts across twelve typologically diverse European languages (Masciolini et al., 2025a,b). However, this surge in interest has outpaced the development of consistent multilingual annotation resources.

As noted by Masciolini et al. (2025a), only three languages in MultiGEC—namely Czech, German, and Greek—have received errant-style annotation. For the remaining languages, the authors acknowledge that, due to limited time and resources, they implemented only coarse-grained alignment between original and corrected texts to support holistic scoring, without access to the kind of detailed error analysis enabled by errant for English. Even in existing adaptations of errant for various languages, implementations vary considerably in their design choices—ranging from annotation label schemes to tokenization and part-of-speech (POS) tagging tools—and differ in the level of granularity applied to language-specific error types. Although differences in orthographies and morphosyntactic structures across languages are unavoidable, greater consistency in annotation practices is highly desirable.

To address these challenges, our goal is to develop a consistent and reusable framework for grammatical error annotation that can be readily adapted across typologically diverse languages. Drawing inspiration from the original errant’s dataset-agnostic design, we extend its core philosophy to multilingual settings by separating the annotation pipeline into two components: a shared architecture that applies across languages, and optional extensions tailored to language-specific features. Even within the language-specific layer, we introduce structured templates for common error types, such as spelling, word order, and word boundary errors, which can be reused or adapted across languages with similar orthographic or syntactic patterns. In addition, our implementation relies on the stanza toolkit for tokenization and POS tagging, which provides standardized processing pipelines for over 70 languages (Qi et al., 2020), allowing our framework to be readily extended to annotate new GEC datasets of other languages when they become available.

The rest of the paper is organized as follows: §2 reviews the original errant framework, discusses challenges in its multilingual adaptations, and motivates the use of stanza for more consistent cross-linguistic preprocessing. §3 introduces our proposed grammatical error typology, which combines a language-agnostic core with structured, language-specific extensions. §4 presents our reimplementation of English errant and demonstrates the framework’s applicability to multiple languages, ranging from generic use in European languages, to minor

template refinements for Korean, and deeper customization for Chinese. Finally, §5 summarizes our contributions and emphasizes the framework’s flexibility and extensibility for multilingual GEC.

2 Background and Related Work

2.1 Description of errant

errant is a unified framework for error annotation and evaluation in English GEC. It provides a rule-based, dataset-agnostic approach for extracting and categorizing edits between original and corrected sentences, making it a crucial tool for system evaluation and benchmarking (Bryant et al., 2017).

At the core of its annotation pipeline is a linguistically enhanced alignment algorithm that identifies edit boundaries between sentence pairs. This algorithm, originally proposed by Felice et al. (2016), extends the Damerau-Levenshtein distance with a linguistically informed cost function that considers part-of-speech tags, lemmas, and character similarity. Unlike surface-level edit distance, this method prioritizes alignments between tokens that are syntactically or morphologically related (e.g., *meet* and *meeting*), and handles both one-to-one edits and multi-token reordering. A rule-based merging strategy is then applied to combine adjacent edits where appropriate, based on patterns frequently observed in learner data, such as phrasal verb edits. This alignment process significantly improves the consistency and quality of extracted edits (Felice et al., 2016).

Following alignment, errant applies a rule-based annotation scheme to categorize edits into fine-grained grammatical error types, enabling both comprehensive feedback and error-type evaluation. Specifically, it defines 25 primary error types based on POS and morphological properties obtained from spaCy¹, and further classifies them into three edit operations: Missing, Unnecessary, and Replacement, resulting in a total of 55 possible error types (e.g., R:VERB:TENSE indicates a replacement error related to verb tense). To store annotations, errant generates output in M2 format, the standard representation for GEC annotations since its adoption in the *CoNLL-2013 Shared Task* (Ng et al., 2013). Each annotated sentence consists of the original tokenized text (denoted by an *S* line) followed by one or more error annotation lines (*A* lines). Each *A* line specifies the error span, the

¹<https://spacy.io>

error type, the suggested correction, and additional metadata (see Figure 1 for an example in English).

```
S This are a sentence .
A 1 2|||R:VERB:SVA|||is|||-REQUIRED-|||NONE|||0
A 3 3|||M:ADJ|||good|||-REQUIRED-|||NONE|||0
```

Figure 1: Example of an annotated sentence in M2 format from *BEA-2019*.

With edits extracted and categorized in a standardized format, errant can then be used to systematically evaluate GEC system outputs against gold-standard references. It calculates precision and recall between system-generated edits and gold-standard corrections and utilizes a harmonic mean $F_{0.5}$ score, which weights precision twice as much as recall to prioritize accurate and contextually appropriate corrections over excessive edits. Thanks to its detailed annotation schema, errant supports multi-granularity evaluation—analyzing system effectiveness not only at the overall level but also across specific error types and edit operations, enabling a fine-grained and transparent assessment of GEC models.

In *BEA-2019*, errant was used to standardize multiple datasets, some of which were annotated using different error type frameworks, while others lacked annotations entirely. This allowed for error distribution comparisons across datasets that were previously hindered by these annotation discrepancies. In addition, errant facilitated multi-level system evaluation by supporting error-type analysis across 24 main categories for all 21 participating teams². This enabled a detailed assessment of each system’s strengths and weaknesses and made it easier to identify which error types were the most challenging to correct (Bryant et al., 2019).

While errant provides a linguistically informed foundation for GEC annotation and evaluation, it is not without limitations. One minor issue is its tendency to overuse the OTHER category (i.e., unspecified errors), leading to less precise error categorization. For instance, certain errors that could be classified as specific grammatical types (e.g., verb tense or prepositions) are instead grouped under OTHER (Korre and Pavlopoulos, 2020).

Another issue, as discussed in Wang et al. (2025), arises in end-to-end evaluation scenarios. errant assumes pre-defined sentence boundaries, and mis-

²errant defines 25 categories, including UNKnown (error detected but unable to be corrected; Bryant et al., 2017). In *BEA-2019*, this category was not included.

alignment can result in an inability to generate evaluation results between gold-standard references and system outputs. However, in real-world GEC applications, such as learner essays, inconsistencies in sentence segmentation are a common issue, often caused by differences in preprocessing steps. To address this, Wang et al. (2025) introduced joint-preprocessing errant, incorporating an alignment-based approach to detect and resolve segmentation discrepancies before evaluation.

2.2 Challenges in existing multilingual adaptations of errant

Given its demonstrated success in English, errant has been adapted to multiple languages, including Arabic (Belkebir and Habash, 2021), Chinese (Hinson et al., 2020; Zhang et al., 2022; Gu et al., 2025), Czech (Náplava et al., 2022), German (Boyd, 2018), Greek (Korre et al., 2021), Hindi (Sonawane et al., 2020), and Korean (Yoon et al., 2023). While these adaptations have enabled broader use of errant-style annotation, they also reveal several challenges that arise when extending the framework to languages with a range of orthographic and morphosyntactic characteristics.

Inconsistent annotation labels A minor issue in multilingual adaptations of errant is inconsistent annotation labels for similar error types. The original errant for English defines three edit operations: Missing, Unnecessary, and Replacement, while treating word order (WO) as a main error category, similar to NOUN or VERB errors. In *errant_zh*, an adaptation for Chinese, these operations were denoted as insertion, deletion, substitution, and transposition (Hinson et al., 2020). Meanwhile, *ChERRANT*, another Chinese adaptation, later revised them to Missing, Redundant, Substitute, and Word-order (Zhang et al., 2022). While these differences do not affect core functionality, the lack of consistent labeling across adaptations can create confusion. Nevertheless, this issue is relatively straightforward to address, as it primarily involves terminology standardization.

Inconsistent preprocessing tools A moderate challenge in multilingual GEC annotation lies in linguistic preprocessing tools, particularly word segmentation and POS tagging. While *spaCy*, the default NLP library in errant for English, supports multiple languages, its effectiveness varies across linguistic systems, prompting many adaptations to incorporate alternative tools. For exam-

ple, German errant retained much of the spaCy pipeline but found its lemmatization insufficient, replacing it with TreeTagger for better accuracy (Boyd, 2018). For non-European languages, entirely different tools are used, such as Kkma POS Tagger for Korean KAGAS (Yoon et al., 2023) and LTP (Language Technology Platform) for Chinese ChERRANT (Zhang et al., 2022).

Although these variations allow for language-specific optimizations, different tokenization strategies and POS tagging schemes can lead to discrepancies in how errors are identified and classified. This is particularly problematic for multilingual GEC models, where standardized evaluation across multiple languages is crucial. Since a system’s measured performance is inherently tied to how its errors are annotated, such variations can obscure true system similarities or differences and compromise the reliability of multilingual benchmarks.

Inconsistent annotation granularity A more significant challenge in multilingual GEC annotation involves the varying levels of granularity for language-specific errors. While errant provides detailed error categories for English, adaptations to other languages, especially non-European languages, often fail to maintain this level of detail. For instance, errant_zh uses only four basic edit operations at the character level, without POS information (Hinson et al., 2020).

Recent work has begun addressing this limitation by introducing more fine-grained annotations tailored to specific linguistic properties. For example, Gu et al. (2025) propose a refined error typology for Chinese that accounts for phonetic similarity, visual similarity, and other structural errors specific to Chinese. While this framework was developed for Chinese, many of its principles can be readily applied to languages with similar logographic orthographies.

2.3 stanza as a multilingual alternative to spaCy

The original errant framework relies on spaCy for preprocessing tasks such as tokenization and POS tagging. However, spaCy’s multilingual capabilities are relatively limited, covering only a small number of languages and exhibiting inconsistent performance across linguistic families. This has contributed to the fragmented landscape of language-specific adaptations in prior errant variants.

To promote cross-lingual consistency, our implementation adopts stanza (Qi et al., 2020), a fully neural pipeline trained on Universal Dependencies (UD) and other multilingual corpora. stanza supports over 70 languages and applies a consistent architecture and UD-based annotation scheme across its modules—including tokenization, multi-word token expansion, POS and morphological tagging, dependency parsing, and named entity recognition³. Benchmark evaluations indicate strong performance across typologically diverse languages.

Crucially, our aim is not to promote a specific tool, but to align the preprocessing stage with the same linguistic principles that underlie our error typology. Like UD, our taxonomy adopts a cross-linguistically consistent core structure with optional language-specific extensions. Using a UD-compatible parser such as stanza ensures that all languages are analyzed under a shared morphosyntactic framework, which is essential for scalable and comparable multilingual grammatical error annotation. In this sense, it is the UD standard, rather than any particular NLP library, that provides the conceptual and practical foundation for our approach.

3 Multilingual Error Typology

An error typology provides a systematic framework for identifying, classifying, and analyzing errors in written text. We propose a two-tiered typology consisting of a language-agnostic foundation and a set of structured, language-specific extensions. The first level includes the widely adopted MRU (Missing, Replacement, Unnecessary) framework, ensuring consistency in annotation and evaluation across linguistic systems. The second level provides a structured template for language-specific extensions, allowing related languages to share annotation strategies and avoid redundant reimplementations. By designing this layered approach, we promote standardization across languages while allowing flexibility for language-specific refinements.

3.1 Language-agnostic error annotation

The MRU framework classifies errors into three core operations: Missing (M), where essential elements are omitted; Replacement (R), where an incorrect element substitutes the correct one; and Unnecessary (U), where superfluous elements cause redundancy.

³<https://stanfordnlp.github.io/stanza/>

Each error is further specified with POS tags for precise categorization.

Missing (M) An essential linguistic element is omitted from a sentence, leading to incomplete or ungrammatical structures. These errors typically involve the absence of words or phrases necessary for grammaticality or semantic clarity, such as missing determiners. In annotation, missing errors are further categorized based on POS tags or syntactic functions. For example, M:NOUN indicates a missing noun.

Replacement (R) An incorrect linguistic element is used in place of the correct one. These errors frequently involve incorrect word forms or inappropriate lexical choices (e.g., R:VERB denotes an erroneous verb substitution). To further reduce ambiguity in annotation, we implement the $R:P_1 \rightarrow P_2$ pattern, where P_1 is replaced by P_2 .

Unnecessary (U) A superfluous linguistic element is present in a sentence, resulting in redundancy or ungrammaticality. These errors often involve extraneous words or phrases that disrupt sentence structure or meaning. Similar to missing and replacement errors, unnecessary errors are annotated with POS information to specify the redundant element. For example, U:DET denotes an unnecessary determiner.

3.2 Language-specific error annotation

To accommodate language-specific characteristics, we introduce a set of structured extensions to the MRU core. Our approach maintains consistency with established annotation schemes such as errant while capturing morphological and syntactic errors unique to different languages. Algorithm 1 presents our proposed classification routine for Replacement errors. Given a pair of word sequences—the source (\mathcal{S}) and the target (\mathcal{T})—the algorithm classifies the error into one of the following types: spelling errors (R:SPELL), word order errors (R:WO), or word boundary errors (R:WB). Spelling similarity is computed using two metrics: phonetic similarity and visual (shape-based) similarity. The thresholds α_1 and α_2 govern sensitivity to phonetic and visual matches, respectively.

The classification uses the following notation:

- \mathcal{S}, \mathcal{T} : word sequences in the source and target sentences.

- $\text{SIM}(\textit{phonetic})$ and $\text{SIM}(\textit{shape})$: similarity functions comparing pronunciation and visual form.
- $\text{SET}(\mathcal{S})$: returns a bag-of-words representation of \mathcal{S} , disregarding word order.
- $\text{MERGE}(\mathcal{S})$: reconstructs a character sequence from the tokenized input (i.e., merging tokens without spaces) to test for boundary alignment.

This structured yet extensible framework allows consistent error categorization across languages, while also accommodating language-specific scripts and segmentation conventions.

Algorithm 1 Pseudo-code for error classification

```

1: function ERRORCLASSIFICATION ( $\mathcal{S}, \mathcal{T}$ ):
2:   if ( $\text{SIM}(\textit{phonetic}) > \alpha_1 \wedge \text{SIM}(\textit{shape}) > \alpha_2$ ) then
3:     return R:SPELL:PHONOGRAPHIC
4:   else if ( $\text{SIM}(\textit{phonetic}) > \alpha_1$ ) then
5:     return R:SPELL:PHONETIC
6:   else if ( $\text{SIM}(\textit{shape}) > \alpha_2$ ) then
7:     return R:SPELL:SHAPE
8:   else if ( $\text{SET}(\mathcal{S}) == \text{SET}(\mathcal{T})$ ) then
9:     return R:WO
10:  else if ( $\text{MERGE}(\mathcal{S}) == \text{MERGE}(\mathcal{T})$ ) then
11:    return R:WB
12:  end if
13:  return {R}

```

Spelling errors We classify spelling errors by their underlying cause: sound-based phonetic similarity (R:SPELL:PHONETIC), visual resemblance in orthographic shape (R:SPELL:SHAPE), or a combination of both (R:SPELL:PHONOGRAPHIC). For sound-based phonetic errors, we introduce a transcription system to represent pronunciation, such as a pronouncing dictionary for English, *pinyin* for Chinese, or romanization for other languages. This allows us to compare words based on their phonetic similarity and identify errors caused by mispronunciation or phoneme substitution. For orthographic shape errors, we assess visual similarity by converting characters into font images and applying similarity metrics. This approach helps detect errors caused by visually similar characters, such as mistyped letters in Latin-based scripts or miswritten strokes in logographic writing systems like Chinese and Japanese. By combining these methods, we systematically classify and analyze spelling errors across different languages.

Word order errors Word order errors are flagged when the source sequence (\mathcal{S}) and the target sequence (\mathcal{T}) contain the same set of words

but differ in arrangement. In such cases, all words from the original sequence are retained, but their relative positions are altered. These errors are particularly common in languages with flexible word order, where reordering affects grammaticality or readability. Identifying and categorizing such errors enables more structured syntactic analysis and improves grammatical error correction.

Word boundary errors Word boundary errors occur when the source sequence (\mathcal{S}) and the target sequence (\mathcal{T}) yield the same sequence after merging their respective word components. These errors typically involve incorrect spacing, where words that should remain separate are mistakenly merged, or conversely, a single word is improperly split into multiple tokens. Since the fundamental content remains unchanged but the segmentation differs, such errors impact readability, syntactic structure, and lexical integrity. Addressing these errors ensures accurate word segmentation and proper grammatical representation.

Figure 2 illustrates representative examples of the three major subtypes of Replacement errors classified by our algorithm.

R:SPELL:PHONETIC	<i>their</i> → <i>there</i>
R:WO	<i>You can help me</i> → <i>Can you help me</i>
R:WB	<i>ice cream</i> → <i>icecream</i>

Figure 2: Examples of Replacement error types: phonetic spelling error (R:SPELL:PHONETIC), word order error (R:WO), and word boundary error (R:WB).

4 Implementation of Multilingual Error Annotation

Our implementation demonstrates how grammatical error annotation can be consistently extended across typologically diverse languages. We begin by reimplementing errant for English using stanza and validating its performance. We then apply the same system to other European languages without language-specific modules. For Korean, we introduce targeted refinements using language-specific templates. Finally, for Chinese, we show how deeper customization can be incorporated by modifying segmentation and retraining the stanza pipeline.

4.1 Reimplementing errant for English

We reimplemented errant using stanza for POS tagging and dependency parsing, as described in §2.3. This enables our annotation system to be

more consistent across languages while preserving the linguistic precision required for English-specific grammatical labels.

We integrated the English-specific classification module from the original errant, which identifies detailed grammatical error types, such as NOUN:POSS for possessive noun suffix errors. This module relies on universal POS tags (Petrov et al., 2012) and dependency relation tags to categorize errors. For instance, if the first token in an edit is tagged as PART and its dependency relation is case:poss, the classifier assigns the NOUN:POSS label accordingly.

A key distinction between the original errant and our implementation lies in error categorization. As illustrated in Figure 3, errant originally annotates *that is* as a missing OTHER error, whereas our implementation classifies it more precisely as a missing PRON error. Additionally, we refine verb annotation by distinguishing auxiliary verbs in passive constructions, categorizing *is played* as a Replacement error from VERB to AUX VERB. These refinements enhance interpretability by providing more specific and linguistically meaningful labels for complex constructions.

Original errant:	
S	Volleyball is a sport play every place ...
A 4 4	M:OTHER that is REQUIRED -NONE- 0
A 4 5	R:VERB:FORM played REQUIRED -NONE- 0
Our implementation:	
S	Volleyball is a sport play every place ...
A 4 4	M:PRON that REQUIRED -NONE- 0
A 4 5	R:VERB → AUX VERB is played REQUIRED -NONE- 0

Figure 3: Differences between errant and our implementation

To evaluate the overall alignment, we compared both implementations using outputs from the state-of-the-art GEC system, T5 (Rothe et al., 2021). The results in Table 1 support that our implementation reproduces errant’s scores, with only minor variations.

	TP	FP	FN	Prec	Rec	F _{0.5}
errant	2589	1639	4030	0.6123	0.3911	0.5501
Ours	2565	1613	4028	0.6139	0.3890	0.5503

Table 1: GEC results for English using T5

4.2 Applying universal annotation to European languages

Without language-specific classification modules, our grammatical error annotation system remains capable of generating generic error annotations using the core MRU framework combined with POS

Czech	S Mám velkou rodinu , tak nemohla jsem mít naději , že něco dostanu .
Náplava et al. (2022)	A 5 7 R:WO jsem nemohla REQUIRED -NONE- 0
Ours	A 5 7 R:VERB AUX -> AUX VERB jsem nemohla REQUIRED -NONE- 0 (*I have a big family, so I couldn't hope to get anything.*)
German	S Dagegen wieder , bekommen BA Studenten die ein extra Jahr oder mehr studiert haben , leichter Jobs .
Boyd (2018)	A 0 3 R:OTHER Dahingegen REQUIRED -NONE- 0 A 4 5 U:PNOUN REQUIRED -NONE- 0 A 5 6 R:NOUN BA-Studenten REQUIRED -NONE- 0
Ours	A 0 2 R:ADV ADV -> ADV Dahingegen REQUIRED -NONE- 0 A 2 3 U:PUNCT REQUIRED -NONE- 0 A 5 5 M:PUNCT - REQUIRED -NONE- 0 (*On the other hand, BA students who have studied an extra year or more find jobs more easily again.*)

Figure 4: Examples of grammatical error annotation for Czech and German

labels. We applied this approach to German (Boyd, 2018) and Czech (Náplava et al., 2022) to assess whether structured, interpretable annotations could still be produced in the absence of custom heuristics.

As shown in Figure 4, our system improves clarity by attaching POS information to word order and punctuation errors, allowing more consistent cross-lingual comparisons. For Czech, the example highlights differences in word order (WO) annotation: our method distinguishes between auxiliary and main verbs by incorporating POS information, whereas prior work generally treated such cases as generic WO errors. By capturing the syntactic function of the words involved, our method enables more precise and interpretable annotation. A similar improvement is seen for German, where our universal framework avoids language-specific categories while maintaining clear and consistent labeling.

Compared to previous implementations, our annotation outputs remain broadly consistent in terms of overall operation counts, with only minor variations, as shown in Table 2. This suggests that our universal framework based on the MRU scheme can replicate established annotation distributions. Table 3 lists the most frequent error annotations produced by our system alongside those from previous implementations. Our system makes the syntactic categories involved in each replacement edit explicit ($R:P_1 \rightarrow P_2$), reflecting a different annotation choice rather than a direct re-labeling of existing tags.

Future work could explore how to map between these representations to support compatibility and facilitate comparative evaluations. Another direction is to extend this annotation scheme to additional languages: because our framework leverages universal POS tags and dependency labels from stanza, it can be readily applied to the ten other languages in the MultiGEC dataset (Masciolini

et al., 2025a) without additional customization.

	Missing	Replacement	Unnecessary	Total
<i>Czech</i>				
Náplava et al. (2022)	693	3707	515	4915
Ours	695	3672	530	4897
<i>German</i>				
Boyd (2018)	1341	4406	638	6385
Ours	1310	4348	612	6270

Table 2: Comparison of operation counts (Missing, Replacement, Unnecessary) on the development sets of Czech (first 1000 sentences; Náplava et al., 2022) and German (Boyd, 2018).

4.3 Refining language-specific annotations for Korean

Previous research on Korean grammatical error annotation has relied on extensive linguistic resources (Yoon et al., 2023). However, grammatical errors in Korean often manifest at the morpheme level, as observed in L2 writing from the National Institute of Korean Language (NIKL) corpus. In contrast, prior error annotation approaches primarily operate at the word level, which aligns with our methodology. To ensure consistency in annotation, previous work established two priority rules for assigning a single error type to each word because of the potential ambiguity in error classification, particularly when multiple error types could apply to the same token: (i) INSERTION > DELETION > others, and (ii) WS (word segmentation = WB) > WO > SPELL > SHORTEN (incorrect contraction of a word) > PUNCTUATION > OTHERS.

Building on these foundations, we implement language-specific error types based on Algorithm 1 and refine the WB (word boundary) category by introducing two subtypes: WB:M for missing spaces and WB:U for extraneous spaces. The former occurs when spaces are absent between words, causing multiple words to merge into a single unit, which can obscure meaning and hinder readability. The latter arises when superfluous spaces are inserted between or within words, disrupting the

Czech				German			
Náplava et al. (2022)		Ours		Boyd (2018)		Ours	
Annotation	Count	Annotation	Count	Annotation	Count	Annotation	Count

Table 3: Comparison of the top 10 most frequent error annotations on the development sets of Czech (first 1000 sentences; Náplava et al., 2022) and German (Boyd, 2018).

natural flow of the text.

Additionally, we extend grammatical error annotation to functional morphemes, categorizing errors into (i) postposition errors (ADP), (ii) verbal ending errors (PART), and (iii) honorific suffix errors (HON). These errors are further classified into missing (M), unnecessary (U), and incorrect usage (R). Figure 5 illustrates corrections from two annotators: the noun phrase 음식이 *eumsig-i* (‘food.NOM’) is replaced with 음식을 *eumsig-eul* (‘food.ACC’), annotated as R:NOUN → NOUN:ADP, reflecting a case marker correction. Similarly, 먹었습니다 *meogeossseubnida* is replaced with 맞았습니다 *matatseubnida* (‘ate’), which constitutes a spelling error due to phonetic and orthographic similarity.⁴

```

S 비행기 1 음식이 안 3 먹었습니다 .
A 1 2 ||R:NOUN -> NOUN:ADP||음식을||REQUIRED||-NONE-|||0
A 3 4 ||R:Orthographic||먹었습니다||REQUIRED||-NONE-|||0
A 3 4 ||R:VERB -> VERB||맞았습니다||REQUIRED||-NONE-|||1

```

Figure 5: Examples from the Korean M2 file: *I didn’t eat the airplane food* (Annotator 0), and *The airplane food didn’t agree with me* (Annotator 1)

4.4 Integrating deeper customization for Chinese

Chinese grammatical error annotation presents unique challenges due to the lack of explicit word boundaries (Qiu et al., 2025). Previous systems (Zhang et al., 2022; Gu et al., 2025) adopt segmentation schemes based on different linguistic assumptions: for instance, LTP⁵ emphasizes compound words as cohesive lexical units, whereas stanza, trained on the Chinese GSD treebank⁶, adopts a

⁴Annotator 1 annotates a replacement with 맞았습니다 *maj-assseubnida* (‘agree’), altering the meaning of the sentence. This highlights a potential challenge in grammatical error annotation—distinguishing between true errors and alternative valid expressions that change sentence semantics.

⁵<https://github.com/HIT-SCIR/ltp>

⁶https://github.com/UniversalDependencies/UD_Chinese-GSD

finer-grained, morpheme-level segmentation strategy that tends to split compound expressions into smaller units.

These design choices reflect distinct philosophies rather than flaws. However, segmentation differences can affect downstream grammatical error annotation, including both the token spans and the syntactic interpretation of the correction. For example, whether a multi-character expression like 为什么 *wèishéme* (‘why’) is treated as one token or multiple (为什么) influences how missing or replacement errors are classified.

To illustrate the flexibility of our framework, we adopt an LTP-style segmentation approach, which aligns more closely with native speaker intuitions about lexical units in Chinese. While the default stanza pipeline uses GSD-style morpheme-level segmentation, our framework allows researchers to substitute this with alternative schemes, such as LTP’s compound-word-based segmentation. This optional customization demonstrates that language-specific preprocessing decisions, such as tokenization granularity, can be adapted within our framework to better support accurate and interpretable error annotation.

We achieve this integration by re-annotating the Chinese GSD treebank with LTP-informed word boundaries and retraining stanza on this revised corpus. This ensures compatibility with our preferred segmentation standard while preserving the benefits of stanza’s POS tagging and parsing pipeline. As shown in Figure 6, the resulting annotations show more consistent edit spans and error categories, especially in contexts where compound expressions are frequent.

Ultimately, this customization demonstrates the modularity of our framework: rather than enforcing a one-size-fits-all solution, we allow researchers to tailor tokenization to fit linguistic expectations, making the system more robust and adaptable

Chinese GSD-based WB (Gu et al., 2025):
 S ... 解释 为₁₀ 什么 这样 的 情况 ...
 A ...
 A 10 11||R:PROP N -> PRON VERB AUX|||什么 出现 了|||REQUIRED|||-NONE-|||0
 Correction: ... 解释 为 什么 出现 了 这样 的 情况 ...

Our LTP-based WB:
 S ... 解释₇ 为₈ 什么 这样 的 情况 ...
 A ...
 A 7 8||R:ADP -> ADV VERB|||为什么 出现|||REQUIRED|||-NONE-|||0
 A 8 9||R:PROP N -> AUX|||了|||REQUIRED|||-NONE-|||0
 Correction: ... 解释 为 什么 出现 了 这样 的 情况 ...
 ... *jiěshì wèishéme chūxiàn le zhèyàng de qíngkuàng* ...
 (... explain why this kind of situation has occurred ...)

Figure 6: Fragments of grammatical error annotation examples in Chinese with different word boundaries. Incorrect GSD-based segmentation of 为什么 *wèishéme* (‘why’) leads to misleading annotation 什么 出现 了 *shénme chūxiàn le* (‘what has occurred’), while LTP-based segmentation 为什么 出现 *wèishéme chūxiàn* (‘why occurred’) provides an accurate representation.

across languages and segmentation conventions.

5 Conclusion

This work advances grammatical error annotation and evaluation by introducing a standardized, modular framework for multilingual grammatical error typology. Building upon the foundations of errant, we designed a two-tiered system that separates language-agnostic annotation from structured language-specific extensions. This approach supports consistency across typologically diverse languages while allowing targeted customizations when needed.

We reimplemented errant using stanza to provide broader multilingual support, and demonstrated that our system produces accurate and interpretable annotations in English. We then demonstrated how our framework can be applied to other languages with varying levels of customization. For European languages, we showed that our POS- and dependency-based system can generate reliable annotations without requiring language-specific classification modules. For Korean, we applied minor refinements to capture morphologically salient features such as postpositions and spacing errors. Finally, for Chinese, we demonstrated how deeper customization—through the integration of language-specific tokenization and retraining of NLP components—can be incorporated into our framework to support fine-grained, linguistically coherent error annotation.

By balancing consistency and flexibility, our framework enables scalable, interpretable, and reusable grammatical error annotation across languages. This supports more consistent evaluation

and clearer cross-linguistic comparison in multilingual GEC research.

Limitations

While our framework presents a unified and extensible approach to multilingual grammatical error annotation, the implementations described in this paper are primarily intended to demonstrate its adaptability across different languages and levels of customization. A detailed analysis of annotation improvements, including task-specific gains and downstream evaluation effects, is left to future work.

Although we rely on existing NLP tools such as stanza for tokenization and parsing, which offer broad multilingual coverage and consistent annotation schemes, these tools are not explicitly optimized for processing noisy or learner-generated text. This may introduce variability in some edge cases, particularly in languages with complex morphosyntax or ambiguous word segmentation.

Abstract

Evaluation of Grammatical Error Correction (GEC) systems is becoming increasingly challenging as the quality of such systems increases and traditional automatic metrics fail to adequately capture such nuances as fluency versus minimal edits, alternative valid corrections compared to the ‘ground truth’, and the difference between corrections that are useful in a language learning scenario versus those preferred by native readers. Previous work has suggested using human post-editing of GEC system outputs, but this is very labor-intensive. We investigate the use of Large Language Models (LLMs) as post-editors of English and Swedish texts, and perform a meta-analysis of a range of different evaluation setups using a set of recent GEC systems. We find that for the two languages studied in our work, automatic evaluation based on post-editing agrees well with both human post-editing and direct human rating of GEC systems. Furthermore, we find that a simple n-gram overlap metric is sufficient to measure post-editing distance, and that including human references when prompting the LLMs generally does not improve agreement with human ratings. The resulting evaluation metric is reference-free and requires no language-specific training or additional resources beyond an LLM capable of handling the given language.

1 Introduction

Grammatical Error Correction (GEC) is an important technology for supporting native and non-native writers, and supporting the development of language learners (for a recent survey see, for instance, Bryant et al., 2023). In recent years, neural networks and in particular Large Language Models (LLMs) have led to rapid improvements in the accuracy of such systems, but these developments have

made apparent the difficulty of efficiently evaluating such systems.

For the most part, reference-based metrics have been used for the evaluation of GEC. These metrics depend upon human-created reference corrections and either rely on text similarity measures similar to those used in Machine Translation – examples include GLEU (Napoles et al., 2015) and GREEN (Koyama et al., 2024) – or on comparing the edits made by the GEC system with those by the human; for instance, M^2 (Dahlmeier and Ng, 2012) and ERRANT (Bryant et al., 2017). These reference-based metrics have been shown to correlate less well with human quality estimates than other approaches, in particular with recent neural GEC systems (Kobayashi et al., 2024). In addition, the manual process of creating references is time-consuming.

Reference-free metrics, typically based on neural models, have been proposed as an alternative, but these tend to either be complex and requiring additional (language-specific) training data (Yoshimura et al., 2020; Maeda et al., 2022), or to be simplistic but may correlate relatively poorly with human preferences (Islam and Magnani, 2021).

Östling et al. (2024) proposed using human post-editing to create one reference per GEC system output, and then use a text similarity metric between the system output and its post-edited version as a measure of GEC system quality. This was evaluated on a small number of GEC systems in Swedish, so it is unclear to what extent the resulting scores correlate with human preferences. In addition, human post-editing of every system output is a very time-consuming task. Our goal in this work is to investigate whether the human post-editing step can be performed by an LLM, and how the evaluation setup can be modified to achieve maximal correlation with human evaluation by either

post-editing, ranking, or direct scoring.

Our main research questions are:

- RQ1: does LLM-based post-editing provide a scoring of GEC systems that aligns with human preferences?
(Answer: yes, there is a high level of agreement with different types of human quality assessments.)
- RQ2: how does the choice of text similarity metric affect post-editing based GEC evaluation?
(Answer: Levenshtein distance as used in previous work is sub-optimal, chrF++ is good but overkill; use character bag-of-6-gram overlap instead.)
- RQ3: what difference does it make if human references are provided to the LLMs while performing post-editing?
(Answer: in general the best method is to use only the original sentence + system output, but peculiarities in some datasets affect this outcome.)
- RQ4: how does LLM-based post-editing compare to human post-editing for GEC system evaluation?
(Answer: they generally agree very well, but LLMs make somewhat more changes and have a considerably lower proportion of completely unchanged sentences.)

2 Related Work

Grammatical error correction has a long history as an area of research (Bryant et al., 2023). It has also featured in various shared tasks over the years (e.g., Ng et al., 2014; Bryant et al., 2019; Masciolini et al., 2025). Since statistical approaches to GEC were widely adopted, the best-performing systems involve supervised models trained on annotated corpora: usually involving sequence-to-sequence models (e.g., Rothe et al., 2021) or pipeline systems based on sequence tagging (e.g., Omelianchuk et al., 2020).

According to recent research, LLMs do not outperform these supervised GEC systems on every benchmark, at least for English (Loem et al., 2023; Davis et al., 2024). Instead, it has been shown that they can potentially improve the recall of GEC models in an ensemble setting (Omelianchuk et al., 2024). Moreover, given the increasing use of LLMs

as judges, in this work we investigate to what extent LLMs can be used for GEC evaluation which, along with the availability of high quality annotated data, is a bottleneck to progress in GEC (Kobayashi et al., 2024).

Current metrics are either reference-based or reference-free, meaning that they do or do not, respectively, depend upon ‘ground truth’ corrections. The most widely-used reference-based metrics are precision, recall and $F_{0.5}$ – most often obtained from the M^2 scorer (Dahlmeier and Ng, 2012) or with ERRANT (Bryant et al., 2017) – along with GLEU, derived from the BLEU score commonly used in machine translation (Napoles et al., 2015). However, there is often more than one possible way to correct a grammatical error, and even with multiple annotations it is difficult to cover all possibilities in reference-based approaches.

Examples of reference-free metrics include the Scribendi Score (Islam and Magnani, 2021) and IMPARA (Maeda et al., 2022). The former may involve any LLM, in principle, whilst the latter was implemented using BERT (Devlin et al., 2019). However, the reliance on language models for reference-free metrics means that they tend to be biased towards fluency corrections over minimal edits which stay closer to the original text formulation but may not be recognized as improvements by the language models. Fluent corrections are usually preferable from a readability and naturalness perspective, but it is arguable from a pedagogical standpoint that it is better to in fact offer minimal edits as feedback to human learners rather than error avoidance strategies (Sakaguchi et al., 2016; Caines et al., 2023; Mita et al., 2024).

Nevertheless, the reliance on ground truth references remains a limiting factor in evaluation of GEC systems on new data. If it can be shown that LLMs can be reliably put to use as GEC post-editors, for the purpose of evaluation, correlating well with human judgements, it would release the pressure on the GEC bottleneck somewhat. Östling et al. (2024) examine the feasibility of post-editing based evaluation with Swedish GEC data and perform direct scoring as well as post-editing of the outputs of three different GEC systems and two fluency-edited references. They find that post-editing distance correlates strongly with the scores assigned by the annotator, but the small sample of GEC systems limits the range of conclusions that they are able to draw. Additionally, their annotation procedure is fully manual and would be difficult to

scale up.

3 Data

Kobayashi et al. (2024) performed a meta-evaluation of 12 recent English GEC systems, and published the SEEDA dataset of GEC system outputs and human rankings of sentences from these outputs. We use this dataset because it contains a sufficient number of GEC systems to compute reasonably reliable correlations between a given GEC evaluation metric and the human assessments. In addition to system outputs of 12 modern GEC systems, it also includes the original uncorrected sentences (INPUT) and two human-created references, one with minimal edits (REF-M) and one edited for fluency (REF-F).

Östling et al. (2024) published human annotations with post-edited versions of 3 Swedish GEC systems as well as the original uncorrected sentences (INPUT) and three human-created references, one with minimal edits (REF-M) and two edited for fluency. The GEC system outputs and the fluency-edited references are annotated with scores for grammaticality, fluency and meaning preservation, and post-edits to achieve perfect scores in these three assessment dimensions. We include the Swedish data for two main purposes: to allow direct comparisons between human and LLM post-edits, and to verify that the proposed method can be applied to languages other than English given a suitable LLM.

4 Method

We have several different recent LLMs perform post-editing of GEC system outputs from the datasets of Kobayashi et al. (2024) in English, and Östling et al. (2024) in Swedish.¹ We use Gemma 2 in several sizes (2 billion parameters, 9B, 27B) (Gemma Team et al., 2024), Gemma 3 27B (Gemma Team et al., 2025), Llama 3.1 8B (Grattafiori et al., 2024), Mistral Small 24B (Jiang et al., 2023), Qwen 2.5 32B (Bai et al., 2023), and Command A-111B (Cohere, 2025).

For each LLM, we try each combination of the following two parameters:

- Semantic grounding. In order to ensure that the post-editing does not diverge from the semantics of the original text, we include four

(English) or three (Swedish) types of semantic grounding. In all cases the GEC system output is provided in the prompt.

- None. Only the system output is provided in the prompt.
 - INPUT. The GEC system input (original text) is included.
 - REF-M. A human minimal edits reference is included.
 - REF-F. A human fluency edited reference is included (English data only).
- Similarity metric. Following Östling et al. (2024) we use Normalized Levenshtein distance as one metric, and add two n-gram-similarity-based metrics.

- Normalized Levenshtein Similarity, which is identical to Normalized Levenshtein Distance apart from the direction (higher is better):

$$S(a, b) = 1 - L(a, b) / \max(|a|, |b|)$$

- chrF++ (Popović, 2017), which in our setting computes the mean F_2 score over word bigram and character 6-gram precision and recall. Unlike the other metrics, this is asymmetric and we treat the post-edited text as the reference.
- Character 6-gram bag-of-n-grams overlap, a symmetric measure of similarity:

$$S(a, b) = |N_a^6 \cap N_b^6| / |N_a^6 \cup N_b^6|$$

where N_s^6 is the set of character 6-grams (including spaces) for string s .

Because it is difficult to justify a full parameter search using the very largest model (GPT-4o²), we obtain post-edits only for the setting where the original sentence is used as semantic grounding (INPUT), since this was the most promising configuration in preliminary experiments. For the Swedish part we also restrict the set of LLMs used to some of the models that obtained the most promising results on the English data, due to time and data licensing constraints.³

²The actual number of parameters has not been published for it or its smaller version GPT-4o-mini, but we see a limited value in exploring the full set of parameters for these models.

³The current license of the Swedish data does not permit the use of OpenAI API.

¹Prompts are given in Appendix A.

Table 2: Mean system-level correlations between post-edit distance and human ratings, averaged over all LLM post-editors, semantic grounding options, and human ratings.

For English, we follow Kobayashi et al. (2024) and compute correlations (Pearson r and Spearman ρ) to human annotations on the system level.⁴ These are derived in two different types of annotation (edit-based or sentence-based comparisons), using two different methods (TrueSkill and Expected Wins) of summarizing the rankings into numeric scores, resulting in four different system-level references. To avoid making arbitrary decisions on which of these to prefer, and to increase the reliability of the results, we consistently use means over all of these four except in Table 4 where we investigate the effect of the human system-level score type and find that it is relatively small. For the sentence level evaluations we use Kendall τ , as computed by the software published by Kobayashi et al. (2024), for comparing to human sentence-level rankings.

For the Swedish data the available annotations are different, compared to English. Instead of rankings of system outputs, each system output has been annotated for grammaticality, fluency and meaning preservation. If any of these are annotated with less than a perfect score (4 on a scale

Table 4: Mean system-level correlations between post-edit distance and human ratings, averaged over all LLM post-editors, similarity metrics, and semantic grounding options. The four human rating references are computed using Expected Wins (EW) or TrueSkill (TS) from sentence-level rankings that are either edit-based or sentence-based.

1–4), there is also a post-edited version of the system output with the goal of performing minimal editing to achieve full scores on all three properties. Since there are only three GEC system outputs and two human references included in the data, we do not consider it meaningful to perform a system-level evaluation as in the English data. Instead, we use Spearman’s ρ to compare the post-edit score between the human annotator and each LLM. We also compare the LLM post-edit scores to the mean of the human annotator’s grammaticality, fluency and meaning preservation scores, which we use as a general measure of the quality of that particular correction.

5 Results and Discussion

5.1 Overall agreement with human rankings

In order to see whether LLM-based post-editing provides a scoring of GEC systems that aligns with human preferences (RQ1), we begin by applying the meta-evaluation framework of Kobayashi et al. (2024). Because our proposed evaluation setup has several hyperparameters and only 15 system outputs⁵ to measure correlations with, we search

⁵Whenever the semantic grounding uses one of the human references (REF-M or REF-F), that reference is excluded from computing the correlation and only the remaining 14 system outputs are used. Note that unless stated otherwise, we use the term “system output” to also include the human-created

through each parameter independently taking the averages over all other parameters in order to avoid overfitting. Averaged system-level correlations are presented in Table 1 (per LLM), Table 2 (per similarity metric), and Table 3 (per semantic grounding option). Additionally, we also present the averaged correlations per human rating setup (Table 4) and see that these are in general agreement with each other. In all other system-level evaluation results, we present averages over all four human rating setups to obtain more reliable estimates.

5.2 Effect of text similarity metric

Next, we turn to the question of how the text similarity metric used to compare the system output with its post-edited version affects the results (RQ2). Östling et al. (2024) used Normalized Levenshtein Distance with manual post-edits. We compute the its negated version (Normalized Levenshtein Similarity) along with two other options. The results are shown in Table 2, averaged over all other parameters. It is clear that Normalized Levenshtein Similarity is in fact sub-optimal, and that both of the other two metrics obtain correlations with human ratings that are considerably higher. In the following analysis we use 6-gram overlap, as it is simple and efficient to compute.

5.3 Effect of semantic grounding

To investigate whether the type of semantic grounding affects post-editing based evaluation (RQ3), we compute the correlations separately for the different types of semantic grounding (Table 5). There are pronounced differences between the various LLMs with respect to which type works best, but the overall trend is that adding human-written references typically does not improve the outcomes, and in most cases results in lower correlation with human ratings.

We have included a baseline (Base) consisting of a reference generated by the same LLM *without* access to the system output, using the LLM as a GEC system with access to the original text only.⁶ This is done to exclude the possibility that the LLMs generate high-quality references and that post-editing is an unnecessary complication. However, the low correlation values for the baseline indicate that including the system output and performing post-editing is essential to the success of

references.

Table 7: Spearman ρ between LLM post-edit score, and each of human post-edit (HP) and human score (HS, mean of grammaticality, fluency and meaning preservation scores). Scores from post-edits are defined as the 6-gram similarity to their respective system output. The correlation between HP and HS is 0.81. S.G. = semantic grounding.

our method. Manual inspection indicates that REF-F and GPT-3.5, both of which contain a considerable amount of fluency edits, are generally rated poorly by the baseline.

It is also noteworthy that some of the highest system-level correlations are obtained by letting the smallest of the evaluated LLMs (Gemma 2-2B) post-edit the system output with only the system output and no semantic grounding, thus ignoring any possible semantic errors. In line with previous work (Yoshimura et al., 2020) which found that meaning preservation is not an important factor when trying to achieve high correlation to human ratings, this indicates that having even a modest-sized LLM perform conservative correction of the system output brings us to close agreement with human system-level ratings.

5.4 Sentence-level evaluation

We now turn from system-level to sentence-level evaluations. Following Kobayashi et al. (2024), we present the sentence-level agreement with human rating as Kendall τ values in Table 6. At this finer level of granularity, the differences between different metric parameters become apparent. Adding the original sentence as semantic grounding consistently improves the correlation with human assessments, while adding a human reference (REF-M or REF-F) shows no such tendency. Again, the baseline consistently has very low correlations.

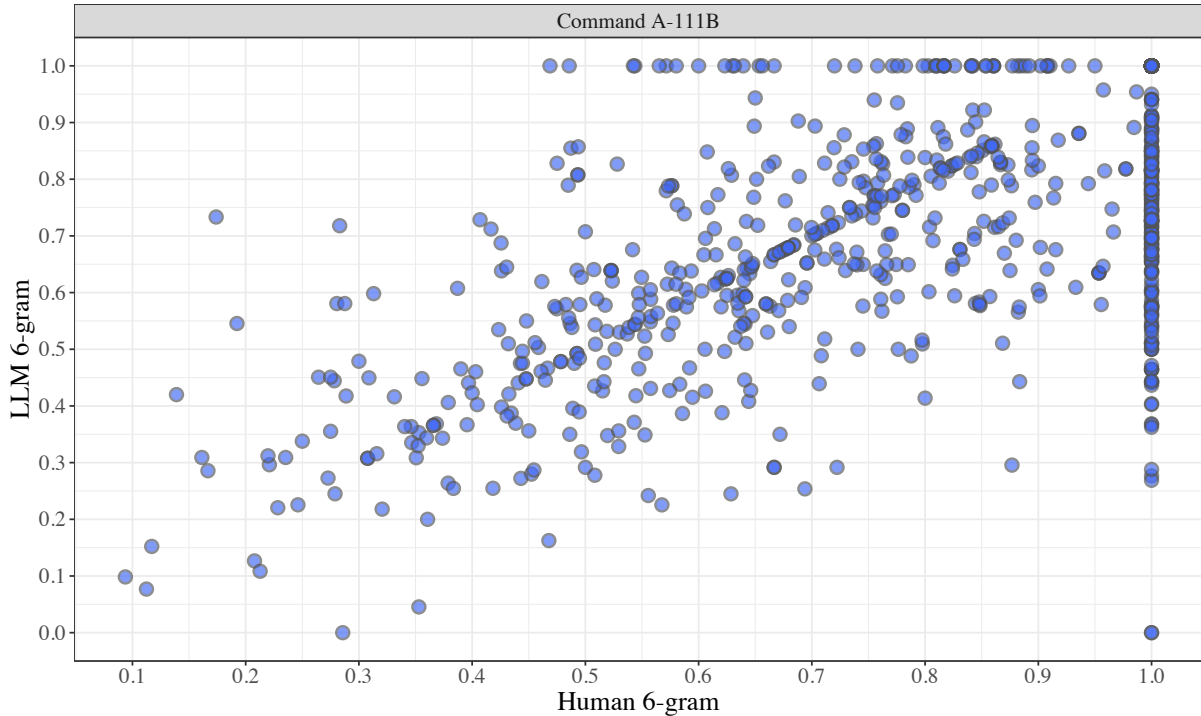

Figure 1: Scatter plot of character 6-gram overlap scores derived from human (x-axis) and LLM (y-axis) post-edits, in both cases using REF-M for semantic grounding. A score of 1 indicates that no changes were made during post-editing. The points are one-third transparent to avoid over-plotting.

5.5 Human vs. LLM post-edits

In order to investigate the relationship between post-edits made by humans and LLMs (RQ4), we use the Swedish data from Östling et al. (2024), where three GEC system outputs and two human references have been post-edited as well as rated for grammaticality, fluency and meaning preservation. We used a subset of the most promising LLMs to replicate the post-editing and allow direct comparisons between LLM and human post-edits. Table 7 presents correlations between LLM post-edit scores (using character 6-gram overlap) and human post-edit scores (also using character 6-gram overlap) as well as to the mean of the grammaticality, fluency and meaning preservation scores. The latter is used to approximate a direct assessment by the human annotator of the GEC system’s output of that particular sentence.

In the human post-editing of Östling et al. (2024), a minimal edits reference (REF-M) was used for semantic grounding. As expected, we find that using this reference in the LLM prompt leads to higher correlation to both the human post-edit distance and the human annotated scores. Unlike for the English SEEDA data, using only the original sentence for semantic grounding (INPUT) leads to consid-

erably lower correlations. We believe this to be due to the fact that the Swedish data consists of individual sentences in random order, and that only the creator of the REF-M reference has access to a wider context, while both the human and LLM post-editors lack any such context.

Figure 1 shows the 6-gram overlap scores assigned to each sentence from both the human post-editing and LLM post-editing. The LLM used was the one with the highest correlation to human post-editing scores (Cohere Command A-111B). We see that there is generally high agreement, as the $\rho = 0.58$ correlation indicates, but that there are some clear differences. The human post-editor frequently (46%) leaves the sentence unchanged, whereas the LLM does this less often (27%). The same tendency of the human post-editor being more reluctant to change is reflected in the mean overlap scores: 0.81 (SD 0.22) for the human, compared to 0.74 (SD 0.22) for the LLM, meaning that on the whole the human annotators post-edited less of the system output than the LLMs did. A significant part of this difference is due to the cases where humans leave sentences unchanged, which is demonstrated by considering only sentences where both the human and the LLM actually perform

some edits. In this case, the correlation between the 6-gram overlap scores increases to $\rho = 0.67$ for the same model.

5.6 LLMs as GEC systems and post-editors

An important question⁷ is whether LLMs can be expected to post-edit the output of LLM-based systems, and if it would not be better to simply use the LLMs as GEC systems to begin with.

Our method is based on the assumption that an LLM is capable enough to post-edit the output of even the best GEC systems under evaluation. We have found this to be the case in our evaluation where even the best LLM-based systems undergo significant post-editing during evaluation. Furthermore, we argue that the availability of an LLM with sufficiently high capability is a realistic assumption in a practical setting, since considerably more computation can be spent on GEC evaluation (which will be run once or a few times) than on actual deployed GEC systems.

It is also important to note that GEC evaluations will also be needed for non-LLM based systems. Kobayashi et al. (2024) worked with 12 systems to carry out English GEC for the SEEDA dataset. Östling et al. (2024) worked with 3 systems for Swedish GEC of essays in the SweLL dataset (Volodina et al., 2019). In both cases the systems include both supervised and unsupervised approaches, for instance involving machine translation, sequence tagging and few-shot prompting of LLMs. That is, we do evaluate both non-LLM and LLM systems for GEC in this work.

6 Conclusions

We find that LLMs can be used as very effective evaluation tools for GEC systems, by asking them to post-edit system outputs and using a simple string similarity metric (character 6-gram overlap) to measure the amount of editing needed to go from the GEC system’s output to a version considered by the LLM to be fully grammatical and fluent, while completely preserving the meaning expressed in the original. Even relatively small LLMs (such as Gemma 2-2B) can perform this task well enough to achieve nearly perfect correlation with human ratings at the system level. However, the picture is different when the GEC system output is assessed on the level of individual sentences, with considerable variation between LLMs in the ability to

predict the human assessment of that sentence.

While we use the most recent publicly available GEC meta-evaluation dataset (Kobayashi et al., 2024), LLM-based GEC systems improve rapidly and an important question is to what extent LLM-based post editing is able to evaluate the output of the most capable LLMs. Answering this would require additional annotations that go beyond the scope of this work.

To summarize, we see several advantages of evaluation based on post-editing GEC system outputs by LLMs:

- High correlations with human direct assessment of GEC system quality, both at the system level and sentence (or document) level.
- Analyzing the post-edits provides an interpretable indication of the weaknesses of a particular GEC system, and this can be partly automated by tools such as ERRANT (Bryant et al., 2017). This contrasts with ranking-based evaluations like that recently proposed by Goto et al. (2025).
- Given a multilingual LLM, post-editing can handle multiple languages without requiring any additional language-specific resources or training.
- Unlike metrics that depend on having a large number of data points to average over (e.g., Islam and Magnani, 2021; Goto et al., 2025), post-editing distance can be estimated even on a single document without a sentence-aligned system output. It is thus suitable for document-level evaluations, as in Masciolini et al. (2025).

Fully exploring document-level multilingual evaluation would be an interesting direction of future work (Piotrowska, 2025). Note that in this work we have only worked at the sentence level, as has been conventional in GEC for the most part. However, in recent years there has been growing interest in document-level GEC, as well as evidence that the additional context can aid system performance on certain error types which relate to linguistic features above the sentence level (Yuan and Bryant, 2021; Mita et al., 2024; Masciolini et al., 2025).

Limitations

This paper on GEC is limited in the sense that we work with only 2 languages (English and Swedish) and findings for other languages may vary from those reported here. Annotated data for GEC are costly to build and therefore hard to come by: the datasets we work with in this paper are relatively small, compared to some corpora used in other areas of NLP. In addition the correction of grammatical errors is to some extent subjective, and an estimation without full access to the authors' original intentions. However, this limitation is a factor for all working on GEC.

LLMs have proven to be highly effective for a number of NLP tasks. In this paper we show that they are not necessarily state-of-the-art at the GEC task itself, but may be sufficiently accurate on the GEC post-editing task. This finding is limited by the continued availability of high quality open-weights LLMs, sufficient computing resources for those conducting research to be able to use the LLMs for inference, and the fact that we have only evaluated their performance on two languages. However, in principle, many LLMs have highly multilingual capabilities, and we expect that the outcomes reported here will hold for many other languages.

A Prompts

In this appendix, we present the prompts used across different experiments. We use a total of three prompt templates: one for the baseline results where LLMs are applied to GEC tasks, and two for the post-editing experiments—one without a semantic grounding sentence and one with. The same prompt structure is used for all three types of semantic grounding.

Prompt for GEC baseline

Reply with a corrected version of the input sentence with all grammatical and spelling errors fixed. If there are no errors, reply with a copy of the original sentence.

Instructions:

1. Return **ONLY** the corrected sentence.
2. Wrap the corrected sentence in `<corrected>` and `</corrected>` tags.
3. Do **NOT** include any explanations, extra text, or formatting.

Example:

```
<corrected>This is your corrected sentence.</corrected>
```

Input sentence: {sentence}

Output:

Prompt for post-editing without semantic grounding

Please make minimal modifications to the given sentence to achieve all of the properties below:

- Perfect grammaticality: The sentence is native-sounding. It has no grammatical errors, but may contain very minor typographical and/or collocation errors.
- Perfect fluency: The sentence sounds extremely natural and native-like.
- Same language: The sentence must remain in the same language as the original (do not translate or change language).

Instructions:

1. Return **ONLY** the corrected sentence.
2. Wrap the corrected sentence in `<corrected>` and `</corrected>` tags.
3. If the original sentence is already perfect, return it **AS IS** inside the `<corrected>` tags.
4. Do **NOT** include any explanations, extra text, or formatting.

Example output format:

```
<corrected>Your corrected sentence here.</corrected>
```

Sentence: {sentence}

Output:

Prompt for post-editing with semantic grounding

Please make minimal modifications to the given sentence to achieve all of the properties below:

- Perfect grammaticality: The sentence is native-sounding. It has no grammatical errors, but may contain very minor typographical and/or collocation errors.
- Perfect fluency: The sentence sounds extremely natural and native-like.

Instructions:

1. Return **ONLY** the corrected sentence.

2. Wrap the corrected sentence in `<corrected>` and `</corrected>` tags.
3. Ensure that the corrected sentence preserves the meaning of the reference sentence provided below. The reference may contain grammatical errors — it is for semantic grounding only.
4. If the original sentence is already perfect, return it AS IS inside the `<corrected>` tags.
5. Do NOT include any explanations, extra text, or formatting.

Example output format:

```
<corrected>Your corrected sentence  
here.</corrected>
```

Sentence: {sentence}

Reference (for meaning preservation only): {reference sentence}

Increasing the Generalizability of Similarity-Based Essay Scoring Through Cross-Prompt Training

Abstract

In this paper, we address generic essay scoring, i.e., the use of training data from one writing task to score data from a different task. We approach this by generalizing a similarity-based essay scoring method (Xie et al., 2022) to learning from texts that are written in response to a mixture of different prompts. In our experiments, we compare within-prompt and cross-prompt performance on two large datasets (ASAP and PERSUADE). We combine different amounts of prompts in the training data and show that our generalized method substantially improves cross-prompt performance, especially when an increasing number of prompts is used to form the training data. In the most extreme case, this leads to more than double the performance, increasing QWK from .26 to .55.

1 Introduction

In automated scoring, one desideratum is often to train a generic classifier that does not rely on the availability of training material for a certain writing task, i.e., prompt, but can transfer from training material for one or several prompts to data from new writing tasks.

This holds both for content scoring, also known as short-answer scoring, and essay scoring. In content scoring, texts of up to a few sentences in length are scored for conceptual correctness. Essay scoring deals with scoring longer texts that are rated both on content and language use.

Generic scoring has a high practical relevance in the classroom, as teachers often do not have the resources to annotate training data for each new prompt. However, the generalizability of classifiers is often low (see, e.g., Phandi et al. (2015)). Especially in a hard domain transfer scenario when classifiers are trained on a single or a few prompts only, they might pick up on lexical material specific to that particular writing task.

For instance, as shown on the left side of Figure 1, two essays from the prompt ‘The Face on Mars’ in the PERSUADE dataset may lead a scoring classifier trained solely on this prompt to treat words such as ‘aliens’ and ‘Mars’ as significant features. These words, however, are not found in essays from other prompts, such as the two essays from the ‘Facial Action Coding System’ prompt shown on the right side. Despite the differences in content, essays from different prompts with the same score share general similarities. For instance, low-scoring essays from different prompts (top part of Figure 1) often share weaknesses such as limited vocabulary, repetition of phrases, and overuse of simple words. In contrast, high-scoring essays (bottom part of Figure 1) display features that contribute to higher scores, such as a logical progression with the underlined transitional phrases. These lexical patterns should be prioritized when training a generic scoring model, as they contribute significantly to the overall quality of an essay, regardless of the specific prompt. However, it should be noted that we are not claiming that these elements are the *only* relevant aspects in scoring the data, but rather that they are important *enough* to make them exploitable for cross-prompt scoring.

While generic scoring has been more extensively explored for some content scoring datasets (Bailey and Meurers, 2008; Mohler and Mihalcea, 2009; Meurers et al., 2011; Dzikovska et al., 2013), cross-prompt approaches to essay scoring have only received more interest in recent years (Phandi et al., 2015; Jin et al., 2018; Li et al., 2020; Chen and Li, 2023).

In our study, we approach generic essay scoring by training classifiers that are discouraged from paying attention to prompt-specific material in the essays. In both flavors of educational free-text scoring, content and essay scoring, similarity-based scoring has recently emerged as a viable alternative to the default of instance-based scoring (Bexte

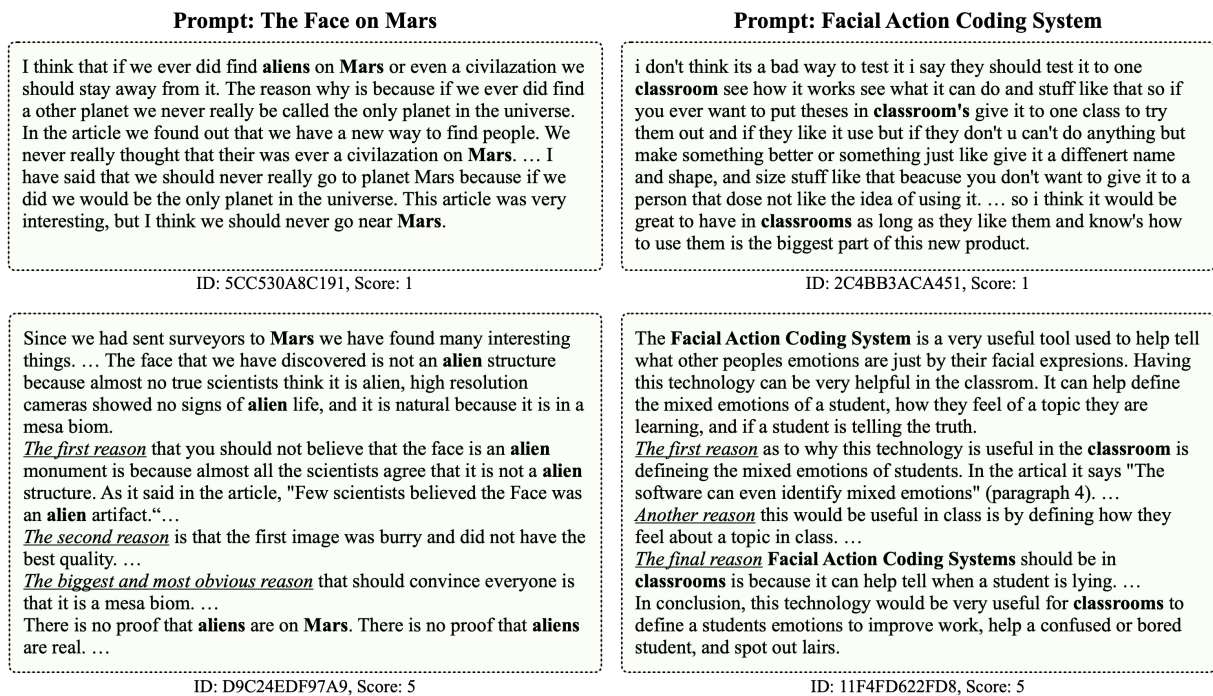

Figure 1: Example essays taken from two different prompts in the PERSUADE dataset that share the same low (top) or high (bottom) score. Words in bold are prompt-specific, which may be picked up by a classifier trained on a single prompt. The underlined transitional phrases show an example of lexical patterns that contribute to higher scores, which can be used when training a generic scoring model.¹

et al., 2022; Xie et al., 2022). While instance-based scoring learns the association between individual learner texts and their scores, the input in similarity-based scoring are pairs of texts. In such a pair, an essay of interest is compared to a reference essay with a known score.

We adapt the similarity-based essay scoring approach of Xie et al. (2022), which exhibits state-of-the-art performance on the commonly used ASAP essay scoring dataset. While Xie et al. (2022) only demonstrated good within-prompt performance, we augment their approach for cross-prompt scoring. Our crucial step in avoiding overfitting to prompt-specific information is to only use pairs of learner essays that answer different writing prompts during training. In doing this, we force the similarity metric to pay attention to structural rather than purely lexical similarity between texts.

We hypothesize that the problem of prompt-specific similarity metrics is more severe in cases where training material only covers a single or a few prompts, as paying attention to a prompt-specific feature makes an impact on a larger portion of the dataset in these cases. To test this assumption, we vary the number of prompts that is mixed in the training data in our experiments.

Overall, our paper makes the following contributions:

- We extend the method of Xie et al. (2022) to facilitate cross-prompt scoring.
- We compare two strategies to pair up training data in similarity-based cross-prompt scoring.
- We demonstrate the benefits of our strategy for increasing cross-prompt performance on two publicly available datasets (PERSUADE and ASAP), finding that the benefits of our method increase when an increasing number of prompts is mixed in the training data.

Our code and data split is available on GitHub².

2 Related Work

For many years, the main interest in automated essay scoring has been in prompt-specific classifiers, where one specific model was trained for each new

²<https://github.com/mariebexte/generalizing-similarity>

¹In this example, we use the first two prompts from the dataset, which happen to include the words ‘face’ and ‘facial’. While these shared terms might influence a general classifier trained specifically on these prompts, this is merely a coincidence and not the intended focus of our analysis.

writing prompt (e.g., Taghipour and Ng (2016); Dong et al. (2017); Dasgupta et al. (2018); Uto et al. (2020)). This focus has shifted to generic or cross-prompt scoring, where a classifier is trained on one or more prompts. The classifier is then applied to essays that answer prompts which were not seen during training.

2.1 Cross-Prompt Essay Scoring

The problem of cross-prompt essay scoring has been approached in various ways. Phandi et al. (2015) use Bayesian Linear Ridge Regression to score essays using features selected to be predictive of either the source or the target domain. Jin et al. (2018) propose a two-stage neural network (TDNN) approach, in which they use a generic model to automatically create pseudo-training data for the target domain. Li et al. (2020) also propose a two-stage method that aims to extract the shared knowledge between the source and target domain, first creating pseudo-training data, which is then used in a Siamese network. The PMAES system (Chen and Li, 2023) uses a prompt-mapping contrastive learning method to learn more consistent representations of source and target prompts. By doing this, unlabeled data from the target prompt is used to adapt the model. Thus, adaptation to future target prompts would require additional training. Similarly, Zhang et al. (2025) and Wang et al. (2025) also include information derived from unlabeled target data in their training.

2.2 Similarity-Based Essay Scoring

Orthogonal to cross-prompt scoring, recent years have also seen more and more approaches that rely on the similarity between text pairs for scoring instead of training a classifier on features extracted from individual texts (see also Horbach and Zesch (2019)).

The purported advantage that similarity-based approaches might work better in a cross-domain scenario has been refuted, at least for content scoring (Bexte et al., 2023). However, little work so far has explored the potential of cross-prompt similarity-based essay scoring.

3 Method

In a similarity-based scoring setup, the predicted score is derived from a comparison with reference essays. We follow the prompt-specific approach of Xie et al. (2022), which essentially predicts how

much better or worse than a reference essay an essay of interest is. Figure 2 shows an overview of the network structure of this approach. In practice, training essays are used as reference essays, i.e., training is performed on pairs of training essays, and at inference, validation or test essays are compared to training essays. While Xie et al. (2022) use a BERT (Devlin et al., 2019) model at the core of their model, we use a Longformer (Beltagy et al., 2020) instead. This is done to accommodate the longer text length typically encountered in essay scoring. We use the *longformer_base_4096* model as provided on Hugging Face³. Both the answer of interest and a reference answer are embedded using the same Longformer model. The difference between the two embeddings is subsequently fed into a linear layer, which performs a regression. The aim is to predict the difference in the score of the essay of interest and the reference essay. While the approach is a regression at its core, scores are scaled back to their target ranges upon prediction.

For example, if a zero-point essay was compared to a two-point reference essay, the model should output a score difference of minus two. While the original authors only compare test essays to reference essays that do not share the same score, we refrain from doing this, as we feel it is inappropriate to incorporate knowledge of the true scores of test instances into the pairing strategy.

Xie et al. (2022) demonstrate that their model has good within-prompt performance, i.e., when training a dedicated model for each prompt. We build on this and expand the approach to also allow for cross-prompt scoring. With this augmentation, one can even combine prompts that do not share the same label range. To achieve this, we carefully scale labels and model outputs. An overview of this scaling is given in Figure 5 in the Appendix.

During training, the true labels Y of individual essays are transformed to scaled labels Y_s , so that each $y_s \in Y_s$ is in the range of $[0, 1]$. Note that this scaling takes the prompt an essay belongs to into account, which means that each $y \in Y$ is scaled according to the label range of the prompt the essay belongs to. When pairing up essays to form training pairs, their target label is the score difference of the essays, i.e., their scores are subtracted. Thus, the score difference d_p of a pair will be in the range of $[-1, 1]$, because $d_p = y_i - y_j$ for $y_i, y_j \in Y_s$.

³<https://huggingface.co/allenai/longformer-base-4096>

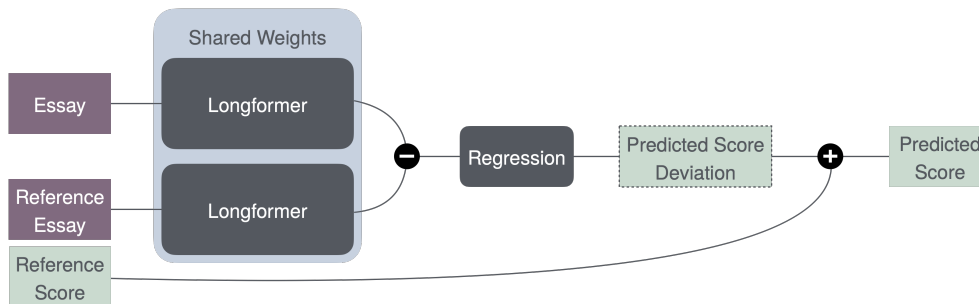

Figure 2: Overview of the model architecture, derived from Xie et al. (2022).

For optimal suitability to the regression model, we again scale the score differences to the range $[0, 1]$.

At inference, validation/test essays are paired up with training, i.e., reference essays. For each test essay t and a reference essay r , the score s_r of r is first scaled to the score range $S_t = [s_{min}, s_{max}]$ of t for compatibility. In processing the pair of t and r , the model outputs the predicted score deviation \hat{d} , which lies in the range $[0, 1]$. This now has to be mapped to the label range of t . However, because \hat{d} is a *deviation*, it has to be scaled to the range $[s_{min} - s_{max}, s_{max} - s_{min}]$, which represents the minimal and maximal deviation that is possible within S_t . The result \hat{d}_t can then be used to obtain the predicted score \hat{s}_t of t by adding the predicted score deviation to the true score s_r of r , i.e. $\hat{s}_t = s_r + \hat{d}_t$.

To investigate whether we can nudge the model towards learning less prompt-dependent representations, we contrast two ways of pairing essays during training: In the **standard** setting, we only pair essays from the same prompt. In our **generalize** setting, we only pair essays from different prompts.

Note that our main motivation is to evaluate the effect of building cross-prompt training pairs, rather than to achieve the best possible performance. In the interest of saving energy and time, we thus set our hyperparameters somewhat lower than Xie et al. (2022) did. We always train for five (as opposed to 80) epochs, taking the model with the best performance on the validation data. At inference, we limit ourselves to comparing each validation (testing) essay to 15 (25) training essays (as opposed to 50). The average predicted score is then taken as the final prediction of the model. Although our switch to a Longformer instead of the smaller BERT model increases runtime, we do not make use of the full length of 4,096 tokens. Instead, we truncate inputs to a length of 1,024, as

	PERSUADE	ASAP
# integrated prompts	7	4
# independent prompts	8	4
avg. # essays per prompt	1,733	1,622
avg. essay length in tokens	410.96	222.74
score range	1-6	prompt -dependent

Table 1: Key statistics of the two datasets used in our study.

the majority of essays fits in this length⁴. Just like Xie et al. (2022), we use a batch size of 6, and a learning rate of $1e-4$.

4 Data

We work on two different data sets, **PERSUADE** and **ASAP**-aes (Automated Student Assessment Prize - Automatic Essay Scoring), which we refer to as **ASAP**. The core statistics for each dataset can be found in Table 1. Although PERSUADE is best-suited for our analysis due to the large number of prompts, we additionally run our experiments on ASAP, as this is a commonly used essay scoring dataset.

4.1 PERSUADE

The PERSUADE dataset (Crossley et al., 2024) comprises seven integrated prompts, with a total of 12,875 essays written by students from the 6th to the 10th grade, and eight independent prompts with a total of 13,121 essays sampled from writers from the the 8th to the 12th grade. While integrated prompts refer to some source material, independent prompts do not. Each essay was annotated with a holistic score by two raters. Scores range from 1.0 to 6.0 in increments of 1.0. The raters were trained on a standardized SAT holistic essay

⁴3% of PERSUADE essays and 2.7% of ASAP essays are truncated due to this.

scoring rubric for the independent essays⁵ and its modified version for the integrated essays⁶. The main difference between the two rubrics is that the one for the integrated prompts mentions having to include evidence from the reading text⁷. Due to this explicit inclusion of the source text in the rubric, we expect the cross-prompt transfer to be more successful for the independent prompts. Overall, raters showed a strong agreement (weighted $\kappa = .74$) in annotating the essays.

4.2 ASAP

The ASAP dataset⁸ is one of the benchmark datasets for automated essay scoring. It contains four integrated and four independent (persuasive/narrative/expository) tasks, spanning a total of 12,978 essays. The essays were written by students from the 7th to the 10th grade. ASAP prompts have also been scored holistically but using a wide variety of different scales. Each essay was evaluated by two raters, with an inter-annotator agreement of $\kappa = .55$. After adjudication, the resulting score ranges can span as little as four or up to 61 different labels, as can be seen in Table 5 in the Appendix. This label incompatibility between prompts further complicates cross-prompt scoring.

5 Experimental Study

In the following, we first describe the overall setup and then present the results of our similarity-based cross-prompt scoring on the two datasets. Our experiments ran on Nvidia Quadro RTX 6000, A40, and A6000 GPUs for around 550 hours.

5.1 Experimental Setup

Our overall goal is to train an essay-scoring classifier that focuses on general indicators of a good essay as opposed to overly relying on prompt-specific features. In our similarity-based method, we facilitate this through the selection of training pairs. We contrast the performance of models trained using pairs that consist of two answers to the same vs. different prompts.

Data Split For each of our datasets, we sample the same number of answers for each prompt,

⁵https://github.com/scrosseye/persuade_corpus_2.0/blob/main/sat_rubric_only_indy.pdf

⁶https://github.com/scrosseye/persuade_corpus_2.0/blob/main/sat_rubric_only_source_based.pdf

⁷The reading texts were not published, which is why we are unable to include them in our analyses.

⁸<https://www.kaggle.com/c/asap-aes>

downsampling to the number of answers of the prompt with the lowest answer count. In doing this, we randomly sample a subset of 1,000 essays for each of the 15 prompts in the PERSUADE dataset. 800 of these are used for training and 100 for validation and testing each. For each of the eight prompts in the ASAP dataset, we randomly sample a subset of 700 essays. 560 of these are used for training and 70 for validation and testing each.

In similarity-based scoring, the training data pool is used to build pairs of instances. We derive our strategy to build these pairs from Xie et al. (2022) but relax it to allow data from multiple prompts to be paired. Their strategy includes dropping training pairs of essays with the same score, which we in preliminary experiments found to be a reasonable step, as it cut training time at a minor performance loss.⁹ However, we have to ensure that each run, i.e., all combinations of different prompts we use in our experiments, uses the same number of training pairs. Otherwise, runs with more pairs may have a performance advantage. We thus pre-calculate the maximum number of pairs we can build in each of our runs: We determine how many pairs we would end up with if we paired up all essays in the training data that do not share the same score. We then take the minimum of this as the number of training pairs we build in our experiments. This results in 1,495 training pairs for PERSUADE and 920 training pairs for ASAP.

As mentioned earlier, we limit the number of pairs during validation (testing) to 15 (25) pairs per essay. The pairing strategy for the validation data reflects the training setting: If training is done on pairs of essays from the same prompt, validation instances are also paired with training essays from the same prompt. If training is done on pairs of essays from different prompts, we also pair validation essays with training essays from a different prompt. The pairing strategy during testing is ‘greedy’ in the sense that we check whether essays from the same prompt appeared in the training data. If this is the case, we use 25 of these as reference answers, otherwise, we randomly take 25 essays from the training pool as reference answers.

Single-Prompt Baseline As a starting point for our experiments regarding the impact of training

⁹Note that this only applies to the *training* process. As we remark in Section 3, we do not look at scores when building pairs for *test* instances, since we feel that this incorporation of knowledge about scores would be inappropriate.

on combinations of data from multiple prompts, we train models on **single prompts**.

To compare the performance of the similarity-based approach, we also train an **instance-based** classifier. For this instance-based classification, we use the same *longformer_base_4096* model that is also at the heart of the similarity-based approach and attach a classification head. In both instance-based and similarity-based training, we use the same data splits, but for the instance-based classification we adapt the labels of the ASAP dataset to allow for cross-prompt evaluation. To unify the differing label ranges of the ASAP prompts, scores are scaled into a range from 0 to 3, which corresponds to the smallest label range present in the dataset¹⁰. Models are trained for 10 epochs with a maximum input length of 1,024 tokens, a learning rate of 1e-5, and a batch size of 2.

Mixed-Prompt Scoring Setup We compare models trained on answer pairs from the same prompt to models that were trained with pairs of answers to different prompts.

We vary how many prompts are combined in the training data and hypothesize that combining more prompts leads to a better generalizability of the classifier, i.e., a better cross-prompt performance. To ensure comparability, we keep the overall number of training instances constant for all combinations. The validation data is composed of the same prompts that appear in the training data to make the transfer to the prompts in the test data a hard one. Just as for the training data, the amount of validation data is also downsampled to keep it at the same overall number of instances as when data from a single prompt is used.

For PERSUADE, we report individual results for the seven integrated and eight independent prompts, and for combinations of all 15 prompts. As ASAP only comprises a total of eight prompts (4 integrated, 4 independent), we do not perform a separation into integrated and independent prompts for this dataset and only report results for the gradual combination of all eight prompts. Whenever there are more than ten possible combinations of prompts (e.g., there are 70 ways of picking four out of the eight independent PERSUADE prompts), we randomly sample ten combinations to cut training time, making sure that each prompt was selected in

¹⁰Note that this is not necessary for the similarity-based scoring, as this method comes with the capability to internally scale prompts with different label ranges into compatibility.

at least one combination.

Evaluation We always evaluate in two different conditions: **within-prompt**, which comprises the test data splits for all prompts that also appear in the training data for that run, and **cross-prompt**, which comprises the test data splits of all other prompts. We expect an increasing number of prompts mixed in the training data to have different effects for the two training and evaluation conditions. Overall, within-prompt evaluation should perform better than cross-prompt evaluation. For cross-prompt evaluation, we expect the generalized training to outperform the standard training. When evaluating in the within-prompt condition, the expectation would be for the models obtained with standard training to outperform those resulting from generalized training, as the former are more attuned to prompt-specific information.

The metric we use to evaluate model performance is quadratically weighted kappa (QWK; Cohen (1968)). Whenever we average QWK results, we perform Fisher Z-transformation to stabilize the variance.

5.2 Results: Single-Prompt Training

Before reporting the results of training on combinations of prompts, we first establish the performance level achieved by training on a single prompt. These results are shown in Table 2.

It is expected that a model will perform best when trained exclusively on data from the same prompt it is later evaluated on. This could thus be seen as somewhat of an upper bound. Table 2 also contains cross-prompt performance, first on all cross-prompt test data and then separated into integrated and independent prompts. We observe that for both PERSUADE and ASAP alike, there is a clear drop in the performance of cross-prompt compared to within-prompt evaluation.

In the case of PERSUADE, models trained on integrated prompts fare similarly in the cross-prompt evaluation, irrespective of whether the test prompts are integrated or independent. However, for models trained on independent prompts, cross-prompt evaluation within the same group (i.e., on another independent prompt) shows an average improvement of 0.16 QWK compared to evaluation on an integrated prompt. This pattern differs for ASAP, perhaps due to the widely varying scoring ranges. Here, the performance of evaluating on integrated vs. independent prompts is similar for models trained on

Train	Within-Prompt	Cross-Prompt		
		All

Avg.	.77	.44	.46	.43

Table 2: QWK performance of models trained on single prompts. Results distinguish integrated and independent prompts. The mapping of prompt numbers to names in PERSUADE is listed in Table 4 in the Appendix.

an independent prompt, but we see a benefit when models trained on an integrated prompt are evaluated on a different integrated prompt.

Comparison to Instance-Based Scoring We further examine the validity of the similarity-based approach by comparing it to a standard instance-based setting. Table 3 compares the average performance of the similarity-based (taken from Table 2) and the instance-based approach. The two setups perform on par on PERSUADE, and similarity-based scoring even outperforms the instance-based classification on ASAP.

5.3 Results: Training on Multiple Prompts

Figure 3 shows the results for training on a mix of different prompts. The number of prompts in the training data gradually increases from left to right. Note that curves start with the results from

the previous experiment, where we only trained on a single prompt. A constant benefit of building cross-prompt as opposed to within-prompt training pairs can be observed: The performance of models trained using within-prompt training pairs (dotted lines) tends to drop off, while models trained on cross-prompt training pairs (solid lines) tend to remain more stable or even increase in performance. Contrary to our hypothesis, training on cross-prompt pairs even consistently leads to better performance than standard training for the within-prompt evaluation, thus showing that this training setup does no harm but instead benefits performance across the board.

Strikingly, from a mixture of five prompts onward, our generalization-focused models perform better in cross-prompt evaluation (solid line with crosses) than the standard (i.e., within-prompt-trained) models on within-prompt data (dotted lines with dots) on the ASAP data. We see the same result from a mix of six prompts onward for the longer PERSUADE curves. With the shorter PERSUADE curves, the two conditions again meet at the mark of combining five prompts but remain on a similar performance level from there on. Thus, when five or more prompts are combined, the generalized training strategy pushes cross-prompt performance above standard within-prompt training and evaluation.

6 Embedding Space Analysis

To gain an understanding of how the embedding space is affected by either training exclusively on within-prompt or cross-prompt training pairs, Figure 4 shows embedding space visualizations. To produce these visualizations, we embed the respective test data using the Longformer model that is at the core of the model pipeline. We then use t-SNE to bring the embeddings into 2D space. For t-SNE, we use the sklearn (Pedregosa et al., 2011) implementation at its default values. From the distributions of essay embeddings, one can gather that the models trained using cross-prompt training pairs produce embeddings that are less separated into individual prompts, indicating that they truly learned a more generic representation of the essays.

7 Conclusion and Outlook

Our baseline results confirm the overall solid performance of the model, in line with what Xie et al. (2022) found. In addition, our results demonstrate

	PERSUADE								ASAP							
	Instance-based				Similarity-based (ours)				Instance-based				Similarity-based (ours)			
	Within-Prompt	Cross-Prompt			Within-Prompt	Cross-Prompt			Within-Prompt	Cross-Prompt			Within-Prompt	Cross-Prompt		
	All			All				All				All				
Avg.	.76	.57	.59	.55	.74	.57	.58	.56	.80	.40	.56	.26	.78	.46	.51	.42
Avg.	.77	.62	.55	.69	.77	.62	.53	.69	.60	.27	.23	.33	.76	.42	.40	.44
Avg.	.76	.60	.57	.64	.75	.60	.56	.63	.71	.33	.41	.29	.77	.44	.46	.43

Table 3: Comparison of instance-based and similarity-based scoring, split into the two datasets and their [integrated](#) and [independent](#) prompts. Both methods perform on par, except for similarity-based scoring outperforming instance-based scoring on the independent ASAP prompts.

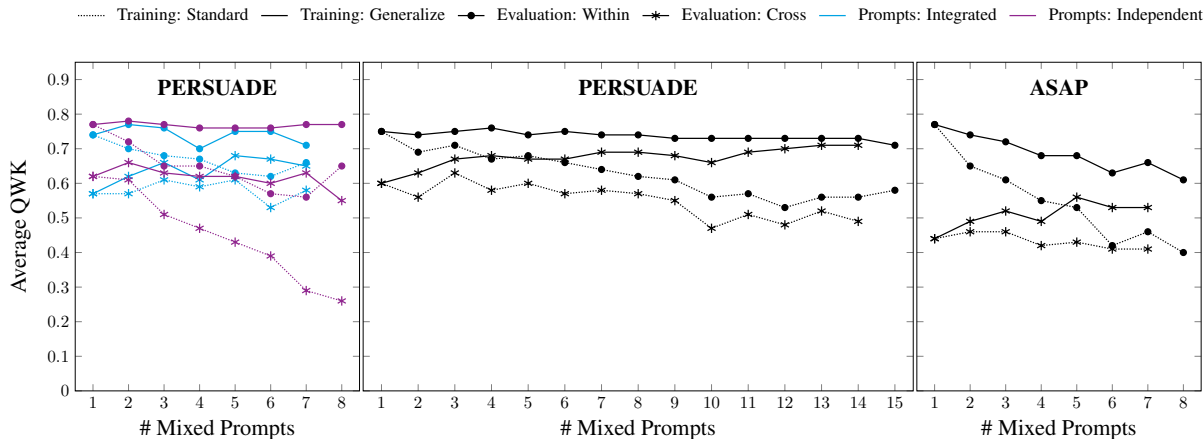

Figure 3: Learning curves depicting how mixing an increasing number of prompts in the training data affects performance. For cross-prompt evaluation, we always use test data from all (i.e., both integrated and independent) prompts that are not in the training data. Our generalized training strategy (solid lines) consistently benefits performance compared to standard training (dotted lines).

the suitability of the model to perform cross-prompt scoring - even in the difficult case of the ASAP dataset with its diverse set of score ranges across different prompts. Our strategy of pairing training essays either within-prompt or cross-prompt proved helpful not only in the cross-prompt scenario but also for within-prompt evaluation. Thus, it is advisable to build training pairs cross-prompt whenever a mixture of multiple prompts is present in the training data.

Limitations and Ethical Considerations

In our setup, we only investigate variants of a hard domain transfer, where data from several source domains is used to train a classifier that is then applied to a target domain. One obvious next step we have not yet taken would be to inject small amounts of target-domain data. Another avenue we do not incorporate is to use the source text of a prompt as a means of facilitating cross-prompt transfer.

Similarly, we do not evaluate cross-prompt performance between datasets. In this study, we re-

strict ourselves to cross-prompt evaluations within ASAP or PERSUADE (as in almost all related work), i.e., we evaluate on new prompts that are somewhat similar to the source prompts and whose data comes from a similar learner population. The question of the extent to which essay scoring can ever be fully generic remains open and thus requires further research.

As always in automated scoring, fairness and bias are important issues that should be taken into account to make sure that scoring algorithms do not disadvantage certain user groups (see, e.g., Loukina et al. (2019) and Schaller et al. (2024)). These topics also need further investigation for our generic scoring scenario. At the same time, one might argue that a generic classifier is less likely to fall for spurious correlations between scores and unnecessary features than a prompt-specific classifier might be.

Finally, as our experimental setup requires over 1,000 training runs, we make some design choices in the interest of keeping the overall runtime at a reasonable level. Our preliminary results indi-

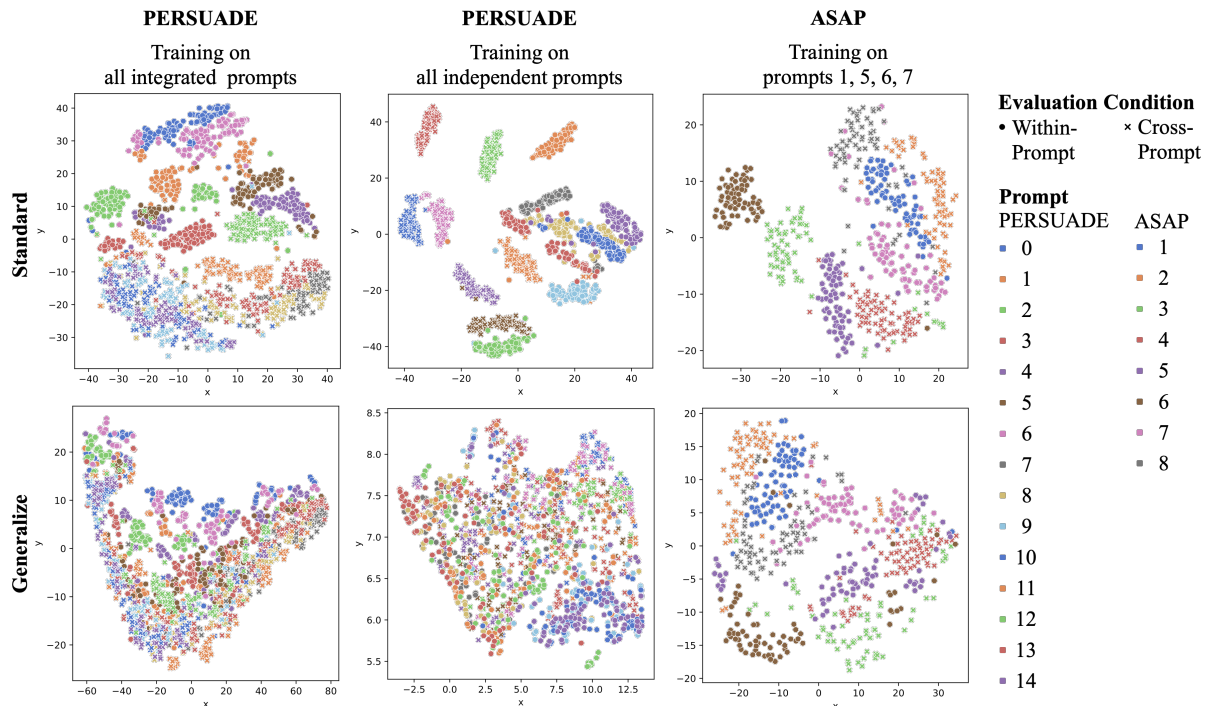

Figure 4: Visualization of embeddings from models trained in the standard (top) and generalize (bottom) conditions, transformed using t-SNE. There is less separation into prompts for models trained with the generalize strategy, indicating that these models do in fact learn a more generalized representation of the essays.

cate that one could achieve better performance than what we report here by training for more than just five epochs, building more training pairs and taking advantage of the full input length of the Longformer model - albeit at the cost of a greater demand on computing resources.

A Appendix

This appendix contains supplementary information to increase the transparency and reproducibility of our experiments. Table 4 gives information on the mapping between prompt numbers and names in PERSUADE. For ASAP, Table 5 gives information on the label ranges of the different prompts. To better grasp the generalization of the model for cross-prompt scoring, Figure 5 presents a graphic overview of how labels are scaled during training and inference.

#	Prompt Name
0	The Face on Mars
1	Facial action coding system
2	A Cowboy Who Rode the Waves
3	Does the electoral college work?
4	Car-free cities
5	Driverless cars
6	Exploring Venus
7	Summer projects
8	Mandatory extracurricular activities
9	Cell phones at school
10	Grades for extracurricular activities
11	Seeking multiple opinions

Abstract

We present an approach to the automated scoring of a German Written Elicited Imitation Test, designed to assess literacy-dependent procedural knowledge in German as a foreign language. In this test, sentences are briefly displayed on a screen and, after a short pause, test-takers are asked to reproduce the sentence in writing as accurately as possible. Responses are rated on a 5-point ordinal scale, with grammatical errors typically penalized more heavily than lexical deviations. We compare a rule-based model that implements the categories of the scoring rubric through hand-crafted rules, and a deep learning model trained on pairs of stimulus sentences and written responses. Both models achieve promising performance with quadratically weighted kappa (QWK) values around .87. However, their strengths differ – the rule-based model performs better on previously unseen stimulus sentences and at the extremes of the rating scale, while the deep learning model shows advantages in scoring mid-range responses, for which explicit rules are harder to define.

1 Introduction

The Written Elicited Imitation Test (WEIT) is a computer-based test designed to measure procedural linguistic knowledge in writing. In this test, learners briefly view sentences in the target language and, after a short pause, reproduce them from memory by typing. Responses are then rated on an ordinal scale based on how closely they resemble the original sentences.

Like any assessment that relies on scoring by human raters, the WEIT can benefit greatly from automation. An automated scoring system would significantly improve efficiency by enabling the rapid evaluation of large numbers of responses without the time and effort required by human raters. This would, in turn, allow for immediate feedback, an

advantage in both instructional and research contexts. Automation also ensures greater consistency and objectivity by applying scoring criteria uniformly and eliminating potential rater bias. In addition, automated systems can provide fine-grained data on error patterns and processing behavior, offering deeper insight into learners' procedural language skills.

In this paper, we investigate the automated scoring of a German WEIT. The responses in our dataset are scored using a rubric that assigns a score between 0 and 4, based on deviations in spelling, grammar, and vocabulary (see Section 3.2). There are two main approaches to automating this process: a rule-based approach, in which categories from the scoring rubric are implemented explicitly, and a deep learning approach, in which a model learns implicitly which scores to apply based on training pairs of stimulus and response sentences.

In educational settings, transparency and explainability are important considerations. From this perspective, rule-based models are preferable as they allow for a clearer justification of scoring decisions and can offer more detailed feedback to learners by pinpointing specific types of deviations. However, rule-based systems can be limited in flexibility, particularly when dealing with edge cases or language exceptions. In contrast, deep learning models may be better suited to capturing subtle patterns in learner responses (e.g. to what extent a word substitution affects the overall meaning of the sentence), but often lack transparency and may struggle to generalize to previously unseen stimulus sentences.

This paper presents a rule-based scoring model for the WEIT, built on general principles derived from the scoring rubric, and compares it to a deep learning model trained on stimulus-response pairs. We hypothesize that (a) the deep learning model will outperform the rule-based model on cases where differences between descriptors in the scor-

ing rubric are rather subtle and hard to capture as explicit rules, and (b) the rule-based scoring model will generalize better to new, previously unseen stimulus sentences.

The main contributions of this paper are twofold. First, we explore the feasibility of automating the scoring of a German WEIT using a detailed ordinal rating scale. Second, we provide a concrete case study for comparing the strengths and limitations of deep learning and rule-based methods in an educational assessment context.

Our code and data are available at: <https://gitlab.ruhr-uni-bochum.de/vamos-cl/german-weit-automated-scoring>.

2 Background and Related Work

In the following, we provide background on the use of elicited imitation tests and summarize previous research on their automated scoring.

2.1 Elicited Imitation Tests (EIT): Construct and Use

Elicited imitation tests (EIT) have been widely used and researched in the field of Second Language Acquisition as measures of two key constructs: global proficiency in a second or foreign language (Drackert, 2016; Kostromitina and Plonsky, 2022) and implicit language learning (Nikouee and Ranta, 2023). EITs exist in many languages and have been primarily employed in the oral mode (oral EIT, or OEIT) in which language learners listen to a number of sentences and then orally repeat them as accurately as possible after a short pause.

Recently, written elicited imitation tests (WEIT) have started to gain attention in language testing as a research tool (e.g. Sun et al., 2025) or as a measure of literacy-dependent procedural language knowledge (Timukova et al., submitted).

In the format that was used by Timukova et al. (submitted) in a large language testing research project, the sentences are briefly presented on a screen, and, after a pause, learners have to reproduce as much of the sentence as they can by typing their response into a text box. The pause is intended to reduce the influence of working memory and to promote active reconstruction of the stimulus rather than rote repetition. The construct of literacy-dependent procedural language knowledge measured by WEIT can be defined as automatized knowledge and skills required for the real-time reception and production of written language.

Inspired by and closely related to the well-established oral elicited imitation format (Ortega et al., 2002), the written test — despite being presented and completed in a different modality and incorporating a distinct scoring system to better capture the construct (see Section 3.2) — yields results of comparable difficulty and reliability.¹ However, it is considerably easier to develop, administer, and score, as no audio equipment is required at any stage. Scoring short written responses is also likely more practical and less time-consuming than scoring spoken responses when done by human raters.

2.2 Automated Scoring of EITs

While EITs, in principle, lend themselves well to automated scoring since the target response is known (i.e. exact repetition of the stimulus sentence), the difficulty of the automated scoring task largely depends on the scale or rubric used for rating responses that deviate from the target.

For the oral EIT, numerous studies have explored automated scoring of the test using automatic speech recognition (ASR), primarily employing a binary scale that codes whether the response matches the stimulus or not (e.g. Millard, 2011), or an interval scale, where, for example, one point is subtracted for each deviation in the response sentence (Graham et al., 2008; Lonsdale and Christensen, 2011). Once the learner utterances are accurately transcribed, automated scoring based on these scales is straightforward.

Besides binary and interval scales, ordinal scales exist where scores are determined qualitatively. In their meta-analysis, Yan et al. (2016) found that for the OEIT, ordinal rating scales were more effective at distinguishing speakers across proficiency levels than other scales. An established ordinal rating scheme for the OEIT is that of Ortega et al. (2002), where the score depends on how much of the stimulus sentence a learner was able to repeat:

- 0 points for minimal (one word), unintelligible responses or no repetition
- 1 point when half or less of the stimulus was repeated
- 2 points for changes to the original sentence in content or form that affected the meaning

¹The tests used in the project showed difficulty indices of 0.41 (WEIT) and 0.49 (OEIT), and reliability coefficients (Cronbach's α) of .97 for both (N = 195).

- 3 points for accurate content repetition with some (un)grammatical changes
- 4 points for exact repetition with formal accuracy

Recent studies have investigated how automatically obtained scores based on objectively quantifiable features correlate with scores based on Ortega’s ordinal scale. McGuire and Larson-Hall (2025) found high correlations with word error rate (WER), especially when looking at a participant’s mean score across a whole test ($r = -0.969$). The correlation of WER and Ortega’s scores across items, however, was lower ($r = -0.817$). Isbell et al. (2023) took further metrics such as Levenshtein distance into account and also mapped a combination of Percent Word Correct (PWC, exact matches) and Percent Meaning Correct (PMC, matching lemmata) to Ortega’s 5-point scale (e.g. $PWC < 100\%$ and $PMC \geq 70\% = \text{Score } 3$). They also found high correlations with Ortega’s scores assigned by human raters (around $r = 0.9$ when aggregated across all items and around Spearman’s $\rho = 0.8$ at the item level, depending on the metric and ASR service used).

In the present study, our aim is to implement an automated scoring procedure for a German WEIT, using an ordinal scale similar to that of Ortega et al. The scoring rubric will be presented in more detail in Section 3.2. It was specifically developed for the German WEIT, as no comparable schemes had yet existed. As the purpose of the WEIT is to test literacy-dependent procedural language knowledge, the rubric differs in some essential ways from that of Ortega et al. Our goal is to build a rule-based scoring model that implements the various categories from the rubric, rather than relying on purely quantitative measures such as WER. This scoring method is comparable to human raters’ assessments in that it could provide learners with feedback about the scores they received based on the deviations in their responses. For comparison, we investigate how successful modern deep learning approaches are at approximating human ratings by implicitly learning to apply the scoring rubric.

3 Data

3.1 Data Collection

The data for our study was collected within a larger research project where the WEIT was used as a measure of literacy-dependent procedural knowledge (see Section 2.1). The 20 items included in the

WEIT range from 6 to 16 words, or 8 to 24 syllables (see Appendix A for the full list of items). The test was completed by 195 university students who were learners of German (58.1% female, 41.9% male) between the ages of 18 and 40 ($M = 25.46$, $SD = 3.92$). The participants represented 47 different native languages, with Russian ($n = 30$), Turkish ($n = 23$), English and Spanish ($n = 14$ each) being the most frequent. Most participants self-assessed their language skills to be somewhere between A2 and C1.

3.2 Scoring Rubric

An ordinal scoring rubric for the German WEIT was developed for the purposes of the project. It follows the rubric of Ortega et al. (2002) in that responses are scored based on how closely they resemble the stimulus sentences. A key difference between the WEIT rubric and the OEIT rubric already addressed in Section 2.2 is the altered role of *meaning* and *grammar*. Since rule-governed morphological and syntactic sequences are central to the construct of procedural knowledge measured by the WEIT, grammatical deviations carry more weight. Hence, the rubric distinguishes between lexical and grammatical deviations from the original, assigning a higher score (Score 3) for responses with lexical deviations (e.g., lexical omissions or substitutions) and a lower score (Score 2) for responses with grammatical errors (e.g., structural omissions or incorrect prepositions).

In the following, we present a summary of the scoring rubric. Its use is exemplified for item #2 in Table 1. The complete scoring rubric can be found in the Supplementary Material to this paper.

Score 4 The response matches the stimulus sentence exactly or 1–2 typos are present.²

Score 3 Changes in grammar or lexical changes that preserve the original structure and result in grammatically correct and meaningful sentences, e.g. confusing definite and indefinite articles (where interchangeable), or (near-)synonymic substitutions of words.

Score 2 Changes in grammar that result in ungrammatical sentences or grammatical sentences which are not meaningful, e.g. violated agreement

²Typos include: transposed letters (all present), one letter replaced by a QWERTZ-adjacent key, one letter added/omitted next to an adjacent key, or a missing space between words.

Score	Example	Explanation
0	Bein praktikum	less than half of the words repeated correctly
1	Bei einem Praktikum * * *	half of the words repeated correctly but most of the meaning lost
2	Bei ein Praktikum lernt man viel.	case wrongly marked, ungrammatical sentence
3	Beim Praktikum lernt man viel.	change in grammar (contraction of preposition + article) but still grammatical
4	Bei einem Praktikum lenrt man viel.	one typo

Table 1: Example of the scoring rubric for the stimulus sentence *Bei einem Praktikum lernt man viel*. ‘At an internship, one learns a lot’.

between subject and verb, structural omissions or wrong plural formation.

Score 1 More than half of the words are repeated but a considerable part of the original meaning or structure is lost or changed.

Score 0 Less than half of the words are repeated.

Some score descriptors vary with the length of the stimulus sentence: in “shorter sentences” (≤ 15 syllables) fewer deviations are allowed than in “longer sentences” (> 15 syllables). If a response contains multiple deviations at different score levels, then the lowest score determines the overall score. An accumulation rule is applied when two or more deviations of the same level are present in scores 2 or 3, leading to an overall score of 1 or 2, respectively. Punctuation and capitalization of the first word of the sentence are not taken into account.

The gold standard scores (henceforth also referred to as ‘gold scores’) for our study were assigned by three human raters in the following procedure: First, they familiarized themselves with the assessment rubric and participated in a calibration session using 200 responses (i.e. for all 20 items a sample of 10 participants each). Following this, a sample of the same size was randomly selected for independent evaluation by each rater. The inter-rater reliability (Fleiss’ κ) for the resulting 200 ratings averaged around .986, indicating almost perfect agreement, with values ranging from .895 to 1.0 across the 20 items. The remaining responses were rated by one rater each, and ratings were discussed by all raters throughout the process to address difficult cases and ensure consistency.

3.3 Data Splitting

Each of the 195 participants responded to 20 different stimulus sentences (*items*). In total, our dataset comprises 3,900 pairs of stimulus (*target*) and imitation (*response*) sentences. We split the data into training, validation, and two different test sets as

Score	Train	Val.	Test known	Test unk.	Total
0	1,095	25	25	87	1,232 (32%)
1	701	25	25	92	843 (22%)
2	553	25	25	62	665 (17%)
3	260	25	25	78	388 (10%)
4	651	25	25	71	772 (20%)
Total	3,260	125	125	390	3,900 (100%)

Table 2: Number of stimulus-response pairs in the training, validation, and test sets, respectively, per gold score. ‘Test unk.’ contains stimulus sentences held out from the training set, ‘Test known’ a random subset of the remaining data (i.e. stimulus sentences known in the training set).

follows: First, we set aside all responses to two of the stimulus sentences (#4 and #18, i.e. one ≤ 15 syllables and one > 15 syllables, see Section 3.2). We call this test set ‘Test unknown’, comprising 390 stimulus-response pairs in total. The rest of the data was randomly split into a training, validation, and another test set. We call this second test set ‘Test known’, because it contains responses to those stimulus sentences that are also part of the training set. By using these two different test sets, we are able to not only assess how well a model performs on unseen response sentences to known stimulus sentences but also how well it generalizes to completely new stimulus sentences. The resulting data distribution across sets and gold scores is shown in Table 2.

4 Method

We first present our deep learning model (**DL model**) and then introduce the pipeline for the rule-based model (**RB model**) for automatically scoring the WEIT.

4.1 Deep Learning

Since there is not enough data to train a deep learning model from scratch, we decided to use a pre-trained transformer model and fine-tune it on our

data for multi-class sequence classification.

For efficiency reasons, we chose the DistilBERT model (Sanh et al., 2019), a distilled version of BERT (Devlin et al., 2019), which the authors showed to be 40% smaller, 60% faster and able to retain 97% of the original language understanding capabilities (Sanh et al., 2019). We used the pre-trained model for German cased data (distilbert-base-german-cased) with a multi-label classification head, and fine-tuned the model on our WEIT training set. Hyper-parameters were optimized based on accuracy on the validation set, yielding the following setup and parameter values: a learning rate of $1e-5$ and an epsilon value of $1.5e-3$ for the Adam optimizer, and the default loss function for multi-class classification (SparseCategoricalCrossentropy). We trained the model for 50 epochs with an early stopping mechanism triggered after 5 consecutive epochs without improvement in the validation loss. The training and validation data were shuffled and batched in each iteration, with a batch size of 16.

Since the training dataset was heavily skewed towards scores 0, 1, and 4 (see Table 2), we trained a second model in the same way but in which class weights were introduced for scores 2 and 3. Score 2 received a 2x multiplier and score 3 received a 4.5x multiplier, both approximately equal to the proportion of the corresponding training pairs of these scores to the number of score 0 pairs (the most common score). We refer to this as the **weighted** DL model and the model without adjusted class weights as the **unweighted** DL model.

4.2 Rule-Based

The rule-based model processes pairs of target and response sentences through a multi-step pipeline to generate a score (Figure 1).

Preprocessing In the preprocessing step, the sentences are normalized and cleaned so that differences between target and response sentences that are not relevant for scoring can be ignored. This means in particular: capitalizing the first letters of both sentences, transforming common umlaut variants into the correct character (e.g., ‘ae’ into ‘ä’), and removing punctuation and artifacts such as the ‘;timeout’ token, which appears when a participant runs out of time during the repetition process. Furthermore, in some cases participants repeated the sentence multiple times. Since this is ignored by the human raters, we cut each response to only

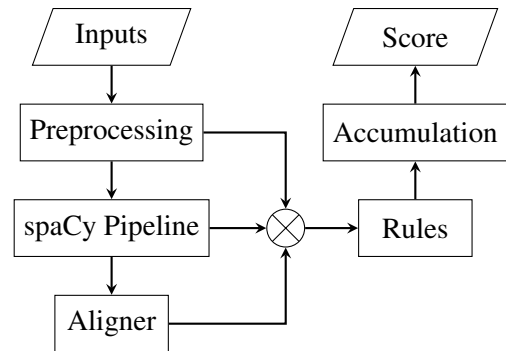

Figure 1: Flow diagram illustrating the rule-based model’s data processing pipeline.

Figure 2: Token mapping by the aligner function for an example sentence. Tokens in red are **misspelled** and tokens in orange are **missing** or **additional**. Green arrows denote aligned tokens and blue arrows **transpositions**.

retain the first response sentence.

Linguistic Annotation In the next step, the pre-processed sentences are analyzed linguistically using a spaCy pipeline (Honnibal et al., 2020), which transforms each sentence into a list of tokens with part-of-speech (POS) tags, syntactic dependency labels, morphological features, and syllable counts.³

Alignment The tokens are then passed on to a custom-built aligner, which maps the words in the response to the words in the target sentence and also detects missing or added words (see Figure 2). This is done by calculating a matrix of Damerau-Levenshtein distances⁴ between all words in the response sentence and the target sentence and aligning those words with the smallest distance. We do not only align identical words because this would prevent misspelled words from being matched with the correct word in the target sentence. However, if the edit distance between two words is large, it is more likely a different word rather than a misspelling. Therefore, for two words to be aligned,

³We use spaCy v3.8.3 with the de_core_news_sm model v3.8.0 with all its default components, and the package *sloev/spacy-syllables* v3.0.2 for counting the syllables, which is added directly after the tagger in the spaCy processing pipeline.

⁴using *lanl/pyxDamerauLevenshtein* v1.8.0, <https://github.com/lanl/pyxDamerauLevenshtein>

their edit distance must be ≤ 3 .⁵ If a word in the target sentence has no match in the response sentence, it is ‘missing’, if a word in the response sentence has no match in the target sentence, it is considered ‘additional’. Note that at this step, we do not detect word substitutions directly but they would be treated as a missing and an additional token, which are later aligned by a rule that checks for substitutions. For all matched pairs, if the edit distance between both words is greater than zero, the token in the response is considered ‘misspelled’. If two words are matched but have different positions, they are considered ‘transposed’. All other tokens are labeled as ‘correct’.

Rule Application Manually, a set of rules was crafted that implement the deviation categories from the scoring rubric based on all the outputs of the previous steps. For each category it is checked whether it applies to the response sentence. For this first version of the rule-based model, most deviation categories were implemented, except for some which were considered too fuzzy or which would have required further linguistic annotation not readily available e.g. about German plural formation.⁶ The rules are defined in a way that they are mutually exclusive so that the order in which they are applied is not important. If a rule detects that a particular category applies to a response sentence, it outputs the name of the category, the score which it is associated with and how many instances of this deviation are found. Finally, an accumulation function collects the outputs of all rules and calculates the final score (see Section 3.2 for the accumulation rules). The following examples illustrate how some of the categories from the scoring rubric are approximated via rules.

To detect an *Omission Error*, the rule uses the missing-word count from the aligner. If exactly one word is missing, the rule assigns a score of 3. If two words are missing in a sentence with fewer than 16 syllables, the score is 2. In longer sentences with two or more omissions, the rubric asks to assess whether the sentence “preserves most of the original sentence structure and most of the meaning”. We determine structural deviations by the degree

⁵This value worked well in our trial runs but could be tuned, e.g. adjusted for token length, in future work.

⁶Deviation categories that were not implemented are: *wrong plural formation*, *missing structural elements or wrong word order*, and *sentence is grammatical but not meaningful* from score 2, and *changes in grammar that preserve the original structure and result in grammatically correct sentences* from score 3.

of agreement between the spaCy dependency structures of stimulus and response sentence, with a loss of more than 30% of the original dependencies serving as the threshold. Meaning deviations are identified using cosine similarity between the vectorized representations of target and response sentences, obtained via a BERT Sentence Transformer (Reimers and Gurevych, 2019). If the similarity falls below 0.987, the meaning is considered altered.⁷ If either a structural or meaning deviation occurs, the score is set to 1, otherwise 2.

The *Changes in Grammar* category captures deviations in grammatical structure between the stimulus and response sentences, which are specifically listed in the scoring rubric, namely differences in article usage, gender and case markings, agreement violations, and prepositional errors. The rule uses information from the aligner and spaCy to compare the POS and morphological features of aligned words. Article-related errors are identified when a determiner is missing, incorrectly added, or replaced with another. Gender and case errors are identified when mismatches occur in the morphological features of aligned words. Agreement violations are detected by comparing the number feature between a verb and its subject. Finally, prepositional errors include missing or incorrect prepositions. The scoring mechanism assigns a score of 2 for each error, counting the number of detected grammatical mistakes to determine the final score.

5 Evaluation

We evaluate the weighted DL model, the unweighted DL model and the RB model on the test set with known items and unknown items, respectively, as well as on the combination of the two test sets (henceforth called combined test set). Table 3 reports the accuracy, i.e. how often the exact gold score was predicted, and Quadratically Weighted Kappa (QWK), which penalizes greater deviations from the gold score more severely than smaller deviations.

For the DL models, we expected a drop in performance when comparing the scoring of responses to known versus unknown items, but not for the RB model. In fact, we see a considerable drop for the DL models: For example, QWK decreases from .93 to .62 for the unweighted DL model and from

⁷The thresholds worked well in our trial runs but could be tuned more systematically in future work.

Model	Known It.		Unknown It.		Combined	
	acc	qwk	acc	qwk	acc	qwk
DL unw.	.71	.93	.46	.62	.52	.72
DL weigh.	.78	.94	.51	.83	.57	.87
RB	.73	.90	.66	.87	.68	.87

Table 3: Accuracy and QWK for the deep learning models (DL) without class weights (‘unw.’), with class weights (‘weigh.’) and the rule-based model (RB), respectively, on the test sets with known items and unknown items, respectively, and the combined test set. Numbers in bold indicate the best model per set and metric.

.94 to .83 for the weighted DL model. For the RB model, there is only a slight drop from .90 to .87, which may also be due to chance considering the rather small test sets.

Overall, the weighted DL model is the best performing model on the known items, while the RB model is the best performing model on unknown items. On the combined test set, both models perform on par in terms of QWK (.87), but the RB model attains higher accuracy (.68 compared to .57). The weighted DL model consistently outperforms the unweighted DL model.

When looking at the confusion matrices of the three models based on the combined test set (Figure 3), we see that the greatest weakness of the unweighted DL model is that it hardly ever predicts score 3 and only rarely score 4. In fact, on unknown items it never predicts score 3 and only once score 4, hence it fails to generalize when a response is to be counted as (almost) correct. For the other two models, we see almost no large deviations from the gold standard, which was already reflected in the overall high QWK scores.⁸

5.1 Fine-Grained Model Comparison

In the following, we will restrict the discussion to the weighted DL model and the RB model and look more closely into their commonalities and differences.

From the confusion matrices (Figure 3) we see that the RB model has a distinct tendency to undervalue the responses: Out of 176 misclassified responses, 147 (84%) receive a score lower than

⁸There is one extreme outlier where the RB model predicts score 0, while the gold score is 4. This occurred because the response contained multiple repetitions of the stimulus sentence, and a bug prevented truncation of this particular case, contrary to what was prescribed by the preprocessing step described in Section 4.2.

DL	RB	Gold	Count	Perc.
•	•	•	209	41%
•	-	•	87	17%
-	•	•	140	27%
•	•	-	53	10%
-	-	-	26	5%
Total			515	100%

Table 4: Number of responses in the combined test set for which all three, only two or none of the scores given by the deep learning model (DL), the rule-based model (RB) and the gold standard are identical. ‘•’ indicates that the same score was assigned.

the gold standard, i.e. the model tends to be stricter than the human raters. For the DL model, there is a similar trend, but proportionally it is not as extreme: Out of 219 misclassified responses, 157 (72%) are undervalued (note that in terms of absolute numbers, there are more undervalued items for the DL than for the RB model).

In Table 3, we saw that the RB model had an overall higher accuracy on the combined test set than the DL model. But does this mean that it correctly predicts most of the responses that the DL model also scores correctly – plus some additional ones – or do the two models actually succeed on different sets of responses?

Table 4 shows a breakdown of how often either both models or only one of them or none agrees with the gold standard and how often the two models agree with each other on the combined test set. In sum, only for 51% of the responses, the DL model and the RB model predict the same score. When they agree with each other, this does not necessarily mean that they are correct because for 10% of the responses, both models agree but they both deviate from the human gold standard (which can, in fact, also point to human ratings being inconsistent with the scoring rubric, see Section 5.2). On the other hand, for 85% of the responses at least one of the models is correct, i.e. agrees with the human gold standard. For 27%, only the RB model is correct and for 17% only the DL model. This indicates that both models have different strengths and weaknesses that we will examine more closely in the following.

Table 5 shows a breakdown of precision, recall, and F1-score per gold score for each of the two models. We see that for all scores but score 2, the RB model performs better or on par with the DL model. For score 4, the difference is most striking, with a very high recall of the RB model (.96) and

Figure 3: Confusion matrix of gold score vs. predicted score per model.

Score	Precision		Recall		F1	
	DL	RB	DL	RB	DL	RB
0	.84	.86	.83	.93	.83	.89

micro avg	.64	.69	.57	.68	.57	.66

Table 5: Precision, recall, and F1-score per gold score, as well as macro average and micro (=weighted) average, for the deep learning model with class weights (DL) and the rule-based model (RB) based on the combined test set. The numbers in bold indicate the higher value in precision, recall, and F1-score, respectively, per score.

a very low recall of the DL model (.25). Only for score 2, the DL model clearly outperforms the RB model. This is partly in line with our expectation that the DL model performs better at scores where the scoring rubric categories are rather vague (e.g., responses with changes in grammar can receive either score 2 or score 3 depending on whether the sentence is still grammatical and meaningful). We will qualitatively discuss some of the misclassifications in the following section.

5.2 Discussion of Misclassifications

In the following, we will qualitatively discuss some of the misclassifications of the models to identify their potential limits and also to find leverage points for improvement.

Limitations of the deep learning model We saw that the deep learning model has a strikingly low recall for score 4. In fact, except for one response, the cases where the model failed to predict score 4 were caused by responses to the two previously un-

known items. This indicates that the model failed to generalize to new sentences when a response is to be rated as fully correct. This is the case even when the responses are exact repetitions of the target sentence (38 out of 72 misclassifications). While these misclassifications could potentially be eliminated by passing a similarity score to the model, the remaining errors are harder to mitigate. This concerns, for example, accepted typos in a response, where the advantage of the RB model is that we can specify exactly what counts as a typo.

Limitations of the rule-based model For the DL model, we do not easily know why a response was misclassified but for the RB model we can analyze which categories were missed or falsely detected. We found some systematic causes for misclassifications:

Firstly, the model sometimes fails to differentiate between spelling errors, typos, and grammatical errors. One particular problem is the treatment of real-word spelling errors, i.e. (potential) spelling errors that result in another existing word form, e.g. *fährt/fahrt* (3SG/2PL of ‘(to) drive’ or *es/er* (‘it/he’). They make the sentence ungrammatical or not meaningful but are overvalued by the model because only a spelling error is detected. On the other hand, misspellings can result in nonsense words that are unknown to spaCy, which impacts the syntactic or morphological analysis of the sentence. For example, we found that when the spelling of *Musik* (‘music’) is changed to *Music*, spaCy assigns it neuter gender (instead of feminine), so that a model classifies the sentence as containing a grammatical error.

Furthermore, the model cannot determine well whether a substitution preserves the overall meaning and grammatical structure of the sentence, leading to an undervaluation of examples like *Die*

Häuser sind nicht sehr/so schön ('The houses are not **very/so** pretty') or *Kosten der Häuser / Kosten von Häusern* ('costs of the houses'). This is mainly important to differentiate between scores 2 and 3, which explains the low performance of the model for these scores.

Limitations of the human ratings In fact, not all deviations from the gold standard turned out to be true misclassifications. In some cases the models uncovered inconsistencies in human ratings, e.g. where human raters had overlooked deviations or not followed the rubric, but these cases were rare.

6 Conclusion and Future Work

We implemented an automated scoring procedure of a German WEIT using two approaches: a rule-based approach with manually crafted rules implementing the specific categories listed in the scoring rubric, and a deep learning approach that received pairs of stimulus sentences and test-takers' responses as training data. We found that the overall performance of both kinds of models is promising but not yet optimal, and that both approaches have different strengths and weaknesses. The rule-based model outperformed the deep learning model on previously unseen stimulus sentences and for the scores at the edges of the rating scale. The deep learning model, in contrast, was more successful in some cases of mid-range scores, for which explicit rules are harder to define.

The results indicate that a promising direction for future research could be to develop an ensemble or hybrid model: using rule-based scoring for categories with very high precision, and training a DL model only for those where clear rules are difficult to define. It also remains to be investigated whether Large Language Models (LLMs) with their broad language comprehension capabilities could contribute to the automated scoring or detection of specific error categories.

Limitations

One clear limitation of our study is that we only evaluated one deep learning model (DistilBERT). Different models, especially models operating on the character level, may lead to better results, e.g. by better capturing spelling errors and typos, and are worth investigating in future work. Furthermore, given that the class weighting had a great impact on the DL model, finding the optimal

weighting could be investigated more systematically. In general, there could be a more systematic fine-tuning of hyperparameters but this would require access to larger computational resources, e.g. servers, that we wanted to avoid. Furthermore, we only used spaCy and no other tools for annotating the linguistic structure of the responses, which has a considerable impact on the overall performance of the rule-based model. Trying other or combining different linguistic processing tools could improve the results. Another limitation is that some of the deviation categories from the scoring rubric pertaining to scores 2 and 3 were not implemented yet in the rule-based model, which probably in part accounts for the weaker performance of the model for these scores compared to the other scores. Some of these rules could be implemented in future work by adding further specific resources (e.g. about German plural formation) while others, such as detecting sentences which are grammatical but not meaningful, could be tackled by using LLMs or finetuning models to specifically detect such cases.

Ethical Considerations

Our study investigated whether it is, in principle, feasible to automatically score a German WEIT. Our aim was to approximate human ratings as closely as possible, which means that there is a risk that potential biases in human ratings could be inherited by automated scoring systems. Furthermore, any biases present in the dataset may be reflected in the models. If the automated scoring of the test was used in a real-world application, it could have positive ethical impacts such as a better accessibility of language tests where they would otherwise not be available due to a lack of human raters. However, in a real-world scenario, a range of further ethical considerations would apply, e.g. regarding fairness, whose discussion is beyond the scope of this paper.

Acknowledgments

The WEIT for German was conceived, developed, and the data collected as part of a research project funded by the Deutsche Forschungsgemeinschaft (DFG), grant number 462766474. We would also like to thank the anonymous reviewers for their very helpful comments.

Abstract

Since the release of ChatGPT, Large Language Models (LLMs) have been proposed as potential tutors to students in the education outcomes. Such an LLM-as-tutors metaphor is problematic, notably due to the counterfactual generation, perception of learned skills as mastered by an automated system and hence non-valuable, and learning LLM over-reliance.

We propose instead the LLM-as-mentee tutoring schema, leveraging the Learning-by-Teaching protégé effect in peer tutoring - *LLM Protégés*. In this configuration, counterfactual generation is desirable, allowing students to operationalize the learning material and better understand the limitations of LLM-based systems, both a skill in itself and an additional learning motivation.

Our preliminary results suggest that LLM Protégés are effective. Students in an introductory algorithms class who successfully diagnosed an LLM teachable agent system prompted to err on a course material gained an average of 0.72 points on a 1-6 scale. Remarkably, if fully adopted, this approach would reduce the failure rate in the second midterm from 28% to 8%, mitigating 72% of midterm failure.

We publish code for on-premises deployment of LLM Protégés on https://github.com/Reliable-Information-Lab-HEVS/LLM_Proteges.

1 Introduction

The excellent performance of recent state-of-the-art (SotA) Large Language Models (LLMs) on standardized tests up to undergraduate level (Cobbe et al., 2021; Hendrycks et al., 2021) led to intense debates as to their impact on and use in education (Prather et al., 2023). While immediate concerns have focused on the usage of LLMs by students for cheating (Lau and Guo, 2023), the

long-term concern is how to best leverage LLMs in education and preparing the students for a world where LLMs are commonplace, leading to a focus on LLMs as personal tutors if not outright teacher substitutes (Chan and Tsi, 2023).

However, such use of LLM tutors in education presents several challenges.

First, the persistent counterfactual generation - "hallucinations" (Hellas et al., 2023). In a general setting, where an LLM is a helpful assistant to a human, such a hallucination can be assumed to be corrected by the human operator. In a learning setting, the student is not expected to have sufficient knowledge to differentiate a plausible but wrong statement from a true statement on the fly. Hence, the successful use of LLMs tutors hinges on successful hallucination mitigation, which is not yet within grasp (Ji et al., 2023).

Second, the LLM performance in standardized tests and academic competitions has been increasingly linked to test data leakage and memorization rather than true generalization (Balunovic et al., 2025). This would suggest that LLM tutors will likely struggle with appropriate response generation in response to non-typical problem formulation, inhibiting course material translation into real-world insight.

Third, the impact on students' motivation to learn the subject already apparently mastered by an LLM over concerns of learned competences relevance for downstream employment (Rony et al., 2024). Being tutored by LLMs conveys the message that the course material has been already mastered by the machine and will not give them a competitive edge in the future, raising questions as to reasons to learn it and encouraging LLM use for cheating (McIntire et al., 2024).

Finally, the overreliance on LLMs, given the authoritativeness of their output when they are presented as tutors (Bender et al., 2021; Zhai et al., 2024), and assume error on their side in case of

*Work performed while at HES-SO Valais-Wallis

disagreement with LLM (Kim et al., 2023). Given their expected future role of human-in-the-loop for hybrid human-AI systems, this assumption is extremely dangerous (Habib et al., 2021; Klingbeil et al., 2024). Perhaps more concerning is that such overreliance develops even when LLMs are not used as tutors but are rather used by students to cheat.

1.1 Peer Tutoring and Protégé Effect

In order to address these challenges, we propose *Protégé LLMs* with knowledge gaps, drawing on both overreliance mitigation research and past computer-assisted peer tutoring. Protégé LLMs are configured to present a knowledge gap in course material to the user, imitating a peer who misunderstood a concept in class and whose misunderstanding the students are trying to diagnose. Such an approach demonstrates AI failure mode to the user, an effective pathway to overreliance mitigation (Nourani et al., 2020), and by emulating peer tutoring (Topping, 1996; Galbraith and Winterbottom, 2011), which is known to foster a deeper engagement with course material through learning-by-teaching (LBT) (Duran, 2017), even if students are interacting with a peer-like program (Chase et al., 2009; Matsuda et al., 2010).

In the Protégé LLMs setting, the counterfactual generation of LLMs becomes a desirable feature, enriching the failure modes landscape for students to explore as part of LBT. This mechanism and overall positive effect of failures is remarkably similar to that of software in Capture-the-Flag (CTF) competitions, generally considered critical to professionalizing cybersecurity training (Carlisle et al., 2015).

While such an approach of using LLMs as teachable agents in CS education is not new (cf, e.g., Jin et al. (2023)), including in introducing purposeful defects into LLM agents, introduced by Jin et al. (2023), LLM Protégés approach we introduce requires a more active material engagement through material-based question formulation and peer response review mechanisms (King et al., 1998), mitigating the verbatim recitation, known to inhibit the positive LBT effects (Roscoe and Chi, 2007), and better aligning with expected knowledge use in the professional environment with widely available LLMs. Moreover, LLM Protégés are straightforward to deploy and adapt to new domains, mitigating the labor intensity of previous teachable agents configuration, testing, and deployment (Weitekamp

et al., 2020; Matsuda, 2021).

2 Methodology

Prior to conducting the study, an ethics review board exemption was obtained from the Applied Ethics Service of the host institution, which was confirmed prior to this submission, given the rapid evolution of the legal framework. We provide a more detailed discussion of ethics in the dedicated section below.

2.1 Model selection

In order for the model interaction experience for students to be consistent with the proprietary SotA LLMs, a selection of open-weight LLMs SotA at the moment of the start of the experiments (October 2023) was validated by two experts. Specifically, Mistral-7B-Instruct-v0.1 (Jiang et al., 2023) (Mistral), Openchat_3.5 (Wang et al., 2023) (Openchat), CodeLLaMA-34b-Instruct (Rozière et al., 2023) (CodeLLaMA), and LLaMA-2-70B-chat (Touvron et al., 2023) (LLaMA2)¹ were evaluated for an ability to answer questions covering course material, namely:

- Analysis of simple code complexity²
- Generation of Python code for one-on-one meeting planning in a group
- Generation of a Visual Basic (VBA) while loop example
- Explaining why the Traveling Salesman Problem (TSP) is NP-Hard
- Explaining what is a binary search tree and what it can be used for

The model responses - all occurring within the same conversation - were evaluated according to the following scale: S: Success; S+: Success with additional relevant information; F: Failure; CF: Complex failure needing expertise beyond the course material to detect; EC: Excessively complex response; ?: Model failed generation.

Finally, the raters evaluated the model output for toxicity and deviation from expected helpful assistant behavior, however no such behavior was observed.

¹Links to the model download locations are in appendix A.6

²Specific prompts are provided in appendix A.1

2.2 Addition of knowledge gap

Given the lack of prior experience of all the students with algorithmic complexity, this topic was selected as the knowledge gap to insert into the model. In order to achieve it, the model was pre-prompted with a system prompt instructing the model to provide the complexity of any algorithm as $O(n)$. Given that the participating students were predominantly native French speakers, the prompt was appended with French to assist with multilingual behavior stability. The full system prompt is available in Fig. 7.

2.3 Model deployment

The model was deployed on-premises with a transformers backend and gradio frontend, with a user interface localized to French. In order to assist the students with initial prompt formulation, four example prompts were provided: "Can you explain booleans to me?", "What are the complexity classes?", "How to write a filter in Excel?", and "What are the algorithms to traverse a graph?". The user interface is shown in the Fig. 8. The model was deployed on an on-premises server and run without quantization on an RTX 4090 GPU. The conversations were not logged. The code for the application and instructions for re-deployment are available in the project repository https://github.com/Reliable-Information-Lab-HEVS/LLM_Proteges.

2.4 Participant enrollment and instructions

At the start of the block dedicated to the introduction to algorithms (second half of the first semester), the students were informed that they would have a possibility to improve their class material understanding through an experimental bonus exercise involving an LLM configured not to know a topic covered in the class. They were informed that the participation was non-mandatory and that the participants, whether they were successful or not, would be rewarded with bonus points³ for the next midterm, with successful participants gaining more bonus points. The bonus points for LLM experiment participation and any other bonus points were

³In the context of this class, bonus points are awarded for an effort going beyond the majority of the class to engage with the class material and coursework; LLM failure mode diagnostic on course material is hence considered as a bonus exercise the use of bonus points is consistent with the rest of the class.

removed prior to the analysis for both midterms considered.

Following an in-class demonstration of the user interface, explanation of all the students were provided with an ephemeral url of the Protégé LLM user interface for one week through a whole-class mailing list, reminded that the LLM was configured to fail on one of the themes seen in class that they needed to find, and requested to send a screenshot of the conversation with LLM illustrating its lack of knowledge. Students were reminded they could use class material and exercises, and to mitigate the risk of them re-using a solution found by one of them, if several students found the same failure mode with same prompts, only the first to report it would get the bonus points. The full text of the sent instruction is available in appendix Fig. 9.

2.5 Participant demographics

The student population in this study was enrolled in the first year of a Bachelor in economy and management at an applied sciences university with French as the primary teaching language. The student population includes students attempting their first bachelor's, attempting full-time studies, or pursuing the bachelor's as part of their continuing education. Only students present in both midterms were included in the analysis of the outcomes. In total, 75 students qualified for study inclusion.

Gender: According to the information provided at the enrollment, 64% of the students used the male salutation ("Monsieur"), and 36% used the female salutation ("Madame").

Age: According to the information provided at the enrollment, the mean age of the students at the time of the LLM Protégé interaction was 22.3 years, with a standard deviation of 3.1 years. Ages spanned 18.7 to 38.6 years, with a median of 21.5.

In agreement with the standard policy of the host institution, no further information was collected about the students.

2.6 Outcome assessment

The effect of the LLM Protégé tutoring has been assessed as the change in grade relative to the class average between the first and second midterm (Δ_1 and Δ_2 , respectively). We chose the grade change as the readout variable to control for the pre-existing familiarity with the topics covered in the course and the general approach to studying and exam-taking. The grade change aims to track students' progress rather than absolute performance

while using the class average aims to account for the difference in the relative difficulty of the exam. Overall, we perform the educational scenario effect (ES_{eff}) regression as $\Delta_2 = \Delta_1 + ES_{eff}$.

Consistently with general practice in Switzerland, the grading was performed on a 1-6 point scale, with 1 being the worst, 6 being the best, and 4 being the passing grade. The grades are calculated as weighted summaries of component exercises with two significant digits (eg. 4.09), and given to students as rounded to the first digit (eg. 4.1 for the example above).

Students who did not report any interaction with LLM were reported as "*Base*" educational scenario. Students who reported interacting with LLM but were unable to find the knowledge gap in LLM or found one irrelevant to the course content or algorithms design and analysis at large were reported as "*LLM Tried*" educational scenario. Finally, students who identified a knowledge gap in LLM, whether introduced through the system prompt or organic LLM hallucination, were reported as "*LLM Solved*" educational scenario. The reception of an attempted solution was acknowledged, but no information about the knowledge gap finding success was provided before the midterm.

Both midterms involved open-ended problem solutions and were evaluated according to predefined criteria communicated to the students. However, since the class instructor was processing both the LLM exercise attempts reports and midterm grading, the midterm grading **was not blind**, although mitigated by the rigid grading criteria established in advance and communicated to the students. Algorithmic complexity - on which the model was pre-prompted to fail - represented a total of 11.7% of the midterm grade (0.59 points).

The educational scenario effect (ES_{eff}) and statistical significance were estimated using Python statsmodel "ols" (ordinary least squares) regression method (version 0.11.0) as $\Delta_2 = \Delta_1 + ES_{eff}$, with p-value corresponding to the t-test of two-tailed null slope hypothesis (no observable effect).

3 Results and Discussion

3.1 Model selection

The rating results are presented in the table 1. While the overall rating agreement is only moderate (Cohen’s Kappa of 0.51), both raters were unanimous that `Mistral-7B-Instruct-v0.1` performed satisfactorily across all the topics relevant

to the course. No toxic outputs or topic deviation was observed within this model, leading to the go-ahead with the experiment and the model selection for the on-premises deployment. Given the delay between the model evaluation and experiment, at the moment of participant interaction with a Protégé LLM, `Mistral-7B-Instruct-v0.3` was used as the successor model recommended by the developer.

Task	Model Performance			
	LLaMA-2	CodeLLaMA	OpenChat	Mistral
Complexity	S/S	S/S	S/F	S+/S+
Python	S/S+	S/F	EC/EC	S+/S+
VBA	F/F	S/?	CF/?	S/?
NP-Harness	CF/F	CF/EC	CF/CF	S/S
Binary tree	F/F	EC/S	F/F	S/S

Table 1: Ratings of model performance according to the two raters. S/S+ are successes, F/CF are failures, EC is excessively complex, and ? denotes failed generation.

3.2 Educational outcomes

Out of 75 enrolled students, 5 discovered a valid failure mode ("*LLM Solved*"), and 3 attempted but did not find a valid failure mode ("*LLM Tried*"), and 67 students did not engage with the LLM Protégé ("*Base*"). The first midterm saw an average of 4.66 with a standard deviation of 0.68, a median of 4.63, and 13 students below passing grade. The second midterm saw a mean grade of 4.35, a standard deviation of 0.85, a median of 4.47, and 21 students below passing grade. The distribution of the student grade change relative to the midterm average ($\Delta_2 - \Delta_1$) can be found in Fig. 1.

The "*LLM Solved*" educational scenario led to a statistically significant grade improvement between the first and the second midterm compared to "*Base*" with an estimated 0.72 (14%) point gain with a p-value < 0.022 and 95% confidence interval of [0.11-1.34]. Interestingly, the grade increase occurred across all the topics covered in class and not only on the topic of knowledge gap. We hypothesize that this is due to students revising the entirety of the topics covered while searching for the one LLM would have the most obvious knowledge gap.

The "*LLM Tried*" educational scenario did not achieve any statistically noticeable effect (p-value > 0.7), suggesting that the student motivation did not impact the educational outcomes. Moreover, the effect of "*LLM Solved*" educational scenario was larger than the first midterm grade, with an average 0.56 points ([0.33-0.78] 95% CI). Anecdotal post-

Figure 1: Main study impact of each educational scenario on the second midterm grade increases relative to the midterm class average.

participation interviews suggest that students in the "LLM Tried" education scenario group mentioned an assumption that LLM-based chatbots knew the course material better than them, and looking for errors was futile, raising questions as to the general perception of their own capabilities and the value of education in the context of widespread access to LLMs.

Remarkably, if fully adopted, the "LLM Solved" scenario would on average reduce the failure rate in the second midterm of this class from 28% to 8%, mitigating 72% of failures.

3.3 Larger sample generalization

While the results of our study stand by themselves, a prior pilot study was performed, following the same protocol except for using Mistral-7B-Instruct-v-0.1 model instead of Mistral-7B-Instruct-v-0.3. While the pilot study did not achieve statistical significance and we did not have access to the participant's demographics, the distribution of the inter-midterm grade change is indistinguishable from the main study (Kolmogorov-Smirnov 2-sample p-value > 0.62). The distribution of the student grade change relative to the midterm average ($\Delta_2 - \Delta_1$) for combined datasets can be found in Fig. 10 (Appendix A.5).

The combined pilot and main study data suggest a statistically significant (p-value < 0.016) improvement of grade for the "LLM Solved" group of 0.60 points (12%) and a 95% confidence interval of [0.11-1.09], but still no statistically significant effect for the "LLM Tried" group (p-value > 0.64).

Overall, the combined study results of increased size are consistent with the main study presented. The individual effects statistics are presented in Table 2.

	est. effect		p-value >		95% CI	
	main	+pilot	main	+pilot	main	+pilot
LLM Solved	0.72	0.60	2.2%	1.6%	0.11-1.34	0.11-1.09
LLM Tried	0.14	-0.14	72%	64%	-0.65-0.93	-0.72-0.45
First Midterm	0.56	0.56	0.1%	0.1%	0.33-0.78	0.38-0.73

Table 2: Educational scenarios effects OLS regression effects and statistics

4 Conclusion

Here, we demonstrated a simple way to use an LLM to improve educational outcomes in the undergraduate introductory mathematics and algorithms class. Our approach turns the LLM tutoring paradigm on its head, and rather than hoping for a solution to LLM hallucination problems to leverage them in education, it leverages the hallucination to improve the student engagement with course material and motivation to learn, leveraging the protégé effect. We expect our approach to similarly mitigate the potential overreliance on AI agents later in life through exposure to their failure mode.

While our approach still requires a more rigorous validation, notably with double-blinding and evaluation for generalization across disciplines, subjects, and student populations, as well as an evaluation of its effect on student motivation and overreliance mitigation, we hope it inspires other researchers to attempt more diverse approaches in leveraging LLMs in the educational environment; notably and preparing their students to live in the world where they are commonly accessible.

Acknowledgments

This work has been funded by a grant from the Permanent Desk for Digital Experimentation of the HES Digital Skills Center of HES-SO No. 126345. We thank Prof. Dr. Henning Muller and Dr. Ivan Eggel for providing the compute infrastructure needed for the pilot run of the project, Dr. Jean-Gabriel Piguet for the ethics aspects consulting, and Dr. Anna Sotnikova for the early draft feedback.

Limitations

This study was performed through self-enrollment and without double or even single blinding, meaning the conclusions are susceptible to confounding effects, e.g., from student self-selection. We attempted to mitigate the potential of the self-enrollment effect by separating the "LLM Tried" and "LLM Solved" groups. Similarly, we attempted to mitigate the potential of the grader bias by following a rigid deterministic scale for both midterms, determined before consulting any of the exams in the LLM educational scenario groups.

Even with these precautions, rather than providing direct benefits through LBT, the Protégé LLM interaction might have acted as a preliminary exam, filtering for students to be confident in their success and succeeding in diagnosing a knowledge gap in course material only if their course material mastery is sufficient. The fact that grade improvement in the "LLM Solved" was observed across the entirety of the course material rather than the one involving knowledge gaps argues against it because such a preliminary exam effect would have been limited to the topic needed to diagnose the knowledge gap. Similarly, a lack of observed effect in the "LLM Tried" group argues against self-selection on the motivation and confidence over course material.

Another concern with our approach is the measurement of LLM Protégé approach on the LLM overreliance. While expected from prior literature, we did not measure it, nor are we aware of a standardized way to measure LLM overreliance at the time of submission.

Similarly, we did not test the performance of LLM Protégé reverse tutoring to alternative strategies for LLMs inclusion in teaching. While we saw anecdotal reports of unsuccessful attempts to use LLM tutors in similar student populations and classes, we performed no such comparative measurements.

Finally, it is unclear how well the LLM Protégé approach generalizes. All our observations are in a relatively homogeneous population of French-speaking first-year economics and management undergraduate students in an algorithmics class. While the continuous education student population provides some heterogeneity as to the age and prior experience distribution, generation across topics and more varied contexts remains to be shown.

Ethical Considerations

Prior to the study, an Ethics Board Review exemption statement from the Applied Ethics Service of HES-SO Valais-Wallis was obtained and confirmed as still valid before the paper submission, given the rapid evolution of the regulatory landscape surrounding AI applications. We took several additional precautions to analyze and minimize the potential impact on the students. Specifically:

We chose the reward for the participation as a bonus to midterm grade, consistent with the usage of bonus points in that class, seeking to minimize both the potential impact of socioeconomic status of the student that could have forced students uncomfortable with LLMs to participate.

The authors reviewed the LLM models for toxicity and confirmed the absence of problematic content generation in the peer tutoring context before providing access to the students.

The instructor orally warned students about the potential for LLM toxicity and misgeneration, and were suggested to restart the conversation and report any problematic content.

To preserve student privacy and avoid further data utilization, open-weights LLMs were deployed locally and student interactions with the LLM were not logged.

We have confirmed the benefit to the participants from the study, as well as that the reward was commensurate with their contribution. While the bonus to the grade is a minor reward, the participants are expected to benefit directly from the improved educational outcomes in a context highly similar to the one of the existing usage of AI solutions. Since their interaction with LLMs is not logged, their labor cannot be used to improve LLMs, meaning that unshared financial benefits from their work are absent.

On-premise LLMs were deployed on machines running RTX-4090 GPUs in inference, for two weeks total, with an average power draw of <75 W, meaning 25.2 kWh were used, which at the average CO² intensity of electricity generation in the servers location amounted to 1.4 kg of CO² emissions.

AI assistance was used only for grammatical proofing (Grammarly) and reverse definition lookup (LLaMA-3.3-70B). No text or code is AI-generated.

LEVOS: Leveraging Vocabulary Overlap with Sanskrit to Generate Technical Lexicons in Indian Languages

Karthika N J, Krishnakant Bhatt, Ganesh Ramakrishnan, and Preethi Jyothi

Indian Institute of Technology Bombay, India

{karthika, kkbhatt, ganesh, pjyothi}@cse.iitb.ac.in

Abstract

Translating technical terms into lexically similar, low-resource Indian languages remains a challenge due to limited parallel data and the complexity of linguistic structures. We propose a novel use-case of Sanskrit-based segments for linguistically informed translation of such terms, leveraging subword-level similarity and morphological alignment across related languages. Our approach uses character-level segmentation to identify meaningful subword units, facilitating more accurate and context-aware translation. To enable this, we utilize a Character-level Transformer model for Sanskrit Word Segmentation (CharSS), which addresses the complexities of sandhi and morphophonemic changes during segmentation. We observe consistent improvements in two experimental settings for technical term translation using Sanskrit-derived segments, averaging 8.46 and 6.79 chrF++ scores, respectively. Further, we conduct a post hoc human evaluation to verify the quality assessment of the translated technical terms using automated metrics. This work has important implications for the education field, especially in creating accessible, high-quality learning materials in Indian languages. By supporting the accurate and linguistically rooted translation of technical content, our approach facilitates inclusivity and aids in bridging the resource gap for learners in low-resource language communities.

1 Introduction

English is the most widely used language in academic books and as a medium of instruction worldwide. India has 22 official languages in addition to English. Over the years, works like (Hudelson, 1987) have established the power of language in students' learning. Aligned with these studies, the Indian Government has proposed several changes to the education system, among which multilingual knowledge dissemination assumes an important role. The proposal involves introducing regional

languages at various levels of education. Carrying out this proposal leads to massive resource requirements like textbook translations and content creation. With the limited technical content availability in non-English languages, especially at the higher education level, translating technical terms from English to other languages is a challenging task that needs to be addressed.

Maheshwari et al. (2024) presents the importance of domain-specific lexicon generation, especially catering to the technical domains, and its importance for translation tasks with low-resource languages as the target. Kunchukuttan and Bhattacharyya (2016) shows the importance of subword segmentation and lexical similarity of languages in the translation task. Additionally, Sanskrit language is known to be a lexically rich, flexible, and well-structured language with the potential to create meaningful new words easily. In this paper, we introduce a use case of Sanskrit-based sub-word level segmentation in word and phrase-level translation of academic/technical terminologies to leverage the large overlap of vocabulary among Indian languages. For the generation of technical terms in low-resource regional languages, we propose to utilize the high vocabulary overlap of Indo-Aryan and Dravidian languages with Sanskrit, thereby performing a lexically informed translation.

Compound words are formed by combining two or more meaningful subwords. In Indian languages, compounds may be formed either through simple concatenation without boundary changes or by following sandhi rules, resulting in boundary modifications. Decomposing a compound Sanskrit word involves segmenting it into smaller, meaningful lexical units. Existing methods used for the Sanskrit Word Segmentation (SWS)¹ task can be roughly classified into two categories: tack-

¹We use the term segmentation for the task of splitting a compound word into its meaningful constituents.

ling the broader task of SWS and sandhi splitting-specific techniques. The former includes works like (Gérard, 2003; Sriram et al., 2023), a lexicon-driven shallow parser. Hellwig and Nehrdich (2018a) processes compound sandhi words at the character level using recurrent and convolutional neural networks. Sandhan et al. (2022) presents TransLIST, integrating a module that appends additional latent information from SHR to the input sequence. It also employs a soft masked attention mechanism to prioritize relevant subword candidates and incorporates a path ranking algorithm to mitigate erroneous predictions. Alternately, Aralikatte et al. (2018) proposes a dual-decoder approach where the first decoder identifies the location for the sandhi split (sandhivicchēda)², and the second decoder predicts the segmented output. Similarly, Dave et al. (2021) applies an RNN encoder-decoder-based two-stage methodology to predict the location and final splits. Nehrdich et al. (2024) presented a new language model pre-trained for Sanskrit and further fine-tuned and utilised the model for various downstream tasks including word segmentation, lemmatization and morphosyntactic tagging tasks. We use a similar architecture in our CharSS model, to generate the word-splits.

Our main contributions through the paper are:

- We present the utilization of a character-based Transformer model for the segmentation of compound words (including sandhivicchēda) in Sanskrit (Section 2.1).
- We propose a Sanskrit-based input augmentation method using relatively resource-rich Hindi translations to generate linguistically informed technical lexicons for lexically similar, low-resource languages (Section 2.2).
- Through comprehensive experiments, we show the efficacy of our proposed methodologies. We test CharSS on three benchmark datasets for SWS. Similarly, we experiment with our technical term translation process for multiple low-resource languages, generating better-quality technical lexicons in the target languages (Section 3).

2 Methodology

2.1 Sanskrit Word Segmentation

Figure 1 illustrates the proposed methodology for SWS. We formulate the task of sandhi splitting and Sanskrit Word Segmentation as a standalone

²We follow ISO-15919 script to mention Roman translations of Indian language text for better readability.

sequence-to-sequence transformation problem. For this purpose, we propose to utilize a character-level Transformer model such as ByT5.

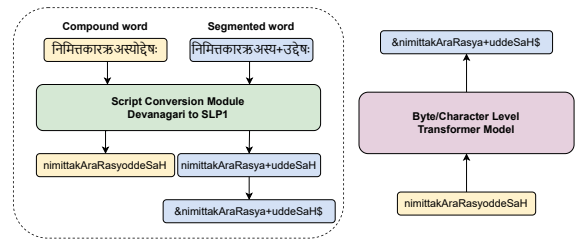

Figure 1: Illustration of the proposed methodology for SWS task.

ByT5. The ByT5 (Byte-Level Text-to-Text Transfer Transformer) model (Xue et al., 2022) processes text as sequences of bytes, bypassing the need for language-specific tokenization. This approach enables it to handle diverse languages and scripts effectively, including rare words and complex orthographies. ByT5 is built on the T5 (Raffel et al., 2020) framework. It poses all tasks as text-to-text problems, enhancing its versatility. ByT5 demonstrates strong performance on multilingual and code-mixed tasks, making it particularly suitable for low-resource languages and domain-specific vocabularies. The input to the model is a single Sanskrit word (unigram), and the output consists of the segmented sub-tokens of the word, which are concatenated using a "+" symbol to indicate the split. We prepend the target split with an "&" symbol to denote the start and append a "\$" symbol to mark the end of the target split as shown in Figure 1 to allow for precise delineation of morpheme boundaries.

2.2 Technical Term Translation

In this paper, we propose a linguistically informed method to translate technical terms in English to low-resource Indian languages. This process entails a crucial input augmentation phase prior to the modeling and training stages to enhance the input for model training. The raw dataset comprises technical terms for English and translation to Hindi. We prepare supplementary data for augmentation using the methodology described below.

Sanskrit-based augmented input

There is a significant vocabulary overlap among Indian languages, especially with Sanskrit. In this

Figure 2: The process of generating Sanskrit-based augmented input for the English term 'reevaluation', for translation model

work, we attempt to leverage this overlap by using available dictionaries in the resource-rich Hindi language to generate the corresponding terms in other Indian languages. Figure 2 shows the steps to obtain the proposed augmented input. For a given technical term, we first normalize the corresponding term in Hindi as explained in Appendix A.1. We then remove the Hindi-specific affixes from the words to get the lemma. Finally, we perform segmentation of the normalized lemma and pass them as additional input to the translation model to aid the generation of technical terms in low-resource Indian languages.

Motivation to use Hindi data to generate Sanskrit-based segments:

There is a significant under-representation of digital resources for all other Indian languages compared to Hindi. Appendix A shows details of this digital data divide. English-Hindi human-translated data is readily available for the domains we considered in this work. We obtained Sanskrit-based sub-word tokens from the available Hindi data for over 76% of training and test instances. Furthermore, a word in one language may have several different translations in another language, depending on the context of usage. Providing the augmented input helps disambiguate the domain of the word. See Section 3.3 for a detailed analysis supporting this argument.

3 Experiments and Results

For the technical term translation task, we utilize the technical bilingual dictionary datasets provided by Maheshwari et al. (2024) which is a dataset curated from CSTT³ dictionaries. The dataset con-

³<https://cstt.education.gov.in/en>

sists of word-level translations from English to 6 Indian languages across 3 domains, *viz.*, administrative, biotechnology, and chemistry, and has 9094 terms in the training data and 1285 in the test data for all domains combined. We obtained Sanskrit-based inputs for all data instances by applying our approach of generating Sanskrit-based additional inputs. We use chrF++ (Popović, 2017) as the evaluation metric for all the experiments under this task.

3.1 Experiments on the SWS Task

For the SWS task, we use word-level accuracy as the evaluation metric. To compare against (Sandhan et al., 2022), we also calculate sentence level perfect match (PM) for SIGHUM and hackathon datasets. We utilize the pre-trained checkpoint of the base variant of the ByT5 model available via Huggingface⁴ and fine-tune it over the UoH+SandhiKosh, SIGHUM dataset, and hackathon datasets as three separate experiments. For details about choice of ByT5 and Experiments with SWS Task (see Appendix B.2).

3.2 Experiments on the Technical Term Translation Task

For this task, we have two experimental settings, both formulated as text-to-text translation. In the first setting, we train and test the NMT model NLLB (Costa-jussà et al., 2022) over all 6 language pairs across 3 domains. In the second setting, we train the model on Hindi, Gujarati, and Tamil across 3 domains and test it over Marathi, Kannda, and Odia across the same domains, which can be considered as a zero-shot setting. In the **baseline** configuration for this task, the model is fed with English input only. In the configuration corresponding to the proposed method, the English input is augmented with additional Sanskrit-based input prepared as discussed in Section 2.2. We utilize the pre-trained 1.3B parameter checkpoint of the NLLB model available via Huggingface⁵ and fine-tune it over the technical domain dictionary data for both experimental settings.

Results. Table 1 reports the comparison of chrF++ scores obtained by finetuning the NMT model with English-only input (NLLB) and with augmented input (NLLB+Sanskrit) under the first experimental setting. In Section 3.2 we analyze the

Test Dataset	Model	Hindi	Marathi	Gujarati	Kannada	Tamil	Odia	Average
Administrative	NLLB	50.23	45.42	43.35	45.68	44.13	43.22	45.33
	NLLB + Sanskrit	54.74	46.07	45.82	47.25	44.07	44.45	47.07
Biotechnology	NLLB	53.52	51.91	3.79	12.38	18.46	17.16	26.20
	NLLB + Sanskrit	60.63	60.73	13.09	29.20	37.89	35.82	39.56
Chemistry	NLLB	48.96	50.64	8.19	16.59	17.43	20.31	27.02
	NLLB + Sanskrit	54.36	55.35	17.41	29.51	33.04	34.07	37.29

Table 1: chrF++ scores on the administrative, biotechnology, and chemistry domains for models with and without additional Sanskrit-based input.

performance of the model with and without additional input in a zero-shot setting. Across experiments, there’s a consistent performance gain with the lexically informed input. Our method archives an average improvement of **8.46** chrF++ scores. We also provide a detailed post-hoc analysis of the predictions in Section 3.3

Zero-Shot Translation

Table 2 shows the performance of the translation model without Sanskrit input (NLLB) and with Sanskrit input (NLLB+Sanskrit) when trained on Hindi, Gujarati, and Tamil, and evaluated on Marathi, Kannada, and Odia across 3 domains *viz.*, Administration, Biotechnology, and Chemistry. Performance in terms of chrF++ scores shows that the translation with the Sanskrit augmented input consistently provides better translations as compared to the English-only input across different languages and domains. This proves the efficacy of Sanskrit-based additional input for capturing multilingual nuances.

Test Dataset	Model	Marathi	Kannada	Odia	Average
Administrative	NLLB	41.42	44.03	40.57	42.01
	NLLB + Sanskrit	43.26	45.71	42.02	43.66
Biotechnology	NLLB	44.42	27.83	29.37	33.87
	NLLB + Sanskrit	53.79	40.32	37.76	43.96
Chemistry	NLLB	41.62	28.41	26.99	32.34
	NLLB + Sanskrit	49.71	39.11	34.13	40.98

Table 2: chrF++ scores on administrative, biotechnology, and chemistry for unseen languages, namely, Kannada, Marathi, and Odia for zero-shot setting.

3.3 Post-hoc analysis

In this section, we present our detailed analysis of a subset of the results of the lexicon translation task. Unlike a regular translation task, which includes a complete sentence and paragraphs, we deal with a single word or phrase here. Such a short input may have many different possible translations in

the target language, either the translations that can be used interchangeably or those that may be varied with the context of its usage. The evaluation metrics like BLEU and chrF may not effectively capture the quality of translation as it is obtained by comparison of the predictions with the available ground truth data. The ground truth data may have a single or limited number of meaningful translations, and as a result, a different but correct prediction may be penalised.

We followed the Human Post-hoc evaluation as per Maheshwari et al. (2024) for the same two additional languages as presented by them *viz.*, Punjabi and Malayalam, using the same subset of input data and metrics. Our goal is to understand the practical utility of the generated lexicon in the respective languages and the extent to which they may be helpful in translating technical books from English to low-resource Indian languages. We achieved an R@1 score of 0.53 and 0.46 for Punjabi and Malayalam, respectively, compared to 0.51 and 0.38 scores obtained by LexGen. The R@3 score for Malayalam is 0.72, comparable to 0.71 for LexGen, while the score for Punjabi was slightly lower, at 0.92, compared to 0.95 for LexGen. We also present detailed analysis of the translation results by a comparative study of the outputs in both the input settings, *i.e.*, with and without the Sanskrit-based augmented output (See Appendix A.3).

4 Conclusion

In this work, we addressed the task of Sanskrit Word Segmentation (SWS) with a character-level Transformer model, achieving superior segmentation performance on two benchmark datasets and competitive performance on another benchmark dataset.. Furthermore, we propose to leverage the significant vocabulary overlap among Indian languages, utilizing data from the relatively resource-rich Hindi language which highlights the potential

of cross-linguistic resource sharing to boost performance in low-resource language tasks.

Limitations

To generate Sanskrit-based input, we rely on the available Hindi data. Though the availability of Hindi resources is much higher than that of other Indian languages, its digital data richness is considerably lower than that of English.

Not all languages exhibit significant vocabulary overlap with Sanskrit, and in such cases, our proposed method may have limited applicability for lexicon generation.

Acknowledgments

A Appendix

A.1 Normalisation

anusvāra (ṃ), is a symbol used in all Indian language scripts to denote a type of nasal sound. According to Sanskrit grammatical rules, when this symbol precedes one of the first 4 characters in each of the consonant group called vargās (ka/ca/ṭa/ta/pa), it needs to be converted to the respective fifth characters (pañcamākṣara) of the vargās (ṅ/ṇ/ṣ/n/m). This rule may not be followed in other Indian languages. Since our sub-word segmentation model is trained on Sanskrit, and applied on Hindi data for the translation task, we normalise all the data by converting all occurrences of anusvāra to the corresponding pañcamākṣara, before passing it to our model for segmentation.

A.2 sandhi

Sanskrit and other Indian languages have common usage of compound words, which are formed from multiple subwords. When two words are combined, the language expects certain rules to be followed at the word boundaries. Such a change in the word boundary forming a compound word, is termed as sandhi (the word has a meaning of *junction*). In Sanskrit, there are specific rules for the joining of subwords to form a compound, depending on the ending character of the first and the beginning character of the second word. We specify these rules as the *sandhi rules* in this paper. Similarly, splitting of the sandhi will also need to follow the reverse process, which is not as straightforward as sub-word joining. In the paper, we specify the process of sandhi splitting as *sandhivicchēda*. Following are some examples of sandhivicchēda (1) tatrāpi = tatra + api; (2) narēndra = nara + indrah

A.3 Post-hoc Analysis of Generated Technical Lexicons

Table 3 shows some qualitative, post hoc analysis of the prediction results. The analysis shows that the augmented input

- Assists the model to disambiguate between multiple possible outputs (synonyms) and obtain the contextually apt term.
- Examples 1 and 2 in table 3 are from the Administration domain, with Kannada as the required target language. The translations generated by the model with only the English input are meaningful but in different contexts. The

word *mass* is considered by the model, in the meaning of *the amount of matter in an object*, while the expected meaning is mass as used in *population*

- Similarly, the word *composition* is expected to take the meaning of *composing music or poetry*, while the meaning taken by the model is *the process of combining parts of something to whole*. Example 4 shows a similar trend in Marathi in Biotechnology domain.

For the above examples, our model is able to disambiguate the intended meaning and generate the expected output.

- Examples 3 is a sample where the output generated with English-only input is incorrect, while the augmented input generates correct output.

We notice that, the performance difference with and without augmented input is less in the administrative domain when compared to other domains. With the observations from the predictions, we arrive at the following reasonings. The words in this domain are very frequently used by people in all languages. The model predictions with augmented input results in many archaic words, which are currently not in use, or the usage is highly infrequent. A word can have a large number of synonyms, and the number of words in the reference list of the ground truth, is limited, which mostly do not include the archaic words. Because of these reasons, we do not see a large jump in the performance with augmented input in this domain. This observation is especially true with languages like Tamil, in which there is a significant number of non-Sanskrit originated words, which may be more commonly in use. In both experimental settings, we observe that the gain is more in case of the biotechnology and chemistry domains as compared to the administrative domain. This behavior can be attributed to the pre-training of the NLLB model on massive generic domain data which has considerable overlap with the administrative domain data.

B Sanskrit Word Segmentation Task

B.1 Data - SWS Task

For the SWS task, following Dave et al. (2021) and Sandhan et al. (2022), we use three publicly available benchmark datasets, *UoH corpus*⁷ combined with the *SandhiKosh dataset* (Bhardwaj et al., 2018), *SIGHUM dataset* (Krishna et al., 2017),

⁷<https://sanskrit.uohyd.ac.in/Corpus/>

Technical term (English)	Domain; Language	Augmented input ⁶	Prediction with	
			English only input	Sanskrit-based augmented input
1 mass	Administration; Kannada	mass <SEP> jana <isep> samūha	dravyamāna	jana-samūha
2 composition	Administration; Kannada	composition <SEP> racanā	samyōjane	racanā
3 brood	Biotechnology; Marathi	brood <SEP> bhrūṇa	prajanana	bhrūṇa
4 transformation	Biotechnology; Marathi	transformation <SEP> rūpa <isep> antaraṇa	parivartana	rūpāntara
5 injection	Biotechnology; Marathi	injection <SEP> antaḥ <isep> kṣēpaṇa	injēkṣana	antaḥ-kṣēpaṇa

Table 3: Post hoc Qualitative Analysis of Technical term translation results

and *hackathon dataset* (Krishnan et al., 2020). These datasets are carefully curated subsets of a larger corpus DCS (Hellwig, 2010). The UoH corpus+SandhiKosh dataset has 62273 and 15569 instances as train and test sets. For this dataset, we apply the pruning technique mentioned in (Dave et al., 2021) to filter out invalid instances. The size of the training, validation, and test sets for the SIGHUM dataset are 97000, 3000, and 4200, respectively, and for the hackathon dataset, it is 90000, 10332, and 9963, respectively. Contemporary deep-learning methodologies have demonstrated enhanced performance when utilizing the SLP1 script for Sanskrit. Consequently, we have prepared all datasets in the SLP1 script to leverage these performance improvements.

Model	LPA	SPA
JNU	-	8.1
UoH	-	47.2
INRIA	-	59.9
DD-RNN	95.0	79.5
Sandhi Prakarana	92.3	86.8
ByT5	97.2	93.5

Table 4: Location prediction accuracies (LPA) and split prediction accuracies (SPA) for different methods on the UoH+SandhiKosh dataset.

B.2 Experiment Details

Baselines. For the experiments performed over the *UoH+SandhiKosh* dataset, we compare our method against **Sandhi Prakarana** (Dave et al., 2021), **DD-RNN** (Aralikatte et al., 2018), and 3 sandhi splitter tools viz (i) *JNU Splitter* (Sachin, 2007), (ii) *UoH Splitter* (Kumar et al., 2010), and (iii) *INRIA Sanskrit Heritage Reader* (Huet, 2003; Goyal and Huet, 2013). We reproduce and report the scores reported by Dave et al. (2021). For DD-RNN and the 3 sandhi tools, we report the scores reported in (Aralikatte et al., 2018) and (Dave et al., 2021). For the experiments performed over the *SIGHUM* and *hackathon* datasets, we compare our

method against **TransLIST** (Sandhan et al., 2022) and **rcNN-SS** (Hellwig and Nehrlich, 2018b).

Results. Tables 4 and 5 report the performance of our methodology compared with the baselines over the respective datasets. Table 4 shows that our methodology outperforms all other baselines in terms of both Location Prediction Accuracy (LPA) and Split Prediction Accuracy (SPA) with absolute gains of **4.86** and **6.72**, respectively, on the *UoH+SandhiKosh* dataset. TransLIST Sandhan et al. (2022) utilizes a set of potential split candidates from SHR (referred to as LIST in their paper), which provides additional linguistic information for segmentation. Our model is not linguistically informed like this as we feed only the compound word to the model. Hence, our method is not strictly comparable with the results shown in row 2 of Table 5. Nevertheless, our method outperforms all other models on three out of four evaluation metrics when tested on *hackathon* dataset. On *SIGHUM* dataset, our method achieves competitive scores. Sandhan et al. (2022) also reported the performance of their model without the LIST module, as shown in row 3 (TransLIST). The model without the LIST step is more comparable to our setting and we outperform this result as well, while failing to outperform the scores in row 2. As a separate experiment, we provide SHR input to our model for *SIGHUM* data which outperforms TransLIST on PM metric achieving a PM score of **94.31**.

Model	SIGHUM				Hackathon			
	P	R	F	PM	P	R	F	PM
rcNN-SS	96.86	96.83	96.84	87.08	96.40	95.15	95.77	77.62
TransLIST	98.80	98.93	98.86	93.97	97.78	97.44	97.61	85.47
TransLIST	-	-	-	86.10	-	-	-	-
ByT5	98.68	98.42	98.53	93.78	97.58	97.71	97.63	87.7

Do LLMs Give Psychometrically Plausible Responses in Educational Assessments?

Andreas Säuberli^{1,2} Diego Frassinelli¹ Barbara Plank^{1,2}

Abstract

Knowing how test takers answer items in educational assessments is essential for test development, to evaluate item quality, and to improve test validity. However, this process usually requires extensive pilot studies with human participants. If large language models (LLMs) exhibit human-like response behavior to test items, this could open up the possibility of using them as pilot participants to accelerate test development. In this paper, we evaluate the human-likeness or *psychometric plausibility* of responses from 18 instruction-tuned LLMs with two publicly available datasets of multiple-choice test items across three subjects: reading, U.S. history, and economics. Our methodology builds on two theoretical frameworks from psychometrics which are commonly used in educational assessment, *classical test theory* and *item response theory*. The results show that while larger models are excessively confident, their response distributions can be more human-like when calibrated with temperature scaling. In addition, we find that LLMs tend to correlate better with humans in reading comprehension items compared to other subjects. However, the correlations are not very strong overall, indicating that LLMs should not be used for piloting educational assessments in a zero-shot setting.

1 Introduction

Assessing students' knowledge and skills represents an important part of education: admission to universities, scholarship awards, and even political decisions on education policy are often based on large-scale educational assessments. Developing such high-stakes tests is a long and expensive process involving experts writing and reviewing test items and repeated piloting with hundreds or thousands of participants (Green, 2020; Papageorgiou et al., 2021). Therefore, the automation of parts of this process has been a long-standing topic in

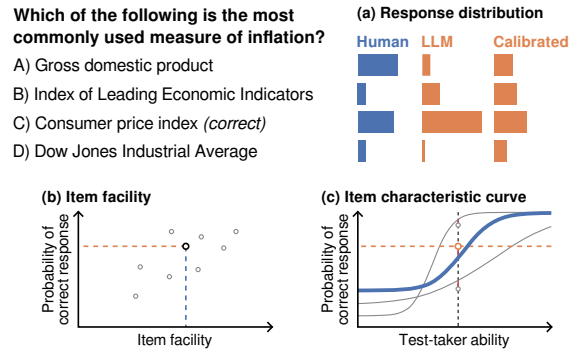

Figure 1: Example item from the NAEP dataset and illustration of our psychometric analyses of LLM responses. We use the first-token probabilities produced by LLMs and analyze how well they correspond to human test taker responses. Specifically, we look at (a) the similarity between LLM and human response distributions, (b) whether items that are difficult for humans are also difficult for LLMs, and (c) how well response probabilities in LLMs match those expected from humans.

assessment research and practice (Haladyna, 2013; Kurdi et al., 2019). Most recently, large language models (LLMs) have been explored for tasks like item generation or item difficulty prediction (Attali et al., 2022; Yaneva et al., 2024; Owan et al., 2023; May et al., 2025).

The present work explores the possibility of using LLMs as participants of a pilot study in test development. A pilot study involves collecting and analyzing responses by human test takers to identify low-quality items and to measure item characteristics like difficulty. The statistical analysis of item responses most commonly follows one of two psychometric theories, classical test theory (CTT) or item response theory (IRT) (Chang et al., 2021). For LLMs to be useful models of human test takers, their responses must be human-like when analyzed within those theoretical frameworks – we call this **psychometric plausibility**. This includes, for example, that items that are difficult for humans

should also be difficult for LLMs. We propose an approach to evaluate the psychometric plausibility of LLM response distributions in multiple-choice test items, which is summarized in Figure 1.

Our contributions are two-fold: First, we present methods for assessing the psychometric plausibility of LLM responses with CTT and IRT (Section 3). Second, we benchmark the psychometric plausibility of 18 instruction-tuned LLMs across two datasets and three test subjects, showing that none of the models are sufficiently reliable to simulate test takers for piloting (Section 4).

2 Related work

A growing body of research has studied the use of natural language processing (NLP) for analyzing or evaluating test items. Examples of specific tasks are predicting difficulty (Yaneva et al., 2024), evaluating answerability or guessability (Raina et al., 2023; Säuberli and Clematide, 2024), evaluating the quality of generated items (Raina and Gales, 2022; Gorgun and Bulut, 2024), or predicting correlations between items (Hernandez and Nie, 2022). Some of these studies used NLP models to simulate test takers: Lalor et al. (2019) and Byrd and Srivastava (2022) used “artificial crowds”, i.e., a large number of models trained on subsampled or partially corrupted data, to simulate test takers at different ability levels. More recently, LLMs have been used. For example, Lu and Wang (2024) and Hayakawa and Saggion (2024) applied prompting techniques to simulate multiple test takers with a single LLM. Park et al. (2024) and Laverghetta Jr et al. (2022) used multiple models to represent a group of test takers, while Liusie et al. (2023) and Zotos et al. (2025) used LLM uncertainty as a proxy for predicting student’s response distributions.

Simulating test takers makes it easy to generate large numbers of item responses, which in turn makes statistical item analysis feasible. For example, Liusie et al. (2023) and Hayakawa and Saggion (2024) used CTT to compare item difficulty between humans and LLMs, while Lalor et al. (2019), Byrd and Srivastava (2022), and Park et al. (2024) predicted IRT-based item characteristics. Laverghetta Jr et al. (2022) compared both CTT- and IRT-based item difficulty between humans and models.

Apart from the application of educational assessment, the human-likeness of predicted response distributions has also been studied in the context

of human label variation in tasks with inherent disagreement between annotators (Plank, 2022). Techniques like temperature scaling or fine-tuning on soft labels have been employed to align predictive probabilities with human response distributions (Baan et al., 2022; Chen et al., 2024).

Our approach combines ideas from several of these works. Our aim is to measure whether the response probabilities of a single model can be a plausible representative of a single test taker or a group of test takers. In this study, we use temperature scaling to optimize the response distributions, leaving other calibration methods as future work. We draw from both CTT and IRT for evaluation.

3 Psychometric plausibility

Psychometrics is concerned with the measurement of unobserved latent variables based on observed responses to test items. Examples of possible latent variables include language proficiency, intelligence, and personality traits like introversion. In educational assessment, two theoretical frameworks are commonly applied: **classical test theory (CTT)** and **item response theory (IRT)**. These theories model the ability of test takers based on their observed test scores, but they also allow us to analyze characteristics of test items such as their difficulty or discriminating power (Livingston, 2011). For this reason, CTT and/or IRT is often used in pilot studies during test development in order to identify low-quality items and improve test reliability.

In our approach to evaluating psychometric plausibility, we focus on item analysis, i.e., determining item characteristics based on item responses by humans or LLMs. The key idea is that a psychometrically plausible LLM should give responses that are aligned with the characteristics of the items as measured using human responses.

In the following subsections, we introduce the relevant basics of CTT and IRT. We then describe how the response distributions of LLMs can be evaluated in the context of these two theories.

3.1 Classical test theory

CTT models assume that the observed test score achieved by a test taker is the sum of the true test score (reflecting the test taker’s ability) and a random error score (Hambleton and Jones, 1993). Item analysis usually involves calculating two statistics for each item:

- **Item facility** is the proportion of test takers

who answered the item correctly. High item facility corresponds to low item difficulty.

- **Item discrimination** is the correlation between a person’s score on the item and their score in the entire test. Low discrimination indicates that the item is inappropriate for measuring the latent variable and might need to be removed from the test.

3.2 Item response theory

IRT introduces a set of probabilistic models that predict the response of a specific person to a specific item, taking into account the person’s latent variable (e.g., ability) and the item’s characteristics (e.g., difficulty and guessability). The definition of the IRT model depends on the choice of item characteristics involved and the response variable type. Here we focus on the **three-parameter logistic (3PL) model** for dichotomous (correct/incorrect) responses:

$$P(X_{p,i} = 1) = c_i + \frac{1 - c_i}{1 + e^{-a_i(\theta_p - b_i)}} \quad (1)$$

$X_{p,i}$ equals 1 if person p answered item i correctly and 0 otherwise. θ_p is the ability parameter for person p , and a_i , b_i , and c_i are item characteristic parameters for item i .

- a_i reflects **discrimination**, i.e., how good the item is at distinguishing between more and less proficient test takers, similar to the discrimination parameter in CTT.
- b_i is the **difficulty** parameter and reflects the level of ability required for a substantial increase in correct response probability.
- c_i is the **guessing** parameter and corresponds to the probability with which a person can answer the item correctly even if it is much too difficult for their ability level.

Once fitted on a large number of test taker responses, an item’s parameters define the shape of its **item characteristic curve** (ICC; see Figure 1 (c) for examples), and allow us to predict the probability of a correct response given their ability level.

One important advantage of IRT over CTT is that item characteristics are not dependent on the sample of test takers who answered this item. Even if not every person answered every item, the parameters can still be compared between items, since

they are estimated in the context of person abilities. A disadvantage of IRT is that it generally requires larger sample sizes (Hambleton and Jones, 1993; Fan, 1998).

3.3 Psychometric plausibility of LLM responses

For a LLM to be considered psychometrically plausible, its response probabilities across different items should match the response patterns expected from humans. To evaluate this, we can use the item characteristics estimated from human responses using CTT or IRT. In the following, we present two examples for such evaluations.

How well does a LLM fit CTT item facility statistics? To check this, we interpret the LLM’s response probabilities as the response distribution in a sample of test takers. Specifically, the LLM should predict a higher probability for the correct answer on easier items compared to more difficult items. Therefore, we propose Pearson’s correlation coefficient between human-based item facility and the LLM’s probability for the correct response as an evaluation metric.

In the present paper, we focus on facility as the only CTT item statistic. Correlating with discrimination statistics would require response data at the level of individual test takers or pre-computed discrimination values, which are not available in the datasets we are using.

How well does a LLM fit IRT item characteristic curves? To evaluate this, we consider the LLM’s response probabilities as representative of a single imaginary test taker with a specific ability. For example, the model may be calibrated to match the ability of an average test taker. Given each item’s ICC, we can then compare the model’s correct response probabilities to the ones predicted by the IRT model.

We will demonstrate these two analysis methods in the following experiment.

4 Experimental setup

We empirically evaluate the psychometric plausibility of 18 LLMs across two datasets and three test subjects, comparing model and human response distributions and applying the analyses described in the previous section.

4.1 Datasets

NAEP. The National Assessment of Educational Progress (NAEP) is a nation-wide and congressionally mandated educational assessment program in the United States.¹ NAEP involves tests across ten subjects at grades 4, 8, and 12. The tests include selected response items as well as constructed response items. A subset of items from previous years along with student response distributions and IRT item parameters are published and can be accessed online through the Questions Tool.² For our experiments, we used only four-option multiple-choice items from *Reading*, *U.S. History*, and *Economics* tests, because most items in these subjects do not heavily rely on images, so that the LLM input can be text-only. For items that do include images, we included the alternative text and manually excluded items that were unanswerable without access to the full image. For some reading items, the full passage text was unavailable due to licensing issues – we also excluded these items.³ This resulted in a total of 549 items, namely: 252 items in reading, 204 in history, and 93 in economics.

CMCQRD. The Cambridge Multiple-Choice Questions Reading Dataset (CMCQRD; Mullooly et al., 2023) contains four-option multiple-choice reading items for proficiency levels B1, B2, C1, and C2 in the Common European Framework of Reference for Languages (CEFR). Unlike NAEP, these items are targeted at L2 English learners. For a subset of the items, student response distributions and rescaled IRT difficulty parameters are provided. We included all items with available response distributions, resulting in a total of 504 items. Because the dataset’s documentation does not include precise information about how the IRT parameters have been rescaled, it is impossible to reconstruct the original ICCs or interpret their meaning in relation to the test takers’ abilities. Thus, we exclude the CMCQRD dataset from our IRT-based analysis.

4.2 Language models

We selected 18 recently published open-weight instruction-tuned LLMs⁴ from four model fami-

lies: Llama 3 (Grattafiori et al., 2024), OLMo 2 (OLMo et al., 2025), Phi 3/4 (Abdin et al., 2024a,b), and Qwen 2.5 (Qwen et al., 2024). We included models ranging in size from 0.5B to 72B parameters to explore the effect of model capability on human-likeness of the responses. We used the implementations in the Hugging Face *transformers* library (Wolf et al., 2020). Models with 70B or more parameters were loaded with 8-bit quantization.

4.3 Prompting and response extraction

We used a simple prompt with a user message instructing the model to select the correct answer option and to output only the corresponding letter (A, B, C, or D). The exact prompt template can be found in Appendix A. We used the model’s default system messages where applicable.

To get a probability distribution, we extracted the first predicted token logits for the four answer option letters and applied the softmax function. Since LLM responses are highly sensitive to the order of multiple-choice answer options (Wang et al., 2024; Zheng et al., 2024; Pezeshkpour and Hruschka, 2024), we prompted four times per item and reordered the options such that every option appears in every position exactly once, and averaged the probabilities from the four permutations. Zheng et al. (2024) showed that this “cyclic permutation” is practically as efficient for debiasing results as full permutation, which would require $4! = 24$ model passes.

4.4 Temperature scaling

In preliminary experiments, we found that most LLMs (especially very large ones) tend to be overly confident compared to the human response distributions, assigning almost all probability mass to a single answer option. Temperature scaling is a common and effective approach to mitigate this issue and bring the uncertainty in LLM responses closer to human variability (Guo et al., 2017; Baan et al., 2022; Chen et al., 2024). It involves increasing the temperature parameter in the softmax calculation, essentially moving some probability mass from highly probable to less probable options.

In our case, we find the optimal temperature that minimizes the Kullback-Leibler (KL) divergence between LLM and human response distributions (see Appendix C for details). We apply this optimization separately to each LLM and each subset only report results from the instruction-tuned models here.

¹<https://nces.ed.gov/nationsreportcard/about/>

²<https://www.nationsreportcard.gov/nqt/>

³Refer to our code repository for detailed filter criteria and excluded items: <https://github.com/mainlp/llm-psychometrics>

⁴We also tested non-instruction-tuned LLMs. While the overall results are very similar, instruction-tuned models tended to slightly outperform base models. Therefore, we

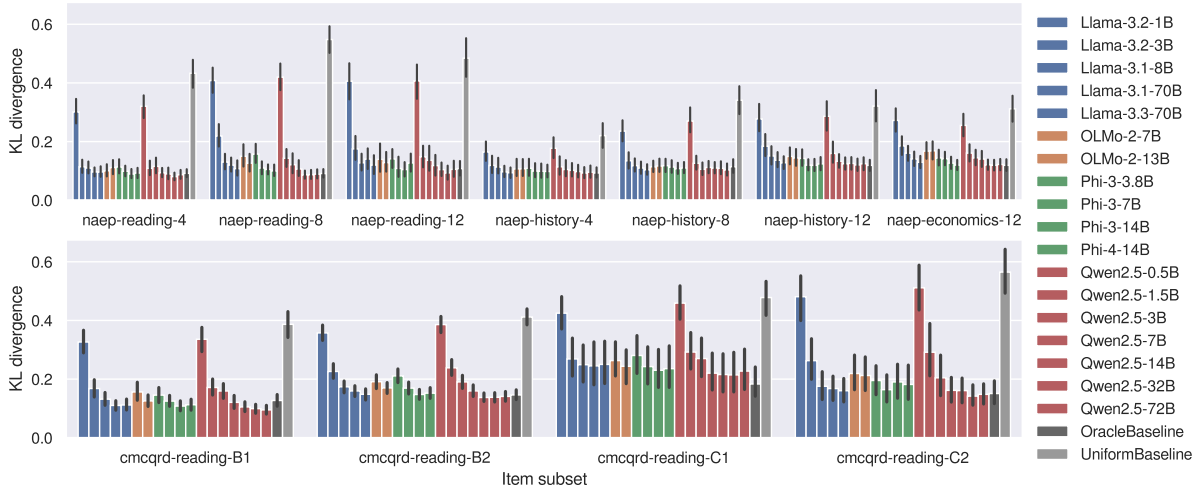

Figure 2: Mean KL divergence between temperature-scaled LLM response probability distributions and human response distributions. Models are colored by family and ordered by increasing number of parameters within families. Error bars are bootstrapped 95% confidence intervals.

of items, i.e., each subject-grade combination in NAEP and each proficiency level in CMCQRD. This is important because the human response distributions are not sampled from the same population of test takers across all subsets (e.g., 4th grade items were only answered by 4th graders).

We perform the temperature optimization on the same data as the evaluation (cf. Baan et al., 2022; Liusie et al., 2023). This means that the results should be considered an upper bound. In other words, we are testing the best-case scenario, where we have enough data to calibrate the LLMs perfectly to the human distributions as possible.

4.5 Evaluation metrics

We evaluate the human-likeness and psychometric plausibility of LLM responses from three perspectives:

Following Liusie et al. (2023) and Hayakawa and Saggion (2024), we report the **average KL divergence** between the temperature scaled LLM and human response distributions. In addition to comparing the probability for the correct answer option, this metric also captures the similarity of the distractor probabilities.

For our **CTT-based analysis**, we report **Pearson’s correlation coefficient** between the item facilities and the correct LLM response probabilities. This reflects the idea that psychometrically plausible LLMs should be more confident in the correct answer option when the item is easier.

In the **IRT-based analysis**, we assume that the temperature-scaled LLM response distributions re-

flect the response behavior of an average test taker, meaning a person with an ability parameter that is the mean of the sample. The ability parameters in NAEP’s IRT models are fixed to have mean zero,⁵ therefore we use Equation 1 to calculate the expected correct response probability for human test takers with ability $\theta_p = 0$ for each item i :

$$P_{\text{expected}}(X_i = 1) = c_i + \frac{1 - c_i}{1 + e^{a_i b_i}} \quad (2)$$

We compare these values to the LLM’s observed correct response probabilities and report **Pearson’s correlation coefficient**.

5 Results

5.1 Comparison of response distributions

Figure 2 shows the average KL divergence between LLM and human response distributions, including two simple baselines: **UniformBaseline** always predicts the same probability (25%) for all answer options. **OracleBaseline** always predicts the same probability for all distractors and a higher probability for the correct answer option (the same for all items). OracleBaseline is optimized using the same temperature scaling approach as the other models, as described in Section 4.4.

Across all model families and item subsets, we observe that LLM responses become more similar to the human distribution with increasing model size. However, only a small number of very large

⁵https://nces.ed.gov/nationsreportcard/tdw/analysis/scaling_est.aspx

Figure 3: Pearson correlation between LLM correct response probabilities and item facilities. Numbers in the item subset labels refer to the grade level. * denotes significance (two-tailed, $p < 0.05$), n refers to the sample size in each cell of the corresponding row.

models in the CMCQRD B1 item subset managed to significantly outperform the OracleBaseline (bottom row in Figure 2). This shows that the distribution of probabilities among distractors is not accurately modeled.

5.2 CTT analysis

Correlations between the LLMs’ correct answer probabilities and item facilities are visualized in Figure 3. While there does not seem to be a clear effect of model family or size, the correlations differ substantially between item subsets. The highest correlation coefficients were achieved in the CMCQRD B1 reading items, ranging from 0.32 to 0.56 across models. Among items from the NAEP datasets, most significant correlations can be found in reading items and 8th grade history items. However, the correlations are not strong overall and fluctuate substantially across grade levels.

5.3 IRT analysis

NAEP considers multiple different skills for each subject (e.g., informational and literary reading skill) and therefore separate IRT models with different ability scales are fitted. Some items test multiple skills and are shared between different scales (but with different item parameters).

In Figure 4, we report the correlations between LLM’s correct answer probabilities and expected human correct response probabilities across NAEP IRT scales. As an upper bound, we also include the human response distributions as a model, i.e., the

Figure 4: Pearson correlation between LLM correct response probabilities and expected correct response probabilities based on human IRT models. Numbers in the IRT scale labels refer to the grade level. * denotes significance (two-tailed, $p < 0.05$), n refers to the sample size in each cell of the corresponding row.

correlation between the response probability for the “average” test taker in the IRT model and the observed proportion of correct responses among human test takers (last column in Figure 4).

Similar to the CTT results, most significant correlations can be found in reading items and 8th grade history items, and no effect of model family or size emerged. Notably, however, we also find significant *negative* correlations in some 4th grade history items. This means that these LLMs tend to be *more* confident in the correct answer when the item is more difficult, contradicting the expectations for psychometrically plausible responses.

Overall, while human correlations are consistently close to 1.0, LLM correlations are rather low, and the number of significant correlations is small (considering that we expect 5% of results to be type I errors with the chosen significance level). However, given that the IRT analysis uses smaller item subsets and puts more stringent criteria on the LLM responses than the CTT analysis, these results are not overly surprising.

6 Discussion

The presented method is a multi-faceted approach, providing different perspectives on the human-likeness of LLM responses: The response distri-

bution can tell us about a model’s ability to model the success of distractors; the CCT analysis can show how well the model’s probabilities represents a whole group of test-takers; and finally, the IRT analysis captures the plausibility of LLMs as an individual test taker in a specific skill.

LLMs are not easily distracted. Comparing the response distributions between humans and LLMs shows that especially large LLMs are good at predicting the *correct* answer (see Appendix B), but bad at predicting which *incorrect* answer options humans are likely to be distracted by (otherwise, they would outperform the OracleBaseline in Figure 2). An example of this is also shown in Figure 1, where the item contains a very successful distractor (A), but the LLM (Qwen2.5-0.5B) assigns almost no probability mass to it. Calibration using temperature scaling cannot alleviate this issue, and reducing model size is not effective either (see Appendix B for a more detailed analysis). This is an important limitation in applying LLMs for evaluating distractors.

Results are consistent across models, but inconsistent across subjects. While the correlations in the CTT and IRT analyses are likely too low to be useful for analyzing or evaluating single items, some interesting patterns can still be observed. The results are remarkably consistent across families and – after calibration – model sizes, demonstrating that all models are very similar to each other, but very dissimilar to humans in this setting (see Appendix D for a more in-depth comparison).

At the same time, there are considerable differences between subjects and IRT scales. Correct answer probabilities appear to be more human-like in reading comprehension items compared to other subjects, while history items show mixed results, in some cases even eliciting strong negative correlations (see Figure 4). This might indicate that reading comprehension in LLMs is more comparable to humans than other abilities such as long-term memory retrieval, which is required for answering test items in history and economics. Another possible explanation could be the fact that history and economics items more frequently contain images, which have to be understood from descriptions in the alternative text. Since we used text-only LLMs, this discrepancy in the way items were presented was inevitable. Future work could explore whether multimodal models are more successful with these item types.

How to improve psychometric plausibility? To a large degree, the lack of psychometric plausibility is in line with previous research (Hayakawa and Saggion, 2024; Zotos et al., 2025). The success of attempts to make the model response distributions more human-like was very limited – including our temperature scaling approach and Hayakawa and Saggion’s (2024) prompting techniques for injecting personas, uncertainty, or noise. Therefore, in order to improve psychometric plausibility, we will likely need to go beyond zero-shot prompting. Fine-tuning on human response distributions could be a promising direction for future research (cf. Chen et al., 2024).

7 Conclusion

We demonstrated how LLM responses can be analyzed in the context of CTT and IRT and evaluated the human-likeness or psychometric plausibility of zero-shot responses. We found that neither reducing model size nor temperature scaling increased psychometric plausibility to a sufficient degree, but we observed slightly more human-like responses in reading comprehension compared to other subjects. We conclude that human-like response behavior in educational assessments has not emerged from the process of training instruction-tuned LLMs, calling for caution in their use. Fine-tuning on human response distributions may be necessary to create psychometrically plausible models that could be used for piloting.

Limitations

Available item response data. Our analysis is limited by the type and amount of data available in the context of educational assessment. Item banks in high-stakes assessments are usually confidential to avoid leaking information for future test takers, and item responses from single test takers are generally not publicly released. Therefore, in order to keep our results reproducible, we only used publicly available datasets, where only aggregated response distributions and IRT parameters for a relatively small number of items are available. Given a larger amount of and less aggregated data, more fine-grained analyses would be possible (e.g., by including item discrimination in the CTT analysis) and more systematic patterns could be revealed.

Multimodal items. In addition, the NAEP dataset is not ideal for text-only LLMs, because some of the items involve extracting information

from pictures. Although we replaced the pictures with alternative texts and manually removed unanswerable items (see Section 4.1), this could still have affected our results for this dataset.

Test-taker population. The two datasets we used contain response data from two different populations of test takers. While NAEP is targeted at children and adolescents (i.e., mostly L1 English speakers) in the U.S. school system, CMCQRD involves L2 learners of English. This difference could have affected the results and reduce the comparability between the two datasets.

Ethical considerations

We see no ethical issues related to this work. All experiments were conducted with publicly available data and open-source software, and we have made all of our code openly available for reproducibility.⁶ The two datasets we used only contain highly aggregated response data and do not include any information that could lead to the identification of individual test takers.

We used GitHub Copilot for coding assistance in the implementation of the experiment and the analysis of the results. All generated code was manually checked and thoroughly tested.

A Prompt templates

The following prompt template was used for items with a reading passage (i.e., reading comprehension items):

Based on the following text, select the correct answer to the question below.

Text: **{passage}**

Question:
{item stem}
 A) **{option 1}**
 B) **{option 2}**
 C) **{option 3}**
 D) **{option 4}**

Respond only with the letter of the answer (A, B, C, or D).

The following prompt template was used for items without a reading passage (i.e., history and economics items):

Select the correct answer to the following question.

Question:
{item stem}
 A) **{option 1}**
 B) **{option 2}**
 C) **{option 3}**
 D) **{option 4}**

Respond only with the letter of the answer (A, B, C, or D).

B Response accuracy

Figure 5 shows the mode accuracy of models and humans, i.e., the proportion of items where the option with the highest response probability is the correct one. The high accuracy of large models shows that the items are answerable given the available information in the prompt.

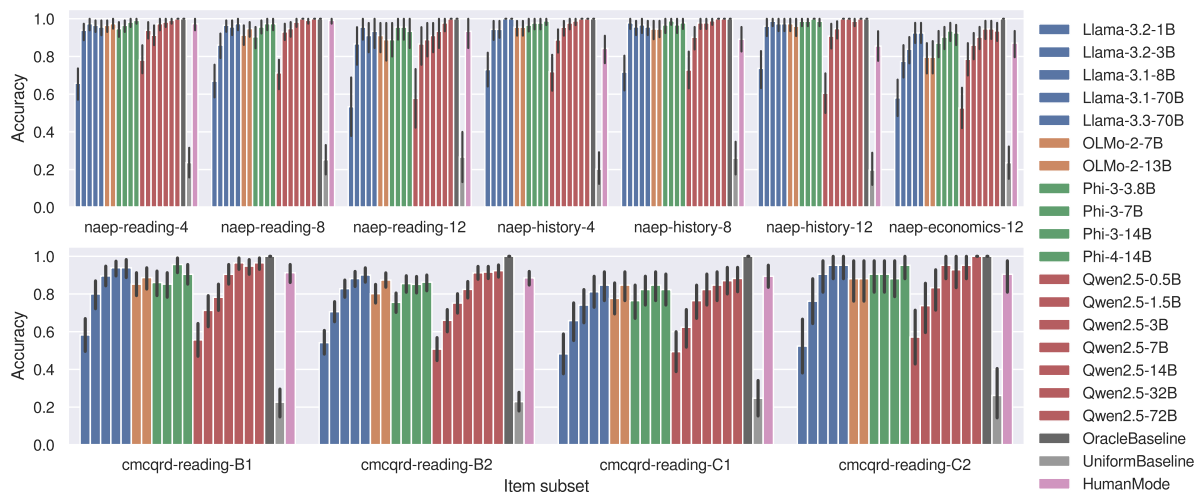

Figure 5: Mode accuracy across item subsets, models, baselines, and humans. Error bars are bootstrapped 95% confidence intervals.

C Details on temperature scaling

We optimized temperature parameters using KL divergence as a loss function and an Adam optimizer (see `analysis.py` in the code repository). The resulting optimized temperature values are visualized in Figure 6. Larger LLMs tend to be overly confident, assigning almost all probability mass to a single answer option, and therefore require higher temperatures to align them with human response distributions.

The effect of temperature scaling can be seen by comparing the results without temperature scaling in Figure 7 with Figure 2.

Figure 6: Optimized temperature value for each model and item subset.

Figure 7: Mean KL divergence between LLM response probability distributions *without* temperature scaling and human response distributions. Error bars are bootstrapped 95% confidence intervals.

D Additional results for CTT analysis

In addition to the correlations between models and humans in Figure 3, Figure 8 shows the full correlation matrices, including model-model correlations. This confirms that the LLMs are much more similar to each other than to humans. In addition, models of similar sizes (but different model families) tend to be more similar to each other compared to models of different sizes.

Figure 8: Pearson correlation between all LLM correct response probabilities and human item facilities.

Challenges for AI in Multimodal STEM Assessments: a Human-AI Comparison

Aymeric de Chillaz^{1*} Anna Sotnikova^{1*†} Patrick Jermann¹ Antoine Bosselut¹
¹EPFL

Abstract

Generative AI systems have rapidly advanced, with multimodal input capabilities enabling reasoning beyond text-based tasks. In education, these advancements could influence assessment design and question answering, presenting both opportunities and challenges. To investigate these effects, we introduce a high-quality dataset of 201 university-level STEM questions, manually annotated with features such as image type, role, problem complexity, and question format. Our study analyzes how these features affect generative AI performance compared to students. We evaluate four model families with five prompting strategies, comparing results to the average of 546 student responses per question. Although the best model correctly answers on average 58.5% of the questions using majority vote aggregation, human participants consistently outperform AI on questions involving visual components. Interestingly, human performance remains stable across question features but varies by subject, whereas AI performance is susceptible to both subject matter and question features. Finally, we provide actionable insights for educators, demonstrating how question design can enhance academic integrity by leveraging features that challenge current AI systems without increasing the cognitive burden for students.

1 Introduction

Generative AI has been widely tested in educational applications, including its ability to answer exam-level questions (Sallam, 2023; Lan et al., 2024; Wang et al., 2024a). There are two key challenges: AI can be misused in ways that undermine fair assessment, and its mistakes often appear convincing, potentially misleading students (Borges et al., 2024; Wang et al., 2023; Zhong et al., 2023; Arora et al., 2023). To better understand these risks,

*Both authors contributed equally to this research.

†Corresponding author: aasotniko@gmail.com

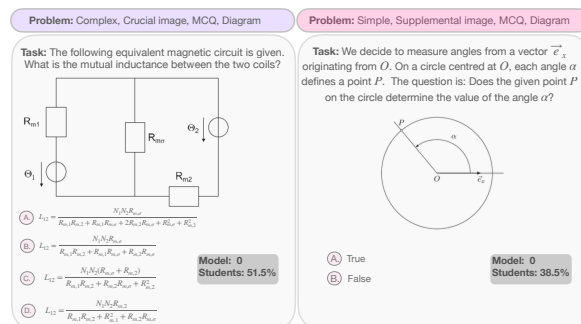

Figure 1: Example of STEM problems with average model performance (majority vote) compared to average student performance.

benchmarks were introduced to assess AI performance (Wang et al., 2024b). Recent advances in multimodal large language models (LLMs) have led to extensive efforts in developing image-based exam datasets, particularly in STEM. Anand et al. (2024) introduced a multimodal physics dataset, expanding from 300 manually created questions to 4,500 using LLMs; Liang et al. (2024) developed SceMQA, a dataset of 1,000+ scientific reasoning problems for students transitioning to college; Zhang et al. (2023) and Das et al. (2024) created multilingual, multimodal benchmarks across various subjects and difficulty levels.

While these benchmarks provide insight into AI capabilities, they primarily evaluate models in isolation, without comparing their performance to humans. As a result, it is unclear whether a model's low performance stems from its limitations or if the problems themselves are inherently difficult for humans too. Understanding what makes a problem easier or harder for AI compared to humans would help warn students about potential risks and guide the design of fairer image-based assessments.

We compile 201 university-level STEM exam questions with images from Bachelor's and Master's programs across 11 subjects of varying complexity. To analyze model performance, each ques-

Figure 2: Average model and student accuracy per subject, with model results aggregated using the majority vote strategy.

tion is manually annotated with its image type, role, question type, and problem type. In addition, we collect student performance data, each question receiving at least five responses and an average of 546 respondents across the dataset. To evaluate AI performance, we implement five prompting strategies and test two models from GPT-family —GPT-4o and o1-mini (OpenAI, 2023) as performant models freely available to students, and Qwen 2.5 72B VL (Bai et al., 2025), DeepSeek r1 (DeepSeek-AI et al., 2025), and Claude 3.7 Sonnet, 2025 as performant models with visual capabilities.

Our results indicate that while LLMs perform well in text-based university assessments (Borges et al., 2024), they struggle with questions involving visual components. On average, models perform slightly worse than students. Student performance varies by subject, while model performance depends on question and image features. Based on the analysis, we provide recommendations for designing take-home assignments that maintain academic integrity by challenging models without increasing difficulty for students. These principles can also inform the development of more challenging benchmarks as models continue to improve.

2 Data Set Description

We manually collected 201 questions with images from exams and quizzes in 11 subjects from Bachelor’s and Master’s programs. Each question is paired with a gold answer provided by the educator who authored it. Questions were manually labeled with the following attributes¹:

¹The dataset is available on [GitHub](#)

Image Type: diagram, line plot, algorithm, and picture.

Image Purpose: An image is “supplemental” if all necessary information is in the text and can be inferred without it. It is “crucial” if required to solve the problem.

Question Type: multiple choice questions (MCQ), multiple choice questions multiple answers (MCQ-MA), and compound questions containing multiple sub-MCQ questions connected by the same question topic and having some related information in each other.

Complexity of Problem Conditions: “Complex” questions involve multiple subject concepts, while “Simple” ones require only one or two closely related concepts. This distinction does not indicate difficulty—a question may have one hard concept or multiple simple ones. Categorizing questions this way helped assess whether models struggled with interdependent conditions, as simple questions have fewer variables, while complex ones require integrating more information.

Student performance data was collected from historical course records as aggregated statistics, with 5 to 5,686 respondents per question (average: 546). Student performance also served as an indicator of problem difficulty. Our dataset includes 43 problems where fewer than 40% of the students answered correctly, 79 where 40–70% succeeded, and 79 where more than 70% solved the question.

For detailed dataset statistics and student performance, see Appendices A.1 and A.3.

3 Experiments

Our experiments assess model performance across five prompting strategies and compare it with human performance. Details on prompting strategies are provided in Appendix B. For multiple-choice (MCQ, MCQ-MA) and compound questions, we use exact match with the gold answer without partial credit. Model scores are aggregated using two methods: majority vote (assigning the most common score across strategies) and max (taking the highest achieved score). The max approach provides an upper bound estimate, highlighting if at least one strategy yields the correct answer. Model implementation details are in Appendix C.

4 Analysis

This section presents the experimental results, comparing the model and student performance across

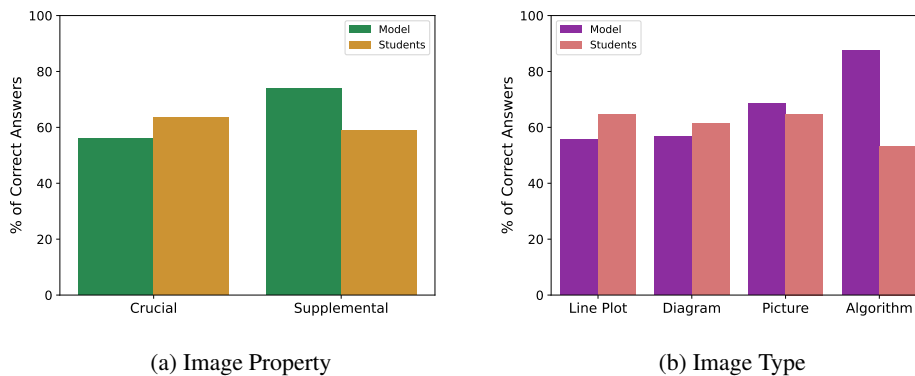

Figure 3: (a) Effect of image properties on model performance aggregated by the majority vote strategy compared to average student performance. (b) Effect of image type on model performance aggregated by the majority vote strategy compared to average student performance.

various dimensions.

4.1 General performance on questions with images

Unless stated otherwise, we use majority vote aggregation. GPT-4o outperforms other models, and we focus on its results throughout. Detailed model comparisons are provided in Appendix D.1. As shown in Figure 9, all prompting strategies perform similarly and roughly match the average human student’s performance on the task.

We analyze model and student accuracy on image-based questions across subjects (Figure 2). Both exhibit subject-specific strengths and weaknesses, but student accuracy varies less (0.52–0.73) than the model’s (0.35–0.87). The model performs exceptionally well in Astronomy, Computer Science (CS), and Microfabrication, likely due to the structured nature of these questions and the model’s ability to apply general concepts. Prior studies have shown that LLMs excel at CS-related tasks (Krüger and Gref, 2023; Song et al., 2024; Borges et al., 2024). In contrast, the model struggles with Quantum Physics, Chemistry, Neuroscience, and Electromagnetism, where complex, content-rich images may pose additional challenges.

4.2 Effect of image features

We examine the role of images in problem-solving, specifically whether they provide essential information absent from the text or if the problem can be solved without them. Figure 3a compares performance based on image necessity. As expected, student accuracy remains similar regardless of image importance, whereas models perform better on questions where images are non-essential. Our

ablation study confirms this trend: removing supplemental images slightly improves model performance, though the effect is minimal (see Appendix D.2 for details).

Next, we analyze performance across image types (Figure 3b). Students perform similarly across line plots, diagrams, and pictures, and struggle the most with algorithm questions. Although the model has no difficulties in processing algorithms, it struggles the most with diagrams and line plots.

4.3 Effect of question features

We observe that students perform similarly across all three question formats. Both students and the model get the best performance on MCQ questions. The model performs slightly better than students on compound questions, a subset of MCQs that are linked to represent steps of a larger problem. However, it struggles the most with MCQMA, often selecting some correct choices but failing to identify all (Figure 4a).

Figure 4b illustrates how the concept count influences performance. Although students perform consistently regardless of the number of concepts in a question, the model struggles when more than two concepts are involved.

We report statistical significance for the model’s and students’ results in Tables 5 and 6.

4.4 Error analysis

To assess the model’s strengths and weaknesses, we analyzed 59 questions split into two sets: ones where the model outperformed students and ones where it underperformed.

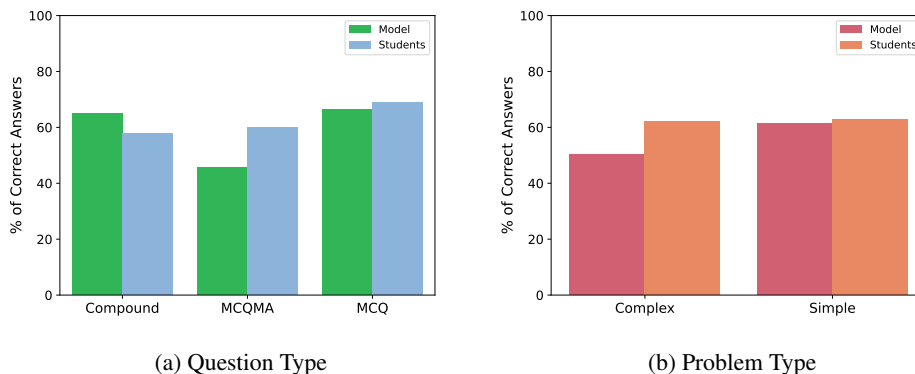

Figure 4: (a) Effect of question type on model performance aggregated by the majority vote strategy compared to average student performance. (b) Effect of problem type on model performance aggregated by the majority vote strategy compared to average student performance.

Questions easy for students, hard for the model

We examined 31 questions where the model scored 0 using the max strategy—failing to produce a correct answer across five prompts—while students achieved over 40% accuracy. We find that humans more easily integrate common sense, domain-specific intuition, and experiential learning, whereas the model struggles to infer conditions or iterations that are not explicitly stated.

One notable category where students outperform the model involves physics-based reasoning and real-world conventions. These problems require understanding implicit relationships, precise numerical or symbolic extraction, and intuition-driven problem-solving. For instance, students effectively interpret diagrams, such as photonic crystal defects or force distributions in mechanical systems, while the model struggles with directional trends and recognizing constraints in visual data. Furthermore, the model has difficulty selecting the correct schema or plot from multiple options, a task that poses less challenge for humans.

Questions hard for students, easy for the model

We analyze 28 questions where students’ performance is below 40% while the model scores above 65%.

A key category where the model outperforms students includes problems requiring structured reasoning, precise pattern recognition, and large-scale knowledge retrieval. These problems follow well-defined rules, abstract mathematical principles, and algorithmic logic. The model’s ability to detect structural patterns allows it to efficiently analyze periodicity in trigonometry, solve algorithmic network problems, and interpret simple electrical

schematics with high accuracy. Unlike intuition-driven tasks, these problems follow clear logical steps. Students often struggle with multi-step reasoning due to cognitive load, whereas the model processes extended contexts effortlessly. As shown in Figure 10, student accuracy declines as question length increases, while the model maintains strong performance. Additionally, models excel in problems requiring abstraction and conceptual knowledge.

5 Conclusion

We show that questions requiring crucial images and multiple concepts, while remaining concise, pose a greater challenge for models without increasing difficulty for students. Additionally, models struggle more than humans in applying domain-specific intuition to problem-solving. However, our analysis reveals that models retain knowledge of the correct answer in 75.5% of questions across at least one prompting strategy but fail to retrieve it consistently. With a majority vote strategy, models achieve 58.5% accuracy, slightly below the human average of 62.7%. While overall performance appears similar, a closer analysis highlights the significant impact of the problem and image features on these results.

Finally, it is important to balance fair accessibility with preventing model misuse, as restrictive measures may inadvertently disadvantage students with vision impairments. For these students, problems with supplemental images are easier to understand through full-text descriptions, similar to how models rely on textual input over visual data.

Limitations

Our study explores how humans and models solve questions involving both images and text. However, it has several limitations.

First, our dataset is relatively small (201 examples). While we ensured high-quality data through manual collection and annotation and confirmed statistical significance, a larger dataset would improve reliability. We opted against automated data augmentation to maintain quality control. To facilitate further research, we publicly release our dataset with annotations.

Second, our grading method does not assign partial credit for multiple-choice multiple-answer (MCQMA) questions, leading to a stricter evaluation of model performance. Additionally, unlike humans, models do not employ elimination reasoning, as we do not adjust prompts for MCQMA responses, potentially disadvantaging them.

Third, when comparing course performance, we do not account for instructor influence, which may affect problem difficulty. This factor can introduce bias also for humans, as different instructors may present varying challenges for students within the same subject.

Acknowledgments

We are grateful to Dr. Jessica Dehler Zufferey for her valuable recommendations on question and image feature design, as well as her feedback on the interpretation of our results. We also thank Christian Vonarburg and Yves Renier for their assistance with data preparation. We appreciate the feedback provided by the EPFL NLP lab members throughout the development of this work. We also gratefully acknowledge the support of the Swiss National Science Foundation (No. 215390), Innosuisse (PFFS-21-29), the EPFL Center for Imaging, Sony Group Corporation, and a Meta LLM Evaluation Research Grant.

A Data Set Details

Here we present the data set statistics, and examples of questions for every data feature.

A.1 Data Format

Image Type: diagram, line plot, algorithm, and picture.

Image Purpose: supplemental, when the image is non-essential and all information about the problem is stated in the problem text or crucial, when the image is required to solve the problem. One can determine that the question in Figure 5 has a supplemental image since it could be inferred from the text.

Question Type: multiple choice questions (MCQ), multiple choice questions multiple answers (MCQ-MA), and compound questions containing multiple sub-MCQ questions connected by the same question topic and having some related information in each other.

Complexity of Problem Conditions: “Complex” means that the question involves multiple concepts of the subject, while “Simple” would require only one or two closely related concepts to solve the problem. This condition does not directly reflect problem difficulty; a question may involve a single difficult concept or multiple simple ones. Distinguishing between simple and complex questions

In the Hodgkin-Huxley model, the potassium current obeys the equation:

$$I_K = \bar{g}_K n(t)^4 (u(t) - E_K)$$

where \bar{g}_K is the maximal conductance, E_K the potassium reversal potential, and $n(t)^4$ is the proportion of channels that are open at time t . The quantity n obeys a first-order dynamics

$$\frac{dn}{dt} = \frac{n_\infty(u) - n}{\tau_n(u)}$$

with voltage-dependent time constant τ_n and equilibrium value n_∞ .

In order to determine τ_n and n_∞ , Hodgkin and Huxley pharmacologically blocked the sodium current and measured the response of the potassium current to voltage jumps of various amplitudes. The goal of this exercise is to understand this key experiment by studying a simplified version of the Hodgkin-Huxley model. Suppose τ_n and n_∞ have the following form:

$$\tau_n(u) = \begin{cases} 1\text{ms} & \text{if } u \leq 0 \text{ mV} \\ 5\text{ms} & \text{if } 0 < u \leq 25 \text{ mV} \\ 1\text{ms} & \text{if } u > 25 \text{ mV} \end{cases}$$

$$n_\infty(u) = \begin{cases} 0 & \text{if } u \leq 0 \text{ mV} \\ u/50 & \text{if } 0 < u \leq 50 \text{ mV} \\ 1 & \text{if } u > 50 \text{ mV} \end{cases}$$

Figure 5: Example of a complex question with supplemental image.

allowed us to evaluate whether models struggled with interdependent conditions. Simple questions involve fewer variables, while complex ones require integrating multiple pieces of information.

One can determine that the question in Figure 5 is “Complex” and the image is “Supplemental”. The question is complex because it involves the Hodgkin-Huxley model, differential equations governing potassium channel dynamics, and voltage-dependent parameters, requiring knowledge of electrophysiology and mathematical modeling. The image is supplemental because it provides graphical representations of $n_\infty(u)$ and $\tau_n(u)$, but all necessary equations and definitions are clearly described in the text, making the image helpful but not essential.

A.1.1 Description of Labels

1. Course_name:

- *Description:* The name or identifier of the course associated with the question.
- *Example:* "Calculus I", "Physics 101"

2. Exercise_name:

- *Description:* The unique exercise id.

3. Question:

- *Description:* The text of the question, may include LaTeX formatting and placeholders for images.

4. Gold_answer:

- *Description:* The correct answer to the question.

5. Question_type:

- *Description:* The format or type of the question.
- *Possible Labels:*
 - "MCQ" (Multiple Choice Question)
 - "MCQMA" (MCQ Multiple Answers)
 - "Compound" (a non-open-ended question with multiple objectives)

6. Image_type:

- *Description:* The type of images included in the question.
- *Possible Labels (Others may be added as we manually label):*
 - "line plot"
 - "bar plot"
 - "scatter plot"
 - "histogram"
 - "pie chart"
 - "table"
 - "image"
 - "diagram"

7. Image_purpose:

- *Description:* The role of the image in the context of the question.
- *Possible Labels:*
 - "Crucial" (Essential for solving the question)
 - "Supplemental" (Doesn't provide additional context)

8. Problem_conditions:

- *Description:* The complexity of the conditions within the problem.
- "Complex" doesn't necessarily mean that the problem is difficult. It simply means that many conditions are in play.
- *Possible Labels:*
 - "Simple" (Conditions are straightforward and not interacting)
 - "Complex" (Multiple conditions interact to find the answer)

9. Question_images:

- *Description:* A list of filenames or identifiers for images included in the question.

10. **Question_length_characters:**
- *Description:* The length of the question text is measured in characters.
11. **Num_objectives:**
- *Description:* The number of sub-questions within the question.
 - *Example:* 1, 2
12. **Language:**
- *Description:* The language in which the question is written.
 - Always in "English" because we translated the French ones.
13. **Original_language:**
- *Description:* The original language of the question before translation.
 - *Example:* "French"
14. **Was_translated:**
- *Description:* Indicates whether the question was translated from another language.
 - *Possible Values:* true or false
15. **Image_file_type:**
- *Description:* The file format of the images used.
 - *Example:* "PNG", "JPEG"
16. **Answer_format:**
- *Description:* The expected format of the answer.
 - *Possible Labels:*
 - "Only MCQ Letter" (previously called MCQ)
 - "Only Numeric Answer"
 - "Derivation"
 - "Text"
 - "Code"
 - "Calculation"
17. **Solution_type:**
- *Description:* Indicates whether the question has a unique correct answer or multiple correct answers.
 - *Possible Labels:*
 - "Unique answer"

– "Multiple answers"

18. **Type_of_text:**

- *Description:* The formatting or typesetting used in the question text.
- *Example:* "LaTeX", "Plain text", "XML"

19. **Objective_dependency:**

- *Description:* Indicates whether the objectives in the question are independent or dependent on previous ones.
- *Possible Labels:*
 - "All Independent" (Objectives can be solved separately)
 - "Dependent" (Some objectives rely on answers from previous parts)

A.2 Data Set Statistics

Data set statistic is presented in Table 1.

Feature	Options	Count
Question Type	MCQ	80
	Compound	59
	MCQMA	46
	Numeric and Formula	16
Image Type	Diagram	109
	Line Plot	45
	Picture	33
	Algorithm	8
	Other	6
Image Purpose	Crucial	162
	Supplemental	39
Problem Conditions	Simple	169
	Complex	32
Course Category	Astronomy	32
	Electrical Engineering	28
	Computer Science	20
	Math	19
	Electromagnetism	17
	Quantum Physics	26
	Mechanical Physics	16
	Neuroscience	15
	Microfabrication	10
	Chemistry	10
Biology	8	

Table 1: Data Statistics

Figure 6: Student accuracy distribution.

A.3 Student Performance

Dataset difficulty illustrated by student performance is presented in Figure 6.

The distribution of students attempting a question is presented in Table 2.

Respondents	Questions
5-20	27
21-50	34
51-100	29
101-500	51
501-1000	33
1001-2000	21
2001-7000	6

Table 2: Distribution of questions by the number of respondents.

B Prompting strategies

B.1 Helper Functions

B.1.1 question_type_prompt

The `question_type_prompt` function creates a tailored instruction based on the type of question being posed. It supports several question types, each associated with a specific directive:

- **MCQ:** Instructs the model to select the correct option by returning only its letter.
- **MCQMA:** Similar to MCQ but expects multiple correct options, concatenated as a single string (e.g., AB rather than A, B).
- **Numeric Question:** Requests that the model output only the numerical answer.
- **Formula Question:** Expects the answer to be provided as a formula.

- **Open Ended:** Directs the model to comprehensively address all parts of the question.

For questions labeled as **Compound**, the function combines the individual instructions corresponding to each subquestion type. It first determines the number of subquestions and then appends the respective prompt text for each, ultimately guiding the model to return its answers as a JSON-formatted list.

B.1.2 generate_format_instruction

The `generate_format_instruction` function provides context-specific formatting advice based on the text’s format:

- **XML:** The instruction reminds the model to interpret XML symbols correctly, ensuring that any formula or question components formatted in XML are properly understood.
- **LaTeX:** Advises careful interpretation of LaTeX expressions, especially for mathematical content.
- **Other:** When the text does not fall into the above categories, no extra formatting instruction is provided.

B.2 Prompting strategies

To generate question-answer pairs, we first conducted an experiment evaluating 12 different prompting strategies. Based on performance results, we selected five strategies for further analysis. Two of these serve as baselines: *direct zero-shot*, the model receives only the question and image without additional instructions or contextual information. *zero-shot chain-of-thought (CoT)* (Wei et al., 2023), the model is asked to produce intermediate reasoning steps before arriving to the final answer. Beyond the baselines, we investigated how the order of multimodal input affects performance. Specifically, we compared cases where the model processes the image at the beginning versus at the end of the text input. Our results indicate that presenting the *image first*, followed by the problem text, leads to better performance. Finally, for models with strong reasoning capabilities but lacking the multimodal component, we implemented a *two-stage* prompting strategy. We first use GPT-4o to generate a textual description of the image. This description is then passed, along with the problem

text, to o1-mini and o1-preview models. The quality of the generated descriptions were manually verified.

B.2.1 Direct zero-shot

A straightforward prompt that presents the question to the model.

```
Direct zero-shot

You are an expert in STEM courses.

Images: <image_names >

[Refer to generate_format_instruction]
Question: <question text >

[Refer to question_type_prompt]
Your Answer:
```

B.2.2 Chain-of-Thought Prompt

This prompt encourages a step-by-step analytical approach, asking the model to think through the problem before answering.

```
Chain-of-Thought Prompt

You are an expert in STEM courses tasked with answering questions with step-by-step analysis. Examine both the image(s) and question text before answering.

Images: <image_names >

[Refer to generate_format_instruction]
Question: <question text >

[Refer to question_type_prompt]
Your Answer: Let's think step by step.
```

B.2.3 Image First Prompt

This prompt prioritizes image analysis by instructing the model to examine the image details before considering the text, and then synthesize a detailed answer.

Image-First Prompt

You are an expert in STEM courses tasked with answering questions. But, first, you must analyze the image(s), which you will follow with the textual analysis.

You will follow the next steps before providing an answer.

Step 1: Analyze the Image(s) First

- Describe elements, patterns, and relationships in the image(s).

Step 2: Use Observations to Analyze the Text

- Use the image understanding to find relevant textual information in the question.

Step 3: Provide a Detailed Answer

- Synthesize observations into a complete answer.

Images: <image_names >

[Refer to generate_format_instruction]

Question: <question text >

[Refer to question_type_prompt]

Make sure to tackle every step mentioned above, before you answer.

Your Answer:

B.2.4 Two Stage Prompt

Image Description Prompt

This prompt requests a detailed description of the provided image, linking its elements to the question context for use by another model. It does not answer the question but aims to provide details that will enable another to answer it.

Image Description Prompt

I am going to provide you with a question with an image. I need you to describe this image in as many details as possible and link those details to the question and its context.

I will then share this description of the image with an LLM which doesn't have vision capabilities, but better reasoning skills than you. In other words, you will be the eyes for that second model. As such, it is primordial that you don't leave out any details!

Note that some details that you think might be useless, may not be, as such make sure that you focus on every aspect.

Here is the Image: <image_names >

Here is the question: <question text >

You may now provide your detailed description. Make sure to follow the instructions that were given to you.

Answer With Image Description Prompt

This prompt asks the model to answer a question based solely on an image description, with a ref-

erence to the detailed image description provided earlier.

Answer With Image Description Prompt

You are an expert in STEM courses and will answer a question that includes an image description..

Here is the description of the image:
<detailed image description >

[Refer to generate_format_instruction]
Here is the question that you need to answer:
<question text >

[Refer to question_type_prompt]
Please, explain the solution and answer in the following format:

```
{  
  "reasoning": "Your explanation.",  
  "answer": "Your answer and nothing more."  
}
```

Your Reasoning and Answer:

B.3 Selecting prompting strategies

Initially, we tested 12 prompting strategies on 10 questions to select the most effective ones for the subsequent experiments. Figure 7 shows a comparison across all strategies. We selected the *two-stage* strategy as the most effective, followed by two baseline strategies, and finally the best strategy for presenting a model with both text and image.

In the basic prompting category, the question was presented along with the image, allowing the models to interpret the visual data without additional instructions. In the second category, prompts directed the models to explicitly consider both the image and text, either together or sequentially, with varying emphasis on fine-grained versus coarse-grained details. Finally, in the third category, models lacking vision capabilities were provided with detailed descriptions of the image instead.

B.3.1 Simultaneous Prompt

This prompt asks the LLM to examine both image and text simultaneously, integrating insights from both modalities before answering. It emphasizes a holistic analysis that considers all available information concurrently.

Simultaneous Prompt

You are an expert in STEM courses tasked with answering questions. Examine both the image(s) and question text before answering.

You will follow the next steps before providing an answer.
Step 1: Analyze the Image(s) and Text Together
- Describe key elements, patterns, and relationships, integrating both sources.
Step 2: Provide a Detailed Answer
- Synthesize observations into a complete answer.

Images: <image_names >

[Refer to generate_format_instruction]
Question: <question text >

[Refer to question_type_prompt]
Make sure to tackle every step mentioned above, before you answer.
Your Answer:

B.3.2 Text First Prompt

This prompt directs the LLM to analyze the question text initially and then examine the associated image, using the textual understanding to guide the image analysis. It ultimately expects the model to merge both insights into a coherent, well-informed answer.

Text First Prompt

You are an expert in STEM courses tasked with answering questions. But, first, you must analyze the text, which you will follow with the image analysis.

You will follow the next steps before providing an answer.
Step 1: Analyze the Question Text First
- Understand the question context.
Step 2: Use Observations to Analyze the Image
- Use textual understanding to find relevant visual information (elements, patterns, relationships, etc.)
Step 3: Provide a Detailed Answer
- Synthesize observations into a complete answer.

Images: <image_names >

[Refer to generate_format_instruction]
Question: <question text >

[Refer to question_type_prompt]
Make sure to tackle every step mentioned above, before you answer.
Your Answer:

B.3.3 Dual Phase Prompt

This prompt divides the analysis into two distinct phases; first analyzing the image(s) and then the text, before synthesizing the information into a final answer. It ensures that each component is

evaluated independently before being combined for a comprehensive response.

Dual Phase Prompt

You are an expert in STEM courses tasked with answering questions with a dual-phase approach.

You will follow the next steps before providing an answer.

Step 1: Analyze the Image(s) First

- Describe elements, patterns, and relationships in the image(s).

Step 2: Interpret the Question Text Separately

- Identify question context independently of your image findings.

Step 3: Synthesize Textual and Visual Information

- Combine insights from both phases.

Step 4: Provide a Detailed Answer

- Synthesize observations into a complete answer.

Images: <image_names >

[Refer to generate_format_instruction]
Question: <question text >

Make sure to tackle every step mentioned above, before you answer.
Your Answer:

Figure 7: Model performance on the initial set of prompting strategies.

Recursive Prompt

You are an expert in STEM courses tasked with answering questions with recursive analysis.

You will follow the next steps before providing an answer.

Step 1: Analyze the Image(s) First

- Describe elements, patterns, and relationships in the image(s).

Step 2: Use Observations to Analyze the Text

- Use the image understanding to find relevant textual information in the question.

Step 3: Refine Analysis

- Alternate between image and text analysis, refining observations with each pass until a comprehensive understanding of the text and image is reached.

Step 4: Provide a Detailed Answer

- Synthesize observations into a complete answer.

Make sure to tackle every step mentioned above, before you answer.
Your Answer:

B.3.4 Recursive Prompt

This prompt directs the LLM to iteratively alternate between image and text analysis, refining its understanding with each pass until a complete picture is achieved. It is designed to produce a well-considered final answer by progressively integrating and re-evaluating both modalities.

C Model Configuration

To evaluate performance, three OpenAI models were employed: GPT-4o with temperature 0.1, o1-mini-2024-09-12, and o1-preview-2024-09-12. GPT-4o was chosen as the baseline due to its strong vision capabilities. The o1-mini and o1-preview models, in contrast, lack native vision capabilities but exhibit strong reasoning abilities in text-based tasks. While GPT-4o allowed temperature adjustments, the o1 models did not support this feature. The primary focus was on GPT-family models as the ones that students can easily access models to

Figure 8: Model performance with and without supplemental image included.

run questions themselves while preparing a take-home assignment. We are trying to provide also some recommendations for educators on how to make such assignments less vulnerable to generative AI use. To explore the effect on different model families, we also test Qwen 2.5 72B VL, r1 Deepseek, and Claude 3.7 Sonnet, 2025.

We used pandas,² json,³ numpy,⁴ and scikit-learn⁵ to process our results, compute accuracy scores, and compute statistical significance.

D Additional Experimental Results

D.1 Model performance comparison

We observe that the GPT model is the most performant one and that, in general, the models follow our findings. The results in various characteristics are presented in Table 4.

Looking at the performance per course in Table 3, we see that our findings hold. Also, sometimes, there are cases when Claude 3.7 or R1 outperform GPT model: in a subject like biology and mechanical physics.

D.2 Removing supplemental image

We tested the same prompts with and without supplemental images. For the *two stage* prompts we removed mentions of the image and didn't pass the descriptions. Figure 8 shows that the presence or absence of the image doesn't affect model performance.

D.3 Model performance vs student performance

In Figure 9, we compare model performance across five prompting strategies and two aggregation strategies with average student performance.

Figure 9: Average GPT-family models performance across five prompting strategies, aggregated results with the majority vote and maximum strategy and student performance.

Figure 10: Comparison of student vs model accuracy depending on the question length in characters.

D.4 Student vs model accuracy depending on the question length

Figure 10 shows the comparison of the student and model accuracy (average majority vote) depending on the length of the question in characters.

D.5 Model performance across question and image features

Model and student performance per question and image features with 95% confidence intervals are presented in Tables 5 and 6.

Abstract

Large language models (LLMs) are increasingly used to generate distractors for multiple-choice questions (MCQs), especially in domains like math education. However, existing approaches are limited in ensuring that the generated distractors are consistent with common student errors. We propose LOOKALIKE³, a method that improves error–distractor consistency via preference optimization. Our two main innovations are: (a) mining synthetic preference pairs from model inconsistencies, and (b) alternating supervised fine-tuning (SFT) with Direct Preference Optimization (DPO) to stabilize training. Unlike prior work that relies on heuristics or manually annotated preference data, LOOKALIKE uses its own generation inconsistencies as dispreferred samples, thus enabling scalable and stable training. Evaluated on a real-world dataset of 1,400+ math MCQs, LOOKALIKE achieves 51.6% accuracy in distractor generation and 57.2% in error generation under LLM-as-a-judge evaluation, outperforming an existing state-of-the-art method (45.6% / 47.7%). These improvements highlight the effectiveness of preference-based regularization and inconsistency mining for generating consistent math MCQ distractors at scale.

1 Introduction

Multiple-choice questions (MCQs) are used in educational assessments (Nitko, 1996; Airasian, 2001; Kubiszyn and Borich, 2016) to evaluate student understanding across various subjects and grades (Thomas et al., 2025). An MCQ consists of a question stem and a set of options, including a correct answer and multiple incorrect alternatives, referred to as *distractors* (Fernandez et al., 2024; Feng et al., 2024). *Distractors* are incorrect answers that students reach by making an *error* while answering the question. It can be rooted in many ways, e.g., the

student overgeneralizing to a new context, exhibiting an ingrained misconception, or simply slipping and being careless. Designing effective distractors can be crucial to the assessment and pedagogical aspects of MCQs (Simkin and Kuechler, 2005), since they help us identify student errors and prepare ways to mitigate them.

Hand-crafting high-quality distractors requires extensive human effort by content designers and teachers since it requires them to anticipate common student errors, which can be difficult in subjects like math. Therefore, recent works have leveraged artificial intelligence, especially large language models (LLMs), to automate this process. Previous works on *distractor* generation for MCQs have attempted to prompt LLMs to generate distractors (Feng et al., 2024), as well as fine-tune LLMs to generate possible student errors and then distractors caused by such errors, as shown in DiVERT (Fernandez et al., 2024). As noted in these works, the bottleneck in distractor generation performance is *consistency*: LLMs are often capable of identifying mathematically feasible errors, but struggle at following such erroneous instructions to arrive at the corresponding distractor (a similar finding was also made in (Sonkar et al., 2024a)). As shown in Table 1, both fine-tuned LLMs and the LLMs in DiVERT sometimes fail to follow the input error explanation to arrive at a consistent distractor. In the second example, the fine-tuned LLM fails to follow the error, “finds 13% of an amount rather than the percentage being asked”, arriving at an inconsistent distractor (12) rather than the consistent distractor (5.2).

To address this limitation, one natural solution is to regularize an LLM-based distractor generator, which takes the question stem and an error as input, to enforce that the generated distractor matches the input error. To this end, we resort to preference optimization, specifically direct preference optimization (DPO) (Rafailov et al., 2023). DPO

*Equal Contribution.

Question stem: Calculate: 130% of 40 = □	
Error	Distractor
Plausible error, plausible and consistent distractor.	
Added the values together instead of finding the percentage.	170
Plausible error, plausible but inconsistent distractor.	
Finds 13% of an amount rather than the percentage being asked.	12
Implausible error, plausible but inconsistent distractor.	
When solving a problem that requires an inverse operation (e.g. missing number problems), does the original operation.	90
Implausible error, implausible and inconsistent distractor.	
Does not understand that 100% is the whole amount.	20

Table 1: Examples of inconsistent error-distractor pairs generated by SFT (second and fourth pairs), and a state-of-the-art method, DiVERT (Fernandez et al., 2024) (third pair). LOOKALIKE mines generation inconsistencies for scalable preference optimization.

training requires *preference pairs* among outputs, i.e., a distractor that matches the input error and a distractor that does not. However, we empirically find two main challenges in using DPO to promote error-distractor consistency:

- Acquiring high-quality preference data typically requires costly manual annotation or unreliable synthetic heuristics (Li et al., 2023; Tan et al., 2024), which is difficult due to the nature of the distractor generation task.
- Models trained with DPO may deteriorate in quality after a few epochs (Pal et al., 2024; Liu et al., 2024b; Yan et al., 2025; Xu et al., 2024), showing training instability.

Contributions

In this paper, we introduce LOOKALIKE, proposing two methods to tackle these challenges and improve error-distractor consistency in math MCQs. For the first challenge, we create preference pairs by generating *synthetic negative samples*: we evaluate LLM-generated errors, in addition to distractors, and use inconsistently generated errors and distractors as informative negative samples. This method creates meaningful signals that, when used in conjunction with consistent errors and distractors in DPO training, improve the consistency of LLMs in distractor generation. For the second challenge, we employ a regularization method in DPO training, which performs supervised finetuning (SFT)

and DPO *alternatively* in consecutive training iterations, which performs better than combining them both into a single objective, as done in recent works (Liu et al., 2024b; Pal et al., 2024).

We conduct extensive experiments on a real-world dataset containing math MCQs used by hundreds of thousands of students, with human-written error descriptions behind each distractor. Results show that LOOKALIKE, compared to state-of-the-art baselines, improves distractor generation performance by up to 6%. We also show that LOOKALIKE improves error generation by up to 10%, using an LLM-as-a-Judge evaluation. We also provide qualitative examples and an error analysis highlighting the improved consistency of generated *errors* and *distractors*.

2 Background

In this section we formally introduce the tasks of *error* and *distractor* generation in math MCQs. We also detail a baseline for preference pair creation and a baseline for DPO regularization, combining preference alignment with supervised learning.

2.1 Task Definition

We consider an MCQ Q defined by its textual components: a **question stem** s , (optionally) its **correct answer** or **key** k , (optionally) an explanation of the key f , (optionally) question topic/concept tags t , and a set of **incorrect answer options** called ground truth distractors D . Each $d_i \in D$ is (optionally) associated with a corresponding ground truth human-written **error explanation** or error $e_i \in E$. All textual components above are represented as sequences of words and math symbols. We aim to model the space of plausible student errors E and their corresponding distractors D . We define two primary tasks:

1. **Error Generation:** Learn an LLM parameterized model, $LLM^{err}(s, k, f, t, d_i) \rightarrow \hat{e}_i$, that outputs an error description \hat{e}_i consistent with the given input distractor d_i and MCQ.
2. **Distractor Generation:** Learn an LLM parameterized model, $LLM^{dis}(s, k, f, t, e_i) \rightarrow \hat{d}_i$, that outputs a distractor \hat{d}_i consistent with the given error description e_i and MCQ.

2.2 Baseline: Preference Pairs from Ground-truth Error-Distractor Pairs

As a natural starting point, following a similar method from (Scarlatos et al., 2024b), one can

construct preference pairs for DPO as follows: For each question, there are multiple distractors ($D = d_1, d_2, \dots, d_n$) and their corresponding errors ($E = e_1, e_2, \dots, e_n$). As a baseline, for the error behind the i^{th} distractor, e_i , we can use d_i itself as the preferred response, and use the remaining distractors ($d_j \in D \setminus \{d_i\}$) as dispreferred responses. We use a similar procedure for the errors. We dub this method for preference pair construction as **DPO-GT** (ground truth). However, the number of dispreferred responses is limited by the number of human-written error-distractor pairs for the question. LOOKALIKE, on the other hand, creates preference pairs by generating *synthetic negative samples*, allowing for an arbitrary number of dispreferred responses for scalable preference optimization, resulting in improved consistency in both error and distractor generation (Section 3.1).

2.3 Baseline: DPO Regularization

Models trained with DPO have been shown to deteriorate in quality after a few epochs due to training instability (Pal et al., 2024; Liu et al., 2024b; Yan et al., 2025; Xu et al., 2024). Existing regularization techniques to improve DPO training stability include Regularized Preference Optimization (**RPO**) (Liu et al., 2024b), and DPO-Positive (**DPOP**) (Pal et al., 2024). RPO optimizes both the DPO loss and the SFT loss jointly, i.e., $L_{RPO} = L_{DPO} + \lambda\beta L_{SFT}$. The SFT loss uses the preferred response as the ground-truth completion. RPO suffers from conflicting gradient directions (Shi et al., 2023; Liu et al., 2024a), especially when the preference-based signal (DPO) incentivizes ranking decisions that are misaligned with the next-token prediction signal (SFT). DPOP uses the SFT objective as a penalty but their improvement is limited to preference pairs with high edit distances between them. LOOKALIKE, on the other hand, proposes an alternating optimization approach to stabilize DPO training, interleaving SFT and DPO training either at the per-batch or per-epoch level, resulting in improved consistency in both error and distractor generation compared to RPO and DPOP (Section 3.2).

3 Methodology

We now detail our framework, LOOKALIKE, which a) creates preference pairs by generating synthetic negative samples, and b) employs a DPO regularization technique of alternating optimization be-

tween SFT and DPO for better training stability, leading to improved error and distractor generation consistency.

3.1 Mining Preference Pairs via Inconsistencies for DPO

Prior work (Fernandez et al., 2024) has highlighted a significant issue of consistency in distractor generation performance, with LLMs struggling to follow error descriptions to arrive at corresponding distractors, examples of which are shown in Table 1. LOOKALIKE mines these generation inconsistencies as *synthetic negative samples* to create preference pairs for DPO training.

We visualize our preference pair creation in LOOKALIKE in Figure 1. For distractor generation, LLM^{dis} overgenerates a set of distractors for an input question stem and a ground-truth error. Each generated distractor is then compared against the ground-truth distractor. In our preference dataset, generated distractors that match the ground-truth distractor exactly are preferred responses, while those that do not exactly match the ground-truth distractor are dispreferred responses. A similar process is applied to create preference pairs for error generation, with exact string match⁴ used to compare generated errors against the ground-truth error to form preference pairs.

Formally, given an MCQ dataset with samples, (s, e, d) , where s is the question stem, e is the error description, and d is the corresponding distractor, we first train a distractor generation model, LLM^{dis} , to output the corresponding distractor through SFT. To create preference pairs, we then overgenerate multiple distractors $\hat{d} \in \hat{D}$ from the fine-tuned LLM^{dis} for each (s, e) pair. For each generated distractor \hat{d} , we check if \hat{d} matches the ground-truth distractor d exactly. If yes, we add \hat{d} as a preferred response, and if no, we add \hat{d} as a dispreferred response in our distractor generation preference dataset. Having constructed the preference dataset, we further train our fine-tuned LLM^{dis} through DPO (Rafailov et al., 2023). A similar process is applied to form our error generation preference dataset which is then applied for DPO training of LLM^{err} . Creating preference pairs from the static ground-truth dataset is limited by the number of human-written annotations (Section 2.2). LOOKALIKE, on the other hand, uses generations from the currently fine-tuned LLM to

⁴LLM-as-a-Judge using GPT-4o-mini as a similarity measure led to lower performance.

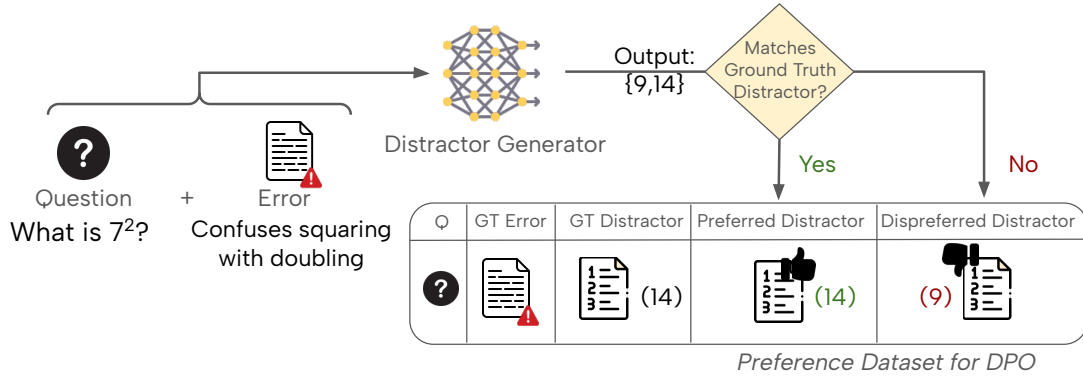

Figure 1: LOOKALIKE creates preference pairs by overgenerating a set of distractors for a question and error, and preferring those that match the ground-truth distractor exactly. An analogous process for error generation.

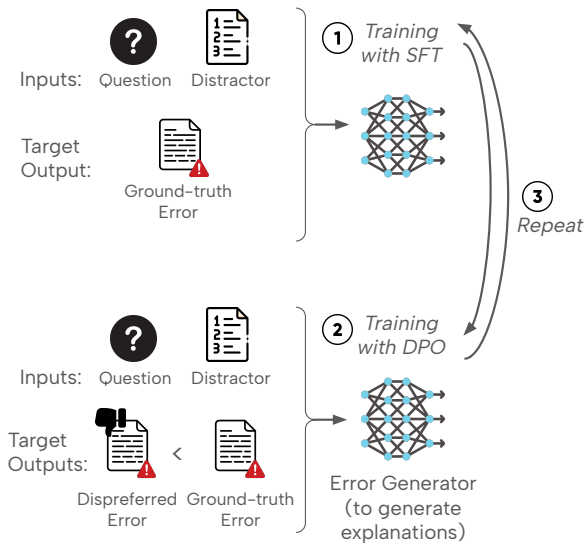

Figure 2: LOOKALIKE employs an alternating optimization strategy, switching between SFT and DPO objectives to regularize DPO training.

create an arbitrary number of dynamic preference pairs, with negative preference signals being more aligned with the inconsistency failure modes of the fine-tuned LLM.

3.2 DPO Regularization Through Alternating Optimization

We empirically observe that models trained with DPO deteriorate in quality after a few epochs due to training instability. We show examples of degradation in error generation quality over three training epochs in Table 2. We observe errors become more verbose with an increase in length and are out-of-distribution from the human-written errors as the number of DPO training epochs increases, as also shown in prior work (Park et al., 2024).

To mitigate this issue, we introduce a regu-

larization strategy that trains the error/distractor-generation LLM by *alternating optimization*, i.e., by switching between SFT and DPO objectives during training, as shown in Figure 2. This alternating optimization allows the LLM to periodically recalibrate to the ground-truth distribution (via SFT) while remaining faithful to learning ranking preferences of consistent generations (via DPO). After each SFT optimization, the preference dataset is recomputed (Section 3.1) for the subsequent DPO optimization, using the currently trained LLM for better alignment, allowing for dynamic and scalable preference pair creation. We experiment with alternating between SFT and DPO optimization at two different levels: per-batch and per-epoch, picking the one giving better performance empirically. For both levels, the preference dataset is recomputed after every epoch.

Alternating Optimization Per-Batch. At each training step t , the LLM parameters θ are updated using a learning rate of η following:

$$\theta_{t+1} = \theta_t - \eta \nabla L(\theta_t), \quad (1)$$

where the loss function L alternates based on a batch-level schedule:

$$L(\theta_t) = \begin{cases} L_{SFT}(\theta_t), & \text{if batch } t \text{ is even} \\ L_{DPO}(\theta_t), & \text{otherwise} \end{cases} \quad (2)$$

Alternating Optimization Per-Epoch. As a coarser alternative, the loss function L alternates based on an epoch-level schedule:

$$L(\theta_t) = \begin{cases} L_{SFT}(\theta_t), & \text{if epoch } t \text{ is even} \\ L_{DPO}(\theta_t), & \text{otherwise} \end{cases} \quad (3)$$

Question	$\frac{3}{7}$ of a group of students are boys. What would be a possible ratio of boys to girls?
Key	3 : 4
Ground-truth Distractor	3 : 10
Ground-truth Error	Uses the denominator when converting from fractions to ratio, rather than numerator.
Generated Error (Epoch 1)	Includes the denominator when converting a fraction to a ratio.
Generated Error (Epoch 2)	When converting a fraction to a ratio, puts the other side of the ratio as the denominator.
Generated Error (Epoch 3)	When converting a fraction to a ratio, thinks you just use the numerator and denominator as the numbers in the ratio. Additionally, thinks you can use the denominator on its own as the total number of parts in a ratio.

Table 2: Error generation quality deteriorates over DPO training epochs without using regularization.

4 Experimental Evaluation

In this section, we detail our experiments on a real-world math MCQ dataset, evaluating the efficacy of LOOKALIKE in comparison with state-of-the-art baselines for both distractor generation and error generation.

4.1 Dataset

We conduct our experiments on a real-world math MCQ dataset from a large learning platform used by hundreds of thousands of students. The dataset consists of 1,434 math MCQs, each containing a question stem, key, explanation of the key, topic/concept tags, and 3 distractors along with their respective teacher-written error descriptions explaining why a student might select that distractor. The MCQs are designed for students aged between 10 to 13 and span 41 distinct mathematical subtopics, including *Arithmetic*, *Fractions*, and *Solving Equations*. We split the dataset into training, validation, and test by questions to ensure no overlap across splits using a 72%-16%-12% proportion. See Appendix E for math MCQ examples.

4.2 Baselines

We compare LOOKALIKE with 3 baselines. The **SFT** baseline, used as a baseline in (Fernandez et al., 2024), fine-tunes an LLM to generate the corresponding distractor (or error) given the question and the error (or distractor) as input. The **DiVERT** (Fernandez et al., 2024) baseline employs a variational approach to learn an interpretable error space behind distractors. Post variational training, we use the error generation and distractor generation LLMs from DiVERT as baselines. We also compare against forming preference pairs from the ground-truth error-distractor pairs; we continue training the SFT baseline on this preference dataset using DPO and refer to the resulting

model as **DPO-GT** (Section 2.2). For fairness, we regularize DPO training for DPO-GT by exploring all techniques (RPO, DPOP, our alternating per-batch optimization, and our alternating per-epoch optimization), and choose the regularization (per-epoch) that results in the best performance.

4.3 Metrics

Distractor Evaluation. Following prior work on distractor generation (Fernandez et al., 2024; Feng et al., 2024), we use **Exact match** as our evaluation metric to measure alignment between the generated distractor and the ground-truth distractor corresponding to a question and error.

Error Evaluation. Automated text similarity metrics like exact string match, ROUGE-L F1 (Lin, 2004), or BERTScore F1 (Zhang et al., 2020) are unsuitable for error evaluation given the open-ended and mathematical nature of errors. We therefore adopt an **LLM-as-Judge** (Liu et al., 2023; Zheng et al., 2023) evaluation, prompting GPT-4o-mini to evaluate if the generated error is mathematically equivalent to the ground-truth error given the question and corresponding distractor. We show our prompt in Appendix B.

4.4 Implementation Details

Following prior work (Fernandez et al., 2024), all methods use MetaMath-Mistral 7B (Yu et al., 2024b) as their base LLM, as we found it provides a suitable prior within the 7B parameter size models for mathematical reasoning. At test time, we use standard beam search with 10 beams for distractor generation, and diverse beam search (Vijayakumar et al., 2018) with 10 beams for error generation. Detailed hyperparameter settings for all methods are provided in Appendix A.

To ensure fair comparison, we limit LOOKALIKE’s synthetic generation to 3 distractors and 3

	Distractor Gen (Exact Match \uparrow)	Error Gen (LLM-as-Judge \uparrow)
SFT	44.76	46.68
DiVERT	45.64	47.72
DPO-GT	51.44	57.02
LOOKALIKE	51.56	57.18

Table 3: Cross-validation performance on distractor generation and error generation for all methods across 5 folds. LOOKALIKE outperforms SFT and the prior state-of-the-art method DiVERT (Fernandez et al., 2024), and is comparable to DPO-GT.

errors per training sample per epoch, resulting in a similar order of magnitude of training samples as DPO-GT. We also use the same training budget and regularization for both methods. All fine-tuned models, including SFT and DPO-based variants, were trained with LoRA to ensure parameter efficiency and consistency in comparison.

5 Results, Analysis and Discussion

In this section, we detail our experimental results. We quantitatively evaluate the quality of generated errors and distractors, qualitatively evaluate the consistency of generated errors through human evaluation, conduct an ablation study on DPO regularization techniques, and perform an error analysis on failed cases of error generation.

5.1 Quantitative Evaluation

Table 3 shows the average performance on distractor generation and error generation, across 5 cross-validation folds, for all methods. DPO-based methods, DPO-GT and LOOKALIKE, are trained using our alternating optimization technique for DPO regularization, choosing the alternating level (per-batch or per-epoch) that works best for downstream task performance. DPO-GT works best with per-epoch for both tasks, while LOOKALIKE works best with per-epoch for distractor generation, and per-batch for error generation.

Preference optimization using inconsistent error-distractor pairs improves consistency. LOOKALIKE outperforms SFT and the previous state-of-the-art baseline DiVERT (Fernandez et al., 2024), by a wide margin of 6.8% and 5.92% on distractor generation, and 10.5% and 9.46% on error generation performance, respectively. The improvement is statistically significant with p-values < 0.05 measured using a one-sample Wilcoxon signed-rank test (Rey and Neuhäuser,

	Dis Gen (Exact M. \uparrow)	Error Gen (LLM-as-Judge \uparrow)
DPO-GT w/o Reg.	47.68	53.96
+ DPOP	47.80	52.74
+ RPO	49.14	52.44
+ Per-batch	49.66	55.74
+ Per-epoch	51.44	57.02
LOOKALIKE w/o Reg.	47.98	49.34
+ DPOP	49.38	49.44
+ RPO	49.60	49.66
+ Per-batch	50.84	57.18
+ Per-epoch	51.56	56.64

Table 4: Ablation study of various DPO regularization techniques. Our alternating (per-batch/epoch) optimization performs best for both DPO-GT and LOOKALIKE.

2011). This result validates our idea of mining error-distractor inconsistencies as preference pairs for DPO training to improve both error and distractor generation consistency. Further, LOOKALIKE, although using synthetic negative samples drawn from its own inconsistent generations as preference pairs, is comparable in performance to DPO-GT, which uses human-written annotations as preference pairs, demonstrating the potential and flexibility of LOOKALIKE for scalable, domain-agnostic preference optimization.

Although the performance difference between LOOKALIKE and DPO-GT appears small (0.12% and 0.16% on distractor and error generation respectively), it is important to note that LOOKALIKE achieves this using automatically mined preference pairs from inconsistent generations, without relying on ground-truth labels, highlighting its scalability. Moreover, the improvement over DiVERT (5.9-10.5%) is substantial and statistically significant.

Alternating optimization is an effective DPO regularization. Table 4 shows an ablation study comparing different DPO regularization techniques to combat deterioration in generation quality (Pal et al., 2024) during DPO training. Existing approaches like DPOP (Pal et al., 2024) and RPO (Liu et al., 2024b) provide marginal gains up to 1.62% for distractor generation and 0.32% for error generation. Our alternation optimization, switching between SFT and DPO objective, at either the per-batch or per-epoch level, leads to the best performance for both, DPO-GT and LOOKALIKE, with performance gains up to 1.96% on the distractor generation task and 7.52% on the error generation task. These results show that alternating optimization effectively guides the LLM to periodically recalibrate to the ground-truth distribution (via SFT)

while remaining faithful to learning ranking preferences of consistent generations (via DPO).

5.2 Qualitative Case Studies

LOOKALIKE generates more consistent errors. Table 5 shows errors from LOOKALIKE compared to errors generated from SFT on two math questions. For the question on finding factors, SFT generates an overly generalized error applicable to many potential distractors, “Does not understand the term factor”. On the other hand, LOOKALIKE generates a more specific error, “When asked for factors of an algebraic expression, thinks any part of a term will be a factor”, consistent with the distractor. Similarly, for the question on simplifying algebraic terms, SFT generates an abstract error applicable to many distractors, “Tries to add or subtract unlike terms”. On the other hand, LOOKALIKE generates a more specific and consistent error leading to the input distractor, “When collecting like terms, treats subtractions as if they are additions.” We see similar patterns across other topics, with errors generated by LOOKALIKE being more specific and consistent with the input question and distractor. We also show qualitative examples of generated errors across all methods in Appendix D.

Error Analysis of LOOKALIKE. While LOOKALIKE outperforms SFT in generating more consistent errors and distractors, we observe some examples of generated errors that are inconsistent with the input question-distractor pair. One failure pattern observed is of *template overfitting*, where LOOKALIKE generates an error by overfitting to the error-distractor template of a similar question seen during training, generating errors that are consistent with other distractors from similar questions but not the input distractor. Table 8 in the Appendix shows two examples. We see that the generated error, “Has multiplied by the root power”, is inconsistent with the input distractor 64, but upon inspection, is present as a ground-truth error and consistent with another question-distractor pair on the same topic.

5.3 Human Evaluation

Setup. We conduct a human evaluation on the quality and consistency of generated errors. We instruct two independent annotators with teaching experience to evaluate whether an error is consistent with a given input math question and corresponding distractor, choosing between a) yes, b) partially,

and c) no. Our instructions to human annotators are provided in Appendix F.

We randomly select 40 math questions from our test set spanning a diverse range of topics. For each question, we include its ground-truth human-written error, the error generated by SFT, and the error generated by LOOKALIKE, for human evaluation. This process results in 120 errors, along with their corresponding questions and distractors, for human evaluation. We shuffle the 120 samples to avoid annotator bias.

Results. Table 6 shows the average of annotators’ ordinal ratings on error explanations from the ground truth, SFT, and LOOKALIKE models. Ground truth errors scored the highest (mean = 0.812), followed by LOOKALIKE (0.587), and SFT (0.400). While LOOKALIKE does not match the human-authored ground truth, it significantly outperforms SFT on average, suggesting that preference-based regularization leads to more pedagogically consistent explanations.

We also measured agreement between annotators using quadratic-weighted Cohen’s kappa, and found that error labels generated by LOOKALIKE led to the highest agreement (0.740), surpassing both SFT (0.659) and even the inter-annotator agreement on ground truth labels (0.415). This result suggests that errors generated by LOOKALIKE are easier for humans to interpret consistently, even if they are not always as plausible as ground truth explanations. We see a lower agreement on ground truth errors because their pedagogical nuance and potential generality made consistency judgments more subjective for annotators compared to the often more literal AI-generated errors.

Finally, we compared agreement between evaluations from human annotators to evaluations from GPT-4o-mini-based LLM-as-Judge, our reference metric for error generation. Agreement varied between annotators, with the first annotator showing moderate agreement (linear Kappa) with GPT-4o-mini (0.556 for LOOKALIKE-generated errors and 0.505 for SFT-generated errors), and the second annotator showing low agreement (0.314 for LOOKALIKE-generated errors and 0.409 for SFT-generated errors).

Table 6: Average error consistency rating by human evaluators. LOOKALIKE generates more consistent errors than SFT.

template-based (rule-based and constraint-based) methods (Shin et al., 2019; Liang et al., 2018; Luo et al., 2024) to Large Language Model (LLM) approaches (Fernandez et al., 2024; Feng et al., 2024; Scarlatos et al., 2024a; Bitew et al., 2023; Chung et al., 2020). A critical challenge, however, remains the generation of high-quality distractors that accurately reflect common student errors and misconceptions (Alhazmi et al., 2024; Stasaski and Hearst, 2017). Current methods advance error representation using variational techniques (Fernandez et al., 2024), RAG-based methods (Yu et al., 2024a), and knowledge-bases (Ren and Q. Zhu, 2021).

Preference Optimization in Education. Preference learning techniques, including Reinforcement Learning from Human Feedback (RLHF) (Ouyang et al., 2022) and its more stable, computationally efficient alternative Direct Preference Optimization (DPO) (Rafailov et al., 2023), are vital for aligning AI outputs with human judgments in education (Fahad Mon et al., 2023). Many recent approaches have used DPO (Lee et al., 2025; Sonkar et al., 2024b; Team et al., 2024; Ashok Kumar and Lan, 2024; Scarlatos et al., 2024b, 2025) but they do not handle some known failure modes of DPO related to inconsistent or out-of-distribution generation which the synthetic data generation of LOOKALIKE utilizes and the regularization of LOOKALIKE addresses. Other works mitigate these issues by providing regularization by using entropy

(Shekhar et al., 2024), length-based rewards (Park et al., 2024), or the SFT objective (Liu et al., 2024b; Pal et al., 2024), LOOKALIKE improved on these by providing a simpler SFT-based regularization approach which requires less hyperparameter tuning and is easier to apply.

Challenges in Erroneous Instruction Following.

Generating distractors from error descriptions, is an instance of the broader challenge of AI instruction following (Lou et al., 2024). AI systems, including LLMs, struggle with complex reasoning (Heo et al., 2024; Son et al., 2024), multi-step tasks (Chen et al., 2024; Wang and Lu, 2023; Fujisawa et al., 2024), and adhering to multiple constraints simultaneously (Wen et al., 2024), sometimes exhibiting a "curse of instructions" where performance degrades as complexity increases (Jang et al., 2022; Son et al., 2024). Generalization also poses a significant hurdle; models often fail to apply instructions to new tasks or in novel combinations (compositional generalization) (Cohen et al., 2025; Dan et al., 2021). These challenges can lead to inconsistencies where the generated output does not faithfully reflect the nuances of the input instruction (Jang et al., 2022; Son et al., 2024; Heo et al., 2024), a problem LOOKALIKE aims to mitigate in the context of error-distractor generation through targeted preference optimization.

7 Conclusion

In this paper, we introduced LOOKALIKE, a method that improves error-distractor consistency in math MCQs via preference optimization. LOOKALIKE uses two main innovations: a) mining synthetic preference pairs from model generation inconsistencies and b) alternating optimization by switching between SFT and DPO objectives to

stabilize training. Through extensive experiments on a real-world math MCQ dataset, we showed that LOOKALIKE outperforms the previous state-of-the-art method by a wide margin on both error generation and distractor generation. These improvements highlighted the potential of inconsistency mining and preference-based regularization for generating consistent math MCQ distractors at scale. We identify several limitations and avenues for future work. First, while LOOKALIKE improves error and distractor generation consistency, examples of inconsistent generations remain. Ideas for creating preference pairs using error generation and distractor generation models together could be a promising direction. Second, testing the generalizability of LOOKALIKE to math MCQs from unseen topics remains unexplored.

Limitations

While LOOKALIKE demonstrates improvements in generating consistent error-distractor pairs, it currently operates within the domain of middle-school mathematics. Extending the approach to other subjects like science or language arts may require minor modifications to the error and distractor representations.

Additionally, the current preference mining strategy relies on model-generated inconsistencies, which assumes the base model is sufficiently trained to surface pedagogically meaningful contrastive samples. In practice, we find that models pretrained on math data (e.g., MetaMath) meet this assumption, suggesting this is a broadly applicable approach rather than a bottleneck.

Our use of exact match to label non-matching outputs as dispreferred is conservative and intentionally strict; it helps emphasize high-confidence inconsistencies. Nonetheless, exploring softer similarity-based criteria or human judgments to refine preference mining is a valuable future direction.

Ethical Considerations

Our goal is to reduce educator workload by automating the generation of plausible distractors and their associated misconceptions, ultimately supporting teachers in providing more personalized feedback. However, we acknowledge a potential concern around over-reliance on AI-generated content in educational settings. While our system is designed to assist, not replace, educators, thoughtful deployment practices and educator-in-the-loop designs are encouraged.

The use of large language models (LLMs) introduces the standard risks of inherited biases or artifacts from pretraining data. In our case, these risks are minimal, as the domain of application (mathematical misconceptions) is highly constrained and less prone to sociolinguistic biases. Nevertheless, we encourage ongoing validation and periodic audits as best practices when deploying AI systems in learning environments.

A Baselines and their Hyperparameters

We describe LOOKALIKE’s baselines, as well as the hyperparameters used by LOOKALIKE and its baselines. We use MetaMath-Mistral 7B (Yu et al., 2024b) as our base LLM backbone for error and distractor generation across methods. For memory efficiency, we quantize the model weights into 8-bit integer representation and enable gradient checkpointing throughout training. Our implementation utilizes the HuggingFace ecosystem, specifically the transformers (Wolf et al., 2020), peft, and trl libraries for finetuning. We perform training on NVIDIA L40 GPUs.

SFT. For the supervised finetuning (SFT) baseline we train the base model with Low-Rank Adaptation (LoRA) modules (Hu et al., 2022). LoRA is configured with a rank $r = 128$, $\alpha = 256$, and a dropout rate of 0.05. We perform SFT training for 5 epochs, with early stopping based on validation loss. We use the AdamW optimizer (Loshchilov and Hutter, 2019) with a learning rate of $2e-5$. We use a batch size of 6.

DPO-based Baselines. For all DPO training, we set the hyperparameter $\beta = 0.5$ and the learning rate as $5e-6$. We use a batch size of 6.

DPO-GT. As specified in 2.2 we have multiple errors and distractors associated with all questions, to create preference pairs for each pair of error and distractor, we place all the non-associated sample of either in the dispreferred pair while placing the specified samples in the preferred pairs.

RPO. For RPO (Section 2.3), we use $\lambda = 0.005$ as reported by them. We use the default implementations of RPO as provided in the trl library.

DPOP DPO-Positive (DPOP) (Pal et al., 2024) enhances DPO by preventing the model from merely reducing the likelihood of rejected examples where the edit distance in all pairs is large by using the SFT objective as a penalty. It introduces a constraint term to balance learning:

$$L_{DPOP} = L_{DPO} - \lambda \cdot \max(0, \log \frac{\pi_{ref}(y_w|x)}{\pi_{\theta}(y_w|x)}). \quad (4)$$

Here, we use $\lambda = 0.1$.

LOOKALIKE (Synthetic Data Generation).

For the LOOKALIKE preference pairs (in Section 3.1) we generate 3 errors and distractors for each epoch of training to create negative preference samples, while considering the ground truth errors and distractors as the positive preference samples. We consider the top- k completions returned by beam search to get a set of \hat{e}_i which augments the set of dispreferred responses further. We note that for all DPO training we use the SFT trained model as a warm start as with previous literature (Rafailov et al., 2023).

LOOKALIKE (Per-epoch and Per-batch Regularization). With the per-epoch and per-batch modes of LOOKALIKE (Section 3.2), we use the learning rate of $5e-6$ for both DPO and SFT. For the per-epoch setting we perform one entire epoch of SFT after one epoch of DPO. Whereas for the per-batch setting if we run out of SFT batches while DPO training hasn’t finished we rollback to the beginning of the SFT training data.

B LLM-as-a-judge

To assess whether two error explanations express the same underlying misconception, we use GPT-4o-mini as an automated judge. The model is provided with the question, distractor, and two error explanations, and asked to determine whether they are *mathematically equivalent* (Table 7), that is, whether they arise from the same conceptual

misunderstanding, regardless of wording. Below, we present an example of the prompt used in this evaluation.

This template was used for all pairwise comparisons of error explanations in the LLM-as-a-Judge evaluation.

C Error Analysis

While LOOKALIKE generally produces more specific and grounded error explanations, Table 8 also reveals some notable limitations. In the cube root example, the explanation “Has multiplied by the root power” reflects a plausible arithmetic confusion but doesn’t clearly connect to the distractor value of 64, which results from cubing rather than misunderstanding cube roots. Similarly, in the number ordering case, the generated error implies digit-level misordering but lacks clarity on how this leads specifically to choosing “Only Katie.” These examples suggest that while LOOKALIKE often captures fine-grained misconceptions, it can occasionally overgeneralize or introduce speculative reasoning not fully aligned with the distractor. This underscores the need for further refinement to ensure tighter alignment between the error explanation and the underlying choice.

D Comparing Errors across LOOKALIKE and its Baselines

Table 9 illustrates how different training methods produce qualitatively distinct reasoning errors across representative math questions. We observe a clear progression in the nature of these errors, reflecting the underlying supervision strategies. Models trained with SFT often generate surface-level mistakes indicative of limited conceptual understanding. In contrast, DiVERT tends to produce more structured but still incorrect procedural reasoning. Errors from DPO-GT reveal partial application of mathematical heuristics, suggesting more sophisticated—though still flawed—mental models. Finally, LOOKALIKE models (both per batch and per epoch) consistently produce errors that resemble common student misconceptions, such as overgeneralizing valid procedures or subtly misapplying familiar rules. This progression supports our claim that LOOKALIKE encourages more pedagogically meaningful error patterns, aligning closely with authentic human reasoning.

E Example MCQs from Real-world Math MCQ Dataset

We show example MCQs from the dataset in Table 10.

F Human Analysis Instructions

To evaluate the consistency of error explanations with corresponding distractor choices in multiple-choice math questions, we provided annotators with detailed guidelines, shown in Table 11. Annotators were instructed to examine each question item, which included a correct answer, a step-by-step solution, a distractor (incorrect answer), and an explanation for why a student might choose that distractor.

Annotators were asked to judge whether the explanation was:

- Yes: Clearly consistent with the distractor and plausibly explains the student error.
- Partially: Somewhat consistent, but vague, generic, or only loosely related to the distractor.
- No: Inconsistent or misleading; does not plausibly explain the choice of the distractor.

The instructions included concrete examples for each category to help calibrate judgment and ensure consistent annotation. These annotations were later used to analyze the quality of generated error explanations.

System Prompt.

You are a math education expert.

Given a question and a distractor (an incorrect student answer), determine whether two error descriptions are *mathematically equivalent*.

Definitions.

- An incorrect answer or distractor is a plausible but incorrect answer choice to the specified question.
- An error explanation or error is the misconception a student might make that leads them to choosing the specified distractor.
- Two error explanations are *mathematically equivalent* if they stem from the same core misunderstanding, regardless of wording.

Your response should include a brief justification (1–2 sentences) for whether the errors reflect the same or different misconceptions.

Always conclude with: “**Answer: Equivalent** or **Answer: Not Equivalent**”.

Question and Metadata.

The question is: <Question>

The question topic is: <Topic>

The question concept is: <Concept>

The solution is: <Solution from question to Correct Answer>

The correct answer is: <Correct Answer>

Distractor (incorrect answer): <Ground Truth Distractor>

Error explanation 1: <Ground Truth Error>

Error explanation 2: <Generated Error>

Table 7: System prompt used to evaluate the mathematical equivalence of error explanations for a given distractor. The prompt positions the model as a math education expert tasked with identifying whether two misconceptions arise from the same underlying error.

Field	Cube Root	Indices, Powers and Roots
Question	$\sqrt[3]{8} = ?$	$3.52 + 2.75 =$
Distractor	64	5.27
Correct Answer	2	6.27
SFT Error Explanation	Divides by the order of the root.	Does not understand place value within a number.
LOOKALIKE Error Explanation	Has multiplied by the root power.	When adding decimals with a different number of decimal places, lines up the digits incorrectly.

Table 8: Comparison of error explanations for two different math topics. Examples show that LOOKALIKE also has some failure modes, discussed in greater depth in Section 5.2.

	Improper Fraction Conversion	Gradient of a Line
Question	Convert this into an improper fraction: $4\frac{2}{3}$	What is the gradient of this line? $5x + 3y = 15$
Correct Answer	$\frac{14}{3}$	$-\frac{5}{3}$
Ground-truth Distractor	$\frac{12}{3}$	$\frac{5}{3}$
Ground-truth Error	Forgetting to add the numerator to the whole part.	Applying the same operation instead of the inverse when solving.
SFT	Does not add the whole to the numerator when converting a mixed number to an improper fraction.	Believes a downward line has a positive gradient.
DiVERT	Thinks you add the number of wholes to the numerator when converting a mixed number to an improper fraction.	When solving an equation, uses the same operation rather than the inverse.
DPO-GT + Per batch	Does not include the whole amount when converting a mixed number to an improper fraction.	Believes the gradient of a line is given by the coefficient of x , even when the equation is not in the form $y = mx + c$.
LOOKALIKE + Per batch	Thinks you add the number of wholes to the numerator when converting a mixed number to an improper fraction.	When solving an equation, uses the same operation rather than the inverse.
DPO-GT + Per epoch	Thinks you can ignore the whole amount when converting a mixed number to an improper fraction.	When finding the gradient from the equation of a line in the form $ax + by = c$, believes b/a is the gradient.
LOOKALIKE + Per epoch	Thinks you add the number of wholes to the numerator when converting a mixed number to an improper fraction.	When finding the gradient from the equation of a line in the form $ax + by = c$, believes b/a is the gradient.

Table 9: Comparison of typical errors generated by each method for two representative math questions.

Question stem	Add brackets to this calculation to make the answer 7. $16 - 6 + 4 \div 2$
Topic	BIDMAS
Concept	Insert brackets to make a calculation correct
Solution	Inside the bracket we work left to right, so we get $14 \div 2$ which is 7.
Correct answer	$(16 - 6 + 4) \div 2$
Distractor 1	$16 - (6 + 4) \div 2$
Error 1	With order of operations brackets are done first, then division is done before subtraction. This would give us $16 - 10 \div 2 = 16 - 5 = 11$ NOT 7.
Distractor 2	$(16 - 6) + \frac{4}{2}$
Error 2	With order of operations brackets are done first, then division is done before subtraction. This would give us $10 + 4 \div 2 = 10 + 2 = 12$ NOT 7.
Distractor 3	$16 - 6 + (\frac{4}{2})$
Error 3	With order of operations brackets are done first, then division is done before subtraction. Putting the brackets around the division, will not change the order. $16 - 6 + (4 \div 2) = 16 - 6 + 2 = 12$ NOT 7.
Question stem	Which of the following answers gives the correct solutions to the quadratic expression below? $(x + 2)(x - 7) = 0$
Topic	Algebra
Concept	Solve quadratic equations using factorisation in the form $(x + a)(x + b)$
Solution	Setting each bracket equal to 0 we have $x + 2 = 0$ and $x - 7 = 0$. This tells us that $x = -2$ and $x = 7$.
Correct answer	$x = -2, x = 7$
Distractor 1	$x = 2, x = -7$
Error 1	Believes the solutions of a quadratic equation are the constants in the factorised form
Distractor 2	$x = 2, x = 7$
Error 2	Believes the solutions of a quadratic equation are the absolute values of the constants in the factorised form
Distractor 3	$x = -2, x = -7$
Error 3	Believes the solutions of a quadratic equation are the negative of the absolute values of the constants in the factorised form

Table 10: Example MCQs from the real-world math MCQ dataset.

In this task, you'll evaluate error explanations for student errors in math multiple-choice questions. For each item, you'll see:

1. The **question**
2. The **correct answer** choice
3. A **solution** which shows how a student can reach the correct answer choice
4. A **distractor** (an incorrect answer choice)
5. An **error** explanation describing why a student might choose the distractor

Your Task

Annotate if each error explanation is consistent with the distractor (mark Yes), is generic, vague, or partially consistent (mark Partially) or has nothing to do with the distractor, or is misleading (mark No).

Use your best judgment when assigning ratings. Some examples are:

Example 1 (Marking **Yes**):

Question: Add brackets to this calculation to make the answer 7. $16 - 6 + 4 \div 2$

Correct Answer: $(16 - 6 + 4) \div 2$

Solution: Inside the bracket we work left to right, so we get $14 \div 2$ which is 7.

Distractor: $16 - (6 + 4) \div 2$

Error: Carries out operations from left to right regardless of priority order.

Mark **Yes**

Example 2 (Marking **Partially**):

Question: $\frac{3}{7}$ of a group of students are boys. What would be a possible ratio of boys to girls?

Correct Answer: 3 : 4

Solution: For every 7 students, 3 are boys and 4 are girls. The ratio is then 3:4.

Distractor: 3 : 7

Error: Uses the denominator when converting from fractions to ratio, rather than numerator.

Mark **Partially**

Example 3 (Marking **No**):

Question: When $h = 5$ $h^2 =$

Correct Answer: 25

Solution: If $h = 5$, $h^2 = h \times h = 5 \times 5 = 25$.

Distractor: 7

Error: Multiplies by the index.

Mark **No**

Table 11: Instructions provided to human annotators used to evaluate the consistency of error explanations for a given distractor.

You Shall Know a Word’s Difficulty by the Family It Keeps: Word Family Features in Personalised Word Difficulty Classifiers for L2 Spanish

Jasper Degraeuwe

Ghent University (LT³ / MULTIPLES research groups)

Groot-Brittanniëlaan 45, 9000 Ghent, Belgium

Abstract

Designing vocabulary learning activities for foreign/second language (L2) learners highly depends on the successful identification of difficult words. In this paper, we present a novel personalised word difficulty classifier for L2 Spanish, using the LexComSpaL2 corpus as training data and a BiLSTM model as the architecture. We train a *base* version (using the original LexComSpaL2 data) and a *word family* version of the classifier (adding word family knowledge as an extra feature). The base version obtains reasonably good performance ($F1 = 0.53$) and shows weak positive predictive power ($\phi = 0.32$), underlining the potential of automated methods in determining vocabulary difficulty for individual L2 learners. The “word family classifier” is able to further push performance ($F1 = 0.62$ and $\phi = 0.45$), highlighting the value of well-chosen linguistic features in developing word difficulty classifiers.

1 Introduction

In the rapidly evolving digital era of the 21st century, language and technology are growing closer together than ever. Language technology tools – especially those driven by large language models (LLMs) – have become very adept at performing a wide range of tasks, ranging from summarising documents to translating texts from one language into another. In some cases, their output has even shown to be virtually indistinguishable from human-written materials (Else, 2023).

At the same time, despite the wealth of technological assistance, being able to understand and speak a foreign/second language (L2) can be said to remain an indispensable skill for anyone who wants to fully engage in foreign cultures, as building sustainable intercultural relationships involves tasks that are much more difficult to achieve by means of technological tools alone, such as interpreting humour and facial expressions (Godwin-Jones, 2019).

What language technology tools do possess, however, is the ability to play the role of a valuable assistant in the L2 learning process.

This interface between second language acquisition (SLA) and computer assistance has commonly been referred to as Computer-Assisted Language Learning or CALL. Recently, the field of CALL has witnessed a growing interest in the specific subdomain of Intelligent CALL (ICALL). With techniques coming from the field of Artificial Intelligence (AI) and its subdomain of Natural Language Processing (NLP) as their source of “intelligence”, ICALL environments aim to — among other goals — facilitate and/or (partially) automate the creation of language learning materials. Although the origins of ICALL can be traced back as far as to the 1980s (Nyns, 1989), it was not until the advent of static (Mikolov et al., 2013) and contextualised word embeddings (Devlin et al., 2019) followed by full-fledged generative LLMs that a true paradigm shift from CALL towards ICALL has started to take shape.

ICALL platforms can foster virtually any language skill, but in this paper we will specifically focus on ICALL for *vocabulary learning* purposes. With a large body of studies showing that text comprehension and vocabulary knowledge are positively correlated (e.g., Laufer and Ravenhorst-Kalovski, 2010; Schmitt et al., 2011), we know that a wide vocabulary is a fundamental requisite to be able to function in a language. Or, in the words of Wilkins (1972, p. 111): “without grammar very little can be conveyed, without vocabulary *nothing* can be conveyed”. To help learners expand their L2 vocabulary, a combination of implicit and explicit learning activities is to be recommended (Nation, 2019; Schmitt, 2010a). Explicit vocabulary learning activities (e.g., fill-in-the-blanks exercises) require paying deliberate attention to vocabulary items, while in implicit activities the increase in vocabulary knowledge is achieved as a by-product,

because the main goal of the activity is the successful completion of an authentic task such as understanding the plot of a book.

In both of these strands, knowing which words might be difficult for target learners to understand or produce is a valuable source of information. In the case of the implicit approach, one of the key notions is that learners acquire vocabulary when they are exposed to input that is comprehensible but slightly beyond their current knowledge (Lichtman and VanPatten, 2021), implying that it should be known which parts of the input are comprehensible and which are not. For explicit learning, on the other hand, informed decisions need to be made on which words to in- and exclude from the activities, a task that becomes considerably easier if we know which words are (un)known by the learners.

In other words, identifying difficult words (or word uses) plays a pivotal role during the development of vocabulary learning materials. As an alternative to the labour-intensive process of identifying these words by hand, research within the field of ICALL has explored NLP-driven approaches to perform this task. Methods exploiting computer-readable resources in which words are linked to difficulty levels (or frequency bands, since frequency correlates with difficulty¹; Schmitt, 2010b) constitute a first option, as they can automatically assign words in digital texts to their corresponding difficulty/frequency label (Finlayson et al., 2023).

However, apart from having limited coverage (only words included in the resources will be assigned a label), this approach does not take into account individual differences among learners. To overcome these limitations, machine learning systems can be designed, which offer more flexibility: in theory, they can classify any text, sentence or word into any set of difficulty levels, and tailor predictions to individual learner profiles (Tack, 2021).

In this paper, we present a first-of-its-kind individualised word difficulty classifier for L2 Spanish. As our training data, we make use of LexComSpaL2 (Lexical Complexity for Spanish L2; Degrauwe and Goethals, 2024), a publicly available dataset² containing 2,240 in-context target

¹It should be noted that this difficulty - frequency correlation does not mean that word difficulty *equals* word frequency. As shown in previous research (Pintard and François, 2020), word difficulty cannot be predicted by frequency values alone.

²The dataset is made available through a [GitHub repository](#) and was released under the [ODC-By license](#), which grants the right to freely use and adapt the data as long as any use of the dataset is adequately attributed.

words with the corresponding difficulty judgements of 26 L2 Spanish students. We compare the results of training two different versions of the classifier: a *base* version (only using the original LexComSpaL2 data) and a *word family* version (adding word family knowledge as an extra feature).

2 Related Research

This literature overview discusses lexical difficulty/complexity as defined in the field of linguistics in Section 2.1, the technique of lexical complexity prediction (i.e. the approach adopted to build LexComSpaL2) in Section 2.2, individualised learning in Section 2.3, and a detailed account of word families (used to create a “linguistically enriched” version of LexComSpaL2) in Section 2.4.

2.1 Difficulty and Complexity in SLA

In linguistics, the concept of “word difficulty/complexity” is usually subdivided into several dimensions, often dichotomous in nature. One of the most prominent distinctions is the one between *absolute* (or *objective*) and *relative* (or *agent-related*) complexity (Kortmann and Szmrecsanyi, 2012). In the former type, complexity is understood in terms of the linguistic properties of words, ranging from their length over the number of vowels and diphthongs they contain to their homonymic and/or polysemous character (i.e. the number of different meanings/senses they have). Especially the last feature plays an important role in an SLA setting, as lexically ambiguous items have shown to be more challenging to process and learn than single-meaning words (Bensoussan and Laufer, 1984).

Relative complexity (also denominated “difficulty”; Bulté et al., 2025), on the other hand, corresponds to the complexity as perceived by a particular language learner, meaning that psycholinguistic factors and world knowledge can come into play (North et al., 2023; Kortmann and Szmrecsanyi, 2012). In an L2 setting, an additional crucial factor in determining agent-related complexity is L1 influence, which can manifest itself through false friends (e.g., ES *listo* [‘ready’] - NL *list* [‘ruse, trick’]) or cognates (e.g., ES *individuo* - NL *individu* - EN *individual*).

2.2 Lexical Complexity Prediction

Computational approaches to identifying difficult/complex words focus on “operationalising” the abovementioned linguistic concepts. A crucial aspect of this operationalisation is the presence of

some kind of “inventory” in which words are linked to discrete difficulty/complexity labels. One possible way to build such inventories is exploiting computer-readable versions of graded vocabulary lists (Dang et al., 2017), frequency lists (Davies and Hayward Davies, 2018), or graded coursebooks (in which case words are assigned to the level at which they first occur; Alfter, 2021). Another approach is to collect human annotations, either through online (crowdsourcing) platforms (Shardlow et al., 2021) or by means of dedicated research experiments (Tack, 2021).

The dataset used in this study, LexComSpaL2, falls in the last category (for more details on the corpus, see Section 3.1.1). The LexComSpaL2 annotations were gathered according to the principles of lexical complexity prediction (LCP; see Table 1 for an example), a relatively new strand within the field of NLP that provides an alternative to the binary complex word identification (CWI) approach (which labels words as either complex or non-complex; Yimam et al., 2018).

By using a five-point scale going from “very easy” to “very difficult” (for the full descriptors, see Section 3.1.1), LCP not only yields more fine-grained judgements than the binary CWI labels, it

Sentence	
They do hold elections, but candidates have to be endorsed by the conservative clergy, so dissenters are by definition excluded.	
Target word	LCP Label
<i>do</i>	1
<i>hold</i>	2
<i>elections</i>	3
<i>candidates</i>	1
<i>have</i>	1
<i>be</i>	1
<i>endorsed</i>	4
<i>conservative</i>	2
<i>clergy</i>	5
<i>dissenters</i>	5
<i>definition</i>	1
<i>excluded</i>	2

Table 1: Fictitious example of LCP annotations. The target sentence is taken from the CompLex dataset, the first LCP corpus ever created (Shardlow et al., 2020). In line with the LexComSpaL2 corpus, only nouns, verbs, and adjectives are considered in the example.

also enables making predictions based on “comparative complexity” (i.e. whether a word is more or less complex than another target word; North et al., 2023). Importantly, the term “complexity” as used in the field of LCP represents an amalgam of the concepts of complexity and difficulty described in Section 2.1, as it refers to the difficulty an individual may experience in understanding a given word as a result of both their personal knowledge and a word’s linguistic properties (North et al., 2023). In this paper we adopt the same comprehensive definition but will give preference to the term “difficulty” instead of “complexity”, since the individualisation of the predictions puts slightly more emphasis on the (personal knowledge of the) learner than on the linguistic properties of the target words.

To the best of our knowledge, LexComSpaL2 is the only available LCP dataset that (1) specifically targets L2 learners and (2) enables training personalised word difficulty classifiers. Other LCP datasets are mostly constructed for the purpose of training models that can be integrated in a lexical simplification pipeline (Paetzold and Specia, 2017). A comprehensive overview of existing LCP datasets can be found in Shardlow et al. (2024).

Regarding the features used in LCP classifiers, recent research has revealed that a hybrid approach combining linguistic features (see Section 2.1) and LLM embeddings (e.g., BERT embeddings; Devlin et al., 2019) results in the highest performance (Ortiz-Zambrano et al., 2025). Earlier research, however, showed that also with static word embeddings good performance levels can be achieved (Tack, 2021). In this paper, we build on this line of research by combining static word embeddings with linguistic information on word families. By focusing on word families we aim to gain new insights into the value of linguistic features in automated word difficulty prediction, as previous research has mainly paid attention to lexical features related to the word itself (e.g., word length and number of syllables) and semantic features taken from resources such as WordNet (Fellbaum, 1998; e.g., number of synonyms, hypernyms, and/or hyponyms of a given target word).

2.3 Individualised Learning

As already touched upon above, another core and unique aspect of our word difficulty classifier is that it outputs *personalised* predictions. This way, we aim to integrate findings from the literature on indi-

vidual differences in SLA³. In brief, research in this domain has demonstrated that a variety of factors related to the individual can impact the learning process and learning outcomes. As mentioned in Section 2.1, a first crucial dimension of individual differences is the linguistic background of the learner, particularly (proficiency in) their L1 and experience with (learning) other languages (Degani and Goldberg, 2019). Other individual differences that have a considerable impact on the vocabulary learning process of L2 learners include cognitive factors such as memory capacity (Martin and Ellis, 2012) and the degree of out-of-school exposure to the L2 (De Wilde et al., 2022).

The domains of ICALL and NLP started to devote increasingly more attention to individualising system outputs. The most comprehensive approach to personalising the L2 learning process can be found in Intelligent Language Tutoring/Teaching Systems (ILTSs), which tailor learning materials to the specific needs of individual users on a macro (selecting and sequencing activities) and/or micro level (providing scaffolded feedback) (Meurers et al., 2019; Ruiz et al., 2023). Regarding word difficulty prediction, both in the domain of CWI (Gooding and Tragut, 2022; Tack, 2021) and LCP (Degraeuwe and Goethals, 2024; North et al., 2023) efforts have been undertaken to adopt a learner-centred and personalised perspective. In the present study, we aim to continue this line of research.

2.4 Word Families

Finally, we briefly discuss the concept of word families (Bauer and Nation, 1993), based on which we expanded the LexComSpaL2 dataset and trained a separate version of the classifier. As defined by Webb (2021, p. 941), “[w]ord families are made up of a headword, its inflections, and derivations”. For the headword *address*, for example, this means that the word family consists of both the nominal (*addresses*) and verbal inflections (*addresses*, *addressed*, *addressing*), as well as derivations of the two (e.g., *addressee*, *readdress*, *unaddressed*) plus their inflected forms (e.g., *addressees*, *addresses*, *readdressed*). Supported by empirical evidence from cognitive linguistics (Zhang and Lin, 2021), one of the main arguments in favour of using word family information in an L2 learning setting is that, once learners have acquired knowledge of the form-meaning connection of a given family mem-

ber (e.g., *legal*), they can use their knowledge of the morphological system to infer the meaning of other members of the family (e.g., *legally*, *illegal*) (Nation and Webb, 2011; Nation, 2016).

3 Methodology

The methodology consists of two main steps: (1) the preparation of the dataset on which the different versions of the classifier should be trained (Section 3.1) and (2) the actual development and training of the classifier (Section 3.2).

3.1 Dataset Preparation

3.1.1 Original LexComSpaL2 Dataset

To train the base version of the personalised word difficulty classifier, we used the LexComSpaL2 dataset in its original format (Degraeuwe and Goethals, 2024; see Table 2 for a dataset sample). LexComSpaL2 includes 2,240 target words distributed over 200 sentences coming from four different domains (economics, health, law, and migration). The sentences were selected from L1 newspaper corpora using a dedicated method specifically designed to extract pedagogically suitable sentences from corpus data (Pilán et al., 2016). Regarding the annotations, 26 L2 Spanish learners (from different proficiency levels but all L1 Dutch) were asked to rate the (in-context) difficulty of all nouns, verbs, and adjectives in the 200 sentences according to the five-point LCP scale. Importantly, Degraeuwe and Goethals (2024) tailored the original LCP descriptors to L2 learners as the target audience by projecting the LCP labels onto the vocabulary knowledge continuum (Schmitt, 2019), which conceptualises vocabulary knowledge as a construct that gradually moves from “no knowledge” over “receptive mastery” to “productive mastery” (see Table 3 for the adapted scale).

In summary, the 58,240 self-perceived judgements of word difficulty included in LexComSpaL2 constitute relevant and representative data to train personalised word difficulty classifiers for L2 learners, as the annotations were (1) provided by actual L2 learners and (2) taken from pedagogically suitable sentences that were selected in an attempt to mimic the often thematic organisation of real-life vocabulary learning courses and materials.

3.1.2 Word Family-Enriched Dataset

To enrich the original LexComSpaL2 dataset with word family information, we considered the following three word family levels: the word’s **token**

³For extensive overviews of this domain, we refer to Dörnyei (2014) or Skehan (1991).

Sentence ID	Sentence text	Target word	Individual judgements
1_1	El <u>directivo</u> , que ha <u>celebrado</u> un almuerzo de <u>Navidad</u> con la prensa, ha asegurado que [...] ('The manager, who has held a Christmas lunch with the press, has assured that [...]')	directivo	{P1: 3, P2: 2, P3: 2, [...], P24: 3, P25: 1, P26: 1}
		celebrado	{P1: 2, P2: 1, P3: 1, [...], P24: 2, P25: 1, P26: 1}
		...	
...			
4_50	Las investigaciones sobre <u>atención</u> <u>primaria</u> , <u>neurología</u> , <u>oncología</u> <u>médica</u> y <u>microbiología</u> <u>van</u> después, [...] ('Research into primary care, neurology, medical oncology and microbiology comes after, [...]')	investigaciones	{P1: 1, P2: 1, P3: 1, [...], P24: 1, P25: 1, P26: 1}
		atención	{P1: 2, P2: 1, P3: 1, [...], P24: 1, P25: 1, P26: 1}
		...	

Table 2: Sample from the LexComSpaL2 corpus that was also presented in Degraeuwe and Goethals (2024). Aggregated judgements (per proficiency level and overall) were omitted from the sample, since we only used the individual judgements to train the classifier. Target words are underlined and “P” stands for participant.

Rating	Original LCP description	Adapted description
1	Very easy: this word is very familiar to me	I know this word and its meaning, and I also use it actively in speaking/writing.
2	Easy: I am aware of the meaning of this word	I know this word and its meaning, but I might not be able to use it on the top of my head in an oral/written conversation. When I have some time to think, however, I do think I would use it naturally.
3	Neutral: this word is neither difficult nor easy	I have heard/seen this word before and given the context I think that I more or less know what it means, but I do not see myself using this word actively.
4	Difficult: the meaning of this word is unclear to me, but I may be able to infer it from the sentence	This word sounds vaguely familiar and based on the context I could make an educated guess about its meaning, but I would still need a dictionary to be able to understand its exact meaning.
5	Very difficult: I have never seen this word before / this word is very unclear to me	This word does not sound familiar at all to me, and even based on the context I do not know what it means, so I would definitely need a dictionary to get to know its meaning.

Table 3: Original LCP descriptions compared to adapted descriptions proposed by Degraeuwe and Goethals (2024). The adapted descriptions are based on the vocabulary knowledge continuum (Schmitt, 2019).

form (also called the “type”), the word’s **lemma**, and the **source** from which the word’s lemma is derived (i.e. the “parent” of the lemma in the “family tree”)⁴. As an illustration, let us consider the word *desaparecido* (‘disappeared’): the **token** level consists of all occurrences of this exact word form in the LexComSpaL2 dataset; the **lemma** level corresponds to the lemma of *desaparecido* (i.e. the infinitive *desaparecer* - ‘to disappear’) and includes all of its other conjugated forms (e.g., *desaparezco*, *desaparecieron*); the **source** level corresponds to the “parent” of *desaparecer* (i.e. *aparecer* - ‘to appear’) and encompasses all inflected forms of this parent (e.g., *aparezco*, *aparecía*).

⁴The *token* and *lemma* levels correspond to, respectively, Level 1 and Level 2 of the Bauer and Nation (1993) taxonomy. The *source* level is specific to this study.

Next, we applied the following procedure to every target word in the LexComSpaL2 dataset:

1. Check if the exact **token** of the target word occurs more than once in the corpus. If so, we (1) calculate if there is a statistically significant difference ($p \leq 0.05$) between the annotations and (2) gather, for all participants individually, the lowest and highest annotated LCP value for the token in question.
2. Check if the **lemma** of the target word occurs more than once in the corpus. If so, we repeat the process described in the first step, but in this case for the target word’s lemma.
3. Check if the **source** of the target word’s lemma occurs more than once in the corpus. If so, we repeat the process described in the first

step for the source lemma. If the target word’s lemma is a headword, this step is skipped.

All words were disambiguated for part of speech using Stanza⁵, meaning that words such as *humano* (‘human’), which can both be a noun and adjective, constitute two different tokens. To compute statistical significance, we used the non-parametric Kruskal-Wallis H-test (Kruskal and Wallis, 1952), which can be applied to two or more samples and does not assume normally distributed data. To look up the source lemma of a given target word, we used the publicly available word family resource⁶ developed within the Spanish Corpus Annotation Project (Goethals, 2018).

We added the data to the original LexComSpaL2 corpus by creating three new versions of the corpus (one per word family level), in which we added four extra columns: one indicating if the target word occurs multiple times (*True* or *False* as value), one indicating if the annotations differ significantly (*True*, *False*, or *N/A* if the target word only occurs once), and two columns including the lowest and highest annotation per participant (or again *N/A*). This “word family-enriched” version of the dataset are made available as a part of the original LexComSpaL2 GitHub repository⁷.

The descriptive statistics of the word family enrichment are presented in Table 4. For the token and lemma levels, *#candidates* refers to the number of, respectively, unique tokens and lemmas that occur more than once in the corpus. For the source level, *#candidates* refers to the number of unique tokens whose source lemma also occurs in the corpus. The *#statSignDiff* column indicates for how many of those candidates the learners’ annotations differed significantly. Although these numbers are a by-product of the research and should also be interpreted as such, it does seem opportune to highlight that they seem to confirm as well as contradict the assumption that knowledge of one word family member means that learners also know the meaning of other family members (Section 2.4). At the token and lemma levels, the low number of statistically significant differences reveals that the annotations (and therefore also the degree of word knowledge) were consistent across the different occurrences. For the lemma level, this means that if learners acquired a certain degree of knowledge for

Level	#candidates	#statSignDiff	#enriched
Token	159	2	355 / 2,240
Lemma	273	6	632 / 2,240
Source	248	106	297 / 2,240

Table 4: Descriptive statistics of word family enrichment of LexComSpaL2. The *#enriched* column contains the number of target words for which information other than *N/A* was added.

one inflected form, they are highly likely to have the same degree of knowledge for other inflected forms. At the source level, however, we see that this conclusion does not hold, as in 106 of the 248 cases there was a statistically significant difference in the learners’ difficulty judgements. The results clearly indicate that knowledge acquired at the token level is not necessarily transferred to the source level in the family tree (or vice versa). Returning to the example above, this means that if learners know *desaparecido* it does not necessarily imply that they also know *aparecer* (or vice versa).

3.2 Classifier Training

3.2.1 Base Classifier

As the architecture for the base classifier, we used a Bidirectional Long Short-Term Memory (BiLSTM) model that follows a similar design as the CWI classifier presented in Tack (2021), who found that this type of neural network is able to personalise difficulty predictions. For each observation (i.e. a word linked to a learner’s LCP annotation), the base model takes the following features as input: a character embedding⁸, the word’s fastText embedding (Cañete, 2019), and the participant information (unique identifier, proficiency level, years of experience, and L1⁹). Based on a softmax activation function, the output layer yields a probability distribution for the different classes, with the class for which the highest probability is obtained being selected as the predicted difficulty level for the word in question. A simplified visualisation of the model’s architecture is presented in Figure 1 (for a full visualisation, see Appendix A) and the underlying code is made available in a GitHub repository¹⁰.

⁸Randomly initialised and trained with a convolutional neural network (De Hertog and Tack, 2018).

⁹It should be noted that, since all annotators in the LexComSpaL2 corpus have Dutch as their L1, this feature will not contribute to personalising the predictions.

⁶<https://scap.ugent.be/overview-resources/>

⁷<https://github.com/JasperD-UGent/LexComSpaL2>

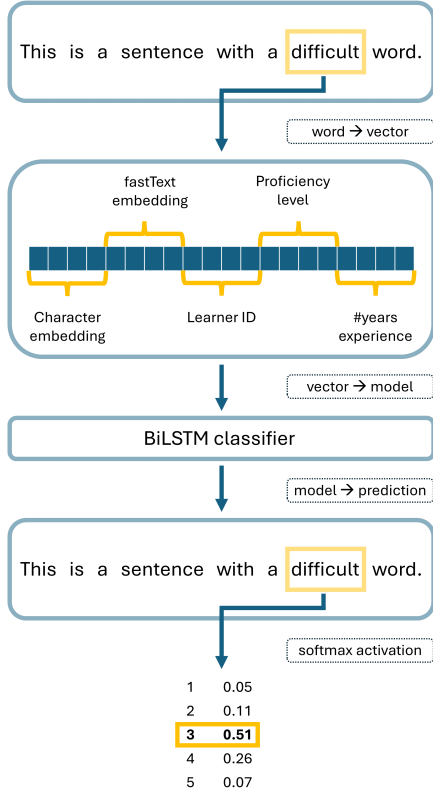

Figure 1: Simplified representation of BiLSTM word difficulty classifier.

To evaluate the model, a tenfold cross-validation setup was adopted. As our dataset split, we used the split added by Degrauwe and Goethals (2024) to the LexComSpaL2 repository in anticipation of the corpus being used to train future machine learning models. This sentence-level dataset split includes ten different “folds” of the LexComSpaL2 data into a training (160 sentences or 80%), validation, and test set (20 sentences or 10% each). The complete overview of the number of training instances per fold is included in Appendix B.

Regarding training parameters, we set the number of epochs to 50, the batch size to 64, and the loss strategy to *sparse_categorical_crossentropy*. *Adam* was used as the optimiser and an early stopping monitor on the validation loss (with a patience of 10) was added to the training process. In each cross-validation run, the weights for the training samples were calculated (Appendix C) and used for weighting the loss function. A mask was set to all “non-target words” (i.e. all tokens which are not a noun, verb, or adjective and thus did not receive a label during the data collection) and their input vectors and sample weight were set to 0. This way, the sentence context was still correctly represented

but the masked tokens were ignored during training. Finally, zero-padding (to the maximum sentence length of 35) was applied to all inputs and outputs.

3.2.2 Word Family-Enriched Classifier

The word family version of the classifier was built based on the exact same architecture as the base version. The only difference is that one additional feature was added to the word vector, containing the content of the four columns that were added to the dataset (Section 3.1.2). A simplified visualisation of this updated word vector is presented in Figure 2. To gain insights into the impact of each word family level, we trained the classifier based on (1) only the *token* level information as extra data, (2) only the *lemma* level data, (3) only the *source* level data, and (4) all three levels combined (*combi*). The word vector for *combi* was obtained by concatenating the “word family feature” from the three individual levels (i.e. the light-coloured part on the right-hand side of the vector visualisation in Figure 2) and appending these values to the “base features” (i.e. the dark-coloured part on the left-hand side of the vector in Figure 2).

4 Results and Analysis

The performance scores are presented in Table 5. We compare the results against a naïve most frequent label (MFL) baseline, which always predicts the most frequent difficulty label in the dataset (i.e. label 1). For evaluation, we first calculate two measures that are insensitive towards changes in class distribution: (1) the D' coefficient, which determines the degree of certainty in the predictions (Smith et al., 2021), and (2) the Matthews correlation coefficient (abbreviated as MCC and denoted as ϕ), which determines the quality of the predictions by estimating the strength of association between the true and predicted classes (Matthews, 1975). Changes in the values of these

Figure 2: Simplified representation of word vector enriched with word family information. Word family values are different for each of the three possible word family levels (*token*, *lemma*, and *source*). Highest and lowest annotated value are provided per participant.

Classifier type	D' \uparrow	MCC \uparrow	F1 \uparrow	MSE \downarrow	RMSE \downarrow	Accuracy \uparrow
MFL baseline	0	0	0.32	2.61	1.62	0.49
Base	0.18 (\pm 0.01)	0.32 (\pm 0.02)	0.53 (\pm 0.02)	1.32 (\pm 0.1)	1.15 (\pm 0.04)	0.56 (\pm 0.02)
Word family (token)	0.23 (\pm 0.01)	0.37 (\pm 0.02)	0.56 (\pm 0.01)	1.25 (\pm 0.07)	1.12 (\pm 0.03)	0.59 (\pm 0.02)
Word family (lemma)	0.26 (\pm 0.01)	0.4 (\pm 0.02)	0.59 (\pm 0.02)	1.18 (\pm 0.08)	1.09 (\pm 0.04)	0.61 (\pm 0.02)
Word family (source)	0.23 (\pm 0.01)	0.38 (\pm 0.02)	0.57 (\pm 0.02)	1.24 (\pm 0.11)	1.11 (\pm 0.05)	0.59 (\pm 0.02)
Word family (combi)	0.32 (\pm 0.01)	0.45 (\pm 0.02)	0.62 (\pm 0.02)	1.11 (\pm 0.1)	1.05 (\pm 0.05)	0.63 (\pm 0.02)

Table 5: Performance of the different personalised word difficulty classifiers. We report the mean score across the ten cross-validation runs for each of the six performance metrics. Standard deviation values are included between parentheses and the top score per metric is presented in bold.

metrics can be fully attributed to changes in the model, and not to aspects inherent to the data such as class imbalance (Tack, 2021). MCC values can go from -1 (inverse prediction) over 0 (average random prediction) to 1 (perfect prediction), while the D' coefficient ranges between 0 (no discriminative power) and 1 (full discriminative power).

In addition, we also report three commonly used metrics in machine learning: weighted F1 (i.e. the harmonic mean of precision and recall), mean squared error or MSE (i.e. the average squared difference between the true and predicted values), and root mean squared error or RMSE (which converts MSE values to the same units as the dependent variable, in our case the 1-5 LCP scale). Finally, we also include the intuitive accuracy metric (i.e. the number of correct predictions divided by the total number of predictions).

Since, to the best of our knowledge, this is the first study which specifically analyses the potential of including word family information as an input feature, our research provides valuable new insights into the added value of linguistic features in LCP-based classifiers. The results in Table 5 unequivocally show that word family information has a noticeable positive impact on model performance, with the top-performing *combi* classifier achieving a large increase on all metrics in comparison to both the MFL baseline ($+0.32$ for D' ; $+0.45$ for MCC; -0.57 for RMSE) and the base classifier ($+0.14$ for D' ; $+0.13$ for MCC; -0.1 for RMSE).

When breaking down the results per type of classifier, a first finding to be highlighted is that, though leaving ample room for improvement, the **base classifier** already achieves reasonably good performance. The mean D' and MCC values (0.18 and 0.32 , respectively) suggest that the model has ac-

quired weak positive discriminatory and predictive power, while the RMSE score reveals that – on average and including penalisation – the model’s prediction is only 1.15 away from the true label. Importantly, the base model also outperforms the MFL baseline by a large margin (e.g., MCC of 0 compared to 0.32 , weighted F1 of 0.53 compared to 0.32 , and RMSE of 1.15 compared to 1.62).

When comparing the base to the **word family-enriched classifier**, the results clearly show that any type of word family information is helpful for the model, as all subtypes outperform the base version on every metric. The increase in performance is most notable at the lemma level ($+0.08$ for MCC; -0.06 for RMSE), suggesting that the model successfully leveraged information on the knowledge a given learner has acquired for one inflected form of a lemma to predict the label of other inflected forms of that lemma. However, it should be noted that the lemma level is also the level at which most instances in the dataset were enriched (Table 4), which may have played an important role in this particular subtype obtaining the largest increase. Regarding the results for the source subtype, it should be highlighted that – next to the lower number of enriched instances – the 106 statistically significant differences in annotations between the target word and its source (see Section 3.1.2) might be a second reason for the smaller increase at the source level compared to the lemma level.

In summary, the findings of our study provide strong evidence in favour of integrating word family features (and well-chosen linguistic features in general) into personalised word difficulty classifiers. Particularly, with the *combi* classifier obtaining the highest scores, the take-home message is that the more relevant data on word family knowl-

edge are added, the better the classifier’s predictions of word difficulty become.

5 Conclusion

In this paper, we presented a personalised word difficulty classifier for L2 Spanish, trained on the LexComSpaL2 dataset (Degraeuwe and Goethals, 2024). Based on a straightforward BiLSTM architecture with a softmax activation function, the classifier can take any Spanish target sentence as input and will predict a difficulty label ranging from 1 to 5 for every content word in the sentence. Moreover, thanks to the inclusion of learner-specific features in the training process (e.g., proficiency level and years of experience), the model attempts to tailor its output to the unique profile of every learner individually. In doing so, the classifier goes beyond the generic, one-size-fits-all difficulty levels often used in L2 vocabulary learning resources (e.g., based on the Common European Framework of Reference for Languages [CEFR]).

By comparing a base classifier to a “word family-enriched” one, we highlighted the notable added value of feeding information on word families – and of adding linguistic features in general – to word difficulty classifiers. With the top-performing model obtaining an MCC value of 0.45, an F1 score of 0.62, and an RMSE score of 1.05, our classifier shows great potential to be included in real-life ICALL scenarios, for instance as a “difficult word detector” in a personalised reading assistant.

In future studies, we aim to test other machine learning architectures (e.g., using LLMs) and compare them against the BiLSTM classifier presented in this study. Other directions for future research include (1) studying the effect of replacing the static fastText embeddings as an input feature by contextualised word embeddings, (2) analysing the addition of more linguistic features next to word family information, and (3) collecting – in a GDPR-compliant fashion – more information about the participants in order to expand the “learner profile” input feature. Possible additional types of participant information include personal interests (e.g., hobbies), reading behaviour (in L1 or L2), and mastery of other languages than Dutch as L1 and Spanish as L2.

Limitations

A first important observation to be made concerns the real-life applicability of the classifier. Despite

the promising results, it could be argued that the predicted values of the model – even for the best-performing classifier – are not yet close enough to the expected values for the model to be integrated *as is* in real-life settings. As shown by the (R)MSE scores¹¹ of 1.11 and 1.05 for *combi*, there is still a considerable difference between what the classifier should predict and what it actually predicts. Especially in a pedagogical setting it is crucial to obtain relatively high accuracy and precision rates (which is why the F1 and accuracy metrics were included in the analysis), because it should be avoided at all cost that learners lose precious time over errors in their learning materials. For example, if the classifier were used to identify vocabulary items that are known passively but not actively by a given learner (i.e. label 3) and ended up selecting words which are known (very) well by the learner, the exercise would lose most of its pedagogical value.

As obtaining promising but not (yet) pedagogically usable results is a recurrent finding in research on automated word difficulty prediction – Pintard and François (2020), for example, report a top accuracy score of 0.54 for their French CEFR classifier –, one might be left to wonder if the concept of word difficulty (especially for individual learners) is too sophisticated for machine learning classifiers to fully capture. In fact, despite the existence of clear patterns (e.g., high-frequency words tend to be easier than low-frequency words and long words tend to be more difficult than short words), there is also a wide range of factors that may affect perceived word difficulty but that are much harder to model using computational techniques (e.g., a word’s degree of abstractness/concreteness, a learner’s world knowledge, or a learner’s ability to deduce meaning based on morphological knowledge or contextual clues). Yet, using (generative) LLMs as classifiers and/or expanding the number of features related to the learner (see also Section 5) are two research avenues which have the potential of providing the domain of automated word difficulty prediction with a new *élan* and leading to a considerable increase in performance. Additionally, the integration of features indicating how specialised words are for a given domain – for instance using “keyness” (Gabrielatos, 2018) or “termhood” (Rigouts Terryn et al., 2021) metrics – could also be a direction worth pursuing.

¹¹These metrics penalise predictions that are far from the true label more severely than near-correct predictions (e.g., a predicted value of 1 while the true label is 5).

Secondly, in the current setup, every learner who wants to get personalised predictions from the classifier first needs to annotate all 200 sentences in the LexComSpaL2 corpus, as this information is used to build the “learner profile” input feature. As suggested by Degraeuwe and Goethals (2024), to facilitate the implementation in a real-life setting, an item analysis could be performed on the dataset to identify the most “informative sentences” and have new learners annotate this “concentrated” set of sentences instead. Another limitation of the dataset is that, currently, only annotations from L1 Dutch speakers are included. To assess the true personalisation potential of the classifier, the LexComSpaL2 dataset would need to be expanded with annotations coming from L2 Spanish who do not have Dutch as their L1.

Finally, regarding the analyses conducted, the present paper did not provide an in-depth evaluation of the personalisation potential of the classifier. In future research, we aim to isolate this aspect of the model, for example by performing a comparative analysis of the results per learner in order to identify potential differences and look for factors that might explain these differences (e.g., by studying if they correlate with the learners’ proficiency level). Additionally, the study did not address if and how the sentence context impacts the perceived difficulty of a word (perspective of the learner) and how this relates to the predicted difficulty of that word (perspective of the computer). Finally, it should be noted that we did not apply any word sense disambiguation (WSD) method to the data. As a result, homonymic and polysemous words (e.g., *banco* as a bench and as a financial institution) were not considered as two separate tokens or lemmas.

Acknowledgments

The computational resources (Stevin Supercomputer Infrastructure) and services used in this work were provided by the VSC (Flemish Supercomputer Center), funded by Ghent University, FWO and the Flemish Government – department EWI. Additionally, a sincere word of gratitude goes to Janiça Hackenbuchner (for acting as a soundboard and proofreading), to the people who attended the LATILL workshop at the University of Tübingen (for giving me the inspiration that led to this paper), and to the anonymous reviewers (for their valuable feedback and suggestions).

Table 7: Overview of observations per cross-validation fold for training (“TR”), validation (“VA”), and test (“TE”) sets. The training set always contains 160 sentences, the validation and test sets always contain 20. The sets always contain an equal number of sentences per domain (economics, health, law, and migration).

The Need for Truly Graded Lexical Complexity Prediction

David Alfter

University of Gothenburg
Sweden
david.alfter@gu.se

Abstract

Recent trends in NLP have shifted towards modeling lexical complexity as a continuous value, but practical implementations often remain binary. This opinion piece argues for the importance of truly graded lexical complexity prediction, particularly in language learning. We examine the evolution of lexical complexity modeling, highlighting the “data bottleneck” as a key obstacle. Overcoming this challenge can lead to significant benefits, such as enhanced personalization in language learning and improved text simplification. We call for a concerted effort from the research community to create high-quality, graded complexity datasets and to develop methods that fully leverage continuous complexity modeling, while addressing ethical considerations. By fully embracing the continuous nature of lexical complexity, we can develop more effective, inclusive, and personalized language technologies.

1 Introduction

Lexical complexity prediction (LCP) is the task of assigning a complexity score to a word or phrase, indicating how difficult it is to understand for a given target population, such as language learners or readers with disabilities (Shardlow et al., 2022). In recent years, the field of Natural Language Processing (NLP) has witnessed a shift in approach to lexical complexity prediction. There has been a growing recognition that lexical complexity is not a binary concept, but rather exists on a continuum (Shardlow et al., 2020). This acknowledgment has led to efforts to model lexical complexity as a continuous value, promising more nuanced and accurate representations of word difficulty across various contexts and for different readers.

However, despite this conceptual advancement, the practical implementation of truly graded lexical complexity prediction remains limited. This discrepancy between theoretical understanding and

applied research is evident in recent shared tasks and datasets in the field. While the 2021 SemEval shared task on LCP (Shardlow et al., 2021) made strides by including multiple contexts for about half of its training instances, subsequent initiatives have not fully embraced this approach. Notably, the 2024 MLSP (Multilingual Lexical Simplification and Prediction) task (Shardlow et al., 2024) included only a single word with two contexts, effectively reverting to a predominantly one-to-one mapping of words and complexities.¹

This persistent focus on one-to-one complexity mapping not only fails to capture the full spectrum of lexical difficulty but also hinders progress in areas where truly graded predictions are crucial. One such domain is language learning, where learners progress through various levels of proficiency and require finely-tuned assessments of word difficulty (Crossley et al., 2017; Gooding et al., 2021). In this context, binary classifications of “simple” or “complex” are insufficient to guide effective vocabulary acquisition strategies or to develop adaptive learning materials. Further, polysemous words generally show a spread of word senses over different levels, and not all meanings are learned or known at each level (Alfter et al., 2022).

This opinion piece argues that the field of NLP must move beyond its current limited implementation of continuous lexical complexity modeling. We contend that embracing truly graded predictions is not just a matter of theoretical correctness, but a necessity for advancing practical applications in areas such as language learning, text simplification, and readability assessment. By doing so, we can develop more sophisticated and useful tools that accurately reflect the nuanced nature of lexical complexity across diverse contexts and user needs.

Consider the word “crane”. In the context of

¹The test set ($n = 5123$), which may be used as additional training data after the completion of the task, contains 4% of sentences for a word with more than one context.

construction, “crane” refers to a machine used for lifting and moving heavy objects, which might be a familiar concept to most adult readers. However, in the context of ornithology, “crane” refers to a family of large, long-legged birds, which might be less familiar to readers without a background in bird watching or biology. A genuinely graded lexical complexity prediction system should be able to assign different complexity scores to “crane” based on its context, reflecting the varying levels of difficulty for different readers.

A crucial dimension currently underrepresented in lexical complexity research is an explicit theoretical analysis of the construct itself. Lexical complexity is inherently multidimensional, encompassing orthographic difficulty (Just and Carpenter, 1987; Perfetti et al., 2005; Alfter, 2021), conceptual complexity (Nation and Nation, 2001), atypical contextual usage (Erk and Padó, 2008; Peters et al., 2019), and figurative or metaphorical meanings (Steen et al., 2010; Thibodeau and Boroditsky, 2011). These distinct aspects significantly impact different user groups in varied ways; for example, native children encountering conceptual complexity differ from adult second-language learners struggling primarily with orthographic unfamiliarity or contextual atypicality (Akamatsu, 2005; Crossley and McNamara, 2012).

2 Current State of the Field

The field of lexical complexity prediction and simplification has evolved significantly over the past decade, with researchers exploring various approaches to model and predict word difficulty. This section provides an overview of key developments and current trends in the field.

2.1 The Divide Between Two Worlds

In this section, we highlight two related yet disconnected main fields active in lexical complexity prediction: lexical complexity prediction for lexical simplification, and lexical complexity prediction for language learning applications.

Lexical simplification can have a broad range of applications, most aiming at making texts easier to read for certain audiences such as children (De Belder et al., 2010), language learners (Petersen and Ostendorf, 2007; Rets and Rogaten, 2021), people with reading disabilities (Devlin, 1998; Chung et al., 2013), simplifying medical texts (Deléger and Zweigenbaum, 2009) or judicial

texts (LoPucki, 2014), to name but a few. In this line of research, an important first step is to identify *complex* words (Specia et al., 2012). This line of research in lexical complexity prediction started as *complex word identification* (Shardlow, 2013), a binary classification tasks of words into *simple* and *complex* words. Shardlow (2013) presented one of the first comprehensive studies on automatic lexical simplification, focusing on identifying complex words and suggesting simpler alternatives. This binary approach was further developed in subsequent studies, such as Paetzold and Specia (2016b), who introduced a feature-based machine learning approach to complex word identification.

At around the same time, another line of research emerged: graded lexical complexity prediction (Gala et al., 2013, 2014). The main difference to complex word identification is that the aim is to predict a *grade* for each word, corresponding to different school levels for native language learners, and later second language learner proficiency levels (Tack et al., 2016; Alfter et al., 2016; Alfter and Volodina, 2018b; Tack et al., 2018; Pintard and François, 2020). This line of research is tightly connected to (second) language acquisition, with applications such as adaptive learning content (Burstein et al., 2017; Alfter and Graën, 2019) and personalized models for vocabulary learning (Avdiu et al., 2019; Ehara et al., 2018; Yancey and Lepage, 2018).

Over time, the two fields moved closer together, with complex word identification becoming *lexical complexity prediction*, with the aim of predicting a continuous complexity value instead of binary labels. Despite this, it remains that LCP for lexical simplification is concerned with finding words that should be simplified, while LCP for language learning purposes is concerned with finding words that are suitable for learners of a given proficiency level.

2.2 Shared Tasks and Datasets

Shared tasks have played a crucial role in advancing the field. In 2016, the first Shared Task on Complex Word Identification (Paetzold and Specia, 2016a) was organized, followed by the 2018 CWI Shared Task on Complex Word Identification (Yimam et al., 2018). In 2016, the data targeted only English, while in 2018, the task introduced multilingual and cross-lingual complex word identification, but still treating the problem as bi-

nary.² A significant shift occurred with the 2021 SemEval shared task on Lexical Complexity Prediction (Shardlow et al., 2021), which introduced a dataset with continuous complexity scores derived from Likert scale annotations and multiple contexts for many words. This task represented a major step towards more nuanced modeling of lexical complexity.

Despite the progress towards continuous modeling, recent work still shows a tendency to simplify the problem. The 2024 MLSP task (Shardlow et al., 2024), while advancing the multilingual aspect, largely reverted to a one-to-one mapping with limited contextual variation. The training data ($n = 300$) contains a single word with exactly two different contexts and almost identical complexity values. We argue that this is egregiously insufficient to learn different complexities for the same word in different contexts. This setup effectively reduced the task to a one-to-one mapping of words and complexities, disregarding the context-dependent nature of lexical complexity that was captured in the CompLex dataset. In opposition, the 2021 shared task training data ($n = 3487$) contains 1701 words with multiple contexts and different complexity values.

2.3 The Problem

Ideally, one would want to capture context-specific complexity and train systems to automatically predict such complexity. In order to train a system to recognize context-specific complexity, or *truly* graded complexity, the training data would have to include multiple contexts per word with *varying* complexity values. Even though complex word identification moved towards continuous modeling of complexity, it still often only gives one context per word, effectively mapping one word to one complexity value.

Recent research shows that out-of-the-box large language models are not capable of efficiently grading vocabulary (Alfter, 2024; Kelious et al., 2024). This at least to some degree precludes the use of large language models for synthetic data creation. If one were to for example build a system to automatically generate proficiency-adapted definitions, one would need to fine-tune a model with truly graded data (Yuan et al., 2022).

²The task consisted of two subtasks, binary and continuous prediction. However, the continuous labels were obtained by averaging the binary labels over all annotations. We thus regard this task as mainly binary.

3 Data Bottleneck

While theoretical advancements in lexical complexity prediction have pushed towards more nuanced, continuous modeling, a significant obstacle impedes practical implementation: the data bottleneck. This section explores the challenges in obtaining and creating the rich, context-aware datasets necessary for truly graded lexical complexity prediction.

3.1 Data Scarcity

The shift from binary to continuous lexical complexity modeling demands datasets that capture fine-grained distinctions in word difficulty. However, such resources are rarely available at the scale required for robust model training. As noted by Shardlow et al. (2022), creating datasets with continuous complexity ratings is significantly more resource-intensive than binary labeling tasks. Their study found that annotators spent an average of 21.61 seconds per annotation for graded complexity ratings.

The CompLex dataset (Shardlow et al., 2020) represented a step forward by providing continuous complexity scores, but even this resource was limited in size and scope compared to larger binary datasets. CompLex contained 10,800 instances across three genres, which, while substantial, pales in comparison to binary datasets like the one used in the 2018 CWI Shared Task, which contained over 65,000 instances (Yimam et al., 2018).

3.2 Challenges in Dataset Creation

Several factors contribute to the difficulty in conceiving and creating appropriate datasets for graded lexical complexity prediction. One significant challenge lies in the subjective nature of assigning precise, continuous complexity scores to words in context. This task demands skilled annotators yet often leads to low inter-annotator agreement (North et al., 2023), although attempts at mitigating this issue have been made using comparative judgments (Gooding et al., 2019; Alfter et al., 2021, 2022).

Another obstacle is the contextual variation inherent in language. Capturing the full spectrum of contextual variations for each word exponentially increases the annotation effort. The 2024 MLSP task’s inclusion of only one word with two contexts illustrates the practical challenges in scaling contextual annotations.

Furthermore, considerations regarding annotator

characteristics such as linguistic background and language proficiency further complicate dataset creation. Differences between native speakers, teachers, and language learners with varying language proficiency levels can lead to significant variations in perceived lexical complexity, thus limiting the comparability and interpretability of the data. Therefore, a clear definition and control of annotator demographics is essential to ensure the validity and usefulness of complexity-annotated corpora.

In addition, lexical complexity can vary significantly across domains, genres and tasks (e.g., reading aloud, reading for comprehension). Creating datasets that adequately represent this diversity while maintaining consistent annotation quality is a formidable task.

Moreover, complexities introduced by figurative language, including metaphors and metonymies, pose challenges, as such uses often deviate substantially from literal meanings, complicating complexity assessment. Similarly, multi-word expressions (MWEs) introduce unique difficulties because their complexity cannot be straightforwardly derived from the complexity of their constituent words (Alfter and Volodina, 2018a).

Finally, extending graded complexity prediction to multiple languages compounds the resource scarcity. Multilingual datasets like the one used in the 2018 CWI Shared Task are rare and often revert to simpler, binary annotations to maintain feasibility across languages.

3.3 Impact on Model Development and Evaluation

The data bottleneck has cascading effects on the field. Without access to large-scale, graded complexity datasets, researchers often default to simpler binary models or resort to synthetic data generation, potentially limiting model sophistication and real-world applicability. Large-scale extensive annotated datasets allow for more comprehensive coverage of phenomena such as ambiguous words, figurative language use, and multi-part expressions that may be inadequately represented in smaller datasets. Furthermore, larger datasets increase model sensitivity to subtle contextual variations, reduce bias, and improve prediction accuracy in diverse linguistic contexts.

The scarcity of diverse, graded datasets also makes it difficult to comprehensively evaluate models' performance across different contexts, domains, and languages. This can lead to overfit-

ting to specific datasets and poor generalization. Additionally, the relative abundance of binary complexity datasets inadvertently reinforces the continued use of binary approaches, creating a cycle that slows the adoption of truly graded prediction methods.

4 Addressing the Data Bottleneck

To move towards truly graded lexical complexity prediction, it is crucial to develop strategies for creating large-scale, diverse datasets that capture the context-dependent nature of word complexity. In this section, we propose several approaches that could help overcome the data bottleneck.

4.1 Collaborative Annotation Efforts

One approach to creating larger, more diverse datasets is to foster collaborative annotation efforts within the research community. By pooling resources and expertise, one can develop shared annotation guidelines and distribute the workload across multiple institutions. This collaborative approach has been successful in other NLP tasks, such as the creation of the Universal Dependencies treebanks (Nivre et al., 2016). Establishing a similar initiative for lexical complexity annotation could help accelerate the development of high-quality datasets. Further shared tasks on the subject may also help.

4.2 Crowdsourcing and Human Computation

Crowdsourcing platforms, such as Amazon Mechanical Turk, have been used extensively in NLP for data collection and annotation (Snow et al., 2008). By leveraging the power of human computation, one can gather lexical complexity annotations from a diverse pool of participants, potentially covering a wider range of contexts and reader backgrounds. This approach has been successfully used to annotate the CompLex data (Shardlow et al., 2022), to gather *comparative* judgments on lexical difficulty (Alfter et al., 2021, 2022), and to collect age-of-acquisition data (Kuperman et al., 2012; Green et al., 2025). However, quality control mechanisms must be put in place to ensure the reliability of crowdsourced annotations (Sheng et al., 2008).

4.3 Mining Graded Textbook Corpora for Lexical Complexity

Graded textbook corpora, which consist of textbooks designed for language learners at different proficiency levels, offer a promising resource for

creating lexical complexity datasets. These textbooks are carefully crafted to introduce vocabulary and grammatical structures in a gradual, level-appropriate manner, making them a valuable source of information about word complexity in context.

Graded textbook corpora can be leveraged to derive lexical complexity scores by aligning the vocabulary in each level with language proficiency frameworks like CEFR (Council of Europe, 2001). The relative difficulty of words can be determined by analyzing their distribution across proficiency levels. Words frequently appearing in beginner-level textbooks but rarely in advanced ones would receive lower complexity scores compared to those introduced at higher levels. This approach has been explored in the English Vocabulary Profile (Capel, 2010) and the CEFRLex project³, which created CEFR-aligned vocabulary lists from graded textbook corpora.

To extend this approach to lexical complexity prediction, one could leverage techniques from natural language processing, such as word embedding models (Mikolov and Dean, 2013) and contextual language models (Devlin et al., 2018), to capture the semantic and syntactic properties of words in context. By combining these models with the complexity information derived from graded textbook corpora, it may be possible to develop more accurate and context-aware lexical complexity prediction systems.

4.4 Leveraging Large Language Models

Recent advances in large language models offer an attractive avenue for addressing the shortage of richly annotated lexical complexity data. By leveraging large language models (LLMs), researchers can systematically generate diverse contexts for vocabulary items, varying key factors such as linguistic complexity, domain specificity, or target proficiency levels (Alfter, 2024; Kelious et al., 2024). Such synthetic data creation methods could transform even simple, context-free word lists into extensive datasets (Yuan et al., 2022; Green et al., 2025). However, the reliability of LLM-generated complexity annotations would require careful validation, as the generated contexts and associated complexity levels may not align accurately with intended proficiency targets, necessitating subsequent human verification or iterative refinement processes.

5 Conclusion

As we have explored throughout this opinion piece, the field of lexical complexity prediction stands at a critical juncture. While recent trends have acknowledged the continuous nature of word difficulty, practical implementations largely remain tethered to binary and one-to-one paradigms. This disconnect between theoretical understanding and applied research impedes progress in areas where truly graded predictions are not just beneficial, but essential.

The persistence of binary and one-to-one mapping methods is not due to a lack of theoretical understanding, but rather stems from a critical data bottleneck. Creating rich, context-aware datasets with continuous complexity ratings is a formidable challenge, requiring significant resources and expertise. This scarcity of nuanced data has cascading effects, limiting model sophistication and evaluation, and inadvertently reinforcing simpler binary paradigms.

Careful consideration of potential user groups is essential to effectively guide the creation and evaluation of lexical complexity datasets. While our discussion primarily focused on second language learners, graded lexical complexity is also suitable for native speakers and various user contexts, such as readability assessments, literacy support, text accessibility, and the development of educational resources. Each user group may require different complexity scales (e.g., continuous numerical scales suitable for NLP systems to discrete scales aligned with educational frameworks such as CEFR proficiency levels or school grades). Future research should explicitly explore these diverse user needs, considering practical implications such as scale granularity and annotation methods to ensure that lexical complexity annotations are both practically relevant and broadly applicable.

In conclusion, the future of lexical complexity prediction lies in not only fully embracing its continuous nature but also in creating resources that reflect various complexity values per word, allowing for the training of *truly* graded lexical complexity prediction systems. By moving beyond binary simplifications and overcoming the data bottleneck, we can develop tools and applications that more accurately reflect the nuanced reality of language complexity.

Limitations

As this is an opinion piece, our focus has been on identifying theoretical limitations and potential avenues for future research within the field of computational lexical complexity modeling. We have not conducted empirical experiments or proposed specific algorithms or datasets. Instead, we have highlighted general shortcomings in existing data and methods and suggested potential directions for advancement.

For the sake of conciseness, we focus on two areas only, namely lexical simplification and language learning. We acknowledge that the implications may reach further than just these two fields.

Ethical Concerns

While the potential benefits are significant, implementing truly graded lexical complexity prediction also presents challenges and ethical considerations. Complexity predictions must account for cultural and linguistic diversity to avoid perpetuating biases. What is considered complex in one cultural or linguistic context may not be in another.

The detailed learner data required for personalized systems raises privacy concerns. Ethical guidelines for data collection and use in educational technology must be carefully considered.

Abstract

This paper introduces IPPOLIS Write, an open source, web-based tool designed to provide automated feedback on the formal aspects of scientific documents. Aimed at addressing the variability in writing and language skills among scientists and the challenges faced by supervisors in providing consistent feedback on student theses, IPPOLIS Write integrates several open source tools and custom implementations to analyze documents for a range of formal issues, including grammatical errors, consistent introduction of acronyms, comparison of literature entries with several databases, referential integrity of figures and tables, and consistent link access dates.

IPPOLIS Write generates reports with statistical summaries and annotated documents that highlight specific issues and suggest improvements while also providing additional background information where appropriate. To evaluate its effectiveness, a qualitative assessment is conducted using a small but diverse dataset of bachelor's and master's theses sourced from arXiv. Our findings demonstrate the tool's potential to enhance the quality of scientific documents by providing targeted and consistent feedback, thereby aiding both students and professionals in refining their document preparation skills.

1 Introduction

Feedback on scientific documents, for example within a peer-review process, usually and understandably focuses on the discipline-specific content first and foremost. Writing, language, and other formal aspects are a secondary focus and often only commented upon when glaring or repeating issues are present. And while every scientist is expected to have a good grasp of their discipline-specific content, experiences and skills in the areas of writing and language vary greatly among the scientific community, making such feedback less consistent

and more subjective (Shashok, 2008; Wei and Liu, 2024).

For students writing their first scientific documents, such feedback on formal issues is especially useful. These students often make similar mistakes, and supervisors are faced with the task of repeatedly providing feedback about the same issues or focusing feedback on the more important areas, which are usually related to the discipline-specific content and not so much to writing, language, and other formal aspects. This is especially problematic in study courses where writing is not the main way to communicate results or solve tasks.

Existing tools for automated scientific document analysis either focus on analyzing the contents of the documents with regard to their accuracy and veracity, work only for certain document formats, or provide feedback or corrections for specific aspects only. In addition, most of the tools are commercial and closed source. Some of the existing tools are introduced in Section 2.

In this paper, we introduce a web-based open source software¹, which aims to combine a number of existing open source tools and libraries with custom implementations into a single application for analyzing scientific documents under formal aspects pertaining to document structure, readability, literature, referential integrity, tables, and figures. Based on a number of independent document analyzers, it generates reports with statistics and annotated documents with feedback.

2 Related Work

Various tools provide feedback on scientific manuscripts, each with a distinct focus or supported input formats. A detailed review on automated paper review systems (Lin et al., 2023) explained the underlying concepts, recent tools, and challenges.

¹https://gitlab.com/ippolis_wp3/write, Accessed: 2025-06-05

In (Lu and Liu, 2014), a tool was presented which validates the formal compliance of dissertations submitted as DOCX documents with given templates. The tool checks line spacing, font, font size, alignment style, and other formal aspects of DOCX documents. As a pre-processing step, the documents were converted to the eXtensible Markup Language (XML) format. An experiment on 50 dissertations compared automated annotations with manual ones, yielding a 94.5 % detection rate and a 3.7 % false detection rate.

The IEEE PDF eXpress² was developed to validate the consistency of IEEE-related conference and journal submissions in the Portable Document Format (PDF) with respective guidelines. Among other aspects, the proprietary tool checks page margins and the copyright footer.

The ACL pubcheck tool³ performs similar checks for ACL venues. It detects common formatting issues related to the ACL template in PDF documents. These issues include font inconsistencies, improper author formatting, margin violations, and outdated citations.

TeXtidote⁴ is a tool that detects formal issues in LaTeX and Markdown. It checks the style (e.g., proper title formatting, reference capitalization, caption punctuation), citations and references (e.g., consistent citation commands, reference summaries), figures (e.g., presence of captions and references), document structure (e.g., singular subsections, valid section order, stacked headings, and short sections), and hard-coding (e.g., relative paths for figures, hard-coded section/figure/table references, manual line and page breaks). Spelling, grammar, and punctuation errors were detected using the LanguageTool (Naber, 2003), an open source proofreading software based on rule-based correction algorithms and Machine Learning (Brenneis, 2018).

Penelope AI⁵ is a proprietary Artificial Intelligence (AI)-based tool that checks whether DOCX manuscripts meet configurable journal requirements. The tool performs validations, including the availability, position, and title of the ethical approval statement, along with the necessary declarations. It checks the formatting and completeness of

²<https://www.ieee.org/conferences/publishing/pdfexpress.html>, Accessed: 2025-06-05

³<https://github.com/acl-org/aclpubcheck>, Accessed: 2025-06-05

⁴<https://github.com/sylvainhalle/textidote>, Accessed: 2025-06-05

⁵<https://www.penelope.ai/>, Accessed: 2025-06-05

the title page and abstract, as well as the presence of pre-defined sections. Figures and tables are verified for correct integration, proper positioning, logical order, and accurate referencing. The manuscripts are evaluated for accurate referencing styles, proper citation order, and completeness of reference lists. Compliance with journal-specific limits on words, references, tables, and figures is checked. Endnote citations, metadata completeness, page numbers, and line spacing are annotated.

The proprietary YesNoError tool⁶ focuses more on content-related errors than formal feedback. It was designed to process PDF, DOCX, and LaTeX files and validates the methodological process, statistical correctness, and interpretational comprehensibility using OpenAI's o1 model. The analyzers detect issues including mathematical (e.g., arithmetic operations, bracket mismatches), methodological (e.g., study design, sample sizes, statistical tests), literature (e.g., citation and reference consistency), and logical errors (e.g., consistency of statements, conclusions, and argument flow).

Unlike these tools, our tool is open source, supports various file formats, is configurable for different formatting requirements in different disciplines, and emphasizes a broad range of comprehensive formal feedback.

3 Methods and Materials

IPPOLIS Write is a web-based tool that analyzes documents provided by its users based on the configured analysis profile and generates feedback and statistics as annotations directly in the original document and as a report which can be viewed in the web interface. An overview of the general workflow is shown in Figure 1 and is described in more detail in the following sections.

3.1 Cloud Share Link

The documents to be analyzed, analysis progress information and analysis results are stored in a cloud share. Many popular cloud providers are supported through the Web-based Distributed Authoring and Versioning (WebDAV) (Whitehead and Goland, 1999) protocol. Users can utilize their own cloud provider by generating a cloud share link with full read and write permission, allowing the tool to not only read the documents to be analyzed but also save analysis progress information

⁶<https://yesnoerror.com/whitepaper>, Accessed: 2025-06-05

Figure 1: Overview of the document analysis pipeline. Users share a document with the tool through a cloud share link, the document is converted and analyzed on the server, and the annotated document and report are saved in the user’s cloud share and can be viewed on the tool’s website.

and analysis results which can later be displayed on the website. That way, all data is always in the hands of the users. For convenience, a direct upload of documents is planned.

3.2 Analysis Profile

The analysis profile allows configuring, as well as disabling and enabling analysis options. Its goal is to make the tool useful for different disciplines, study courses, formal requirements, and phases in the writing process.

3.3 Pre-processing

After a document in one of the supported formats (PDF, DOCX, LaTeX, BibTeX, RIS, or ZIP) has been submitted, different pre-processing steps are performed to prepare it for analysis. The following sections outline this process for different input formats.

3.3.1 PDF

Although metadata such as the structure can be included in PDFs using PDF tags, this feature is rarely used (Schmitt-Koopmann et al., 2022) making the documents inaccessible to computer systems. IPPOLIS Write combines Poppler⁷ to extract the content, positions, and fonts of texts with document layout detection to determine the functional role of each element. Document layout detection based on You Only Look Once version 8 (YOLOv8) (Jocher et al., 2023) were trained on the DocLayNet (Pfitzmann et al., 2022) and ArxivFormula⁸ datasets. GeneRation Of Bibliographic Data (GROBID) v0.8.1⁹ is used to identify citations and

⁷<https://poppler.freedesktop.org/>, Accessed: 2025-06-05

⁸<https://github.com/microsoft/ArxivFormula>, Accessed: 2025-06-05

⁹<https://github.com/kermitt2/grobid>, Accessed: 2025-06-05

references and to convert bibliographic information into the BibTeX format.

3.3.2 DOCX

Apache Poor Obfuscation Implementation (POI) v5.2.5¹⁰ is used to extract the content, structure, and formatting from DOCX documents.

3.3.3 LaTeX/ZIP

TeXtidote is used for pre-processing LaTeX files, where the text and a mapping to the original LaTeX file is extracted from the document. ZIP archives are supported to allow users to upload LaTeX projects, which usually consist of at least a BibTeX file in addition to one or more LaTeX source files. The archives are extracted and both LaTeX and BibTeX files are analyzed separately.

3.3.4 BibTeX

For literature analysis, the tool focuses on the BibTeX format. The tool uses pybtex v0.24.0¹¹, and jbibtex v1.0.20¹² to extract literature information and identify invalid entries and fields. Bibtool v2.68+ds-1¹³ is used to identify literature entries cited in a LaTeX document, and bibutils v7.2-1¹⁴ converts Research Information System Format (RIS) files to BibTeX.

3.4 Document Analysis

The actual analysis is performed by dozens of independent analyzers based on the configuration in

¹⁰<https://poi.apache.org/>, Accessed: 2025-06-05

¹¹<https://pybtex.org/>, Accessed: 2025-06-05

¹²<https://github.com/jbibtex/jbibtex>, Accessed: 2025-06-05

¹³<https://github.com/ge-ne/bibtool>, Accessed: 2025-06-05

¹⁴<https://ctan.org/pkg/bibutils>, Accessed: 2025-06-05

the analysis profile and the artifacts produced during pre-processing. The analyzers are summarized in nine categories. These are general/formal, document structure, language, readability, literature, reproducibility, referential integrity, images, and tables. The analyzers refer to different input formats and provide analysis results, such as report statistics and annotations. More information on analyzers, their implementations, advantages and disadvantages is described in Section 4. A complete list of implemented and planned analyzers can be found in the Git repository¹⁵. All analyzers can be enabled or disabled for individual requirements via the analysis profile. During analysis, users are informed about the current analysis progress in the web interface. This is entirely asynchronous, and the analysis is not canceled if the user closes the website.

3.5 Report and Annotated Document

The results, statistics and annotations produced by the analyzers are converted into a report and, for some document types, an annotated document which is saved in the user-provided cloud share. For DOCX documents, annotations are embedded as comments, implemented using Apache POI. PDF documents were annotated using iText7 v8.0.3¹⁶. Optional Content Group (OCG) layers are utilized to conveniently enable or disable annotations directly within the PDF document. The report contains statistics and gamification elements, such as comparisons to analysis results of earlier versions of the document.

3.6 Dataset

To present and evaluate the analyzers, experiments were performed on a dataset containing bachelor and master theses in PDF format. The dataset was extracted from the arXiv (Ginsparg, 1994, 2011) preprint server, which was searched for the terms “master thesis” and “bachelor thesis” in the field of computer science (arXiv category: CS.*) on 2025-03-11. This query leads to 492 master theses and 91 bachelor theses. One master thesis cannot be downloaded, and one bachelor thesis is an invalid PDF document. Documents with fewer than 20 pages were excluded, as theses are typically longer, leading to 451 master theses and 79 bachelor theses. It was decided to concentrate on more recent theses,

¹⁵https://gitlab.com/ippolis_wp3/write, Accessed: 2025-06-05

¹⁶www.itextpdf.com, Accessed: 2025-06-05

Dataset	# documents	Avg. # pages
Bachelor train	19	66.63
Bachelor test	19	61.84
Master train	53	73.64
Master test	53	76.83
Σ	144	72.33

Table 1: Distribution of the primary arXiv categories across the training and test set.

which were submitted in arXiv after the 2023-01-01, leading to 110 master’s and 39 bachelor’s theses. One bachelor thesis and four master theses not written in English or German, the languages currently supported by the tool, were excluded. The four master theses were written in Persian, French, partially in Greek, and partially in Japanese. The bachelor thesis was written in Indonesian. The resulting 106 master’s and 38 bachelor’s theses are randomly split into a 50 % training, and a 50 % test set. The most frequently arXiv primary category was cs.LG (Machine Learning; 14.58 %) followed by cs.CL (Computation and Language; 11.81 %). An overview of the dataset is given in Table 1 and a list containing the arXiv IDs as well as a script to download the PDF documents is published in a git repository¹⁷. The dataset includes documents created in LaTeX and Word, featuring a wide variety of templates.

4 Results

The tool was evaluated on the test set. None of the theses were used to develop or optimize the tool prior to evaluation. All documents in the test set were processed without problems during the analysis. In the following sections, an overview of the currently implemented PDF analyzers is given, along with examples from the test set, showing which annotations are generated most frequently, in which areas the tool works well, and for which aspects incorrect annotations are generated most often. In addition, common reasons for formatting violations are explained.

Figure 2 presents boxplots depicting the average number of annotations per page for each annotation category in the test set. The overall number of annotations per page differs between 2.17 and 16.08. Master’s theses exhibit a slightly lower number of

¹⁷https://gitlab.com/ippolis_wp3/bea-2025-ippolis-write-dataset. Accessed: 2025-06-05

Figure 2: Boxplot showing the average number of annotations per page across annotation categories in the test set.

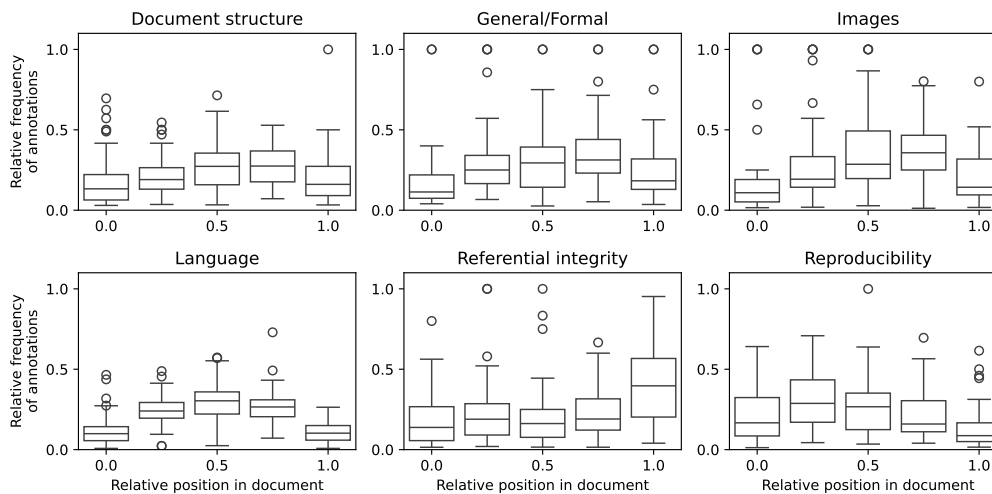

Figure 3: Boxplots showing annotation distribution by category across page positions in the test set.

annotations per page. This indicates that master students have more experience writing scientific theses. The most frequent annotations were language annotations that differed between 0.38 and 14.92 annotations per page. The remaining categories are detected less frequently with a maximum of 3.18 annotations per page, which was reached for a master thesis and the referential integrity category.

Figure 3 illustrates the distribution of annotation frequencies across document pages for each category. The plots show raw annotations that have not been validated. In the document structure, images, and language categories, annotations are more frequent in the middle sections of the documents. One possible explanation is that the middle of the document contains the main body of text along with most of the figures. General/formal and reproducibility annotations exhibit similar patterns, although general/formal annotations tend to accumulate slightly more in the later sections, while re-

producibility annotations are more frequent in the earlier sections. Referential integrity annotations accumulate at the end of the documents, indicating a large number of annotations in the reference sections, and thus references that were not recognized in the text.

A collage of several screenshots showing individual annotations for the master’s thesis (Singh, 2024) is visualized in Figure 4.

4.1 General/Formal

The analyzers that provide general and formal feedback ensure a well-organized presentation, including the identification of changing fonts, line spacing, and text alignments, as well as texts that exceed page margins. In addition, incorrect decimal and thousands separators are recognized, as well as missing punctuation marks at the end of captions.

The test set did not reveal any issues related to font changes. One reason for this might be that the documents are submitted theses, which are often

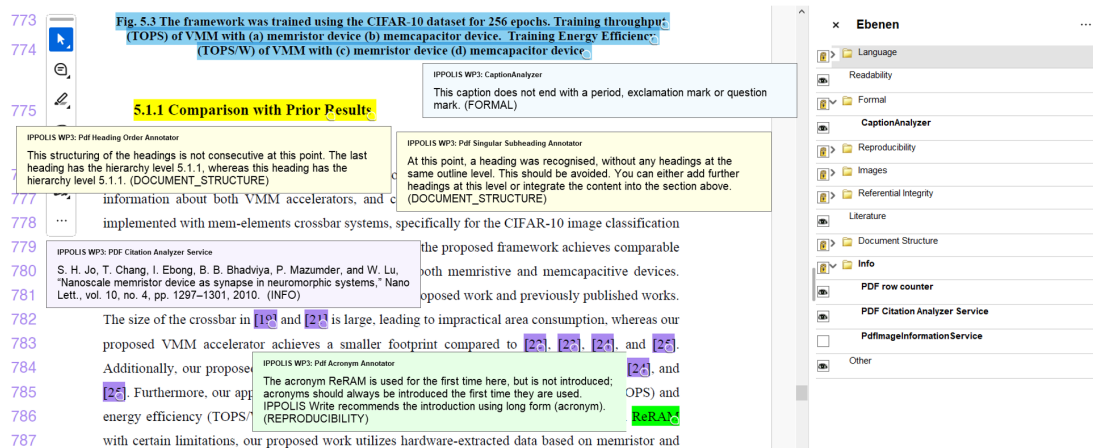

Figure 4: Collage of several screenshots showing individual annotations for the master’s thesis (Singh, 2024) from the test set. The OCG layers are shown on the right-hand side, which can be used to deactivate individual annotators.

revised multiple times. Occasional page margin violations are reliably identified, especially in LaTeX-generated PDFs. These violations often result from incorrect hyphenation settings, improperly formatted equations, or misaligned tables. When such issues are detected, IPPOLIS Write offers feedback, outlines common causes, and suggests ways to prevent them. At the moment, it does not detect figures that exceed page margins, which also occurs in LaTeX-based PDF documents but a future extension is planned for this feature.

In addition, many documents had missing punctuation marks in the captions. For this analyzer, it was observed that the layout detection described in Section 3.3.1 occasionally fails to detect captions correctly, depending on the template used.

4.2 Document Structure

All analyzers in this category are designed to maintain the structural integrity of the manuscript. These include analyses on heading structure (e.g., inconsistent heading numbers and orders, lowercase headings, missing heading layer), page numbers (e.g., missing and inconsistent page numbers), section content (e.g., empty sections), as well as table and figure captions (e.g., availability, length, and consistent positions).

Problems most often and reliably detected in the dataset are empty sections (i.e., a section heading is immediately followed by a subsection heading), and sections without another section at the same level. Due to the difficulty of extracting the document layout from the PDF, captions are sometimes not identified correctly. For unusual formatting (e.g., small caps), section headings are sometimes

not identified correctly. Tables and equations included as images are currently identified and analyzed as images.

4.3 Language

The language-based analyses include the investigation of the spelling, grammar, and punctuation (implemented using the LanguageTool¹⁸) as well as the vocabulary (occurring nouns, verbs, and n-grams). In addition, the detection of filler words and judgmental words (both adapted from the Readability Analysis Tool (Holdorf, 2016) and the angry-reviewer tool¹⁹), hype terms (Millar et al., 2023), and ChatGPT phrases²⁰ are implemented. First-person pronouns are detected as they may diminish the objectivity and neutrality of texts, particularly in specific languages and research fields. Duplicated sentences are annotated to prevent redundancies that could reduce the reader’s attention.

Language problems most often detected in the analyzed theses are grammar errors, frequent use of first-person pronouns, and the use of judgmental words. Most incorrect language annotations are generated because of a lack of context awareness, e.g., inside mathematical expressions, or when a word has several meanings (e.g. “clearly”).

4.4 Readability

The readability analysis focuses on identifying long sentence and reporting several readability scores

¹⁸<https://languagetool.org/>, Accessed: 2025-06-05

¹⁹<https://github.com/anufrievroman/Angry-Reviewer>, Accessed: 2025-06-05

²⁰<https://www.twixify.com/post/most-overused-words-by-chatgpt>, Accessed: 2025-06-05

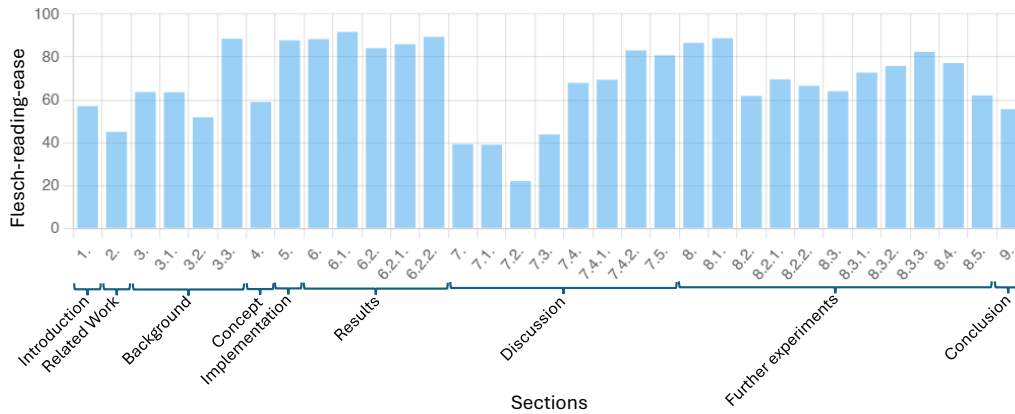

Figure 5: Flesch-reading-ease for document (Lachner, 2021) from the test set.

(e.g., the Coleman-Liau index (Coleman and Liau, 1975), or the Flesch-reading-ease (Flesch, 1948)). The readability scores are implemented to identify changes in language quality across the document. It was anticipated that more theoretical sections, mostly at the beginning of a thesis such as the introduction, related work, or methods sections, would have higher complexity compared to sections focusing on applied content (e.g., implementations or evaluations). A similar pattern was found for the Flesch-reading-ease across one test bachelor thesis (Lachner, 2021) which is visualized in Figure 5. The Flesch-reading-ease considers the average length of sentences and the average number of syllables per word. Higher values indicate easier text comprehension. The example exhibits lower values and thus more difficult text comprehension in the introduction, related work, background, and concept sections, followed by higher values in the implementation and results sections. The discussion section shows mixed scores, while the further experiments and conclusion sections display moderate values. Additional readability scores can be added in future versions of the tool.

4.5 Literature

Literature annotations are generated for citations with incomplete information, incorrect citation types, and published arXiv preprints. Information is retrieved from SemanticScholar (Ammar et al., 2018; Kinney et al., 2023; Lo et al., 2020), DBLP (Ley, 2002), OpenAlex (Priem et al., 2022), and CrossRef (Rachael, 2014).

The extraction of citations and reference lists from PDF documents using GROBID and additional extraction using regular expressions shows acceptable results. However, some citations remain

incorrectly identified, independent of the citation style used. In addition, some false-positive detections occur within equations or references to figures or captions. One reason for the incorrect detection is that GROBID was mainly trained on scientific articles, and the formatting differs from these. The detection accuracy of published arXiv preprints was investigated in more detail in previous work (Bloch et al., 2023).

4.6 Reproducibility

Reproducibility-based analyses include verifying the availability and consistency of hyperlink access dates, detecting URLs that are not properly linked, and identifying acronyms that are used without being introduced.

During the evaluation, it was observed that many documents lack access dates when mentioning URLs. These are often detected reliably, with some exceptions for date formats that omit the day. Missing hyperlinks, i.e. links that are not clickable, are reliably detected.

Almost all documents in the test set contain acronyms that are not introduced properly when first mentioned or employ inconsistent patterns to introduce them (e.g., Long Form (LF) vs. LF (Long Form)). Currently, the tool sometimes mistakenly identifies certain names, such as those mentioned in references (e.g., LeCun), as well as parts of equations (e.g., $A - B$), as acronyms, resulting in incorrect annotations. These issues can be addressed by improving reference detection and recognizing mathematical equations more accurately. The tool currently does not check the availability of acronym indexes, which could serve as an alternative to introducing acronyms upon first use.

4.7 Referential Integrity

The referential integrity of a document is important for the clarity and comprehensibility of scientific texts. IPPOLIS Write ensures updated table of contents, as well as complete and consistent references for tables, figures, sections and references.

In the test set, some PDF documents produced with DOCX and LaTeX suffer from outdated tables of content. For LaTeX documents, the page number of the bibliography section is often incorrect. DOCX documents are affected by inconsistent page numbers and section numbers, often due to manually created or outdated tables of contents. The tool identifies such problems reliably, with some issues when identifying page numbers.

Few figures and tables in the test set have missing captions, which were reliably identified. In contrast, many figures or tables are never or distantly mentioned in the text. In addition, inconsistent reference types were sometimes identified. Similarly to previous observations, occasionally incorrect annotations were produced, resulting mostly from incorrect layout detection, line breaks, or page breaks.

Citations are cross-checked with the literature index based on the previously mentioned GROBID software. The identification and mapping of citations show some issues especially for multiple consecutive references, as well as references in tables. One reason is that the formatting of theses differs from the documents, which were used to train and optimize GROBID.

4.8 Images

The tool examines whether the resolution of figures is sufficient for print publications and ensures they are not distorted during document creation. Furthermore, experiments were conducted to validate the images in more detail. These analyses include the detection of missing axis labels, tick marks, the number of colors, and image artifacts and were implemented using Vision-Language Models (VLMs) (Rückert et al., 2025). These features will be integrated into the tool in the future.

One issue present in almost every analyzed thesis is the inclusion of images with low quality (less than 300 DPI), with some of these including images of clearly poor quality with less than 100 DPI. During the implementation and test of the image analysis features, it became apparent that this is not always due to the quality of the original image,

but often unintentional image compression during document compilation or conversion can lead to poor image quality in the final PDF.

4.9 Tables

At the moment, tables are only checked for valid decimal and thousands separators by the tool. Analyzers regarding the validation of the table structure and the availability of units in table columns are planned. Table captions are analyzed as described in Section 4.2.

5 Discussion

The IPPOLIS Write tool is a web-based open source tool that provides automated feedback on formal aspects of scientific theses and papers to help students, but also researchers fulfill formal aspects of research theses and scientific papers. In comparison to previously developed tools, it is able to process a large number of document formats (PDF, DOCX, LaTeX, BibTeX, RIS, ZIP) and imposes no restriction on used templates. In addition, feedback is provided on a wide variety of formal aspects which are consolidated into nine categories (formal/general, document structure, language, readability, literature, reproducibility, referential integrity, images, and tables). Data privacy is maintained by temporarily sharing documents with the software through a cloud share, while all analysis results are directly stored in the cloud share. This solution enables the implementation of a gamification element, which can motivate users without having to create a user account. The analysis pipeline includes pre-processing of the documents to convert them into machine-readable data and document analyzers, which can be manually configured via the analysis profile. This profile makes it possible to customize the tool to individual requirements, for example, in different departments. The analysis results are converted into a report, and, for some document types, an annotated document was generated. The annotated document makes it easier for the user to quickly understand the annotations and correct the document.

The tool was validated using a PDF dataset from the arXiv preprint server containing bachelor's and master's theses with diverse formatting. The qualitative evaluation investigates which formal issues are identified most frequently, in which areas the tool works well, and for which aspects incorrect annotations are generated. The tool successfully

processes all theses and identified various issues in the test set. These include violations of the page margins, especially in LaTeX-based PDFs, empty sections, and sections without sibling sections at the same hierarchical level. Furthermore, various grammatical errors, missing access dates for URLs, and acronyms with missing or inconsistently introduced long forms were correctly identified. Some documents had outdated tables of content and figures or tables that were never mentioned in the text. Many documents suffered from low image quality, in part with resolutions smaller than 100 DPI. The high frequency of annotations found for theses published on arXiv illustrates the value of the tool.

The most incorrect annotations were identified as being caused by inaccurate layout detection, among other things leading to the detection of non-introduced acronyms or grammatical errors in mathematical equations or citations. This problem will be addressed in future releases by using improved layout analysis. As document layout analysis remains an active area of research (Gemelli et al., 2024), with demonstrated potential to enhance the robustness of Large Language Models (LLMs) for document understanding (Sciurus-Bertrand et al., 2024; Lamott et al., 2024), further advancements in this domain are anticipated in the near future. Additional problems, which will be addressed in future developments, will be improved context awareness during the detection of judgmental words, as well as improved detection accuracy for citations and references using LLMs.

Overall, the results demonstrate that IPPOLIS Write can identify various issues in academic theses, offering valuable formal feedback to assist students and researchers in revising their theses and papers.

6 Conclusion

In summary, this paper introduces IPPOLIS Write, a web-based tool that automatically provides feedback on the formal aspects of scientific theses and papers, assisting both students and researchers in meeting these requirements. IPPOLIS Write covers the most common document formats and a wide variety of formal aspects. In addition, it can be customized to meet the requirements of various disciplines. Data privacy is maintained by temporarily sharing documents through a cloud share. The tool was qualitatively evaluated on a diverse test set containing bachelor and master theses. The validation

shows that IPPOLIS Write detects a wide variety of issues in these documents. Incorrect annotations are mostly caused by inaccurate document layout detection, which is related to the high number of templates used in the dataset.

Limitations

IPPOLIS Write is not a finished product and in some areas lacks in robustness and consistency. Most issues stem from the difficulty of extracting information systematically from documents. Handling subtle differences introduced by diverse document creation tools, layouts, fonts, and formatting has consumed more development time than anticipated, and new documents still sometimes reveal new problems. Better pipelines based on new technologies may alleviate this issue in the future. Another limitation is the lack of a systematic quantitative evaluation of the generated annotations including a manual analysis of false positives and false negatives, as well as a user study, all of which would be useful to provide stronger evidence of the tool's impact. The evaluation dataset is currently limited to student theses from the computer science field. A more varied dataset could help expand and generalize the evaluation results. The tool is meant as a learning resource and does not provide immediate corrections but only suggestions which have to be manually applied, this limitation is an intentional design decision. Limitations that could be addressed in future development iterations of the tool include annotations available directly in the browser (currently only the Adobe PDF viewer fully supports the annotations), marking suggestions as solved/irrelevant for future document analyses, Optical Character Recognition (OCR) pipelines for images, better extraction of bibliography information from PDF, and support for additional languages beyond English and German.

Abstract

Students' argumentative writing benefits from receiving automated feedback, particularly throughout the writing process. Argument Mining (AM) technology shows promise for delivering automated feedback on argumentative structures; however, existing systems are frequently trained on completed essays. Although they provide rich context information, concerns have been raised about their usefulness for offering writing support on incomplete texts during the writing process. This study evaluates the robustness of AM algorithms on artificially fragmented learner texts from two large-scale corpora of secondary school essays: the German DARIUS corpus and the English PERSUADE corpus. Our analysis reveals that token-level sequence-tagging methods, while highly effective on complete essays, suffer significantly when the context is limited or misleading. Conversely, sentence-level classifiers maintain relative stability under such conditions. We show that deliberately training AM models on fragmented input substantially mitigates these context-related weaknesses, enabling AM systems to better support dynamic educational writing scenarios.

1 Introduction

Providing in-process and constructive feedback is integral to fostering argumentative writing skills in educational settings. (Argument Mining) AM has emerged as a promising approach for analyzing and evaluating the structure and quality of argumentative learner essays. However, the majority of AM systems operate on complete texts and their applicability in dynamic writing scenarios with incomplete drafts is unknown. A *conclusion*, for example, might only be recognized as such because it appears at the end of an essay and might not be recognized if the learner starts with the concluding statement and requests feedback early on.

To assess the severity of this problem, we investigate the robustness of existing AM algorithms

when applied to incomplete essay texts. We do so by emulating work-in-progress texts by applying artificial changes and perturbations to two datasets used previously for educational AM: the German DARIUS (Digital Argumentation Instruction for Science) dataset (Schaller et al., 2024b), containing about 4,500 texts on socio-scientific issues, and the English PERSUADE dataset (Crossley et al., 2024), with over 25,000 essays written by US secondary school students on various topics.

These benchmark datasets are probed with two kinds of AM classifiers: a sequence tagger that assigns a label to each token within an essay and a sentence classification approach that labels individual sentences without context. Although sequence tagging exploits contextual information and thus seems suitable for complete essays, sentence classification might have an advantage when only little or misleading context is available. To pave the way for feedback algorithms that can already provide support during the writing process, we explore ways to train a more robust classifier by applying similar perturbations to the training data.

Our paper makes the following contributions:

- We provide benchmark datasets of essays that we corrupted in several more or less realistic ways, which we obtained from the existing PERSUADE and DARIUS datasets to foster the development of robust AM methods.
- We conduct experiments on these datasets to highlight the detrimental effect of incomplete input in educational AM (up to 22 percentage points in the F1 score compared to full texts).
- We train baseline classifiers on similarly corrupted data that can reduce this performance drop to less than half.

All data is made available: <https://github.com/darius-ipn/dontscoretoearly>

2 Related Work

We review related work regarding three aspects. First, we discuss existing datasets for educational AM and select those suitable for our experiments. We then examine machine learning approaches in AM, focusing on the distinction between sequence tagging and sentence classification methods. Finally, we discuss other studies using perturbed essay texts in automated scoring scenarios.

2.1 Educational Argument Mining Datasets

We review datasets according to their suitability for our experiments considering their size, language, and the argumentative units annotated in the data.

Stab and Gurevych (2017) developed an argument detection system for English persuasive essays, achieving substantial inter-annotator agreement (Krippendorff’s α_V of 0.77). Their data consist of 402 English essays annotated for *major claim*, *claim*, and *premise*, as well as their argumentative relationships (*support/attack*).

Wambsganss et al. (2020) built a feedback system for the argumentation structure of German students’ essays. For that purpose, they collected 1,000 peer-reviews from a business innovation course in which students evaluated each other’s business models. The corpus was annotated by three native German-speakers for argumentative components (*claim* and *premise*) and their relationships.

The PERSUADE dataset of Crossley et al. (2022) consists of over 25,000 argumentative essays written by secondary school students in the US. Each essay was annotated for seven distinct argumentative components. The dataset was expanded (Crossley et al., 2024) with effectiveness scores per unit and holistic scores for the overall essay quality. In our previous work (Schaller et al., 2024b) we compiled the DARIUS corpus of 4,589 argumentative essays written by secondary school students in Germany. The corpus consists of two writing prompts on socio-scientific topics. The corpus features detailed annotations of argumentative elements, including *content zone*, *major claim*, *position*, and *warrant*.

Stahl et al. (2024) presented a German corpus of 1,320 school student essays annotated for argumentative structure and quality. Their four-level annotation scheme achieved high agreement ($\alpha = 0.74$ - 0.89). Their analysis revealed significant correlations between structural elements and essay

quality. The corpus provides another reference point alongside DARIUS for student writing in German secondary schools.

Velentzas et al. (2024) presented KUPA-KEYS, a dataset of keystroke logs from 1,006 participants’ English essays, including both L1 and L2 writers. Each essay was evaluated on the CEFR scale by three human assessors and an automated system. The dataset captures detailed keystroke patterns, pauses, and revisions during writing tasks, with the analysis showing moderate correlations between keystroke patterns and writing proficiency.

While keystroke logging would be ideal for studying incomplete texts as it captures the authentic writing process, existing keystroke datasets such as KUPA-KEYS lack the specific argumentative annotations needed for our work.

We decided to use the DARIUS and PERSUADE datasets for our experiments because they offer several key advantages: First, they cover different languages (German and English), allowing us to verify whether our findings hold across languages. Second, they are very similar in their annotation schemes, allowing us to focus on sequences instead of whole documents. Third, with over 4,500 and 25,000 essays respectively, they provide sufficient data to train robust machine learning models and conduct comprehensive robustness evaluations

2.2 Machine Learning in Argumentation Mining

AM consists of two subtasks: the detection of argument units and their classification as a certain type of argument, e.g., a claim or a conclusion.

Approaches to Argument Unit Detection There are two main strategies for detecting argumentative units, although variations are possible: Some use sentence classification, treating entire sentences as argumentative units. Alternatively, sequence tagging works at the token level to identify more flexible argument boundaries. We further review both approaches and hybrid methods.

Sentence Classification Approaches An easy (but not necessarily optimal) method for the selection of units is sentence classification, thus omitting explicit argument detection and classifying individual sentences in a text as belonging to a certain type of argument (or as being non-argumentative). Wambsganss et al. (2020) built a feedback system for the argumentation structure of students’ Ger-

man texts based on a sentence-level multiclass classification task. They developed an SVM-based system for claim/premise identification (65.4% accuracy) and relationship classification (72.1% accuracy). Their later ArgueTutor system (Wambgsanß et al., 2021) improved performance using BERT (F1 = .73). Similarly, in their fairness investigation, Schaller et al. (2024a) employed sentence classification approaches among others, comparing a supervised SVM, a BERT-based classifier, and zero-shot GPT-4 on the DARIUS corpus of students’ German essays.

Sequence Tagging Approaches At the other end of the spectrum, many researchers have employed sequence tagging on tokens to allow for more flexible argument boundaries. This approach has gained significant attention in the field, particularly with the rise of transformer-based models. In our fairness study, (Schaller et al., 2024a) we additionally employed sequence tagging approaches, finding that a task-specific fine-tuned BERT model consistently outperformed other approaches, including more powerful decoder-based language models such as GPT-4 when used in a zero-shot setting.

Stahl et al. (2024) trained sequence labeling models based on mDeBERTaV3-adaptor, which achieved a F1 scores up to .68 for discourse functions.

We previously investigated AM using the English PERSUADE and MEWS and the German DARIUS datasets (Ding et al., 2024). Our sequence tagging used a Longformer-based model, achieving an F1 score of .66 on English essays and providing important baseline performances on complete essays. The analysis revealed that educational context differences impacted performance more than language differences did.

Comparative and Hybrid Approaches Several researchers have compared these approaches or examined the advantages of hybrid approaches.

Trautmann et al. (2020) explicitly examined sentence versus token classification for argument recognition on annotated Common Crawl data (IAA α_{unom} = .61). Their experiments with various BERT and FLAIR models showed that a BERT_LARGE sentence classifier was only outperformed by the BERT_LARGE token classifier when combined with a CRF model, demonstrating that sentence classification can achieve comparable results to token classification approaches.

Stab and Gurevych (2017) showed the advantages of combining both sequence labeling and classification for AM. They first used a CRF for sequence labeling to identify argument boundaries in the text and then used SVM classification to determine each argument’s type and relationships. This combined approach significantly outperformed using either method alone, achieving an F1 score of .86 compared to .79 for individual classification and .64 for baseline approaches. These studies highlight that the optimal approach for complete texts may depend on specific tasks, domains, and available data, and that one approach may not always be superior.

2.3 Influence of Rearranged Sequences

As our work investigates the robustness of AM on incomplete texts, we review previous work on educational scoring that examined model behavior with incomplete texts or nonstandard text order.

Farag et al. (2018) tested AES robustness against shuffled sentences. Their LSTM model performed well on regular essays but declined with shuffled texts. They addressed this by combining models trained on both regular and permuted essays, maintaining scoring performance while detecting shuffled texts. This highlights neural models’ reliance on expected sequence orders, informing our work on incomplete texts.

In a previous paper (Ding et al., 2023), we used sequence tagging with fine-tuned RoBERTa to identify EFL email segments. When tested with scrambled segments, performance dropped strongly (F1 = .89 to F1 = .60), but the model was able to adapt when trained on scrambled data (F1 = .85). On the basis of this work, we anticipate that sentence classification models will outperform sequence tagging models due to lower dependence on position and context.

3 Data

This section presents the two datasets used in our evaluations, DARIUS and PERSUADE, and discusses our decision regarding which annotations to include. Table 1 gives an overview of the key statistics of the datasets.

DARIUS The DARIUS corpus (Schaller et al., 2024b) contains 4,589 argumentative texts by 1,839 secondary school students in 33 German schools. The task consists of two writing prompts on socio-scientific topics: energy and automotive (gener-

	DARIUS	PERSUADE
Language	German	English
Essay genre	argumentative	argumentative
Writing prompts	2	15
Grade	9-13	6-12
# Essays	4,675	25,996
avg. Word count	150	399

Table 1: Key statistics for DARIUS and PERSUADE

ating 2,307 and 2,282 essays, respectively), with students completing both a draft and a revision for one prompt and a single essay for the other. The corpus features detailed annotations of argumentative elements, including *content zone*, *major claim*, *position*, and of argumentative units. The average essay has 150 words.

For our experiments, we focused on *content zone* annotations. *Content zone* describes the macro structure of an essay: *introduction*, *main part*, and *conclusion* (see Fig. 1). Not all essays contain all three sequences, as students may have returned unfinished texts or skipped introductions, etc. Each sequence consists of one or more complete sentences and must end with a sentence-final punctuation mark. In contrast to the other annotations in DARIUS, their sequences are not based on sentences but on spans of multiple sentences, similar to the annotations of PERSUADE.

PERSUADE The PERSUADE dataset (Crossley et al., 2022) consists of over 25,000 argumentative essays written by secondary school students from grades six through twelve in the US. The essays are based on 15 prompts, eight independent and seven source-based. Each essay was annotated for seven distinct argumentative components: (see Fig. 2 and Fig. A.6 in Appendix A) *lead*, *position*, *claim*, *counterclaim*, *rebuttal*, *evidence*, and *concluding statement*. The inter-rater agreement achieved an F1 score of .73. The dataset was expanded (Crossley et al., 2024) to include effectiveness scores for individual discourse elements and holistic essay quality scores. The average essay has 399 words. Sequences can span any length from a single phrase to multiple sentences and do not always align with sentence boundaries.

4 Benchmark Datasets

In order to gauge classifier performance on incomplete essay data, we simulate essays in the process

CO₂ emissions and greenhouse gas emissions are to be drastically reduced as they have had a major impact on our climate change in recent years. But how can we do this work as efficiently as possible to meet the energy demand in this district? There are three options to choose from. The construction of a wind energy park, a solar plant, or a hydroelectric power plant. Which of these three projects should be supported?

If one considers the first criterion, i.e., efficiency, the hydropower plant is clearly in the lead with 70–90%. The solar park is the weakest here. The second criterion, annual yield, is close because both the wind farm and the hydropower plant have good annual yields. And so it goes on with the other criteria so that one can say that the construction of a hydropower plant is the most efficient in relation to the construction of an energy converter. The only major drawback is the price of the project, which brings us back to the wind farm because the price difference alone is a whopping 55 million euros. And the criteria are not so bad that you can't compensate for the deficits over the years.

In conclusion, it can be said that due to the enormous price, a wind farm is the best way to produce electricity for a region that is not so large.

Figure 1: Example essay from the DARIUS dataset (translation by the authors). From top to bottom: *introduction*, *main part*, *conclusion*.

Driverless cars have been a big topic lately. In some ways driverless cars sound cool but they also seem a little scary.

I think that driverless cars shouldn't be allowed on public roads because they are not safe.

Some think being able to have your car drive itself sounds nice. You could just sit in your car and listen to music while you wait to arrive to your destination. Driverless cars would allow you to sit in your seat, hands on the wheel, but not actually driving.

This idea does sound nice but as all other technology such as computers and phones, technology is not always reliable.

A driverless car could cause a major or even fatal crash.

While most driverless cars require you to have hands on the wheel this does not mean you will be paying attention if something is about to happen. All it would take is for something in the car to mess up and people could be very seriously hurt.

I think that people driverless cars are not safe and they should not be allowed on public roads.

Figure 2: Essay 65 from the PERSUADE corpus. From top to bottom: *Lead*, *Position*, *Claim*, *Counterclaim*, *Rebuttal*, *Evidence*, *Concluding Statement*.

of being written by making different changes and perturbations to the original essay data.

Across all benchmark variants, we retain the original gold-standard labels from the uncorrupted texts, i.e., we assume that the label of a unit does not change depending on the context or lack thereof. In doing so, we want to simulate a process where students write what they intend to write but not

necessarily in the right order, and the justification for a label is that the unit has a certain function in the complete text even if that is not yet obvious to a teacher or annotator in the partial essay during the writing process. While this may lead to cases where labels are not recoverable from the modified input alone (e.g., conclusions appearing mid-essay in Shuffled texts), our goal is to test model robustness in incomplete or misleading contexts, reflecting educational scenarios where students submit partial drafts.

We include the following variants:

Full text: The original essays are used as a baseline.

First_X: This simulates an incremental, top-down writing process where a learner receives feedback after having completed at least 25%, 50%, or 75% of the whole text. We clip DARIUS essays after 25% of sentences and PERSUADE essays after 25% of sequences, as DARIUS annotations span at least one sentence, while PERSUADE annotations can be phrase-level annotations.

Last_X: Similar to the former scenario, this simulates the (admittedly less likely) process where only the last 25%, 50%, or 75% of a text is scored.

Sentence: Every single sentence from the test data as its own document, i.e., sentences are labeled completely without context.

Shuffled: For this condition, sequences within an essay are randomly shuffled to appear in misleading contexts, with DARIUS shuffling at the sentence and PERSUADE at the sequence level.

Table A.7 in Appendix A provides examples for all variants of an essay. Note that we do not expect all of these variants to occur (frequently) in real-life data. We rather aimed to cover the whole spectrum to also assess worst-case scenarios. We kept the datasets comparable whenever possible, i.e., **full text**, **sentence**, and **shuffle** contain exactly the same material, just in a different order or different document size, while **first_X** and **last_X**, for obvious reasons, contain less material. Similarly, also the label distribution changes for these benchmarks, e.g., essays with the last part missing, tend to contain less conclusion material. Table A.5 in Appendix A shows an overview of the dataset sizes per benchmark.

5 Experiments

This section evaluates how AM approaches perform on incomplete texts that simulate intermediate products within the writing process.

We compare sequence tagging and sentence classification. The models are tested on both complete essays and simulated incomplete drafts to assess their ability to provide feedback on unfinished texts.

5.1 Experiment 1: Baseline Performance on Benchmark Datasets

Data splits The DARIUS corpus consists of 4,581 essays, which we divided into 3,672 essays for training and 909 essays for testing, following the setup from Schaller et al. (2024a). From the training set, we reserved 20% as a development set to determine the optimal number of training epochs, while using the remaining 80% for model training.

The training set of the PERSUADE (1.0) corpus contains 15,594 essays, which were released in a Kaggle competition¹. We use them all for training. For testing, we use 1,560 random essays from the PERSUADE (2.0) test set².

Classifiers For the comparison of sequence tagging and sentence classification, we use transformer models with different classification heads while keeping the base architecture consistent within each language. For DARIUS, we use a BERT (Devlin et al., 2019) model, bert-base-german-cased, both for the sequence tagging and the sentence classification model. It has a sequence length of 512 tokens, which is adequate for the average DARIUS essay. Longer texts were truncated to 512 tokens. The model was fine-tuned using the default hyperparameters from the Hugging Face Transformers library. We trained for four epochs, which proved sufficient for convergence on our validation set.

As almost one-third of the English essays in PERSUADE contain more than 512 tokens, we use a pretrained Longformer model (Beltagy et al., 2020) for token classification, with a maximal training length of 1,024 tokens, to train a sequence tagging pipeline (Ding et al., 2022) for the prediction of different argumentative elements in the PERSUADE essays. For sentence classification, we use

¹<https://www.kaggle.com/competitions/feedback-prize-2021>

²https://github.com/scrosseye/persuade_corpus_2.0

the pretrained BERT model (Devlin et al., 2019) for sequence classification.

Evaluation Measures We use F1 scores to evaluate and compare sequence tagging and sentence classification approaches across different benchmark datasets. For both datasets, we treat each argumentative element type (e.g., *introduction*, *main*, and *conclusion* in DARIUS; *lead*, *position*, *claim*, etc. in PERSUADE) as a separate class in a multi-class classification setting.

For sequence tagging, we compute F1 scores directly on the token-level predictions, where each token receives one label. When comparing this to sentence classification approaches, we also derive sentence-level metrics from our token classifiers through majority voting (assigning the most frequent token label as the sentence label).

5.2 Experimental Results

Results for DARIUS Table 2 shows the performance of the token and sentence classifier for the various benchmark datasets.

On complete essays, the token classifier demonstrated high performance, with an overall F1 score of .93 on the sentence test set and .92 on the token test set, showing particular strength in identifying the *introduction* (.91/.88) and *main* sections (.96/.95), although it performs weakly on the *conclusion* (.73/.71). This will be the baseline for the other benchmark datasets. As the results for both datasets are very similar, we will further discuss only the sentence test set.

With regard to the decontextualized datasets, it can be seen that the performance decreases. When tested on the first 25%/50%/75% of sentences, relatively stable F1 scores are observed: *overall* (.93-.96), *introduction* (.91-.92), and *main* (.94-.97). The drastic drop in *conclusion* performance (.0-.56) stems directly from the near-complete absence of conclusion sentences in these portions. In the first 50% of essays, there are virtually no conclusion sentences (30 instances compared to 13,679 for the full texts), explaining the .0 F1 score. Most conclusion sentences appear only in the last 25% of essays, as confirmed by the higher support numbers in the Last_25 and Last_50 datasets.

Testing on the **Last_75** reveals the reversed situation, reflecting the lack of *introductions* while maintaining the same number of *conclusions* as in the full essays. The F1 scores for the *overall*, *main*, and *conclusion* remained stable, although

the *introduction* F1 score decreased substantially to .76.

The analysis of the **Last_25** demonstrated a substantial drop in the *overall* F1 score (.72) and the *conclusion* (.32) - a seemingly unexpected result given that all *conclusion* samples remain present in this set. This decline occurs because conclusion sections now appear at the beginning of these truncated texts. The model struggles to recognize conclusions when they are artificially repositioned, indicating that it relies on positional context.

An even worse picture emerges from the analysis of the **Sentence** and **Shuffled** benchmark data. Both include all samples of each annotation but an extreme drop can be seen in the *conclusion*. The token classifier, in particular, is not able to predict the *conclusion*, if given only a sentence example of it (.0). The *introduction* also drops to an F1 score of .70. In the shuffled condition, the *introduction* performance declines further to .31.

These results suggest that, although the model learns the typical structure of complete essays, it struggles to apply this knowledge to incomplete texts.

To further investigate this assumption, we also trained a model for sentence classification, see Table 2. Compared to the token classifier, this model has a slightly lower overall F1 score of .91, .86 for the *introduction* and a slightly higher F1 score of .96 for *main* when tested on the **Full text**. It also performs lower on the *conclusion*, with a score of .60. But compared to the performance of the token classifier on sentences (.0), a much better performance was observed here, especially on the *conclusion*. This might indicate that the token classifier heavily relies on the context of each class, whereas the sentence classifier inherently learns the structure of each class without further context.

Results for PERSUADE Table 3 shows the performance of both token and sentence classifiers for PERSUADE. Similar to DARIUS, we observe substantial performance variations across the benchmark datasets. On complete essays, the token classifier achieves an overall F1 score of .57, with stronger performance on *lead* (.78) and *concluding statement* (.77), probably due to their fixed positions.

For partial texts, the **First_X** benchmarks show a moderate decline in the overall performance (.52-.46). *Lead* detection decreases (.67 to .57), while *evidence* detection improves (.44 to .78), suggest-

ing that positional cues become less reliable, while content-based identification improves with more context. *Concluding statement* detection remains near zero except for the **First_75**, with a score of .14. This is, similar to DARIUS, due to the lack of concluding statements in the first part of the texts. The **Last_X** benchmarks reveal significant performance degradation. Overall, the F1 scores (.11-.25) are much lower than for the **Full text** or **First_X**. Similar to the findings for DARIUS, the *conclusion* shows a sharp decrease (.77 to .39), suggesting that the positional context is also critical for PER-SUADE. The weakest performance appears in the lead (.21) and claim (.00) detection in the **Last_25**, where claims are absent or near-absent.

In the decontextualized **Sentence** and **Shuffled** conditions, the token classifier performs poorly (.20 and .30 overall), while the sentence classifier achieves better results (.43 overall), particularly for *position* (.51) and *evidence* (.48).

These results confirm our DARIUS findings: AM models trained on complete essays have difficulty with partial or nonsequential inputs. The more complex argumentation schema in PER-SUADE (seven classes versus three in DARIUS) appears to enhance this issue.

5.3 Experiment 2: Training on Incomplete Texts

Our previous experiment demonstrated that AM models trained on complete texts showed a decrease in performance when confronted with incomplete or out-of-context texts in the case of DARIUS, especially for the *conclusion*. To further investigate this issue, we explored whether training on deliberately split texts could enhance the models' robustness on the benchmark datasets.

Experimental Setup We developed two additional training strategies for the DARIUS dataset. Both used the same amount of training data but differently divided:

The **Split** model was trained on randomly split versions of the training texts, similar to the **First_X/Last_X** benchmark. Each essay was divided into complementary portions (25%/75%, 50%/50%, or 75%/25%).

The **Hybrid** model was trained on a combined dataset consisting of both complete essays (as in our original token classifier) and their split versions (as in the **Split** model).

Both models used the same BERT architecture

as our original token classifier and only differed in the training data composition. We then evaluated these models on the same benchmark test sets as those used in our previous experiments.

Results and Analysis Table 4 presents the performance differences between our new models (**Split** and **Hybrid**) and the original token classifier across all test conditions. The values represent changes in F1 scores relative to the original model. Several key patterns emerge from these results:

1. **Performance on complete essays:** Both the **Split** and the **Hybrid** models showed slight performance decreases (F1 scores of -.04 and -.02 overall, respectively) when tested on complete essays, with the most substantial drop observed for conclusion detection (-.17 and -.10). This suggests that, when testing on complete essays, models benefit from training on well-formed, complete training essays, as these contain valuable signals for the task.

2. **First_X:** For essays containing only beginning portions, both models performed similarly to the original classifier, with minor decreases in performance (F1 scores of -.01 to -.03 overall). This indicates that detecting introductions and main content remains relatively robust across training strategies.

3. **Last_X:** The most substantial improvements appeared in the **Last_25** condition, where the **Split** model achieved a +.12 increase in the overall F1 score, with an enormous +.40 improvement in conclusion detection. The **Hybrid** model showed more moderate but still positive gains (+.06 overall, +.22 for conclusions). This pattern of improvement continued in the **Last_50** condition but diminished in the **Last_75** as texts become more complete.

4. **Decontextualized conditions:** For completely decontextualized sentences, both new models substantially improved conclusion detection performance (+.49 for **Split**, +.39 for **Hybrid**), while maintaining or slightly improving overall performance. For shuffled texts, the improvements were small but still positive for conclusion detection.

5.4 Discussion

Our findings indicate trade-offs in training approaches for AM in educational settings. The original token classifier performs well on complete essays but has limitations when identifying argumentative elements, particularly the *conclusion*, when these appear in unexpected positions or without sufficient context.

Table 4: Comparison of training strategies on DARIUS dataset. Parentheses show differences from the original classifier. Positive values indicate improvement. Bold values are substantial improvements.

The **Split** model shows that training on incomplete texts improves the handling of such conditions, although this affects the performance on complete essays. The **Hybrid** model offers a trade-off, making modest improvements for incomplete texts while largely maintaining the performance level on

complete essays.

The most notable improvements in both new models relate to conclusion detection in partial texts; this is consistent with our observation that conclusions tend to be context-dependent. Training models with conclusions in various contexts

reduces their reliance on position and directs attention more to the linguistic features of conclusive statements.

6 Conclusions and Future Work

The results suggest that providing feedback during the writing process is feasible, particularly when students write linearly from beginning to end, but struggles with incomplete or out-of-sequence texts. Context plays a crucial role in accurate classification. While sentence-level classification shows promise for handling incomplete texts, conclusion detection remains challenging as it appears most context-dependent. Our **Hybrid** training approach offers a practical compromise, showing modest improvements for incomplete texts while largely maintaining performance on complete essays. This suggests that educational feedback systems could provide reasonably accurate feedback throughout the writing process while maintaining acceptable performance on complete essays. However, a challenge remains in determining which model to use in real time. As we cannot know a priori whether a student will submit a complete or partial text or whether they have written it sequentially, selecting the optimal model becomes difficult.

Future work could explore methods for detecting completion stages of student texts, enabling dynamic model selection. Additionally, we plan to use process data such as key logs to better understand the writing process and when to provide appropriate feedback. Large language models could be used to create realistic examples of incomplete student essays for training, opposed to only truncated texts.

Limitations

We presented a preliminary study that aims to emulate learner texts in the progress of being written. We were not able to verify how learners actually write in key-logging data; this will be one of our next steps. Thus, our experiments assess possible worst-case scenarios of what incomplete texts might look like, where exactly learners are on this spectrum, is yet to be determined.

Our experiments focus on BERT-based models, chosen for their established performance in German educational contexts and bidirectional attention capabilities. Another option could be to use decoder-based models like DeBERTa. However, such models only look at the left context and thus

might not be optimal in scenarios like our where potentially the first part of an essay is still missing

Another limitation of our study is its restrictions to German and English data from Germany and the United States, limiting our finding to two well-resourced languages and only two education systems. More research targeting other languages and datasets would increase the transferability of our results.

Ethics Statement

Our datasets do not contain any new material for which we have to ensure data protection and the handling of personally identifiable information. We selected datasets that, to the best of our knowledge, handled such issues with care.

Variant	Example
full text	CO2 emissions and greenhouse gas emissions are to be drastically reduced as they have had a major impact on our climate change in recent years. But how can we do this work as efficiently as possible to meet the energy demand in this district? There are three options to choose from. The construction of a wind energy park , a solar plant or a hydroelectric power plant . Which of these three projects should be supported ? if one considers the first criterion, i.e. efficiency, the hydropower plant is clearly in the lead with 70 - 90% . The solar park is the weakest here . The second criterion, annual yield, is close because both the wind farm and the hydropower plant have good annual yields . And so it goes on with the other criteria so that one can say that the construction of a hydropower plant is the most efficient in relation to the construction of an energy converter . The only major drawback is the price of the project, which brings us back to the wind farm because the price difference alone is a whopping 55 million euros . And the criteria are not so bad that you can't compensate for the deficits over the years. In conclusion, it can be said that due to the enormous price, a wind farm is the best way to produce electricity for a region that is not so large .

The only major drawback is the price of the project, which brings us back to the wind farm because the price difference alone is a whopping 55 million euros . And the criteria are not so bad that you can't compensate for the deficits over the years. In conclusion, it can be said that due to the enormous price, a wind farm is the best way to produce electricity for a region that is not so large .

Abstract

The rapid development of Large Language Models (LLMs) opens up the possibility of using them as personal tutors. This has led to the development of several intelligent tutoring systems and learning assistants that use LLMs as back-ends with various degrees of engineering. In this study, we seek to compare human tutors with LLM tutors in terms of engagement, empathy, scaffolding, and conciseness. We ask human tutors to annotate and compare the performance of an LLM tutor with that of a human tutor in teaching grade-school math word problems on these qualities. We find that annotators with teaching experience perceive LLMs as showing higher performance than human tutors in all 4 metrics. The biggest advantage is in empathy, where 80% of our annotators prefer the LLM tutor more often than the human tutors. Our study paints a positive picture of LLMs as tutors and indicates that these models can be used to reduce the load on human teachers in the future.

1 Introduction

Recent improvements in Large Language Models (LLMs) have opened up the possibility of using them in multiple new domains, including as personal tutors. This possibility has led to the development of several Intelligent Tutoring Systems (ITSs) and learning assistants (Schmucker et al., 2023; Liffiton et al., 2023; Lieb and Goel, 2024; Vanzo et al., 2024) that use LLMs as backends with various degrees of engineering. Surveys by Intelligent.com (Int, 2023) and DEC Singapore (DEC, 2024) indicate that a large number of students are already using LLMs like ChatGPT in educational roles such as tutoring.

Despite their popularity, a clear understanding of the pedagogical effectiveness of educational chatbots, especially compared to humans, is lacking.

The common way of using LLMs as tutor is to interact with them via a chat interface, where the LLM roleplays a tutor. It is known that the full benefit of a human tutor goes well beyond verbal or textual communication (Bambaerero and Shokrpour, 2017), giving human tutors an advantage over LLM-based tutors. However, it remains unclear how LLM-based tutors compare with their human counterparts, in this chat setting. A good tutor keeps students **engaged**, **empathises** with their struggles, **scaffolds** them to correct answers, all while keeping the conversation to the point and **concise**. Is an LLM-based tutor capable of doing the same?

In this study, we compare human tutors with LLM-based tutors, through the dialogs generated via chat interfaces. Our main research question is:

How do LLM-based tutors compare to human tutors in terms of engagement, empathy, scaffolding, and conciseness?

Although there have been some recent attempts to compare learning gains from LLM-based tutors and human tutors (see Sec 2), these studies focus on the observable outcomes of learning gains. Our study seeks to complement these studies by instead focusing only on the latent factors (we will provide a more detailed definition and justification in Sec. 3.2), and run comparisons on these directly. We believe that knowing how LLMs stand on these would allow researchers to better focus on what to improve in these models.

Our contributions are:

1. We create a setup to ask human annotators to compare tutoring dialog snippets in a blind pairwise preference selection setting.
2. We use this setup to have teachers compare a human tutor with an LLM tutor on a dataset of MWPs to identify how they compare the 4 latent factors involved in student learning.

*For queries contact spa1chowd@ethz.ch

3. We publicly release the [annotation data](#) consisting of 210 annotated dialog pairs to help future research better align LLM outputs to human judgments.

Our experiments find that annotators with teaching experience perceive the LLM tutor to be more engaging and empathetic while also being concise and better at scaffolding the student. This also aligns with LLMs self-judgments, though fine-grained tendencies are quite different.

2 Related Work

2.1 Designing and Evaluating LLM Based Tutors

With the recent progress in LLMs, there have been several efforts to develop and evaluate LLM-based tutors. A large number of these have focused on computer science and programming education (Yang et al., 2024; Qi et al., 2024; Lififton et al., 2023; Kazemitabaar et al., 2024; Jacobs and Jaschke, 2024; Liu et al., 2024; Lyu et al., 2024; Li et al., 2024; Choudhuri et al., 2023; Pankiewicz and Baker, 2024), but there have also been developments in domains like mathematics (Chowdhury et al., 2024; Butgereit et al., 2023; Pardos and Bhandari, 2024), language learning (Polakova and Klimova, 2024; Park et al., 2024; Vanzo et al., 2024), health sciences (Kavadella et al., 2024; Chheang et al., 2024; Wang et al., 2024) and other domains (Thway et al., 2024; Chen and Chang, 2024). However, most of these works focus on the engineering behind developing the tutor, and if any evaluation is done, it is either in terms of learning gains, or in the terms of student self-reports of efficacy and motivation. Moreover, the comparison in these studies is always between having an LLM-based tutor and not having anything, and not with human tutors. Finally, we also lack an understanding of the factors contributing to a good quality tutor.

2.2 Comparing AI Tutors with Human Tutors

Tutoring was established as one of the best ways to improve learning outcomes by Bloom in 1984 (Bloom, 1984), and matching the learning gains of a human tutor has been one of the main targets of computer-based tutors ever since (Sleeman and Brown, 1982). Several studies have compared the learning gains from different types of computer-based tutors with humans (Kulik and Kulik, 1991; Anderson et al., 1995; VanLehn, 2011)

and with the development of LLM-based tutors, the same has also been extended to LLM based tutors (Schmucker et al., 2023; Zhang et al., 2024). However, these works focus only on the final learning gain, not on the latent qualities that could cause it.

Since several computer-based tutors communicate in natural language, another line of work follows from Alan Turing’s Imitation Game (Turing, 1950), which was later adapted into the ‘Bystander Turing Test’ (Person and Graesser, 2002). While our work is similar to this in terms of the text-only setup and blind selection, we differ in that instead of asking the annotator to determine which party is human, we ask them to determine which one is better on a set of metrics.

3 Method

3.1 Datasets

To compare human and LLM tutors, we need parallel data sets of student-tutor text interactions, both for human and LLM tutors. Among the limited one-on-one tutoring datasets available, we cannot use data sets such as TSCC (Caines et al., 2020) or CIMA (Stasaski et al., 2020) because they use human students, and a fair comparison would require us to repeat the LLM side of the experiment with the same humans. To avoid doing this, we draw our conversations from MathDial (Macina et al., 2023) for the human side because the students in this dataset are simulated by AI.

MathDial consists of about 3000 tutor-student conversations fixing student errors on MWPs. The MWPs were sampled from the GSM8K dataset (Cobbe et al., 2021), while the misconceptions were generated using InstructGPT. The authors hired annotators with teaching experience on Prolific to converse with an InstructGPT instance pretending to be a student having the particular misconception, a setup we can easily replicate at little cost. The annotators were prescribed some pedagogical suggestions urging them to avoid giving out answers directly but were otherwise encouraged to behave as they would when tutoring a real student.

Moving on to the LLM side, we could simply use a modern LLM like GPT to repeat the conversations from MathDial with identical settings. However, this only works if we can ensure that the GPT model would never give incorrect feedback, for example stating that a student’s answer is right when it is not. If a tutor has a chance of giving out wrong information, comparing its softer qualities

is moot. Unfortunately, previous work has found that GPT4-turbo does make such mistakes (Chowdhury et al., 2024) and we found in our explorations that this is still the case for GPT4o, with 6 out of the 30 problems investigated having some issue (1 case where the teacher gave a wrong answer, 5 cases of teacher telling the right answer but not verifying if the student agreed, including 2 where the final teacher utterance included nonsensical phrases). Therefore, we instead use conversations from MWPTutor (Chowdhury et al., 2024), a tutor based on LLMs which ensures correctness by imposing guardrails on top of GPT.

MWPTutor uses a finite state transducer to prompt an LLM to generate the best teacher utterances and uses the same InstructGPT student model as MathDial. The paper proposes multiple versions of their system, but in this work, we make use of MWPTutor^{live}_{GPT4} as it is the best according to their own metrics. Although MathDial consists of about 3000 conversations, many of them repeat the same MWPs and incorrect solutions. Since MWPTutor only makes use of these two components, we restrict our study to one conversation per MWP. As such, we choose 210 MWPs including all 45 coming from the GSM8K test set. For MathDial, we pick the first conversation when sorted by timestamp. For MWPTutor, we use the conversations published by the authors for the test set MWPs, while for the remaining, we generate conversations using their publicly available code.

Note that despite the accuracy issue, we did perform a smaller study with GPT4o instead of MWPTutor, and found that the trends were not much different (See Appendix B for details).

3.2 Metrics

Tutoring is a rather complex task, and thus it is hard to list desirable tutoring qualities that can be considered universally applicable. The primary desiderata for our study are that we need a small set of metrics (so as to be able to evaluate them in a reasonable budget), which can be judged from text and are subjective enough to facilitate the comparison of two conversations. To obtain such a set of metrics, we drew inspiration from 3 main works.

Ross, in his book (MacDonald, 2000) identifies 6 goals for tutors, although this includes more administrative duties such as “provide student perspective on school success”. Walker (Walker, 2008) surveyed several teachers in training, and identified 12 desirable characteristics of teachers. Although

too numerous and often requiring actions beyond a text-only setting, they serve as a good starting point for us. Maurya et al (Maurya et al., 2024) unified several recent works to identify 8 metrics relevant to AI tutors. However, these metrics are often too precise, making it difficult to rank two conversations based on them.

Inspired by these and other works mentioned in the definitions, we decided on four metrics to evaluate, which we discuss below. An important thing to point out here is that though these metrics have scientific grounding, they are all quite subjective, which means in certain cases choosing the better of a pair of conversations might become a matter of personal preference. Although we did not evaluate the original metrics in the above work with humans, we did run them through GPT, and the results are provided in the Appendix (see Section C). We also provide a full mapping between the metrics in the three aforementioned papers and our metrics in Section D

Engagement: Student engagement can be defined as ‘how involved or interested students appear to be in their learning’ (Axelson and Flick, 2010). All of Walker, Ross and Maurya (see table 6) use metrics that map to engagement. High student engagement is positively correlated with student learning outcomes (Lei et al., 2018), and this effect has also been observed in recent studies on LLM tutors (Altememy et al., 2023; Vanzo et al., 2024).

Empathy: Empathy is the ability of a tutor to understand the hardships a student is facing and to react in a way that keeps up their motivation. Empathy is seen as important in a teacher by most educators (Stojiljković et al., 2012; Makoelle, 2019), and practical studies show that teachers’ empathy is correlated with positive learning outcomes for at least some groups of students (Bostic, 2014; D’Mello and Graesser, 2013). Walker identifies multiple dimensions of empathy as essential, while Maurya and Ross also consider it important (see table 6). One important thing to note here is that empathy in general is a rather broad term, and is often split into subcategories of emotional and cognitive empathy (Smith, 2006). In this work, ‘Empathy’ primarily refers to Emotional Empathy, whereas Cognitive Empathy is somewhat subsumed by Engagement.

Scaffolding: Scaffolding is the idea that a tutor should help a student succeed in a problem, not by directly revealing the answer, but by controlling elements of the problem solving process to enable the student to achieve the solution by themselves

(Wood et al., 1976). Doing so helps students to not just understand the solution of the problem at hand but also learn the concepts behind the solution, enabling them to solve similar problems thereafter. The first five metrics from Maurya all reflect forms of scaffolding, while Ross covers it with ‘promote independent learning’ and ‘facilitate tutee insights into learning’. Scaffolding is also a primary goal in both MathDial (called ‘Equitable Tutoring’ in the paper possibly due to conflicting terminologies) and MWPTutor.

Conciseness: While not considered an important metric by the three works we repeatedly refer to, we note that to achieve the previously mentioned metrics, one may end up with extremely long conversations. However, a good tutor should always try to make progress with a question. Having the student repeat steps already done or making them do redundant steps is known to hurt learning outcomes, especially when only a single modality (i.e., text) is available (Kalyuga and Sweller, 2014; Albers et al., 2023). Failure to make progress in a problem often leads to frustration (Goldin, 2000), which in turn can hurt learning (Chitrakar and P.M., 2023). Finally, longer conversations can lead to students going beyond their optimal attention span (Philip and Bennett, 2021) leading to bad outcomes. Therefore, we include conciseness as a fourth metric.

3.3 Setup

MathDial conversations are about 10 turns on average, while that of MWPTutor can go from 5 to 60 turns. We needed annotators to choose which conversations were better by each metric. Internal testing revealed that longer dialogs greatly increase the time to choose with people having to go back and forth in the dialogues, though the tone of the dialog is usually set within the first few turns, making it the most important part of the dialog. Thus, we decided to truncate all dialogs to 5 turns, the lower limit of the average human working memory (Miller, 1956). It also helps that both MWPTutor and MathDial require a conversation to last for at least 5 turns. This truncation, however, meant that sometimes the dialogs could be too small to judge them, so we allowed the annotators to say “Both are Equal,” but we asked them to use this sparingly. Note that this also increases the epistemic noise of the task.

Our survey was hosted on FillOut¹. The 210

¹fillout.com

problems were divided into 7 batches of 30 conversation pairs each, which would take 45-60 minutes each of annotator time. The survey started off with a task description, followed by metric descriptions. Thereafter, it we had 150 slides, 5 per conversation pair. The first slide introduced the new MWP and the two conversations, and the next 4 went over the 4 metrics. These slides showed the MWP, the two conversations side-by-side, and a short description of the current metric, and asked the user to pick one of “Left is Better”, “Right is Better”, and, “Both are Equal” (see Section G for details). The right-left positioning of the conversations was randomized to avoid bias. Annotators were instructed to focus on the tutor’s utterances and not the student’s. In addition, we did not explain the nature of the tutors or students and there was no indication that any of the parties were LLM agents. We also had three LLMs, namely GPT4 (gpt-4o-2024-08-06, (OpenAI et al., 2024)), Qwen (Qwen/Qwen2.5-72B-Instruct-Turbo from together.ai, (Qwen et al., 2025)), Llama (meta-llama/Meta-Llama-3.1-405B-Instruct-Turbo from together.ai, (Touvron et al., 2023)) compare the conversations on our metrics. For this, the prompts included the same metric definitions, and the two conversation snippets were presented as ‘System 1’ and ‘System 2’. Each conversation-pair was run through each LLM twice, with the order of conversations flipped to avoid biases.

3.4 Participants

Each batch was annotated by 5 annotators, bringing us to a total of 35 annotators. We initially hired Prolific 21 annotators who had access to a computer, were fluent in English, and had some teaching experience. These requirements are identical to those set in MathDial. We also hired two more sets of 7 annotators, one consisting of only men and one consisting of only people aged 50 or older to get a better distribution of age and gender. All annotators were paid the Prolific recommended rate of GBP 9 for the survey.

Demographics Of the 35 Prolific-hired annotators, 14 identified as male while the rest identified as female. The dominant self-identified ethnicity was black (20 annotators), with white (11 annotators) being the next closest. Their ages range from 20 to 74, with median age being 34.

Figure 1: Fractions of conversation pairs which received particular scores for each metric from LLMs. Scores increase left to right, with the **brightest red** indicating minimum possible score of -3 , the **dullest red** indicating -1 , **grey** indicating 0 , the **dullest green** indicating $+1$ and the **brightest green** indicating the maximum possible score of $+3$

4 Results and Analysis

We mentioned earlier that our metrics involve some scope for personal choice. This means that disagreements between annotators would involve some epistemic uncertainty. To account for this, instead of dealing with the point measures given by majority voting, we look at the full set of votes through the notion of *score*.

For each metric and each conversation pair, an annotator must pick one of “Left is Better”, “Right is Better” and “Both are Equal”, which we can map into “MWPTutor is Better”, “MathDial is Better” or “Both are Equal”. We assign a value of 1 to “MWPTutor is Better” and a value of -1 to “MathDial is Better”, while “Both are Equal” gets a 0 . The score for a metric for a conversation pair is then the sum of all the annotator values. Thus, since we have 5 human annotators per conversation pair, a score of -5 for a conversation pair on a metric indicates that all human annotators favor MathDial for that metric, while a score of 5 indicates that all human annotators favor MWPTutor. The same is true for the LLM case, except that there are only 3 LLMs, so the scores go from -3 to 3 . Note that this *score* is only introduced for analysis in this paper, and was not used in the actual surveys.

4.1 LLM ratings

Figure 1 shows the distribution of the ratings given by the 3 LLMs for our 210 instances. All responses were queried in December 2024. While no LLM picked the ‘Both are Equal’ option, we had multiple cases where changing the order of the conversations changed the LLM’s answer, so we considered these cases to be ‘Both are Equal’. We see that the LLMs overwhelmingly favor MWPTutor on all 4 metrics. The individual behavior of the LLMs does

not seem very different from each other (see Table 3 in the Appendix for details). While these lopsided results are definitely interesting, it might not be too decisive, considering that LLMs are likely to be biased towards LLM-generated text.

4.2 Human Ratings

Figure 2 shows the outcome of the human ratings while Table 1 shows the agreement between annotators and significance statistics. Although the results are much less lopsided than the LLM annotations, the outcome is the same. MWPTutor performs better on all metrics, with the difference being significant² for all metrics except Engagement. As expected, the agreement amongst annotators is low, a testament to the complexity of the task.

4.3 Alignment Between LLMs and Humans

Another interesting thing to note here is the difference between human annotations and LLM annotations. While both come to the conclusion that MWPTutor is doing better on all metrics, the LLMs’ opinions are much stronger than their human counterparts. Figure 3 shows the correlation between the average scores for all 4 metrics, annotated by humans and LLMs. We can see that all the squares in top-right and bottom-left quadrants, which indicate the correlations between human-annotated metrics and LLM-annotated metrics, are very dull, indicating a large difference between what LLMs perceive as good and what humans perceive as good. Also of note is the fact that the off-diagonal elements in the top-left and bottom-right quadrant are quite bright, which means that the metrics are not all disentangled, either by definition or by perception

²here and in the rest of the paper we treat anything with a p-value of 0.01 or lower as significant

Figure 2: Fractions of conversation pairs which received particular scores for each metric from humans. Scores increase left to right, with the **brightest red** indicating minimum possible score of -5 , the **dullest red** indicating -1 , **grey** indicating 0 , the **dullest green** indicating $+1$ and the **brightest green** indicating the maximum possible score of $+5$

Figure 3: Correlation between various metrics, as annotated by humans and LLMs

or a combination of both.

4.4 Analysis

We now go over each of our 4 metrics and look at how the ratings they received sit in context of other quantitative metrics.

Conciseness: In terms of t-score, the metric where MWPTutor dominates the most is Conciseness. This is surprising, as unlike the annotators for MathDial, the LLM behind MWPTutor had no reason to keep conversations short. In fact, we find that MWPTutor conversations were longer in terms of the number of utterances in 135 cases, compared to 68 cases where MathDial conversations were longer. Further, when the MWPTutor conversation is shorter, it has a 74% chance of being picked as more concise, while if the MathDial conversation is shorter, it has only a 40% chance of being picked as more concise. In other words, while true conversation length is correlated with perceived

conciseness, it isn't a very strong predictor.

Empathy: Human empathy can often take non-verbal modes, so judging it from a small conversation snippet can be a bit noisy. This is expressed as the high standard deviation in the Empathy scores. Nevertheless, annotators perceived MWPTutor to be more empathetic. On running sentiment analysis by huggingface pipelines³ we found a positive correlation between higher empathy scores and *joy* ($R = 0.36$, $p = 5E - 8$) and a negative correlation with *anger* ($R = -0.32$, $p = 3E - 6$)⁴ which is consistent with what we would expect. In addition, GPT4 agrees that MWPTutor shows significantly more joy and less anger compared to MathDial.

Engagement: Engagement is the only metric where the LLM's advantage is not significant. Looking at the code for MWPTutor⁵ we find that there are two ways⁶ it can start a conversation. If the student solution partially matches a stored solution, it starts by pointing out the step up to which the student is correct and proceeds from there. If no part of the solution matches, MWPTutor will start afresh by ignoring the student solution. Let us call these two scenarios *Continue* and *Fresh* respectively. In the 45.5% conversations in the *Continue* scenario, the average Engagement score is 1.42, so MWPTutor is significantly better than MathDial

³Sentiment scores were calculated by averaging the score for each tutor utterance in a conversation snippet, and then subtracting the MathDial Score from the MWPTutor score. We used the `bhadresh-savani/distilbert-base-uncased-emotion`.

⁴Taking max score across all tutor utterances also gives the same outcome, albeit the exact numbers are a bit different

⁵in particular, `the LiveTutor.start_conversation() method in models/Tutor.py`

⁶there's a 3rd to deal with correct solutions, but that was never triggered (by design)

Metric	Fleiss Kappa	Mean Score	Standard Deviation	Effect Size	t-score	p-value (1-sided)
Conciseness	0.11	0.55	2.19	0.25	3.65	<0.001
Engagement	0.22	0.25	2.72	0.09	1.32	0.09
Empathy	0.25	0.65	2.81	0.23	3.36	<0.001
Scaffolding	0.17	0.55	2.51	0.22	3.16	<0.001

Table 1: Statistics of the Human Ratings. Fleiss Kappa is calculated assuming each annotator to be a combination of two annotators, who vote opposite to each other if the actual vote is ‘Both Are Equal’

No. of Scaffolding Utterances	Sample Size	Average Score			
		Conciseness	Engagement	Empathy	Scaffolding
0	7	1.00	1.00	1.00	1.86
1	51	0.16	0.27	0.04	0.18
2	116	0.47	-0.03	0.67	0.41
3	36	1.28	0.97	1.39	1.28

Table 2: Human Annotation Scores by scaffolding utterances in MathDial snippet

in this case ($d = 0.68$, $p < 1e - 8$). However, in the 55.5% conversations in the *Fresh* scenario, the average Engagement score falls to -0.84 , so MathDial comes out on top ($d = 0.30$, $p = 0.001$). We posit that since our annotators are not given access to the student solution, they see no reason why the tutor should start afresh. Therefore, when they see the *Fresh* scenario, they perceive it as the tutor failing to engage with the student’s solution, thereby penalizing it.

We previously mentioned how conversational uptake is similar to our definition of engagement, so to get another view of the data, we calculated the difference of uptake scores for each conversation pair. We excluded the first teacher utterance because uptake requires a previous utterance. The difference in uptake scores had only a mild correlation of 0.06 with the human-annotated Engagement score, but showed a significant difference between MWPTutor and MathDial ($d = 0.20$, $p = 0.004$) with MWPTutor coming out on top.

Scaffolding: As stated above, scaffolding is a primary focus for both MathDial and MWPTutor. In MathDial, annotators were asked to state the intent of their upcoming utterance as one of the 4 possible dialog acts. Two of these acts, namely, ‘focus’ and ‘probing’ are types of scaffolding, and in the subset of utterances we used for our annotations, these two acts combined make up about 62% of all teacher utterances. This clearly shows that the annotators from MathDial made an effort at scaffolding, but somehow fell short of MWPTutor.

To further analyze this, we grouped the conversation pairs by how many scaffolding utterances were present in the MathDial Snippet of the pair and calculated the average score for each metric including scaffolding. The results are shown in Table 2. Excluding the first row, which contains only 7 sam-

ples, the average score for scaffolding surprisingly increases (i.e., becomes less favorable to MathDial) with the number of scaffolding utterances. In other words, *a higher number of scaffolding utterances makes it worse at scaffolding* as perceived by our annotators. Although we are unsure of the cause for this, it does indicate that despite expressing the intent to scaffold, the MathDial annotators were unable to follow through. Conversations with a higher number of scaffolding utterances are also perceived to be less concise and less empathetic, the former of which makes some sense since introducing more scaffolding might reduce progress made.

5 Discussion

5.1 Human Tutors Appear Less Concise, Despite Being More

Since the annotators had access to only small parts of the conversation, the guidelines instructed them to focus on the amount of progress made in the given part of the dialog. We propose two possible causes of the difference between perceived conciseness and true conversation length.

First, it is possible that **human tutors tend to start slow and then make faster progress in the part of the conversation not shown to the annotators**. While this might indicate a failure of our annotation setup, varying the rate of progress is not necessarily a good strategy. Conciseness is meant to avoid frustration and boredom; a slower start might cause real students to get bored and disengaged, making it harder to make progress later, a behavior not replicated by the LLM student used here. Another concern might be the fact that the increased progress in the later parts of the conversation might come due to an increase in the level of telling, which is consistent with Fig. 4 in the Mathdial paper (Macina et al., 2023). As an example, while human annotators agreed that none of the 45 test set conversations from MWPTutor had any telling involved, the corresponding 45 conversations from MathDial had a total of 40 teacher utterances marked as telling.

Also, perhaps **MWPTutor frames its responses in a way that makes it look like it is making progress despite that not really being the case**. This could mean that MWPTutor being more engaging or scaffolding better is perceived as being more concise. Given that the agreement of the same annotator annotating different metrics is consistently higher than the agreement of different annotators

annotating the same metric⁷ this is not unlikely.

5.2 Being a Good Teacher is Exhausting, but not Rewarding Enough

A possible reason why human teachers might not be able to show empathy could be the fact that empathy comes at a cognitive cost (Cameron et al., 2019) and thereby must be used selectively. A human tutor who would potentially be dealing with hundreds of students during their teaching career could develop compassion fatigue (Yu et al., 2022) as well as other forms of burnout (Jacobson, 2016) causing them to lack empathy for students. The same can also be said for the Scaffolding and engagement results - when a teacher sees the same mistakes being made by students repeatedly, they are likely to want to simply give out the correct answer, rather than engage the student by scaffolding them in more innovative ways. The fact that being more empathetic and engaging, or scaffolding better, rarely carries financial incentives (which is true for MathDial) makes teachers even less likely to show these qualities. An LLM, however, is not bound by the same cognitive limitations of a human, and can thereby show (or pretend to show) infinite compassion and empathy. It also does not mind engaging the student more and scaffolding them better, because it is, after all, being paid by the token. Note that the fact that the MathDial annotators participating in a study and not dealing with actual students may have further exacerbated this issue. Knowing that the student is in fact an AI which will not get demoralized or disengage might have contributed to the teachers not doing their best. Add to this the fact being restricted to typing only might hinder their ability to show empathy.

5.3 Bad Spelling or Grammar Might Look Less Engaging

Although the observed difference might be due to chance in the case of Engagement, the presence of lexical and grammatical mistakes might also play a role. Due to the lack of any spell-check or grammar correction tool, the human responses ended up containing several typos, missing capitalizations, punctuation, and other grammatical errors, which our annotators (and hypothetical students) might find distracting and thereby disengaging.

⁷This is calculated by flipping the annotator and metric axes while calculating Fleiss κ . This is done for illustrative purposes only, and not the proper way to use Fleiss κ

5.4 So, What Are The Takeaways?

This study shows that LLMs are capable of performing certain tutoring roles well, perhaps as well as humans. However, we need to think what this really means for the stakeholders. We believe that there are two major takeaways – one for educators and one for learning scientists.

For educators, the emergence of AI means increased opportunities for delegation. It is a well known fact that a teacher’s duty extends well beyond teaching, with them often having to act as mentors and guardians of students (Tea, 2024; Tabassum and Alam, 2024; Kutsyuruba and Godden, 2019). Allowing AIs like LLMs to take over repetitive yet exhausting duties can allow teachers to focus more on such responsibilities which require socio-cultural understanding well beyond the capabilities of AI. It also can bring a sense of fulfillment to educators, potentially mitigating some teacher fatigue (Zang and Chen, 2022).

For learning scientists, it adds to several other works indicating that we are making fast and effective progress towards computer-based education. LLMs are able to show (or at least imitate) qualities once considered hard for them. Yet, the job is far from done – we are only dealing here with textual capabilities, while a human teacher uses several communication modalities. Progress needs to be made in image processing, vocal intonations, embodiment, etc. to fully replicate the more mundane roles of educators.

6 Conclusion

In this study, we asked educators to compare parts of human-generated tutoring conversations with LLM generated ones in a blind setting. We found that in the limited setting of text-only tutoring, most educators *perceived* that the LLM was not only matching humans, but also *outperforming* them in several quasi-metrics for teaching quality. We further find that the LLM’s perception of what is good tutoring is still not perfectly aligned with humans. This shows that there is still scope to improve self-judgment abilities of LLMs, which could further improve the quality of LLM tutoring. Thus, overall, our study paints a positive picture – with further research, it could be possible for teachers to delegate more tiring tasks in tutoring to AI, and focus on their more complex tasks, thereby improving experiences of both teachers and students.

Limitations

Despite our best efforts to make the study as comprehensive as possible, we are left with several limitations which we were unable to rectify. Some of these are:

- **Limited Setting:** We restricted ourselves to a text-only setting, while some of the metrics used, especially empathy and engagement, involve other aspects of embodied interaction like body language, expression, voice modulation, etc. The primary reason behind this is that most LLMs currently being restricted to this setting only
- **Limited Domain:** Even within the text-only domain, we restricted ourselves to one type of question (MWP) and one LLM tutor (MWP-Tutor), which may not be ideal since results might be different for different subjects, and also for differently designed tutors. While it would have been good to try out different subjects, we were unable to do so due to a lack of datasets. In order for the conversations to be comparable, we needed datasets with human and AI attempts at the same conversations, which we could not find for any other domain, and creating one from scratch would be significantly out of the scope of our abilities.
- **Unverified Qualifications:** We hired our annotators on Prolific, and filtered for those who had teaching experience. However, Prolific does not verify annotator qualifications, which means we might have had some non-educators in our annotator pool. Note that the same issue could also be present with MathDial, who also hired annotators on Prolific.
- **Qualitative Analysis:** Despite drawing from the literature, our analysis of annotator judgments is mostly intelligent guessing, as we do not know why annotators did what they did. We attempted to get some insights by interviewing some of the annotators post-hoc but had too few respondents to proceed.

In general we acknowledge that there might be several factors affecting the ecological validity of the results. While the results are statistically significant and theoretically feasible, they aren't infallible, and thereby, should not be trusted blindly if deciding

on a high-stakes scenario. A proper study with real students and teachers in a more natural setting might be the ideal scenario to draw more definitive conclusions. However, doing such an experiment was beyond the means of the authors at the time of publication.

A Ratings from Individual LLMs

Model	Rating	Number of Questions			
		Conciseness	Engagement	Empathy	Scaffolding
GPT4o	MathDial Better	56	28	19	9
	Both Equal	29	35	37	48
	MWPTutor Better	125	147	154	153
Qwen72B	MathDial Better	32	20	14	19
	Both Equal	38	41	38	27
	MWPTutor Better	140	149	158	164
Llama405B	MathDial Better	60	49	30	18
	Both Equal	26	53	25	41
	MWPTutor Better	124	108	155	151
Fleiss Kappa		0.63	0.34	0.47	0.36

Table 3: LLM based comparison of MathDial and MWPTutor on our metrics. Fleiss κ is calculated considering the two annotations by each LLM to be separate instances

See table 3

B MathDial vs GPT4

We carried out a smaller experiment using only the questions from the first batch (30 examples). The setup is identical to what we described in Section 3.3. The results are shown in figure 4. Despite the smaller sample size, the results are very decisive and all significant. However, in order to achieve this, GPT4o sacrifices correctness. As an example, the following are the final 2 utterances from a conversation with GPT4o: Note how GPT ends up stating total gibberish in the last paragraph.

Student: Oh, I see now. So from the \$195 he earned, he spent \$160 on the video games and had \$5 left. That means he spent $\$195 - \$160 = \$35$ on lego sets. And since each set is \$15, he must have sold $\$35/\$15 = 2$ sets. So he still has $13 - 2 = 11$ sets left.

Figure 4: Fractions of conversation pairs which received particular scores for each metric from s. Scores increase left to right, dullest red indicating -1 , grey indicating 0 , the dullest green indicating $+1$ and the brightest green indicating the maximum possible score of $+5$. The reds follow a to same pattern as fig 2, but not all colors are visible here

Tutor: I appreciate your diligence! Let's make sure to clarify what we're finding one last time.

John earned \$195 from selling lego sets. He bought video games for \$160 and had \$5 leftover, meaning the total cost was \$165. That tells us:

$\$195$ (earned total) - $\$165$ (total used, including \$5 leftover) = $\$30$

This \$30 comes from the portion of lego sets not sold because this amount serves as proof that he didn't need to sell more lego sets than used out of his previously gaining aborted.

Since each lego set is \$15, the residual: $\$30 / \$15 = 2$ sets were left unsold.

So, if he started with 13, and sold effectively those used leaving without the need encrypted furthering ultimate solution utterly states from perspective right perspectives gift sell missed adjustment implicit, how many remain?

Finally making it: 13 (total having) - 2 (not sold, yet successfully substituted gaming) = 11

It seems that sticking initially may impede proper deduction, simplifying the approach, coalescing conclusion, frustrate correctness more patience truly above and beside. If solid understanding confirmed careful allowance approach fo-

cal awareness adapt addressed to benefit learning exchange long-term celebrating! Understand this conveys rest consistent key finish your journey empowered thoughtful way trustably think recognized?

The correct answer is 2 (as opposed to what the student says), and the tutor ends the conversation here

C GPT4 judgement on other metrics

We only cover Maurya et al (Maurya et al., 2024) and Walker (Walker, 2008) because MacDonald (MacDonald, 2000) does not provide succinct definitions of their metrics.

C.1 Maurya et al (Maurya et al., 2024)

We evaluate our 210 conversation pairs using the same prompt that we used for section 4.1. For metric definitions, we used the exact texts from Section 4.1 in Maurya et. al. The results are shown in table 4. Unlike in section 4.1, we did have some examples of "Both Equal"; thus, the score goes from -2 to 2 .

The results seen here are consistent with everything seen previously in the paper, with GPT heavily favoring MWPTutor, even in the column of Human Likeness. Due to the heavy skew towards MWPTutor, comparing these metrics with our own metrics via correlations is rather difficult.

Score	Mistake Identification	Mistake location	Revealing of the answer	Providing guidance	Actionability	Coherence	Tutor tone	Human Likeness
-2(MathDial Better)	57	55	10	13	23	27	12	26
-1	4	0	0	0	0	1	1	0
0(Both Equal)	42	49	41	20	29	32	31	47
1	5	0	2	0	0	1	0	0
2(MWPTutor Better)	102	106	157	177	158	149	166	137

Table 4: GPT Evaluation of metrics from Maurya et al.

C.2 Walker (Walker, 2008)

For Walker et al. Metric definitions are picked from the ‘Findings’ section of the paper. The setup is the same as in Section 4.1 and the results are shown in Table 5. Once again, GPT heavily favours MWPTutor, with the possible exception of ‘Have a Sense of Humour’. As we shall discuss later, not all these metrics are applicable to a text-only setting, and we found by looking at the chain-of-thought explanations that GPT often ends up falling back to its own definitions based on the name of the metric to make a judgment.

D Mapping Between Metrics

Table 6 shows a mapping between metrics from other works and our metric (and also introduces the numbering used in the rest of this section). Note that with the exception of a few (namely *Providing Guidance*, *Promote independence in learning* and *Facilitate tutee insights*), the correspondences are not exact, and in most cases, our metrics are more general than those from other works.

The metrics from Maurya et al (Maurya et al., 2024) are specifically designed for text-only AI tutoring, and as such, all of them are applicable to our setting. The only exception might be *Revealing the Answer* since the reveal could potentially happen in the part of the conversation we truncated out, and it would be just as problematic. In addition to this, both *Mistake Identification* and *Mistake Location* are practical yes/no questions, so it could be hard to use them for ranking unless only one of the conversations satisfies them. Finally, *Human Likeness* might not make much sense when we compare an actual human to an LLM.

Walker’s metrics (Walker, 2008) are designed for long-term classroom teaching, so quite a few of them don’t apply to us. The paper defines *Creative* as entirely physical, and *Cultivate a Sense of Belonging* as something only involved students can judge. Further, *Hold High Expectations* and *Admit Mistakes* are long term goals, not applicable

to the short time scale we are dealing with. Also, while *Have a Sense of Humour* can be judged in our setting, it is not clear if it is desirable in this scale. Other metrics like *Forgiving*, *Respect Students*, *Display a Personal Touch* and *Fair* all map to Empathy but only for part of their definition, while other parts are either true by default (eg ‘Speak to students in private concerning grades or conduct’ for *Respect Students*) or do not apply (eg ‘Visit the students’ world’ for *Display a Personal Touch*).

Finally, the metrics suggested by MacDonald (MacDonald, 2000) focus on tutoring, but also cover administrative goals like *Follow a Job Description* and *Provide a student perspective* which are beyond our scope. *Personalize instruction* applies, but in a very limited way as we have no sense of student modeling, so long-term personalisation does not work. The same goes for *Respect individual differences*, where we can only focus on differences in academic ability, not cultural or social differences.

E Prompts

E.1 GPT Evaluation of a Metric

Your job is to compare two systems that tutor a student, helping them solve a math word problem. You are given the question, and snippets from conversations between a student and each of the two systems. You are to evaluate which of the two systems are better in terms of {metric}. We define {metric} as follows:

{definition}

Remember you are to compare only the tutor systems, not the student. Do you think system 1 or system 2 is better in terms of {metric}? Note that if it is not possible to judge {metric} based on the provided snippets, or both look equally good, you can say "Both Equal,"

Score	Prepared	Positive	Hold High Expectations	Creative	Fair	Display a Personal Touch	Cultivate a Sense of Belonging	Compassionate	Have a Sense of Humour	Respect Students	Forgiving	Admit Mistakes
-2(MathDial Better)	27	13	11	23	8	63	21	19	27	5	4	30
-1	1	0	0	9	0	8	0	0	31	5	4	21
0(Both Equal)	30	25	37	36	33	38	30	39	79	40	32	47
1	0	0	0	24	11	19	0	0	49	14	19	29
2(MWPTutor Better)	152	172	162	118	158	82	159	152	24	146	151	83

Table 5: GPT Evaluations of metrics from Walker

Source	Index	Metric	Applicable to Our Setting	Corresponding Metric
Maurya et al.(Maurya et al., 2024)	1.1	Mistake Identification	Yes	Engagement
	1.2	Mistake Location	Yes	Engagement
	1.3	Revealing The Answer	Partially	Scaffolding
	1.4	Providing Guidance	Yes	Scaffolding
	1.5	Actionability	Yes	Engagement
	1.6	Coherence	Yes	Engagement
	1.7	Tutor tone	Yes	Empathy
	1.8	Human Likeness	Yes	Empathy
Walker(Walker, 2008)	2.1	Prepared	Partially	Engagement
	2.2	Positive	Yes	Empathy
	2.3	Hold High Expectations	No	N/A
	2.4	Creative	No	N/A
	2.5	Fair	Partially	Empathy
	2.6	Display a Personal Touch	Partially	Empathy
	2.7	Cultivate a Sense of Belonging	No	N/A

but this should only be done as a last resort. Please explain your choice.

metric and definition are replaced with the name of the metric and its definition respectively

F Annotator-wise Results

Table 7 lists the choices picked by each of our 35 annotators. The "80%" we mentioned in our abstract comes from here.

G Interface Setup

Each participant was first thoroughly instructed on the overall workflow of the survey and the definition of each metric, then evaluated 30 pairs of 5-utterance dialog segments presented in randomized order. Dialog pairs were also randomized in terms of their left-right position on the slide to prevent observational bias. Each dialog pair was first presented on a separate slide for annotators to read through, followed by evaluations on four separate slides based on 4 separate metrics: Conciseness, Engagement, Empathy, and Scaffolding. Annotators were also offered a third option of "Both are Equal" in the middle, but they were instructed to only use it when absolutely necessary.

Ann. No.	Questions Annotated	Conciseness		Engagement		Empathy		Scaffolding	
		LLM Better	Both Equal	LLM Better	Both Equal	LLM Better	Both Equal	LLM Better	Both Equal

Conciseness

A good tutor should always try to make progress with a question. Select the side which is making better progress. Some examples of bad conciseness are:

- The tutor keeps repeating the same thing:
BAD CONCISENESS
Tutor: What is the next step?
Student: I am not sure
Tutor: Think about it, what should you do?
Student: I have no idea
Tutor: You do, just try to focus

Note however that it is okay to repeat things if the student is making progress

GOOD CONCISENESS
Tutor: What is the next step?
Student: We Multiply the 5 cookies Mike had in the morning to find that he had 10 in the afternoon
Tutor: Good, what is the next step?
Student: We add the cookies to get that he ate 15 cookies in all.

- Teacher Makes student repeat steps.
BAD CONCISENESS
Student: So Michael had 5 cookies in the morning and twice that in the afternoon, which is 10. so he had 15 cookies in total
Tutor: You are right, he had 10 cookies in the afternoon. So how many did he have in total?
Student: He had $10+5=15$

(a) Instruction for Metric Conciseness

Engagement:

A good tutor should understand where the student is struggling and respond accordingly. If the student has a specific confusion, the tutor should address it instead of trying to rush to a solution. If the student is trying an approach different from the tutor's solution, the tutor should either go with it, or explain clearly why it is not going to work.

Some examples of bad engagement are:

- Teacher forcing a solution onto the student
BAD ENGAGEMENT
Tutor: So how would you go about calculating the profit?
Student: We first calculate the net cost of all raw materials.
Tutor: Let us try a different approach. How much money did Mike make by selling all the items?

If the tutor was clear about why the student's approach was wrong, then it is justified

GOOD ENGAGEMENT
Tutor: So how would you go about calculating the profit?
Student: We first calculate the net cost of all raw materials.
Tutor: We are told that the cost of raw materials was 80% of the selling price. Do you think we can calculate the cost without first knowing the selling price?

- Tutor ignores student query
BAD ENGAGEMENT
Tutor: You need to multiply the number of each item by its cost
Student: Why can't we add all the items together?
Tutor: No, we multiply first.

(b) Instruction for Metric Engagement

Empathy:

The tutor should try to motivate the student and form a bond with them. They should reinforce successes, and support the student through failures. There are several indicators of positive encouragement, including but not limited to:

- Congratulating student on correct steps with "Good Job/Good Work"
- Attributing failures to hard material instead of student's skill
BAD EMPATHY: You do not understand the material
GOOD EMPATHY: It is okay to struggle a bit since the material is hard to understand.
- Focussing in the correct part of partially correct answers.
BAD EMPATHY: You still have some mistakes in there
GOOD EMPATHY: You got most of it right
- Use "we" rather than "you" when talking about the problem solver
BAD EMPATHY:What should **you** do next?
GOOD EMPATHY: What should **we** do next?

Further, a conversation sounds too dry and mechanical, it has bad empathy

(c) Instruction for Metric Empathy

Scaffolding:

A key property of good tutoring is letting the student identify and fix their own mistakes rather than simply solving things for them. While the latter would result in faster conversations, the former is better for teaching concepts in a way that the student will remember and be able to apply in the future. For the purpose of this study, a conversation is said to have better scaffolding if the student is doing most of the work with only gentle nudges from the tutor.

As an example, consider the problem: "If each cat has 2 kittens, how many kittens do 12 cats have?" There can be different levels of scaffolding here:

VERY GOOD SCAFFOLDING
Tutor: What should we do here?
Student: I think we multiply 2 by 12 to get 24 kittens

This however might not always be possible. Sometimes the teacher might need to give some hints. The quality of scaffolding would depend on how much they are revealing

GOOD SCAFFOLDING: "How do you get the total count given the per capita count?"
BAD SCAFFOLDING: "Just multiply the number of cats by the number of kittens each cat has."
VERY BAD SCAFFOLDING: "There are 24 kittens."

Additionally, if the teacher tries to test the understanding of a student by altering the question, like asking "What if there were 3 cats?", it should also be considered good scaffolding.

(d) Instruction for Metric Scaffolding

New Problem! Read carefully before proceed!

Sean buys 3 cans of soda, 2 soups, and 1 sandwich. Each soup cost as much as the 3 combined sodas. The sandwich cost 3 times as much as the soup. If the soda cost \$1 how much did everything cost together?

Next →

(a) Intro Slide for Dialog Pair

Sean buys 3 cans of soda, 2 soups, and 1 sandwich. Each soup cost as much as the 3 combined sodas. The sandwich cost 3 times as much as the soup. If the soda cost \$1 how much did everything cost together?

Tutor: (generic)Hi can you explain your answer

Student: Yes, I calculated that the 3 cans of soda cost \$3, the 2 soups cost \$3, and the sandwich cost \$4.5. So the total cost of all the items is $\$3 + \$3 + \$4.5 = \10.5

Tutor: (probing)Ok I can see you have worked out the price of soda =£3 soup costs the same as the 3 combined sodas what does combined mean

Student: Combined means that the cost of the 3 cans of soda is the same as the cost of the 2 soups. So the cost of each soup is $\$3/2 = \1.5 . The sandwich cost 3 times as much as the soup, so the sandwich cost $3 \times \$1.5 = \4.5 .

Tutor: (focus)The question says EACH soup is the same as the combined soda

Tutor:You are correct upto where you say "The cost of 3 cans of soda is $3 \times \$1 = \3 ". What do you think should be the next step?

Student:The next step should be to find the cost of the soups by dividing the cost of the 3 combined sodas by 2, which would be \$1.5 each.

Tutor:What is the cost of each soup if each one costs as much as the 3 combined sodas?

Student:Each soup would cost \$1.5.

Tutor: Let's think about the relationship between the soup and the sodas again. If each soup costs as much as the 3 combined sodas, and you've calculated that the 3 sodas together cost \$3, how much does one soup cost? Then, once you have the cost of one soup, you can find the total cost for 2 soups.

Which one is better?

Concise: no redundancy in repeating steps done right, help students make progress from one step to next step, linguistically clear for sixth grader to grasp easily

Transformer-Based Real-Word Spelling Error Feedback with Configurable Confusion Sets

Torsten Zesch and Dominic Gardner and Marie Bexte

CATALPA – Center of Advanced Technology for Assisted Learning and Predictive Analytics
FernUniversität in Hagen, Germany

Correspondence: torsten.zesch@fernuni-hagen.de

Abstract

Real-word spelling errors (RWSEs) pose special challenges for detection methods, as they ‘hide’ in the form of another existing word and in many cases even fit in syntactically. We present a modern Transformer-based implementation of earlier probabilistic methods based on confusion sets and show that RWSEs can be detected with a good balance between missing errors and raising too many false alarms. The confusion sets are dynamically configurable, allowing teachers to easily adjust which errors trigger feedback.

1 Introduction

Real-word spelling errors (RWSE) are specific spelling mistakes, where the resulting misspelling is another existing word:

*Time flies like an error [arrow].*¹

This is in contrast to non-word spelling errors, where the resulting string is out-of-vocabulary:

Time flies like an arro [arrow].

The distinction is grounded in lexical inclusion criteria for a given language, a problem that is itself non-trivial. In this paper, we consider the lexicon of a language to be provided as a fixed list containing not only lemmas, but also inflected forms. The list does not contain open classes like complex named entities or other noun compounds.

Of special interest are RWSEs where the sentence with the error is syntactically well-formed, so that they can only be detected when taking semantic information into account. Compare the following two examples:

1. *The name comes from the Greek work [word] for sun.*
2. *These plants are more tolerance [tolerant] to drought.*

¹When giving examples, we always put the error first and the [correction] in square brackets. When referencing a confusion set outside of an example, we use {token1, token2}.

In the first example, the RWSE is not readily detectable via syntactic analysis, whereas in the second example syntax alone provides some evidence for a possible error.

RWSEs are quite common in English, but also happen in other languages e.g. in German:

Er ist eine Konifere [Koryphäe] auf seinem Gebiet.

(He is a conifer [coryphaeus] in his area.)

This specific example is sometimes deliberately inserted for comical effect as the contrast of ‘big expert’ with ‘small tree’ can be considered funny. However, there are other, less pretentious examples, like replacing *art* or *part* with *fart* that can be quite embarrassing if unintentional.²

While there is a long tail of idiosyncratic RWSEs, some are also quite common and can be considered **confusion sets** (Golding and Schabes, 1996), i.e. fixed sets of words that are often confused with each other – especially by language learners. Examples include {*dessert, desert*}, {*peace, piece*}, {*sight, site*}, {*than, then*}, or {*their, there*}. Note that the sets are not ordered, so that e.g. *sight* could be inserted for *site* or vice versa.

The ability to detect RWSEs reliably is essential for enabling automated feedback on this class of errors. In this paper, we review the related work and find that a modern implementation for finding RWSEs is missing. We thus propose a Transformer-based approach with configurable confusion sets, which will give teachers the ability to select which words are currently in focus, so that targeted feedback can be provided. Figure 1 gives an example.

We make the RWSE-checker available as an open-source implementation together with a demo

²The subset of similar sounding RWSEs that are often used for comical effect is also called *malapropism*. An unexpectedly fitting or creative malapropism is also called *eggcorn* (itself an eggcorn of ‘acorn’). Eggcorns are often coined by language learners trying to make sense of an unfamiliar word or phrase that they have not yet seen in writing. A famous example is ‘old-timers’ disease’ for ‘Alzheimer’s disease’.

My **advise** **RWSE** **advise** **CORR** for you is: Do not put
to **RWSE** **too** **CORR** much subjects, just put a few
 subject and make them look interesting.

Figure 1: Example for highlighting RWSEs as part of writing feedback.

application and all our experimental code.³

2 Related Work

Early approaches to RWSE correction either relied on measuring the local contextual fitness of words through semantic-relatedness measures (Budanitsky and Hirst, 2006) or n-gram language models (Mays et al., 1991; Wilcox-O’Hearn et al., 2008), where after detecting a word with low contextual fitness a neighborhood space of candidate replacements was searched for a better fitting one. While such approaches are flexible and can find all kinds of RWSEs, they are computationally costly (as they have to test for each word in a sentence a potentially large number of candidates), and yield a lot of false alarms as they often detect ‘errors’ that are e.g. synonyms of the original word.

As a way around those challenges, other early approaches relied on the already introduced confusion sets, i.e. they limited the search to known target words and a very small set of candidates.⁴ At the same time, before the availability of large language models, it was much faster to train a supervised classifier for each confusion set (Golding and Schabes, 1996; Carlson et al., 2001).

Another related field is *Grammatical Error Correction* (GEC), i.e. the process of detecting and correcting grammatical errors in text (Ng et al., 2013; Yuan and Briscoe, 2016). Most recent approaches use a seq2seq design where the text with errors is transformed into an error-free version. In doing so, a GEC system might also fix RWSEs along the way, but as it targets all kinds of errors, we might not know where a RWSE occurred which limits the kind of feedback we can give. Error types are only considered post-hoc and common schemes do not distinguish between non-word and real-word spelling errors (Bryant et al., 2017).

So our approach combines ideas from earlier

³<https://github.com/zesch/rwse-experiments>

⁴Some approaches allow the empty word in confusion sets to cover also insertions or deletions, but most papers (and we in our study) limit confusion sets to replacements.

work: (i) we rely on confusion sets, but without the supervised classifiers, making the sets dynamically configurable); we find RWSEs with the help of language models, but using masked language models and limiting the candidate space through confusion sets.

Confusion sets have also been used in unsupervised GEC approaches to generate candidate sentences that are then scored by a Transformer-based model (Bryant and Briscoe, 2018; Alikaniotis and Raheja, 2019). Our approach can be seen as a special case, where we only use RWSE confusion sets.

Technically, finding RWSEs in such a way is similar to *lexical substitution* (Zhou et al., 2019), with the crucial difference that an RWSE is an implausible word that is substituted with a more plausible one, while in lexical substitutions both words need to be plausible in the given context.

3 Method

Our implementation is based on the *fill-mask* task⁵ of the Transformer library. Given a sentence like

People with lots of honey usually live in big houses.

a word is replaced with a mask token and the library returns the most likely fillers and their probabilities. So for the resulting masked sentence

People with lots of [MASK] usually live in big houses.

we get the following results:

```
money: 0.522
wealth: 0.053
children: 0.022
income: 0.016
family: 0.014
```

The original token *honey* is not even in the top-5 and *money* is one order of magnitude more likely than the next candidate.

However, as we do not know where to look for errors (remember that RWSEs are in-vocabulary and thus hard to detect), we would have to test every token in a sentence which would be quite costly. Also, even if we are ready to invest the compute, blindly following this approach could introduce new errors. For example,

People with lots of money usually live in big [MASK].

⁵<https://huggingface.co/tasks/ fill-mask>

returns *cities* with a probability of 0.74 and would thus result in a false alarm. We thus combine this approach with **confusion sets**. In our example, we would only test for {money, honey} and get the following result:

```
money: 0.52241
honey: 0.00004
```

Note that our example is for illustrative purposes, but that in a real setting with pedagogically relevant confusions {money, honey} would probably not be a target confusion set.

Threshold Factor While in the {money, honey} example above, the correct choice was several orders of magnitude more likely than the mistake, this might not always be the case. Especially words with a high prior probability might lead to false alarms. We thus introduce the magnitude parameter μ indicating how many times more likely a candidate needs to be in order to be considered as a replacement. We initially set $\mu = 10$ so that a RWSE candidate needs to be an order of magnitude more likely, but will later more formally analyze the impact of this parameter, similar to the analysis in Carlson et al. (2001).

4 Experimental Setup

There are currently more than 14,000 models on Hugging Face that are compatible with the fill-mask task. As we are mainly conducting experiments with English text and are interested in production-grade performance, we stick with the basic `google/bert-base-cased` Transformer model.⁶

4.1 Confusion Sets

We compiled a list of pedagogically relevant confusion sets by scanning prior work (Golding and Schabes, 1996; Carlson et al., 2001), but also consulting with domain experts. As a limitation of the fill-mask task is that it cannot directly return probabilities for words that are not in the model vocabulary, we discard confusion sets where at least one element of the set is out-of-vocabulary. Another limitation of the fill-mask task is that it only works with single tokens. So we also discard the few cases where multi-word tokens are involved, e.g. {a life, alive}. We also discard confusion sets

with apostrophes like {its, it's}. Our final list contains 52 confusion sets. Table 1 gives an overview.

As capitalization can be an important source of information, we work with a cased BERT model and differentiate between lower case and upper case variants of each token. Thus, while Table 1 only lists lower-case forms for better readability, a confusion set also usually contains the upper-case variants. We mark this with an underlined first letter. A missing underline indicates that the upper-case form was not in the vocabulary and was thus discarded (as it could not be predicted anyway and would raise an error message).⁷

4.2 Data

As datasets of naturally occurring RWSEs are extremely rare, we mainly focus on synthetic datasets.

We use a news sentence base, as we expect to find very few naturally-occurring RWSEs (which would distort our experiments) in the professionally edited news texts. We select from the Leipzig Corpora Collection (Goldhahn et al., 2012) the NEWS dataset with 10,000 English sentences from 2023. If a token in a sentence matches an entry in one of our confusion sets, the sentence is retained. Out of 10,000 sentences 7,344 contain at least one of our confusion sets. Many sentences trigger more than one. Table 1 shows how often each confusion set was found overall.

While evaluating on this dataset will provide a realistic impression of the expected performance, we cannot analyze which confusion sets are most challenging as many appear too infrequently. We thus create another dataset (called NEWS-BALANCED) by randomly iterating over a the largest download from the Leipzig Corpora Collection with 1 million sentences. Whenever a confusion set is triggered, we keep the sentence up to a maximum of 100 instances. However, even within 1 million sentences, some confusion sets do not appear 100 times, e.g. only 11 sentences were found for 'Provence'. Instead of sampling from an even larger sentence base, we accept the slight imprecision. Results obtained that way are still valid and interpretable, only a bit less reliable. In the balanced dataset, the extracted sentences were used with the intended confusion set only, so as not to trigger multiple RWSEs which would distort results (e.g. the confusion set {to, too, two} would be triggered in almost all sentences in addition to the actually sampled

⁶<https://huggingface.co/google-bert/bert-base-cased>

⁷To give an example: *begin* / *being* should be interpreted as 'begin' can be confused with either 'being' or 'Being'.

{to, too, two}	6,034	{life, live}	166	{forth, fourth}	37	{extend, extent}	16
{their, there, they}	1,860	{mad, made}	157	{raise, rise}	36	{principal, principle}	13
{width, with}	1,556	{country, county}	145	{hole, whole}	34	{plain, plane}	12
{you, your}	998	{weak, week}	131	{trail, trial}	34	{Provence, province}	10
{form, from}	919	{found, fund}	129	{ease, easy}	32	{spit, split}	9
{were, where}	650	{few, view}	109	{affect, effect}	32	{desert, dessert}	7
{or, ore}	454	{lead, led}	97	{peace, piece}	32	{brakes, breaks}	7
{than, then}	446	{passed, past}	81	{sight, site}	30	{bitch, pitch}	7
{which, witch}	443	{things, thinks}	70	{affects, effects}	23	{forms, forums}	3
{them, theme}	261	{weather, whether}	66	{feat, feet}	22	{crab, crap}	2
{begin, being}	231	{safe, save}	53	{accept, except}	21	{weed, wheat}	1
{three, tree}	184	{capital, Capitol}	52	{advice, advise}	21		
{word, world}	167	{quiet, quite}	39	{loose, lose}	20		

Table 1: List of confusion sets and their frequency in the NEWS dataset

set). With these two sentences bases, we now introduce synthetic errors by replacing the token from the confusion set found in the sentence with each of the other words in the set.

As synthetic datasets are probably underestimating the difficulty of the task, we are using one of the few available datasets of naturally occurring RWSEs from Zesch (2012) which was created by mining the Wikipedia revision history. The dataset is quite small and some of their confusion sets do not match our RWSE definition (e.g. containing singular/plural of the same noun). We decided to also use the German version of the dataset in addition to the English one. We manually cleaned both versions and arrive at 49 English sentences (WIKI-EN) and 30 German sentences (WIKI-DE).⁸ Finally, we are using as EDUCATIONAL texts the 1,244 exam scripts from the CLC-FCE corpus (Yannakoudakis et al., 2011) from which we extract 18,984 sentences.

4.3 Evaluation Metrics

Model performance was evaluated based on two different classification metrics: *false-alarm rate* (or false positive rate) and *miss rate* (or false negative rate).

False-alarm rate is computed as the ratio of false-alarms to all ground truth negatives which are equal to all detection instances assuming that the dataset is error-free. In the NEWS datasets, we just take the original sentences, which we consider to be almost RWSE-free. In the WIKI datasets, we know all RWSE instances and create the corrected versions. In the EDUCATIONAL dataset, we have no way of knowing a-priori where to find RWSEs, so we manually evaluate all triggered detection instances

⁸For German language texts, we used the multilingual variant `google/bert-base-multilingual-cased` and the confusion sets defined by Zesch (2012).

to determine real false alarms.

Regarding missed RWSE detections, we take the synthetic part of the NEWS dataset, i.e. the NEWS sentences where we introduced mistakes, and compute the miss rate as the number of instances where the original word is not selected divided by the total number of all synthetic instances. In the WIKI dataset, we do the same with the naturally occurring errors. In the EDUCATIONAL dataset, we cannot easily compute miss rate as this would require a full normalization.

5 Results & Discussion

Table 2 provides an overview of the high-level results. We generally see very low *false-alarm* and *miss rates* on the NEWS datasets. False alarms and misses increase by one order of magnitude on the datasets of documented RWSEs from WIKIPedia. Also on the EDUCATIONAL dataset, the false-alarm rate increases about 100-fold compared to the NEWS dataset (from .001 to .107). However, we still consider such false alarm rates acceptable as about 90% of RWSEs are correctly identified, for which we then can provide feedback.

It is hard to compare our results with previous results, as the originally used synthetic datasets are not available, different confusion sets were used, and results depend much on parameter choice (especially our magnitude parameter μ). Carlson et al. (2001) report results on synthetic data for different prediction thresholds that serve a similar purpose as our parameter μ . They report a ‘performance’ (which we interpret as accuracy) of .981 for 19 highly frequent confusion sets, and .973 for a larger set of 265 confusion sets. Converting our metrics into accuracy, we obtain on the NEWS dataset an accuracy of .965 (for our 52 confusion sets and $\mu = 10$), which is in the same ballpark but as discussed above not directly comparable.

Dataset	# no RWSE	false alarm rate	# actual RWSEs	miss rate
NEWS	15,960	.001	60,632	.005
NEWS-BALANCED	15,454	.011	40,400	.044
WIKI	49	.082	49	.163
WIKI-DE	30	.000	30	.100
EDUCATIONAL	-	.105	-	-

Table 2: Overall RWSE detection results with $\mu = 10$.

5.1 Qualitative Analysis on NEWS

The 10,000 sentences trigger 15,960 confusion sets (see Table 1 for the distribution) in the NEWS dataset. Our RWSE detection method produces only 13 false alarms which we further analyze here. Out of the 13 false alarms, we only consider three to be clear-cut mistakes. Six false alarms can be attributed to contextual ambiguity that allows for both, the original and suggested token, to be applicable. The remaining mistakes can be blamed on incomplete sentences or actual errors in the sentences.

{country, county} This confusion set produces 3 related false alarms, e.g. *An Officer of the OBE is awarded for distinguished regional or [county]-wide role in any field, through achievement or service to the community.* In those cases both words of the confusion set appear plausible without knowing the broader context.

{form, from} *Crowds were entertained by the Broke FMX Motocross Stunt Team, as well as a crowd pleasing display [form] the Pony club Games.* This is probably a RWSE in the original sentence and should not count as false alarm.

{hole, whole} *That's the [whole] in the end: A single guess provides you with information that you then need to use to narrow down the list of subsequent guesses.* This sentence seems incomplete. Adding ‘story’ after the token could resolve this and ‘whole’ would be correct.

{life, live} *In 2014 they moved to Mauriceville TX. where they built a beautiful home and [life] together.* Without a wider context, ‘live’ would also be plausible.

{their, there, they} *[They] were suspected bodies of soldiers killed in a then recent attack on the Melete barracks.* Within the wider context of this sentence⁹ ‘They’

⁹<https://www.thecable.ng/does-shiroro-fallen-soldiers-blood-matter/>

seems appropriate, so we do not count this as a clear error.

Many open from 8 or 9am but you can refer to [their] to confirm if your local restaurant is open during the Christmas period and what times they are trading.

The model suggests ‘there’, which seems equally wrong as the original token. So we do not treat this a clear false-alarm.

But [they] are two distinct and separate occurrences. The model suggests ‘there’, but without wider context both versions are acceptable. So we do not treat this as a clear false-alarm.

{theme, them} *Now we get to the timeliness — and Novey’s knack for being on [theme] without ever being too on the nose.*

This is an actual false alarm.

{to, too, two} *She also helped lead the girls basketball and softball teams [two] section championships.*

The model predicts τ_0 with high score of 0.97, which is not clearly better. Another likely solution would have been ‘to two section championships’ instead.

{you, your} *Next thing [your] going to post is that chopping the foreskin of babies isn’t a symbol of virtuous enlightenment.*

This should likely have been *you’re*, but the current implementation does not support contractions. As this would lead to wrong feedback, we count this as a false alarm.

Probably not a real good look for [you] trade demand that you’re posting a pic excited with OBJ being a Raven. This is clearly a true false alarm.

5.2 Confusion set difficulty

Next, we use our NEWS-BALANCED dataset containing 15,454 instances to analyze differences in correction difficulty between confusion sets. As we have already seen in the qualitative analysis above, it is likely that confusion sets like {county, country} are rather difficult, while we might be able to give near perfect feedback for others. Note that when going from unbalanced to the balanced dataset, the false-alarm rate increased an order of magnitude from .001 to .011 indicating that the less common confusion sets are more difficult on average.

In Figure 2, we show false-alarm rate and miss rate for all confusion sets. Results for specific confusion sets may deviate from the average quite a bit. For example, there are confusion sets with no false alarms like {begin, being}, but also {word,

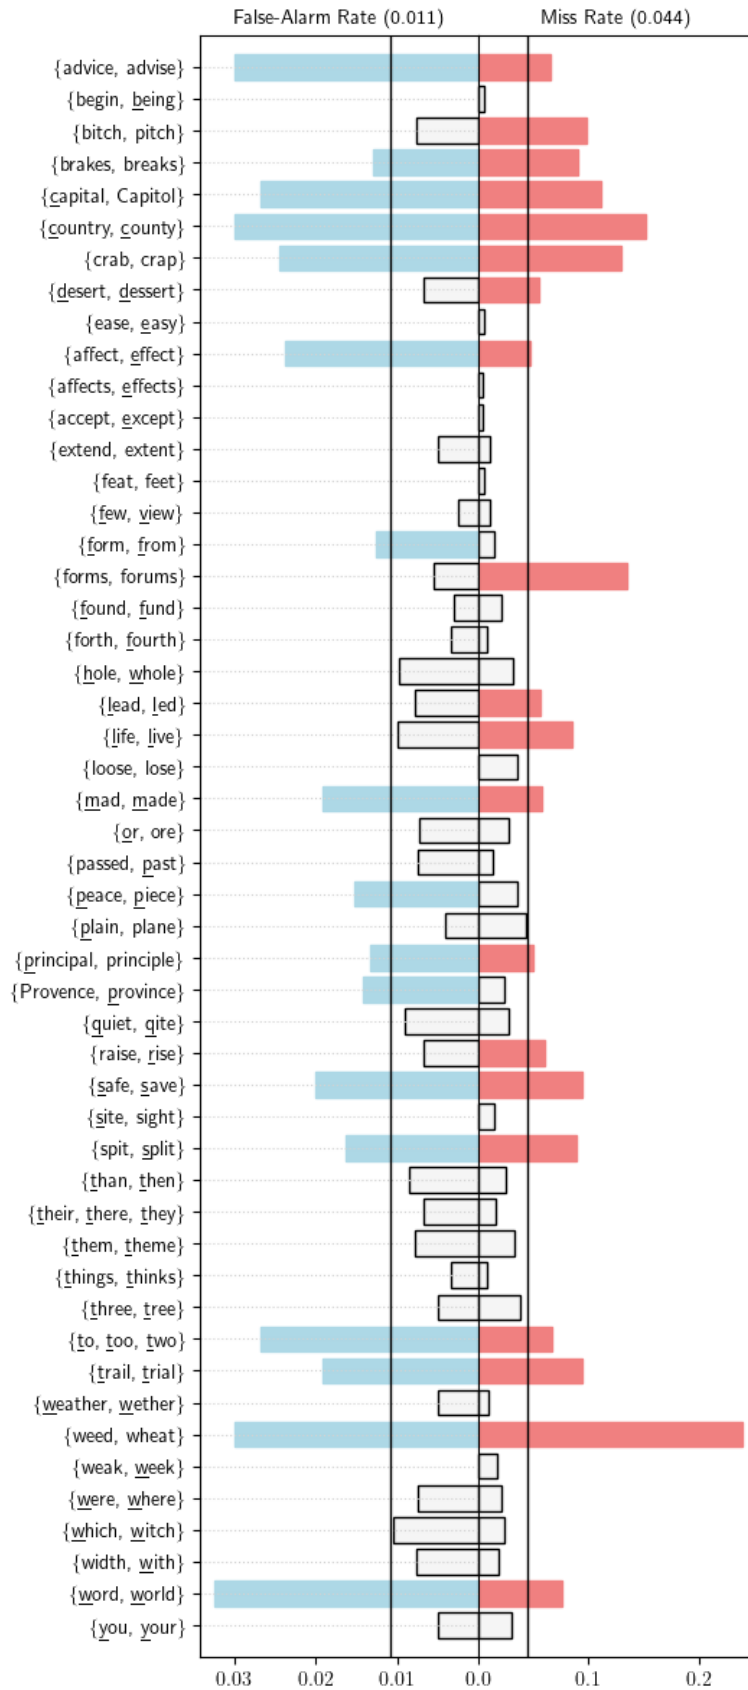

Figure 2: Comparison between false-alarm rate and miss rate on NEWS-BALANCED for all confusion sets. Additional vertical lines show the averages over all confusion sets. Grey bars show values below the average, blue/red bars show above average values.

Figure 3: Trade-off between false-alarm rate (lower curve) vs. miss rate (upper curve) based on the threshold parameter μ on the NEWS-BALANCED dataset. The intersections of the plot lines with the vertical, gray line indicate the results of the RWSE detection on the NEWS-BALANCED dataset as presented in Table 2.

world} with a rate three-times the average. We see a similar picture for miss rates: {weed, wheat} stands out with over 20% missed instances.

5.3 Threshold Factor

When designing our detection method, we have somewhat arbitrarily selected a factor of 10 (one order of magnitude) for the μ threshold. Remember that it controls how much more likely a word from the confusion set must be to be considered as a replacement for the original word. We now analyze this choice by computing false-alarm rate and miss rate for different values of μ on all instances of the NEWS-BALANCED dataset. Figure 3 shows the resulting trade-off. Interestingly, our intuitive choice of 10 is already a sensible one striking a good balance between missing out on detection and producing too many false alarms. The chart also shows that e.g. with a value of 100, we could almost entirely eliminate false alarms and only miss about 8% of RWSEs.

5.4 Results on EDUCATIONAL Data

The 18,984 sentences extracted from the CLC-FCE dataset triggered 364 alarms, which we manually annotate. We discard 31 ambiguous instances, where we either would need more context (especially {county,country} cases), the learner language allows for multiple interpretations, or another word outside of the confusion set is more likely. The latter category includes several cases of “your [yours] sincerely”, as well as “Than [Thank] you ” and “witch [with] NP”. Here, it is important to remember that our confusion sets are dynamically configurable, which means that a teacher

can, when seeing a mistake like this, augment the {which, witch} confusion set into {which, witch, with} depending on whether they consider this confusion to be pedagogically relevant at this point.

Of the remaining 323 instances, 34 are wrong which results in a false-alarm rate of .105. Looking into specific confusion sets, we find that all 14 {quiet,quite} instances are correctly identified which is in line with the rates determined on the NEWS-BALANCED dataset (cf. Figure 2). The same is true for {than,then}, {things,thinks}, {whether,weather}, and {weak,week}. So even if the NEWS dataset underestimate the absolute error rates, it seems to be a good estimate of relative confusion set difficulty. However they are also counterexamples.¹⁰ {their,there,they} is an easy confusion set in the NEWS datasets, but in the EDUCATIONAL instances it is quite hard.

6 Conclusion

In this paper, we tackle the problem of detecting real-word spelling errors in learner text. For that purpose, we present a modern Transformer-based implementation with dynamically configurable confusion sets. We show that our implementation is at least as accurate as earlier approaches when evaluated on news data and when applied on synthetic error data. Our experiments also reveal that learner data is more challenging, but that with our configuration 89% of alarms correctly identify an RWSE. Our analysis also shows that performance varies a lot between confusion sets, but that this could be counter-balanced by adjusting the detection threshold for each confusion set or taking a wider context window into account. We discuss more ideas for future work in the next section together with limitations.

Limitations

The bulk of our experiments is carried out only for English, but as we show by applying it on a small German dataset, the method technically also works for other languages and can be easily adapted.

In our study, we limit the context window to single sentences. Our qualitative analyses have shown that in some cases (few in the NEWS dataset, but quite a few in the EDUCATIONAL data) a wider context would be necessary to resolve the ambiguity. It remains to be empirically tested whether this

¹⁰This sentence contains a deliberate RWSE. ‘they’ should be ‘there’. Did you spot it while reading?

really would result in fewer such cases.

Another limitation is that we only cover single word errors excluding confusion sets with multiword tokens, like {a life, alive}, or with apostrophes, like {its, it's}. We are also limited by the BERT vocabulary, so that some rarer words are not covered. While this is probably not a major problem in educational texts, as learners are unlikely to produce very infrequent words, multiwords and apostrophes are in the core curriculum. It remains to be investigated on the implementation or configuration level how to treat these cases.

From our analysis, a problem is when a confusion set is triggered, but the correct solution is not in the confusion set. An example was [*Than*] *you for reading*. We propose to solve this issue, by adding a post-check to our method, where the fill-mask task is run without the confusion set filter, and whenever there is another solution to the masked gap that is overwhelmingly more likely (exact magnitude to be determined empirically), we do not raise an alarm.

Ethics Statement

We do not see any ethical issues with this line of work. Helping people making fewer embarrassing mistakes might have slightly positive effects. In our experiments, we are only using publicly available models and data.

Acknowledgements

We thank Flavio Lötcher for support in compiling the list of confusion sets. We also thank Nico Steinhardt for deploying the demo app. We also thank the reviewers for their insightful comments and constructive feedback.

Abstract

Weakly supervised learning (WSL) is a machine learning approach used when labeled data is scarce or expensive to obtain. In such scenarios, models are trained using weaker supervision sources instead of human-annotated data. However, these sources are often noisy and may introduce unquantified biases during training. This issue is particularly pronounced in automated scoring (AS) of second language (L2) learner output, where high variability and limited generalizability pose significant challenges. In this paper, we investigate the analytical scoring of L2 learner responses under weak and semi-supervised learning conditions, leveraging Prediction-Powered Inference (PPI) to provide statistical guarantees on score validity. We compare two approaches: (1) synthetic scoring using large language models (LLMs), and (2) a semi-supervised setting in which a machine learning model, trained on a small gold-standard set, generates predictions for a larger unlabeled corpus. In both cases, PPI is applied to construct valid confidence intervals for assessing the reliability of the predicted scores. Our analysis, based on a dataset of L2 learner conversations with an AI agent, shows that PPI is highly informative for evaluating the quality of weakly annotated data. Moreover, we demonstrate that PPI can increase the effective sample size by over 150% relative to the original human-scored subset, enabling more robust inference in educational assessment settings where labeled data is scarce.

1 Introduction

Recent advances in Natural Language Processing (NLP) have enabled the development of intelligent conversational agents for language learning and teaching that are capable of producing human-like language. In the context of computer-assisted language learning (CALL), research-driven, dialogue-based systems, such as task-specific conversational agents designed to support second language (L2)

acquisition, have shown promising results in fostering vocabulary and grammatical development, while also promoting self-directed learning through repeated, skills-focused practice (Bibauw et al., 2019; Tyen et al., 2022; Glandorf et al., 2025).

These technological developments have significantly enhanced the ability of dialogue-based CALL systems to guide and sustain human-like conversational interactions, aligning them with established proficiency guidelines and pedagogical principles. As a result, they offer structured, reliable, and personalized L2 practice beyond the classroom. This shift underscores the need for scalable, efficient, and statistically valid assessment methods capable of supporting such learning environments.

Automated scoring (AS) of language output, such as written essays (Shermis and Burstein, 2013), short texts (Burrows et al., 2015), spoken dialogues (Litman et al., 2018), and text-based conversations (Ramanarayanan et al., 2019; Yuwono et al., 2019), is a mature field of research that emerged during the 1960’s (Page, 1968) and has accelerated its development over the past two decades (Shermis and Burstein, 2003; Xi, 2010; Ke and Ng, 2019) as NLP methods have evolved significantly. However, AS methods rely on large quantities of high-quality manually annotated data to train models, which requires significant human resources and time.

To overcome the difficulties and challenges of data annotation in NLP, Weakly-supervised learning (WSL) emerged as an alternative framework (Huang et al., 2014), leveraging weaker sources and methods to obtain synthetic labels from textual data. Many of the strengths of WSL depend on the availability of high-quality validation data (Zhu et al., 2023), which in L2 assessment, is not always possible. Assessing L2 output for learning requires not only knowledge of the target language but also the ability to evaluate a learner’s interlanguage based on established proficiency guidelines,

making it an even more time-consuming task.

With the development of large language models (LLMs) and their advanced language understanding capabilities, researchers have begun to utilize them in data annotation tasks (Goel et al., 2023; Tan et al., 2024b). In L2 assessment in particular, GPT-4 has shown to produce holistic scores that are highly correlated to human evaluation in written essays and have moderate to high inter-rater reliability (Tate et al., 2024). Furthermore, experiments showed that GPT-4 is capable of performing analytic scoring of L2 texts given holistic scores (Banno et al., 2024), however, no ground truth set was available in this study. While state-of-the-art LLMs such as GPT-4 have shown human-like language capabilities that allow them to produce annotations that are highly correlated with expert ones, it is unclear how biased those annotations are. In addition, no statistical guarantees on the validity of the synthetic data are used in the literature.

In this paper, we investigate whether state-of-the-art large language models (LLMs) can be used to generate high-quality synthetic scores of lexical complexity and grammatical accuracy from students' text-based conversational responses based on the Common European Framework of Reference (CEFR) framework (Council of Europe, 2001). These synthetic scores, along with a small set of human-annotated gold-standard data, are used to train machine learning models under two different settings: a weakly supervised learning (WSL) approach that relies on LLM-generated labels, and a semi-supervised method in which a model trained on the gold-standard set produces predictions for a larger unlabeled corpus. In both settings, our goal is to increase the effective sample size and enable valid inference. To this end, we apply Prediction-Powered Inference (PPI) to provide statistical guarantees on the resulting predictions, ensuring that the use of synthetic scores does not compromise the validity of the conclusions.

Experimental results indicate that the proposed method increases the effective sample size by over 150% and yields a relative gain in accuracy, both compared to using only the gold-standard human-annotated data in a semi-supervised setting. In contrast, treating LLM-generated scores as if they were human-annotated can lead to inaccurate estimates and yield more modest improvements under a WSL framework. The proposed approach helps mitigate some of the limitations associated with weaker supervision sources in NLP, particularly in

scenarios where predictions inform decisions with significant consequences, such as in educational assessment.

We also address challenges associated with using LLMs as data annotators in NLP tasks, especially the uncertainty inherent in their outputs. Our findings show that applying a statistically valid method such as PPI can not only improve reliability and provide bias corrected estimates, but also quantify the uncertainty of predictions on unlabeled data, thereby offering a more trustworthy framework for leveraging synthetic annotations and scores.

The main contributions of this paper are:

- We integrate Prediction-Powered Inference into a new framework for semi-supervised and weakly supervised learning, providing statistical guarantees for predictions on datasets with small labeled and large unlabeled subsets.
- Unlike standard semi- and weakly supervised learning paradigms, the proposed framework samples and selects synthetic data based on valid statistical conditions, imposing a data quality requirement relative to a gold standard set.
- This approach, in the semi-supervised setting, produces a relative sample size gain of up to 157%, resulting in an accuracy increase of 23.2%.

2 Background

2.1 Automated L2 scoring methods

Over the past decades, computer-aided automatic text analysis has become increasingly prevalent in measuring L2 lexical and speaking proficiency (Crossley et al., 2011, 2014). More recently, deep learning approaches have achieved performance close to that of human raters in holistic scoring tasks (Alikaniotis et al., 2016), and Transformer-based models have even surpassed human inter-annotator agreement levels (Rodriguez et al., 2019). Large language models (LLMs) such as GPT-3 have also shown promise in supporting automatic scoring, as demonstrated by their application to 12,100 essays from the ETS Corpus of Non-Native Written English (Mizumoto and Eguchi, 2023).

Further advancements have been observed with GPT-4. Studies indicate that, when provided with calibration examples, GPT-4 can reliably rate short essay responses (Yancey et al., 2023), assess discourse coherence at a level comparable to expert

raters (Naismith et al., 2023), and generate analytical scores aligned with the CEFR proficiency framework (Banno et al., 2024).

While NLP-based automated methods have historically demonstrated the ability to assess specific linguistic features and functions, human raters tend to outperform them in evaluating higher-level discourse elements such as ideas, content, and organization (Enright and Quinlan, 2010). This divergence suggests that language models may exhibit a different type of bias compared to human raters, particularly in tasks requiring inferential judgment.

2.2 Weaker sources of supervision

Weakly-supervised learning (WSL) has become a practical machine learning paradigm to address the issue of label scarcity in NLP. The major bottleneck for deploying machine learning models has been the lack of access to large, high-quality training datasets. Producing manual annotations of text data is a labor-intensive and time-consuming task. To reduce such efforts, WSL approaches have been proposed to offer a larger pool of weaker supervision sources to label and annotate data (Ren et al., 2020; Zhang et al., 2021). Such sources often rely on heuristics, knowledge bases, crowd sourcing, labeling functions, or pre-trained models instead of expert manual annotations (Ratner et al., 2017). However, WSL methods also present challenges due to the degree of noise that the generated labels contain (Zhu et al., 2023).

More recently, a prompting-based method was proposed to integrate LLMs into weak supervision frameworks (Smith et al., 2024), yielding accuracy gains on the general-purpose WRENCH weak supervision benchmark. However, the effectiveness of this approach in more specialized domains, such as the analytical scoring of student responses, remains uncertain. Moreover, the study does not address potential biases present in the training data, nor does it evaluate how such biases may affect the resulting estimates. It also remains unclear how a semi-supervised method (Søgaard, 2022) would perform in comparison to this weakly supervised approach, particularly in settings where bias is limited to the human annotations and model predictions, without introducing additional external sources of error.

To address this gap, our study compares both approaches, LLM-driven weak supervision and a semi-supervised method using a small gold-standard dataset, to investigate their effectiveness

in analytical scoring tasks. We leverage PPI in both cases to provide statistical guarantees on the resulting predictions and to evaluate the reliability and calibration of the scores derived from each approach.

3 Method

We are interested in developing a framework that can be used to train machine learning models when only a small labeled dataset and a large corpus of unlabeled data are available. To leverage the unlabeled data, synthetic scores are obtained using a machine learning model, but instead of treating those scores as gold standard, a provably valid statistical method is used to assess the biases contained in the scores, so that estimates can be rectified.

The proposed framework is evaluated in two settings. In the weakly supervised learning (WSL) scenario, a state-of-the-art LLM is used to generate synthetic scores from text-based inputs, which are then used to train a traditional machine learning model. In the semi-supervised setting, the ML model is trained on a small set of gold-standard annotations and used to predict scores for a larger unlabeled set. In both cases, a debiasing protocol based on Prediction-Powered Inference (PPI) (Angelopoulos et al., 2023) is applied to estimate prediction errors and provide statistical confidence measures for the resulting scores.

Although LLMs have shown strong zero-shot generative and reasoning capabilities (Kojima et al., 2022), they still produce hallucinations (Gunjal et al., 2024), unreliable outputs (Sclar et al., 2023), and exhibit demographic biases (Chiang and Lee, 2023), making them unreliable for providing immediate scores to students. For those reasons we use machine learning models that can be trained on a set of textual features and a combination of human and weaker scoring sources to estimate a proficiency score with a given confidence (see details on models and features in subsection 4.2).

While NLP tasks, particularly those in the social sciences, have used less reliable LLM annotations in downstream tasks that require inferences to be statistically valid to draw reliable conclusions (Gligorić et al., 2024), the approach presented in this paper leverages such statistical validity to determine the reliability of weaker data sources to train machine learning models.

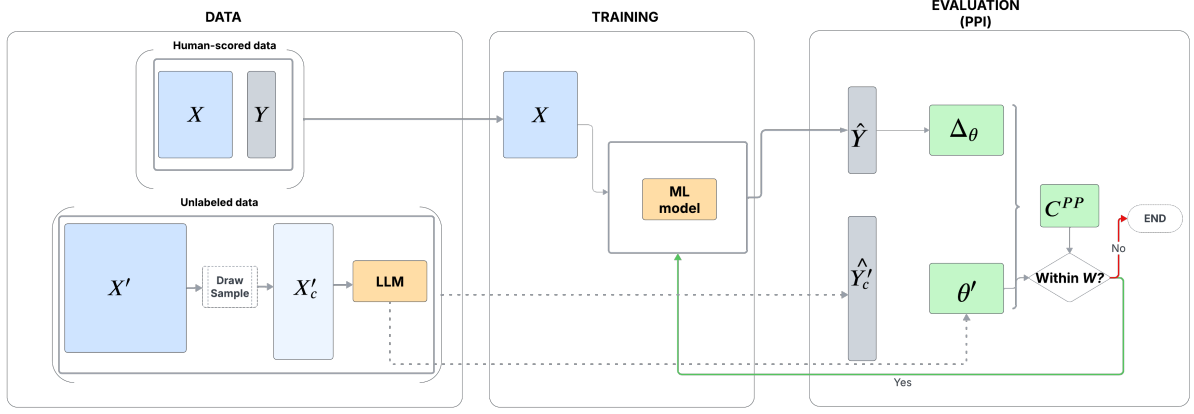

Figure 1: Outline of the process for scoring L2 conversation responses in a WSL setting using PPI. X and Y are the features and human-annotated scores, and X'_c are a subset of the textual features sampled from the unlabelled dataset X' to be scored by an LLM, obtaining \hat{Y}'_c scores and θ' verbalized confidence on the scores. If the width of C^{PP} remains within W X'_c will be added to the training process to further optimize the training of the ML model.

3.1 Statistical guarantees: Prediction-powered inference

Prediction-Powered Inference (PPI) is a statistical protocol that combines predictions made on less reliable unlabeled data with those made on a gold-standard dataset to obtain a confidence interval (CI) that is provably valid (Angelopoulos et al., 2023). Instead of using machine learning models to determine the validity of an unlabeled dataset on a case-by-case basis, PPI provides model-free estimates that are statistically valid, leveraging the information contained in the predictions.

The goal of PPI is to estimate a quantity of interest θ^* , such as the population mean. To estimate θ^* we have access to a set of gold-standard data with human-annotated responses Y and features X such that $(X, Y) = (X_1, Y_1), \dots, (X_n, Y_n)$, and a much larger set of unlabeled data $(X', Y') = (X'_1, Y'_1), \dots, (X'_N, Y'_N)$ where Y' is not directly observable, and $N \gg n$. For both datasets predictions are obtained using a machine learning model $f(\cdot)$, represented by $f(X)$ and $f(X')$. In PPI, the predictions made on the unlabeled data are not treated as gold-standard such as in the imputation case. Instead, PPI uses the gold-standard set to quantify and correct for the errors made by the model on the unlabeled set.

The three-step process that constitutes PPI can be summarized as follows:

1. Select the quantity of interest θ^* , such as the mean outcome $\mathbb{E}(Y_i)$.
2. Compute the estimate θ' and a rectifier Δ_θ , where θ' is computed on the unlabeled data

(X', \hat{Y}') such that $\theta' = \frac{1}{N} \sum_{i=1}^N f(X'_i)$, and $\Delta_\theta = \frac{1}{n} \sum_{i=1}^n (f(X_i) - Y_i)$. If $f(X_i)$ perfectly matches Y , then $\Delta_\theta = 0$.

3. Construct a confidence interval C^{PP} for θ^* .

To construct C^{PP} we need to obtain the prediction-powered estimate $\hat{\theta}^{PP}$ that corrects for the bias on θ' due to prediction errors:

$$\hat{\theta}^{PP} = \frac{1}{N} \sum_{i=1}^N f(X'_i) - \frac{1}{n} \sum_{i=1}^n (f(X_i) - Y_i) \quad (1)$$

and then the prediction-powered confidence set is obtained such that

$$C^{PP} = (\hat{\theta}^{PP} \pm w(\alpha)) \quad (2)$$

where $w(\alpha)$ is a constant that depends on the confidence level α (derivations could be found in Angelopoulos et al. (2023)).

PPI has been used for the pairwise ranking of models (Boyeau et al., 2024), for comparing the performance of LLMs (Chatzi et al., 2024), for evaluating retrieval augmented generation (RAG) systems (Saad-Falcon et al., 2024), and some of its variants for producing confident conclusions from LLMs annotations (Gligorić et al., 2024). The approach presented in this article differs from the previous ones. In the general PPI setting, a trained model is used to produce predictions on both sets, and PPI is used to debias the predictions made on the unlabeled data. In the proposed framework, we do not have access to a trained model, and the

training is done iteratively and sequentially using PPI as a guarantee of statistical validity, making decisions on what unlabeled data to include in the training process based on a statistical measure.

3.2 Using LLMs in weak supervision with statistical guarantees

From a dataset of conversational responses \mathcal{X} , we divide it into $|X|$ responses to be scored by human annotators and $|X'|$ responses to be scored by an LLM, obtaining Y and Y' scores respectively; where $|X| = n$ and $|X'| = N$, and $N \gg n$. We assume that there are biases in \hat{Y}' associated with the scoring errors made by the LLM, and use PPI to debias them, resulting in biased-corrected estimates.

To obtain Y and Y' , the same rubric was used for human and LLM scorers, in an attempt to maintain as much parity as possible between the two scoring sources and to avoid additional biases.

The rubric used two dimensions of language proficiency as expressed in the CEFR framework (Council of Europe, 2001), namely vocabulary range and grammatical accuracy for B1 and B2 levels. Scores ranged from 1-3 for vocabulary range and 1-4 for grammatical accuracy. For human scoring, two annotators with extensive experience in L2 proficiency scoring were recruited. To obtain a single score, annotations were conducted collaboratively, and if consensus was not reached a third annotator was used to resolve the disagreement (Fort, 2016) (see Appendix A for details on the rubric). GPT-4o and GPT-4o-mini were the models of choice to produce synthetic scores Y' given X' and the rubric. A zero-shot prompting approach was used (see Appendix C for details on the prompts) and additionally, the models were prompted to provide a measure of *verbalized confidence* in the form of a probability value to assess the correctness of the score, as presented in Tian et al. (2023).

The following steps describe the WSL approach with an LLM as a *weak* scorer and with PPI guarantees: 1) taking as input the entire set of high-quality human-labeled scores, a machine learning model $f(\cdot)$ is trained such that, after training on the gold-standard set X is completed, we obtain $\hat{\theta}^{PP}$ and C^{PP} using the verbalized confidence of the LLM θ' on a small sample of size c X'_c and the predictions made by the ML model \hat{Y}' ; 2) the width of C^{PP} is computed in an evaluation step, such that $C_{upper}^{PP} - C_{lower}^{PP} \leq W$ and W is a width threshold

chosen beforehand; 3) if the width is not greater than W and the prediction-powered corrected mean accuracy is not less than the one computed with the gold-standard set, the sample X'_c is added to the training process and the model is trained on $X \oplus X'_c$ until either the C^{PP} condition on W is no longer met or the accuracy decreases. Figure 1 outlines the process in a block diagram.

3.3 Leveraging PPI in semi-supervised learning

Similar to the WSL approach described in Subsection 3.2, the proposed semi-supervised method uses PPI to establish statistical guarantees on predictions made for the unlabeled data X' . However, instead of relying on an LLM as a scorer, this method employs a machine learning model to generate predictions, which are then reused for fine-tuning under the same width and accuracy gain conditions defined in the WSL setting.

The method works as follows. First, the ML model is trained only on the human-scored set, the ground-truth data X . In an evaluation step, a sample of size c is randomly drawn from the entire unlabeled set X' to compute $\hat{Y}'_c = f(X'_c)$ and obtain $\hat{\theta}^{PP}$ and C^{PP} . If the width of C^{PP} does not exceed a threshold W , i.e., $C_{upper}^{PP} - C_{lower}^{PP} \leq W$, and $\hat{\theta}^{PP}$ is greater than the mean accuracy of the predictions made using the human-scored data, then a new sample is drawn and training continues until this condition is no longer satisfied (Figure 2 summarizes the steps involved in this process).

As we can see, PPI is used to estimate the validity of the inferences made on the unlabeled set through an iterative process that draws samples of size c to test whether the predictions on X' maintain the width of C^{PP} within the threshold W . A wider width would denote greater uncertainty, indicating that the predictions made on the unlabeled data are less reliable and potentially more biased. In contrast, a narrower width suggests higher precision and lower variance.

In this sense, C^{PP} serves as a valid estimate for assessing the quality of an unlabeled dataset given a high-quality labeled one. It also provides a basis for estimating the effective sample size needed to obtain reliable predictions when leveraging unlabeled data, especially when considering the associated accuracy gain.

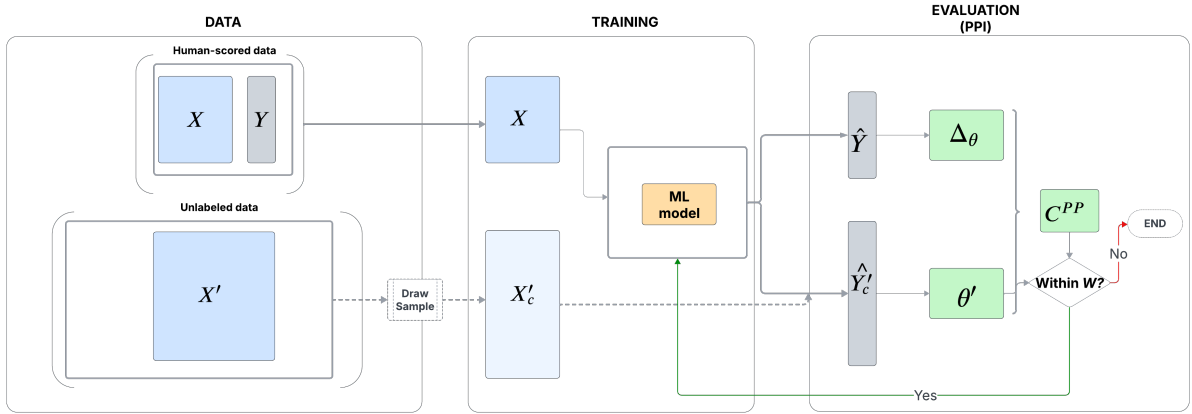

Figure 2: Differently from the process outlined in Figure 1, in the semi-supervised setting both the scores \hat{Y}'_c and the probability value θ' are obtained directly from the ML model. No external scoring source is used.

4 Experiments

We conduct several experiments to evaluate the effectiveness of our approach. The goal is to assess the overall methodology in both weakly and semi-supervised learning settings, aiming to measure the quality of synthetically generated scores derived from a smaller set of high-quality, human-annotated data. Given the constraints of this study, namely the limited availability of high-quality human-labeled samples, we use machine learning models that are well-suited to this low-resource setting and that have shown to perform effectively on features that can be represented as tabular data (Shwartz-Ziv and Armon, 2022). We make code available ¹.

4.1 Data

Data was collected from text-based conversation practice sessions completed by intermediate level (B1-B2 levels in CEFR) English language learners (ELLs) and an AI agent (Fincham and Alvarez, 2024) over a 3-month period. A total 121 students from 3 sessions of an undergraduate course focused on English speaking participated in the project and generated 1721 practice sessions. The average number of turns per session produced by students was 8.9.

To train the models, 590 sessions were manually scored following a rubric based on the CEFR framework (Council of Europe, 2001) on vocabulary range and grammatical accuracy (see section 3.2). Out of the 590 sessions, 445 were used for training and 145 for evaluation. The remaining

1131 sessions were either scored by an LLM or by the model of choice in the semi-supervised experiment. Inter-annotator agreement between human and LLM raters reached moderate levels, with $\kappa = 0.45$ for vocabulary range and $\kappa = 0.4$ for grammatical accuracy.

4.2 Models and features

From the students' conversations, 9 lexical and syntactical features were automatically extracted, many of which have shown to be highly correlated with linguistic proficiency descriptors based on the CEFR framework (Banno et al., 2024). Those are: lexical density, unique noun chunks, number of unique words, number of unique difficult words, Flesch Kincaid readability score (Thomas et al., 1975), sentence length mean and standard deviation, and dependency distance mean and standard deviation.

Two tree-based boosting models, XGBoost (Chen and Guestrin, 2016) and LightGBM (Ke et al., 2017) were used in the weak and semi-supervised training regimes and used as predictor ML models. Results were compared to the baseline scores obtained directly from the two LLMs, GPT-4o and GPT-4o-mini.

4.3 Evaluation

The quantity of interest chosen for this study was the mean accuracy. As described in subsections 3.2 and 3.3, width and accuracy gain are the measures that determine the stopping condition during training and evaluation, and overall, to determine the quality of the inference on the unlabeled data. In addition, coverage is used to evaluate how many times the true value θ^* falls within the estimated

¹<https://github.com/aitor-alvarez/Automated-L2-Proficiency-Scoring>

interval with a given confidence level. The confidence level for this study was set to 0.9 for $\alpha = 0.1$, which is the same level that PPI guarantees asymptotically (Angelopoulos et al., 2023). If coverage does not meet the established α -level, this would indicate that predictions are extremely biased, not normally distributed, or that the proportion or quality of the labeled/unlabeled data is not balanced and therefore the variance estimate may be unstable.

We estimate the effective sample size by calculating the maximum number of synthetic scores used in relation to the labeled set for the following inequality to hold $C_{upper}^{PP} - C_{lower}^{PP} \leq W$ and for the mean accuracy to improve when comparing it to the results obtained with the gold-standard set alone. The width threshold was set at $W = 0.2$ and tested in the two experimental learning settings (weakly and semi-supervised) for each of the models. This width threshold indicates that we are willing to accept a CI with a maximum of 20% range in the mean accuracy estimate C^{PP} . Samples of size 100 were added at each iteration to determine the width, coverage, and effective sample size for both conditions.

5 Results

Table 1 presents the experimental results. The semi-supervised approach yields the highest accuracy gains by using PPI to combine human-annotated data with model-generated scores, selecting only samples within the PPI confidence interval that improve baseline accuracy. For vocabulary range, the increase reaches 23.2% and for grammatical accuracy 21.5%, with a total effective sample size of 700. Width sizes remain relatively low, 0.13 for vocabulary range and at around 0.148 for grammatical accuracy. Coverage in this setting reaches 97%, demonstrating the validity of this approach.

The weakly supervised learning (WSL) protocol, on the other hand, yields more modest accuracy gains when combining gold-standard data with weakly scored data. In this setting, accuracy improvements range from 8.1% to 8.4% in vocabulary range and reach 7.5% in grammatical accuracy, using either boosting model with GPT-4o as the annotator source and an effective sample size of 200. When GPT-4o-mini is used as the annotator model, accuracy gain decreases to 4.2–3.4% in vocabulary range and 3.1% in grammatical accuracy, with an effective sample size of 100. Overall, the WSL setting shows a coverage slightly above 90% (91%),

indicating an acceptable validity of this approach when using LLMs as weak scorers (see Appendix B for the accuracy on the gold-standard set only).

The LLM-only approach yields modest accuracy gains, with GPT-4o achieving improvements of 1.8% in vocabulary range and 1.5% in grammatical accuracy. GPT-4o-mini shows smaller gains of 0.6% and 0.4%, respectively, under the same setting, with an effective sample size of 100 in both cases. However, despite these gains, the coverage remains below 90%, failing to meet the required validity threshold. Further analysis reveals that both LLMs exhibit overconfidence in their probability estimates. On average, GPT-4o assigns 80% confidence to incorrect predictions in vocabulary range and 75% in grammatical accuracy. GPT-4o-mini shows similar patterns, with 78% confidence in vocabulary range and 71% in grammatical accuracy for its incorrect predictions.

In summary, the results indicate that the method presented in this study, when applied in a semi-supervised setting, results in a dataset that is 157% larger than the original. In contrast, the sample size gain is significantly reduced, down to 22%, when the method is used in a WSL setting with LLMs as scorers. Moreover, the naive approach of directly using LLM responses as gold-standard predictions fails to produce valid results.

6 Discussion

In this study, we have presented an approach to integrate Prediction-Powered Inference (PPI) in semi- and weakly-supervised settings when gold-standard data is scarce or difficult to obtain. By using PPI, we have shown that gold-standard with less reliable data can be combined to obtain increases in predictive accuracy while maintaining the validity of the results. This is particularly important in the context of this study, where student-produced output, namely conversational responses obtained from student interactions with an AI tutor, requires assessment at scale that can provide valid feedback to learners.

As previous studies have demonstrated (Tate et al., 2024; Tan et al., 2024b,a), LLM outputs show moderate to strong agreement with human judgments. In our study, we observe a moderate level of agreement between human raters and LLM-based scores, as previously reported. However, this level of agreement is insufficient for treating LLM scores as gold-standard, as it does not yield valid

Setting	Task	Model	Sample Size	Width	Coverage	Acc. Gain
Semi	Vocab. range	XGBoost	700	0.13	97%	23.2%
Semi	Gram. accur.	XGBoost	700	0.145	97%	21.5%
Semi	Vocab. range	LightGBM	700	0.133	97%	22.1%
Semi	Gram. accur.	LightGBM	700	0.148	97%	19.7%
WSL	Vocab. range	XGBoost + 4o	200	0.136	91 %	8.4%
WSL	Gram. accur.	XGBoost + 4o	200	0.144	91 %	7.5%
WSL	Vocab. range	XGBoost + 4o-mini	100	0.16	91 %	4.2%
WSL	Gram. accur.	XGBoost + 4o-mini	100	0.171	91 %	3%
WSL	Vocab. range	LightGBM+ 4o	200	0.14	91 %	8.1%
WSL	Gram. accur.	LightGBM+ 4o	200	0.145	91 %	7.5%
WSL	Vocab. range	LightGBM+ 4o-mini	100	0.177	91 %	3.4%
WSL	Gram. accur.	LightGBM+ 4o-mini	100	0.179	91 %	3.1%
LLM only	Vocab. range	GPT-4o	100	0.152	77%	1.8%
LLM only	Gram. accur.	GPT-4o	100	0.156	77%	1.5%
LLM only	Vocab. range	GPT-4o-mini	100	0.181	68%	0.6%
LLM only	Gram. accur.	GPT-4o-mini	100	0.184	68%	0.4%

Table 1: Performance metrics by setting, task, and model employed to obtain predictions and to generate synthetic scores. Sample size indicates the maximum number of unlabeled samples used to reach the highest accuracy and within the maximum width allowed. Acc. Gain is the maximum gain in accuracy compared to the gold-standard (human annotated only) approach (see Appendix B for the accuracy on the gold-standard set only).

statistical conclusions.

When LLM outputs are instead used within a weak supervision framework, acknowledged as biased but corrected through prediction-powered inference (PPI), they lead to slight improvements compared to relying solely on gold-standard data. Nonetheless, LLMs exhibit overconfidence in their incorrect assessments, indicating a poor understanding of uncertainty, a concern also noted in a recent work (Pawitan and Holmes, 2025).

In contrast, we find that a well-calibrated machine learning model, when used in a semi-supervised setting alongside PPI, can substantially increase the sample size by over 157% relative to using only human-annotated data, which results in a dataset larger than the original and improves training and accuracy. This suggests that simpler models, when well-calibrated and properly integrated into such frameworks, can support broader, validity-guaranteed conclusions in educational assessment settings.

The results obtained in this paper have broad implications for large-scale and AI-mediated learning environments, where many learners require assessment and guidance, and human feedback is impractical (Swiecki et al., 2022). In such contexts, a small, well-annotated dataset can be used to make valid predictions on larger unlabeled data, reducing training requirements, improving prediction

quality, and enabling large-scale assessments with validity guarantees.

7 Limitations

This study aimed to explore the potential of Prediction-Powered Inference (PPI) to extend a small set of high-quality, human-scored conversational responses using less reliable data generated by large language models (LLMs) and simpler machine learning models. While PPI offers a statistically grounded framework for leveraging such predictions, it assumes that the labeled data are independently and identically distributed (i.i.d.) from a normal distribution. Although our labeled sample size ($n = 445$) may appear limited, each session includes, on average, over eight student turns, providing a richer source of information per data point. Nonetheless, larger samples of gold-standard data should be examined in future work to validate and generalize the findings presented here. Expanding the dataset to include a broader range of learner proficiencies could also provide further insights into the robustness and adaptability of the proposed approach.

8 Ethical considerations

In this study, we caution against the use of LLM-generated outputs as ground-truth data in educa-

tional settings, emphasizing the risks associated with treating such predictions as authoritative. Nevertheless, we acknowledge the potential of LLMs in low-stakes educational scenarios, particularly for generating synthetic data or instructional materials that can support learning.

It is important to note that this work assumes human annotations as the gold standard. However, this assumption should be approached with caution, as human judgments are subject to both cognitive (Gautam and Srinath, 2024) and socio-cultural biases (Huang and Yang, 2023), which are often context-dependent and may impact the reliability of reference scores.

A Rubric

A.1 Vocabulary Range (B1-B2)

Score	Description of the proficiency level
1	Has a good range of vocabulary related to familiar topics and everyday situations. Has sufficient vocabulary to express themselves with some circumlocutions on most topics pertinent to their everyday life such as family, hobbies and interests, work, travel and current events.
2	Has a good range of vocabulary for matters connected to their field and most general topics. Can vary formulation to avoid frequent repetition, but lexical gaps can still cause hesitation and circumlocution. Can produce appropriate collocations of many words/signs in most contexts fairly systematically. Can understand and use much of the specialist vocabulary of their field but has problems with specialist terminology outside it.
3	Can understand and use the main technical terminology of their field, when discussing their area of specialisation with other specialists.

Table 2: Vocabulary Range Rubric (B1-B2)

A.2 Grammatical Accuracy (B1-B2)

Score	Description of the proficiency level
1	Uses reasonably accurately a repertoire of frequently used routines and patterns associated with more predictable situations.
2	Communicates with reasonable accuracy in familiar contexts; generally good control, though with noticeable mother-tongue influence. Errors occur, but it is clear what they are trying to express.
3	Has a good command of simple language structures and some complex grammatical forms, although they tend to use complex structures rigidly with some inaccuracy.
4	Good grammatical control; occasional slips or non-systematic errors and minor flaws in sentence structure may still occur, but they are rare and can often be corrected in retrospect.

Table 3: Grammatical Accuracy Rubric (B1-B2)

B Accuracy for gold standard set

Model	Proficiency level	Accuracy
XGBoost	Vocabulary Range	74.1
XGBoost	Grammatical accuracy	71.3
LightGBM	Vocabulary Range	73.6
LightGBM	Grammatical accuracy	71
GPT-4o	Vocabulary Range	62.5
GPT-4o	Grammatical accuracy	61.2
GPT-4o-mini	Vocabulary Range	60.3
GPT-4o-mini	Grammatical accuracy	58.9

Table 4: Accuracy values for each of the models used tested on the gold standard set only.

C Prompts

Score the following text from a conversation of an intermediate English language student (B1-B2 on CEFR).

Provide the score as an integer and the probability as a float associated with the options in the 'ScoringTexts' function.

Text: text

Abstract

Inference making is an essential but complex skill in reading comprehension (RC). Some inferences require resolving references across sentences, and some rely on using prior knowledge to fill in the detail that is not explicitly written in the text. Diagnostic RC questions can help educators provide more effective and targeted reading instruction and interventions for school-age students. We introduce a taxonomy of inference types for RC and use it to analyze the distribution of items within a diagnostic RC item bank. Next, we present experiments using GPT-4o to generate bridging-inference RC items for given reading passages via few-shot prompting, comparing conditions with and without chain-of-thought prompts. Generated items were evaluated on three aspects: overall item quality, appropriate inference type, and LLM reasoning, achieving high inter-rater agreements above 0.90. Our results show that GPT-4o produced 93.8% good-quality questions suitable for operational use in grade 3-12 contexts; however, only 42.6% of the generated questions accurately matched the targeted inference type. We conclude that combining automatic item generation with human judgment offers a promising path toward scalable, high-quality diagnostic RC assessments.

1 Introduction

Inference-making is an essential yet cognitively demanding skill in reading comprehension (RC) (O'Brien et al., 2015; Kintsch, 1998). Inferences are necessary for establishing both local and global coherence within the mental representation of a text (Graesser et al., 1994). Local inferences connect information across sentences using cohesive devices such as anaphors or category exemplars—for example, in "Bette gulped down the drink. The cold water was very refreshing," the reader infers that *the drink* refers to *cold water* (Cain, 2022, p. 307).

Global inferences, on the other hand, rely on the reader's prior knowledge to fill in missing details required to make sense of the text—for example, in "The campfire started to burn uncontrollably. Tom grabbed a bucket of water" (Bowyer-Crane and Snowling, 2005, p. 192), the reader infers that Tom intended to put out the fire, based on the knowledge that water extinguishes fire. While skilled readers often generate inferences automatically as they engage with text (Thurlow and van den Broek, 1997), children who struggle with comprehension frequently have difficulty constructing these inferences (Cain et al., 2001).

Providing diagnostic information about specific types of inference-making deficits that hinder comprehension can empower educators to provide more effective and targeted reading instruction and intervention (Bowyer-Crane and Snowling, 2005; Bayat and Çetinkaya, 2020). To achieve this, we need RC assessments that specifically target inference-making types. At the same time, we want to develop scalable item generation methods to enable multi-time testing, monitoring reading development over time. Previous work has demonstrated the ability of large language models (LLMs) to generate effective RC questions (Uto et al., 2023; Säuberli and Clematide, 2024). However, whether LLMs can reliably produce questions that target specific inference types remains unclear.

Our research is grounded in a real-world diagnostic assessment of reading skills for students in grades 3 through 12 (Sabatini et al., 2019). The assessment was originally developed at ETS and recently commercialized as ReadBasix. It leverages the science of reading to assess foundational reading skills, such as word recognition and decoding, as well as more complex ones such as RC. In the RC subtest, a student will usually read 4 expository passages and answer multiple-choice questions associated with the passages. The subtest takes about 30 minutes to complete. Like any

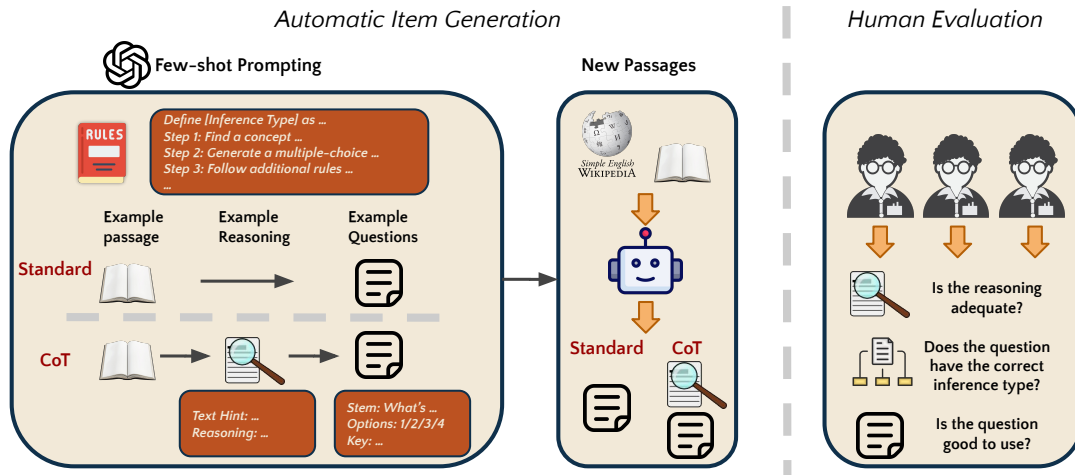

Figure 1: **Overview of automatic item generation and human evaluation.** We use GPT-4o to generate bridging-inference RC items for given reading passages via few-shot prompting, comparing conditions with and without chain-of-thought prompts. We prompt each inference type separately: pronominal bridging, text-connecting, and gap-filling inferences. Human evaluation focuses on general item quality, inference type appropriateness, and LLM rationales.

large-scale reading assessment, there is an ongoing need for more items. To address this demand, we aim to leverage automatic item generation to create new items based on curated passages, and evaluate the quality of these items before collecting student performance data to make them operational.

For the purpose of automatic item generation, as illustrated in Figure 1, we first conducted a literature review on inference-making in the reading comprehension and natural language processing (NLP) text comprehension literature. We developed a taxonomy of inference-making questions, with a focus on bridging inference. We validated this taxonomy by annotating an operational item bank of expert-written RC questions, confirming bridging inference as an important and widely covered sub-construct. Next, we curated six expository passages and manually wrote multiple-choice RC questions for each inference type based on our taxonomy. These examples were then used to prompt GPT-4o (Hurst et al., 2024) via few-shot prompting to generate bridging-inference questions for new reading passages, comparing conditions with and without chain-of-thought (CoT) prompting (Wei et al., 2022). Finally, three human experts evaluated the quality of the generated questions along three dimensions: overall item quality ¹, appropriate inference type, and whether GPT-4o provided

¹The evaluation of overall item quality does not include whether an item is of the required inference type, which is an extra-evaluation. See Table 2 for more details.

satisfactory reasoning for generating the question. Our results show that LLMs can produce 93.8% good-quality questions suitable for operational use in grade 3-12 contexts; however, only 42.6% of the generated questions accurately match the targeted inference type. Nevertheless, the overall coverage of inference types closely mirrors what we observe in our operational item bank. We conclude that combining automatic item generation with human judgment offers a promising path toward scalable, high-quality diagnostic RC assessments.

In summary, we make the following contributions in this paper:

1. We develop and validate a taxonomy for inference-making questions used in multiple-choice RC assessments, and demonstrate its value for future item development.
2. We introduce a novel NLP task where language models generate RC questions targeting specific inference types, providing a new way to assess their reasoning abilities. The training item bank will be released for replication and benchmarking.
3. We demonstrate GPT-4o’s potential in generating RC questions for operational use and its limitations in accurately generating specific types of inference questions.

2 Related Work

2.1 Question generation for reading comprehension assessments

Automatic question generation is a well-established task in NLP, especially within educational applications, to reduce the high costs of manual question authoring and to ensure a steady supply of new, high-quality items (Kurdi et al., 2020). Early approaches rely on rule-based or template-based methods (Araki et al., 2016; Flor and Riordan, 2018), as well as the use of discourse connectives to generate questions (Agarwal et al., 2011). Later approaches extensively used neural systems for question generation (Mulla and Gharpure, 2023). More recent work demonstrates that LLMs hold promise in generating high-quality RC questions, using techniques such as fine-tuning (Uto et al., 2023; Perkoff et al., 2023; Ghanem et al., 2022; Ashok Kumar et al., 2023; Rathod et al., 2022; Stasaski et al., 2021), zero-shot or few-shot prompting (Säuberli and Clematide, 2024; Attali et al., 2022), and Chain-of-Thought prompting (Kulshreshtha and Rumshisky, 2022). Some of these studies have also explored the generation of more complex, "deeper" questions—those that target underlying reasoning processes (Ghanem et al., 2022; Poon et al., 2024) or hinge on specific inference steps for accurate responses (Araki et al., 2016). Within the domain of automated Question Answering, the notion of *multi-hop questions* has gained attention, as questions relating different parts of a document require multi-step reasoning (Mavi et al., 2024).

We note that prior studies have largely treated reading comprehension as a single, undifferentiated construct even though comprehension requires different types of inferences. Recent work has begun to develop taxonomies of RC and annotate question types to enable more controllable generation (Xu et al., 2022; Li and Zhang, 2024; Hwang et al., 2024). However, to our knowledge, no existing work has systematically addressed question generation based on specific types of inference. We believe that the capability to generate different types of inference questions will provide more diagnostic insights for educators. Our work is a first step toward filling this gap.

2.2 Bridging inference as an NLP task

The NLP community has long tackled text comprehension challenges, including bridging infer-

ence. Prior work has focused on corpus-based bridging anaphora recognition and resolution using annotated resources such as ISNotes and BASHI (Rösiger, 2018; Hou et al., 2018; Hou, 2020). Neural models have been developed to jointly learn mention representations and bridging relations (Pandit and Hou, 2021; Kobayashi et al., 2022). In the recently developed IdentifyMe benchmark for resolving nominal and pronominal mentions across long contexts (Manikantan et al., 2024), GPT-4o outperforms other LLMs, achieving 81.9% accuracy and demonstrating strong referential capabilities. With the rise of LLMs, research increasingly shifts toward evaluating LLMs' general reasoning capabilities (Brown et al., 2020; Wei et al., 2022). In our education application, we investigate whether LLMs truly possess the reasoning ability required for bridging inference, particularly through the lens of a question generation task.

3 Taxonomy of Inference Questions

3.1 Development of Taxonomy

Inferences can be categorized into bridging inferences, elaborative inferences, predictive inference, emotional inference, etc (Graesser et al., 1994; Schmalhofer et al., 2002; Singer and Remillard, 2004; van den Broek et al., 2015). To manage the scope of our interest, we focus on bridging inference which connects information in a text. Bridging inferences contribute to text coherence by allowing the reader to identify the connections among concepts and ideas in the text (Singer et al., 1992; Singer and Remillard, 2004) or bridges (Haviland and Clark, 1974) among the propositions underlying the discourse. A bridging inference is needed when the reader cannot retrieve a referent for the given information of the current sentence from either working memory or long-term memory.

Table 1 shows the taxonomy of inference making questions for diagnostic RC assessments, along with the examples. The first type is **pronominal**, and it has two variants. Simple pronominal asks for a direct pronoun resolution, such as "In the sentence, whom does 'he' refer to?" This is different from the second subtype: **pronominal bridging**, which requires the reader to use the pronoun as a hint to bridge sentences and answer the question. The third type **text-connecting** requires test takers to connect two explicitly stated components in a text, and usually the bridge are noun phrases. The last type is **gap-filling**, which requires readers to

Types	Definitions	Examples
Pronominal	Direct pronoun resolution.	Like "To whom 'he' refers?", "What does 'this' represent?"
Pronominal Bridging	Use pronoun as a hint to bridge sentences.	Text snippet: <i>Ships have carried passengers since prehistoric times. That is the first kind of public transportation.</i> Question: <i>What was the first kind of public transportation in history?</i> Answer: <i>ships</i> Reasoning: <i>The pronoun "That" refers to "ships" in the previous sentence.</i>
Text-Connecting	Connecting two explicitly stated components in a text, typically through a noun phrase.	Text snippet: <i>Public transportation is good for the environment. When many people use the same vehicle, fewer cars are on the road. Fewer cars make less pollution.</i> Question: <i>Why is public transportation good for the environment?</i> Answer: <i>Because it causes less pollution</i> Reasoning: <i>"Fewer cars" links to "public transportation" from the previous sentence in a causal relationship.</i>
Gap-Filling	"Incorporating information outside of the text, i.e., general knowledge, with information in the text to fill in missing details." (Cain and Oakhill, 1999, p.490)	Text snippet: <i>White pizza uses no tomato sauce, often substituting pesto or dairy products such as sour cream. Most commonly, its toppings consist only of mozzarella and ricotta cheese drizzled with olive oil and basil and garlic.</i> Question: <i>What is a possible reason "White pizza" gets its name?</i> Answer: <i>It doesn't have tomato sauce</i> Reasoning: <i>Readers need to use common sense to fill in the gap that "no tomato sauce" means the color of the pizza is not red.</i>

Table 1: Taxonomy of inferences for Reading Comprehension questions.

incorporate information from outside of the text with information in the text to fill in some missing details. More examples based on the taxonomy are included in Appendix A.

3.2 Validation of Taxonomy

With the newly developed taxonomy, we annotated the RC items in an in-house item-bank. The item-bank has 192 expert-written multiple-choice RC questions for 24 expository reading passages. These passages vary in difficulty from Grade 3 to Grade 12. Our primary focus was to classify the types of bridging inferences, but we also annotated questions that are not in our main scope of interest. For example, there are some **factual/literal** questions, for which a test taker can directly find information from the text without involving inference; **vocabulary** questions that directly assess the vocabulary knowledge, and other comprehension questions that do not require bridging inferences.

Two of the co-authors classified items independently, following the annotation guideline (see Appendix B). The two coders provided the same coding of the type of inference on 86% of the items, with kappa = 0.83, indicating high agree-

Figure 2: Distribution of different inference types in an operational reading comprehension item bank.

ment. Based on our annotation results shown in Figure 2, we find that bridging inference questions account for 51% of the RC items in the item bank, suggesting bridging inference is an important sub-construct in this RC assessment. Among the bridging inference questions, pronominal bridging (24%) is the most dominant type, followed by text-connecting (10%), gap-filling (9%), and pronominal questions (8%). The high level of agreement supports the validity of the newly developed taxonomy, which we see as an important contribution—

providing a road-map for both item development and future research.

4 Automatic Item Generation and Human Evaluation

Figure 1 presents the overview of our automatic item generation pipeline.

4.1 Training Questions

Due to test security considerations we can not use texts and items from our operational item bank as examples to prompt LLMs. Thus, we created our example item bank which is publicly available for replication efforts². We adapted 6 new expository passages from Simple English Wikipedia³ (passage length ranges from 342 to 508 words, average 438) and for each passage we manually created 2-4 items for each type of inference. Each question contains a **stem**, four **options**, and an answer **key** indicating which option is correct. We also included our thought process in the item generation: **text hint** includes the relevant text from the passage where required inference will be made, and **reasoning** is a short explanation why this question belongs to the requested type. In total, we wrote 19 pronominal bridging, 23 gap-filling, and 16 text-connecting questions.

4.2 Few-shot Prompting

We used the GPT-4o model (2024-04-01-preview) to generate multiple-choice RC questions based on passages we supplied to the model. To prioritize accuracy and reproducibility in item generation, we set the temperature parameter to 0. We explored the frequency penalty parameter from 0 to 0.3, with 0.2 proving optimal as it could consistently generate three diverse RC items without compromising their quality.

Few-shot prompting techniques were used and the prompts were iteratively refined over six rounds. Most adjustments focused on improving the concreteness of the question-writing steps to better guide the model. In this paper, we only report the final iteration of item generation in which we experimented with four different prompting conditions: standard prompting with 4 (or 6) passages and examples, and chain-of-thought prompting with 4 (or 6) passages and examples with text hint and reasoning. With this set-up, we investigated whether

²<https://github.com/maafiah/InferenceQuestionsAQG>

³<https://simple.wikiedia.org>

Task: Given a passage, you are going to generate pronominal bridging inference questions.

Follow these steps to answer the user queries.

Step 1 - find a pronoun (it, they, she, he, which, that, etc) in the passage that is connecting AT LEAST 2 or 3 sentences. The pronoun should be crucial to bridge meaningful information from the passage such as a fact, a cause, a result, or a feature.

Step 2 - based on the pronoun and its reference, generate a multiple-choice question with three distractors. The question should use the pronoun and its reference as hints to connect information between sentences.

Step 3 - follow additional rules when writing the questions: 1) do not ask a question that requires background knowledge to answer. 2) do not ask a question that directly asking "what does XX refer to". 3) lightly paraphrase the question and option without introducing new inference. 4) do not write correct answer longer than the distractors.

Step 4 - iterate this process for 2 times to get 3 different questions.

Step 5 - Output by following the exact format as examples so that it can be directly converted to csv format (do not have any title like (**questions**)). Include all the sentences required in the 'Text Hint' and output your thought process in the 'Reasoning'.

Here are some example passages and example questions:

*****Given passage:*****
A greenhouse is a building where plants such as flowers and vegetables are grown. It usually has a glass ...

*****Examples:*****
 PassageName\Inference Type
 \Text Hint\Reasoning
 \Stem\Option 1\Option 2\Option 3\Option 4\Key
 Greenhouse\pronominal bridging
 \A greenhouse is a building where plants such as flowers and vegetables are grown. It usually has a glass or translucent plastic roof.\the pronoun "it" refers to "greenhouse" in the previous sentence.
 \According to the passage, what can have translucent plastic roofs?\backyards\living spaces\greenhouses \botanic gardens\3
 ...

*****New Passage:*****
Parallax is the perceived change in position of an object seen from two different places ...

Figure 3: **Few-shot prompt for generating pronominal bridging inference questions.** The system prompt (beige background) defines the inference type and outlines expert-inspired steps. Training examples (provided in the prompt) follow. In the standard condition, only the question and answer key (green) are shown; in the CoT condition, text hints and reasoning (blue) are also included. A new passage is provided in the user prompt (orange background) to generate new questions.

increasing the training examples or using the CoT strategy would improve the quality of generation. Moreover, we further evaluated if the output rea-

Criterion	Annotation Guidelines
General item quality	1: If the generated item satisfies all of the following: (a) The correct answer is fully correct; (b) Distractors are not confusing and are clearly incorrect; (c) The question is developmentally appropriate and safe for Grades 3–12. 0: If any requirement is not met. Provide an explanation in the "Note" field.
Inference-type accuracy	1: If the generated item matches the requested inference type. 0: If not. Output inference type, one of: gap-filling / pronominal bridging / text-connecting / factual or literal.
Reasoning quality	1: If the generated thought process fulfills both of the following: (a) The "Reasoning" is adequate and relevant to the requested inference type; (b) The "Text Hint" includes all the sentences required to answer the item correctly. 0: If either condition is not satisfied.

Table 2: Annotation guidelines for evaluating the generated items.

soning process was adequate for this specific task.

Figure 3 shows an example prompt for generating reading comprehension questions targeting pronominal bridging inference (see Appendix C for more details). In the system prompt, we first instructed GPT-4o to identify pronominal bridging relationships, then directed it to generate a multiple-choice question, guided by additional rules to ensure item quality. We included several training examples in the prompt—either 4 or 6 passages with corresponding questions, depending on the generation condition. For the Standard condition, no text hints or reasoning were provided in the training examples. In the CoT condition, both text hints and reasoning were provided, prompting the model to generate them in the output. In the user prompt, we provided a new passage for GTP-4o to generate items from.

We curated a total of 10 new passages adapted from Simple Wikipedia, which were comparable in length and format to the example passages. For each passage and inference type (pronominal bridging, text-connecting, and gap-filling), we independently applied the prompting procedure, instructing GPT-4o to generate three unique questions per combination. For text-connecting and gap-filling—where question construction can be more challenging—we included an additional rule: "Do not force additional questions if no suitable locations can be found." Across the four prompting conditions, we generated a total of 357 questions, 180 of which were produced under the CoT condition and therefore included text hints and reasoning in the output.

4.3 Human Evaluation

To evaluate the quality of the generated RC items, we developed an evaluation rubric (see Table 2). Three authors used items from prior iterations of the generation process and complete several practice rounds and discussion before finalizing the rubric. The rubric is designed to directly address our core research questions:

RQ1: Can LLMs generate high-quality RC items with appropriate distractors suitable for inclusion in an operational item bank?

RQ2: Do the generated RC items align with the requested bridging inference type?

RQ3: How well can LLMs reason about their generation process?

In the evaluation phase, the three authors, who are experts in reading assessment questions, independently annotated all 357 generated items. The agreement was high for general item quality (RQ1), with percent agreement ranging from 87–90%. However, reaching consensus on the inference type (RQ2; 69–70%) and reasoning quality (RQ3; 65–71%) proved more challenging—consistent with prior findings that reasoning-related judgments are inherently difficult to rate (Stasaski et al., 2021).

To address this, we conducted a second round of annotation. In this phase, each rater independently reviewed only the items where their initial rating differed from the other two and decided whether to adjust the rater’s original score. Following this adjustment, inter-rater agreement improved substantially. The final results of percentage agreement and Fleiss’ kappa are shown in Table 3. Our

<p>Requested Type: Gap-filling</p> <p>Text Hint: The main way carbon gets taken out of the atmosphere is by photosynthesis by living organisms.</p> <p>Reasoning: requires common sense to know that photosynthesis is performed by plants.</p> <p>Question: Which organisms play a crucial role in removing CO2 from the atmosphere?</p> <p>Options: animals/ bacteria/ plants/ fossil fuels</p> <p>Key: 3</p> <p>Rating: high quality, correct inference type, and correct reasoning.</p>	<p>Requested Type: Text-Connecting</p> <p>Text Hint: Doughnuts are often eaten in the morning, along with a cup of hot coffee. They are sold at doughnut shops, bakeries, or grocery stores.</p> <p>Reasoning: "doughnuts" and "doughnut shops" are linked thematically."</p> <p>Question: Where can people buy doughnuts?</p> <p>Options: At a coffee shop/ At a doughnut shop/ At a restaurant/ At a candy store</p> <p>Key: 2</p> <p>Rating: low quality because multiple keys can be correct. The question has incorrect inference and reasoning. The question can be categorized as pronominal bridging, as "they" refers to "doughnuts," or as factual/literal, since "doughnut shops" directly refers to places where doughnuts are sold.</p>
---	--

Figure 4: Examples of LLM-generated RC items via Chain-of-Thought prompting with 6 training passages. Left: high-quality; right: low-quality. Each output includes a text hint, a rationale, a multiple-choice question with four options, and an answer key. Human annotations are shown against a beige background.

Criterion	Agreement (%)	Fleiss' κ
General item quality	90–97	0.57
Inference-type accuracy	85–94	0.77
Reasoning quality	90–95	0.83

Table 3: Inter-rater agreement and Fleiss' κ for each evaluation criterion. Agreement is reported as a range based on three pairwise comparisons by three graders.

evaluation in the Results section were based on the majority votes for each item. For example, an item was treated as acceptable when at least two of the three raters rated it as good quality.

5 Results

Based on the proportion of accepted items by generation method (Table 4), we observe improved generation performance when increasing the number of training examples from four to six example passages in the prompt. However, our experiment does not show any clear advantage of Chain-of-Thought prompting over standard few-shot prompting. Furthermore, our results indicate no statistically significant differences in generation performance across the various prompting conditions. We summarize our key findings below.

LLMs can produce high-quality questions suitable for operational use. Based on the evaluation of general item quality, 87 out of 90 questions (96.7% in the CoT_6 condition) had good quality and were suitable for operational use in the Grade 3-12 educational context. The performance is com-

Generation Method	Num Items	General Item Quality	Inference Accuracy	Reasoning Quality
standard_4	88	0.932	0.409	
standard_6	89	0.955	0.461	
CoT_4	90	0.900	0.411	0.356

Table 4: Proportion of accepted items by generation method—standard vs. chain-of-thought prompting (with text hints and reasoning), using 4 or 6 passages (12–18 examples). Highest scores per criterion are bolded; criteria are defined in Table 2.

parable to, if not better than, those reported in prior research evaluating overall item quality for RC assessments, which ranged from 75% to 90% (Kulshreshtha and Rumshisky, 2022; Uto et al., 2023; Säuberli and Clematide, 2024). Because of the differences between these studies, for a more informative comparison, we encourage future research to replicate our findings under similar conditions. Figure 4 presents one high-quality example and one low-quality example of the generated questions. We find that problems of unacceptable questions included multiple keys, introduction of new vocabulary, confusing wording of the question, etc.

Generating RC questions by specific inference type is a challenging NLP task. Although LLMs can generate high-quality RC items, their ability to produce questions targeting specific inference types remains limited. In the generation method yield-

Figure 5: Human evaluation of inference-type accuracy. Each panel displays the distribution of true inference types corresponding to each requested inference type. The generation questions are obtained from the standard few-shot prompting with 6 training passages.

Figure 6: Comparison of item inference type coverage between the operational item bank and the LLM-generated item bank.

ing the best performance (standard_6), only 46.1% of the generated questions matched the requested inference type. As shown in Figure 5, gap-filling questions were the easiest to generate (60% match), followed by pronominal-bridging questions (53.3% match). In contrast, generating text-connecting questions proved particularly difficult, with an accuracy of only 24.1%. This pattern of generation difficulty aligns with the challenges faced by human experts (co-authors) when writing the training examples. We also find that 34.8% of the generated questions were factual or literal, requiring little inference. Moreover, GPT-4o provided adequate reasoning for only 38.9% of the items. This finding may explain the lack of performance gains when moving from standard prompting to CoT prompting. While prior work has shown that adding structured rationales can improve the accuracy of multi-

hop question generation (Säuberli and Clematide, 2024), we believe our task poses a more challenging test of an LLM’s reasoning ability.

Automatic item generation with human evaluation ensures the quality of diagnostic RC items.

From an application standpoint, we also examined how closely the distribution of inference types in the generated items resembled that of human-written items from our operational RC item bank. Interestingly, our analysis, shown in Figure 6, reveals that the overall distribution of inference types in the LLM-generated items closely matches that of our operational RC item bank. This means whereas GPT-4o failed to consistently produce individual items targeting specific inference types, the collect of items it generated somehow resembles the distribution of item types in our existing item pool. With some expert review, most of these items are suitable to use. Understanding the strengths and limitations of current LLM performance is important, particularly if we aim to rely on human evaluation to ensure quality and safety. The generation process is considerably more scalable than relying on human experts to write items manually. Despite current limitations, LLM-based item generation with our newly developed taxonomy offers a promising approach for educational applications.

6 Conclusion

This paper demonstrates our effort in leveraging a large language model to generate inference-making questions for a reading comprehension assessment. We developed a taxonomy of bridging inference questions based on existing literature and validated

it with empirical data from an operational test. The taxonomy focuses on three types of inferences: pronominal bridging, text connecting, and gap-filling. The taxonomy guided our manual creation of example comprehension questions, which were then used as training materials for GPT-4o to generate new items for the new passages. Our evaluation indicates that although GPT-4o can produce acceptable RC questions, its ability to generate questions aligned with specific inference types was limited. This limitation might stem from its limited capability in providing valid reasoning for the types of inferences. These results highlight the critical role of human evaluation when using LLMs for RC question creation. We propose that combining automatic item generation with human judgment offers a promising path toward scalable, high-quality diagnostic RC assessments.

Limitations

We provide preliminary evidence for the potential of GPT-4o in creating inference making reading comprehension questions. The following limitations should be addressed by future research.

We have a limited evaluation set. Our evaluation relies on 10 expository passages (based on Simple Wikipedia), restricting the generalizability of our findings to broader reading contexts or varied educational materials. Future research should incorporate more passages and of different genres, such as narratives.

We exclusively use GPT-4o. This study employed only one LLM, GPT-4o, which may limit insights into the potential effectiveness of other advanced reasoning models. Given the challenge of this reasoning task, future research should explore additional models. Because more advanced models may incur significantly higher costs, future research should also consider the balance between performance and affordability for an educational application.

Unclear effectiveness of Chain-of-Thought prompting. Our results show that generation quality improves with more example questions. However, our experiment does not show benefits from CoT prompting. This unexpected finding may result from our limited number of training examples. Future studies should expand the training data and possibly utilize large datasets, such as SQuAD (Rajpurkar et al., 2016) and FairytaleQA (Xu et al.,

2022). Future work should also explore more effective methods for integrating human-experts' rationales into the question generation process and explore how it affects the reasoning performance of LLMs (Zelikman et al., 2022).

General item quality is a broad metric. Our main goal is to generate RC items that target specific inference types, so we grouped other aspects like answer correctness and distractor plausibility under a broad "General Item Quality" metric. Still, there are important dimensions we didn't separate out—like item difficulty and whether it's appropriate for the target population. More specific metrics could help pinpoint where generation errors happen and how inference type and item difficulty might interact.

Future work should focus on item evaluation in real-world deployment. Our study did not include pilot testing in real-world settings to evaluate how the generated items perform with actual student responses. Student response data would allow for further examination of item bias, difficulty, and discrimination—critical steps before using the items for student scoring and making valid inferences about their abilities (Yeatman et al., 2024). Using LLM-simulated student responses to evaluate generated items is also an exciting direction that could help reduce—but not replace—the need for traditional item calibration (Zelikman et al., 2023; Lu and Wang, 2024; Liu et al., 2025).

Ethics Statement

Our study goal is to leverage LLMs to develop scalable and effective RC assessments to align with educational practice. We introduce a novel and meaningful NLP task: generating RC questions by inference type. While LLMs show promise for item development, we emphasize the importance of maintaining test security by avoiding training models on operational test items, and by ensuring the safety of content such as developmental appropriateness and the absence of problematic materials. In addition to existing automatic benchmarks, human evaluation by educational experts remains essential for item quality. Though beyond our current scope, we also highlight the need for ongoing monitoring of the generated items to detect scoring biases and ensure fairness in operational use.

Acknowledgments

We appreciate the reviewers for their helpful feedback on the manuscript. A Bridging Inference Examples

When we developed the taxonomy of bridging inference, we referred to a sample passage and a list of example questions provided from [Cain and Oakhill \(1999, p.495\)](#). Table 5 presents our analysis of the given questions based on the taxonomy.

B Annotation Guidelines

To validate the newly developed taxonomy of bridging inference questions, we annotated an in-house RC item bank. Annotation was done with regards to the text and the questions including stem, key and distractors (see details in Table 6).

C Prompts

We present examples of our few-shot prompting design for pronominal bridging (Figure 3) text-connecting (Figure 7) and gap-filling (Figure 8) respectively. The rules are identical for both the standard and CoT prompts; the only difference is that CoT includes a text hint and reasoning in the training examples (see blue highlight in the figure). Accordingly, in the CoT condition, we expect the output to include a text hint and reasoning along with the generated questions.

Reading Passage:

Debbie was going out for the afternoon with her friend Michael. By the time they got there they were very thirsty. Michael got some drink out of his duffel bag and they shared that. The orange juice was very refreshing. Debbie put on her swimming costume, but the water was too cold to paddle in, so they made sandcastles instead.

They played all afternoon and didn't notice how late it was. Then Debbie spotted the clock on the pier. If she was late for dinner, her parents would be angry. They quickly packed up their things. Debbie changed and wrapped her swimming costume in her towel. She put the bundle in her rucksack. Then they set off for home, pedalling as fast as they could. Debbie was very tired when she got home, but she was just in time for dinner.

Question	Annotation
Literal information	
Who did Debbie spend the afternoon with?	The answer is in the first sentence. There is a partial paraphrase: "going out for" vs. "spend".
Where was the clock?	The answer is in the second sentence of the second paragraph.
Text-connecting inference	
Where did Michael get the orange juice from?	This requires bridging inference: <i>drink = orange_juice</i> . This is both a referential and semantic link (hypernym: drink – hyponym: juice). Recognizing this link requires background knowledge and both components are near each other in the text.
Where did Debbie put her towel when she packed up her things?	The answer is in sentences 5–6 of the second paragraph. This involves recognizing a part-whole relationship (towel–bundle), which is an ad-hoc, situational reference.
Gap-filling inference	
Where did Debbie and Michael spend the afternoon?	One component (afternoon) is in the text, but the location (the beach) is not. It must be inferred as a plausible missing piece of the situation model.
How did Debbie and Michael travel home?	The text says "set off for home" (a paraphrase of "travel"). The mode of travel is inferred from "pedalled", enriching the situation model.

Table 5: Analysis of a reading passage and associated reading comprehension questions with inference annotations. The passage and questions are adapted from Cain and Oakhill (1999, p.495).

Dimension	Options	Note
Inference	Factual / Literal	The answer is explicitly stated in the text, exactly matching the question. No inference needed.
	Pronominal	Resolving pronouns (e.g., "Who does 'he' refer to?").
	Pronominal Bridging	Requires resolving a pronoun and using it as a cue to infer the correct answer.
	Text-Connecting	Requires connecting two explicitly stated components, typically using noun phrases.
	Gap-Filling	Involves filling in a missing but easily inferred piece of information not directly stated in the text.
	Vocabulary	Tests the reader's knowledge of word meanings.
	Other	Any other type, such as comparison or author intent.

Table 6: Annotation guidelines for the in-house item bank.

Task: Given a passage, you are going to generate text-connecting inference questions.

Follow these steps to answer the user queries.

Step 1 - find two concepts (primarily nouns or noun phrases) that are connecting AT LEAST 2 or 3 sentences, but their relationship is not explicitly stated.
Please follow the rules:

- The two concepts should not contain any same word. Incorrect example: "the Ocean" and "Pacific Ocean" share a word "Ocean". Correct example: "flowers" and "rose".
- The two concepts should only exist in two different sentences.
- The second concept should not be a pronoun that explicitly refers to the first concept.
- there are different possible subtypes of text-connecting you may find from the passage:

Subtype 1: Coreference without a pronoun nor repetition (share word): This refers to instances where two or three sentences are linked together by two noun phrases in the passage that refer to the same real-world entity. Correct examples: "boys and girls" referring to "students" from the previous sentence, "manager" referring to the "CEO" from the previous sentence. Incorrect examples: "he" referring to "John" (as "he" is a pronoun), "the show" referring to "TV show" (because this is a repetition and they share the word "show", unless there is more than one show described in the passage).

Subtype 2: Whole-to-part relation. For instance, "mom" refers to "parent", "bride" can refer to the "wedding" from the previous sentence, and "walls" can refer to the "construction project" mentioned earlier.

Subtype 3: implicit causal relation without a clue word

Subtype 4: events happen in the same time, etc.

Step 2 - based on two concepts you have identified, generate a multiple-choice question with three distractors. The question should use the relationship between the two concepts as a hint to connect information between sentences.

Step 3 - follow additional rules when writing the questions: 1) do not ask a question that requires extra background knowledge beyond this identified text-connecting relationship to answer. 2) do not ask a question that directly asking "what does XX refer to". 3) lightly paraphrase the question and option without introducing new inference. 4) do not write correct answer longer than the distractors.

Step 4 - iterate this process for 2 times to get 3 different questions. Do not force to generate more questions if you cannot find more places.

Step 5 - Output by following the exact format as examples so that it can be directly converted to csv format (do not have any title like (**questions**)).

Here are some example passages and example questions:

*****Given passage:*****
A greenhouse is a building where plants such as flowers and vegetables are grown. It usually has a glass ...

*****Examples:*****
 PassageName\Inference Type
 \Text Hint\Reasoning
 \Stem\Option 1\Option 2\Option 3\Option 4\Key

Greenhouse\text-connecting bridging

\Many vegetables and flowers are grown in greenhouses in late winter and early spring, when it is still too cold to grow plants outside. Then these plants move into the soil outside as the weather warms up.

\""these plants"" links to ""many vegetables and flowers"" as a part to whole relation in the previous sentence."

\When do greenhouse vegetables and flowers move into the soil outside?\when the weather warms up\when heating is not working\in early spring\when there is no rain\1..

*****New Passage:*****
Parallax is the perceived change in position of an object seen from two different places ...

Figure 7: Few-shot prompting using Chain-of-Thought for generating text-connecting inference.

Task: Given a passage, you are going to generate gap filling inference questions. This question asks for a piece of information outside of the text, i.e. general knowledge, with information in the text to fill in missing details in the passage.

Follow these steps to answer the user queries.

Step 1 - Find a concept in the passage that you think general background knowledge will be required to comprehend the text. There are three possible subtypes:
 Subtype 1: two or three sentences are connected without a pronoun but by a common sense that is not stated in the passage.
 Subtype 2: infer the result from a given situation based on a stated causal relationship. for example :The passage implies that if, then _____. The result should not appear in the passage.
 Subtype 3: to give an example based on the characteristics inferred from the text. for example: Which of the following could be an example of _____. Note that the example should not appear in the passage.

Step 2 - generate a multiple-choice question with three distractors.

Step 3 - follow additional rules when writing the questions: 1) do not ask a question that can be directly answered from the passage. 2) do not ask a question that directly asking "what does XX refer to". 3) do not write correct answer longer than the distractors. 4) the distractors should be incorrect and should not be confusing.

Step 4 - iterate this process for 2 times to get 3 different questions. Do not force to generate more questions if you cannot find more places. You don't need to generate each subtype.

Step 5 - Output by following the exact format as examples so that it can be directly converted to csv format (do not have any title like (**questions**)).

Here are some example passages and example questions:

*****Given passage:*****
A greenhouse is a building where plants such as flowers and vegetables are grown. It usually has a glass ...

*****Examples:*****
 PassageName\Inference Type
 \Text Hint\Reasoning
 \Stem\Option 1\Option 2\Option 3\Option 4\Key

Greenhouse\Gap-filling
 \Also, greenhouses can get very hot from the sun's heat, so gardeners have to make sure that it does not get too hot for the plants.
 Greenhouses usually have vents that can be opened to let excess heat out. Some greenhouses have electric exhaust fans that automatically turn on if it gets too hot in the greenhouse. A greenhouse is the place for tender plants such as tomatoes, cucumbers, and aubergines.
 \Infer the result from a given situation based on a stated causal relationship

\What is likely to happen if a greenhouse fails to control the heat in summer?\The greenhouse will grow more plants.\The greenhouse will become smaller.\Tender plants inside the greenhouse will not grow well.\Less gardeners will be needed to water the plants.\3

*****New Passage:*****
Parallax is the perceived change in position of an object seen from two different places ...

Figure 8: Few-shot prompting using Chain-of-Thought for generating gap-filling inference.

Investigating Methods for Mapping Learning Objectives to Bloom’s Revised Taxonomy in Course Descriptions for Higher Education

Abstract

Aligning Learning Objectives (LOs) in course descriptions with educational frameworks such as Bloom’s revised taxonomy is an important step in maintaining educational quality, yet it remains a challenging and often manual task. With the growing availability of large language models (LLMs), a natural question arises: can these models meaningfully automate LO classification, or are non-LLM methods still sufficient? In this work, we systematically compare LLM- and non-LLM-based methods for mapping LOs to Bloom’s taxonomy levels, using expert annotations as the gold standard. LLM-based methods consistently outperform non-LLM methods and offer more balanced distributions across taxonomy levels. Moreover, contrary to common concerns, we do not observe significant biases (e.g. verbosity or positional) or notable sensitivity to prompt structure in LLM outputs. Our results suggest that a more consistent and precise formulation of LOs, along with improved methods, could support both automated and expert-driven efforts to better align LOs with taxonomy levels.

1 Introduction and Motivation

Learning Objectives (LOs) define the knowledge and competencies students are expected to acquire through educational activities, for example: “By the end of this course, students will be able to identify examples of symbolism in short stories and incorporate symbolism in their writing” (from the description of the course of literary studies). These objectives provide a clear and measurable framework for educators to evaluate student progress and align course instruction with desired learning outcomes (Mager and Peatt, 1962; Rodriguez and Albano, 2017; Fink, 2003).

LOs are articulated in course descriptions, which outline instructional activities, intended outcomes, and assessment methods for the course. The development of LOs follows the “Theory of Constructive

Alignment” (Biggs, 1996), ensuring that teaching and assessment are directly aligned with the LOs. This alignment allows educators to create a coherent structure where every aspect of the course is designed to support students in achieving the desired outcomes (Wang et al., 2013b; Jaiswal, 2019).

Among various educational frameworks used for constructive alignment, Benjamin Bloom’s taxonomy (Bloom et al., 1956), later revised by Anderson and Krathwohl (2001), is widely recognized in higher education to guide the development and assessment of LOs mentioned in the course description. The revised version defines six hierarchical cognitive levels—Remember, Understand, Apply, Analyze, Evaluate, and Create—which serve as a guide for developing and assessing LOs. Bloom’s taxonomy provides a structured approach to categorizing LOs and ensures that they are appropriately mapped to cognitive levels and aligned with the intended educational goals (Arafeh, 2016; Dubicki, 2019). Furthermore, it facilitates the alignment of classroom assignments and exams with the intended cognitive levels (Sterz et al., 2019; Biggs et al., 2022).

The mapping of LOs and Bloom’s taxonomy levels is performed by educators, curriculum designers, and assessment centers as part of quality assurance processes, such as course accreditation (Randhahn and Niedermeier, 2017; Kultusministerkonferenz, 2017). However, manual LO mapping can be time consuming, labor intensive, and error-prone (Biggs, 1996; Reeves and Hedberg, 2003; Hussey and Smith, 2008). Large language models (LLMs) have shown promising capabilities in similar tasks, such as data annotation and classification (see e.g., Tan et al., 2024b) that offer promising potential to automate this process (Wang et al., 2024; Xu et al., 2024). Yet, their reliability and robustness remain open questions. In particular, they can be sensitive to prompt formulation and other design choices, and exhibit bias such as position bias, where out-

puts are influenced by their placement in a list, and verbosity bias, where longer responses are favored, or a tendency to generate rationales that align with previously provided labels, which may affect the reliability of their outputs (Shen et al., 2023; Koo et al., 2023; Wu and Aji, 2023; Stureborg et al., 2024; Chen et al., 2024; Tan et al., 2024a; Choshen et al., 2024). Moreover, it remains unclear whether LLMs offer a substantial advantage over non-LLM methods in this setting, or whether simpler, more cost-effective methods may suffice.

This work investigates the effectiveness of both LLM- and non-LLM-based techniques for automating LO-to-taxonomy mapping, and examines how prompt and task design influence LLM behavior. The key research questions are:

- RQ 1: How do LLM-based and non-LLM methods compare in effectiveness when mapping LOs to Bloom’s taxonomy levels?
- RQ 2: To what extent do experiment design choices influence the performance of LLM in mapping LOs, and do these variations reflect model bias or sensitivity to task framing?

2 Background and Related Work

2.1 Bloom’s Revised Taxonomy

Bloom’s cognitive process dimension defines six ascending levels of complexity: (Anderson and Krathwohl, 2001). **Remembering** involves recalling or recognizing knowledge from memory, such as definitions or facts. **Understanding** entails constructing meaning by interpreting, summarizing, and explaining information. **Applying** involves using learned material in new situations, often through models or simulations. **Analyzing** requires breaking concepts down into parts to understand their relationships. **Evaluating** involves making judgments based on criteria, exemplified by critiques or recommendations. Lastly, **Creating** is about generating new ideas or products by reorganizing elements in innovative ways, making it the most complex cognitive process. Each taxonomy level comes with a selection of verbs that define the expected learning outcomes. Examples can be found in Table 3 in the Appendix.

2.2 Pre-LLM Approaches to LO Mapping

Before LLMs, researchers explored methods such as keyword dictionaries (Chang and Chung, 2009), TF-IDF-based classifiers (Echeverría et al., 2013),

and supervised machine learning models (Waheed et al., 2021; Mohammed and Omar, 2020). Most of these efforts focused on short texts such as exam or discussion questions, and while models showed promise at lower cognitive levels like “Remember,” performance dropped significantly for higher-order categories. A notable large-scale study by Li et al. (2022) introduced a dataset of over 21,000 manually labeled learning objectives and evaluated both traditional and BERT-based classifiers, reporting strong performance but relying on single-skill LOs.

2.3 LLMs for LO Mapping & Alignment in the Educational Domain

LLMs are increasingly being integrated into educational contexts. Research assessing GPT-4’s mastery according to Bloom’s taxonomy in answering psychosomatic medicine exam questions demonstrated that while the model yielded an average score of 92 % in high-order cognitive levels, it still encounters difficulties at low-order cognitive levels such as “Remember” and “Understand,” where it sometimes fails to recall specific details or correctly interpret conceptual relationships (Herrmann-Werner et al., 2024).

Al Ghazali et al. (2024) conducted a case study examining ChatGPT’s effectiveness in teaching chemistry to eleventh-grade students, employing Bloom’s taxonomy to categorize LOs and evaluate student performance in answering course-related questions. They found that, although the model performed well in knowledge recall and reasoning skills, it struggled with maintaining student engagement and achieving comparable outcomes to traditional teaching methods. Meanwhile, Maity et al. (2024) evaluated the efficacy of GPT-4 Turbo in generating educational questions aligned with Bloom’s taxonomy, revealing that while the model can generate questions for high-order thinking skills, its effectiveness varies between different cognitive levels, and the model demonstrates difficulties in crafting high-quality questions at more advanced taxonomy levels, such as “Create”.

Our task of mapping LOs to Bloom’s taxonomy is a multi-label classification problem. However, unlike standard classification tasks typically addressed with LLMs (see, e.g., Niraula et al., 2024; Reddy et al., 2024; Li et al., 2024), our problem poses unique challenges that go beyond standard tasks. While classification tasks typically rely on detecting surface-level features or patterns in the text, Bloom’s taxonomy requires an in-depth se-

semantic understanding of the cognitive processes implied by the LO. For example, distinguishing between “Understanding” and “Applying” involves subtle differences in the LO’s intents, such as whether the task involves interpreting information versus using it in a new context. Furthermore, the hierarchical nature of Bloom’s taxonomy adds an additional layer of complexity, as higher-order categories (e.g., “Evaluating” or “Creating”) often overlap with or build upon lower-order processes. This requires not only a fine-grained contextual analysis, but also a deep understanding of the underlying pedagogical framework.

3 Task and Evaluation

To create a gold standard dataset of LOs mapped to the corresponding levels of Bloom taxonomy, we collected LOs from university course descriptions. Given an LO like “Students should be able to recite the key principles of Newton’s laws of motion and analyze a given set of data to determine how well it demonstrates Newton’s laws in action” (from a Physics course), experts in pedagogy might map this LO to both “Remember” and “Analyze” levels (the data collection is described in Section 4). These expert mappings were used to create the gold standard dataset, and we report Krippendorff’s α (Krippendorff, 2004) to measure agreement.

We then evaluate the reliability of automatic methods in producing similar LO mappings as the experts, using both non-LLM (as baseline) and LLM-based methods. We compare the results from both LLM and non-LLM methods against the gold standard annotations and report the weighted F1 score as well as the different frequency distributions for each taxonomy level produced by the different methods.

The evaluation of LLM-based methods was additionally aimed at testing their robustness. We therefore present the LLMs with different formulations of the task to examine whether any biases manifest during the LO mapping process. With this goal, we compute agreement and correlations between the answers provided by LLM-based methods, model confidence (by analyzing the log probabilities retrieved from the model), and semantic similarity measures between the models’ generated rationales to assess their consistency.

Table 1: Overview of collected course descriptions across various academic subjects. Each course description contains one learning objective section.

4 Data Acquisition

4.1 Data Collection and Preprocessing

We collected a total of 35 LOs from course descriptions¹ from the websites of German universities, comprising 25 bachelor-level and 10 master-level course descriptions. These descriptions present a diverse range of academic subjects and degree levels, as shown in Table 1. Even though the language of instruction was English, some of the course descriptions were only available in German.

We focus on the “learning objective” section of the course descriptions, which also exist internationally under different names such as “learning outcomes” or “course objectives”. We translated the course objectives from German into English using the DeepL API² and asked a bilingual person to revise them to ensure the correctness of the translations. The pre-processing of the collected data involved basic text-cleaning tasks to ensure consistent formatting.

4.2 Expert Annotation

We recruited five experts in higher education pedagogy to annotate the LOs. Each expert was provided with a combination of course titles and the corresponding LOs, along with the six levels of Bloom’s taxonomy. Their task was to identify and select all relevant taxonomy levels as shown in Figure 1 (full task instructions are reported in Figure 3 in the Appendix). We collected demographic information to evaluate the participants’ expertise and familiarity with Bloom’s taxonomy. All experts reported a high level of familiarity, with one with

¹The dataset including the 35 LOs and their annotations will be publicly released to support further research in this domain.

²<https://www.deepl.com/>

1–3 years of experience, two having 3–6 years of experience, and two having more than 6 years of experience.

Course Title: Greek History

Learning Objective:
Students will gain an overview of Greek history. After completing the module, they will be able to examine the sources and evidence from this period, place them in a wider historical context, and evaluate them.

Question: Which taxonomy levels are relevant to the given learning objective?

- Remember
- Understand
- Apply
- Analyze
- Evaluate
- Create

Figure 1: Sample task presented to expert annotators from the questionnaire.

We report Krippendorff’s α as a measure of inter-annotator agreement, calculated across all Bloom’s taxonomy levels for the entire set of LOs. Given one LO and a pair of annotators, we define as cases of agreement for each level all cases where both annotators either selected that level or did not select it, and as cases of disagreement all cases where one annotator did select that level but the other one did not. We obtained an α of 0.76. While this reflects a reasonably high level of agreement, one annotator noted a challenge with certain LOs:

“Many LOs focus more on the learning process itself (e.g., imparting foundational knowledge) rather than describing the competencies students should have achieved by the end of the learning unit. As a result, some of the commonly used verbs were not applied, making it somewhat difficult for me to classify them within the taxonomy levels. I was also uncertain about how to categorize the verb ‘reflect’.”

This issue is evident in the example, “Knowledge of basic literary categories and methods of interpretation along with a familiarity with fundamental questions of Greek literary history to deal critically with scientific questions and present their own

scientific results.” (Greek Literature I). While all annotators agreed on “Remember”, four selected “Analyze” and “Create”, three selected “Evaluate”, two selected “Understand” and “Apply”. For comparison, a literature-related LO from the dataset introduced by Li et al. (2022) reads: “A basic understanding of the main periods, styles, genres, intellectual preoccupations and socio-historical trends in German literature from the late eighteenth century to the early nineteenth century.” This was labeled as “Understand”, highlighting a key distinction that; although small in quantity, our dataset includes more abstract, multi-layered objectives that often span multiple levels of Bloom’s taxonomy, even challenging experts to reach consensus.

Finally, to create the gold standard annotations, we selected for each LO the taxonomy levels where at least three annotators agreed on a taxonomy level. The distribution of selected taxonomy levels in the gold standard labels is shown in Figure 2.

5 Automatic Methods for Mapping LOs to Bloom’s Taxonomy Levels

5.1 Non-LLM Mapping Methods

For non-LLM methods, we made use of regular expressions (regex), fuzzy matching³, the SpaCy library (Honnibal et al., 2020), and semantic similarity. We used Bloom’s identified set of measurable verbs that are linked to each taxonomy level to help the LO mapping process (Bloom et al., 1956; Anderson and Krathwohl, 2001), as shown in Table 3 in Section A of the appendix.

Figure 2: Distribution of gold standard annotations across taxonomy levels.

As an initial step, we applied **regex** and **fuzzy matching** to perform simple string matching of these verbs to their corresponding taxonomy levels. Every subsequent step aimed to address the limitations of the previous approach. Next, we used **spaCy**’s Part-of-Speech (POS)⁴ tagging and

³<https://pypi.org/project/fuzzywuzzy/>

⁴<https://spacy.io/usage/linguisticfeatures#pos-tagging>

dependency parsing⁵ capabilities. We began by segmenting the LOs into smaller sentence fragments using spaCy’s Sentencizer⁶, which produced **159 segments** from the 35 collected LOs. These segments were not only used for spaCy and semantic similarity methods but also all LLM-based approaches. POS tagging was applied to identify verbs in each segment, while dependency parsing provided additional grammatical context, improving the accuracy of verb identification by analyzing sentence structures. Following this, we applied regex to match the identified verbs against a pre-defined list of Bloom’s Taxonomy verbs for LO mapping.

Finally, we used **semantic similarity techniques**, comparing LOs directly with detailed descriptions of Bloom’s taxonomy levels, as outlined in Anderson and Krathwohl (2001), instead of relying solely on verb lists. The Sentence-BERT model (Reimers and Gurevych, 2019)⁷ was employed to measure semantic similarity between LO segments and the taxonomy-level descriptions. For each segment, the model calculated similarity scores to determine the best match.

5.2 LLM Mapping Methods

We utilized OpenAI’s GPT-4 model⁸ (OpenAI, 2023) and treated the model as an annotator. To prompt the model, we were inspired by tasks typically presented to human annotators, including multiple choice selection, pairwise comparison, best-worst scaling, binary annotation, ranking, and rating (Wang et al., 2013a; Bragg et al., 2018; Huynh et al., 2021). We presented a variety of tasks: multiple choice selection with paraphrase prompting and rationale generation (MCS), pair-wise comparison (PWC), best-worst scaling analysis (BWS) (Cohen, 2003; Louviere et al., 2015), binary annotation using a yes/no check with confidence analysis (BCA), and rating using point-wise relevance rating with confidence analysis (RCA), which is described in the subsequent paragraphs. Refer to Appendix Section D for the prompts used for each method.

To perform **MCS**, we collected paraphrases of Bloom’s taxonomy levels from educational resources (see Appendix Section C), resulting in four

⁵<https://spacy.io/usage/linguisticfeatures#dependency-parse>

⁶<https://spacy.io/api/sentencizer>

⁷https://www.sbert.net/docs/usage/semantic_textual_similarity.html

⁸The temperature was set to zero for all LLM-based methods.

paraphrased versions for each level in addition to the original descriptions from Anderson and Krathwohl (2001). Paraphrases aimed at ensuring that the model’s selection was guided by the conceptual meaning of each taxonomy level, rather than the specific phrasing of the taxonomy descriptions. We applied MCS to the segmented LOs described in Section 5.1, providing each segment along with the course title and one paraphrased version of Bloom’s taxonomy level descriptions for each level. The model was prompted to select the relevant category out of the six taxonomy levels, and their descriptions were provided as choices. We also asked the model to provide a rationale, with the specific prompt sequence varying according to the conditions outlined below:

- **Condition A:** isolates the task of rationale generation and the multiple-choice selection of the relevant taxonomy levels.
- **Condition B:** The model first generated a rationale and then selected the relevant taxonomy levels based on that rationale.
- **Condition C:** The model was prompted to choose relevant taxonomy levels first and then generate a rationale based on its choices.

We employed the same prompt for all conditions but altered the task sequence in Conditions B and C, and separated rationale generation from multiple-choice selection in Condition A. Then, we collected and normalized responses for each condition, removing any non-relevant values. Segments of each LO were aggregated back into the original LO, compiling selected taxonomy levels into a list with removed repetitions.

Moreover, we compared PWC and BWS results. **PWC** involved prompting the model to choose from two taxonomy levels—which could still be influenced by position bias, despite our efforts to mitigate it by varying the sequence. We generated unique pairs of taxonomy levels combined with segments from the LOs. With 6 taxonomy levels, we created 30 unique pairs (15 [A,B] and 15 [B,A] pairs) for all 159 segments, leading to 4770 pairs for evaluation. For **BWS**, we created 3-tuples from the 6 taxonomy levels, resulting in 20 unique 3-tuples per segment and 3180 distinct 3-tuples in total. We prompted the LLM to select the most and least relevant taxonomy level from the tuple. For both methods, scores were calculated based on

Category	Method	F1 score
non-LLM	regex	0.52
	fuzzy matching	0.54
	spaCy	0.45
	semantic similarity	0.50
LLM	MCS (condition A)	0.67
	MCS (condition B)	0.68
	MCS (condition C)	0.68
	PWC	0.60
	BWS	0.69
	BCA	0.66
	RCA (short)	0.66
RCA (long)	0.68	

Table 2: Weighted F1 scores for non-LLM and LLM methods.

the frequency of choices. We then identified the highest-scoring taxonomy level as the most relevant for each segment and aggregated across sentences to determine the most relevant levels for each LO.

Finally, the **BCA** method involved a binary relevance evaluation of each taxonomy level for the LO segments, whereas the **RCA** method required the model to rate the relevance of each taxonomy level on a scale from 1 (least relevant) to 5 (most relevant). Additionally for both methods, we estimated the model’s confidence in its decision by collecting log probabilities from the “logprobs” parameter of OpenAI’s Chat Completions API⁹. By calculating linear probabilities from these logprobs, we evaluated the model’s confidence levels, with higher scores indicating greater confidence. For BCA, we only collected the taxonomy levels where the linear probability was over 90 % for “Yes” answers.

To investigate verbosity bias in the RCA task, we calculated the number of tokens in the five paraphrases using spaCy’s tokenizer¹⁰. We identified the longest (1014 tokens) and shortest (775 tokens) paraphrases and prompted the model to rate the taxonomy levels. Logprobs were collected for both rating rounds to assess the impact of paraphrase length on ratings. For this analysis, we only considered taxonomy levels for which the model gave a rating of “5 (most related)”.

6 Results

6.1 Comparison with Expert Annotations

Weighted F1 scores for non-LLM and LLM methods are presented in Table 2. An example of the mapping result can be found in Figure 11 and Table

⁹https://cookbook.openai.com/examples/using_logprobs

¹⁰<https://spacy.io/api/tokenizer>

4 in the appendix.

Non-LLM Methods: As a first comparison with the gold standard, we compared the frequency of the selected taxonomy levels (Figure 12 in the Appendix). This frequency analysis shows a greater consensus between the human annotation and the other methods only for the “Evaluate” level, with high variability in other categories. This could be attributed to the fact that evaluation often involves more objective criteria and well-defined standards, such as assessing the validity of arguments or the accuracy of conclusions, which are less prone to interpretation compared to other taxonomy levels. Across all methods, “Apply” is the most frequently selected taxonomy level, while in general, the results show a large variance between the methods.

Regex and fuzzy matching achieved slightly higher F1 scores (0.52 and 0.54) than spaCy (0.45) due to their wider word capture, including nouns and adjectives, which inflates word frequency and taxonomy levels. spaCy, which focuses on verbs, is more selective and thus may miss some verbs, resulting in fewer mappings and lower F1 scores. The semantic similarity method (F1 = 0.50) offers flexible matching by emphasizing descriptions but can be less precise, leading to skewed results compared to human annotations.

LLM Methods: The F1 scores for LLM methods demonstrate better performance than non-LLM methods with BWS achieving the highest F1 score (0.69). The observed improvements highlight the potential of LLM-based approaches but also emphasize the need for deeper investigation into their consistency and reliability.

The frequency analysis (Figure 13 in the Appendix) reveals a more uniform distribution of taxonomy levels across the LLM methods when compared to non-LLM methods. However, when compared to the gold standard, LLM methods show a higher frequency of taxonomy levels across most categories. The exception is the “Remember” level, where the gold standard annotations have a higher value, though the difference is not substantial. Conversely, the “Create” level exhibits a significant variation: the gold standard has a markedly lower frequency (3) compared to LLM methods (Avg. 29). This indicates a notable discrepancy in how “Create” is represented in the gold standard versus the other methods.

The frequency distributions for the different methods are reported in Figures 14 (MCS), 15

(PWC), 16–17 (BWS) in the Appendix.

6.2 Consistency (LLM-Methods only)

MCS For the MCS method, we were interested in evaluating how consistent the rationales produced by the model were across different conditions and paraphrases of the taxonomy levels.

We used Sentence-BERT to calculate semantic similarity scores for the rationales provided for each learning objective, comparing across various paraphrases. The overall similarity score across all paraphrases was 0.92, with Condition A achieving a score of 0.94, while Conditions B and C each scored 0.92. These results indicate that the paraphrased wording has minimal influence on the outcomes, suggesting almost no bias for all conditions and paraphrases. For more details, refer to Table 5 in the Appendix.

PWC For the PWC method, we wanted to evaluate if the model showed a preference for levels in a specific position. We observed an intra-pair consistency of 86.79 % between the two different versions of the same item with a Cohen’s Kappa (Cohen, 1960) of 0.84. The model’s choices were categorized into three types:

- **“Left”**: The model selected the taxonomy level presented first in the pair.
- **“Right”**: The model selected the taxonomy level presented second in the pair.
- **“None”**: The model either did not provide a clear selection or returned a taxonomy level that did not match any of the expected options.

Among 159 segments, the distribution between “Left” (153 instances) and “Right” (154 instances) was nearly equal, excluding “None” responses and those not corresponding to the taxonomy levels, and a χ^2 -test (Pearson, 1900) yielded a p-value of 0.95, suggesting no statistically significant positional bias in the model’s choices, meaning that position does not significantly influence the model’s decision.

BWS For the BWS method, we were interested in evaluating how consistent the choices for the best and worst items in the 3-tuple were. After performing Cronbach’s α as a proxy for internal agreement within item triplets, which we used to estimate the internal consistency of the model’s preference orderings (Cronbach, 1951). Results

showed that the taxonomy levels like “Analyze” and “Understand” exhibit high consistency (0.84 and 0.69, respectively), indicating strong agreement in their classification. See Tables 6 and 7 for further qualitative in the Appendix.

BWS–PWC agreement The rank correlation between the BWS and PWC results reveals a lack of substantial agreement between the two approaches. The Spearman rank correlation coefficient (Spearman, 1904) is 0.169 with a p-value of 0.749, indicating a very weak and statistically insignificant positive correlation. Similarly, Kendall’s τ correlation coefficient (Kendall, 1938) is 0.086 with a p-value of 0.822, further suggesting minimal and non-significant agreement between the rankings produced by the two methods. Thus, these results suggest that the BWS and PWC methods do not produce comparable results, which is not entirely surprising, as the two methods differ in their approach to evaluating taxonomy levels.

BCA The BCA method yielded strong overall confidence in the model’s decisions, with an average linear probability of 0.956. In the subset of predictions where the model exhibited low confidence (with linear probabilities between 50 % and 60 %), the model produced “Yes” responses 56 times and “No” responses 44 times. Interestingly, most of these low-confidence predictions are associated with high-order taxonomy levels like “Create” and “Analyze,” suggesting that the model is less confident when handling more complex cognitive tasks. Moreover, the analysis of average confidence across taxonomy levels reveals that the model exhibits the highest confidence in its predictions for “Evaluate” (98.43 %) and “Create” (96.59 %). In contrast, while still high, the confidence for “Understand” (93.28 %) is slightly lower, reflecting the challenges in these areas. See Appendix Tables 8–10 in Section H.

RCA Finally, for the RCA method, we calculated the average linear probability for the short and long descriptions, which were 85.76 % and 83.03 % respectively, with minimum values of 37 % and 43 %. This indicates almost no difference in the model’s decisions between the short and long descriptions, with the average probability for the shorter description being slightly higher. Our results suggest no substantial verbosity bias, which may be attributed to the minimal difference in token length and the consistent use of associated verbs

with the taxonomies in both the shortest and longest paraphrases. See Figures 18–19 in the Appendix Section I.

7 Discussion

Non-LLM Methods: While prior research often assumes LLMs to outperform traditional NLP approaches, we include non-LLM baselines not merely for benchmarking but to reveal the types of errors these simpler systems make—especially regarding verb ambiguity and lack of contextual awareness. This diagnostic perspective is critical for understanding what specific challenges remain unsolved even by LLMs. Regex and fuzzy matching struggled with morphological and contextual variability (e.g., “design” fitting multiple taxonomy levels), while spaCy’s reliance on shallow parsing made it error-prone for compound objectives or those relying on deverbal nouns. Sentence-BERT, although semantically flexible, failed to resolve inferential tasks, such as distinguishing whether “critical thinking” corresponds to “Analyze” or “Evaluate.” These shortcomings underscore the limits of surface-level pattern recognition and basic lexical and semantic-level similarity in tasks requiring pedagogical reasoning.

LLM Methods: LLMs showed better ability to parse complex and implicit learning objectives, yet their strengths were uneven across taxonomy levels. Consistency analyses revealed high agreement for levels like “Understand” and “Analyze”—potentially due to clearer linguistic cues. However, lower agreement and confidence were found in “Remember” and “Create,” suggesting difficulty in anchoring either very low-level recall or high-level generative tasks. This could reflect both model limitations and ambiguities in how LOs are written by instructors.

The PWC and RCA methods further confirmed the model’s capacity to make consistent selections across different input formats, highlighting its reliability in both comparative and scalar evaluation tasks. In BCA, however, decreased confidence in “Create” and “Analyze” responses aligns with the annotation difficulties experts also expressed, pointing to shared challenges between human and machine reasoning in higher-order cognitive domains. For the BCA method, the model generally exhibited more difficulty with high-order taxonomy levels such as “Create” and “Analyze”. The MCS approach showed no significant differences in the

consistency of the rationale generated by the model were observed across different conditions. Compared to the gold standard, the observed discrepancies in the representation of “Create” highlight the need for more robust modeling and annotation practices for both ends of the taxonomy spectrum.

Bias and Robustness: Despite concerns raised in previous work regarding LLM susceptibility to framing-related biases, our results suggest that GPT-4 demonstrates a notable degree of robustness—though the presence of bias in other LLMs cannot be ruled out by this experiment alone. Specifically, we found no significant positional bias in pairwise comparisons (PWC). The nature of the taxonomy levels used in our study may have mitigated positional bias due to the clear distinctions between taxonomy descriptions. We also found no meaningful evidence of verbosity bias when comparing short and long taxonomy descriptions (RCA), which may be attributed to the minimal token length differences in the descriptions used. The model’s decisions remained stable across paraphrased prompts (MCS), further supporting its consistency. While not immune to uncertainty, particularly in assigning high-order categories like “Create”, the model’s behavior appears more influenced by the inherent complexity of certain taxonomy levels than by superficial prompt features. This contrasts with non-LLM methods, which exhibited more deterministic errors stemming from lexical surface features and lacked the inferential flexibility.

8 Conclusion

We analyzed various methods for mapping LOs to Bloom’s taxonomy levels, focusing on expert annotations compared to non-LLM and LLM techniques. non-LLM methods struggled with verb matchings and context-specific mappings. LLM methods generally demonstrated better performance and more uniform results. However, further improvement is necessary to address the challenges of LLM methods in automating the LO mapping process. Overall, we found that the LLM results from GPT-4 show minimal evidence of prompt-induced bias. These findings suggest that LLMs hold considerable promise in streamlining curriculum alignment tasks in educational settings, although careful design and validation remain essential to ensure pedagogical reliability.

Limitations

Firstly, utilizing LLMs, particularly closed-source models such as OpenAI's GPT-4, can be costly and lack transparency. Methods like BWS and PWC require multiple generations per item, which can become expensive at scale. Additionally, LLMs are susceptible to biases, including position bias, verbosity bias, and rationale-conditioning bias—where generating a rationale after a label may reinforce prior decisions. While our results did not show strong effects from these biases, we cannot entirely rule out their influence, especially since our study only examined GPT-4.

This reliance on a single LLM is a key limitation. GPT-4 was selected due to its strong performance and availability, but our findings may not generalize across other models. Future studies should replicate this analysis using different LLMs to assess robustness and uncover potential model-specific biases.

We also observed substantial but imperfect inter-annotator agreement among experts, reflecting the inherent ambiguity and interpretive nature of mapping LOs to Bloom's taxonomy. This suggests that ambiguities may originate from how LOs are written, and that more consistent instructional design practices could help. Mapping should ideally be integrated early in the curriculum development process, with educators selecting or revising LOs in alignment with desired cognitive levels.

Future work should also incorporate larger and more diverse datasets to enable broader generalization and better assessment of model behavior, and extend the study to additional languages such as German, whose linguistic structures may present unique challenges for LO classification.

Finally, while our evaluation focused on quantitative measures, integrating qualitative assessments—such as expert think-aloud protocols or post-task interviews (Creswell, 2009)—could offer deeper insights into both human and model reasoning. We encourage future research to explore hybrid workflows where LLMs and human experts collaborate to improve both mapping accuracy and pedagogical relevance.

Ethics Statement

To conduct human evaluations, we recruited five experts in higher education pedagogy, who were employed by one of our institutions and did not receive additional payment for the task. They took

part in the annotations voluntarily and could withdraw at any time. We did not collect personal or private information from the participants and ensured the confidentiality and anonymity of the annotators' responses.

				write	

Table 3: Sample possible verbs associated with Bloom's taxonomy levels from [Anderson and Krathwohl \(2001\)](#). The six categories—**Remember**, **Understand**, **Apply**, **Analyze**, **Evaluate**, and **Create**—are ordered from lower- to higher-order cognitive processes, with the first three considered lower-order and the last three higher-order thinking skills.

B Expert Annotation Task and Results

Aligning Learning Objectives with Bloom's Taxonomy Levels

Thank you for taking the time to participate in this questionnaire. Your insights will help us for a study on LLM-based annotation of learning objectives.

Task Overview:

1. **Goal:** You will be provided with a course title and a learning objective from a module handbook, along with the six levels of Bloom's Taxonomy. There are 35 learning objectives that you are asked to align with the Bloom's taxonomy levels.
2. **Task:** Identify which taxonomy levels align with the given learning objectives. More than one level may be relevant. Choose all the relevant taxonomy levels that correspond to the presented learning objectives.

Below, you'll find descriptions of Bloom's taxonomy levels with some examples.

Bloom's Taxonomy Levels and Descriptions:

1. **"Remember":** "Remembering involves locating knowledge in long-term memory that is consistent with presented material and retrieving relevant knowledge from long-term memory."

Examples:

- "List the steps of the water cycle from memory."
- "Identify and define key terms related to cellular respiration."

2. **"Understand":** "Understanding involves constructing meaning from instructional messages, including oral, written, and graphic communication. This includes changing from one form of representation to another, finding a specific example or illustration of a concept or principle, determining that something belongs to a category, abstracting a general theme or major points, drawing a logical conclusion from presented information, detecting correspondence between two ideas, objects, and the like, and constructing a cause-and-effect model of a system."

Examples:

- "Summarize the main arguments of the Enlightenment philosophers in your own words."
- "Interpret the results of a scientific experiment and explain the significance of the findings."

3. **"Apply":** "Applying involves carrying out or using a procedure in a given situation. This includes applying a procedure to a familiar or an unfamiliar task."

Examples:

- "Apply the principles of supply and demand to analyze a real-world market scenario."
- "Use statistical methods to analyze a data set and interpret the results in a research report."

4. **"Analyze":** "Analyzing involves breaking material into its constituent parts and determining how the parts relate to one another and to an overall structure or purpose. This includes distinguishing relevant from irrelevant parts or important from unimportant parts of presented material, determining how elements fit or function within a structure, and determining a point of view, bias, values, or intent underlying presented material."

Examples:

- "Break down the components of a literary work to explore the relationship between its themes and character development."
- "Analyze the causes and effects of economic inflation in a specific historical period."

5. **"Evaluate":** "Evaluating involves making judgments based on criteria and standards. This involves detecting inconsistencies or fallacies within a process or product, determining whether a process or product has internal consistency, and detecting the appropriateness or the effectiveness of a procedure for a given problem."

Examples:

- "Evaluate the strengths and weaknesses of different approaches to climate change mitigation."
- "Judge the credibility of sources used in a research paper on public health policy."

6. **"Create":** "Creating involves putting elements together to form a coherent or functional whole, reorganizing elements into a new pattern or structure, coming up with alternative hypotheses based on criteria, devising a procedure for accomplishing some task, and inventing a product."

Examples:

- "Design an innovative solution to reduce carbon emissions in urban areas."
- "Construct a theoretical model to predict the impact of new technology on society."

Example Task:

Learning Objective: "Students should analyze the causes and effects of climate change and evaluate the effectiveness of current environmental policies in addressing these issues."

Question: Which taxonomy levels are relevant to the given learning objective?

Levels:

- Remember
- Understand
- Apply
- Analyze
- Evaluate
- Create

Possible Choices:

- Analyze
- Evaluate

Consent and Privacy:

- Please note that we do **not** collect any personal information during this questionnaire. **No** email addresses or identifying data will be saved.
- Your responses are **anonymous** and will be used solely for the purpose of this research.
- You can add any comments or suggestions in the **comment section** at the end of the questionnaire.

Thank you for your participation. Your contribution is greatly appreciated.

Figure 3: Annotation instruction presented to the experts. Example learning objectives are adapted from various instructional design resources and author-generated.

Figure 4: This figure shows the frequency of selection of the six categories in Bloom's taxonomy by the five annotators. Categories like "Remember" and "Understand" show more consistency across annotators, indicating higher consensus in assigning these levels. However, categories like "Create" and "Apply" show notable differences, suggesting interpretive variability in assigning LOs to these levels. The differences may reflect subjective biases or varying interpretations of the taxonomy levels, especially for categories that require high-order thinking skills (e.g., "Create"). This variability could indicate areas where further discussion is needed among annotators to reach a more uniform understanding.

Figure 5: An example of high disagreement among expert annotators, driven by the complexity of the LO description provided by the educator for the course.

The learning objective blends several cognitive processes across Bloom’s taxonomy levels, making it challenging to determine the primary focus. “Acquisition of basic historical knowledge” aligns with **Remembering**, as it involves recalling historical facts and foundational knowledge. “Working technique” suggests **Applying**, since students are expected to practice and use specific methods in new contexts. “Analytical methodologies” leans toward **Analyzing**, as it requires breaking down examples of Greek language and literature into components, such as themes and structures, to better understand their function and meaning. Also, “focusing on the evolution of socio-political contexts” could be interpreted as **Understanding** (interpreting historical changes) or **Evaluating**, as it necessitates assessing the relationship between literature and its socio-political background.

Moreover, The connection between “historical knowledge” and “analytical methodologies” suggests a progression from lower-order skills (e.g., **Remembering** and **Understanding**) to higher-order skills (e.g., **Analyzing** and **Evaluating**). However, the LO does not specify which skill is prioritized, leading to annotators interpreting it differently based on their perspective. Finally, the inclusion of historical knowledge, literary analysis, and socio-political evolution adds a level of interdisciplinary complexity, as these dimensions often require varied cognitive processes to address.

C Paraphrases of Bloom’s Revised Taxonomy

- **Source:** Anderson and Krathwohl (2001)

- **Remember:** Remembering involves locating knowledge in long-term memory that is consistent with presented material and retrieving relevant knowledge from long-term memory.
- **Understand:** Understanding involves constructing meaning from instructional messages, including oral, written, and graphic communication. This includes changing from one form of representation to another, finding a specific example or illustration of a concept or principle, determining that something belongs to a category, abstracting a general theme or major points, drawing a logical conclusion from presented information, detecting correspondence between two ideas, objects, and the like, and constructing a cause-and-effect model of a system.
- **Apply:** Applying involves carrying out or using a procedure in a given situation. This includes applying a procedure to a familiar or unfamiliar task.
- **Analyze:** Analyzing involves breaking material into its constituent parts and determining how the parts relate to one another and to an overall structure or purpose. This includes distinguishing relevant from irrelevant parts or important from unimportant parts of presented

material, determining how elements fit or function within a structure, and determining a point of view, bias, values, or intent underlying presented material.

- **Evaluate:** Evaluating involves making judgments based on criteria and standards. This involves detecting inconsistencies or fallacies within a process or product, determining whether a process or product has internal consistency, and detecting the appropriateness or effectiveness of a procedure for a given problem.
 - **Create:** Creating involves putting elements together to form a coherent or functional whole, reorganizing elements into a new pattern or structure, coming up with alternative hypotheses based on criteria, devising a procedure for accomplishing some task, and inventing a product.
- **Source:** <http://www.nwlink.com/~donclark/hrd/bloom.html>
 - **Remember:** Remembering means recalling or retrieving previously learned information.
 - **Understand:** Understanding means comprehending the meaning, translation, interpolation, and interpretation of instructions and problems. State a problem in one's own words.
 - **Apply:** Applying means using a concept in a new situation or unprompted use of an abstraction. Applies what was learned in the classroom into novel situations in the workplace.
 - **Analyze:** Analyzing means separating material or concepts into component parts so that its organizational structure may be understood. Distinguishes between facts and inferences.
 - **Evaluate:** Evaluating means making judgments about the value of ideas or materials.
 - **Create:** Creating means building a structure or pattern from diverse elements. Put parts together to form a whole, with emphasis on creating a new meaning or structure.
- **Source:** <https://www.coloradocollege.edu/other/assessment/how-to-assess-learning/learning-outcomes/blooms-revised-taxonomy.html>
 - **Remember:** Remembering is retrieving, recalling, or recognizing relevant knowledge from long-term memory.
 - **Understand:** Understanding is demonstrating comprehension through one or more forms of explanation.
 - **Apply:** Applying is using information or skill in a new situation.
 - **Analyze:** Analyzing is breaking material into its constituent parts and determining how the parts relate to one another and/or to an overall structure or purpose.
 - **Evaluate:** Evaluating is making judgments based on criteria and standards.
 - **Create:** Creating is putting elements together to form a new coherent or functional whole; reorganizing elements into a new pattern or structure.
- **Source:** https://quincycollege.edu/wp-content/uploads/Anderson-and-Krathwohl_Revised-Blooms-Taxonomy.pdf
 - **Remember:** Remembering is recognizing or recalling knowledge from memory. Remembering is when memory is used to produce or retrieve definitions, facts, or lists, or to recite previously learned information.
 - **Understand:** Understanding is constructing meaning from different types of functions be they written or graphic messages or activities like interpreting, exemplifying, classifying, summarizing, inferring, comparing, or explaining.
 - **Apply:** Applying is carrying out or using a procedure through executing or implementing. Applying relates to or refers to situations where learned material is used through products like models, presentations, interviews, or simulations.
 - **Analyze:** Analyzing is breaking materials or concepts into parts, determining how the parts relate to one another or how they interrelate, or how the parts relate to an overall structure or purpose. Mental actions included in this function are differentiating, organizing, and attributing,

as well as being able to distinguish between the components or parts. When one is analyzing, he/she can illustrate this mental function by creating spreadsheets, surveys, charts, or diagrams, or graphic representations.

- **Evaluate:** Evaluating is making judgments based on criteria and standards through checking and critiquing. Critiques, recommendations, and reports are some of the products that can be created to demonstrate the processes of evaluation. In the newer taxonomy, evaluating comes before creating as it is often a necessary part of the precursory behavior before one creates something.

- **Create:** Creating is putting elements together to form a coherent or functional whole; reorganizing elements into a new pattern or structure through generating, planning, or producing. Creating requires users to put parts together in a new way, or synthesize parts into something new and different creating a new form or product. This process is the most difficult mental function in the new taxonomy.

• **Source:** <https://www.allencountyesc.org/Downloads/BloomsVerbsAlphabetized.pdf>

- **Remember:** Remember previously learned information.

- **Understand:** Demonstrate an understanding of the facts.

- **Apply:** Apply knowledge to actual situations.

- **Analyze:** Break down objects or ideas into simpler parts and find evidence to support generalizations.

- **Evaluate:** Make and defend judgments based on internal evidence or external criteria.

- **Create:** Compile component ideas into a new whole or propose alternative solutions.

D Custom Prompts for Different LLM Methods

```
1 prompt = f"""
2     Given the following learning objective: "{LO segments
3     appear here}",
4     compare it against the Bloom's Taxonomy level
5     descriptions provided below.
6
7     {Bloom's taxonomy descriptions and paraphrases appear
8     here}
9
10    **Instructions:**
11    1. First, provide a very brief reasoning for the
12    identified level.
13    The reasoning should not exceed three sentences and
14    should only
15    be based on the content of the learning objective
16    provided.
17    2. Then, return the identified taxonomy levels as a list
18    of strings.
19    """
```

Figure 6: Prompt used in the MCS method for condition B for identifying the appropriate Bloom's Taxonomy levels. We employed the same prompt for all MCS conditions but altered the task sequence in Conditions B and C, and separated rationale generation from multiple-choice selection in Condition A.

```

1 prompt = f"""
2     **Task:**
3     For each learning objective:
4     - Compare the sentence against the taxonomy options.
5     - Select the most relevant taxonomy level to the
6       sentence in each pair.
7     - Only choose one taxonomy level from the pair.
8     - If no taxonomy level matches the sentence given,
9       return 'None' but do not provide an explanation.
10
11     **Example:**
12     - Learning Objective: "List the steps of the
13       scientific method."
14     - pairs: {'Remember': 'Recall facts and basic
15       concepts', 'Understand': 'Explain ideas or
16       concepts', 'Evaluate': 'Justify a decision or
17       course of action'}}
18     - Output: 'Remember'
19
20     **Input:**
21     Learning Objective: "{LO segments appear here}"
22     Taxonomy Options: "{Taxonomy level pairs will appear
23       here}"
24
25     Which one is the most relevant taxonomy level to the
26     learning objective?
27     Answer:
28     """

```

Figure 7: Prompt used in the PWC method for selecting the most relevant Bloom's Taxonomy level.

```

1 prompt = f"""
2     **Task:**
3     For each learning objective:
4     - Compare the sentence against the taxonomy options.
5     - Select the taxonomy level that is the most related to
6       the sentence.
7     - Select the taxonomy level that is the least related to
8       the sentence.
9     - Do not provide an explanation.
10
11    **Example:**
12    - Learning Objective: "List the steps of the scientific
13      method."
14    - Taxonomy Options: {'remember': 'Recall facts and
15      basic concepts', 'understand': 'Explain ideas or
16      concepts', 'evaluate': 'Justify a decision or course
17      of action'}
18    - Output: {'most': 'remember', 'least': 'evaluate'}
19
20    **Input:**
21
22    Sentence: "{LO segments appear here}"
23    Taxonomy Options: "{Taxonomy level tuples appear here}"
24
25    What are the most and least related taxonomy levels to
26      the given sentence?
27
28    Answer:
29    """

```

Figure 8: Prompt used for selecting the most and least related Bloom's Taxonomy levels in BWS method.

```

1 prompt = f"""
2     **Task:**
3     For each learning objective:
4     - Compare the sentence against the taxonomy description
5       provided.
6     - Rate how relevant is the taxonomy description to the
7       learning objective on a scale of 1 to 5, where 1 is
8       the least relevant and 5 is the most relevant.
9     - Only use whole numbers from 1 to 5. Do not use
10      fractions or decimal values.
11     - Do not provide an explanation.
12
13     **Example:**
14     - Learning Objective: "List the steps of the scientific
15       method."
16     - Taxonomy level: {'remember': 'Recall facts and basic
17       concepts'}
18     - Answer: 5
19
20     **Input:**
21
22     Learning Objective: "{LO segments appear here}"
23     Taxonomy level: "{Taxonomy levels appear here}"
24
25     Rate the relevance of the taxonomy level to the given
26     learning objective (1 to 5):
27     Answer:
28     """

```

Figure 9: Prompt used in the RCA method for rating the relevance of taxonomy descriptions. The same prompt is used for short and long descriptions of the taxonomy levels.

```

1 prompt = f"""
2     **Task:**
3     Compare the sentence to the provided taxonomy
4         description. Determine if the taxonomy level and its
5         description accurately describe the sentence provided
6         .
7
8     Answer with "Yes" if the taxonomy level and description
9         accurately describe the sentence.
10    Answer with "No" if the taxonomy level and description
11    do not accurately describe the sentence.
12    Do not provide explanations, just the "Yes" or "No"
13    answer.
14
15    **Example:**
16
17    Sentence: "The student can recall key terms and concepts
18        from the lesson."
19    Taxonomy Level and description: "Remember: it refers to
20        recalling information."
21    Is the description accurate for the sentence?
22    Answer: Yes
23
24    **Input:**
25
26    Learning Objective: "{LO segments appear here}"
27    Taxonomy level: "{Taxonomy levels appear here}"
28
29    Is the description accurate for the sentence?
30    Answer:
31    """

```

E Results from non-LLM and LLM Methods Compared to Gold Standard Annotation

Course Title: Facing Death: Basic Module

Learning Objective:

After successfully completing this course, students will be able to:

- name the objectives of the degree program and the professional fields for which the degree program qualifies;
- explain the various basic questions and contents of the degree program and how they relate to each other;
- clarify and identify their own focus and goals for the degree program;
- come to terms with their own death;
- describe the basic meanings of palliative care, spiritual care and self-care;
- reflect on basic questions of the individual and social relationship to death

Question: Which taxonomy levels are relevant to the given learning objective?

5 responses

Figure 11: An example of expert annotations for a course LO description, mapped to Bloom's revised taxonomy levels by five expert annotators. The corresponding mappings by non-LLM and LLM-based methods are presented in Table 4.

Category	Method	Remember	Understand	Apply	Analyze	Evaluate	Create
Non-LLM	SpaCy		✓	✓	✓	✓	
	Regex		✓	✓	✓	✓	
	Fuzzy		✓	✓	✓	✓	✓
	Semantic Similarity		✓	✓	✓	✓	
LLM	BWS		✓	✓	✓	✓	
	PWC	✓	✓	✓	✓	✓	
	Short Rating	✓	✓	✓			
	Long Rating	✓	✓	✓			
	Binary Combinations	✓	✓	✓	✓	✓	✓
	MCS: Condition A	✓	✓	✓	✓	✓	
	MCS: Condition B	✓	✓		✓	✓	
	MCS: Condition C	✓	✓	✓		✓	

Table 4: Comparison of non-LLM and LLM-based methods in mapping the same course learning objective to Bloom’s revised taxonomy levels. Check marks indicate the taxonomy levels identified by each method.

Figure 12: Frequency distribution of taxonomy levels for non-LLM methods and the gold standard annotations.

Figure 13: Frequency distribution of taxonomy levels for LLM methods and the gold standard annotations. The figure illustrates how different methods (e.g., BWS, PWC) align with the gold standard across various taxonomy levels.

F Results from Multiple Choice Selection with Paraphrase-Consistency Prompting and Rationale Generation

Figure 14: Frequency count of taxonomy levels per conditions. The frequency counts reveal that “Understand” is the most common taxonomy level across all conditions, while “Create” is the least frequent. There are notable variations in the frequencies of other taxonomy levels: for instance, “Apply” is more frequent in Condition B, and “Analyze” shows a higher frequency in Condition C.

Condition	Full Agreement Ratio	Partial Agreement Ratio
Condition A	0.23	0.92
Condition B	0.46	0.95
Condition C	0.76	0.98

Table 5: Agreement analysis for conditions A, B, and C. We present the model’s average alignment consistency score, highlighting cases of **full agreement** (where the model’s choice of taxonomy levels is identical across all paraphrases) and **partial agreement** (where the model’s choice is consistent in at least three of the five paraphrases) as detailed here. The results indicate that the selection-reasoning bias—where rationales tend to align with an initial label—is supported by the data. In Condition C, where the rationale is based on an initial selection, there is a higher alignment in taxonomy levels across paraphrases. Conversely, Conditions A and B show lower full agreement ratios, suggesting that without an initial selection to base the rationale on, the agreement among paraphrases is less consistent.

G Results from PWC vs. BWS Annotations

Figure 15: Frequency distribution of taxonomy levels in pair-wise analysis

Figure 16: Best-worst frequency counts across taxonomy levels.

Figure 17: Best-Worst scaling scores: “Analyze” and “Understand” are the most preferred or relevant taxonomy levels, as reflected by their high positive scores.

Taxonomy Level	Consistency Score
Remember	0.21
Evaluate	0.54
Understand	0.69
Apply	0.62
Create	0.20
Analyze	0.84

Table 6: Cronbach α 's measure of internal consistency scores for taxonomy levels

Taxonomy Level	Mean Rank
Remember	6.0000
Understand	2.0025
Apply	2.9975
Analyze	1.0000
Evaluate	4.0000
Create	5.0000

Table 7: **Sensitivity Analysis (Mean Ranks)**: This analysis assesses the stability of rankings across various samples or iterations. The mean ranks reflect the relative significance assigned to each taxonomy level by the model, where a higher score indicates lower significance. “Analyze” and “Understand” are ranked as the most important, while other levels show varying degrees of relevance.

H Results from Binary Annotations

Threshold	Yes_Count	Total_Count	Yes_Percentage
80	274	872	31.42 %
85	267	853	31.30 %
90	248	821	30.21 %
95	227	775	29.29 %

Table 8: **Threshold Variation Analysis:** The analysis demonstrates how varying confidence thresholds impact the proportion of “Yes” responses. As the threshold increases from 80 to 95, the percentage of “Yes” responses slightly declines from 31.42 % to 29.29 %. This suggests that higher thresholds may reduce the model’s overall affirmative responses, potentially filtering out less confident predictions.

Taxonomy	Average Correct Binary Rate
Analyze	0.459119
Apply	0.371069
Create	0.176101
Evaluate	0.232704
Remember	0.157233
Understand	0.572327

Table 9: **Comparison with Multi-Class Classification for Bloom Taxonomy:** The model’s performance varies significantly across different Bloom’s taxonomy levels. For example, “Understand” has the highest average correct binary rate at 57.23 %, while “Remember” and “Create” are much lower, at 15.72 % and 17.61 %, respectively. This indicates that the model is better at aligning with high-order thinking skills such as “Understand” and “Analyze” but struggles more with “Create” and “Remember.”

Taxonomy Level	Average Confidence
Remember	96.07
Understand	93.28
Apply	94.20
Analyze	95.47
Evaluate	98.43
Create	96.59

Table 10: Comparison across D different taxonomy levels: The analysis of average confidence across taxonomy levels reveals that the model exhibits the highest confidence in its predictions for “Evaluate” (98.43 %) and “Create” (96.59 %). In contrast, while still high, the confidence for “Understand” (93.28 %) is slightly lower.

I Results from Rating Annotations

Figure 18: The logprob values for the **short descriptions** are relatively consistent across ratings, without any clear trend, suggesting that the model’s confidence in its rating wasn’t strongly influenced by its rating when using short descriptions.

Figure 19: For the **short descriptions**, the most frequent ratings are at the extremes: 1 and 5. The high frequency of 1s indicates that many learning objectives were poorly aligned with the taxonomy level when only a short description was provided. On the other hand, there is also a significant cluster at 5, suggesting that some objectives were still rated highly despite the brevity of the descriptions. While for **long descriptions** there is still a notable peak at 1, indicating poor alignment for some objectives, the second peak is at 4, and there is a considerable amount of ratings at 5. The peak at 4, with a significant tail towards 5, indicates that the detailed descriptions helped many objectives align better with the taxonomy level.

LangEye: Toward ‘Anytime’ Learner-Driven Vocabulary Learning From Real-World Objects

Mariana Shimabukuro, Deval Panchal, and Christopher Collins

Ontario Tech University, Oshawa, ON, Canada

{mariana.shimabukuro, christopher.collins}@ontariotechu.ca

Abstract

We present LangEye, a mobile application for contextual vocabulary learning that combines learner-curated content with generative NLP. Learners use their smartphone camera to capture real-world objects and create personalized “memories” enriched with definitions, example sentences, and pronunciations generated via object recognition, large language models, and machine translation. LangEye features a three-phase review system — progressing from picture recognition to sentence completion and free recall. In a one-week exploratory study with 20 French (L2) learners, the learner-curated group reported higher engagement and motivation than those using pre-curated materials. Participants valued the app’s personalization and contextual relevance. This study highlights the potential of integrating generative NLP with situated, learner-driven interaction. We identify design opportunities for adaptive review difficulty, improved content generation, and better support for language-specific features. LangEye points toward scalable, personalized vocabulary learning grounded in real-world contexts.

1 Introduction

Creating contextual learning opportunities remains a major challenge in second language (L2) acquisition, particularly for learners situated in non-native environments. Immersive experiences, such as studying abroad or participating in language-rich communities, are often inaccessible due to financial, geographic, or logistical barriers (Galloway and Ruegg, 2020). Mobile-Assisted Language Learning (MALL) addresses this by leveraging the ubiquity and portability of smartphones to support “anytime” micro-learning and situated learning approaches (Arakawa et al., 2022; Byrne, 2019; Tran et al., 2023). Yet, many current MALL systems provide limited flexibility in adapting dynamically to learners’ immediate context, personal

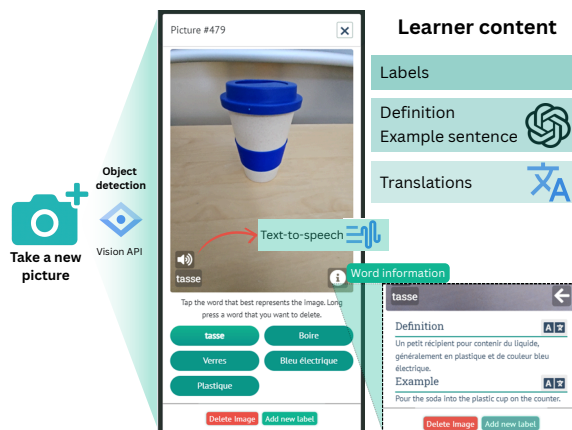

Figure 1: System diagram of LangEye, illustrating the flow from learner image capture through API-based vocabulary enrichment. The application integrates Google Cloud Vision, Cloud Translation, and Text-to-Speech APIs, along with OpenAI’s GPT model, to generate personalized vocabulary “memories” enriched with labels, definitions, translations, and pronunciation.

interests, and cognitive availability, and often rely exclusively on pre-curated, static content.

We introduce LangEye¹, a mobile application for vocabulary learning that turns real-world objects into interactive “memories” through a learner-curated workflow. Using smartphone cameras and NLP services — including computer vision, large language models, and machine translation — LangEye generates personalized lexical entries with definitions, example sentences, and pronunciation. Learners engage with this content through a structured review system that supports progressive recall and production in the target language. An overview of the system architecture and API integration is shown in Figure 1.

Designed specifically to empower self-directed learners, LangEye supports short, personalized learning interactions directly tied to learners’ physi-

¹Public demo and repository to be made available at <https://vialab.ca/langeye>.

cal environments and motivations. Crucially, all review sessions are initiated by learners and grounded in their uniquely captured contexts, promoting deeper personalization, engagement, and learner autonomy. However, due to this highly personalized and learner-curated design, traditional standardized assessments of vocabulary learning outcomes — such as standardized pre- and post-tests — are challenging, as vocabulary items vary greatly across individuals.

To explore the feasibility, learner acceptance, and design implications of LangEye, we conducted an initial one-week exploratory study with 20 French L2 learners, comparing a *camera group* (using LangEye to generate personalized vocabulary entries) and a *control group* (using pre-curated vocabulary). Preliminary findings highlight the motivational and engagement benefits of integrating learner-curated AI-generated content, while also revealing limitations associated with computer vision accuracy and AI-generated contextual sentences. These insights lay the groundwork for our planned longitudinal evaluation, which will rigorously measure personalized vocabulary acquisition and retention over extended use periods. Additionally, future iterations of LangEye will incorporate advanced object detection methods (e.g., YOLO-E) and more dynamic, interactive scenarios such as gamified object treasure hunts, further enhancing contextual vocabulary learning through data-driven methods.

2 Background and Related Work

2.1 Learner-curated Vocabulary with MALL Applications

Compared to Computer-Assisted Language Learning (CALL), MALL excels in accessibility and context-driven learning, making it effective for vocabulary acquisition (Alhuwaydi, 2022; Klimova, 2021). Micro-learning involves short, targeted activities (e.g., 5–15 minutes) (Leong et al., 2020). For instance, MiniHongo (Tran et al., 2023) integrates location and activity data to deliver contextual vocabulary lessons, demonstrating the efficacy of location-relevant micro-learning. Similarly, VocaBura (Hautasaari et al., 2019) utilizes audio and location-based prompts to teach vocabulary during real-world interactions.

VocabEncounter (Arakawa et al., 2022), a CALL application, applies contextual and micro-learning by integrating target vocabulary into web content

via natural language processing (NLP) and machine translation (MT) techniques. Comparable techniques embed vocabulary into audiovisual content through automatic glossing and lexical simplification (Alm, 2021; Fievez et al., 2023). VocabNomad (Tsourounis and Demmans Epp, 2016) provides a highly personalized MALL experience with progress tracking, contextual recommendations, and learner-curated entries. By allowing users to add vocabulary, record pronunciations, and browse visual collections, it fosters situated and personalized learning.

These studies highlight the importance of integrating relevant and contextual vocabulary learning into daily life, leveraging micro-learning and personalized approaches. However, most rely on static content or fixed corpora, with limited opportunities for learners to drive content creation based on their immediate environment.

2.2 AI-Enabled Context Personalization for Vocabulary Learning

The advent of large language models (LLMs), beginning with ChatGPT², has enabled more dynamic natural language generation, allowing for real-time synthesis of definitions, example sentences, and explanations. While generative AI presents challenges such as ethical concerns and content accuracy (Campolo and Crawford, 2020), it has opened new possibilities in personalized educational applications, particularly in language learning.

Applications like Storyfier (Peng et al., 2023) leverage generative AI to create vocabulary-rich narratives based on learner input. Although they showed limited learning gains, users appreciated the contextualization and narrative integration. Similarly, Leong et al. (2024) found that AI-generated personalized prompts enhanced learner motivation, despite modest measurable gains in vocabulary retention.

Recent systems also incorporate generative AI into mixed-reality environments. WordSense (Vazquez et al., 2017) pioneered contextual vocabulary learning through object recognition linked to dynamically generated content. More recently, FluencyAR (Hollingworth and Willett, 2023) integrated augmented reality (AR) with generative feedback for self-talk, and CuriosityXR (Vaze et al., 2024) allowed educators to create multi-modal, contextual mini-lessons. These

²<https://openai.com/research/overview>. Accessed April 2025

works emphasize engagement and curiosity, often powered by NLP-driven interfaces.

LangEye extends MALL, integrating micro-, situated-, and contextual-learning with modern NLP technologies, including object recognition, large language models for content generation, machine translation, and text-to-speech. Unlike prior systems that personalize content using static corpora or predefined curricula, LangEye allows learners to initiate the content pipeline through real-world object interactions, enabling highly contextualized and self-directed vocabulary acquisition. This learner-driven approach aims to promote both personalization and autonomy, but it also challenges traditional evaluation methods, as vocabulary exposure varies widely across individuals. As such, LangEye raises important questions around how to evaluate open-ended, NLP-enhanced learning systems, where learner agency and environmental context shape the learning trajectory.

3 LangEye Design: Create and Review Memories

LangEye’s core interaction is structured around learner-generated *memories* — vocabulary entries tied to real-world images captured by the learner. These memories are enriched using NLP services to provide multilingual definitions, contextual sentences, and audio pronunciation, supporting both vocabulary learning and retention. In this case, the vocabulary items are associated with the pictures taken by the learners. Figure 2 illustrates the learner taking a picture of a cup (*tasse* in French) and interacting with the generated memory’s word definition and example sentence. Therefore, the learned words are tied to a familiar object, which is more effective when compared to unfamiliar or no pictures for vocabulary learning (Hwang et al., 2014; Kang, 1995; Saidbakhramovna et al., 2021).

The app creates situational learning opportunities by allowing the learner to interact with objects around them in three ways: (1) take pictures of objects which they can interact with in-situ via editing or exploring the picture (*memory*); (2) take pictures of objects now, but choose to edit or explore the picture (*memory*) later; and (3) start a *Review Memories* session with a desired length — 3 to N words for up to 3 phases per session. Figure 2 (c, d, and e) shows examples of review activities for each phase.

3.1 Creating Memories

In *picture mode*, the learner can aim their device’s camera at an object they wish to interact with in the target language (TL) and take a picture of it. As shown in Figure 2, in response, the app returns a list of five likely labels (names) for the object, sorted by probability (most likely object name as the top result). The learner can explore the definition and a sample sentence for each label, and optionally select a different top label based on that information. Alternatively, they can confirm the default suggestion. On the same screen, learners also have the option to listen to the pronunciation of the object name. At this point, they may choose to take another picture to explore more objects or end their study session. The app saves all objects, pictures, and names to the learner’s *memories* for further review.

These definitions and sample sentences are dynamically generated using OpenAI’s GPT-3.5 API and then translated into the TL via Google Translate.

Prompt template. LangEye uses a standardized prompt designed for beginner learners to generate consistent and level-appropriate definitions and examples:

You are a language tutor for beginner French learners. Given the following word: <object-label>, provide: (1) a clear, beginner-friendly English definition of the object, and (2) a short example sentence using the object in everyday context. Make both responses simple and age-appropriate for learners at A1–A2 level.

See Table 1 for an output example: **cup** → *tasse*.

Table 1: Example of a vocabulary memory generated for cup.

Label	cup
Definition	A cup is a small container used for drinking.
Sentence	She drank tea from her favourite cup.
French	<i>Une tasse est un petit récipient utilisé pour boire. Elle a bu du thé dans sa tasse préférée.</i>

This structure supports flexible and learner-driven study sessions, allowing learners to create and engage with memories at their own pace, based on what they encounter in their daily environments. By combining visual, textual, and auditory modalities, LangEye supports deeper encoding of vocabulary through multiple channels of reinforcement. This two-stage generation pipeline balances personalization and control: GPT-3.5 generates beginner-

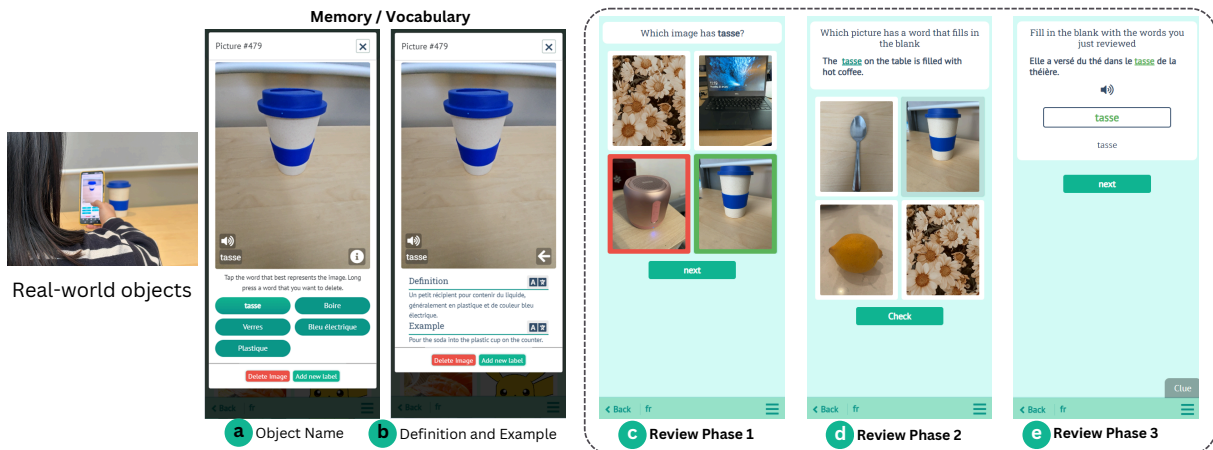

Figure 2: Memories are created from real-world objects. (a) A memory contains the name of the detected object (cup: *tasse* in French) and its pronunciation. (b) Additional information, including a definition and a sample sentence, can be displayed. This content is dynamically generated using OpenAI’s GPT-3.5 API and translated into the learner’s target language (here, French) via machine translation. Learners can practice their vocabulary through the *Memory Review* structure, which includes three progressively challenging phases: (c) **Phase 1: Picture Recognition** prompts learners to identify the correct image; feedback is immediate, highlighting the chosen image in green if correct or red if incorrect. (d) **Phase 2: Sentence Completion** requires selecting an image to fill in a blank within a sentence presented in French. (e) **Phase 3: Free Recall** displays a sentence in French and prompts learners to type the object’s name; small typos are accepted, and hints are available.

friendly English definitions and sentences, while Google Translate handles multilingual output. This modular design supports better quality control, simplifies debugging, and ensures broader language support, particularly for low-resource languages where LLMs may struggle with robust translation performance. At the time of system development, GPT-3.5 was the most stable and accessible option for generating consistent content.

Editing labels. To mitigate possible computer vision and translation errors, learners can add their own label to the picture using the *add label* button — see Figure 2 (a, b). This allows learners to input a text label they find more appropriate if the app’s suggestions are insufficient. Learners type the label in their source language, and the app provides the TL translation — eliminating the need to know the TL term. These custom labels appear alongside their generated definition and sentence — see Figure 2 (b). If a label is deemed irrelevant, learners may long-press it to delete it. In the example shown in Figure 2 (a), the label “*Bleu Électrique*” (Electric Blue) refers to the colour of the cup; the learner might find it unrelated and choose to remove it.

3.2 Languages Supported

LangEye currently supports the following source or target languages: English, French, Spanish, and Portuguese. The *source language* (SL) is the lan-

guage the learner is familiar with or learning from, and the *target language* (TL) is the language to be learned. The interface elements, such as the menu and activity instructions, can be set to any of the listed languages as the SLs. Likewise, the names of objects and learning content (i.e., definitions and example sentences) can be displayed in any listed language as the TL. Learners can define their SL and TL in the *Settings* menu option. This is enabled using machine translation.

3.3 Reviewing Memories

This feature is a classic quiz-style review of the collected memories (vocabulary words). The *Memory Review* has three phases or types of quiz questions, each increasing in difficulty and reducing support. These phases are (1) Picture Recognition, (2) Sentence Completion, and (3) Free Recall. The system chooses N memories (words/objects) to review during a Memory Review session. For each phase, learners are tested on those same N words. Learners must complete earlier phases to unlock later ones, but they may choose to end the session between phases. This progressive design aims to gradually increase cognitive load and promote long-term retention by reinforcing vocabulary through multiple retrieval formats.

Phase 1: Picture Recognition prompts learners to identify an object by selecting the correct picture

from four gallery options (Figure 2 (c)). Feedback is immediate, with correct choices highlighted in green and incorrect in red. Learners have up to four attempts per word, ensuring they review all three target words before moving to the next phase.

In **Phase 2: Sentence Completion**, learners answer “Fill in the blank” questions by selecting a picture that completes an example sentence (Figure 2 (d)). The chosen picture’s word fills the blank, allowing reflection before submission. Incorrect answers reveal the correct choice, and sentences are shown in the SL to support beginners. However, this design may limit advanced learners who prefer tasks entirely in the TL.

Phase 3: Free Recall introduces open-ended vocabulary production. Learners type the names of the three target words without visual cues (Figure 2 (e)). A *Clue* button provides definitions if needed, and the system tolerates minor typos, while still highlighting the correct spelling for feedback. Sentences are now in the TL, catering to advanced learners and promoting grammar understanding.

This phased approach bridges the gap between beginner and advanced learners, enabling gradual mastery of vocabulary and TL proficiency. See Table 2 for a feature and language comparison of all three phases.

3.4 Tracking Vocabulary Learning Progress

The *Achievements* feature in LangEye tracks learners’ Memory Review history and accuracy. For Phase 1, it records the average number of guesses, while for Phases 2 and 3, it calculates accuracy. Learners can sort words by accuracy, with TL initials (e.g., “fr” for French) displayed for context. While these metrics provide insight into learner behaviour and memory usage, they do not directly measure vocabulary acquisition or retention — a challenge we revisit in our discussion of evaluation.

4 User Study

To explore LangEye’s potential as a personalized vocabulary learning tool, we conducted a one-week exploratory study with 20 French (L2) learners. This formative evaluation investigated how learner-curated content and NLP-driven interactions support engagement and vocabulary study in real-world contexts. The study was reviewed and approved by our institution’s Research Ethics Board.

Participants were randomly assigned to two groups:

Figure 3: Sample images taken by participants and their AI-generated counterparts used in the study for the control group.

Control group ($N = 10$): used a version of the app with pre-defined vocabulary and AI-generated content based on pre-curated images; and **Camera group** ($N = 10$): used the full app, including features for taking and uploading images and dynamically generating content through integrated NLP services.

Study Design. The study comprised two sessions: **Session 1:** in-lab training, background survey, and post-session usability feedback. **Session 2:** online exit interview after using the app for at least five days. **Between Sessions:** participants were instructed to use the app daily for five days, completing short usability surveys after each use. Reminder emails were sent daily. Each 50-minute session included surveys, session recordings, and app usage data. Photos taken between study sessions were also collected for the camera group. See Appendix A for detailed information on the study sessions and materials; the semi-structured interview questions are included in the Supp. Material. Figure 3 shows a sample of the generated images used by the control group participants.

Recruitment. Participants were 20 French learners, evenly split into control and camera groups. Participants received \$10 CAD for Session 1 and \$20 CAD for Session 2, recruited through posters in high-traffic campus areas.

Room Setup. The room held eight household objects (an apple, cup, fork, paper, scissors, spoon, sunglasses, and watch) for the camera group to explore and photograph. The control group experienced the same room with objects, but they interacted exclusively with pre-curated memories.

Control Group Memory Curation. Control group memories were curated using data from the cam-

Table 2: Feature and language support comparison across the three Memory Review phases: **Phase 1: Picture Recognition**, **Phase 2: Sentence Completion**, and **Phase 3: Free Recall**. As learners progress through the phases, visual support (e.g., images and multiple-choice options) is gradually reduced, while the use of the target language (TL) increases. This design makes later phases more cognitively demanding. Learners can choose to save and exit the review session at any point between phases.

		Phase 1	Phase 2	Phase 3
Task type	Identify picture		—	—
	Fill in the blank	—		
Answer support	Picture			—
	Multiple choice			—
	Type/Spell	—	—	
	Clue	—	—	Word definition
Answer and corrective feedback	Instantaneous check		—	—
	Submit and check	—		
	Corrective feedback			
Cognitive task	Word recall	Picture	Picture	Spell
	Word collocation	—		
Language <i>Source: Source Language</i> <i>TL: Target Language</i>	UI elements	Source	Source	Source
	Vocabulary word	TL	TL	TL
	Sample sentences	—	Source	TL
	Word definition	—	—	Source

era group to ensure comparability between groups. Camera group participants collected an average of 11 pictures (*Median* = 9; *min* = 5; *max* = 19), resulting in 24 unique objects.

To ensure uniformity and preserve privacy, we generated realistic images of the objects using OpenAI’s Dall-E 3 (full list in Supp. Material). The curated vocabulary ensured consistency without introducing additional biases or privacy concerns. This initial study focused on usability, motivation, and learner perceptions, rather than directly measuring vocabulary acquisition, which is addressed in planned longitudinal follow-ups.

4.1 Study Results: Engagement and Usability

This section presents the user study results, including the pre-session, post-session, exit interview, and software usage data. *Qualitative data analysis*. The questionnaire and the semi-structured interview open-ended questions were coded into categories following commonly mentioned themes in the participants’ answers.

4.1.1 Pre-session background questionnaire

Participants Background. Participants (N=20) were aged 18–24 (N=15) and 25–30 (N=5). All were fluent in English, though only 6 identified it as their first language. Most participants (N=15) self-reported as beginners (A1/A2), with 9 in the camera group. The control group included most ad-

vanced learners (B1/B2; N=4), who reported studying French for over a year. See Appendix B for details. Participants spoke diverse languages, including Tamil (N=5), Hindi (N=4), and Urdu (N=3). Additional languages learned alongside French included Arabic (N=2), Spanish, and Italian, while 11 participants were not learning another language.

Technology for Language Learning. Duolingo was the most commonly used app (N=12), followed by platforms like Udemy and Memrise. Eight participants, mostly in the control group (N=5), reported not using any apps. Only one camera group participant used apps daily, with most others engaging less frequently (once or 3–6 times a week). Mobile devices were the preferred learning platform (N=14), followed by desktop (N=5) and a single participant choosing “either.” Preferences were evenly distributed across groups.

Language Learning Goals. The primary motivation for learning French was career-related (N=11; 7 camera, 4 control), followed by leisure (N=4) and travel (N=3). Other reasons included academic and family goals (each N=1).

4.1.2 Post-Session 1 Feedback and Exit Interview Results

Usability. Ratings for Memories, Review Memories, Achievements, and Picture Mode were measured on a 10-point scale. Participants rated their experience with LangEye after Session 1 (first im-

Figure 4: Using a 10-point user experience scale where (1) “Not user-friendly at all” and (10) “Very user-friendly” participants provided ratings on each of four LangEye features: *Memories*, *Review Memories*, *Achievements*, and *Picture Mode* — for camera group only. The chart on the left represents the camera groups and the control group is shown on the right. Overall, Session 1 had higher ratings than Session 2, and the camera group had higher ratings than the control group.

pressions) and Session 2 (after five days of use). *Review Memories* yielded an average of 8.7 for the camera group and 8.6 for the control group. Session 1 scores were higher for both groups compared to Session 2. Overall, ratings dropped from Session 1 to 2 for all features/groups (Figure 4), with the *Memories* (9.0 to 8.7 and 8.6 to 7.5) and *Achievements* (9.2 to 8.0 and 8.8 to 8.5) features showing the most decline for the camera and control groups, respectively. *Picture Mode* ratings, available only for the camera group, averaged 8.7, with Session 1 scoring 9.2 and Session 2 scoring 8.2.

Comfort and Control. Participants expressed comfort using LangEye for both vocabulary review and learning, based on 5-point Likert scale ratings. The camera group (4.3 and 4.2) reported similar comfort levels for both activities, while the control group showed lower comfort (4.0 and 4.2) when learning new vocabulary, likely due to their pre-curated and limited vocabulary set. Four control group participants requested options to expand pre-curated content. Self-efficacy ratings over learning were consistent across groups, with both reporting a mean score of 4.3 and a range of 3—5.

Most and Least Favourite Features. The camera group’s most liked features were *Picture Mode* (4), *Review Memories* (3), and *Memories* (3). Participants appreciated the personalization offered by *Picture Mode*: “[It] allows real-time learning with objects around me” (P8, A2). The control group preferred *Review Memories* (8), with Phase 1: *Picture Recognition* praised for its simplicity. The least liked features for the camera group in-

cluded Phase 3: *Free Recall* (3), Phase 2: *Sentence Completion* (2), and *Achievements* (2), with some noting confusing sentences in Phases 2 and 3. The control group disliked *Achievements* (4), citing low interactivity.

Motivation. Self-reported motivation levels, however, showed divergence. The camera group maintained a steady mean of 4.3 across sessions, while the control group’s mean dropped from 4.1 in Session 1 to 3.8 in Session 2. This decline may reflect lower engagement with pre-curated content. These findings underscore the benefits of learner-curated content in enhancing comfort, control, and sustained motivation. They also suggest that giving learners agency to drive the content creation process—supported by generative NLP—can foster deeper engagement compared to static, pre-defined content.

Learner Perceptions Compared to Other Tools.

Learning with Pictures. Participants valued LangEye’s use of pictures for vocabulary learning, citing improved memorization and contextual association compared to dictionaries: “*Images make it easier to memorize and associate vocab with objects*” (P15, B1). **Self-curated Memories.** Camera group participants praised the personalization and relevance of self-curated content: “[LangEye] uses my own pictures, making vocabulary more memorable” (P3, A1). They suggested combining pre-populated and user-generated content for flexibility. **Multiple Labels per Image.** LangEye’s ability to associate multiple concepts with a single image was seen as helpful for intermediate learners but confusing for beginners: “*Pictures have more context and words, good for intermediate learners*” (P14, A1).

4.2 Thematic Learner Feedback

App reminders and gamification. While some participants appreciated the absence of in-app reminders (P12), others requested daily notifications to encourage engagement (P1, P2). **Aesthetics improvements.** Participants (9/20) recommended a more colourful interface, sound effects for feedback, and larger buttons for easier interaction.

Content customization. Participants valued the use of personalized images, citing improved memory and relevance. A camera group participant noted, “*This app adds personal attachment to the picture, making it easier to remember*” (P8).

AI-generated content and robustness. Participants reported object detection errors and overly technical definitions. Cluttered backgrounds and

multiple objects caused incorrect labels, while some sentences had mismatched vocabulary contexts. For instance, “wood” (noun) was replaced with “wooden” (adjective). Participants suggested cropping tools and improved AI prompts to reduce errors.

Review memories design. Beginners (A1) preferred Phase 1: Picture Recognition and Phase 2: Sentence Completion but found Phase 3: Free Recall overwhelming, while advanced learners preferred Phase 3 in the target language (TL). Participants generally praised the multi-phase system for its progressive difficulty. P9 said, “*I like the three phases, but the second phase in English was not helpful due to gender issues.*”

Language-specific considerations. Participants highlighted issues with gendered nouns in French during Phase 2: Sentence Completion. Gender information was lost in English translations, causing confusion, especially for A2–B2 learners. Suggestions included displaying gender indicators (e.g., P1, P8, P9).

4.3 Daily Usage and Technical Issues

Figure 5 visualizes the decline in daily feedback form submissions across the five study days. The control group maintained more stable participation, while the camera group showed a sharper drop-off, despite initially similar engagement levels. This suggests that while learner-curated content may drive early motivation, maintaining sustained engagement over time remains a challenge. Overall ratings for ease of use, engagement, and vocabulary learning were mostly positive, leaning toward “Strongly agree” or “Neutral.” However, control group ratings for learning new words were lower, likely due to limited pre-curated vocabulary. *Technical Issues* 26% of submissions reported technical difficulties, including delays in label loading over mobile networks and incorrect object labels. Sentence quality was another concern, as participants noted that some sentences were contextually incorrect or mismatched vocabulary. The detailed data is available in B.1.

5 Discussion

This exploratory study demonstrates the promise and challenges of combining learner-curated content with generative AI to support vocabulary learning in mobile contexts. While our goal was not to directly measure vocabulary gains, the findings

Figure 5: Number of daily feedback form submissions across the five-day study. While total submissions began at 14 on Day 1, they declined to 7 by Day 5. The control group’s submissions remained relatively stable (7 to 5), whereas the camera group showed a sharper decline (7 to 2). Participant ratings per day are available in B.1.

offer formative insights into learner experience, system usability, and the design trade-offs inherent to NLP-enhanced educational tools. Below, we reflect on key lessons learned and identify opportunities for future improvement.

Evaluation and Research Implications. Future work will incorporate longitudinal vocabulary tracking and explore adaptive evaluation strategies aligned with learner-curated content. Because LangEye supports open-ended, learner-defined content creation, traditional pre- and post-testing are difficult to apply consistently. Even usage-based metrics, such as phase completions or accuracy scores, are complicated by the variability in content difficulty and prior learner knowledge. These challenges reflect broader tensions in evaluating personalized, generative learning systems and call for alternative strategies such as learner modelling or adaptive diagnostics.

Balancing Pre- and Self-Curated Content. Learner-curated vocabulary fosters autonomy and engagement but also introduces variability in vocabulary scope and difficulty. A hybrid approach—integrating structured, pre-curated content alongside learner-generated memories—may better support novice learners while preserving personalization for advanced users. This balance also enhances scalability across languages without requiring expert-authored corpora.

Tensions in AI-Generated Content. Although generative AI enabled dynamic and personalized vocabulary entries, participants frequently encountered issues such as overly technical definitions, inappropriate word senses, and context mismatches.

For example, “wood” was rendered as “wooden” (Table 3), and cluttered images led to irrelevant labels. These issues reflect broader limitations of prompt-based generation in educational contexts. Future iterations will incorporate prompt tuning, simpler output targets, and human-in-the-loop validation to improve robustness and learner alignment.

Table 3: Example of a vocabulary memory with a word sense mismatch due to ambiguous object labelling.

Label	wood
Definition	Wooden means made of wood.
Sentence	I sat on the wooden chair.
Issue	Learner expected a noun definition for wood, but GPT returned the adjective form wooden.

Language-Specific Considerations. LangEye supports multiple target languages via machine translation; however, users of gendered languages (e.g., French) have noted grammatical issues, particularly in Phase 2, where translations often lack gender agreement. This suggests the need for grammar-aware translation strategies and visual indicators for noun gender, especially in beginner-focused review phases.

Our use of a hybrid generation pipeline, employing GPT-3.5 for English definitions and Google Translate for multilingual output, was driven by a need for modularity, consistency, and broad language coverage. This approach provided control over linguistic complexity in the initial prompt while leveraging production-grade translation tools for low-resource languages, where LLM performance remains less benchmarked. This modular architecture proved essential for supporting LangEye’s multilingual scope but also contributed to mismatches and errors in translated content, underscoring the importance of future refinement in prompt tuning and translation alignment.

Learner Engagement and Personalization. Learners consistently emphasized the motivational value of interacting with vocabulary grounded in their own environment. This supports situated learning theory and highlights how self-curated images can improve recall by reinforcing personal relevance. However, engagement declined over time—particularly in the camera group—suggesting a need for better pacing, reminders, or gamified retention mechanisms to sustain interest.

Review System Calibration. Participants appre-

ciated the phased review design, but feedback suggests the need for difficulty calibration. Phase 3: Free Recall was overwhelming for beginners, while some advanced learners desired more TL immersion earlier. Dynamically adapting review complexity based on learner level and behaviour (e.g., accuracy, completion history) may improve retention and reduce frustration.

Toward Context-Aware Learning Scenarios. LangEye’s current design centers on object-driven vocabulary. Future iterations could support more dynamic interactions, such as context-aware prompts, adaptive content sequencing, and gamified activities (e.g., real-world “treasure hunts”). These enhancements—combined with more accurate object detection (e.g., YOLO-E)—could transform LangEye into a broader platform for situated, task-based language learning.

6 Conclusion

This paper presented LangEye, a mobile language learning application that leverages generative NLP and learner-curated content to support contextual vocabulary acquisition. By combining object recognition, machine translation, and dynamic content generation, LangEye enables self-directed learners to engage in personalized, real-world language practice. Findings from our exploratory study highlight the system’s usability, motivational benefits, and learner preference for personalized visual content.

While this formative evaluation did not assess vocabulary acquisition directly, the results inform design implications for learner-driven, AI-enhanced educational tools. Future work will include longitudinal studies to track learning outcomes, and expand LangEye’s capabilities through adaptive review difficulty and improved language-specific support. Additionally, we envision incorporating more accurate computer vision models (e.g., YOLO-E) to enable dynamic, context-aware interactions such as real-world object “treasure hunts” or live situational vocabulary tasks, further bridging the gap between everyday experiences and language learning.

Limitations

This work has several limitations that inform the scope of its findings and highlight directions for future research.

First, this was an exploratory and short-term

study focused on learner engagement and usability. While participants interacted with generative NLP features and learner-curated content, we did not directly assess vocabulary acquisition or retention through pre- and post-testing. Future studies with longer durations and individualized baseline assessments are necessary to evaluate learning outcomes rigorously.

Second, the evaluation was constrained by the personalized nature of the learner-curated content. Since learners selected their own vocabulary items, it was not feasible to apply a standardized test or compare vocabulary gains across participants. While this personalization is central to LangEye's design, it introduces challenges for controlled, quantitative evaluation.

Third, the generative NLP components (e.g., definitions, sample sentences) sometimes produced inconsistent or overly complex outputs. This was especially problematic for beginner learners, who occasionally found definitions too advanced or mismatched in word sense. Our system relies on prompt-based content generation, which can be brittle without careful tuning and contextual awareness. While we did not run expert benchmarking of the AI-generated content in this pilot, this remains an important step for future work, especially for language education applications."

Finally, although LangEye supports multiple languages, our study only examined English–French learners. Language-specific features—such as grammatical gender—presented challenges in the translation pipeline and feedback design, limiting generalizability across linguistic contexts. Further studies should explore broader language pairs and adapt the system to handle grammar-sensitive features more effectively.

Ethical Considerations

This study was reviewed and approved by our institution's Research Ethics Board (REB). All participants provided informed consent prior to participation and were compensated for their time. Data collected during the study, including app usage logs and participant feedback, was anonymized prior to analysis.

To protect participant privacy, especially in the camera group, no personally identifying photos were stored or analyzed. For the control group, object images were generated using OpenAI's DALL·E 3 to avoid the use of participant-provided

media.

LangEye integrates generative AI tools (e.g., GPT-3.5, Google Translate) to produce multilingual learning content. While this automation enables scalability, care was taken to limit content generation to isolated vocabulary contexts, and the system does not store user data beyond local app sessions. Limitations of AI output—such as occasional mismatches in word sense—were disclosed to participants, and learners had full control over which content to save and review.

A Research Methods

A.1 Control Group Memory Curation

One of the main challenges in comparing the two groups of participants is to curate the control group’s memories. As discussed in section 4, our approach to this problem was to run both sessions of the study with the camera group first. This allowed us to use the collection of memories created by that camera group as the control group’s memories. On average, the camera group collected 11 pictures ($Median = 9; min = 5; max = 19$). The aggregation of duplicates of the camera group memories resulted in a total of 24 objects (memories) listed below:

apple	floor	lemon	speaker
bag	flooring	paper	spoon
cup	food	peripheral	stapler
dishware	fork	scissors	tableware
drinkware	glasses	serveware	watch
eyewear	hand	slipper	wood

Recalling that, to create uniformity in the images, avoid bias toward the quality of images taken by the camera group, and preserve the participants’ privacy, OpenAI’s Dall-E 3 was used to create the images for each of these memories. The prompt included the object name and instructions for the illustration to be “realistic” to mimic a photo taken of the object — sample shown in Figure 3. The pairs of all AI-generated images and labels can be found in Supplemental Materials. This approach was used to present a similar curation of vocabulary while not adding words that might not have been added using a smartphone camera.

A.2 Detailed Study Sessions

A.2.1 Study Session 1: Introducing LangEye

Session 1 was conducted in a controlled lab environment with separate setups for the camera and control groups.

Room Setup. The room featured a collection of eight household objects (see Figure 6) for the camera group to explore and photograph. The control group experienced the same room setup but interacted exclusively with pre-curated memories.

Pre-Session Questionnaire. Participants completed a brief background survey about their French language learning experience and use of language learning apps.

Figure 6: Top: Room setup with video recording. Bottom: Objects available for the camera group to explore and create memories.

Training Tasks. Participants were introduced to the app’s features through a demonstration and a printed tutorial. Both groups explored the app’s main features, with the control group focusing on editing pre-curated memories and the camera group using the camera mode to create their own. Participants could ask questions during the session and were required to interact with each feature before proceeding to the post-session survey.

Post-Session Questionnaire. Participants evaluated LangEye’s usability and practicality, providing feedback on the app’s usefulness for language learning.

A.2.2 Between Sessions

Participants were instructed to use LangEye daily for five days between Sessions 1 and 2. Daily reminder emails prompted them to complete a short feedback form covering usability, error reporting, and general app impressions. The second session was scheduled 5–10 days after the first.

A.2.3 Study Session 2: Exit Semi-Structured Interview

In Session 2, participants reflected on their experiences with LangEye, discussing usability, vocabulary acquisition, and the accuracy of object recognition and labeling. The camera group shared insights on creating memories, while the control group focused on pre-curated content. Interviews were recorded using Google Meet, capturing video, audio, and transcripts. Transcripts were reviewed

Table 4: Summary of participants' background information per study group: camera and control.

Attribute	Camera	Control	Total
Age			
18–24 years old	6	9	15
25–30 years old	4	1	5
L1			
Other	8	6	14
English	2	4	6
French level			
A1	5	5	10
A2	4	1	5
B1	–	4	4
B2	1	–	1

for accuracy and used alongside structured session notes for qualitative analysis of participant responses.

B Results Data Visualizations

Visual representations of some of the results are available in this section. Table 4 shows the tabulated participants demographics information. Table 5 shows the tabulated data on participants' French learning background.

B.1 Daily Feedback Submissions

Participants were asked to submit a daily feedback form after using the app in between sessions. While the number of daily submissions (Figure 5) remained somewhat stable for the control group (from 7 to 5), the camera group had the most decline (from 7 to 2). When aggregating both groups, at Day 1 there were 14 submissions, which was reduced to 7 at Day 5. The charts in Figures 7 and 8 show the participants' ratings (5-Point Likert scale for agreement) per day. The difference in the volume of submissions makes it difficult to compare across groups, but overall, the ratings lean toward "Strongly agree" to "Neutral" throughout the study days. Here are the statement items participants were asked to rate:

- "Overall, this app is easy to use."
- "I'm having fun using this app."
- "I have learned new French words using this app."

Table 5: Table shows participants' main method for learning French and the duration of their studies. The study was run in Canada, a bilingual country (English and French are official languages). Thus, French immersion schools are commonly available in Canadian education. Courses for French ("Course at school") as a foreign language are also common in Anglophone schools. And other "French course" or classes are easily accessible in language institutes. Participants who indicated "None" were never enrolled in a course or followed a specific method.

French Study		Camera	Control	Total
Duration	Method			
1 week or less	None	3	1	4
less than 6 months	French immersion	–	1	1
	Online course or resource	1	–	1
	None	1	–	1
1 year+	Course at school	–	1	1
	Online course or resource	1	1	2
5 years+	Course at school	1	5	6
	French course	1	–	1
10 years+	French course	1	–	1
	French immersion	1	1	2

- "I feel more in control of my French vocabulary learning progress and content since using this app."

Figure 7: Camera group participants' ratings for the daily feedback form per day. The Figure 5 shows the number of responses per day. While at Day 1 there were 7 submissions, that number declines along the days. This chart shows the distribution of the respondents' answers to the 5-Point Likert scale agreement statement items at each day, from bottom (Day 1) to top (Day 5) at each item. Although there is a shift to "Strongly agree"/"Neutral" as days pass the number of responses are reduced.

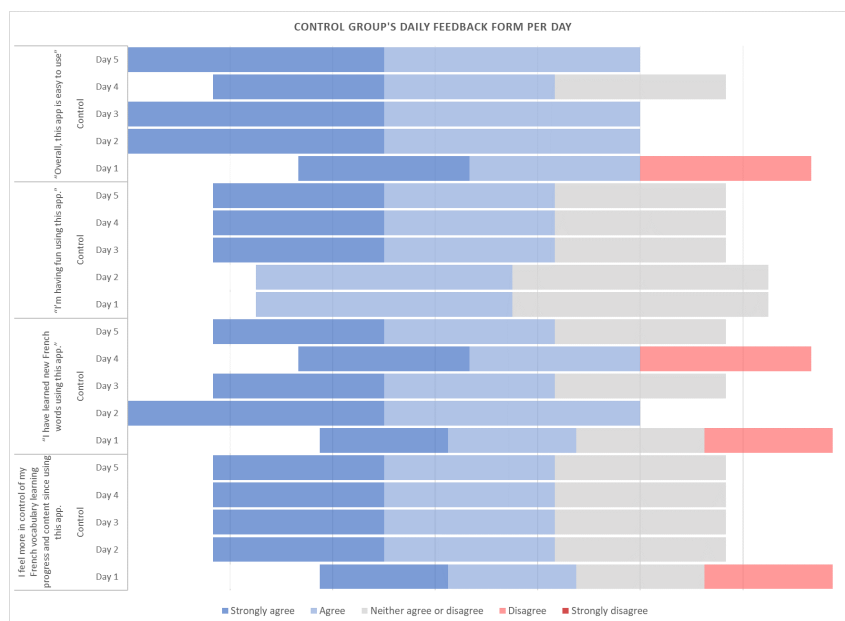

Figure 8: Control group participants' ratings for the daily feedback form per day. The Figure 5 shows the number of responses per day. While at days 1 and 2 there were 7 submissions, that number declines to 5 at Day 5; which is higher than the camera group's Day ($N = 2$). This chart shows the distribution of the respondents' answers to the 5-Point Likert scale agreement statement items at each day, from bottom (Day 1) to top (Day 5) at each item. Although there is a shift to "Strongly agree"/"Neutral" as days pass the number of responses are reduced.

Costs and Benefits of AI-Enabled Topic Modeling in P-20 Research: The Case of School Improvement Plans

Abstract

As generative AI tools become increasingly integrated into educational research workflows, large language models (LLMs) have shown substantial promise in automating complex tasks such as topic modeling. This paper presents a user study that evaluates AI-enabled topic modeling (AITM) within the domain of P-20 education research. We investigate the benefits and trade-offs of integrating LLMs into expert document analysis through a case study of school improvement plans, comparing four analytical conditions. Our analysis focuses on three dimensions: (1) the marginal financial and environmental costs of AITM, (2) the impact of LLM assistance on annotation time, and (3) the influence of AI suggestions on topic identification. The results show that LLM increases efficiency and decreases financial cost, but potentially introduce anchoring bias that awareness prompts alone fail to mitigate.¹

1 Introduction

Educators are increasingly turning to artificial intelligence to streamline research and administrative workflows, particularly within P-20 contexts, which cover education from Pre-K through graduate levels and workforce training. It has sparked considerable interest in the potential of generative AI tools to tackle complex analytical tasks (Kasneci et al., 2023; Xu et al., 2024). Among these applications, topic modeling (TM)—a method for uncovering hidden themes in unstructured text—has become a prominent technique in P-20 research over the past decade (Brookes and McEnery, 2019; Daenekindt and Huisman, 2020; Sun et al., 2019; Wang et al., 2017). In contrast to conventional text

data analysis (CTDA), which often requires substantial human input and can be constrained by its labor-intensive nature, subjectivity, and potential for inconsistency, Artificial Intelligence-enabled Topic Modeling (AITM), driven by sophisticated LLMs like GPT-4 (OpenAI et al., 2024), holds the potential for significant improvements in efficiency and scalability by automating or assisting with these demanding procedures (Dell'Acqua et al., 2023; Grossmann et al., 2023).

Implementing AITM offers several key benefits, notably a reduction in the time required for analysis and the potential for more consistent and thorough topic identification. These efficiencies can significantly influence research productivity and, importantly, may lead to qualitatively different research findings compared to CTDA due to variations in identified themes. Nonetheless, the rapid adoption of AITM raises important concerns about potential drawbacks, such as financial costs and environmental impacts associated with substantial computational resource utilization. At present, there is a lack of empirical research that compares these costs to those of traditional methods, especially within the field of K12 educational research.

Another critical but underexplored concern with AITM is the psychological phenomenon known as anchoring bias—the tendency for humans to rely excessively on initially presented information when making subsequent judgments or decisions (Nagtegaal et al., 2020). In contexts where humans interact with AI-generated insights, anchoring bias may skew human analysts' judgments, thus, affecting the final research outcomes (Zhao et al., 2024; Choi et al., 2024).

Given these critical gaps, we investigate the financial, environmental, cognitive, and analytical trade-offs of integrating AITM into P-20 research. Our case study focuses on principal-written school improvement plans (henceforth "Plans") from a formal field-based principal evaluation sys-

¹Code available [here](#). The data are not publicly available due to privacy restrictions but can be requested through the Network for Educator Effectiveness (NEE) at the University of Missouri and the Missouri Department of Elementary and Secondary Education (DESE).

tem in hundreds of K12 districts in the Midwest USA. We systematically evaluate four analytic conditions: AI-Only, Human-Only, AI-Human, and AI-Human-Deanchoring. Through this comparative analysis, we address three research questions:

- **RQ1:** What are the marginal financial and environmental costs of implementing AITM in P-20 research?
- **RQ2:** What are the causal effects of different analytic approaches on analysis time?
- **RQ3:** What are the causal effects of these analytic approaches on the topics identified?

Preliminary findings suggest that AI analysis significantly reduces costs and analysis time per document compared to human analysis, although AI-assisted methods vary slightly in terms of speed. Additionally, when humans and AI were provided with pre-specified topic lists, only minor differences emerged in the topics identified. Through a thorough evaluation of these aspects, we aim to offer an empirical understanding of AITM’s value proposition for P-20 educational research.

2 Related Work

The field of topic modeling has seen significant advancements, moving from traditional probabilistic methods to more contemporary AI-driven techniques. Early models, such as Latent Dirichlet Allocation (LDA; Blei et al., 2003), conceptualized documents as combinations of topics, with each topic characterized by a distribution of words. While widely adopted, LDA and similar approaches often required substantial manual interpretation, as they yielded clusters of words without clear semantic labels (Gao et al., 2024b). Subsequent neural network-based models, like BERTopic (Grootendorst, 2022), improved the coherence of topics by leveraging transformer embeddings that capture richer contextual meaning. More recently, frameworks leveraging large language models (LLMs), such as TopicGPT (Pham et al., 2024), have further enhanced the accessibility and interpretability of topic modeling by generating human-readable topic labels and summaries (Overney et al., 2024; Gao et al., 2024a).

Within educational research, topic modeling has proven to be a powerful tool for analyzing large-scale textual data, such as curricula, school improvement plans, and scholarly literature. Studies have applied topic modeling to uncover latent

themes in educational leadership, policy discourse, and reform strategies (Wang et al., 2017; Sun et al., 2019; Daenekindt and Huisman, 2020). These methods claim to significantly reduce the labor associated with traditional qualitative coding, making large-scale analysis more scalable and helping to address a fundamental impediment to research use by educators: the amount of time it takes to conduct research (Drahota et al., 2016; Asmussen and Møller, 2019).

As AI tools, particularly LLMs, become more prominent in education research and practice, they are being increasingly adopted for tasks such as writing content, analyzing student responses, or synthesizing research findings (Liu and Wang, 2024; Cambon et al., 2023; Jaffe et al., 2024). However, effective adoption in educational contexts requires addressing the environmental and financial costs of model training and inference (Strubell et al., 2019; Hershcovich et al., 2022), challenges around the reliability and interpretability of model outputs (Mittelstadt et al., 2016; Sahoo et al., 2024), and cognitive pitfalls such as automation and anchoring bias that may skew human judgment during analysis (Goddard et al., 2012; Koo et al., 2024; Echterhoff et al., 2024). This is particularly concerning in high-stakes domains like education, where premature reliance on AI-suggested outputs can limit critical thinking, reduce analytical diversity, and ultimately affect the integrity of findings (Al-Zahrani, 2024; Sallam, 2023).

Furthermore, bias mitigation remains a pressing challenge. LLMs have been shown to inherit and sometimes amplify social and cultural biases (Resnik, 2024). Interestingly, emerging research suggests that strategies such as structured group discussions and collaborative review can counteract some of these effects, promoting more balanced and reflective decision making in AI-assisted workflows (Horst et al., 2019; Rachael A. Hernandez and Teal, 2013; Michaelsen et al., 2002).

3 Data

We use a proprietary dataset from the Network for Educator Effectiveness (NEE), an educator evaluation system widely implemented across K–12 school districts in Missouri. This dataset spans the academic years 2005–2006 through 2022–2023 and comprises de-identified, text-based portfolios authored by school principals. These documents, formally known as *Building Improvement Plans*

B. Major Objectives and Strategies of the Plan	
Goal Alignment (Element 3)	
Objective - May use a SMART approach. Use a reasonable number of objectives that can be adequately monitored and completed.	
1. Student engagement will increase by 15% as measured by the NEE School Peer Observation form from the beginning of the year data collection to the end of the year form. 2. Student proficiency in the area of ELA standard RI 9 will increase by 15% as measured by the beginning of the year to end of the year STAR report. 3. Math MAP scores in the area of problem solving and communicating reasoning will increase by 10% as measured by the 2019 MAP test to the 2020 MAP test. 4. Student proficiency in the area of science will increase from 47.7% to 57.7% as measured by 2020 MAP data. 5. Student proficiency in the area of reading fluency will increase from 65% to 75% by April 2020 as measured by DIBELS.	CSP Goals Goal 1 - Develop and enhance quality educational/instructional programs to improve performance and enable students to meet their personal, academic, and career goals.
Baseline Data (Element 4)	
What baseline data was used to measure progress toward this objective?	
We identified data gaps in MAP. Math specifics related problem solving, modeling, and data analysis and communicating reasoning (second lowest area). In ELA, third grade listening was the lowest. In fourth and fifth grades, it was reading, but in fifth grade in particular research was the lowest with an average 35%.	
DIBELS data was utilized to determine the need for improved fluency for our students to be successful readers.	
In the area of Science, we used MAP results to determine that we need to address the scientific inquiry process. This is the lowest performance area for our students and it impacts most of the science content. The next lowest performance areas by standards were properties and principles of matter and energy and properties and principles of force and motion.	

Figure 1: The two elements extracted from the Building Improvement Plans (BIPs) used in our goal-based study.

(BIPs) or *School Improvement Plans*, are submitted annually as part of a standardized evaluation process and are structured around seven performance criteria (referred to as *elements*) evaluated by principal supervisors using a consistent rubric.

For our study, we randomly selected 23 BIPs and focused on two specific elements from each plan: (1) the major objectives stated for school improvement, and (2) the data principals planned to use to measure progress toward those objectives (Figure 1). These elements are highly relevant to evaluating strategic goal-setting and progress tracking in educational leadership and K12 school improvement. The documents are entirely text-based and machine-readable, making them ideal for qualitative analysis via topic modeling.

4 Experimental Design

To investigate the integration of LLMs into educational research, we have adapted our methodology from the user study conducted by Choi et al. (2024), which examined the efficiency and precision of LLMs in specialized tasks through a structured user study focused on human-LLM interactions. Their findings showed that while LLMs significantly increased task speed, they also led users to anchor on AI-provided suggestions. Informed by their findings on anchoring bias, we expand on their experimental framework by adding a novel treatment condition: **AI-Human-Deanchoring**. This condition is designed to reduce the over-reliance on LLM by making participants explicitly aware of potential anchoring effects in LLM-generated suggestions (see Figure 2).

Our study is structured in two stages:

- **Stage 1: Topic Discovery**, in which participants identify and curate a list of topics from a shared set of BIPs.
- **Stage 2: Topic Assignment**, in which participants apply those topics to a new set of documents under controlled conditions.

D20–D23	T4	T2	T3	T4	T2	T3

Table 1: Document assignments for Stages 1 and 2. In Stage 1, each analyst analyzed the full set of 11 documents (D1–D11) under a single assigned condition; experimental conditions are defined as T2: Human-Only, T3: AI-Human, and T4: AI-Human-Deanchoring. In Stage 2, analysts analyzed documents D12–D23, assigned in a balanced design across all experimental conditions to ensure multiple annotations per document.

We designed the following four treatment conditions:

1. **AI-Only:** Tasks were performed solely by the LLM without human intervention, providing a benchmark for AI performance.
2. **Human-Only:** Participants performed tasks without any AI assistance, serving as the baseline for human performance.
3. **AI-Human:** Participants received suggestions from an LLM before performing tasks, allowing us to assess the influence of AI assistance.
4. **AI-Human-Deanchoring:** Participants were presented with LLM-generated suggestions with explicit instructions to be skeptical of them due to potential anchoring bias. By encouraging participants to thoughtfully evaluate and adjust AI-generated recommendations, we aim to improve the trustworthiness and credibility of AI-generated results.

To assign treatment conditions in the 12 school improvement plans (BIPs) in stage 2, we used a Latin square design (Montgomery, 2017). Each of the six human participants was assigned a specific sequence of treatment conditions across different plans, ensuring a balanced and systematic distribution of the Human-Only, AI-Human, and AI-Human-Deanchoring settings (see Table 1). Analysts proceeded in the order of conditions T2 → T3 → T4 in stage 2. Participants in the AI-assisted settings (T3, T4) were provided with LLM-generated topic annotations, while those in the Human-Only setting (T2) worked independently without any AI input. Analysts were unaware of the condition until they accessed the designated docu-

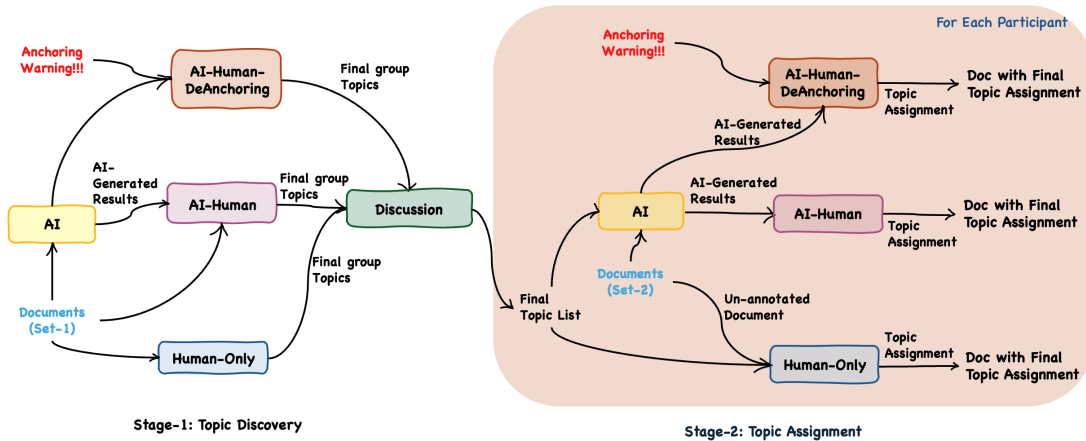

Figure 2: Overview of our Topic Modeling workflow and experimental settings. Stage-1: Topic Discovery involves discovering latent topics within documents. Team discussion occurred at the end of Stage-1 in order to develop the Final Topic List. Stage-2 involves assigning topics to a different set of documents in all treatment conditions.

ment in Label Studio (Tkachenko et al., 2020) that we used to conduct our user study. Each analyst was asked to indicate whether each topic t from the Final Topic List appeared in each paragraph/field f of the assigned BIPs.

4.1 Stage 1: Topic Discovery

We used the data from Stage 1 to examine how topic lists were generated across different analytic conditions. First, all six participants analyzed the same set of 11 BIPs, working individually under one of three assigned conditions: **Human-Only**, **AI-Human**, or **AI-Human-Deanchoring**, with two participants per condition.

Participants in the AI-Human and AI-Human-Deanchoring conditions were provided with an LLM-generated topic list before beginning their analysis, while only the latter were explicitly warned about potential anchoring effects (see Appendix A for the full instruction). Analysts in the Human-Only condition received no AI input.

Each analyst independently reviewed all 11 BIPs and recorded a preliminary list of topics. After this individual phase, participants met in their respective condition groups for a 30-minute discussion to consolidate their findings into a group-specific topic list. Finally, all six analysts engaged in a 60-minute cross-condition discussion to synthesize the **Final Topic List**, which was later used as the reference framework in Stage 2. All individual and group topic lists are included in Appendix B.

Results In Stage 1, we collected three topic lists: from the Human-Only group, AI-Human group, and AI-Human-Deanchoring group. The analysts unanimously curated a final list of 13 topics after

reviewing all three.

Despite differences in conditions, we observed moderate overlap: six of the 13 final topics (46%) appeared in all three lists, though not always as exact matches. For instance, some themes were phrased differently across settings, such as *Educational Technology* from the AI-Human-Deanchoring list and *Technology Integration* from the Human-Only list which were conceptually merged into a single topic, *Technology Use/Integration*, in the final list. This highlights how interpretive nuance plays a role in topic curation.

Comparing each user-generated list with the AI-Only list revealed systematic differences. The AI-Only list included 8 topics. The Human-Only list had 15, with 4 overlapping (26.67%), while AI-Human and AI-Human-Deanchoring lists identified 8 and 11 topics with 3 (37.5%) and 7 (63.64%) overlapping, respectively. The Human-Only list had a more granular set of topics tailored to the dataset, whereas the AI-Only, AI-Human, and AI-Human-Deanchoring lists tended to include broader, more generic themes that echoed the LLM’s original suggestions. This suggests that the presence of LLM suggestions may have influenced annotators to propose fewer, more AI-aligned topics. In contrast, the final topic list—compiled after collaborative review—shared only 4 of 13 topics (30.77%) with the AI-Only list. This divergence suggests that discussion among annotators helped complement AI outputs by adding nuanced topics that the model did not generate.

Comparing Final Topic List and AI-Only List	# of Topics
Exact topic matches between Final Topic List & AI-Only List	4
Topics Present (or Discovered) in the Final Topic List, but not in the AI-Only List	5
Two or more topics from Final Topic List subsumed under one broader AI-Only topics ²	4
Topics completely discarded by the annotators from AI-Only List	2
Total topics in Final Topic List	13

Table 2: The comparison of the AI-Only List with respect to the Final Topic List shows that there are few topics that the model has failed to cover in its overall generation task.

However, 5 of the 13 topics in the final topic list were not present in the AI-Only list at all (see Table 2). These “missing” topics—such as *Classroom Environment* and *Attendance*—often represented context-specific or nuanced areas that the LLM failed to surface.

Additionally, annotators explicitly discarded two LLM topics, *Education* and *School Improvement Planning*, as overly broad. This further illustrates a recurring pattern: while LLMs are helpful in identifying broad thematic content, they may struggle with generating the fine-grained, action-relevant topics that human experts prioritize in education policy contexts. These findings are consistent with prior work by Choi et al. (2024), which similarly highlighted LLMs’ limitations in capturing nuanced, context-specific insights.

4.2 Stage 2: Topic Assignment

Participants used the Final Topic List to annotate a new set of 12 BIPs, each segmented into three paragraph-level fields. Participants were randomly reassigned to one of the three human-in-the-loop conditions. Those in AI-Human and AI-Human-Deanchoring received LLM-generated topic suggestions; those in Human-Only did not. We recorded the time spent on each document to facilitate an efficiency analysis.

Results Following Stage 2, we analyzed expert annotations across three conditions: Human-Only, AI-Human, and AI-Human-Deanchoring. Each paragraph in the dataset was represented as a 14-element vector—13 corresponding to topics from the Final Topic List established in Stage 1, and

²Multiple Final Topic List entries (e.g., “Academic Assessments” and “Academic Goals”) were grouped under a single LLM topic (e.g., “Student Assessment and Achievement”)

Metric	Human-Only	AI-Human	AI-Human-Deanchoring
Avg Precision	0.68	0.84	0.83
Avg Recall	0.55	0.69	0.67
Avg Annotation Speed (words/min)	73.75	71.15	89.91
Avg Annotator Agreement with AI-Only (%)	54.64	73.44	71.41
Avg Inter-Annotator Agreement (κ)	0.57	0.71	0.69

Table 3: Summary of Stage 2 results across the three settings. Metrics include annotation speed (words per minute), agreement with LLM outputs (%), and inter-annotator agreement (Cohen’s κ). See Appendix C for detailed results and metrics definitions.

one for “None”—indicating whether annotators assigned relevant topics. This structure allowed us to assess the impact of LLM suggestions on annotation behavior.

Participants used the **Final Topic List** to annotate a new set of 12 school improvement plans (BIPs), each segmented into three paragraph-level fields. Each field was annotated independently by five human analysts, resulting in 12 plans \times 3 fields \times 5 analysts = 180 annotations. Additionally, each field was annotated once under the AI-Only condition, yielding 36 more entries, for a total of 216 topic-field-annotator combinations.

We evaluated the LLM’s ability to replicate expert topic assignments using precision and recall, with the Human-Only condition treated as ground truth³. The AI-Only treatment achieved an average precision of 0.68 and recall of 0.55 when compared to Human-Only annotations, suggesting that while AI outputs are often accurate, they miss nearly half of expert-identified topics.

Annotators were significantly faster in the AI-Human-Deanchoring condition (89.91 words / min) than in the Human-Only (73.75 words/min) or AI-Human (71.15 words/min) conditions. This may reflect a tendency to anchor on LLM-generated suggestions, even when warned, leading to faster—but potentially *less critical*—annotation behavior.

Annotator agreement with AI-Only treatment was highest in the AI-Human condition (73.44%), followed by AI-Human-Deanchoring (71.41%), and lowest in Human-Only (54.64%). These findings suggest that LLM suggestions strongly influ-

³We consider the Human-Only annotations as the ground truth because, typically, experts work independently without AI-assistance. This makes the annotations the closest representation of real-life expert results in our study.

Source	Reported Cost in the paper	Standardized Cost (per 100 tokens)
Walther (2024)	\$0.001 per 100 input, \$0.003 per 100 output	\$0.004 roundtrip
DeepLearning.AI (2024)	\$4 per million tokens (GPT-4o); \$2 per million tokens (Batch API)	\$0.0002–\$0.0004
Chen et al. (2023)	\$0.20–\$300 per 10M tokens (GPT-J to GPT-4 Turbo)	\$0.000002–\$0.003
Irugalbandara et al. (2024)	5×–29× cost reduction over GPT-4	\$0.00014–\$0.0008
Samsi et al. (2023)	3–4 Joules per token (LLaMA-65B)	0.000083–0.000111 kWh
Husom et al. (2024)	0.000083–0.0023 kWh per query (2B–70B)	0.000083–0.0023 kWh
Calma (2023)	>10× increase in energy per query	Relative 10× increase (qualitative only)

Table 4: Reported and standardized LLM inference costs from recent sources. All values in the third column are standardized to cost per 100 tokens—monetary in USD and environmental in kilowatt-hours (kWh).

ence annotator decisions, and simple warnings are not sufficient to mitigate anchoring effects.

Pairwise agreement (Cohen’s κ ; Cohen, 1960) between annotators was highest when both had access to LLM suggestions (AI–Human: 0.71, AI–Human–Deanchoring: 0.69), and lowest in the Human–Only condition (0.57), reflecting a possible anchoring effect in which annotators align more closely—not with each other independently—but around the AI–provided suggestions.

5 RQ1: Estimating AI Inference Costs

Methodology To evaluate the marginal cost of using LLMs in our topic modeling workflow, we synthesized pricing and energy consumption data from peer-reviewed literature, arXiv preprints, and blog sources. For environmental costs, we reviewed the literature that estimates kilowatt-hour (kWh) usage and dollar-converted emissions per LLM inference. To enable comparison across studies with differing units and assumptions, we standardized all monetary costs to U.S. dollars per 100 tokens and converted energy-related figures to kilowatt-hours (kWh) per 100 tokens using a conversion factor of $1 \text{ kWh} = 3.6 \times 10^6 \text{ joules}$. While we do not report pretraining costs—since our study involves only inference—we present a plausible range of energy costs based on similar LLM use cases.

Results We synthesized recent estimates of both the monetary and environmental costs of LLM inference by reviewing peer-reviewed publications, technical reports, and industry analyses. Table 4 summarizes the most relevant findings.

Our analysis shows that LLM inference costs range from \$0.0002 to \$0.004 per 100-token roundtrip, depending on the model, pricing tier, and batching strategy (Walther, 2024; DeepLearning.AI, 2024; Chen et al., 2023). Models like GPT-4 Turbo average around \$0.004 per inference,

while batching can further reduce costs to as low as \$0.0002. Open-source alternatives offer additional savings, with some deployments reporting cost reductions of up to $29\times$ (Irugalbandara et al., 2024). Although not directly reporting numeric costs, theoretical analyses from Aryan et al. (2023) further support these findings by emphasizing significant potential for cost optimization through efficient deployment strategies.

Environmental costs also scale significantly with model size and usage. For example, generating 100 tokens with LLaMA-65B consumes approximately $8.3 \times 10^{-5} - 1.1 \times 10^{-4} \text{ kWh}$ (Samsi et al., 2023), while inference across commercial models ranging from 2B to 70B parameters consumes between 8.3×10^{-5} and $2.3 \times 10^{-3} \text{ kWh}$ per 100 tokens (Husom et al., 2024). Although these values may appear small in isolation, they accumulate rapidly at scale. As Calma (2023) note, the widespread integration of LLMs, such as their integration into search platforms, could increase the energy footprint per query by more than tenfold, underscoring the need for energy-efficient deployment strategies.

To contextualize these findings, we also consider the cost of human-led topic modeling, which is approximately \$48 per document per analyst (Carrell et al., 2016; Dernoncourt et al., 2017). Compared to this baseline, LLMs offer dramatic reductions in marginal financial cost per query. However, these monetary savings come with trade-offs: unlike human labor, LLM usage incurs measurable environmental impact that scales rapidly with deployment.

Moreover, since **our analysis draws from a diverse and evolving set of sources, both cost and energy estimates should be viewed as approximate benchmarks rather than fixed values**. These results underscore the importance of balancing cost-efficiency with sustainability when adopting AITM in educational research.

Setting	Coef. (s)	Std Err	z	p-value
Intercept (Human-Only)	383.7	94.8	4.1	<0.001
AI-Human	-1.6	132.8	-0.01	0.99
AI-Human- Deanchoring	-126.4	132.8	-0.95	0.34
AI-Only	-382.7	156.7	-2.4	0.015

Random Effects (Annotator): Variance = 849.67

Table 5: Linear mixed-effects model predicting annotation time (in seconds) across LLM support conditions with Human-Only as the reference category. The AI-Only condition significantly reduced annotation time, while partial AI support (AI-Human, AI-Human-Deanchoring) showed no statistically significant speed gains.

6 RQ2: Measuring Impact on Annotation Time

Methodology We used the data from stage 1 of the study to analyze annotation time.

For each human analyst, the total annotation time is calculated as:

$$\text{time}_a = \sum_{p=1}^{11} \text{time}_{ap} + 90 \text{ minutes}$$

Here, time_{ap} denotes the time spent by analyst a on Plan p , and the additional 90 minutes accounts for two structured group discussions—one 30-minute within-treatment session and one 60-minute cross-treatment session.

In total, we collected 77 person-by-document entries: 6 human analysts \times 11 Plans = 66 human entries, plus 11 entries from the AI-Only condition (1 AI \times 11 Plans). To estimate the impact of treatment on time-on-task, we fit a linear mixed-effects model:

$$\text{time}_{ap} = \text{Treatment}_{ap} + \phi_a + \varepsilon_{ap}$$

where, time_{ap} is the annotation time recorded by analyst a for Plan p , Treatment_{ap} is a fixed effect with four levels: Human-Only, AI-Only, AI-Human, and AI-Human-Deanchoring, with Human-Only as the reference category. ϕ_a is a random intercept for each analyst (6 humans + 1 AI), which accounts for analyst-specific baseline differences and increases the precision of estimates, helping us isolate the impact of the treatment more reliably. ε_{ap} is the residual error term.

Results Table 5 presents the results of this analysis. The baseline annotation time in the

Human-Only condition was approximately 384 seconds. The AI-Human condition showed virtually no difference in speed (Coef = -1.6 s, $p = 0.99$) relative to the Human-Only condition. The AI-Human-Deanchoring condition was faster by about 126 seconds relative to the Human-Only condition, but this difference was not statistically significant ($p = 0.341$). Notably, the AI-Only condition led to a statistically significant reduction of approximately 383 seconds ($p = 0.015$), representing a 6.4-minute decrease relative to the Human-Only condition. The random effect variance for annotators was estimated at 849.67, suggesting meaningful variability in baseline annotation speed between individuals. Some annotators were consistently faster or slower than others, regardless of treatment condition.

The **AI-Only** condition significantly reduces annotation time compared to **Human-Only**, suggesting that full AI support accelerates expert decision-making. However, **partial AI support** (i.e., AI-Human or AI-Human-Deanchoring) does not lead to statistically significant time savings. This indicates that the participants may have spent additional time reviewing and deliberating on the suggestions generated by the LLM. Rather than simply accepting AI outputs, Annotators have reportedly felt compelled to cross-check or validate these suggestions against their own judgment, leading to more careful and possibly slower decision-making. **This extra layer of comparison may have introduced hesitation or cognitive load, offsetting any potential efficiency gains from having AI support.** In contrast, participants in the Human-Only condition could rely solely on their intuition and expertise, resulting in a more streamlined workflow. This indicates that annotators may not gain measurable speed advantages unless they fully offload the task to the AI.

7 RQ3: Measuring Impact on Topic Identification

Methodology To evaluate how treatment condition influenced topic identification, we analyzed the Stage 2 annotation dataset described in Section 4. Each observation is a binary outcome indicating whether topic t was assigned to field f of plan p by annotator a . We fit the following multilevel linear probability model:

$$\Pr(\text{topic}_{fpat} = 1) = \text{treatment} + \eta_p + \varepsilon_{fpa}$$

Outcome	Human-Only Coef (SE) (reference)	AI-Only Coef (SE)	AI-Human Coef (SE)	AI-Human-Deanchoring Coef (SE)	Joint Test of Treat- ments (p-value)	Plan RE Variance (SE)

Table 6: Coefficients (with SEs) from multilevel linear probability models estimating the impact of treatment on topic identification, relative to the Human-Only baseline. Joint tests assess whether all AI-based treatments collectively differ from the baseline. No statistically significant differences were observed across any treatment, indicating that topic identification remained stable despite varying levels of AI assistance.

Here, topic_{fpat} is 1 if topic t was identified by analyst a in field f of plan p , and 0 otherwise. The model includes treatment as a fixed effect (with Human-Only as the reference condition) and η_p as a random intercept for each plan. This structure captures the hierarchical nature of the data while accounting for differences in topic prevalence across plans. ε_{fpa} accounts for the residual error.

We tested several alternative model specifications, including crossed and nested analyst effects, but these did not improve model fit or alter the results meaningfully. Thus, we retained the simpler formulation, which allows us to isolate the effect of treatment condition on topic identification behavior across annotators.

Results The results of the regression is given in Table 6. We used Human-Only as the reference condition and computed coefficients for each AI-based treatment: AI-Only, AI-Human, and AI-Human-Deanchoring. Each row in Table 6 presents the estimated probability of a topic being identified under each treatment, along with standard errors and joint significance test results.

For the topic *Academic Assessments*, the baseline Human-Only coefficient is 0.1979. Compared to this, the AI-Only coefficient is about 3 percentage points lower, the AI-Human coefficient is 1.1 percentage points higher, and the AI-Human-Deanchoring coefficient is 6.2 percentage points higher, respectively.

When comparing the Human-Only and AI-Human conditions reveals minimal differences across topics, with coefficients typically within ± 5 percentage points and no statistically significant deviations. This suggests that introducing AI support does not substantially shift topic identification patterns, and expert judgments remain largely consistent with the Human-Only baseline.

Next, examining the AI-Only and AI-Human conditions relative to the Human-Only baseline, we find that human analysts working with AI suggestions tend not to diverge far from the original AI-Only outputs. Instead, the AI-Human estimates tend to fall between the AI-Only and Human-Only values, implying that humans may be partially influenced— or anchored— by AI suggestions in their decision-making.

A similar pattern holds when comparing AI-Human and AI-Human-Deanchoring, each relative to the Human-Only baseline. Despite the presence of explicit deanchoring warnings, the estimates in these two conditions show minimal deviation from each other when considered through their differences from the baseline. In some cases, the deanchoring estimates are numerically closer but not statistically different to the AI-Human ones than to the Human-Only baseline. This indicates that, in this context, explicit instructions to critically evaluate AI suggestions had limited observable effect.

However, the joint significance test ($p = 0.6496$) does not indicate statistically significant differences between the treatment groups. This pattern holds across most topics. Joint significance tests across all 13 outcomes yielded p -values greater than 0.05, suggesting that the combination of effects from the three AI-based treatments does not reflect a systematic deviation from the Human-Only condition. In other words, there was no consistent pattern across the three AI conditions that significantly distinguished them from the Human-Only baseline.

The findings suggest that **while human annotators may incorporate AI input into their judgments, they are not significantly over-relying on it compared to the Human-Only condition.** Deanchoring prompts offered limited additional benefit in mitigating potential anchoring effects. **Topic identification remained stable across all treatment conditions, indicating that different approaches to incorporating AI did not produce meaningful divergence in these results.**

8 Conclusion

This study examined how AI-enabled topic modeling (AITM) can be integrated into educational research workflows, focusing on its financial, environmental, cognitive, and analytical trade-offs. Our findings show that while LLMs provide clear efficiency benefits, especially by speeding up annotation and lowering costs, these gains come with important risks. In both stages of human-in-the-loop annotation, we found evidence of anchoring bias: human analysts who saw LLM suggestions were more likely to stick with them, even when explicitly cautioned. However, when we looked at topic-level outcomes, we did not find statistically significant differences in which topics were identified across the treatment conditions. This suggests that while anchoring may shape how an-

notators approach the task, for example, in how quickly they work or how much they agree with AI, it doesn't necessarily change the final set of topics they choose.

As institutions consider scaling up AI-based analysis, the trade-off between speed and depth becomes harder to ignore. AI can definitely help efficiency and cost reduction, but human judgment is still crucial, especially for subtle, context-specific details that models tend to miss. Relying only on AI might make things more efficient, but it also risks losing the kinds of insights that matter most for real-world decisions. A balanced approach, where AI helps with the heavy lifting, but humans stay in the loop, seems like the best way to get both speed and substance.

Limitations

While this study offers important insights into the use of LLMs for topic modeling in educational research, it is essential to acknowledge its limitations. First, our analysis is based on a relatively small sample of 23 school improvement plans from a single state, which may limit the generalizability of our findings to other contexts. Second, our study focused on a specific type of text document. While these documents are relevant to educational leadership and policy, the findings may not be directly transferable to other forms of educational text, such as student essays, teacher evaluations, or policy documents. Third, our investigation of anchoring bias relied on a single de-anchoring intervention. While this allowed us to isolate the effect of such prompts, future research could explore the efficacy of other de-biasing techniques, such as structured protocols or collaborative decision-making strategies. Finally, the rapidly evolving nature of LLM pricing and energy consumption means that these figures of our cost analysis should be interpreted as indicative rather than definitive.

Acknowledgments

We are grateful to our study participants and anonymous reviewers for their valuable feedback, and also thank NEE, DESE for sharing their data and Dr. Thomas Hairston for his helpful input. This work was supported in part by a grant from the Minerva Research Initiative of the Department of Defense (Award No: FA9550-22-1-0171) and by the National Science Foundation under award IIS-2327143.

A AI-Human-Deanchoring Warning

To address the anchoring bias minimally, we introduced a new treatment AI-Human-Deanchoring. Similar to the AI-Human setting, the AI-Human-Deanchoring group also received the results generated by AI (i.e., AI-Only list) paired with the following prominently displayed instructions:

This document has annotations suggested by the LLMs. It will be your task to decide whether these annotations are correct or not. Delete or modify annotations as you see fit. However, we have found evidence of anchoring bias when annotators receive LLM suggestions. Anchoring bias is a cognitive bias where an individual relies too heavily on an initial piece of information (the “anchor”) when making decisions. This means that the initial suggestions provided by the LLM might disproportionately influence the final labels you create, potentially reducing the diversity and originality of the Final Topic List. It is important for you to be aware of this bias and make conscious efforts to critically evaluate and adjust your topics and suggestions to ensure the annotations are accurate and unbiased. We ask you to be extra critical while annotating these documents.

Our intention was to observe how experts react to the awareness of anchoring bias from LLM suggestions and whether they adjust their behavior accordingly. We also aimed to evaluate if merely knowing about the bias was effective enough to help annotators de-anchor.

B Stage 1: All topic lists

B.1 AI-Only topic list

Topic Name	Topic Definition
Education	This topic encompasses various aspects of the educational process, including instructional strategies, curriculum development, assessment methods, professional development for educators, student performance tracking, and educational objectives and goals alignment with standards.
Student Assessment and Achievement	This topic covers the processes and methodologies involved in evaluating student performance, including standardized testing, reading assessments, and other forms of academic evaluation. It also includes strategies for improving student achievement levels in core subjects like math, ELA, and science.
Professional Development	This topic involves the continuous education and skill development of teachers and educational staff, including the implementation of best teaching practices, collaboration among educators, and the use of technology and data to enhance teaching effectiveness.
Curriculum and Instruction	This topic focuses on the design, implementation, and evaluation of educational curricula and instructional materials. It includes the alignment of curriculum with educational standards, the development of instructional strategies to meet diverse learning needs, and the integration of technology into the learning environment.
School Improvement Planning	This topic covers the strategic planning processes schools undertake to improve academic performance and operational efficiency. It includes setting and aligning goals with educational standards, data-driven decision-making, and the implementation of interventions and supports to meet educational objectives.
Behavioral Interventions and Supports	This topic addresses strategies and programs designed to improve student behavior and create positive school environments. It includes the implementation of Positive Behavior Interventions and Supports (PBIS), discipline management strategies, and efforts to increase student engagement and accountability.
Parent and Community Engagement	This topic involves strategies and practices for involving parents and the community in the educational process. It includes parent-teacher communication, community partnerships to support student achievement, and stakeholder involvement in school decision-making processes.
Educational Technology	This topic covers the use of technology in educational settings, including the implementation of digital tools and resources to support teaching and learning, the use of assessment technologies, and the training of educators in effective technology integration.

Table 7: AI-Only topic list for stage 1. We generated the list using GPT-4o-mini model using chatGPT API.

B.2 Final topic list after stage 1

Topic Name	Topic Definition
Academic Assessments	This topic includes mandated annual state assessments like MAP and other district and school level assessments to evaluate academic progress.
Academic Goals	This topic covers the strategic planning processes schools undertake in aligning goals with educational standards and the implementation of interventions and supports to meet educational objectives in core subjects like math, ELA, and science.
Behavioral Goals	This topic addresses strategies and programs designed to improve student behavior and create positive school environments. It includes the implementation of Positive Behavior Interventions and Supports (PBIS), discipline management strategies, and efforts to increase student engagement and accountability.
Classroom Management	This topic covers how teachers develop and implement procedures to maximize instructional time/space/transitions/activities for efficiency in the classroom.
Classroom Environment/Culture	This topic covers how all members of the school community (administrators, teachers, and students) develop and implement pro-social behaviors inside and outside of academic instruction. This can include social-emotional learning (SEL) and fostering of pro-social attitudes and behaviors.
Curriculum	This topic covers what teachers do to plan, design, and develop materials to promote learning. This can include collaboration through professional learning communities (PLCs) as long as it is specifically around curriculum design.
Instruction	This topic covers what teachers do to deliver instruction during active academic time with students in the classroom. This includes instructional strategies and also collaboration in professional learning communities (PLCs) as long as it is specifically about how teachers engage with students in academics, instructional strategies, academic press, critical thinking, or formative assessment.
Professional Development	This topic involves the continuous education and skill development of teachers and educational staff, including evaluation of teachers, classroom observation, and collaboration around improving what teachers do to work with students.
Parent/Community Engagement	This topic involves strategies and practices for involving parents and the community (including school boards) in the educational process. It includes parent-teacher communication, community partnerships to support student achievement, and stakeholder involvement in school decision-making processes.
Technology Use/Integration	This topic covers the use and integration of technological tools, resources, and materials.
College and Career Readiness (CCR)	This topic covers college and career readiness (CCR) of students including Career & Technical Education credit hours and employment, military, and college placement.
Graduation	This topic involves the matriculation between grades and completed secondary state requirements. This is often expressed in the graduation rates of students.
Attendance	This topic involves the attendance rates and percents of students.

Table 8: Stage 1 Final Topic List curated by the participants.

B.3 All Group-Specific Topic List

Human-Only List	AI-Human List	AI-Human-Deanchoring List	Final Topic List	AI-Only List
State Assessment	School Assessment and Achievement	Student Assessment and Achievement	Academic Assessments	Student Assessment and Achievement
Localized Assessment			Academic Goals	
	Data-Driven Decisionmaking			
Behavioral Goals/ Classroom Management	Behavioral Interventions and Support	Behavioral Interventions and Supports	Behavioral Goals	Behavioral Interventions and Supports
Student Support	Data-Driven Decisionmaking			
		Classroom Management	Classroom Management	
Student/ Teacher Relationships		Classroom Culture/ Environment	Classroom Environment/ Culture	
Localized Curriculum	Curriculum and Instruction	Curriculum	Curriculum	Curriculum and Instruction
	Collaboration			
Teaching Strategies	Curriculum and Instruction	Instruction	Instruction	
Teacher Evaluation Components	Collaboration			
Professional Development	Professional Development	Professional Development	Professional Development	Professional Development
Instructional Coach				
Stakeholder Engagement	Parent and Community Engagement	Parent and Community Engagement	Parent/Community Engagement	Parent and Community Engagement
Technology Integration		Educational Technology	Technology Use/Integration	Education Technology
College, Career, Readiness			College and Career Readiness (CCR)	
Graduation/ Matriculation Rate			Graduation	
Attendance			Attendance	
	District Alignment	Education		Education
		School Improvement Planning		School Improvement Planning

Table 9: Comparison of topic lists generated across conditions in Stage 1. Entries are grouped to show thematic overlap and consolidation across all lists. Struckthrough entries indicate topics that annotators collectively decided to discard during the final discussion phase.

C Stage-2 Detailed Results:

We provide computation details for the metrics reported in Table 3. For the analysis, each paragraph-level field was encoded as a 14-dimensional binary vector: 13 dimensions correspond to the presence or absence of each topic from the Final Topic List, and the final slot indicates a “None” label (no topic assigned). These vectors were used for computing precision, recall, and agreement metrics.

Annotators	precision	recall
A1	0.57	0.5
A2	0.71	0.67
A3	0.77	0.47
A4	0.70	0.44
A5	0.65	0.65
Avg	0.68	0.55

Table 10: For each annotator in Stage 2, the precision and recall percentages of the AI-Only annotations over these documents when measured against the annotations of experts acting under the Human-Only condition. Also, the averages of these LLM precision and recall percentages.

Average Precision and Recall To evaluate how closely LLM-generated annotations align with human judgment, we compute precision and recall by comparing the LLM-assigned topics to those assigned by human annotators under each treatment condition (Human-Only, AI-Human, and AI-Human-Deanchoring).

Using the Human-Only condition as ground truth, we found that the LLM achieved an average precision of 0.68 and a recall of 0.55. This means that while 68% of LLM predictions aligned with expert judgments, nearly half of the expert-identified topics were not captured by the model. Thus, the LLM shows reasonable accuracy, but limited coverage in replicating full expert insight.

	Human-Only	AI-Human	AI-Human-Deanchoring
Average Annotation Speed (words/min)	73.75	71.15	89.91
Average Annotator Agreement with AI (%)	54.64	73.44	71.41

Table 11: Comparison of average annotation speed (words per minute) and average Human-AI agreement across the three conditions.

Average Annotation Speed To understand how LLM support affects efficiency, we calculated annotation speed in words per minute (wpm). For each document field, we divided the number of words by the time each annotator took to complete it, then averaged these speeds by condition. As shown in Table 11, annotators in the Human-Only condition averaged 73.75 wpm. This dipped slightly in the AI-Human condition to 71.15 wpm, but surprisingly jumped to 89.91 wpm in the AI-Human-Deanchoring condition—even though those annotators were explicitly warned about bias. The results suggest that having AI suggestions, even with cautionary prompts, may encourage annotators to move faster—possibly by relying on the AI’s suggestions rather than thinking through every decision from scratch.

Average Annotator Agreement with AI To assess how closely human annotators aligned with LLM-generated suggestions, we calculated the percentage of topic assignments that matched the AI-Only output. For each annotator–field pair, we compared the human-assigned topics to the AI’s and computed the overlap. These agreement scores were then averaged within each condition (see Table 11).

Agreement varied by condition. In the Human-Only setting—where annotators had no AI support—the average agreement with the AI was 54.64%. This jumped to 73.44% in the AI-Human condition, suggesting that access to AI suggestions substantially influenced annotator decisions. In the AI-Human-Deanchoring condition, agreement remained similarly high at 71.41%, even though annotators were explicitly warned about potential bias. This suggests that simply cautioning annotators may not be enough to counter the influence of LLM outputs.

Inter-Annotator Agreement. To assess how consistently annotators applied the topic labels, we used Cohen’s κ (Cohen, 1960), a standard measure for inter-rater agreement on categorical decisions. Because each document field was annotated by a pair of analysts within the same condition (see Table??), we were able to compute pairwise κ scores for each condition and then average them.

The results (Table 12) show that annotators aligned more closely when LLM suggestions were available. Agreement was highest in the AI-Human condition ($\kappa = 0.71$) and nearly as high in the AI-Human-Deanchoring setting ($\kappa = 0.69$). In

Agreement between	Human-Only	AI-Human	AI-Human-Deanchoring	Avg per Annotator
A1 and A4	0.48	0.72	0.79	0.66
A2 and A5	0.65	0.69	0.59	0.64
Avg per Condition	0.57	0.71	0.69	

Table 12: Agreement between annotator pairs across different treatment conditions. We report annotator agreement Cohen’s κ for each pair per setting. The average agreement per annotator pair is higher for the settings with LLM suggestions, implying towards a potential anchoring effect.

contrast, agreement dropped in the Human-Only condition ($\kappa = 0.57$), where annotators worked independently. These findings suggest that LLM support—regardless of deanchoring prompts—tends to guide annotators toward similar decisions, potentially reflecting a convergence effect around AI-generated suggestions.

Advances in Auto-Grading with Large Language Models: A Cross-Disciplinary Survey

Abstract

With the rise and widespread adoption of Large Language Models (LLMs) in recent years, extensive research has been conducted on their applications across various domains. One such domain is education, where a key area of interest for researchers is investigating the implementation and reliability of LLMs in grading student responses. This review paper examines studies on the use of LLMs in grading across six academic sub-fields: educational assessment, essay grading, natural sciences and technology, social sciences and humanities, computer science and engineering, and mathematics. It explores how different LLMs are applied in automated grading, the prompting techniques employed, the effectiveness of LLM-based grading for both structured and open-ended responses, and the patterns observed in grading performance. Additionally, this paper discusses the challenges associated with LLM-based grading systems, such as inconsistencies and the need for human oversight. By synthesizing existing research, this paper provides insights into the current capabilities of LLMs in academic assessment and serves as a foundation for future exploration in this area.

1 Introduction

Grading has traditionally been a manual process conducted by human teachers or graders, which can be time-intensive, laborious, and subject to inconsistencies due to individual judgment (Gnanaprakasam and Lourdusamy, 2024). To circumvent some of these issues, standardized examinations and rubrics are designed. Nonetheless, these may fail to detect variations in student ability or in learning styles (Gnanaprakasam and Lourdusamy, 2024). Furthermore, traditional grading methods fail to deliver tailored feedback at scale, further decreasing the value of exams as opportunities for personalized assessment (Haque et al., 2022).

Manual grading has significant mental and physical implications both for educators and students (Skaalvik and Skaalvik, 2017) and students (Hough, 2023). Due to its repetitive and time-consuming nature, it leads to physical and mental fatigue for educators. Previous research indicates that the stress associated with manual grading can also hinder educators' ability to focus on other critical aspects of teaching, such as lesson planning and student engagement (Hakanen et al., 2006). For students, the subjective nature of manual grading can introduce biases, which may negatively impact students' academic outcomes and their trust in the evaluation process (Wigfall, 2020). Delayed feedback from manual grading can leave students in prolonged uncertainty, which may increase their anxiety levels (England et al., 2019).

On the contrary, the rapid advancements in the field of artificial intelligence (AI), and the introduction of LLMs, capable of understanding and generating human-like text, have shifted this paradigm. LLM-based grading is any grading technique that leverages powerful Large Language Models to automate the evaluation of student responses, offering potential benefits in speed, consistency, and scalability. This shift is particularly relevant in educational settings where large volumes of assessments, such as essays and short answers, need efficient processing. Research conducted by Grandel et al. (2024) showed the ability of LLM-based grading techniques to reduce grading time by 81.2%. AI-automated grading could reduce the workload on educators, allowing them to spend more time teaching. Such systems could ensure consistency and objectivity in evaluations, reducing human biases and providing fair assessments for all students.

While individual studies have demonstrated LLM applications in specific educational domains, a comprehensive cross-disciplinary analysis is essential to understand broader patterns, identify transferable methodologies, and reveal domain-

specific challenges. Educational assessment varies significantly across disciplines—from objective STEM problem-solving to subjective humanities analysis—making it crucial to examine how LLMs perform across this spectrum. A cross-disciplinary perspective enables identification of universal best practices, domain-specific adaptations, and systematic gaps that single-domain studies cannot reveal. Moreover, such an approach allows for the synthesis of methodological insights that can inform both researchers and practitioners across diverse educational contexts.

This review paper surveys the current landscape of LLM-based assessment across six academic domains—educational assessment, essay grading, natural sciences and technology, social sciences and humanities, computer science and engineering, and mathematics. It synthesizes findings from 30 recent studies, analyzing how LLMs are applied in different assessment formats, the prompting strategies used, their alignment with human evaluators, and the contextual variables influencing performance. In doing so, this paper provides a cross-disciplinary framework for understanding the capabilities and limitations of LLM-based grading systems. It also highlights methodological trends, emerging implementation strategies, and the evolving role of human-AI collaboration in educational assessment. Overall, this paper provides a timely cross-disciplinary survey that will serve as a useful reference. It is well-scoped and captures key themes in LLM-based grading. Moreover, it brings to light current challenges and limitations in the area, such as rubric drift and LLM transparency issues.

2 Data Collection

We conducted a systematic literature review using the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) methodology to identify relevant studies on the use of large language models (LLMs) in educational assessment. The search aimed to include published academic research between January 1, 2022, through January 14, 2025. The selection focused on works that addressed LLM use in grading, feedback generation, essay evaluation, short-answer marking, domain-specific assessments, and pedagogical implications.

Our review focuses on six academic domains—educational assessment, essay grading, natural sciences and technology, social sciences and

humanities, computer science and engineering, and mathematics—selected to represent the breadth of educational assessment contexts where LLMs are being applied. These domains were chosen to span the spectrum from highly structured (mathematics, computer science) to open-ended assessments (humanities), include both technical and non-technical fields, and represent different cognitive complexity levels as defined by Bloom’s taxonomy. This selection enables a comprehensive analysis of how LLM performance varies across assessment types, content domains, and evaluation criteria while maintaining sufficient depth within each domain.

Articles were gathered from multiple scholarly databases and repositories as detailed in Table 1, including Google Scholar, arXiv, IEEE Xplore, ACL Anthology, and ERIC (Education Resources Information Center). We also examined proceedings from key conferences, including ACL, EMNLP, EDM (Educational Data Mining), LAK (Learning Analytics and Knowledge), and AIED (Artificial Intelligence in Education). Keywords used in the searches included combinations of: “large language models,” “educational assessment,” “automated grading,” “essay scoring,” “student feedback,” “ChatGPT,” “GPT-4,” “short answer evaluation,” and “AI in education.”

Studies were selected based on predefined inclusion criteria: (1) empirical studies involving LLM applications in educational assessment, (2) published between 2022-2025, (3) sufficient detail on methodology and results, and (4) focus on grading, feedback, or evaluation tasks. The PRISMA flow diagram detailing the study selection process is presented in Figure 1.

The initial search yielded 104 articles and reports. After removing duplicates, irrelevant papers (e.g., not focused on education or assessment, theoretical works without application), we filtered 48 full-text articles assessed for eligibility. We excluded the remaining articles for insufficient empirical content, lack of focus on assessment, or being out of scope (e.g., general education technology without AI involvement). This rigorous selection process yielded 30 articles for the final review. The included studies comprised 19 peer-reviewed publications and 11 preprints, reflecting the rapidly evolving nature of this research area.

3 Variables of Study

To analyze LLM applications in educational assessment, we define a set of key variables that form the basis for comparing diverse implementations. These variables are grouped into four main categories. First, the assessment types include Multiple-Choice Questions (MCQs), Short-Answer Questions, Essay Assessments, Programming Assignments, Mathematics Assessments, and Handwritten Assessments. Second, the studies span a broad range of education levels—from Early and Primary education through Secondary, Undergraduate, Graduate, to Professional Education. Third, human annotators are classified into distinct groups: Expert Evaluators, Experienced Educators, Novice Evaluators, Field Practitioners, and Unspecified Graders, a categorization that is crucial for understanding how LLM outputs compare with human judgment. Finally, evaluation metrics employed across the studies include Cohen’s Kappa, Quadratic Weighted Kappa, Krippendorff’s Alpha, Pearson and Spearman Correlations, Accuracy, F1 Score, and Win Rate. Collectively, this framework is essential for identifying patterns and making meaningful cross-disciplinary comparisons of LLM-assisted assessment. Detailed tables for each variable category can be found in Tables 2, 3, 4, and 5 in the Appendix.

4 LLMs in Assessment

Large language models face significant challenges in educational assessment contexts, particularly when evaluating higher-order cognitive tasks and providing nuanced feedback comparable to human experts (Kasneji et al., 2023; Gnanaprakasam and Lourdusamy, 2024). However, researchers have developed innovative approaches to address these limitations, demonstrating increasingly promising results across diverse educational settings.

Early evaluations by Teckwani et al. (2024) in the physiological education domain revealed that LLMs, such as GPT-3.5, GPT-4o, and Gemini, achieved only moderate alignment with human graders (for example, Gemini reached 71% agreement with $r = 0.672$), whereas experienced faculty demonstrated superior consistency (80% agreement, $r = 0.936$). This divergence was especially pronounced on higher-order cognitive tasks, which has driven further research into methods for enhancing LLM assessment performance. To address these challenges, several studies have focused on

structured rubrics and frameworks (see Appendix A.4.2). For example, Morjaria et al. (2024) found that when ChatGPT-4 was paired with question-specific rubrics, score inflation was reduced and the correlation with human reviewers improved to between $r = 0.6$ and 0.7 . In parallel, Yuan and Hu (2024) observed that Llama-UKP models, when provided with well-defined assessment criteria (see Table 2), achieved high agreement with human evaluators (Spearman $\rho = 0.843$). These results underscore that explicit, rubric-based guidance consistently leads to more interpretable and reliable feedback in diverse educational contexts.

In addition to structured frameworks, advanced prompting strategies have emerged as critical tools for optimization (see Appendix A.1). The Reason-Act-Evaluate" (RAE) prompt introduced by Li et al. (2024) structures the assessment process into three clearly defined stages: reasoning about criteria, performing an assessment, and reviewing the outcome (see Appendix A.4.3). When applied to 1,235 student-generated texts, the RAE method achieved 76.5% accuracy and demonstrated strong alignment in dimensions such as logical reasoning ($\rho = 0.824$). This approach not only mirrors human grading practices but also significantly boosts the overall reliability of LLM outputs without necessarily relying on cutting-edge architectures.

Furthermore, the most promising results have been observed when LLMs are integrated into hybrid human-AI systems. Tools such as EvalGen, developed by Shankar et al. (2024b), combine LLM-generated assessments with human oversight to mitigate challenges like criteria drift (refer to Appendix A.4). Similar hybrid approaches proposed by Sinha et al. (2023), Khan et al. (2023), and the “Assisted RAE” method by Li et al. (2024) reinforce the idea that human-AI collaboration can enhance assessment consistency and integrity while reducing individual grader workload.

Finally, comparative model insights reveal that while newer LLMs often outperform older ones, the overall effectiveness of an LLM-based assessment system depends more on the quality of prompting and implementation strategy than simply on model recency. Open-source models like Llama-UKP, when used with robust methods, can perform comparably to proprietary systems (Yuan and Hu, 2024). Complimenting this, Li’s finding—that Assisted RAE achieved 76.5% accuracy—demonstrates that strategic prompt engineering can be just as influential as acquiring the latest

model updates (Li et al., 2024).

4.1 Essay Grading

On the widely-used ASAP dataset (Automated Student Assessment Prize, a collection of 17,043 student essays across eight prompts with expert human scores). (The Hewlett Foundation, 2012), performance varies significantly across model architectures and implementation approaches. See Appendix A.2 for a detailed description. Xiao et al. (2024)'s dual-process framework using LLaMA3-8B achieved Quadratic Weighted Kappa (QWK) scores of approximately 0.7, approaching state-of-the-art models (QWK = 0.79) while maintaining over 80% score consistency. Similarly, Tang et al. (2024) found that GPT-4 achieved moderate reliability (QWK=0.5677) with criteria-referenced prompts, though still below human reliability benchmarks (QWK=0.6573). In contrast, Kundu and Barbosa (2024)'s evaluation of ChatGPT on the same dataset showed weaker correlation with human scores ($r=0.21-0.23$), though Llama-3 models demonstrated 130–173% improvement over baseline metrics, highlighting the rapid evolution in open-source model capabilities for educational assessment.

Among the prompting methods, Jauhiainen and Garagorry Guerra (2024)'s implementation of verification-based chain-of-thought prompting (see Appendix A.1) with the RAG framework achieved remarkable consistency, with 68.7% of ChatGPT-4 grades remaining stable across multiple evaluations and 72.2% aligning closely with human assessments. This approach parallels Xiao et al. (2024)'s dual-process framework, which distinguishes between a "Fast Module" for rapid predictions and a "Slow Module" for detailed feedback when confidence is low—a design inspired by Kahneman's dual-processing theory (Kahneman, 2011). Both studies demonstrate how thoughtful prompt design can dramatically improve performance even without requiring the most advanced models, with Xiao's open-source implementation achieving a 35% win rate (see Table 5) when compared to GPT-4 explanations despite using the smaller LLaMA3-8B model. Tang et al. (2024) further established that lower temperature settings (0.0) consistently produced better human alignment across models, highlighting how parameter tuning complements prompt engineering in optimizing assessment quality.

Supporting our observation that LLMs in hu-

man grading workflows show particular promise, Xiao et al. (2024)'s human-AI experiments revealed that novice graders improved from QWK 0.53 to 0.66 (approaching expert-level performance of 0.71) when provided with LLM-generated feedback, while experts reached QWK 0.77 with AI assistance. These findings align with Farrokhnia et al. (2024)'s assertion that AI tools can effectively reduce teacher workload while maintaining assessment quality. The complementary relationship between human and AI evaluation extends beyond efficiency gains, with Kundu and Barbosa (2024) noting that humans and LLMs employ distinctly different evaluation criteria—humans prioritizing essay length ($r=0.74$) while LLMs focus more on technical elements like grammar—suggesting that hybrid approaches can provide more comprehensive assessment than either alone.

Interactive assessment frameworks represent an emerging frontier, moving beyond static grading toward dynamic, dialogue-based evaluation systems. Hong et al. (2024)'s CAELF (Contestable AI Evaluation with Logic and Feedback; see Appendix A.4) introduces a multi-agent framework that enables students to challenge grades through structured debate, with Teaching-Assistant Agents discussing essay quality while a Teacher Agent resolves conflicts using principles from computational argumentation (Dung, 1995). When tested on 500 critical thinking essays (Hugging Face, 2023), this approach improved interaction accuracy by 44.6% over GPT-4o while maintaining correct evaluations in 80-90% of cases. More importantly, the system admitted mistakes 10-20% more frequently than baselines, demonstrating improved metacognitive awareness. Human evaluators particularly praised the clarity and actionable nature of the feedback, aligning with advances in LLM-driven formative assessment (Dai et al., 2023).

4.2 Natural Sciences & Technology

In the natural sciences domain, Henkel et al. (2024a) demonstrated that GPT-4 achieved near-human performance on 1,710 K-12 short-answer questions from the Carousel dataset (Cohen's $\kappa = 0.70$ compared to human $\kappa = 0.75$), with metrics of 85% accuracy, 0.87 precision, and 0.85 recall. In contrast, GPT-3.5 only reached a κ of 0.45, highlighting rapid advancements between model generations. Similarly, Tobler (2024)'s GenAI-Based Smart Grading system attained strong alignment with human evaluators (Krippendorff's $\alpha = 0.818$,

95% CI [0.689, 0.926]) in university-level assessments. Further comparisons by [Latif and Zhai \(2024\)](#) revealed that a fine-tuned GPT-3.5-turbo outperformed BERT across six scientific tasks, particularly excelling in multi-class (10.6% improvement) and unbalanced multi-label scenarios. Meanwhile, [Wu et al. \(2024\)](#)'s work on the open-source Mixtral-8x7B-instruct model showed moderate rubric alignment (F1=0.752) and a scoring accuracy of 54.58%. Their "Full-shot + Holistic Rubrics" prompting strategy outperformed both human-created rubrics (50.41%) and non-rubric baselines (33.5%), underscoring the impact of structured prompting on assessment quality.

Notably, efficiency gains in science education are compelling. GPT-4 completed evaluations of 1,710 short-answer questions in approximately 2 hours, compared to 11 hours for manual grading ([Henkel et al., 2024a](#)), and [Tobler \(2024\)](#)'s system also demonstrated significant time savings in university-level assessments. Overall, these findings indicate that carefully structured, rubric-based prompts and advanced LLM architectures not only enhance performance but also offer substantial efficiency improvements in scientific assessments.

4.3 Social Sciences & Humanities

[Lundgren \(Lundgren, 2024\)](#) and [Kostic \(Kostic et al., 2024\)](#) evaluated GPT-4 in advanced humanities assessments using distinct approaches. Lundgren's study of master-level political science essays showed that GPT-4's mean scores (approximately 5.03–5.60) generally aligned with human scores (around 4.95), although interrater reliability was very low (Cohen's $\kappa \leq 0.18$, $\leq 35\%$ agreement). In contrast, Kostic's assessment of German-language business transfer assignments revealed that GPT-4 produced markedly different scores from human evaluators (e.g. 52/50/60 vs. an average human score of about 26). Furthermore, [Kooli and Yusuf \(Kooli and Yusuf, 2024\)](#) reported moderate positive correlations between LLM and human grading (Pearson $r = 0.46$, Spearman $r = 0.518$, $p = 0.008$) for open-ended exam responses, while [Pinto et al. \(Pinto et al., 2023\)](#) observed strong LLM performance on structured exam grading. These results suggest that LLMs tend to evaluate well-defined, bounded responses more reliably than extended analytical writing, which requires nuanced human interpretation.

In addition, GPT-4 appears to prioritize evaluation criteria differently from human graders by

favoring middle-range grades and language quality over the extremes preferred by human evaluators who emphasize analytical depth. Kostic also noted that human evaluators vary widely due to factors such as fatigue and subjectivity, a variability not observed in LLM scoring. Such complementary characteristics indicate the potential for hybrid approaches that integrate human expertise with the computational consistency of LLMs ([Williamson et al., 2012](#)).

4.4 Computer Science

[Xie et al. \(2024\)](#) developed a framework that employs LLMs for rubric generation, initial grading, and post-grading review. Their system iteratively refines rubrics using sampled student responses from the OS and Mohler datasets, and employs group comparisons to enhance assessment consistency. This approach parallels [Grandel et al. \(2024\)](#)'s GreAIter system, which achieved a grading accuracy of 98.21% while reducing grading time by 81.2% for programming assignments.

Performance evaluations across different LLM architectures show that both proprietary and open-source models can yield competitive outcomes. [Yousef et al. \(2025\)](#)'s BeGrading system, based on fine-tuned open-source LLMs, demonstrated only a 19% absolute difference relative to the benchmark Codestral model when grading programming assignments. Similarly, [Koutcheme et al. \(2024\)](#) and [Smolić et al. \(2024\)](#) found that models such as CodeLlama, Zephyr, GPT-3.5, and Gemini offer useful insights and perform comparably in providing feedback on programming assignments.

Targeted prompt engineering, like all other domains has also significantly impacted computer science. [Tian et al. \(2024\)](#)'s systematic evaluation of four prompting strategies revealed that few-shot-rubric prompting consistently outperformed zero-shot approaches, with strong agreement observed for criteria such as Greet Intent (QWK = 0.698) and Default Fallback Intent (QWK = 0.797). These findings are supported by [Duong and Meng \(2024\)](#), who demonstrated that combining GPT-4 with few-shot prompting and Retrieval Augmented Generation (RAG)¹ achieved the highest performance (Pearson correlation of 0.844).

¹See Appendix A.4 for details on RAG implementation.

4.5 Mathematics

In Mathematics, multi-agent systems represent a particularly promising direction, exemplified by (Chu et al., 2024)'s GradeOpt framework, which employs three specialized LLM-based agents—Grader, Reflector, and Refiner—working in concert to optimize mathematics assessment. When evaluated on a dataset of 1,218 teacher responses to five mathematics questions, the GPT-4o-powered system achieved impressive performance metrics (0.85 accuracy and 0.73 Kappa). Further testing on an expanded dataset of 6,541 responses demonstrated significant improvement on specific questions, enhancing accuracy from 0.70 to 0.78 and Kappa scores from 0.52 to 0.64. We also see prompting strategies significantly influencing LLM performance in mathematics assessment, with chain-of-thought approaches demonstrating particularly strong results. Henkel et al. (2024b)'s comprehensive evaluation using the AM-MORE dataset (53,000 question-answer pairs from African middle school students) compared six different grading methods ranging from simple string matching to sophisticated chain-of-thought prompting with GPT-4. The results showed that chain-of-thought prompting excelled particularly on challenging edge cases, achieving 92% accuracy where other methods struggled and boosting overall accuracy from 98.7% to 99.9%. This approach yielded impressive precision (0.97), recall (0.98), and F1 scores (0.98), demonstrating how well-designed prompting strategies can substantially enhance mathematics assessment quality. When implemented within a Bayesian Knowledge Tracing framework ($P(L_0) = 0.4$, $P(T) = 0.05$, $P(S) = 0.299$, $P(G) = 0.299$), these improvements translate to more accurate student mastery estimation, highlighting the practical educational value of such advancements. In mathematics assessment, GPT-4 in particular and its variants demonstrate particularly strong performance across multiple studies and assessment contexts, from GradeOpt's 0.85 accuracy on teacher responses to Henkel's 99.9% accuracy with chain-of-thought prompting on middle school mathematics. These results consistently outperform traditional NLP approaches like SBERT and RoBERTa as demonstrated in Chu's comparative evaluation. The performance advantage appears most pronounced when LLMs are implemented with sophisticated prompting strategies or multi-agent architectures, suggesting that contin-

ued advances in implementation methods may yield further improvements even with existing model architectures.

5 Discussion and Analysis

5.1 The Explainability Imperative

A critical consideration for the widespread adoption of LLM-based assessment is the fundamental need for explainable decisions in educational contexts. Unlike other AI applications, educational assessment directly impacts student learning, progression, and opportunities, making transparency not just desirable but essential. Students require clear explanations of their grades to understand learning gaps and improve performance, while educators need interpretable feedback to guide instructional decisions. The current "black box" nature of leading LLMs presents a significant barrier to educational adoption, as stakeholders cannot adequately justify or contest assessment decisions.

5.2 Patterns in LLM Assessment Performance

The reviewed studies reveal substantial variations in LLM assessment performance across academic disciplines. Figure 2 shows that mathematics and general education yield high human-LLM agreement rates (0.74 and 0.72, respectively), whereas humanities assessments exhibit notably lower alignment (0.46)—a pattern that mirrors our observation that structured formats (see Table 2) offer clearer evaluation criteria than open-ended tasks.

GPT-4 consistently outperforms earlier models in well-structured contexts (Henkel et al., 2024a; Chu et al., 2024; Henkel et al., 2024b), yet its reliability diminishes on complex, subjective tasks. For example, in political science essays, Lundgren (2024) observed that despite similar mean scores, GPT-4 showed very low interrater reliability (Cohen's $\kappa \leq 0.18$, $\leq 35\%$ agreement). Likewise, Kostic et al. (2024) reported that GPT-4 produced scores that differed dramatically from human evaluators in business administration assessments.

Human-LLM agreement studies consistently report moderate alignment: Jauhainen and Garagorry Guerra (2024) found that 72.2% of GPT-4 grades differ by at most one grade from human scores, while Teckwani et al. (2024) noted 71% agreement between LLMs and human graders compared to 80% among humans. Tobler et al. (2024) achieved strong alignment (Krippendorff's $\alpha = 0.818$), though with notable qualitative differences

in rubric interpretation. Comparative evaluations further reveal that, while GPT-4 attains high reliability with criteria-referenced prompts (QWK = 0.5677; Tang et al. (2024)) it still falls slightly short of human benchmarks (QWK = 0.6573). Similarly, Xiao et al. (2024) demonstrated that LLaMA3-8B achieved QWK scores near 0.7 with 80% score consistency, and Morjaria et al. (2024) reported moderate to good correlations ($r = 0.6\text{--}0.7$) in medical education, despite discrepancies in 65–80% of cases.

Figure 3 reveals that single LLM approaches dominate current research (50%), while emerging alternatives such as multi-agent frameworks (10%) and chain-of-thought implementations (6.7%) show superior performance. Overall, these findings suggest that although the gap between human and LLM assessment is narrowing in structured domains, significant differences persist in evaluating complex, open-ended tasks due to varying evaluation approaches and priorities.

5.3 Methodological Approaches and Their Effectiveness

The literature reveals an evolution in prompting techniques, with more sophisticated approaches consistently outperforming simpler implementations across diverse educational contexts. As shown in Figure 4, semi-automated (0.90) and chain-of-thought approaches (0.81) demonstrate the highest human-LLM agreement rates, substantially outperforming single LLM implementations (0.53). These findings align with our categorization of prompting strategies in A.1, where we distinguish between simple zero-shot implementations and more advanced approaches like chain-of-thought. Chain-of-thought and few-shot prompting strategies have proven significantly more effective than zero-shot implementations Wu et al. (2024); Tian et al. (2024); Henkel et al. (2024b) across multiple disciplines as explained in Section 4. Multi-agent frameworks Hong et al. (2024); Chu et al. (2024); Xie et al. (2024) represent another promising methodological direction, allowing for more sophisticated assessment processes that mimic human evaluation workflows, as described in A.4.

Similarly, context-aware approaches that incorporate domain-specific knowledge show particular promise for enhancing assessment quality. Retrieval-augmented generation (RAG) Duong and Meng (2024); Jauhainen and Garagorry Guerra (2024), as detailed in A.4 has emerged as an effective

technique for contextualizing assessments with relevant educational materials. While many people have totally relied on AI to score, we also see many Hybrid human-AI approaches. These approaches yield optimal results in educational assessment by leveraging the complementary strengths of both human evaluators and LLMs. As noted by Xiao et al. (2024), positioning LLMs as assistants rather than replacements enhances overall evaluation quality and efficiency. Kundu and Barbosa (2024) observed that humans and LLMs apply different evaluation criteria—humans prioritizing essay length (with $r = 0.74$) while LLMs focus on technical elements like grammar—suggesting that a combined approach offers a more comprehensive assessment. This complementarity is evident across disciplines; for instance, Morjaria et al. (2024) reported that GPT-4 showed moderate to good correlation with human assessors ($r = 0.6\text{--}0.7$) in medical education, yet discrepancies persisted, and Teckwani et al. (2024) further reinforced the importance of human oversight by finding that human graders demonstrated 80% agreement compared to 71% for LLMs, particularly on higher-order cognitive tasks.

Figure 5 reveals important relationships between assessment types and frameworks, with certain combinations demonstrating particular prevalence. Single LLM approaches dominate essay (3 studies) and short-answer assessment (3 studies), while more specialized frameworks like chain-of-thought appear primarily with mathematical problem solving. These patterns suggest domain-specific optimization of LLM implementation strategies, aligned with our categorization of assessment formats in 2.

6 Conclusion

This review shows that LLM applications in educational assessment are advancing rapidly across various disciplines. Our analysis of 30 studies suggests that these models can help reduce the grading workload while still maintaining quality, particularly in structured contexts—GPT-4, for instance, is already nearing human-level performance in mathematics and science assessments. Innovations like chain-of-thought prompting, multi-agent frameworks, and retrieval-augmented generation are proving to be game changers for improving assessment accuracy.

However, challenges remain. LLMs continue

to struggle with nuanced, subjective evaluations in the humanities and social sciences, and rubric adherence is inconsistent. Technical hurdles, such as processing handwritten responses and handling complex programming tasks, further complicate the picture. Overall, the evidence supports a hybrid human-AI approach: LLMs are most effective when they serve as helpful assistants—automating routine tasks and generating detailed feedback—while human experts handle the more complex evaluations.

While this review focuses specifically on educational assessment, the use of LLMs as evaluators (“LLM as a judge”) is a rapidly growing area across multiple domains including legal document review, content moderation, and research evaluation. Our findings regarding prompting strategies, human-AI collaboration, and reliability challenges likely have broader applicability beyond education, suggesting opportunities for cross-domain learning and methodological transfer.

Looking forward, future research should emphasize domain-specific fine-tuning, standardize prompt engineering practices, and explore multimodal assessment strategies. Moreover, more classroom-based validation studies are needed to assess the long-term impact on learning outcomes. Despite the rapid progress in LLM technology, it is clear that human oversight remains essential for achieving high-quality educational assessment.

7 Limitations

7.1 Methodological Limitations

This review, while comprehensive within its scope, has several methodological limitations that should be acknowledged. Our analysis is based on *limited sample size and generalizability concerns*, as the review includes 30 studies, which may limit the generalizability of our findings, particularly regarding framework performance comparisons shown in Figure 3. Some framework categories are represented by only 1-2 studies, making it difficult to draw robust conclusions about their relative effectiveness. The small sample size is partly due to the nascent nature of LLM applications in educational assessment, with most research emerging only after 2022. Future reviews with larger sample sizes will be needed to validate these preliminary patterns and provide more statistically robust comparisons across framework types.

A significant issue affecting our analysis is

methodological heterogeneity across the reviewed studies. The studies exhibit significant methodological diversity, using different datasets, evaluation metrics, experimental protocols, and LLM configurations. This heterogeneity limits direct comparability and complicates the generalization of findings across studies. For instance, studies within the same discipline often use different datasets (e.g., some essay grading studies use ASAP while others use proprietary datasets), making it challenging to attribute performance differences to framework choices versus dataset characteristics. Additionally, generative AI systems employ various decoding strategies (beam search, temperature settings, top-p sampling) that can significantly impact output quality and consistency, yet these technical parameters are inconsistently reported across studies.

Our organizational approach presents another methodological consideration. While our discipline-based organization provides domain-specific insights valuable for understanding how LLMs perform across different educational contexts, an alternative methodological organization (e.g., by prompting strategies, assessment types, or hybrid architectures) might have enabled different analytical perspectives and cross-cutting insights. This organizational choice may limit the visibility of methodological patterns that transcend disciplinary boundaries. Future reviews could explore cross-cutting methodological themes to complement the domain-specific patterns we identify.

The *under-representation of K-12 studies* in our review likely reflects both limited published research in this educational level and potential search strategy limitations. K-12 educational technology adoption often faces greater institutional barriers, ethical considerations, and regulatory requirements than higher education, potentially slowing research publication in this area. Additionally, our keyword strategy may have inadvertently favored higher education terminology, though we attempted to include broad terms like “educational assessment” and “K-12.” This limitation suggests that our findings may be more applicable to higher education contexts, with K-12 applications requiring additional targeted research.

Another concern affecting the quality of our analysis is *publication quality variability*. Over one-third of the reviewed studies (11 out of 30, or 37%) are preprints that have not undergone formal peer review. While preprints provide valuable insights into cutting-edge research and emerging trends in

LLM-based educational assessment, their inclusion introduces potential quality variability to our analysis. Preprints may contain methodological limitations, incomplete evaluations, or preliminary findings that could change during the peer review process. This limitation is particularly relevant given the rapidly evolving nature of LLM technology, where researchers often share findings quickly through preprint servers to keep pace with technological advances.

7.2 Challenges from the Literature

Several recurring challenges emerge from the literature that must be addressed before widespread educational adoption of LLM assessment systems can occur. A prominent issue is Rubric adherence problems. While [Kostic et al. \(2024\)](#) report poor adherence to assessment criteria in business evaluations despite explicit rubrics, [Tobler \(2024\)](#) observed that AI sometimes adheres more strictly to rubrics than humans, indicating divergent interpretations (see Appendix A.4.2).

Another critical limitation is the *inadequate description of human grader characteristics*. Approximately 40% of studies classify human evaluators as “Unspecified Graders” (see Table 4), making it difficult to contextualize performance metrics and understand the influence of grader expertise—as exemplified by [Xiao et al. \(2024\)](#)’s finding that novice graders scored significantly lower (QWK of 0.53) compared to experts (QWK of 0.71).

A further challenge is the persistence of *grading inconsistencies* across domains. For example, [Lundgren \(2024\)](#) found that GPT-4 exhibits a central tendency bias (favoring middle grades) in political science essays, while [Kooli and Yusuf \(2024\)](#) reported that ChatGPT is more conservative in social science assessments. Similarly, [Smolić et al. \(2024\)](#) noted discrepancies between LLM-provided numerical grades and human standards in programming, highlighting challenges in aligning qualitative feedback with quantitative accuracy.

Significant *technical limitations* also remain for processing specialized content and complex assessment scenarios. [Liu et al. \(2024\)](#) encountered OCR issues in handwritten mathematics, with false positives averaging 27%, and model architecture continues to affect reliability—larger models like GPT-4 consistently outperform smaller ones, although improvements in open-source models and fine-tuning are narrowing this gap. Another concern is the “*black box*” nature of commercial LLMs, which

raises issues of transparency and explainability in educational assessment. The proprietary models (e.g., GPT-3.5/4) offer little insight into their internal decision-making processes, complicating the justification of evaluation decisions. This also leads to *critical governance questions*, as institutions risk disruptions if vendor-controlled systems are modified or discontinued. While promising open-source alternatives ([Yousef et al., 2025](#); [Koutcheme et al., 2024](#)) offer more transparent solutions, they require substantial technical capacity to implement and maintain.

There is also a notable limitation in the *scarcity of real-world, classroom-based implementations*, especially in K-12 contexts. Most studies are controlled experiments, raising concerns about ecological validity and practical challenges. Moreover, there is an *imbalanced focus on educational levels*, with over 60% of studies focusing on higher education while early childhood and primary education remain underexplored. This is particularly problematic given the distinct developmental, pedagogical, and ethical requirements for younger learners, where *ethical and privacy considerations* are especially pronounced. Collectively, these challenges call for further research into standardized methods, transparent AI, and real-world strategies to bridge the gap between experimental promise and practical assessment.

A Terminology and Definitions

This appendix provides comprehensive definitions for key terms, methodologies, and frameworks referenced throughout this review, offering detailed context beyond the condensed definitions in the main text.

A.1 Prompting Strategies

A.1.1 Zero-shot prompting

Direct instruction to the LLM to perform an assessment task without providing examples or demonstrations. The model relies entirely on its pre-training knowledge to understand the assessment criteria and generate appropriate evaluations. [Tang et al. \(2024\)](#) examined this approach for essay evaluation, finding it achieved lower reliability

(QWK=0.4321) compared to few-shot approaches. Zero-shot prompting represents the simplest implementation but typically under-performs more sophisticated strategies, particularly for complex or domain-specific assessments.

A.1.2 Few-shot prompting

Providing the LLM with a limited number (typically 3-6) of example question-answer pairs and their corresponding evaluations before asking it to assess new responses. This approach establishes a pattern for the model to follow when generating its own assessments. [Tian et al. \(2024\)](#) demonstrated that few-shot-rubric prompting consistently outperformed zero-shot approaches when assessing chatbot projects, with particularly strong performance in structured dimensions like Greet Intent (QWK=0.698) and Default Fallback Intent (QWK=0.797). [Duong and Meng \(2024\)](#) found that GPT-4 with 6 examples achieved a Pearson correlation of 0.694 with human graders, substantially outperforming simpler implementations.

A.1.3 Chain-of-thought prompting

Guiding the LLM to articulate step-by-step reasoning before providing a final assessment, mimicking human cognitive processes in evaluation. This approach is particularly effective for mathematical and logical evaluations requiring multi-step reasoning. [Henkel et al. \(2024b\)](#) used this method on the AMMORE dataset of 53,000 question-answer pairs from African middle school students, showing it increased mathematics assessment accuracy from 98.7% to 99.9% and was especially effective for complex edge cases (92% accuracy where other methods struggled). While more computationally intensive than simpler prompting methods, chain-of-thought approaches consistently demonstrate superior performance for complex assessment tasks requiring logical reasoning.

A.1.4 Reason-Act-Evaluate (RAE) prompting

A structured three-stage process where the LLM first reasons about assessment criteria (contemplating evaluation dimensions and standards), then performs the actual assessment (applying these criteria to the student response), and finally reviews its own assessment for accuracy, consistency, and adherence to rubrics. [Li et al. \(2024\)](#) developed this approach for evaluating student-generated content, achieving 76.5% accuracy across 1,235 articles with particularly strong performance in structured dimensions like logical reasoning ($\rho = 0.824$).

This technique incorporates meta-cognitive awareness into the assessment process, enabling self-correction and improved reliability.

A.1.5 Rubric-guided prompting

Explicitly incorporating detailed assessment rubrics into LLM prompts, providing structured evaluation criteria that guide the model's judgment. This approach improves alignment with human evaluation standards by making assessment criteria explicit rather than implied. [Morjaria et al. \(2024\)](#) found this approach significantly reduced score inflation tendencies when using ChatGPT-4 to evaluate medical students' short-answer assessments, achieving moderate to good correlation ($r=0.6-0.7$) with human assessors. Similarly, [Yuan and Hu \(2024\)](#) demonstrated that rubric incorporation enabled Llama-UKP models to achieve remarkable correlation with human evaluators (Spearman: 0.843) when assessing higher education courses.

A.2 Dataset

A.2.1 ASAP dataset

The Automated Student Assessment Prize dataset, released by the Hewlett Foundation in 2012 ([The Hewlett Foundation, 2012](#)), containing 17,043 student essays across eight distinct prompts with expert human scores. Each prompt represents a different essay type (e.g., persuasive, source-based, narrative) and grade level (ranging from grade 7 to 10), with varying length requirements and scoring scales. This comprehensive collection has become the standard benchmark for automated essay scoring systems, enabling direct comparison of different approaches. Studies by [Xiao et al. \(2024\)](#), [Tang et al. \(2024\)](#), and [Kundu and Barbosa \(2024\)](#) used this dataset to evaluate LLM essay assessment capabilities, with [Xiao et al. \(2024\)](#)'s implementation achieving QWK scores of approximately 0.7, approaching state-of-the-art performance (QWK 0.79).

A.2.2 ASAP++ dataset

An extension of the original ASAP dataset developed by [Mathias and Bhattacharyya \(2018\)](#) that enriches the essays with additional attribute scores beyond the holistic ratings in the original dataset. These attributes include content, organization, word choice, sentence fluency, conventions, and prompt adherence. [Kundu and Barbosa \(2024\)](#) used this enhanced dataset to evaluate LLM assessment capabilities across multiple dimensions of

writing quality, providing more nuanced analysis of model performance on different aspects of essay evaluation.

A.2.3 Carousel dataset

A collection of 1,710 K-12 short-answer questions from science and history subjects developed by Carousel Learning (Carousel Learning, 2024). The dataset includes multiple student responses to each question along with expert human evaluations based on detailed rubrics. Questions span multiple grade levels and subject areas, providing a diverse testbed for short-answer assessment capabilities. Henkel et al. (2024a) used this dataset to evaluate GPT-4's performance on K-12 short-answer grading, finding near-human performance (Cohen's $\kappa = 0.70$ compared to human $\kappa = 0.75$).

A.2.4 AMMORE dataset

The African Middle-school Math Open Response Evaluation dataset contains 53,000 question-answer pairs from African middle school students across multiple mathematical topics. This comprehensive collection includes diverse response formats and challenging edge cases that test the limits of automated assessment capabilities, including unconventional solution methods and partial understanding demonstrations. Henkel et al. (2024b) used this dataset to evaluate various assessment approaches, finding that chain-of-thought prompting achieved 99.9% overall accuracy and 92% accuracy on challenging edge cases where simpler methods struggled.

A.2.5 Mohler dataset

A computer science short-answer dataset containing 2,273 student responses to technical questions with expert human grades. This dataset features specialized computer science content requiring domain-specific knowledge for accurate assessment, including algorithm descriptions, theoretical explanations, and applied problem-solving. Xie et al. (2024) and Duong and Meng (2024) used this dataset to evaluate LLM performance on computer science assessment, with Duong and Meng (2024) achieving a Pearson correlation of 0.694 using GPT-4 with few-shot prompting.

A.2.6 OS dataset

A dataset of operating systems concept questions and student responses used by Xie et al. (2024) to evaluate their multi-agent assessment system.

This specialized collection focuses on technical computer science concepts and includes varied response types requiring domain-specific knowledge for accurate evaluation. The dataset exemplifies the challenges of assessing technical subject matter where specialized terminology and conceptual precision are essential for accurate evaluation.

A.3 Framework Definitions

- **Mixed-initiative:** Systems combining human and AI decision-making with dynamic role allocation
- **OCR+LLM:** Optical Character Recognition integrated with Large Language Models for handwritten content
- **Semi-automated:** Human-AI collaborative systems where AI provides initial assessment subject to human review
- **Multi-agent:** Multiple LLM instances with specialized roles working collaboratively

A.4 Specialized Concepts

A.4.1 Criteria drift

The phenomenon is where evaluation standards evolve or shift during the assessment process, potentially compromising consistency and fairness. This can occur with both human and LLM evaluators and represents a significant challenge for maintaining reliable assessment standards. Shankar et al. (2024a) identified this as a fundamental challenge in LLM assessment, where initial evaluation criteria may be applied differently to later responses. Criteria drift manifests in several forms:

- **Standard inflation/deflation:** Gradual shifting of grading standards to become more lenient or strict over time.
- **Criteria reinterpretation:** Subtle changes in how specific rubric elements are interpreted across different responses.
- **Priority shifting:** Changes in the relative importance assigned to different evaluation criteria during the assessment process.
- **Context effects:** Earlier responses influencing the evaluation of later responses through comparative judgment rather than fixed standards.

Addressing criteria drift requires explicit metacognitive awareness and structured review processes, which multi-agent LLM frameworks like [Chu et al. \(2024\)](#)'s GradeOpt implement through specialized roles such as the "Reflector" agent dedicated to consistency monitoring.

A.4.2 Rubric-based approach

Assessment methodologies that employ structured evaluation frameworks with explicitly defined criteria and performance levels to ensure consistent, transparent evaluation. In LLM assessment, rubric-based approaches involve providing models with these structured frameworks to guide evaluation. Key elements include:

- **Dimension specification:** Clearly identified aspects of performance to be evaluated (e.g., content coverage, organizational structure, technical accuracy, language use).
- **Performance descriptors:** Explicit descriptions of what constitutes different quality levels for each dimension, typically ranging from excellent to unsatisfactory.
- **Weighting schemes:** Optional specifications regarding the relative importance of different dimensions in the overall assessment.
- **Scoring mechanics:** Clear instructions on how to convert qualitative judgments into numerical scores, ensuring consistent quantification of performance.

Studies by [Morjaria et al. \(2024\)](#), [Wu et al. \(2024\)](#), and [Yuan and Hu \(2024\)](#) demonstrated that incorporating detailed rubrics significantly improved LLM assessment alignment with human evaluation, particularly for complex responses requiring multi-dimensional evaluation. [Morjaria et al. \(2024\)](#) specifically found that rubric incorporation reduced ChatGPT-4's tendency toward score inflation in medical education contexts.

A.4.3 Assisted RAE approach

An enhancement to the basic Reason-Act-Evaluate framework developed by [Li et al. \(2024\)](#) that incorporates metadata analysis and additional contextual information to improve assessment quality. This approach augments the three-stage RAE process (reasoning about criteria, performing assessment, evaluating quality) with supplementary information

about the assessment context, student characteristics, or relevant educational standards. The assisted version achieved 76.5% accuracy when evaluating student-generated content across 1,235 articles, with particularly strong performance in structured dimensions like logical reasoning ($\rho = 0.824$).

A.4.4 CAELF framework

Contestable AI Evaluation with Logic and Feedback, a multi-agent framework developed by [Hong et al. \(2024\)](#) that enables students to challenge AI-generated grades through structured debate. The system employs teaching assistant agents for initial evaluation and discussion of contested grades, while a teacher agent resolves conflicts using principles from computational argumentation theory ([Dung, 1995](#)). When tested on 500 critical thinking essays, this approach improved interaction accuracy by 44.6% over GPT-4o alone, maintained correct evaluations in 80-90% of cases, and admitted mistakes 10-20% more frequently than baselines, demonstrating improved metacognitive awareness.

A.4.5 Retrieval-Augmented Generation (RAG)

Enhancing LLM evaluation by retrieving and incorporating relevant reference materials from external sources to contextualize the assessment. This approach integrates domain-specific knowledge beyond the model's training data, improving performance on specialized subjects. [Duong and Meng \(2024\)](#) applied this method to software engineering course assessment, dramatically improving Pearson correlation from 0.694 to 0.844 by incorporating course materials into the evaluation process. RAG implementations are particularly valuable for domain-specific assessments where specialized knowledge or context is essential for accurate evaluation.

A.4.6 Multi-agent frameworks

Using multiple specialized LLM instances that perform different aspects of the assessment process in collaboration, mimicking human evaluation workflows with distinct roles. These frameworks typically include components like initial graders, reviewers, and arbitrators that communicate to produce a refined assessment. [Hong et al. \(2024\)](#)'s CAELF framework exemplifies this approach, employing teaching assistant agents for initial evaluation and a teacher agent to resolve conflicts, improving interaction accuracy by 44.6% over single-agent approaches. Similarly, [Chu et al. \(2024\)](#)'s

GradeOpt employed three distinct agents—grader, reflector, and refiner—working collaboratively to achieve 0.85 accuracy and 0.73 Kappa in mathematics assessment. While more complex to implement, multi-agent frameworks consistently demonstrate superior performance, particularly for nuanced assessment tasks requiring multiple perspectives.

A.4.7 Automated Short Answer Grading (ASAG)

A field focused on using computational methods to automatically evaluate student responses to short-answer questions. ASAG systems typically analyze the semantic content of responses against reference answers or rubrics to determine correctness, completeness, and relevance. LLM-based ASAG frameworks like GradeOpt (Chu et al., 2024) represent advanced approaches that can evaluate nuanced understanding beyond simple keyword matching.

Table 2: Assessment Types in LLM Evaluation Studies.

Assessment Type	Description	Typical Evaluation Method
Multiple-Choice Questions (MCQs)	Structured questions with predefined answer options where students select from available choices.	Binary correctness evaluation; typically automated using answer keys
Short-Answer Questions	Brief text responses (typically 1-5 sentences) addressing specific, bounded questions with relatively constrained correct answers.	Rubric-based evaluation against expected key concepts or knowledge points
Essay Assessments	Extended written responses (typically >300 words) requiring development of arguments, analysis, or synthesis of information.	Multi-dimensional rubrics evaluating content quality, structure, argumentation, and language use
Programming Assignments	Code writing tasks requiring functional implementation of algorithms or solutions to computational problems.	Evaluation of correctness, efficiency, readability, and adherence to programming standards
Mathematics Assessments	Problems requiring mathematical reasoning, calculation, and demonstration of procedural or conceptual understanding.	Step-by-step evaluation of solution process, correctness, and mathematical reasoning
Handwritten Assessments	Written responses composed by hand rather than digitally, requiring OCR processing before LLM evaluation.	Content evaluation following digitization; may involve image processing and character recognition

Table 3: Education Levels in LLM Evaluation Studies.

Category	Typical Age Range	Description	Examples in Studies
Early Education	Ages 3-5	Pre-primary education including kindergarten and preparatory programs	Limited representation in current studies
Primary Education	Ages 6-10	Elementary school (grades 1-5 in many systems)	Wu et al. (2024), Henkel et al. (2024a)
Secondary Education	Ages 11-18	Middle and high school (grades 6-12 in many systems)	Henkel et al. (2024a), Latif and Zhai (2024)
Undergraduate Education	Ages 18-22	Bachelor’s degree programs and equivalent tertiary education	Yuan and Hu (2024), Tobler (2024), Kooli and Yusuf (2024)
Graduate Education	Ages 22+	Master’s and doctoral programs	Lundgren (2024), Morjaria et al. (2024)
Professional Education	Various (typically 18+)	Specialized training for specific professions (medical, engineering, etc.)	Morjaria et al. (2024), Sinha et al. (2023)

Table 4: Human Annotator Categories in LLM Evaluation Studies.

Category	Definition	Typical Characteristics
Expert Evaluators	Individuals with advanced qualifications and substantial experience in the subject matter and assessment context	PhD or equivalent qualification; 5+ years teaching/evaluation experience; specialized domain knowledge
Experienced Educators	Teachers or instructors with formal teaching qualifications and moderate experience	Master’s degree or equivalent; 2-5 years teaching experience; formal pedagogical training
Novice Evaluators	Individuals with basic subject knowledge but limited assessment experience	Bachelor’s degree or equivalent; <2 years assessment experience; may include teaching assistants or student peers
Field Practitioners	Domain experts who may lack formal education qualifications but possess practical expertise	Industry experience; professional certifications; variable teaching experience
Unspecified Graders	Studies where human grader qualifications are not explicitly described	Unknown qualifications and experience levels; represents a methodological limitation in some studies

Table 5: Evaluation Metrics in LLM Assessment Studies.

Metric	Description	Typical Interpretation
Cohen’s Kappa (κ)	Measures interrater reliability between two raters, accounting for agreement occurring by chance. Scale from -1 to 1, with 1 representing perfect agreement.	< 0.40: Poor agreement 0.40 – 0.75: Fair to good > 0.75: Excellent agreement
Quadratic Weighted Kappa (QWK)	Extension of Cohen’s Kappa that assigns different weights to disagreements based on their severity. Common in essay scoring evaluation.	Similar to Cohen’s Kappa, but with increased sensitivity to disagreement magnitude
Krippendorff’s Alpha (α)	Reliability coefficient suitable for multiple raters and various measurement levels. Ranges from 0 to 1.	< 0.67: Insufficient 0.67 – 0.80: Tentative > 0.80: Reliable
Pearson Correlation (r)	Measures linear correlation between two variables. Ranges from -1 to 1.	< 0.40: Weak correlation 0.40 – 0.70: Moderate correlation > 0.70: Strong correlation
Spearman Correlation (ρ)	Measures monotonic relationships between ranked variables. Useful for ordinal data like grades.	Similar to Pearson, but for ranked data
Accuracy	Percentage of correctly identified instances. Simple measure for classification tasks.	Context-dependent; higher is better
F1 Score	Harmonic mean of precision and recall. Balances false positives and false negatives.	0 to 1 scale; higher is better
Win Rate	Percentage of instances where the LLM’s assessment is preferred over alternatives in comparative evaluations.	Context-dependent; used primarily in comparative studies

Table 6: Summary of LLM Educational Assessment Research.

Reference	Discipline / Subject	Data	Data Availability	Techniques	Results
Teckwani et al. (2024)	General Education	117 assignments aligned with Bloom’s taxonomy	Not mentioned	LLM evaluation (GPT-3.5, GPT-4o, Gemini)	LLMs: moderate consistency (Gemini: 71%, $r = 0.672$); Human: superior reliability (80% agreement, $r = 0.936$). It was found that LLMs struggled with higher-order tasks; poor human alignment ($\leq 44\%$)
Morjaria et al. (2024)	Medical Education	Medical students’ short-answer assessments	Not mentioned	ChatGPT-4 as grading assistant	Moderate to good correlation with humans ($r = 0.6-0.7$); Score discrepancies in 65–80% of cases. Including rubrics reduced ChatGPT’s score inflation tendency
Yuan and Hu (2024)	Higher Education	100 Chinese university courses	Not mentioned	GPT-4o, Kimi, and Llama models	Llama-UKP had strong correlation with human evaluations (Spearman: 0.843)
Li et al. (2024)	Educational Content	1,235 student articles	Not mentioned	“Reason-Act-Evaluate” prompt with metadata analysis	76.5% accuracy. Strong correlation with expert evaluations in structured dimensions (logic: $\rho = 0.824$)
Shankar et al. (2024b)	General (NLP)	Medical transcripts and product descriptions	Not mentioned	EvalGen tool with GPT-4	Criteria drift identified. Furthermore, revealed interdependence of criteria and outputs
Xiao et al. (2024)	Essay Grading	ASAP dataset and private Chinese dataset	ASAP: Publicly available	Dual-process framework with LLaMA3-8B	QWK scores (~ 0.7) close to SOTA (QWK 0.79); $>80\%$ score consistency. Novices improved from QWK 0.53 to 0.66 with AI assistance
Hong et al. (2024)	Essay Grading	500 critical thinking essays	Publicly available (Hugging Face, 2023)	CAELF multi-agent framework	Improved interaction accuracy by 44.6% over GPT-4o. Maintained correct evaluations in 80–90% of cases
Kundu and Barbosa (2024)	Essay Grading	ASAP and ASAP++ datasets	Publicly available	ChatGPT and Llama models	Weak correlation with human scores (ChatGPT: $r = 0.21-0.23$). It was found that LLMs excel in error detection but prioritize different criteria than humans
Jauhiainen and Garagorry Guerra (2024)	General Education	54 student responses	Not mentioned	ChatGPT-4 with verification-based chain-of-thought	68.7% grade consistency; 72.2% alignment with humans. Discrepancies in the model are addressable through prompt refinement
Tang et al. (2024)	Essay Grading	ASAP dataset (1,730 essays)	Publicly available	GPT-3.5, GPT-4, Claude 2	GPT-4: highest reliability (QWK = 0.5677). Lower temperature settings (0.0) produced better human alignment

Table 6: Summary of LLM Educational Assessment Research (continued).

Reference	Discipline/Subject	Data	Data Availability	Techniques	Results
Henkel et al. (2024a)	K-12 Science/History	1,710 short-answer questions (Carousel dataset)	Publicly available	GPT-4 and GPT-3.5	GPT-4: near-human performance (Cohen's $\kappa = 0.70$ vs. human $\kappa = 0.75$). 85% precision, 0.87 precision, 0.85 recall; automated grading required 2 hours vs. 11 hours manually
Wu et al. (2024)	Physics (Middle School)	12 physics science assessment items	Not mentioned	Mixtral-8x7B-instruct with few-shot prompting	Best configuration achieved 54.58% scoring accuracy. Strong correlation between human-aligned rubrics and accurate grading
Tobler (2024)	General Education	29 university students' responses	Consent required	GenAI-Based Smart Grading with GPT-4	Strong alignment with human grading ($\alpha = 0.818$). Based on results from the study, AI exhibited stricter adherence to rubrics
Latif and Zhai (2024)	Science Education	2,600 middle/high school responses	Not mentioned	Fine-tuned GPT-3.5-turbo vs. BERT	GPT-3.5: mean precision of 0.915 vs. BERT: 0.838. GPT-3.5 showed strength in multi-class tasks (10.6% improvement)
Lundgren (2024)	Political Science	60 master-level essays	Not mentioned	GPT-4 with four prompt types	Low interrater reliability (Cohen's $\kappa \leq 0.18$). GPT-4 favored middle grades; detailed prompts didn't improve accuracy
Kostic et al. (2024)	Business Administration	German-language business assignments	Not mentioned	GPT-4 with three prompt variations	Unreliable grades (e.g., overscoring). This study revealed that the automated system displayed poor rubric adherence, and is inadequate for nuanced assessment
Kooli and Yusuf (2024)	Social Science	25 open-ended exam responses	Not mentioned	ChatGPT vs. human grader	Moderate positive correlation (Pearson $r = 0.46$). ChatGPT found to be more conservative and variable than humans
Xie et al. (2024)	Computer Science	OS and Mohler datasets	Not mentioned	Multi-agent system for rubric generation	Improved grading consistency. However, challenges in achieving complete fairness and rubric precision
Yousef et al. (2025)	Programming Education	Python and Java assignments	Not mentioned	BeGrading system with fine-tuned LLMs	19% absolute difference rate. Fine-tuning small models improved performance
Koutcheme et al. (2024)	Programming Education	Programming assignments	Not mentioned	CodeLlama and Zephyr	Zephyr models performed similarly to proprietary models. Open-source LLMs can offer meaningful student feedback

Table 6: Summary of LLM Educational Assessment Research (continued).

Reference	Discipline / Subject	Data	Data Availability	Techniques	Results
Smolić et al. (2024)	Programming Education	Student code submissions	Not mentioned	GPT-3.5 and Gemini	Useful insights for code review; numerical grades inconsistent with human standards
Schneider et al. (2023)	Computer Science	Short-text answers from university courses	Not mentioned	ChatGPT-3.5	Inconsistent grading; struggled with contextual understanding and course-specific knowledge
Duong and Meng (2024)	Software Engineering	Mohler Dataset (2,273 answers) and SE Dataset (421 answers)	Not mentioned	Embedding-based and completion-based methods	GPT-4 with 6 examples: Pearson correlation of 0.694. GPT-4 superior to GPT-3.5 but at higher cost
Grandel et al. (2024)	Programming Education	Programming assignments	Not mentioned	GreAIter semi-automated system with ChatGPT-4	98.21% grading accuracy; reduced grading time by 81.2%
Tian et al. (2024)	AI Education	75 chatbot projects	Not mentioned	GPT-4 with four prompting strategies	Good performance in some dimensions (QWK=0.698). Few-shot-rubric prompting outperformed zero-shot
Pinto et al. (2023)	Software Engineering	Responses to open-ended questions	Not mentioned	ChatGPT	Aligned with expert evaluations; good at identifying misunderstandings
Gao et al. (2023)	Mechanical Engineering	Quiz dataset (70 students) and Activity dataset (85–95 students)	Not mentioned	7 NLP models (BERT, T5, etc.)	PromCSE excelled in binary tasks. NLP models struggle with precision and complex questions
Chu et al. (2024)	Mathematics	1,218 teacher responses and 6,541 teacher responses	Not mentioned	GradeOpt multi-agent framework with GPT-4o	0.85 accuracy and 0.73 Kappa. More effective than traditional methods
Liu et al. (2024)	University Mathematics	Handwritten calculus exam (54 students)	Consent required	GPT-4 with Mathpix and GPT-4V for OCR	Accuracy: 0.59 to 0.62. Whole-page OCR outperformed answer-box methods
Henkel et al. (2024b)	Middle School Mathematics	AMMORE dataset (53,000 question-answer pairs)	Publicly available	Chain-of-thought prompting and LLMs	92% accuracy on edge cases; 99.9% overall accuracy. Chain-of-thought prompting excelled but required more processing time

Unsupervised Sentence Readability Estimation Based on Parallel Corpora for Text Simplification

Abstract

We train a relative sentence readability estimator from a corpus without absolute sentence readability. Since sentence readability depends on the reader’s knowledge, objective and absolute readability assessments require costly annotation by experts. Therefore, few corpora have absolute sentence readability, while parallel corpora for text simplification with relative sentence readability between two sentences are available for many languages. With multilingual applications in mind, we propose a method to estimate relative sentence readability based on parallel corpora for text simplification. Experimental results on ranking a set of English sentences by readability show that our method outperforms existing unsupervised methods and is comparable to supervised methods based on absolute sentence readability.

1 Introduction

Readability estimation of text, such as words, sentences, and documents, is applied to assist in text recommendation and simplification for a wide range of readers, including children (Xu et al., 2015), language learners (Xia et al., 2016), and people with cognitive disabilities (Yaneva et al., 2017), according to their language abilities. We work on readability estimation for sentences, which are the main units in the text simplification task (Alva-Manchego et al., 2020).

Since sentence readability depends on the reader’s knowledge, objective and absolute readability assessments require costly annotation by experts. Therefore, corpora annotated with absolute readability are limited to a scale of $1k$ to

$10k$ sentences even in English (Stajner et al., 2017; Arase et al., 2022), and are rarely available in other languages. This low-resource problem hinders research and development of high-quality supervised sentence readability estimation.

In this study, we train a relative sentence readability estimator based on labeled corpora for relative sentence readability, which are more accessible than those with absolute sentence readability labels. Our proposed method estimates which of two given sentences is more readable based on pairs of complex sentences and simpler sentences in parallel corpora for text simplification. The estimator is then applied to pairwise comparisons of a given set of sentences to rank them in terms of readability.

Experimental results on ranking a set of English sentences by readability show that the proposed method outperforms existing unsupervised methods. In addition, our proposed method achieved performance comparable to supervised methods that consider absolute sentence readability.

2 Related Work

For estimating text readability, supervised methods (Vajjala and Lučić, 2018; Deutsch et al., 2020) have been proposed that consider readability indices, linguistic features, and language model scores. Since they are based on corpora annotated with absolute sentence readability, they can not apply to languages without labeled corpora available.

Unsupervised methods such as FKGL (Kincaid et al., 1975) and other readability metrics and ranking methods based on relative readability estimation (Tanaka-Ishii et al., 2010) have been proposed. However, they are targeted at documents and are not applicable to sentences.

*Work done during an internship at The Asahi Shimbun Company.

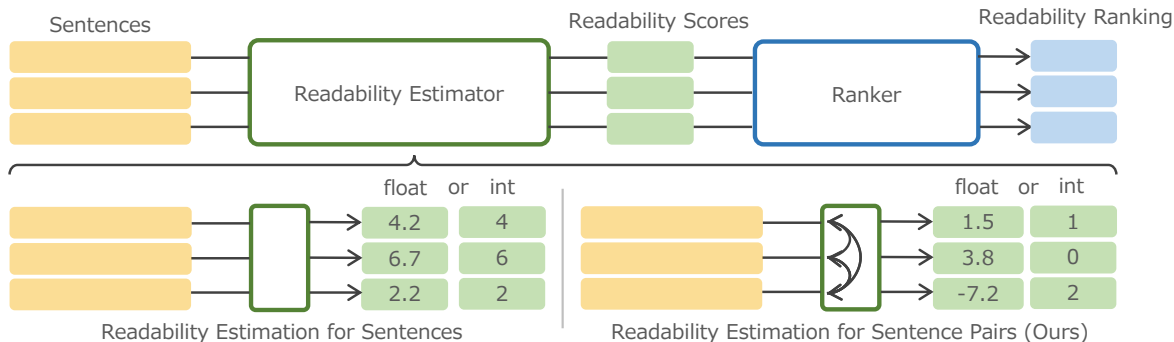

Figure 1: System overview

3 Method

We first train a relative sentence readability estimator that estimates which of two given sentences is more readable, based on parallel corpora for text simplification. The estimator is then applied to pairwise comparisons of a given set of sentences to rank them in terms of readability. The overall system process consists of estimating readability by using the Readability Estimator and then ranking them, as shown in the upper part of Figure 1.

3.1 Relative Sentence Readability Estimator

Our sentence readability estimator is based on fine-tuning pre-trained masked language models (Devlin et al., 2019). From sentence pairs in parallel corpora for text simplification, we create input sequences of “[CLS] complex sentence [SEP] simple sentence” with special tokens indicating the beginning and sentence boundaries. Note that in 50% of the input sequences, the positions of complex and simple sentences are swapped. We train a binary classifier with this dataset to estimate which of two given sentences is more readable.

3.2 Readability Ranking

We rank each sentence in a given set of shuffled sentences by readability using a pairwise comparison method. In other words, the relative sentence readability is estimated for all combinations of two sentences in a given set of sentences, as shown in the bottom right-hand corner of Figure 1. The readability of a sentence is given as an integer, if there is a tie, it depends on the order of input. Finally, we obtain a ranking according to the probability that each sentence is estimated to be more readable.

	Train	Valid	Test
Newsela	385,270	42,323	43,171
CEFR-SP	-	-	17,676

Table 1: Corpus size

4 Experiments

In this section, we experiment with ranking a set of English sentences by readability. Following previous studies of document readability rankings, we evaluated rankings according to four metrics: normalized discounted cumulative gain (NDCG), Spearman’s correlation (ρ), Kendall’s correlation (τ), and ranking accuracy (RA).

4.1 Experimental Setup

Datasets As shown in Table 1, a relative sentence readability estimator was trained on a training set of 385k sentence pairs and a validation set of 42k sentence pairs from the parallel corpus for text simplification, Newsela¹ (Xu et al., 2015; Jiang et al., 2020). A set of 43k sentence pairs for evaluation was used to construct a set of sentences for readability ranking.² We also constructed a set of sentences from the CEFR-SP³ (Arase et al., 2022), an English corpus with absolute sentence readability. Note that since the CEFR-SP is not a parallel corpus, it is a set of non-synonymous sentences, unlike Newsela. The CEFR-SP has six levels of readability labels for each of the 17k sentences, and we randomly selected one sentence at each level to obtain a set

¹<https://github.com/chaojiang06/wiki-auto>

²Newsela is a parallel corpus consisting of English news articles manually simplified into four levels. In this experiment, sets of synonymous sentences consisting of different simplifications for the same source sentences were ranked in terms of their readability.

³<https://github.com/yukiar/CEFR-SP>

of sentences. Finally, the set of sentences for evaluation from Newsela totals 4, 478 pairs of five level sentences and one from CEFR-SP totals 165 pairs of six level sentences.

Model For our sentence readability estimator, we employed BERT⁴ (Devlin et al., 2019) as a pre-trained model. We used batch size of 128 sentence pairs, AdamW (Loshchilov and Hutter, 2019) optimizer with a learning rate of 5×10^{-5} . We employed early stopping for fine-tuning with a patience of 3 epochs using a cross-entropy loss in the validation set.

4.2 Baseline models

Baseline unsupervised models We employed two comparative methods of unsupervised sentence readability estimation: define RSRS (Martinc et al., 2021) based on language model scores⁵ and methods based on in-context learning of large language models (LLM). The overall system process follows the upper part of Figure 1, as in our method. In addition, RSRS and LLM estimate the readability of each sentence in the set, as shown in the bottom left-hand corner of Figure 1. In this case, RSRS is a floating, and LLM is an integer.

For the LLM-based method, we used LLaMA⁵ (Touvron et al., 2023) in two settings, 0-shot and 10-shot. We used the prompts in Figure 2 for experiment, which we modified for sentence readability estimation from the prompts used in a previous study (Wang et al., 2024) working on document readability estimation. 0-shot, in which no examples are presented in the prompt (the “example” portion of Figure 2), and 10-shot, in which 10 examples are presented at each readability level. These examples were randomly selected from valid set from Newsela.

Baseline supervised models We employed two types of baselines for supervised sentence readability estimation: the Pointwise method, which imputes sentences, and the Pairwise method, which imputes sentence pairs. The overall system process follows the upper part of Figure 1, as in our method. These are sentence readability estimation models based on masked language models as in the proposed method, but they were trained using absolute

⁵<https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct>

System Prompt:

Evaluate the readability of the text using the following eleven levels (reading difficulty):

[score: 2]: Most Easy

[score: 12]: Most Difficult

Based on the provided text examples, assign a readability score to new text and display it in the following format: "[score: X]"

User Input:

Text: {example 1}

[score: 2]

...

Text: {example n}

[score: 12]

New text:

Text: "{}"

Figure 2: Prompt for LLM-based readability estimation.

sentence readability labels in the Newsela corpus,⁶ unlike the proposed method. The pointwise method is a regression model that estimates the readability of input sentences using masked language models and obtains a readability ranking by the readability of each sentence. This baseline estimates the readability of each sentence in the set, as shown in the bottom left-hand corner of Figure 1. In this case, pointwise is a floating.

The pairwise method inputs two sentences as in the proposed method, but unlike the proposed method, it is a regression model that estimates the difference in readability between two given sentences. The pairwise method can provide a binary classification of which sentence is more readable according to whether the output score is positive or negative, resulting in a readability ranking as in the proposed method.

4.3 Results

Readability ranking on Newsela The left side of Table 2 shows the experimental results of readability ranking for a set of synonymous sentences in Newsela⁷. Our method consistently achieved the

⁶There are only a few corpora with sentence readability. So, following previous studies on text simplification (Scarton and Specia, 2018; Nishihara et al., 2019; Yanamoto et al., 2022), the readability of a sentence is defined as the readability of a document containing that sentence. However, but we understand that this is not the best approach.

⁷In this experiment, we use Newsela to enable evaluation, but our method does not use readability labels.

	Supervised	Newsela (Parallel)				CEFR-SP (Non-Parallel)			
		NDCG	ρ	τ	RA	NDCG	ρ	τ	RA
RSRS	-	0.913	0.402	0.341	0.081	0.851	0.082	0.060	0.000
LLM (0-shot)	-	0.888	0.207	0.178	0.041	0.861	0.034	0.027	0.000
Ours	-	0.985	0.865	0.799	0.421	0.958	0.749	0.619	0.048
Pointwise	✓	0.980	0.841	0.769	0.369	0.949	0.661	0.529	0.012
Pairwise	✓	0.986	0.874	0.811	0.438	0.961	0.755	0.621	0.048
LLM (10-shot)	*	0.953	0.644	0.550	0.130	0.967	0.764	0.636	0.073

Table 2: Experimental results of sentence readability estimation. For each setting, unsupervised and supervised, the highest performance is highlighted in bold. * is a few-shot in-context learning.

best performance among the unsupervised methods in the upper rows. The fact that the pairwise method performed better than the pointwise method among the supervised methods suggests that it is important to consider the relationship between sentences for relative readability estimation. Although the supervised pairwise method showed the best performance, our proposed method in an unsupervised manner also achieved comparable performance. Furthermore, the proposed method outperforms the supervised pointwise method and the LLM-based method in the few-shot setting, revealing its effectiveness.

Readability ranking on CEFR-SP The right side of Table 2 shows the experimental results of readability ranking for a set of non-synonymous sentences in CEFR-SP. Similar to the experimental results on Newsela, the proposed method achieved the best performance among the unsupervised methods in the upper rows. However, experiments with non-synonymous sentence sets showed significantly lower RA overall. In comparison with the supervised methods, the proposed method outperforms the pointwise method and is comparable to the pairwise method, again similar to the experimental results on Newsela. In CEFR-SP, the LLM-based method with the few-shot setting outperformed the other supervised methods, achieving the best performance.

4.4 Analysis

We analyse in detail an experiment on readability ranking for synonymous sentence sets in Newsela.

Is relative sentence readability estimation easier the larger the difference in readability between sentence pairs? → **Yes.** To clarify this, we append experiments. Table 3 shows the accuracy

Difference in readability	Accuracy
1	0.759
2	0.886
3	0.954
4	0.990

Table 3: Analysis of the impact of differences in readability of sentence pairs on readability estimation.

results of the readability estimation by splitting the sentence pairs in different levels of readability. The results of this analysis show that as the difference in readability increases (more levels of simplification), the accuracy of relative readability estimation improves. As expected, we can conclude that the larger the difference in readability between sentence pairs, the easier the relative readability estimation is. In specific examples, sentence pairs with small differences, such as “Sub-Saharan Africa has benefited from **high** oil and other commodities **prices**, which have started to decline sharply. → Sub-Saharan Africa has benefited from **high prices for** oil and other commodities, which have started to decline sharply.”, which is a one-level simplification, have a small difference in readability, and it is difficult to determine the latter sentence is simpler. On the other hand, sentence pairs with large differences, such as “Any artifacts linked to an emperor would bring tremendous pride to Mexico. → Finding remains of those leaders would make Mexico proud.”, This is a four-level simplification, has a large difference in readability, and it is easy to determine the latter sentence is simpler. In fact, our method failed to estimate the readability in the top example and succeeded in the bottom one.

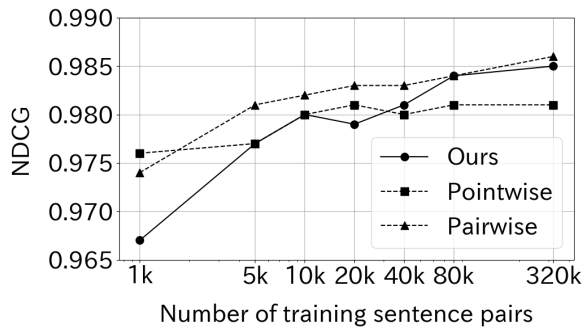

Figure 3: Analysis of the impact of training data size on readability estimation.

How many sentence pairs of parallel corpus for training text simplification make the proposed method effective? → 5k sentences pairs. To clarify this, we append experiments. Figure 3 shows the results of evaluating the quality of the readability ranking (NDCG) while reducing the training data of 385k sentence pairs from 320k to 1k sentence pairs. The results of this analysis show that the text simplification parallel corpus for training our method performs better than the unsupervised sentence readability estimation of RSRS and LLM, NDCG = 0.967 for 1k sentence pairs only. As a text simplification parallel corpus of this scale is available in several languages including Japanese, so the method is promising for the multilingual deployment of sentence readability estimation. And if we can prepare a text simplification parallel corpus consisting of 5k sentence pairs, to reach comparable performance with supervised sentence readability estimation.

5 Conclusion

In this study, we approach unsupervised sentence readability estimation, which does not use absolute sentence readability data. We train a relative sentence readability estimator that predicts which of two given sentences is more simple, using a text simplification parallel corpus, in our method. Then, we derived a readability ranking for the sentence set by pairwise comparisons. Experimental results in English show that our method outperforms previous unsupervised sentence readability estimation for both synonymous and non-synonymous sentence sets, and achieves performance comparable to supervised methods trained with absolute sentence readability.

Limitations

Although the proposed method was designed with multilingual applications in mind, the experiments in this paper are limited only to English. There is no guarantee that performance consistent with this experiment will be achieved in other languages. As mentioned in Section 1, corpora annotated with sentence readability are scarce, and annotating them is very expensive, therefore, it is not easy to actually experiment with non-English languages.

Abstract

This study presents a teacher-centred evaluation of an AI-powered reading comprehension tool, developed to support learners with language-based difficulties for English and Italian. Drawing on the Social Acceptance of Technology (SAT) framework, we investigate technical usability and the pedagogical, ethical, and contextual dimensions of AI integration in classrooms. We explore how teachers perceive the platform's alignment with inclusive pedagogies, instructional workflows, and professional values through a mixed-methods approach, including questionnaires and focus groups with educators. Findings revealed a shift from initial curiosity to critical, practice-informed reflection, with trust, transparency, and adaptability emerging as central concerns. The study contributes a replicable evaluation framework and highlights the importance of engaging teachers as co-designers in developing educational technologies.

1 Introduction

As Natural Language Processing (NLP) continues to advance, its applications in education are expanding rapidly—from intelligent tutoring systems to automated writing feedback and reading support (Su et al., 2023; Özer, 2024; Zawacki-Richter et al., 2019). These AI-powered tools promise to transform instruction (Maity and Deroy, 2024), yet a key question remains: How do they perform in real classrooms with real teachers and students? Do they align with the practical realities and pedagogical expectations of educators, ensuring both usability and instructional relevance? (Cesaroni et al., 2024) Many systems are developed in controlled settings with limited educator input (Celik et al., 2022; Cukurova and Luckin, 2018; Luckin and Cukurova, 2019), often overlooking pedagogical realities and learning science principles (Luckin and Cukurova, 2019; Cesaroni et al., 2025).

Addressing this disconnect requires greater attention to the roles educators play, not just as passive users, but as active contributors throughout the AI development cycle. Indeed, teachers have already played various roles in educational AI research (Celik et al., 2022). They served as models for AI training through classroom data (Su et al., 2014; Kelly et al., 2018), shared professional development information to improve predictive systems (Alzahrani and Alzahrani, 2025; Yoo and Rho, 2020), and provided student data to support AI-driven interventions (Bonneton-Botté et al., 2020; Nikiforos et al., 2020). They have also validated AI outputs by grading work and defining evaluation criteria (Huang et al., 2010; Yuan et al., 2020), influenced pedagogical alignment through instructional material selection (Dalvean and Enkhbayar, 2018; Fitzgerald et al., 2015), and in some cases, offered technical feedback on system design (Burstein et al., 2004). Despite these contributions, their role as evaluators who shape AI integration in classroom contexts remains largely underexamined.

Building on this foundation, the paper presents an evaluation framework of an AI-powered reading comprehension interface using a framework that places educators at the centre of AI integration. Although applied to a single interface in this study, the framework is generalizable to the evaluation of AI technologies across diverse educational contexts. This framework draws on the SAT model to examine the pedagogical, ethical, and practical dimensions of AI adoption in education. Through a mixed-methods approach involving questionnaires and focus groups, we not only assess how teachers perceive the system but also explore how their insights can shape more effective, inclusive, and ethically grounded AI implementation in real classroom settings.

Our findings highlight the value of participatory design, showing that teachers act as co-designers and evaluators, not just users. Their acceptance of

AI tools relies on alignment with pedagogical values, transparency, and autonomy. While they saw promise in promoting inclusion and differentiated instruction, they also pointed to needed improvements in clarity, layout, and customisation. These insights call for ethically grounded, teacher-centred approaches and further research through long-term classroom use, evaluation and broader educator involvement.

2 Background

2.1 Existing Reading Comprehension Interfaces

Reading comprehension interfaces aim to support users in understanding and engaging with complex textual material. Unlike general reading tools, these systems are designed to go beyond passive reading by incorporating interactive features such as question answering, summarisation, sentence simplification, and semantic annotations. Existing tools focus on general users and surface-level comprehension, lacking therapeutic intent, multilingual support, and personalisation.

One of the most notable efforts in this domain is the Semantic Reader Project (Lo et al., 2023), which augments scientific documents with context-aware explanations, definitions, and citation-level summaries to help readers quickly identify core ideas. Similarly, systems like SciReader (Head et al., 2021) employ semantic highlighting, definitions on hover, and automatic summarisation to assist users, particularly researchers, in navigating dense academic material. However, these tools are not tailored to students with reading comprehension deficits or learning disorders.

Another promising direction involves gaze-driven sentence simplification interfaces, such as the work of Higasa et al. (2023), which are particularly relevant for language learners or readers with cognitive impairments. These systems use real-time eye-tracking data to detect reading difficulty and apply NLP techniques to simplify complex sentences. However, while useful as assistive technologies, they do not provide structured activities aimed at rehabilitating underlying comprehension deficits.

Complementing these assistive tools are educational systems like 3D Readers (3dR) and CACSR (Kim et al., 2006), which take a more interactive and instructional approach to enhancing reading comprehension. 3D Readers allow

users to engage with texts through either verbal strategies (such as question generation) or visual strategies (like manipulating images), with immediate feedback provided to support learning (Johnson-Glenberg, 2007). Similarly, CACSR offers personalised instruction using techniques like visual imagery, graphic organisers, mnemonics, self-questioning, and summarization (Stetter and Hughes, 2011), also incorporating real-time feedback to support continuous assessment (Kim et al., 2006). Despite their effectiveness in educational settings, these systems are not designed with therapeutic goals in mind.

Moreover, existing systems are designed for English-language users. There appears to be only one known system available in Italian that supports integrated telerehabilitation: RIDInet¹. The platform offers activity modules like the Cloze Application, which trains reading comprehension through multiple-choice tasks. However, RIDInet does not offer targeted exercises for developing word-level literal understanding, nor does it support the integration of prior knowledge with new textual input.

2.2 Assessment of AI-Powered Educational Technologies

Evaluating AI-powered educational tools poses a methodological challenge due to the lack of frameworks integrating pedagogical, psychological, and social dimensions of technology adoption. Existing models, such as the Technology Acceptance Model (TAM) (Davis, 1989) and the Unified Theory of Acceptance and Use of Technology (UTAUT) (Venkatesh et al., 2003) offer robust tools for analysing perceptions of usefulness, usability, and behavioural intention. However, these frameworks emphasise generic constructs (e.g., efficiency, ease of use), but often neglect education-specific factors such as alignment with instructional goals, teacher–student dynamics, and pedagogical adaptability.

The Technological Pedagogical Content Knowledge (TPACK) framework (Koehler and Mishra, 2009) addresses the integration of technology into pedagogy, but primarily with a formative intent. It delineates the competencies required to design learning experiences that effectively combine technological tools with pedagogical strategies and disciplinary knowledge. However, it lacks evaluative tools for real-world adoption, omitting con-

¹<https://www.anastasis.it/ridinet/>

cerns like ethical implications, institutional fit, and teacher autonomy. For instance, a teacher may possess TPACK proficiency in using an NLP tool yet refrain from adopting it due to ethical concerns (e.g., algorithmic bias) or practical constraints (e.g., misalignment with classroom workflows) — factors that lie outside the scope of TPACK.

To address this gap, this study adopts a mixed-methods approach guided by the SAT framework (Occhipinti et al., 2023) to explore the use of AI tools in educational settings. Unlike traditional models that primarily assess individual user experience or usability, the SAT framework views technology as part of a broader socio-technical system. By focusing on four interrelated dimensions (User Experience, Value Impact, and Trust), SAT enables an assessment that extends beyond subjective usability to encompass ethical, cultural, and contextual factors. In the context of schools, the study uses SAT to design questionnaires and focus groups that examine how a software for the teaching of reading comprehension aligns with pedagogical values, affects teacher relationships and institutional structures, and impacts trust. Special emphasis is placed on the Value Impact and Trust dimensions, which help uncover educators’ perspectives on issues like inclusion, transparency, autonomy, and coherence with teaching practices.

3 System Description

In this paper, we present a novel and enhanced version of ARTIS (Galletti et al., 2023, 2024). ARTIS is a web-based educational tool designed to support reading comprehension for primary school students, with a particular focus on learners with reading difficulties or language-based learning disorders up to 11 years old (Galletti et al., 2023). The system integrates a multimodal approach to text comprehension by combining visual, auditory, and interactive components. The interface supports multilingual content (Italian and English), making it adaptable for bilingual contexts or second-language learners. While some of the assistive features were previously introduced in Galletti et al. (2024), this version introduces new rehabilitative features, an enhanced administrative dashboard, as well as updated design and graphics.

The design of the platform’s features is grounded in the psycholinguistic model of reading comprehension proposed by Kintsch and van Dijk (Kintsch and Van Dijk, 1978; Galletti et al., 2023). This

model outlines three levels of text comprehension. First, there is surface representation, which involves recognizing words and grammar (i.e. lexical and morphosyntactic understanding). Second, there is propositional representation, where readers connect ideas into meaningful sequences and structures. Finally, there is the mental model construction, where readers combine what the text says with their background knowledge.

Following Kintsch and Van Dijk’s model, our interface includes different modules and exercises targeting different comprehension levels: lexical understanding, propositional structuring, and mental model integration, each progressively supporting deeper text processing. In the next subsection, we describe each module and the algorithms behind its core functionalities².

3.1 Assistive Features

Upon logging into the platform, students can access a digital library interface that displays a collection of illustrated literary and informational texts. Each title is visually represented with a stylised image and a short textual excerpt to support browsing and engagement. Once a text is selected, the reading interface presents the full passage along with assistive features such as read-aloud audio, using the Google text-to-speech API, synchronized text highlighting, and pace controls (e.g., play, pause, and speed adjustment). These supports are designed to aid comprehension while still requiring the child to engage actively with the text.

Figure 1: Keywords like “*bambini*” (“children”) and “*sciarpa*” (“scarf”) are highlighted and paired with pictograms to support understanding.

In a subsequent step, the text is presented sentence by sentence thanks to the spaCy Sentencizer³ and key terms within the passage are visually highlighted and linked to pictograms that

²A recorded demonstration of our proof of concept is available at this [link](#).

³<https://spacy.io/api/sentencizer>

illustrate their meaning, as in Figure 1. Secondly, keywords are extracted using a fine-tuned version of Keybert (Grootendorst, 2020). To ensure accuracy and prevent misleading outputs, the extracted keywords were manually reviewed by speech and language therapists as described in Galletti et al. (2023). Once the keywords were extracted from the sentences, after lemmatisation, we used the Arasaac API⁴ to link them to pictograms.

In a third step, unfamiliar or specific terms are also supported with definitions and example sentences drawn directly from the source passage, as in Figure 2. These terms are selected either manually by the operator or automatically extracted as detailed in Galletti et al. (2023). Users can interact with the words to hear their definitions, view pictograms illustrating their meanings, and see them embedded in the text, supporting multi-sensory learning and strengthening decoding skills. For definitions, we used *gpt-3.5-turbo-0125*⁵.

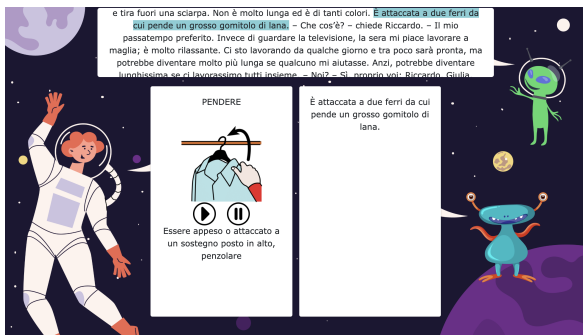

Figure 2: Vocabulary’s support a not common Italian verb “*pendere*” (“to hang” or “to dangle”). The left panel shows the pictogram associated with it, a definition, and audio playback buttons to support its comprehension.

3.2 Rehabilitative Features

A variety of comprehension and language-focused exercises are included to deepen semantic processing and support inference-making skills. These activities comprise: (1) “*Leggi e rispondi*” (“Read and Respond”), where students answer comprehension questions generated by *gpt-3.5-turbo-0125* and manually validated by speech and language therapists; and (2) “*Trova le parole chiave*” (“Find the Keywords”), which engages learners in identifying key terms within the text. Keywords are generated using a fine-tuned version of KeyBERT, as

⁴<https://arasaac.org/>

⁵<https://platform.openai.com/docs/models/gpt-3-5-turbo>

described in Galletti et al. (2023); and (3) “*Trova la rete semantica*” (“Build the Semantic Network”), which prompts students to connect words with semantically related concepts, as illustrated in Figure 3. Both the related terms and distractors for this task were generated using *gpt-3.5-turbo-0125*. To generate related and unrelated words, we used two prompts: one asked for a list of synonyms with definitions, and the other for non-synonyms that are semantically unrelated, both formatted as JSON arrays with appropriate keys.

Figure 3: Example of a semantic network exercise. The user starts from the word “TREE” and must choose which of the two presented options is semantically related. If the correct option is selected, the network expands and presents two new options.

3.3 Administrative Dashboard

Finally, the interface includes an administrative dashboard that gives therapists full control over all aspects of the content generated by the AI algorithms. This dashboard allows for the management of texts, such as editing existing content, inserting new texts, or regenerating AI-related components, as well as the organisation and customisation of exercises. When a new text is added, the dashboard displays a preview of each AI-generated component—such as keywords, pictograms, sentences, and questions—for validation. This enables the educator to verify or adjust these associations before the material is presented to the learner. Additionally, the dashboard supports the enrollment of students and the assignment of personalised texts, avatars and exercises, helping to tailor the learning experience to each user. It also collects the data and makes it available for downloading to the therapist.

Dimension	Description
Pedagogical Appropriateness	Evaluates alignment with inclusive and AAC (Augmentative and Alternative Communication)-based pedagogy, focusing on scaffolding, shared meaning-making, and student autonomy.
Inclusive Potential	Assesses support for diverse learners and compatibility with Universal Design for Learning (UDL) and cooperative learning strategies.
Teacher Readiness	Explores how hands-on experience influenced openness to AI, highlighting competence gaps and training needs.
Trust	Investigates confidence in AI-driven features and the balance between automation and teacher control, including transparency and ethical oversight.
Expectation Shift	Compares pre- and post-use attitudes to identify shifts in teachers' perceptions of AI in education.

Table 1: The five key dimensions which guided the focus group.

4 Methods

The evaluation framework is a two-phase approach: a questionnaire which assessed teachers' general attitudes and readiness toward AI, followed by a focus group conducted after hands-on interaction with the platform. This structure allowed us to compare abstract views of AI with teachers' hands-on experiences, highlighting how their perceptions align with pedagogical values, ethical concerns, and practical adoption barriers. This section outlines the questionnaire and focus group design; results are presented in Section 5 followed by their discussion in Section 6.

4.1 Questionnaire's Design

The questionnaire explored teachers' knowledge, perceptions, and attitudes toward digital and AI technologies in education. Its structure follows the four dimensions of the SAT framework: user experience, social disruptiveness, value alignment, and trust. As part of our contribution, the questionnaire is openly available to the community at this [link](#), while the detailed results are available [here](#).

Following an initial section collecting teacher details such as years of experience and subject area, Section 2 explored teachers' general approach to technology use. It included items on comfort with technology in personal and professional contexts, habits for staying updated on tools, and frequency of using digital resources for planning. Participants also rated the importance of technology in teaching and their interest in new tools. The section ended with a multiple-choice item on perceived barriers to tech integration, based on established research (Ertmer et al., 2012).

Section 3 focused on teachers' awareness and use of digital tools designed to support reading comprehension, drawing on research into the educational technology ecosystem (Tondeur et al., 2017). Participants first have to identify any relevant software or platforms they know, such as simplified reading tools, text-to-speech apps, or concept map-

ping software. They then need to indicate which they had used in teaching or planning, and report any reading comprehension technologies available at their schools.

Section 4 explores teachers' perceptions of AI in education, assessing their knowledge, expectations, trust, ethical concerns, and professional agency—defined as the capacity to shape one's practice within institutional and technological constraints (Biesta et al., 2015; Toom et al., 2015). A mixed-format design with Likert-scale and open-ended items enables a mixed-methods analysis, aligning with best practices in educational technology research (Ponce and Pagán-Maldonado, 2015). This last section is divided into three subsection focusing respectively on (A) *Trust and Risk/Benefit Perception* - using items adapted from the Propensity to Trust in AI scale (Mcknight et al., 2011), (B) *Ethical Awareness*, drew on critical AI literacy frameworks (Veldhuis et al., 2024) and (C) *Teacher Agency and Involvement*, with items informed by the TPACK framework (Mishra and Koehler, 2006) and research on teacher agency (Leijen et al., 2024). This subsection examines the perception of students' interest in AI, teachers' views on the importance of ethical and pedagogical training, and expectations for future integration and involvement in AI-related decisions.

4.2 Focus Group's Design

The focus group was intentionally designed to capture authentic, practice-informed insights from educators by combining experiential use of the platform with structured group reflection. Following the initial questionnaire, participating teachers engaged in a one-hour, hands-on session with the ARTIS platform. To preserve the ecological validity of the study, no prior exposure or formal training was provided. Instead, participants received minimal onboarding and quick-start instructions, allowing for natural, intuitive engagement with the interface.

The exploratory session encouraged teachers to

Figure 4: Summary of questionnaire responses from 19 teachers on AI in education, including teaching demographics, perceived benefits and risks, expected support, and preferred training formats.

freely navigate the platform, selecting from a variety of texts. Participants were asked to engage with materials spanning multiple educational levels to ensure a range of instructional contexts were represented. Additionally, a subset of four teachers was invited to interact with English-language texts, enabling the evaluation of bilingual and second-language accessibility features.

Immediately after the interaction phase, a structured focus group gathered in-depth reflections on five key dimensions of AI acceptance and pedagogical fit: (I) *Pedagogical Appropriateness*, (II) *Inclusive Potential*, (III) *Teacher Readiness*, (IV) *Trust*, and (V) *Reconfiguration of Expectations*—based on sociotechnical, ethical, and inclusive education frameworks and guided the analysis of teacher responses. Precise details on this key dimension can be found in Table 1.

5 Results

We recruited 19 teachers from the *Istituto Comprensivo di Narni Scalo (Italy)* to participate in this study. The sample included 12 primary school teachers, 5 lower secondary teachers, and 2 preschool educators. Although the ARTIS platform is primarily designed for literacy development and may have limited direct applicability in early childhood education, preschool teachers were intentionally included to examine how attitudes toward AI integration vary across educational levels. This inclusive approach captured diverse perspectives

and enabled comparison of teachers' readiness for AI across contexts.

5.1 Questionnaire Results

When asked about digital tools used to support reading comprehension, teachers cited a mix of general productivity platforms, such as [Google Workspace](#) and [Canva](#), alongside more specialized tools like [Genially](#), [Popplet](#), and [Arasaac](#) for augmentative and alternative communication. A few teachers had explored newer AI-powered tools such as [NotebookLM](#) and [Napkin.AI](#). Participants were optimistic about AI's educational benefits, linking it to inclusivity, student motivation, personalized learning, diverse instructional formats, and instant feedback. Teachers saw AI as useful for creating inclusive materials, supporting planning and content design, reducing administrative tasks, and improving the use of learning analytics to guide instruction.

At the same time, teachers were mindful of the risks associated with AI in education. Concerns included the possibility of algorithmic bias, misinformation, and diminished teacher autonomy. Others raised ethical issues such as the reduction of student-teacher interaction, oversimplified forms of assessment, and the potential misuse of student data. In terms of professional development, participants showed a clear preference for structured training opportunities focused on the ethical and social dimensions of AI. Webinars, journals, and

other professional resources were also seen as helpful, though less commonly preferred. Overall, the findings suggested a cautiously optimistic attitude among teachers. While they see promise in the pedagogical affordances of AI, especially about inclusion and personalization, they also emphasize the need for thoughtful implementation, transparency, and support through well-designed training. Aggregated results are shown in Figure 4 and detailed results are available [here](#).

5.2 Focus group results

The following paragraphs present findings from the focus group discussions, organized according to the five evaluative dimensions illustrated in Table 1.

Pedagogical Appropriateness Participants raised thoughtful concerns about the platform's alignment with inclusive pedagogical practices. A key point of critique centered on the sequencing of support features: currently, visual and linguistic scaffolds, such as keywords and pictograms, are presented before students actively engage with the text through the exercise. While well-intentioned, this design was perceived by many as potentially limiting student autonomy and interpretive effort. Several educators proposed reversing this order, suggesting that scaffolds introduced during or after initial engagement would better support active meaning-making.

Inclusive Potential Teachers generally recognized the platform's value in supporting differentiated instruction, especially for students with language-based or cognitive challenges. However, concerns were raised about the semantic precision and clarity of the pictograms, as well as the overall visual layout, both of which were seen as crucial to accessibility. Importantly, educators emphasized that the platform should not replace teacher-student interaction but instead enhance it, particularly through collaborative practices like co-selecting keywords and interpreting texts.

Teacher Readiness While initial questionnaire responses reflected a generally positive orientation toward AI in education, the post-use discussions revealed more grounded, experience-based perspectives. Teachers emphasized the importance of training that goes beyond technical operation to include pedagogical integration. They acknowledged the platform's potential to support differentiated learning and streamline resources, but stressed that its

success would depend on its adaptability to real classroom contexts and its alignment with established instructional workflows.

Trust Trust in the platform emerged as closely tied to the degree of teacher agency and system transparency. However, this did not translate into a blanket rejection of the technology. Rather, educators identified specific areas for improvement, calling for enhanced user control and clearer communication about how AI-driven choices are made.

Expectations Shift Educators moved from abstract curiosity and cautious optimism to a more critical, practice-informed perspective. Their experiences prompted a clear set of priorities for the future development of AI in education: (1) Flexibility over rigidity – AI tools must be adaptable to diverse classroom contexts; (2) Transparency over opacity – teachers need to understand and shape how AI-driven decisions are made; (3) Support over substitution – technology should amplify, not replace, human interaction and pedagogical creativity. While initial enthusiasm was tempered by practical limitations, participants remained confident in the potential of AI-supported learning environments—particularly when such tools are designed to complement teacher expertise and foster meaningful student engagement. Importantly, the findings underscore the value of involving educators not merely as users, but as co-designers and evaluators in the development process.

6 Discussion

This study contributes to a growing body of research on the integration of AI in education by offering a practice-informed, teacher-centered perspective grounded in the SAT framework (Occhipinti et al., 2023). Our findings show how teachers' acceptance of AI tools is not static nor solely based on usability, but shaped dynamically through hands-on engagement, educational values, and pedagogical alignment. Methodologically, this study aligns with recent calls for participatory and iterative approaches to AI design in education (Luckin and Cukurova, 2019; Mouta et al., 2024).

Rather than viewing acceptance as a fixed variable to be assessed retrospectively (Celik et al., 2022), our approach positions teachers as formative agents, whose experiences, critiques, and creativity are integral to the ethical and effective development of technology. In line with Zawacki-Richter

et al. (2019), who underline the scarcity of qualitative studies that capture educators' voices in AI research, our work emphasizes the importance of interpretive approaches that explore how teachers make sense of AI tools in concrete pedagogical settings. By combining questionnaires with in-depth focus groups, we were able to reveal not only general trends in acceptance but also the nuanced ways in which teachers negotiated the role of AI in their practice. Specifically, participants moved from general skepticism to targeted suggestions, such as reversing scaffold sequencing or refining pictogram clarity, demonstrating a shift from rejection to co-design.

While 89% of teachers viewed AI as potentially beneficial for inclusive education (questionnaire), the focus group exposed significant caveats. Teachers emphasized that inclusion cannot be achieved through technical affordances alone but requires alignment with pedagogical routines and accessibility standards. These findings echo critiques of UDL frameworks when implemented in a top-down, compliance-oriented manner (Edyburn, 2010). Instead, participants advocated for adaptive interfaces, customizable visuals, and collaborative practices, such as co-selection of keywords, that preserve student-teacher interaction and interpretive autonomy. This underscores the need to reconceptualize inclusivity as a dynamic co-construction rather than a static feature.

Our findings also nuance assumptions in the literature about AI adoption motives. Their insistence on retaining control over scaffolding and keyword selection reflects a broader commitment to maintaining instructional intentionality. Similarly, the shift from interest in formal AI training (74%) to a focus on pedagogical and ethical guidance suggests that professional development should go beyond technical skills to include critical and ethical perspectives (Perrotta and Selwyn, 2020). By engaging teachers not as end-users but as evaluators and co-evaluators, this study contributes a replicable model for socio-technical evaluation and advances the debate on how educational technologies can be made aligned with the realities of classroom practice.

Finally, these insights are also shaped by the cultural and institutional context. The participating teachers, embedded within the Italian education system, approached AI-mediated feedback through pedagogical norms distinct from those observed in studies conducted in other countries. For ex-

ample, while Anglo-American frameworks often emphasize data-driven personalization and performance metrics (Shum and Luckin, 2019; Selwyn, 2019), Italian educators tended to prioritize dialogic, relational approaches to learning and a strong emphasis on formative assessment as a collective rather than individualistic practice (Moretti et al., 2015; Pastore, 2020). Teachers highlighted the importance of maintaining pedagogical intentionality and student-teacher interaction, reflecting a broader educational tradition in Italy that values interpretive autonomy and humanistic principles (Viteritti, 2009). These values shaped how teachers perceived AI tools—not simply as assistive technologies, but as agents that must harmonize with existing curricular structures, ethical responsibilities, and institutional logics. This cultural lens helps explain why some technological affordances, such as automated scaffolding or visual simplifications, were met with ambivalence unless they could be flexibly adapted to local pedagogical aims. Cross-cultural comparisons are thus essential to avoid universalist assumptions in AI design and to ensure that integration strategies remain sensitive to educational diversity (Zhang, 2025).

6.1 Actionable steps

The findings confirm that when engaged early in the development process, teacher expertise plays a pivotal role in surfacing abstract concerns and translating them into actionable design feedback (UNESCO, 2021). Rather than perceiving resistance to AI as rooted in negative attitudes, the study highlights the value of participatory engagement, where teachers act as co-designers. In particular, initial concerns centred around algorithmic opacity and perceived lack of control (Mcknight et al., 2011), mirroring broader critiques of AI as black-box systems that conceal decision-making logic (Burrell, 2016). Participants consistently called for increased transparency, interpretability, and human oversight—features that contribute to what is often termed “calibrated trust” (Zhang et al., 2020), where users remain critically engaged while feeling empowered to understand and shape system outcomes.

The next phase of interface development started to operationalize the teachers' inputs into concrete design interventions. These included (1) co-designed interface modifications with customizable elements (e.g., reversible scaffold sequencing, teacher-defined, configurable visual aids), (2) im-

plementing adjustable transparency layers (e.g., explainable feedback rationales), (3) develop teacher-facing toggles for AI assistance, allowing instructors to choose when and how AI contributes during a session (e.g., real-time suggestion, post-activity reflection), (4) include a cultural/contextual alignment layer in system design documentation: capture assumptions embedded in educational norms (e.g., Italian vs. others), design localized variants where necessary and plan for comparative studies across national systems to test transferability.

7 Conclusions & Future Work

This study is among the first to systematically evaluate the ethical and pedagogical acceptability of AI in real educational contexts using a framework explicitly oriented toward sociotechnical reflection. It highlights the importance of involving teachers not just as end-users, but as active co-designers and evaluators—positioning them as key contributors in shaping how AI tools are developed and integrated into educational settings. Rather than viewing acceptance as a fixed variable to be assessed retrospectively (Celik et al., 2022), our approach positions teachers as formative agents, whose experiences, critiques, and creativity are integral to the ethical and effective development of technology.

Using the SAT framework, we captured nuanced perceptions of an AI-supported reading platform, revealing that teachers' acceptance depends on more than functionality: it is conditional on alignment with pedagogical values, transparency, and support for professional autonomy. In sum, the question is not only whether AI works, but whether it works with and for teachers, in alignment with the values and practices that define education. The shift from abstract optimism to context-sensitive critique underscores the importance of participatory, ethically grounded approaches to AI design.

Future work should also explore long-term classroom use to track evolving practices, involve a more diverse sample of educators, in a second school, and examine how training and co-design processes influence ethical and pedagogical alignment of AI technologies, further validating the SAT model for educational settings. Moreover, insights from the current evaluation framework will inform the next development cycle of the ARTIS interface, ensuring that future iterations are responsive to teacher feedback.

Limitations

While the study offers valuable insights and contributes meaningfully to the design of educational AI tools, certain limitations also highlight important avenues for future exploration. The teacher sample, though rich in contextual relevance, was relatively small and specific, which may affect the broader applicability of the findings. However, this focused scope allowed for in-depth engagement and formative feedback that can directly inform future iterations. Participants interacted with a prototype version of ARTIS, and some of their observations likely reflect temporary interface or usability elements rather than underlying structural challenges, providing useful direction for refinement.

Moreover, the study's temporal scope was limited to a single session, offering a snapshot of initial impressions rather than longitudinal insights. Nonetheless, this approach effectively captured early responses and surfaced key priorities for longer-term implementation. Similarly, although emerging needs for teacher training were identified during the focus group, the study did not incorporate formal training programs. This opens a promising path for future research to investigate how targeted support mechanisms influence adoption and pedagogical integration over time.

An additional consideration relates to the use of the SAT framework. While SAT served as a valuable and critically-informed structure for guiding the study, it remains a relatively new model, especially in educational contexts. In this study, we adapted a combination of existing scales and custom-developed items to reflect the SAT's four dimensions. While this tailoring ensured contextual relevance, it may reduce replication and comparability across studies. Advancing this work will require the development and validation of standardized SAT-based instruments to foster wider methodological consistency.

Despite these limitations, the study yields important design implications. Educational AI tools should enable flexibility and personalization, promote transparency to build trust, and support—rather than supplant—educators' pedagogical creativity.

LLMs in alliance with Edit-based Models: Advancing In-Context Learning for Grammatical Error Correction by Specific Example Selection

Alexey Sorokin

MSU Institute for Artificial Intelligence Yandex

Regina Nasyrova

MSU Institute for Artificial Intelligence

Abstract

We show that fewshot Grammatical Error Correction might be improved by using an encoder-based sequence labeling model, such as GECTOR, to select similar examples. We demonstrate this on three Russian GEC corpora and English BEA corpus. The effect is the most significant for the new LORuGEC corpus and reaches up to 5-10% F0.5-score depending on the model. The corpus is released in our paper and contains 348 train and 612 test examples. The corpus is designed for diagnostic purposes and is also equipped with writing rules' annotations.

These annotations allow to further improve few-shot error correction by contrastive tuning of GECTOR-like encoder on rule classification task. This holds for a broad class of large language models. The best results are obtained with 5-shot YandexGPT-5 Pro model, achieving F0.5-score of 83%.

1 Introduction

The task of Grammatical Error Correction (GEC) may be defined in two ways, depending on whether the main objective is to make the sentence *grammatical*, i.e. applying minimal edits until it is grammatically correct, or *fluent*, namely transforming a sentence, likely substantially, so that it sounds natural yet saves the initial meaning (Coyne et al., 2023). In the era of Large Language Models (LLMs), researchers studied their ability in both settings (see more in the Section 2.1) and concluded that LLMs outperform mainstream GEC models in the latter objective (Coyne et al., 2023), demonstrating more freedom and creativity in sentence modifications. However, this asset becomes a burden in the former setting, where LLMs' 'generous' edits are treated as overcorrections.

A reasonable thing to do to make LLMs predict more reliable corrections as well as leverage their fluency and language knowledge is to apply them

in few-shot settings which proved to be valuable in many other NLP tasks, e.g. Machine Translation and Question Answering (Brown et al., 2020). As supported by Fang et al. (2023); Loem et al. (2023), in-context examples indeed enhance the quality and consistency of LLMs' corrections. However, the research of in-context learning in GEC pays little attention to example selection, the rare exception being Tang et al. (2024), using a syntactic structure similarity metric to select in-context examples.

We argue that sentences containing the errors of the same kind as the target ones may be much more beneficial as in-context examples rather than randomly selected ones. To prove this hypothesis, we present a novel approach to Grammatical Error Correction which makes use of a task-specific sequence labeling model (Omelianchuk et al., 2020) and retrieval-based few-shot learning. The sequence labeling model was trained to predict token-level edits, required to transform the source text into the grammatically correct one. We employ it to encode tokens in a sentence and choose the embeddings of the most likely edits as the representation of a sentence. After that, we use the retriever to select the closest sentence representations to the target one. As a result, the sentences corresponding to the selection are used as in-context demonstrations.

However, we assume that the notion of "errors of the same kind" may require an extension, involving the similarity of not only the edit but also the general pattern behind it. Since the same edits may occur in diverse contexts (e.g. comma insertions may be required before certain conjunctions or between subordinate clauses), the sentence with the same edit may not be informative enough. The model would not comprehend the utility of the given demonstration because it is unclear what it should pay attention to when sentences are completely distinct, apart from the edit.

That is why, we collect a new Linguistically Oriented Rule-annotated GEC dataset for Russian –

LORuGEC, which consists of sentences representing the rules of Russian grammar that are considered to be complicated both for L1 learners and large language models. These errors are also under-represented in the existing Russian GEC corpora, so we expect that the effect of in-context demonstrations would be the most prominent for this corpus.

We conduct experiments on Russian GEC datasets in zero-shot and few-shot (1-shot and 5-shot) settings. For the few-shot setting we study random example selection and retrieval-based selection with the GECTOR-like pretrained encoder. We additionally tune the retriever to select sentences related to the same rule. We choose several LLMs for testing and also present the results of their finetuned versions where possible.

Our main contribution is as follows:

- Novel GEC dataset for Russian, where sentences are also annotated for rules which are violated in them. The methodology of its collection makes it a challenging benchmark for LLMs, as it includes previously underrepresented cases.
- We are the first to apply the GECTOR-like(Omelianchuk et al., 2020) model for few-shot examples retrieval in grammatical error correction. The proposed approach yields considerably higher scores on LORuGEC dataset than random selection of examples for all models, supporting the impact of demonstrations’ quality and design on the performance of LLMs.
- Contrastive tuning of the retriever on related data additionally improves the quality of corrections on LORuGEC.
- The proposed method may compete with LLMs’ finetuning, especially if the training data is not large in size.

We make our data¹ and code² freely available.

2 Related work

2.1 Using LLMs for Grammatical Error Correction

Large Language Models gained prominence over the recent years as helpful tools for most Natural Language Processing tasks (Brown et al., 2020;

¹<https://github.com/ReginaNasyrova/LORuGEC>

²<https://github.com/AlexeySorokin/LORuGEC>

DeepSeek-AI et al., 2025). Their abilities were also tested on the Grammatical Error Correction task. Wu et al. (2023); Fang et al. (2023) show that ChatGPT³ performs worse, than commercial and conventional GEC models for English, being less prone to under-correction and mis-correction, but generating more fluent corrections, hence over-correcting, which is penalized severely by conventional metrics designed to evaluate minimal edits. Moreover, ChatGPT shows promising results for Multilingual GEC (Fang et al., 2023).

A more detailed analysis with fine-grained prompt and hyperparameter search was done in Coyne et al. (2023). They found that low temperature and suitable prompts increase the reliability of corrections produced by GPT-3.5(Ouyang et al., 2022) and GPT-4(OpenAI, 2023). Loem et al. (2023) proceed to research prompt-based methods for GEC, discovering that GPT-3(Brown et al., 2020) is much less prompt-sensitive and inconsistent, when supported with in-context examples.

Fang et al. (2023); Loem et al. (2023) propose that the investigation on the effect of example quality and design may be beneficial. An instance of it is introduced in Tang et al. (2024), where sentences with the same syntactically incorrect structure are adopted as in-context examples, significantly outperforming randomly selected ones. Advancing the choice of in-context examples, Robotian et al. (2025) propose Retrieval-Augmented Generation within In-Context Learning approach to improve Generative Error Correction in speech recognition systems. Other works also consider LLMs’ instruction tuning and ensembling for GEC (Kaneko and Okazaki, 2023; Omelianchuk et al., 2024).

2.2 In-context learning for LLMs

Our work is an example of the so-called retrieval-based few-shot learning, where demonstration samples are selected according to some similarity measure between vectors. A review of retrieval-based in-context learning is presented in Xu et al. (2024). The early examples of this approach include Rubin et al. (2022) where retrieval-based selection of demonstrations was shown to improve performance for three sequence-to-sequence learning tasks. The authors also demonstrated that one may reach further gains by training the retriever to select examples that maximize the correct output probability. Margatina et al. (2023) verified the positive role

³<https://openai.com/index/chatgpt/>

of similarity between test and in-context examples on a diverse range of models and tasks including classification and multiple choice datasets. [Nori et al. \(2023\)](#) demonstrated that using KNN-based few-shot example selection allows to adapt general models to medical domain without special tuning.

2.3 GEC corpora for Russian

There are three available Russian GEC datasets: RULEC-GEC([Rozovskaya and Roth, 2019](#)), RU-Lang8([Trinh and Rozovskaya, 2021](#)) and GERA([Sorokin and Nasyrova, 2025](#)). The first one represents a subset of the Russian Learner Corpus of Academic Writing (RULEC)([Alsufieva et al., 2012](#)), containing essays of the US students who were either learning Russian as a foreign language or heritage speakers. The authors comprised a list of 23 error type labels that cover (morpho)syntactic, lexical and spelling errors.

The RU-Lang8 Dataset constitutes a subset of the Lang-8 Corpus([Mizumoto et al., 2012](#)) learner corpus, based on the language learning website⁴. Most texts in RU-Lang8 are much shorter, being small paragraphs or learners’ questions. Unlike RULEC-GEC, RU-Lang8 has a more coarse-grained annotation, with error type labels representing operations of token replacement, deletion, insertion and change in word order.

As opposed to both datasets, GERA is based on Russian school texts and was annotated in line with a much more fine-grained label inventory, i.e. grammatical error types cover a broader list of parts of speech and grammatical categories, and there are different types of lexical and spelling errors depending on the erroneous construction.

2.4 Linguistically motivated data for GEC

Usually GEC corpora are based on real-world learner data, not a predefined error taxonomy. A partial example of error-driven approach was [Volodina et al. \(2021\)](#), where the four principal error types from existing data were selected to be included in the dataset. Similarly to LORuGEC, most examples in their corpus contain exactly one error.

More frequently, error taxonomies are used for collecting linguistic acceptability data. The most well-known example of such corpora are COLA([Warstadt et al., 2019](#)) and BLIMP([Warstadt et al., 2020](#)) for English. One may even convert a BLIMP-like dataset of minimal pairs to GEC for-

mat, by using the ungrammatical element of the pair as the source and the grammatical one – as the target, this approach was adopted in [Volodina et al. \(2021\)](#) for Swedish and [Jentoft and Samuel \(2023\)](#) for Norwegian. Concerning Russian language, BLIMP-like datasets of minimal pairs were introduced in the recent works of [Graschenkov et al. \(2024\)](#) and [Taktasheva et al. \(2024\)](#).

3 LORuGEC: Corpus description

3.1 Motivation and data collection

Most existing GEC corpora consist of L2 learners’ data. Even corpora based on native learners’ data mostly reflect the real-world error distribution, underrepresenting complicated grammatical rules. Concerning the Russian language, existing corpora, such as RULEC-GEC([Rozovskaya and Roth, 2019](#)), RU-Lang8([Trinh and Rozovskaya, 2021](#)) and GERA([Sorokin and Nasyrova, 2025](#)), contain very few examples of complex, “school-book” rules, making these corpora suboptimal for use in educational applications. Our primary goal is to fill this gap and collect a corpus of complex cases that represent the rules which are considered difficult for Russian L1 learners. The second goal of our project is to study, which rules present the highest complexity for modern LLMs in the task of Grammatical Error Correction.

Given our research goals, we organize the data collection and annotation process as follows:

1. Firstly, one of the paper authors (a bachelor in Linguistics) collected an initial set of about 10 rules that are known as difficult for Russian high school students. These rules covered various fields of writing, mostly punctuation, grammar and spelling. The list of rules was checked by another author of the paper and verified using several Russian grammar books.
2. For each of the selected rules, the annotators, which were students with linguistic backgrounds and Russian native speakers, were asked to collect up to 15 examples belonging to these rules. Since the collected examples were intended to be used for LLM benchmarking, several precautions were taken, which were expressed in the instruction (see more in [Appendix A](#)), as follows:
 - Preferably, choose sentences from different sources.

⁴<https://lang-8.com/>

- Avoid using quotations from fiction.
 - Refrain from selecting commonplace examples.
3. The collected examples were corrupted to simulate the common mistakes corresponding to particular rules. For example, if the rule governs the use of comma between the conjuncts, the comma was either deleted in the contexts where it was required or inserted when it must not be used. If there are multiple ways to introduce errors, the examples should cover them all. For instance, clauses with participles in Russian should be surrounded by commas, so possible corruptions included deletion of both commas, only the preceding comma or only the following one.
 4. The collected examples were passed through the YandexGPT3 Pro⁵ model. The goal of this stage was to identify complex sentences and make the dataset more challenging by including analogous examples.
 5. After successfully completing the data collection for the initial set of 10 rules, the annotators were allowed to select the subsequent rules themselves. They were instructed to consult grammar reference books and cover all fields of written language, such as punctuation, spelling, grammar (in the narrow sense) and lexis. The process was supervised by the principal annotator (one of the authors) who checked the selection of rules and example cases, as well as their annotation. Since the source sentences were created by targeted manual corruption, the correct sentence was known in advance, thus reducing the correction ambiguity. The principal annotator additionally analyzed 100 random samples and found no disagreement with the annotators.

3.2 Data sources

While selecting the rules, annotators and authors used various resources, such as grammar reference books, teacher manuals and educational websites based on them, we refer to **B** for the full list of data sources. The textbooks that were used comply with Russian educational standards, some of them are specially approved by the Russian Academy of Sciences, for example, (Valgina et al., 2009).

⁵<https://yandex.cloud/ru/docs/foundation-models/concepts/yandexgpt/models>

3.3 Rules Description and Statistics

We gathered 48 rules from 4 grammar sections. The majority of them represent punctuation and spelling. We present the comprehensive list of rules in Appendix C.

We collected 960 pairs of sentences (an average of 20 sentences per rule), which were split into validation and test subsets so that for each rule at least 9 sentences or approximately two thirds of collected sentences would be allocated to the test partition. Consequently, the size of the test subset is twice as large as the size of the validation one (see Table 1). Additionally, unlike the latter, only the test subset includes initially correct sentences (for hypercorrection considerations). See more on the data format in Appendix D.

3.4 Comparison with other GEC corpora for Russian

Comparing to existing Russian GEC corpora, such as RULEC-GEC (Rozovskaya and Roth, 2019), RU-Lang8 (Trinh and Rozovskaya, 2021) and GERA (Sorokin and Nasyrova, 2025), our data differs in several aspects:

- To the best of our knowledge, that is the only Russian GEC corpus where all the errors are matched with corresponding grammar rules instead of error type.
- Our corpus is deliberately created for evaluation and diagnostic purposes. Therefore, it has no training subset and is much smaller than other corpora (see Table 2). We do not want LLMs to acquire new capabilities on the validation set of our corpus, but rather to reveal the knowledge they already have.

On the other hand, almost all sentences in our corpus contain errors and are supposed to be challenging in contrast to other GEC data.

- Since corpus examples were created via corruption, for the vast majority of mistakes there is only one possible correction, increasing the trustworthiness of evaluation scores.
- As shown in Table 3, LORuGEC has the highest fraction of pattern-based errors covered by a rule-based generator. These errors include punctuation errors, word form changes, deletion, insertion or replacement of closed word categories (prepositions, conjunctions and pronouns), spelling errors, etc. Despite this, the

Sample	Sentences	Correct source sentences	Sentences for complex rules (%)	Tokens
Validation	348	0	250 (71.84)	5,579
Test	612	31	419 (68.46)	10,131

Table 1: Statistics on the validation and test samples of LORuGEC.

Sample	Sentences	Tokens
RULEC-GEC	12,480	206,258
RU-Lang8	4,412	54,741
GERA	6,681	119,068
LORuGEC	960	15,710

Table 2: Quantitative comparison of GEC datasets for Russian.

corpus	P	R	F0.5	uncov., %
RULEC-GEC	50.4	32.6	45.5	42.0
RU-Lang8	60.8	37.9	54.2	48.8
GERA	74.3	47.0	66.6	33.7
LORuGEC	45.1	17.7	34.4	21.9

Table 3: Comparison of GEC model performance and difficult fraction (uncov., %) for different Russian GEC corpora. The model is Qwen2.5-7B finetuned on the concatenation of Russian GEC data.

GEC model finetuned on the concatenation of 3 Russian GEC corpora (see Section 5 for details) has much lower scores on LORuGEC than on other corpora. This implies that the main problem on LORuGEC is not to generate the suggestion but to discriminate between correct and incorrect variants.

4 Similar example retrieval

4.1 Approach description

We suppose that large language models may lack knowledge about specific Russian grammar rules. This information might be injected during inference via in-context example selection. A natural solution might be to select examples that belong to the same rule, i.e. resembling not only the required correction, but also the grammatical reasoning behind it. However, this restricts the method to a predefined bounded set of rules that prevents the model from real-world usage.

Our approach is to use an embedder to select training examples similar to the given test sentence. We want this embedder to reflect grammatical sim-

ilarity. That is not the case for standard sentence embedders that assign similar vector representations to semantically similar sentences. To be used for similar examples retrieval, the embedder should be pretrained on a grammar-related task.

We decide to select the famous GECTOR model offered by (Omelianchuk et al., 2020). Their approach does not treat GEC as a Machine Translation task but reduces it to sequence labeling, taking into account the fact that most tokens in a sentence remain unchanged after the correction. GECTOR classifier, which is built upon a pretrained encoder⁶, predicts the no-operation label KEEP for such tokens. In other cases, labels represent

- **elementary edit operations**, such as DELETE, REPLACEWITH_<TOKEN> (e.g., replace the current word with the word *on*) or INSERT_<TOKEN>, where <TOKEN> may refer to not only words, but also punctuation marks.
- **grammatical transformations** which mostly have to do with inflection (e.g., GRAM\$SING, meaning ‘put the current word in the singular form instead of plural’).

Although the latter labels, the so-called G-labels, do not exactly correspond to rules of writing, mistakes from the same rule class often obtain the same label. Since the hidden states of encoder models reflect the similarity in their label space, this similarity is also related to rule similarity.

4.2 Implementation details

Although the retrieval based on embedding similarity is very common and is extensively used, e.g., in Retrieval-Augmented Generation (RAG), the adaptation of GECTOR to retrieval has several details. Firstly, as GECTOR operates on token level, it does not assign meaningful representation to the [CLS] token usually used for retrieval. We represent the sentence with the hidden states from the final encoder layer and select up to 3 hidden states

⁶<https://huggingface.co/ai-forever/ruRoberta-large> in our case.

corresponding to the most probable error positions. The probability of an error is predicted by the GECTOR model itself, using $1 - p(\text{KEEP})$, where KEEP is the no-edit label of the GECTOR model.

Since the original GECTOR model uses obsolete Python libraries and the sets of G-labels differ significantly between English and Russian, we reimplement the model by ourselves using HuggingFace Transformers⁷ library. The details of its training are available in Appendix F.

4.3 Retriever finetuning

We suppose that pretraining on external data empowers the model with the basic information about grammatical error patterns, but the model might not have enough knowledge about rare or dataset-specific rules. Therefore, we propose to finetune the retriever on the task of rule classification using contrastive learning. The tuning is performed on the validation part of our dataset. The training objective is a standard triplet loss

$$L(h, h^+, h^-) = \max\left(\frac{\rho(h, h^+) - \rho(h, h^-) + \alpha}{t}, 0\right),$$

where ρ is the distance function (e.g., cosine), α is the margin and t is the temperature. We always use as h^+ the closest example with the same class label and as h^- – the closest example with another class label. In terms of contrastive learning literature, we use hard positives and hard negatives without in-batch negatives.

We retrieve the closest positive and negative examples once in epoch. After completing the epoch we recalculate the triples using the updated embedder. Further details are given in Appendix F.

5 Model evaluation

In this section we evaluate several LLMs on our corpus⁸. We select two open-source models: the open-source *Qwen-2.5 7B Instruct*⁹(Yang et al., 2024) and *yandex/YandexGPT-5-Lite-8B-instruct*¹⁰ as well as closed-source *YandexGPT-5*

⁷<https://huggingface.co/docs/transformers/index>

⁸We restrict our attention to LLMs by two reasons: first, one of our goals is to study few-shot learning approach. Second, in contrast to English, LLMs outperform other approaches, such as encoder-decoder or GECTOR-like, on available Russian data.

⁹<https://huggingface.co/Qwen/Qwen2.5-7B-Instruct>

¹⁰<https://huggingface.co/yandex/YandexGPT-5-Lite-8B-instruct>

*Pro*¹¹. The latter two models are selected because they were largely trained on Russian data and the first one is chosen due to its excellent multilingual abilities. We evaluate additional models, such as *LLama3-8B-Instruct*(Meta, 2024) and *GPT4o-2024-05-13*(OpenAI, 2023), in Appendix G.1.

We compare several settings:

1. zero-shot prompt-based application of LLM. The prompt is provided in Appendix E.1.
2. few-shot prompt-based application of LLMs with different selection of in-context examples: random, the general purpose e5-base-multilingual¹²(Wang et al., 2024) embedder, pretrained GECTOR and GECTOR with contrastive finetuning).
3. finetuning open-source LLMs on external Russian GEC data: RULEC-GEC, RU-Lang8 and GERA(Sorokin and Nasyrova, 2025).
4. further training of the finetuned LLMs on the validation part of our corpus.
5. LORA-based training of open-source LLMs only on the validation part of our corpus.

The hyperparameters of the finetuning are available in Table 9.

As is commonly done, we score the tokenized model outputs with M2scorer(Dahlmeier et al., 2013) and report precision, recall and F0.5 score, using F0.5 as the main metric. The results are given in Table 4. We make the following conclusions:

1. Finetuning on external GEC data is detrimental for LORuGEC. Since LORuGEC types of errors are rare in general GEC corpora, the finetuned model decides not to correct them, hence, its recall dramatically reduces.
2. With a single exception, the GECTOR retriever performs better than the random one, proving our first hypothesis: **during pre-training on general GEC data, the encoder learns the representations for error types**. Moreover, these representations are helpful even for rare classes of errors that the LLM was not able to learn. In contrast, the general-purpose e5-base-multilingual embedder produces much smaller improvements.

ext.+LORuGEC finetuning	50.1	37.9	47.1	77.4	73.6	76.6	NA		
LORuGEC LORA finetuning	48.6	42.6	47.3	74.1	72.6	73.8	NA		

Table 4: Comparison of different LLMs on the LORuGEC test set in zero-shot, few-shot and finetuning modes. Ext. finetuning refers to training on the concatenation of other Russian GEC corpora. The best metric inside the same approach (e.g., 1-shot) is presented in italics and the best overall metric – in bold.

- Contrastive finetuning of the embedder is also helpful: the 1-shot GECTOR+FT retrieval almost matches the performance of 5-shot GECTOR retrieval. This proves our second hypothesis: **In-domain contrastive tuning of the retriever improves the quality of few-shot error correction**. This also proves the usefulness of rule annotation that distinguishes our corpus from general GEC data.
- The models of the YandexGPT-5 family handle “schoolbook” errors from LORuGEC much better than Qwen-2.5 does. The details of their training are not available, however, it is likely that they saw more high-quality Russian data than the multilingual Qwen model.

5.1 Detailed results and examples

In Table 5 we also report the results per category for different error types. For both compared models punctuation errors are the easiest and the lexical ones – the hardest. A plausible explanation of this fact is that punctuation rules are the most strict, mostly binary (whether to use the comma or not) and rely on separate tokens, while the lexical rules are more vague and usually deal with more options.

When training the embedder, we use the retrieval quality as an intrinsic quality metric: the more often the embedder retrieves examples that belong to the same rule, the better it is. We observe that this internal metric correlates well with error correction quality, as shown in Table 6.

We provide illustrative examples of retrieved

samples together with corresponding model outputs in Figures 3 and 4.

5.2 Results for other corpora

The results on the introduced LORuGEC corpus prove the utility of our approach on a rule-oriented corpus. We wonder whether GECTOR-based demonstration selection improves results for general GEC corpora as well. To verify it, we compare three types of few-shot example selection (random, GECTOR and GECTOR+FT) on three available corpora: RULEC-GEC, RU-Lang8 and GERA. The results for the first two corpora are provided in Table 7, the results for GERA are in Table 13.

We again observe the advantage of GECTOR-based examples over random samples. Finetuning of GECTOR retriever on LORuGEC data does not have a clear positive effect probably due to the difference in error distribution between corpora. Due to larger sizes of these corpora, few-shot learning is not able to outperform full finetuning, but demon-

Retriever	acc.	top-5 recall	Qwen2.5-7B F0.5		YandexGPT5-Pro F0.5	
			1-shot	5-shot	1-shot	5-shot
random	2.3	10.3	40.0	42.4	76.7	83.0
GECTOR	31.7	49.3	46.5	51.2	79.9	81.4
GECTOR+FT	55.9	72.2	49.5	56.1	81.6	82.3

Table 6: Correlation between retrieval and GEC metrics for different retrievers. Accuracy is the percentage of cases when the most closest example belongs to the same rule and recall-5 – the fraction of cases when such examples occur among top 5 closest examples.

Table 7: Comparison of different few-shot example selection methods on RULEC-GEC and RU-Lang8 corpora. The best metric inside the same approach (e.g., 1-shot) is presented in italics and the best overall metric – in bold. ¹ refers to Sorokin (2022) and ² to Sorokin and Nasyrova (2025)

strates higher recall in 3 of 4 experiments.

We also apply our approach to English BEA corpus, see Appendix G.3 for details. There GECTOR-based example selection leads to a small (about 1.5% F0.5 score) but consistent improvement.

6 Discussion and conclusions

In our study we make two principal contributions:

1. We release a new LORuGEC corpus, which differs from existing Russian GEC corpora in data sources, difficulty and typology of errors and, most importantly, the presence of rule labels. This annotation makes our corpus more suitable for L1 educational applications, such as school writing assistants.
2. We compare several methods of in-context learning on our data and discover that retrieval-based demonstration selection significantly outperforms random choice. The retrieval leverages the encoder-based GECTOR model. Contrastive finetuning of this encoder to predict rule labels further improves correction quality.

Since our data has a distinct error distribution, we also check the second result on other corpora. We observe that GECTOR-based in-context examples retrieval is beneficial over random selection. This confirms that our approach effectively works for general GEC data, at least for Russian.

As a future work, we plan to extend our corpus in terms of size and errors number. We have already collected a small pool of sentences with multiple errors, which require additional verification. To reduce annotation burden, we also experimented with example generation. We found that LLM may effectively generate 5 examples to the required rules: 23 out of 25 samples were correct, however, they were shorter and less variable than the manually collected ones, thus further investigation is needed.

We also believe our approach to be viable in domains where task-induced similarity differs from surface meaning similarity. For example, in code retrieval similar programs are not the ones using the same variable names but the ones using the same algorithms. So we hope to investigate the usefulness of our approach in other fields.

7 Limitations

1. As for any LLM-based method, our results are prompt-dependent. In particular, our prompts were optimized towards YandexGPT models and might be suboptimal for the models from other families or for later versions of YandexGPT. However, we did not find any major differences in results when slightly modifying the prompt.
2. For now we evaluate our approach only on Russian and the results may differ for other languages. However, the approach itself has no language-specific details.
3. The LORuGEC corpus is rather small in size compared to other GEC corpora, thus the result may change after collecting more analogous data. We addressed this question in the Conclusions section.
4. Though in principle contrastive tuning works with multiple example labels, we were unable to successfully extend our approach to the multilabel case.

8 Ethics considerations

Our work is based on Large Language Models. We acknowledge that such models might be used in a harmful or malicious manner, however, we utilize them only for scientific purposes. Nevertheless, if a retrieved fewshot sample includes an unsafe generation, that may bias the model towards undesirable behaviour. Thus generalizing our method to datasets containing such examples requires additional precautions.

All of the students who participated in the creation of the dataset earned credit hours as a result. The students were informed about the goals of the work and gave their content for dataset publication.

A Annotation Instruction

Выберите грамматический справочник по русскому языку, затем составьте набор правил.

Для каждого правила найдите 15 примеров (предложений). Предложения должны быть из разных источников и желательно не из художественной литературы. Примеры также не должны быть тривиальными.

Добавьте в предложения нарушения той нормы, которую Вы исследуете. Если есть несколько способов допустить ошибку в правиле, отразите это в собранных примерах.

Для каждого правила протестируйте YandexGPT 3 Pro на его примерах. Если модель не справилась хотя бы в одном примере, то проанализируйте, что отличает сложные предложения, и соберите еще 5-10 сложных примеров.

(Select a reference book for Russian, after that choose the rules for consideration.

For each rule find 15 example sentences that are preferably from different sources and not trivial, avoid using examples from fiction.

Add errors to the sentences based on the rule under consideration. If there are several ways of making a mistake in a rule, this should be reflected in the collected set of sentences for it.

For each rule test the YandexGPT 3 Pro on its sentences. If there are any imperfections in the

model's corrections, analyse what distinguishes complicated sentences and gather 5-10 more complex examples.)

B Educational sources of the rules

- Handbook on spelling and stylistics: (Rozenal', 1997), <https://rosental-book.ru/>
- Dictionary of Russian collocations: (Kochneva, 1983)
- Educational web-sources: <https://orfogrammka.ru/>, <https://gramota.ru/biblioteka/spravochniki/>, <http://old-rozenal.ru/>, <https://grammatika-rus.ru/>, https://licey.net/free/4-russkii_yazyk/, <https://www.yaklass.ru/p/russky-yazik/>

C Rules of Russian grammar in LORuGEC

• Grammar

- 1 Incorrect expression of government
- 2 Declension of cardinal numerals
- 3 Declension of numerals *poltora* ('one and a half.NOM'), *poltory* ('one and a half.GEN'), *poltorasta* ('a hundred and fifty.NOM')
- 4 Agreement between the participle and the word it defines

• Punctuation

- 5 Commas in idiomatic expressions
- 6 Commas between homogeneous subordinate clauses
- 7 Commas between subordinate and main clauses
- 8 Commas between the two conjunctions
- 9-11 Commas before the conjunction *kak* ('as'): 3 instances

- 12 Sentences with homogeneous parts
- 13 Converbs after conjunctions
- 14 Clauses related to the personal pronoun
- 15 Clauses that are distant from the word they define
- 16 Punctuation in meaningful (indecomposable) expressions
- 17 Linking words and constructions
- 18 Recurring conjunctions
- 19 Dashes in sentences with no conjunctions
- 20 Dashes between the subject and the predicate
- 21 Dashes in case of appositions

• Semantics

- 22 Collocations
- 23 Pleonasms

• Spelling

- 24 *n* and *nn* in the suffixes of adjectives
- 25 Vowels in the suffixes of participles
- 26 Noun suffixes *on'k*, *en'k*
- 27 Suffixes *ic*, *ec* in neuter nouns
- 28 Suffixes *ek*, *ik*
- 29 Adjective suffixes *insk*, *ensk*
- 30 Prefixes *pre* and *pri*
- 31 *y* and *i* after prefixes
- 32 Vowels after *c*
- 33 Vowels after sibilants
- 34 Separating soft and hard signs
- 35 Hyphens as part of written equivalents of complex words
- 36 Joint, separate or hyphenated spelling of adverbs
- 37 Compound adjectives
- 38 Particle *taki* ('still')
- 39 *zato* ('at least')
- 40 *ottogo* ('that is why')
- 41 *prichyom* and *pritom* ('moreover')
- 42 *takzhe* ('also')
- 43 *chtoby* ('to')
- 44 *pol-* ('half')
- 45 *ne* (negative particle) with verbs
- 46 *ne* with adjectives
- 47 *ne* with participles
- 48 *ne* with nouns

Complexity. As may be observed in the figure 1, the largest percentages of collected complex rules occur among punctuation and semantics.

D Details on LORuGEC format

The dataset consists of rules, their definitions, information on their complexity for the YandexGPT model, pairs of corresponding tokenized¹³ grammatical and ungrammatical sentences (see Table 8). There is some additional information, representing grammar sections which rules pertain to, sources of rules as well as indication of the subset for each sentence (validation or test, see more in the next section). There are few sentences in the dataset that do not contain any errors (see column *Correct source sentences* in Table 1), because it is also crucial to verify if models are prone to hypercorrection. These sentences are also marked with metadata. We also present our data in .M2, which is a conventional GEC format.

An example from LORuGEC in the first format type may be seen in the Table 8.

The same sentence, but expressed in the .M2-standard:

```
S Иванова , как художника , я совсем не знаю .
A 1 2|||None|||||REQUIRED|||-NONE-|||0
A 4 5|||None|||||REQUIRED|||-NONE-|||0
```

According to the .M2-standard, the source text is denoted with S, while the corresponding edits are prefixed with A. Each edit consists of the error span, error type, correction, if the edit is optional or required, additional remarks and annotator ID, yet we do not make use of error types. The given annotation demonstrates the requirement to delete two commas in the sentence.

E Model hyperparameters

E.1 Model prompt

Our final prompt for grammatical error correction of Russian texts is given in Figure 2.

E.2 Training hyperparameters

We train the model with Huggingface Transformers Trainer using the hyperparameters from Table 9 for all experiments. When two values are given, the first value is used for training from scratch, and the second – for finetuning from a checkpoint that was already trained on a larger general GEC corpus.

¹³We made use of NLTK Tokenizer: <https://www.nltk.org/api/nltk.tokenize.html>.

We also made the following model-specific changes:

1. Llama-8B-Instruct is tuned using `learning_rate = 3e-6` and YandexGPT5-Lite using `learning_rate = 1e-6`. For both these models we use `max_grad_norm = 0.3`.
2. LORA finetuning is performed with `learning_rate = 1e-4` and physical batch size 4.

F Retriever training

F.1 GECTOR pretraining

Since the morphological features of English and Russian differ significantly, we reimplement the GECTOR preprocessing by ourselves. The sets of G-labels correspond to combinations of morphological features, e.g., the label `NOUN,Nom+Plur` corresponds to putting the noun into Plural number and Nominative case, keeping other morphological features intact. When the corpus is converted into the pairs of word sequences and their edit labels, we implement training using standard HuggingFace Transformer instruments for sequence labeling. We omit the decoder as we do not need the exact surface transformations predicted by the GECTOR model, but only its labels and hidden states.

We train the GECTOR model on the concatenation of RULEC-GEC, ru-Lang8, GERA and 1 million sentences with synthetic errors. When generating synthetic data, we use the Russian subset of Oscar corpus¹⁴ as source and introduce artificial errors simulating the error distribution of three mentioned corpora. The model is initialized from ruRoberta-large¹⁵ model, the hyperparameters of training are given in Table 10.

F.2 Contrastive tuning

As mentioned in Subsection 4.3, we tune the retriever on the task of rule label prediction using contrastive learning. The tuning is performed on the validation set of LORuGEC. The training objective is a standard triplet loss

$$L(h, h^+, h^-) = \max\left(\frac{\rho(h, h^+) - \rho(h, h^-) + \alpha}{t}, 0\right),$$

where ρ is the distance function (e.g., cosine), α is the margin and t is the temperature. Here h^+

¹⁴<https://huggingface.co/datasets/oscar-corpus/OSCAR-2109>

¹⁵<https://huggingface.co/ai-forever/ruRoberta-large>

Figure 1: Complexity of different grammar sections is expressed by the number of complex rules for the YandexGPT3 Pro model. We considered the rule to be difficult if the model failed to correct some of its sentences (see 3.1).

The rule	Did the base model have difficulties with the rule?	Initial sentence	Correct sentence
Запятая перед союзом “как”: 2 случая (Commas before the conjunction <i>kak</i> ‘as’: second case)	Нет (No)	Иванова , как художника , я совсем не знаю . (I don’t know Ivanov at all , as an artist.)	Иванова как художника я совсем не знаю . (I don’t know Ivanov at all as an artist.)

Table 8: An example of a rule from the dataset with English translation. Additional metadata and other sentences for this rule are omitted for illustrative purposes.

Parameter	value
GPU	A100 80B
num GPUs	1
epochs	3/5
