5 Conclusion

We have described our approaches for the detection of PCL as part of the SemEval-2022 Task 4. We attempted to inject knowledge into prediction models and leverage the uncertainty present in the task. The injection of additional knowledge did not increase the F_1 score significantly. Leveraging the uncertainty in different ways produced mixed effects. Training the models on soft instead of hard labels consistently increased the F_1 score, while using MCD on its own was not beneficial. However, using MCD in combination with soft labels and threshold optimization brought consistent improvements in the F_1 score and produced our best score.

Both directions of our research have potential for further work. In our knowledge injection experiments, we have only experimented with a single type of additional knowledge at a time. To inject multiple types simultaneously, we would need to create special tokens for each combination, which could lead to overfitting due to relatively small and imbalanced data. Therefore, in further work we will try a different method for knowledge injection considering multiple types of additional knowledge simultaneously. In leveraging uncertainty, we have constructed the soft binary labels from the two annotations per example and aggregated the annotations by weighing them equally. A possible further work would experiment with different weighting schemes.

Abstract

The paper describes the SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification (MAMI),which explores the detection of misogynous memes on the web by taking advantage of available texts and images. The task has been organised in two related sub-tasks: the first one is focused on recognising whether a meme is misogynous or not (Sub-task A), while the second one is devoted to recognising types of misogyny (Sub-task B). MAMI has been one of the most popular tasks at SemEval-2022 with more than 400 participants, 65 teams involved in Sub-task A and 41 in Sub-task B from 13 countries. The MAMI challenge received 4214 submitted runs (of which 166 uploaded on the leader-board), denoting an enthusiastic participation for the proposed problem. The collection and annotation is described for the task dataset. The paper provides an overview of the systems proposed for the challenge, reports the results achieved in both sub-tasks and outlines a description of the main errors for a comprehension of the systems capabilities and for detailing future research perspectives.

1 Introduction

Women have a strong presence online, particularly in image-based social media such as Twitter and Instagram: 78% of women use social media multiple times per day compared to 65% of men (Department, 2019). However, while new opportunities for women have been opened on the web, systematic inequality and discrimination offline is replicated in online spaces in the form of offensive contents against them (Frenda et al., 2019; Anzovino et al., 2018; Farrell et al., 2019; Plaza-Del-Arco et al., 2020; Gasparini et al., 2018). A popular communication tool in social media platforms are image macros popularly connoted as "memes" (Shifman, 2013). An internet meme is usually an image communicating pictorial content with an overlaid text that is added *a posteriori* by the meme author, with the main goal of being funny and/or ironic (Shifman, 2013). Although many memes are created with humorous intent, others have political or activist ambitions. Few familiar with the format would be surprised to learn that memes can be used to express hate against women, via sexist and aggressive messages in online environments (Paciello et al., 2021) that subsequently amplify the sexual stereotyping and gender inequality of the offline world (Franks, 2011). In order to counter this phenomenon, the Multimedia Automatic Misogyny Identification (MAMI) shared task has been organised at SemEval-2022 (Emerson et al., 2022). The proposed challenge consists of the identification of misogynous memes, taking advantage of both text and images available as sources of information. The task is organised around two main sub-tasks:
- **Sub-task A:** a basic task of misogynous meme identification, where a meme should be categorised either as misogynous or not misogynous;
- **Sub-task B:** an advanced task, where the type of misogyny should be recognised among potential overlapping categories such as stereotype, shaming, objectification and violence.

Some other tasks related to this topic, but that did not consider the same data and a multimodal approach have been previously organised in the same area of interest, i.e. AMI@Evalita (Fersini et al., 2018a; Elisabetta Fersini, 2020), AMI@IberEval (Fersini et al., 2018b), HatEval (Basile et al., 2019) and OffenseEval (Zampieri

et al., 2020). However, the proposed MAMI challenge is a step forward the previous ones for two main reasons: (1) it is focused on multi-modality and (2) the type of misogynous contents are expressed in a completely different form, i.e. in the former challenge the presence of hateful contents was explicit within the text, while here it is often implicit.

2 Dataset and Annotation Process

Candidate memes have been collected by focusing on the following main types of misogyny:

- *Shaming*: The practice of criticising women who violate expectations of behaviour and appearance regarding issues related to gender typology (such as "slut shaming") or related to physical appearance (such as "body shaming") (Van Royen et al., 2018). This category focuses on content that seeks to insult and offend women because of some characteristics of their body or personality.

- *Stereotype*: a stereotype is a fixed, conventional idea or set of characteristics assigned to a woman (Eagly and Mladinic, 1989). A meme can use an image of a woman according to her role in the society (role stereotyping), or according to her personality traits and domestic behaviours (gender stereotyping).

- *Objectification*: A practice of seeing and/or treating a woman like an object (Szymanski et al., 2011).

- *Violence*: A meme that indicates physical and/or a call to violence against women (Andreasen, 2021).

Examples of the above mentioned types of misogynous memes are presented in Figure 1.

The procedure for collecting relevant memes for this shared task consisted of: (1) searching the most popular **social media platforms**, such as Twitter and Reddit; and (2) downloading samples from **websites** dedicated to meme creation and sharing, such as 9GaG, Knowyourmeme and Imgur, by site scraping and manual download. In both cases, in order to collect a proper number of misogynous memes, 4 main activities have been performed: (1) searching for threads dedicated to memes with women as the subject; (2) searching for threads or conversations dedicated to or written by persons who identify as anti-women or anti-feminist (such as the MGTOW website and the related threads on Reddit); (3) exploring discussions in recent events involving famous women (such as *Michelle Obama*); (4) searching by keywords and/or hashtags such as #girl, #girlfriend, #women, #feminist.

The final collection is composed of 15k memes that have been labelled by human annotators (duplicates have been previously removed). Among the labelled memes we obtained an adequate number of misogynous and non misogynous memes. The final benchmark dataset released for the MAMI challenge is composed of 10k memes for training and 1k for testing (balanced between classes). The dataset has been labelled using crowd-sourcing platforms according to the following primary questions[1]:

- Is this meme misogynous or not?

- If the meme is misogynous, what are the main categories to which the meme belongs (shaming,

[1]The prototype of the annotation interface and the annotation guidelines are reported in Appendix A

file_name	misogynous	shaming	stereotype	objectification	violence	Text Transcription
10846.jpg	1	0	1	1	1	SANDWICH!!!!!! don't make me tell you twice woman.

Table 1: Annotation format of the training and testing instances.

stereotype, objectification, violence)?
In the last case, i.e. related to the misogyny category, multiple overlapping labels have been considered. The memes were shown one at a time to avoid bias introduced by the annotators seeing multiple memes simultaneously.

Memes were annotated by 3 observers and the final label was given according to the majority of the labels (2/3). The text of the memes have been transcribed using Google Cloud Vision[2]. We report an example of a meme that has been provided to the participants as training example, which is composed of raw image (Figure 2) and the corresponding labels available through a csv file (Table 1).

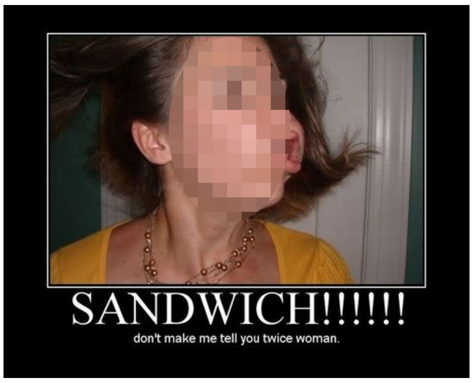

Figure 2: Raw image (10486.jpg)

We estimated the inter-annotator agreement using the Fleiss-κ coefficient (Fleiss, 1971). In particular, we used the traditional Fleiss-κ measure for estimating the agreement related to the misogynous vs not misogynous annotation necessary for Sub-task A, while we adopted the Fleiss-κ with the MASI (Jaccard) index (Passonneau, 2006) to calculate the agreement between annotators on multiple (overlapping) annotations necessary for Sub-task B. Regarding the agreement on the misogynous vs not misogynous annotations, we estimated a coefficient equal to 0.5767, while for the type of misogyny labelling we derived a coefficient equal to 0.3373. We report in Table 2 the details about the dataset provided to the participants. The values of the Fleiss-κ measure suggest that the agreement for the misogynous labelling is moderate, denoting a quite simple task for humans, while the agreement for the type of misogyny annotation is fair, denoting a quite hard task.

3 Evaluation Measures and Baseline

Sub-task A. Systems have been evaluated using macro-average F1-Measure. In particular, for each class label (misogynous and not misogynous) the corresponding F1-Measure has be computed, and the final score has been estimated as the arithmetic mean of the two F1-Measures. The baseline models used as benchmark with respect to the participants are:

- **Baseline Text**: a deep representation of text, a fine-tuned sentence embedding using the USE (Cer et al., 2018) pre-trained model;
- **Baseline Image**: deep representation of image content, based on a fine-tuned image classification model grounded on VGG-16 (Simonyan and Zisserman, 2014);
- **Baseline Image_Text**: a concatenation of the previous deep image and text representations through a single layer neural network.

We also used two multi-label models introduced for Sub-task B and detailed in the following paragraph.

Sub-task B. Systems have been evaluated using weighted-average F1-Measure. In particular, the F1-Measure has been computed for each label and then the average has been weighted by the number of true instances for each label. For Sub-task B, the baselines are grounded on:

- **Baseline Flat Multi-label**: a multi-label model, based on the concatenation of deep image and text representations for predicting simultaneously if a meme is misogynous and the corresponding type;
- **Baseline Hierarchical Multi-label**: a hierarchical multi-label model, based on text representations for predicting whether a meme is misogynous or not and, if misogynous, the corresponding type.

4 Participant Systems and Results

MAMI has been one of the most popular tasks in SemEval-2022, with 65 teams that joined Sub-task

	Misogyny Labelling (Sub-task A)			Type of Misogyny Labelling (Sub-task B)				
	Misogynous	**Not Misogynous**	**Fleiss-k Agreement**	**Shaming**	**Stereotype**	**Objectification**	**Violence**	**Fleiss-k Agreement**
Training Set	5000 (50%)	5000 (50%)	0.5767	1274 (25.48%)	2810 (56.20%)	2202 (44.04%)	953 (19.06%)	0.3373
Test Set	500 (50%)	500 (50%)		146 (29.20%)	350 (70.00%)	348 (69.60%)	153 (30.60%)	

Table 2: Dataset characteristics.

A and 41 teams that participated in Sub-task B. We received a total of 4,214 submissions, of which 166 submitted to the leader-board. Among the teams joining the MAMI challenge, 41 groups have provided the details about their participation (team name, number of team members, country, and description of their system). In Appendix B (Table 8), we report features about the teams that have provided team information for further analysis and discussion. On average, the teams are composed of 2 members, varying from 1-person teams (the most frequent case) to 7 members (the largest team). Regarding geographic distribution, the majority of the participants come from India (12 teams), followed by USA and Germany (5), UK and China (4), Italy and Spain (3) and the remaining countries with 1 team each.

As a general overview of the results, we report in Table 3 the mean, standard deviation (StDev), minimum, maximum, median and the first and third quartiles (Q1 and Q3) of the performance achieved by the participant teams.

In Sub-task A, we notice that the maximum value

	Min	Q1	Mean	Median	StDev	Q3	Max
Sub-task A	0.481	0.649	0.680	0.679	0.064	0.722	0.834
Sub-task B	0.467	0.634	0.663	0.680	0.059	0.706	0.731

Table 3: Basic statistics of the results for the participating systems in Sub-task A and Sub-task B, expressed in terms of macro-averaged and weighted-average F_1-score respectively.

(0.834) is much higher than the corresponding one in Sub-task B (0.731), while the difference is less evident when considering the mean (from 0.680 to 0.663) and the median value (from 0.679 to 0.680). When considering the max values, it emerges that Sub-task B seems to be more difficult than Sub-task A, while the median values indicates that for the 50% of the systems both tasks are equally challenging.

In regards to the models adopted by the participants, it has been observed that the majority of the teams exploited pre-trained models, distinguished in text-based, where the most used ones are based on BERT (Devlin et al., 2019) such as RoBERTa (Liu et al., 2019), and image-based models, where the most adopted ones are based on VisualBERT (Li et al., 2020a). Among these systems, considered by 90% of the teams, half of them adopted an ensemble strategy to make the final prediction. The remaining ones adopted either traditional neural networks (30%) or multi-task (20%) approaches to classify the memes. Few teams exploited models, such as CLIP (Radford et al., 2021) and ViLBERT (Lu et al., 2019), to jointly learn the characteristics of misogynous and not misogynous memes, and the related misogyny categories.

4.1 Sub-task A

Sub-task A was attempted by 65 teams, where 47 of them (72%) outperformed the best provided baseline, the Baseline Hierarchical Multi-label model, in terms of macro-averaged F_1-score. The highest score (0.834) has been obtained by the SRCB team (Zhang and Wang, 2022), which defined an ensemble model of deep multi-modal features with Multi Layer Perception (Kubat, 1999), Extreme Gradient Boosting (Chen and Guestrin, 2016) and Gradient-Boosted Decision Trees (Si et al., 2017).

We report in Table 4 the Top-10 teams in Sub-task A, ranked according to macro-average F_1-score (the overall leader-board is reported in Appendix C.) Regarding the top-3 systems, DD-TIG

	Team Name
1	SRCB (Zhang and Wang, 2022)
2	DD-TIG (Zhou et al., 2022)
3	RIT Boston (Chen and Chou, 2022)
4	NLPros
5	ASRtrans (Rao and Rao, 2022)
6	Poirot (Srivastava, 2022)
7	R2D2 (Sharma et al., 2022b)
8	PAIC (ZHI et al., 2022)
	ymf924
	RubCSG (Yu et al., 2022)
9	hate-alert
10	AMS_ADRN (Li et al., 2022)

Table 4: Top-10 teams in Sub-task A, ranked according to macro-average F_1-score.

(Zhou et al., 2022), ranked second place by defining an ensemble of different pre-trained models: (1) ERNIE-Vil (Yu et al., 2021), which incorporates structured knowledge obtained from scene graphs to learn joint representations of vision-language; (2) Uniter (Chen et al., 2020), which learns a joint multi-modal embedding through a Transformer-based architecture over four image-text datasets; (3) VisualBERT (Li et al., 2020a), which is composed of a stack of Transformer layers that implicitly align elements of an input text and regions in an associated input image with self-attention; (4) Oscar (Li et al., 2020b), which exploits object tags detected in an image as anchor point to learn the alignment with the caption fragments.

RIT Boston (Chen and Chou, 2022) ranked third and used OpenAI's CLIP model (Radford et al., 2021) to obtain high-quality multi-modal features and then used a logistic regression (LR) model to make a binary classification. In their model, a data-centric AI principle was used to further improve performance by manually rating a subset of test data and adding this extra data into the train set.

4.2 Sub-task B

Sub-task B was attempted by 41 teams, where 35 of them (85%) outperformed the best MAMI baseline, which also in this case is the Baseline Hierarchical Multi-label model. We report in Table 5 the Top-10 teams in Sub-task B, ranked according to weighted-average F_1-score (the overall leaderboard is reported in Appendix C). The highest result (0.731) has been obtained by three teams, i.e., SRCB (Zhang and Wang, 2022), TIB-VA (Hakimov et al., 2022) and PAIC (ZHI et al., 2022). The SRCB team (Zhang and Wang, 2022) adopted the same ensemble model used for Sub-task A. The system developed by TIB-VA is instead based on a Deep Learning model grounded on CLIP image and text features combined with a LSTM (Hochreiter and Schmidhuber, 1997), while PAIC (ZHI et al., 2022) did not provide any information about their approach. In second place, the ymf924 team did not provide any information about their approach, while in third place is the DD-TIG (Zhou et al., 2022) team with the same approach used for Sub-task A.

	Team Name
1	SRCB (Zhang and Wang, 2022)
	TIB-VA (Hakimov et al., 2022)
	PAIC (ZHI et al., 2022)
2	ymf924
3	DD-TIG (Zhou et al., 2022)
4	NLPros
5	QMUL
6	Unibo (Muti et al., 2022)
7	RubCSG (Yu et al., 2022)
8	AMS_ADRN (Li et al., 2022)
9	taochen (Tao and jae Kim, 2022)
10	ASRtrans (Rao and Rao, 2022)

Table 5: Top-10 teams in Sub-task B, ranked according to weighted-average F_1-score.

In general, the most predominant models for addressing Sub-task B are multi-class approaches, multi-task learning, and/or ensemble methods, where the feature space for learning has been derived either by image and text pre-trained models or by a joint embedding space.

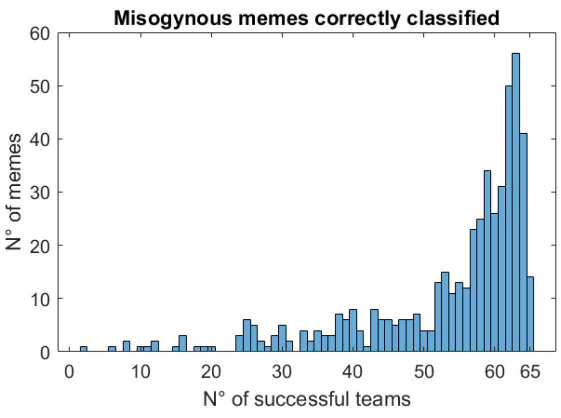
5 Error Analysis

In order to gain deeper insight into the prediction capabilities of the systems and delineate the open issues about the recognition and classification of misogynous memes, we conducted a detailed error analysis on both sub-tasks, considering all participating teams. The error distributions and the types of the most common errors in regards to the labels to be predicted are detailed in the following subsections. We considered memes misclassified by at least 25%, 50% and 75% of the teams, distinguishing False Positive (FP) and False Negative (FN), according to the labels available in each sub-task. For the memes misclassified by at least 75% of the teams, we reported the most frequent types of errors by analysing the visual and textual content of the memes.

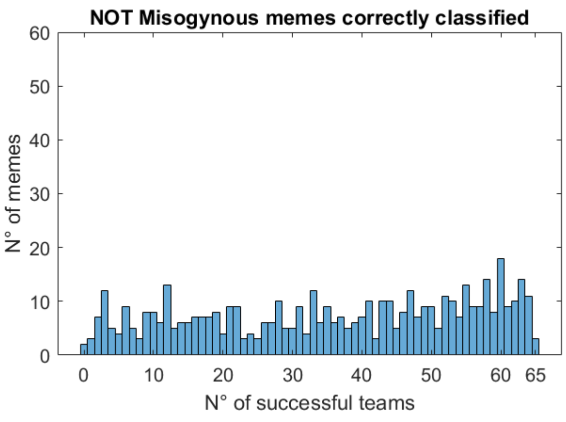
5.1 Sub-task A

In Figure 3, the distribution of correct classifications with respect to the number of successful teams is reported for misogynous and not misogynous memes. The distribution of correctly classified misogynous memes (Figure 3(a)) is uni-modal and peaked towards higher values, implying that most memes have been correctly classified by most teams. On the other hand, considering the not misogynous ones, the distribution is more uniform (Figure 3(b)), denoting that in general the models are more recall than precision oriented. There are 14 memes out of 500 (2.8%) correctly classified as misogynous by all the teams (Figure 3(a), last bin), while no one is misclassified by all the teams. In the worst case, only one misogynous meme was misclassified by 63 out of 65 teams.

In Table 6 the error distribution of Sub-task A is reported, considering the misclassification of misogynous memes and not misogynous ones sepa-



(a)



(b)

Figure 3: Distributions of correct classifications with respect to the number of successful teams for misogynous (a) and not misogynous (b) memes.

Teams	Misogynous memes predicted as NOT Misogynous (FN)		NOT Misogynous memes predicted as Misogynous (FP)		Overall misclassified memes (FP+FN)	
25% (16 teams)	128	25.60%	340	68.00%	468	46.80%
50% (33 teams)	46	9.20%	220	44.00%	266	26.60%
75% (49 teams)	12	2.40%	109	21.80%	121	12.10%

Table 6: Error distribution on Sub-task A.

rately, and finally the overall errors. In general, the percentage of classification errors of non misogynous memes are higher than misogynous ones, confirming that the methods are more precision than recall oriented. This suggests that most of the systems tends to be biased towards the misogyny category due to the presence of text or images that mislead the systems. Focusing on the memes misclassified by at least 75% of the teams, the most frequent types of errors can be summarised in the following paragraphs.

Misogynous memes predicted as NOT misogynous (FN). Twelve memes belong to this set. Five of them involve sexual objectification, that requires correlation of textual and visual content to classify. In particular, the meme depicted in Figure 4 is characterised by a neutral text and depicts a neutral object. In this case, the shape of the object together with the text needs to be correlated to grasp the sexual meaning. This meme was correctly classified by only 6 teams out of 65. Another group of misclassified memes, corresponding to one third of this set, is related to violence, both physical (visually represented), and sexual, which is less explicitly evoked.

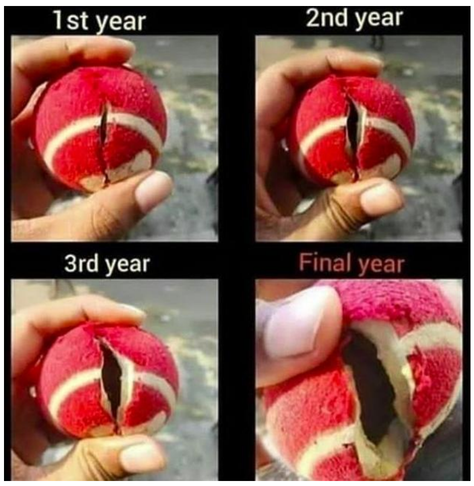


Figure 4: A misogynous meme classified as a non misogynous one (Raw image: 17013.jpg).

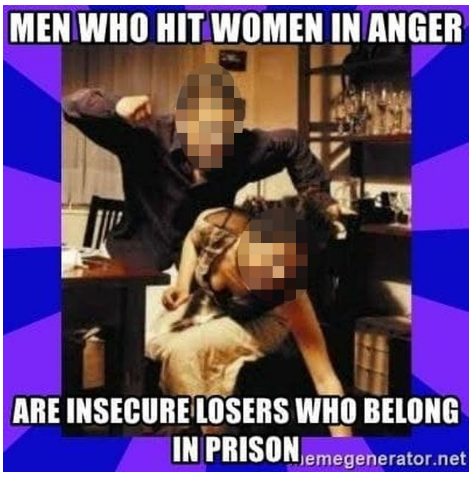
NOT Misogynous memes predicted as misogynous (FP). 109 NOT misogynous memes were incorrectly predicted by at least 75% of the teams. The majority of the misclassified memes contain textual or visual content that are often contained in misogynous memes. For example, 38% of the memes contain words and phrases such as “woman, man, fat, boobs, kitchen, dishwasher, chicks, make me a sandwich, . . . ”, and 31% depict close up images of women, which often emphasise the neck-



MEN WHO HIT WOMEN IN ANGER
ARE INSECURE LOSERS WHO BELONG IN PRISON
memegenerator.net

Figure 5: Example of meme with an antithetical content (Raw image: 15138.jpg).

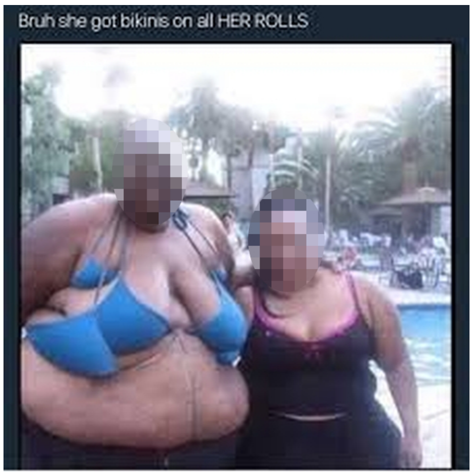


Figure 6: Most common example of Shaming meme misclassified as NOT Shaming (Raw image: 15559.jpg)

line, or depict faces with evident makeup. An interesting group of misclassified memes (7 out of 109) shows antithetical content. In general, most of the visual and textual information recall typical misogynous memes (with viral phrases such as "back to the kitchen" or depicting misogynous scenes such as physical violence), however additional information both visual and textual, with an opposite meaning, changes the overall message conveyed, as depicted in the example in Figure 5.

Memes featuring famous characters or actors who are often depicted associated to messages of all kinds, such as Ryan Gosling with the "hey girl" memes, Dwight Schrute or Willy Wonka, are also frequently misclassified (about 10%). Finally it is worth noting that other misclassified memes are those that convey feminist ideals and content.

5.2 Sub-task B

We report in Table 7, the error distribution of Subtask B, accordingly to the labels predicted (i.e., Stereotype, Violence, Shaming and Objectification). The first interesting insights involve the misogyny categories that are misclassified by at least 75% of the teams, in a ranked order: Objectification (14.60% of memes are wrongly classified by at least 31 teams in the over 41 participating teams), Stereotype (13.10%), Violence (3.30%) and Shaming (3.2%). A further interesting insight relates to the ability of the models with respect to the False Negative (FN) and the False Positive (FP) of each class. While for Shaming and Violence the percentage of FP (0.82% and 0.12% respectively) is much lower than the percentage of FN (17.2% and 20.92%), for Stereotype and Objectification the opposite is true, where FP (27.71% and 35.92% respectively) rates are much higher then FN (5.23% and 3.22%). We analysed the most predominant errors, with respect to each misogyny category.

Shaming. Regarding the first misogyny category, the most frequent error by at least 75% of the teams relates to the classification of Shaming memes as NOT Shaming (17.12%). The majority of the memes wrongly classified relates to the concept of *fat shaming* where overweight women are compared, implicitly or explicitly, to a narrow standard. An example of such errors is reported in Figure 6.

Violence. With the Violence category, the most frequent error by at least 75% of the teams relates to the classification of Violence memes as NOT Violence ones (20.92%). In this case, the majority of the memes wrongly classified as NOT Violence relates to the concept of *physical assault* typically depicted with a violent image (e.g., woman with bruises) but with neutral text (e.g., "don't tell her twice") or by a neutral image (e.g., standing men) coupled with a violent text (e.g., "women need a good beating once in a while"). An example of a misclassified violent meme is shown in Figure 7.

Stereotype. In the Stereotype category, the most frequent error by at least 75% of the teams relates to the classification of NOT Stereotype memes as Stereotype ones (27.71%). In this case, the most frequent misclassification concerns memes that are related to the concept of *men in the kitchen*, where the image typically represents men and the text is related to the stereotype of woman in kitchen ("cooking"). An example of such errors is re-

Teams	Shaming predicted as NOT Shaming (FN)		NOT Shaming predicted as Shaming (FP)		Overall misclassified Shaming memes (FP+FN)	
25% (11 teams)	92	63.01%	143	16.74%	235	23.50%
50% (21 teams)	59	40.41%	44	5.15%	103	10.30%
75% (31 teams)	25	17.12%	7	0.82%	32	3.20%
	Violence predicted as NOT Violence (FN)		**NOT Violence predicted as Violence (FP)**		**Overall misclassified Violence memes (FP+FN)**	
25% (11 teams)	90	58.82%	32	3.78%	122	12.20%
50% (21 teams)	65	42.48%	6	0.71%	71	7.10%
75% (31 teams)	32	20.92%	1	0.12%	33	3.30%
	Stereotype predicted as NOT Stereotype (FN)		**NOT Stereotype predicted as Stereotype (FP)**		**Overall misclassified Steretype memes (FP+FN)**	
25% (11 teams)	236	36.31%	278	79.43%	514	51.40%
50% (21 teams)	94	14.46%	190	54.29%	284	28.40%
75% (31 teams)	34	5.23%	97	27.71%	131	13.10%
	Objectification predicted as NOT Objectification (FN)		**NOT Objectification predicted as Objectification (FP)**		**Overall misclassified Objectification memes (FP+FN)**	
25% (11 teams)	151	23.16%	260	74.71%	411	41.10%
50% (21 teams)	65	9.97%	205	58.91%	270	27.00%
75% (31 teams)	21	3.22%	125	35.92%	146	14.60%

Table 7: Error distribution on Sub-task B.

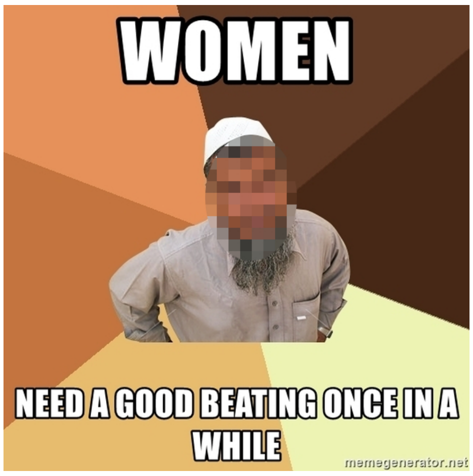

Figure 7: Most common example of Violence meme misclassified as NOT Violent (Raw image: 16067.jpg)

ported in Figure 8. The analysis of the errors in the stereotyped category is controversial and interesting. Some of the memes that our annotators have labelled as non-stereotypical could be considered expressions of benevolent sexism (Glick and Fiske, 1996). Benevolent sexism is a subtle form of prejudice, which apparently values women more than men but does it connecting this positive evaluation to their traditional roles. This is a manifestation of sexism that is difficult to detect and it is still not consensual in society. In fact, these memes were considered by our annotators not to be an expression of stereotype. The task team decided to keep the annotators' view that reflects the majority thinking in society today, however, the models seem to have detected benevolent sexism and the errors go in that direction. If models are only detecting the kitchen scenario or a more subtle form of prejudice is an intriguing question for future research.

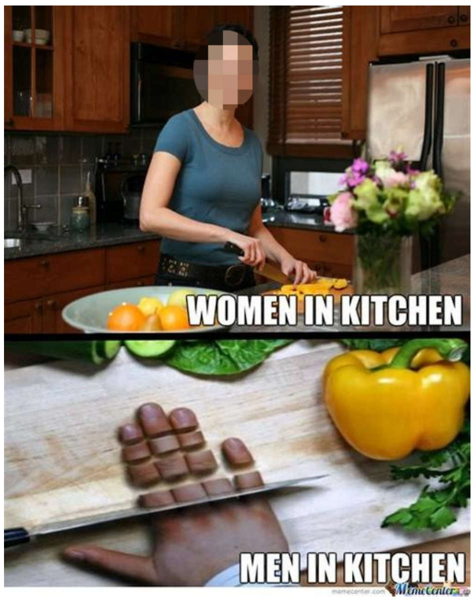

Figure 8: Most common example of NOT misogynous and NOT Stereotype meme misclassified as Stereotype (Raw image: 15137.jpg)

Objectification. In the Objectification category, the most frequent error by at least 75% of the teams relates to the classification of NOT Objectification memes as Objectification (35.92%). In this case, there is not a predominant archetype over the others that confounds the majority of the models.

6 Conclusions

The high number of participating teams at the MAMI challenge at SemEval-2022 confirms the growing interest of the research community not only in detecting abusive language but also pictorial content as sources of information. Overall, results and error analysis confirm that the detection of misogynous memes is challenging, with many open issues that need to be addressed. First of all, the fact that the most predominant error in misogyny recognition relates to the misclassification of NOT misogynous memes as misogynous ones suggests that some potential issues could be related to biased models. The research community is therefore encouraged to pay attention not only to accuracy metrics, but also to ensure models are unbiased before applying them in a real context. Another open issue relates to the capability of the systems to model the dynamics of the memes. Every day different memes, with different images and different text are generated on the web and shared online.

A Annotation Guidelines

We report here the annotation guidelines provided to the annotators participating in the crowdsourcing annotation process of the collected memes. Since some memes contain sensitive content, we provided an explicit advisory message to the annotators.

A.1 Overview

The job aims at labelling English memes shared by users on the web as misogynous or not misogynous. The first step is about collecting socio-demographic information about the annotators:

- Gender: indicate your gender as female, male, unspecified
- Age: please choose your age range between 18-15, 25-35, 35-45, 45-60, over-60
- Location: please indicate your country of birth

The second step is about misogyny labelling. Annotators have to decide whether a meme is misogynous or not. If a meme is labelled as misogynous, then two other questions will be answered:

- Type of misogyny: the annotator should indicate (multiple choice) if the meme represents shaming, stereotype, objectification and/or violence.
- Misogyny rating: the annotator should provide a rating about how much the meme is misogynous using stars, i.e. *, ** or ***.

A.2 Guidelines and examples

Misogyny Labelling. Looking at a meme at a time, annotators should label it as misogynous or not according to the following definitions:

- ***Misogynous***: a meme is misogynous if it conceptually describes an offensive, sexist or hateful scene (weak or strong, implicitly or explicitly) having as target a woman or a group of women. Misogyny can be expressed in the form of shaming, stereotype, objectification and/or violence.
- ***Not Misogynous***: a meme that does not express any form of hate against women.

Remark: a meme is NOT misogynous if it is conceptually not related to women or even if it is related to women, but it does not represent an offensive, sexist or hateful concept against women.

Type of misogyny. If a meme is considered misogynous, then the annotator has to choose one or more types of misogynous categories, according to the following definitions:

- ***Shaming:*** memes aimed at insulting and offending women because of some characteristics of the body. These types of misogynous memes are related to denigrating the physical appearance of women (body shaming).
- ***Stereotype*:** memes are aimed at representing a fixed idea or set of characteristics assigned to women. These types of memes convey the image of women according to their role in the society (i.e., Role Stereotyping), to her personality traits and domestic behaviours (i.e., Gender Stereotyping) or to fixed ideological characteristics related to women's rights (i.e., Feminism Stereotype).
- ***Objectification:*** it is a practice of seeing and/or treating a woman like an object. These types of memes usually report an over-appreciation of women's physical appeal, depicting woman as an object (sexual objectification or human being without any value as a person).
- ***Violence:*** indicates a physical or verbal violence represented by textual or visual content. These types of misogynous memes are aimed at showing violence against women or at alluding to the intent of physically assert power over women.

Misogyny Rating. If a meme is considered misogynous then the annotator has to indicate, according to his/her opinion, how misogynistic it is using a 1 to 3 ratings: * indicates weak misogyny, ** means medium misogyny, *** means strong misogyny.

B Team Information

We report here the details provided by those teams that have responded to a request for team information.

Team Name	Country	Members

C Leader-boards

C.1 Leader-board of Sub-task A

We report in Table 9 the leader-board for Sub-task A. Team Names marked with * have submitted team name and additional information for further analysis and discussion. For those teams that have not provided the Team Name, we maintained the user name used on Codalab for submitting their predictions.

To produce the reported leader-board, we filtered the ranking defined by the evaluated metrics to maintain only the highest achieved score per group. Afterwards, we scrolled through this ranking from top to bottom in order to create clusters based on the obtained scores and the statistical difference resulting from the application of the McNemar test (McNemar, 1947).
In particular, starting from the first entry in the ranking, we have included in the same cluster the groups that presented (1) the same score or (2) had a statistical equality in performance.
As stated before, statistical equality was computed with a pairwise analysis performed with the McNemar test: we evaluated the equality in performance of the analysed algorithm with the algorithm that obtained the highest score within the cluster, considering a value of alpha equal to 0.05. According to this criterion, in the event that the algorithm under analysis could not be included in the cluster, a new one was created; the subsequent ones would have been compared with the latter.

Notice that in the leader-board were maintained all the baseline results for comparison.

C.2 Leader-board of Sub-task B

We report in Table 10 the leader-board for Sub-task B. Team Names marked with * have submitted team name and additional information for further analysis and discussion. For those teams that have not provided the Team Name, we maintained the user name used on Codalab for submitting their predictions.

To obtain the reported leader-board, a similar approach to the one used for Sub-task A has been adopted. A McNemar test (McNemar, 1947) was adopted to evaluate the similarity in performance for the identification of every single type of misogyny. Two algorithms have been considered statistically equal in performance if there was statistical significance in all 4 tests (i.e., if there was a statistical significance for the performance related to all 4 types of misogyny). Thus, a difference in performance for the prediction of only one of the four types has been valued sufficient to consider the analysed algorithm as statistically unequal. As for Sub-task A, the grouping depends on statistical equality and on the scores obtained.

Notice that in the leader-board were maintained all the baseline results for comparison.

Abstract

Social media is an idea created to make the world smaller and more connected. Recently, it has become a hub of fake news and sexist memes that target women. Social Media should ensure proper women's safety and equality. Filtering such information from social media is of paramount importance to achieving this goal. In this paper, we describe the system developed by our team for SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification. We propose a multimodal training methodology that achieves good performance on both the subtasks, ranking 4th for Subtask A (0.718 macro F1-score) and 9th for Subtask B (0.695 macro F1-score) while exceeding the baseline results by good margins. The code will be available here[1]

1 Introduction

With the rising usage of social media and the Internet, it is tougher to establish an inclusive and welcoming community among users. Offensive speech, hate speech, and targeted insult have been increasing among users, disturbing everyone. With the rising utilization of the Internet in a pandemic, hate speech prevalence on the Internet is also increased. Online hate speech with targeted discrimination also creates threats and crimes offline.

Among these, online misogyny or sexist comments have been increasing among women (Salter et al., 2018), which includes name-calling, sexual threats, shaming. This emphasizes the need for specialized automatic misogyny detection in online platforms. Platforms such as Twitter [2] and Facebook already have policies for banning hateful content. However, these systems are primarily through manual methods and might not scale well for large users and multimodal content. Moreover, hate speech is also prevalent in multimodal form since most social media platforms support Images, text, audio and video content. These memes have been popular among users to express their opinions since people express information through memes, GIFs, and videos. But, unfortunately, this also causes the rise of multimodal hate, and offensive content, which is disturbing to users (Suryawanshi et al., 2020). This includes misogynistic posts, which are targeted towards women.

Previous works on Misogyny detection have been primarily focusing on one modality, which is text (Pamungkas et al., 2020). Misogyny detection in text falls under an area of text classification. Text classification methods such as BERT, LSTM, Naive Bayes have been used to detect misogynistic comments. In this work, we have used the provided data, which contains both images of the memes and the extracted OCR text from the memes.

This paper describes our submission for the task; we have used multiple concatenation-based fusion models and ensembled them for the final submission.

2 Related Work

The past works have concentrated on collecting the dataset from popular social media sites such as Facebook, Reddit, and Twitter. Recent statistics do not simply focus on hate but also on the kind of hate the meme attempts to spread. Work has also been done in detecting offensive memes using various pre-trained models. (Fersini et al., 2019) presents a novel dataset for the sexist meme classification task. Sexism could be of several forms that could be categorized based on the context of the caption and the objects on the meme. The main types of sexism against women addressed in the dataset are shaming, stereotypes, objectification and violence. The research paper largely focused on a comparison between the unimodal and multimodal classifiers. The article has attempted to answer various research concerns such as whether unimodal architectures can predict the target correctly, will merging the features of both text and picture capture the inherent complexity of the sexist memes, and which one of the two modalities dominates the other. The research discovered that unimodal classifiers have shown that textual information is an excellent indicator, whereas visual information is a poor indicator to identify sexist memes. This study between unimodal and multimodal showed that unimodal architectures performed better than multimodel architectures.

In the paper, (Zia et al., 2021) the analysis is done on the dataset that focuses beyond hateful or not hateful by annotating the hate meme dataset further by the kind of hate the meme is actually spreading. This would help in understanding the meme and the intention of the person who created the meme better rather than just labelling it as hateful or not. The paper focused on two tasks. The first task was to identify the kind of hate the meme intended to spread. The second task was to detect the type of attack the meme did on a particular group such as slurs, inferiority, and mocking. Models such as CLIP (Contrastive Language Image Pre-Training) and LASER (Language Agnostic SEntence Representations), LaBSE (Language agnostic BERT Sentence Embedding) were used to extract features from the image and text. The paper concluded that multimodel architectures outperformed unimodal architecture. The multimodal, concatenated textual features (CLIP, LASER, and LaBSE) and visual features (CLIP) was the best performing model with AUROC of 0.96 and 0.97 for task A and task B, respectively.

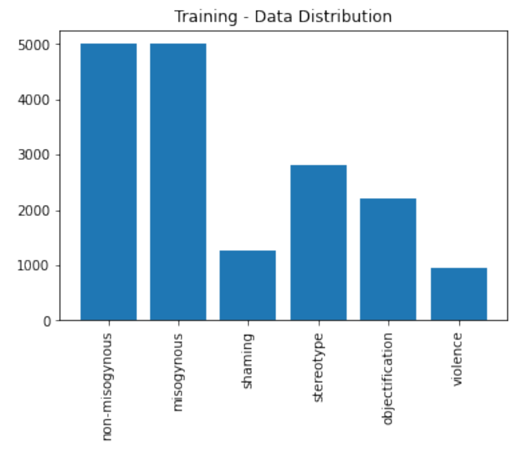

Figure 1: Training data distribution. It can be seen that the positive and negative classes are in equal proportions.

(Guest et al., 2021) introduced a taxonomical dataset of 6,383 samples from Reddit. The dataset has a three-level taxonomy which makes this dataset very different from what already exists. The first level is a binary classification between misogynistic content and non-misogynistic content. The second level corresponds to the subtypes of misogynistic and non-misogynistic content. Misogynistic content categories include misogynistic pejoratives, misogynistic treatment, misogynistic derogation and gendered personal attacks against women. Non-misogynistic content categories include counter speech against misogyny, non-misogynistic personal attacks and None of the categories. In the third level, additional flags for some of the second-level categories have been defined. BERT based models were trained on the dataset to achieve a test accuracy of 0.93.

3 Dataset

The dataset provided for the competition (Fersini et al., 2022) consisted of images of memes and OCR extracted text and labels for both subtask A and B. For Subtask A, the binary label of misogynous is given; for Subtask B, four labels were given: they are shaming, stereotype, objectification and violence, each of them containing binary values 0 or 1. The provided dataset contains 10,000 training images, 100 validation images and 1000 images for test set submission. The training dataset was randomly shuffled and split into five-folds, with each fold containing 2000 images each. The first four folds were used to train the model, and the last fold, along with the eval dataset provided, was chosen as the validation dataset to improve the model performance. The final number of samples in training, validation and test set are reported in Table 1. The Data distribution is given in Figure 1.

4 Preprocessing

Since the text was extracted from the memes using OCR tools, much noise in the text had to be cleaned manually. First, all internet links, stopwords and Twitter user handles were removed from the text. Then, the text was lemmatized using a word-net based lemmatizer. The text truncation length was set to 256. An interesting observation in the dataset was that memes that were not misogynistic in nature did belong to the other four classes. So, it was evident that a meme might not be misogynistic yet belong to any of the other subcategories.

5 Methodology

5.1 Models

Since this topic was multimodal in nature, we finetuned multiple text-based models and image-based models to handle this task. Convolutional Neural Networks (CNNs) excel in image classification challenges due to their intrinsic spatial inductive bias. CNNs have been leading the computer vision research arena for the last two decades due to their superior spatial comprehension ability. The CNN based image models chosen for this task are: InceptionV3 (Szegedy et al., 2015) and EfficientNetB7 (Tan and Le, 2020) from the TensorFlow library. The BERT (Devlin et al., 2019) model was used as the text feature extraction backbone. We also tried finetuning CLIP (Radford et al., 2021) for this task, as it was trained in a multimodal fashion. For both CLIP and other multimodal models we added a fully connected layer with softmax for classification.Another approach was to extract a set of embeddings from State-of-the-Art Text and Image models and classify the features using Support Vector Machines (SVMs). The models selected for this approach were: XLM-RoBERTa (Conneau et al., 2020), DistilBERT(Sanh et al., 2020), ResNext (Xie et al., 2017) and Data-efficient Image Transformer (Touvron et al., 2021).

5.2 Experiment Setup

We implement our multimodal training in TensorFlow using Tensor Processing Units (TPUs) offered by Google Colab for training. TPUs greatly shortened the time required to conduct numerous tests and hyper-parameter optimization. All the photos were resized to 256x256. The TensorFlow version of the BERT and CLIP models from the transformers library was used. A CUDA-accelerated implementation of SVM from the cuML library created by NVIDIA was used in the SVM training.

Split	No. of Samples
Training	8,000
Validation	2,100
Test	1,000

Table 1: Dataset Split

Image Augmentation methods Typically, CNNs are trained using millions of images to attain good accuracy. However, since the number of photos available in the dataset was less in nature, image augmentation methods were added to generate synthetic augmented images and thus boost the amount of data utilized to train the model. This ensures that the model better generalizes to the patterns present in the image modality. We employ (i) random resizing, (ii) random cropping, (iii) random horizontal flipping and (iv) random vertical flipping as the augmentation methods.

The SVMs were trained using a single K80 GPU provided by Google Colab.

5.3 Multimodal Training

The Multimodal training illustrated in this section follows the procedure shown in Figure 2. The model using InceptionV3 and BERT backbone is termed as Model A, EfficientNet B7 and BERT as Model B, CLIP Image and CLIP Text Backbone as Model C. Models A and B use Adam optimizer with a base learning rate of 1e-06 and a linear learning rate decay. Model C uses Adam optimizer with a base learning rate of 6e-05 and a linear learning rate decay. Image preprocessing is done as provided by the model authors. Text cleaning and tokenization is performed for feeding to the text model. All the models are trained for 50 epochs with an Early Stopping callback to terminate the training when the model does not learn any discriminatory features and/or overfits to the training set. A fully connected layer is added at the end to perform classification.

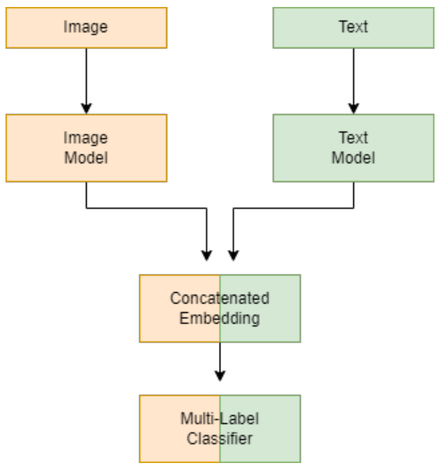

Figure 2: **An overview of the multimodal training approach.** Late fusion is adopted for effective classification.

5.4 SVM Training

In the multimodal training approach, complete models were finetuned for classification. In this approach, the pre-trained image and text models are used as feature extractors alone, and the features are supplied to SVMs for classification. Since the time complexity of training SVMs increases quadratically with respect to the available data, when the data becomes higher than tens of thousands of samples, it practically becomes impossible to train SVMs on CPUs. Since there is a significant amount of data in the training set, SVMs accelerated using CUDA from the cuML library were utilized for training the SVMs. Due to the highly parallel nature of GPU computation, the time required to train the SVM is reduced to seconds. Since SVM is a binary classifier, the multiclass classification problem is broken down into smaller binary classification problems. Thus, 5 SVMs are employed for classification.

6 Results and Discussion

The Test set results are reported in Table 2. Finetuning the CLIP model (Model C) gave results worse than the baseline findings provided by the task authors. So, Model C is not used when building the ensemble. Model A, Model B and SVM results exceed the baseline results by a good margin. This also illustrates that finetuning the models on a downstream task helped boost the accuracy, unlike the case of SVM where it was trained to classify using features extracted by a pre-trained network.

Model	Task A	Task B
Baseline	0.6500	0.6210
Model A	0.6893	0.6774
Model B	0.7005	0.6823
Model C	0.6537	0.5937
SVM	0.6760	0.6447
Ensemble	**0.7182**	**0.6949**

Table 2: Test Set Results

7 Conclusion

Thus we illustrate the system developed by us for SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification. We compare multimodal finetuning vs classification of pre-trained network feature extraction. We have also discussed various methods adopted to train such models and also the data preprocessing done. We show the potential of employing such a model in real-world use cases.

Abstract

This paper describes our system used in the SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification (MAMI) . Multimedia automatic misogyny recognition consists of the identification of misogynous memes, taking advantage of both text and images as sources of information. The task will be organized around two main subtasks: Task A is a binary classification task, which should be identified either as misogynous or not misogynous. Task B is a multi-label classification task, in which the types of misogyny should be identified in potential overlapping categories, such as stereotype, shaming, objectification, and violence. In this paper, we proposed a system based on multi-task learning for multi-modal misogynous detection in memes. Our system combined image features with text features to train a multi-label classification. The prediction results were obtained by the simple weighted average method of the results with different fusion models, and the results of Task A were corrected by Task B. Our system achieves a test accuracy of 0.755 on Task A (ranking 3rd on the final leaderboard) and the accuracy of 0.731 on Task B (ranking 1st on the final leaderboard).

1 Introduction

In the era of mass online communication, more and more people like to share their thoughts on social media platforms. Social media platforms provide users with the ability to express themselves freely.However, it has also led to a rise in cyber hate, such as bullying, sarcasm, and misogyny, on the internet. A study has shown that women have a strong presence online, particularly in image-based social media such as Twitter and Instagram: 78% of women use social media multiple times per day compared to 65% of men. The Web has opened up a whole new world of opportunities for women, but systematic inequality and discrimination in the real world are also found in online spaces in the form of offensive content against them. Now that we live in a world where everything is connected through social media, hate speech against women used to be limited to a specific place or time. There's no need to wait for a specific time or place. All you have to do is type a few keys on the keyboard. Because people on big social media sites make millions of posts every day, it is not possible to manually check all misogynistic posts. To help human curators, it is important to make algorithms that can tell when users post inappropriate content.

Memes are one of the most popular ways to communicate on social media platforms. A meme is essentially an image characterized by a pictorial content with an overlaying text a posteriori introduced by human, with the main goal of being funny and/or ironic. Most of them are made to be funny, but in a short time, people started to use them as a form of hate against women, which led to sexist and aggressive messages in online environments that made the sexual stereotypes and gender inequality in the real world even worse. Misogyny is a type of offensive speech directed at women. It is common on all social media platforms and is becoming more and more of a problem. Previous work on automatic misogyny detection mostly focused on text mode, and they came up with a bunch of supervised methods, like traditional machine learning methods with lexical features and deep learning methods. It can't be certain, though, if memes are misogynistic if only text mode is used to detect them. Memes are intuitively important for automatic misogyny identification tasks.

In this paper, we describe a system that we submitted for detecting misogynous memes. More specifically, we introduce an ensemble model that uses a multi-task learning mechanism based on multi-modal inputs (image information and text information). In our system, image feature representation was extracted by the pre-trained model of ConvNeXt, and text feature representation was extracted by different pre-trained models (deberta-v3-large and roberta-large model). The two features then undergo representation fusion, where they are transformed into reconstructed representation vectors and pumped into a classification layer to yield the final result. Finally, a modality fusion layer performs a weighted average on the fusion results, which results in different text and image features, and the threshold of the final results is adjusted.

2 Background

Many researches worked on identification misogynous in texts. Earlier methods extract carefully engineered discrete features from texts, including n-grams, keyword's sentiment, punctuations, emoticons, etc(Bouazizi and Ohtsuki, 2015), (Ptácek et al., 2014). Recently, researchers have used the powerful technology of deep learning to obtain a more accurate semantic representation of twitter text, including CNN (Convolutional Neural Network), LSTM (Long Short Term Memory) and pre-trained model, etc. Shushkevich and Cardiff (2018) proposed a technique based on combining several simpler classifiers into a more complex blended model. The model considers the probability of classes calculated by simpler models (Logistic Regression, Naive Bayes, and Support Vector Machines - SVM) . Another method from Liu et al. (2018) was proposed, which three classifiers trained by using SVM with a linear kernel, Random Forests (RF) and Gradient Boosted Trees (GBT). In the testing stage, the same way of text pre-processing and feature extraction is applied to test instances separately, and each pair of two out of the three trained classifiers (SVM+RF, SVM+GBT and RF+GBT) are fused by combining the probabilities for each class by averaging.

The primary driver was the renaissance of neural networks, particularly convolutional neural networks (ConvNets). The introduction of AlexNet (Krizhevsky et al., 2017) precipitated the "ImageNet moment", ushering in a new era of computer vision. Since then, this field has developed rapidly. Representative ConvNets like VGGNet (Simonyan and Zisserman, 2015), ResNe(X)t (He et al., 2016), DenseNet (Huang et al., 2017), MobileNet (Howard et al., 2017) and RegNet focused on different aspects of accuracy, efficiency and scalability, and popularized many useful design principles. However, the introduction of Visual Transformer (VIT) completely changed the landscape of network architecture design, which soon replaced ConvNets and became state-of-the-art image classification model. Although the effect of swin transformer is much better than ResNet on the premise of the same size. However, due to the shift operation, it is difficult to design different networks for different sizes of inputs and restart training. And like Detection Transformer (DETR), the convergence is too slow when training. This year, researchers from Facebook AI Research (FAIR) and UC Berkeley reexamined the design space and tested the limits that pure convnet can reach, which shows that the performance of convolutional neural network is no less than that of visual transformer. This series of pure convnet models is named ConvNeXt. It is constructed entirely from standard convnet modules and competes with transformers in terms of accuracy and scalability.

However, little has been revealed by far on how to effectively combine textual and image information to automatic misogyny identification of memes. Schifanella et al. (2016) simply concatenate manually designed features or deep learning based features of texts and images to make prediction with two modalities. Cai et al. (2019) proposed a hierarchical fusion model to deeply fuse three modalities. Different from there works, We proposed a multitask learning and multi-model.

3 System overview

Figure 1 shows the architecture of our proposed. In this work, we treat text and image classification tasks as two models. Image features are mined using a fine-tuned image classification model based on ConvNeXt. Text features are extracted using a fine-tuned sentence embedding based on the pre-trained RoBERTa model. Image features and text features are fused by direct splicing. A classification layer is connected to the fused model to obtain the category probability of memes. Additionally, we create another fused model that adopts the pre-trained model DeBERTa instead of RoBERTa for text feature exaction progress. Our final submitted labels are voted on by the results inferred by these two proposed models (ConvNeXt + RoBERTa and ConvNeXt + DeBERTa). The threshold value selected for the weighted voting method is 0.405. The classification label returns 1 when the classification probability is greater than 0.405, otherwise it returns 0.

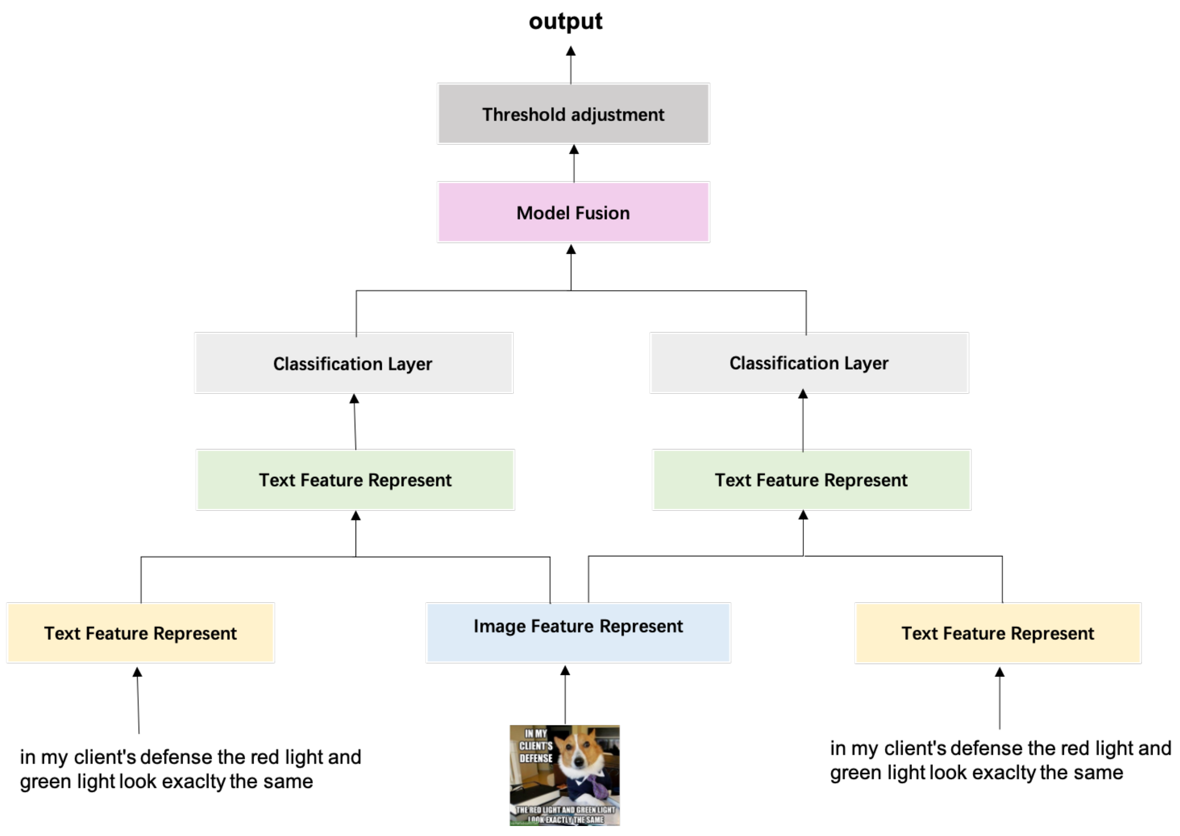

Figure 1: Overview of our proposed model

3.1 Image Feature Representation

In this work, we extracted image feature representation based on an image classification model of ConvNeXt, which trained a baseline model with the Vision Transformer training procedure. Additionally, ConvNeXt (Liu et al., 2022) applied a series of design decisions which are summarized as 1) macro design, 2) ResNeXt, 3) inverted bottleneck, 4) large kernel size, and 5) various layer-wise micro designs. In macro design, ConvNeXt adjusts the number of blocks in each stage and adopts depth-wise convolution. And in micro design, ConvNeXt used fewer activation functions, replacing ReLU with GELU and fewer normalization layers, substituting Batch Normalization (BN) with Layer Normalization (LN), etc. It is worth mentioning that ConvNeXt used data augmentation techniques such as Adamw optimizer, Mixup, Cutmix, RandAugment, Random Erasing, and regularization schemes including Stochastic Depth and Label Smoothing. This was of great help in improving the performance of the model.

3.2 Text Feature Representation

Different pre-trained modals (RoBERTa and DeBERTa) was used as the text feature representation extractor.

RoBERTa - RoBERTa(Liu et al., 2019) is essentially a BERT model with optimal parameters. Compared with BERT model, it used more training data and larger batch size to training longer time. In addition, RoBERTa was trained with dynamic masking instead of static masking, and without NSP loss.

DeBERTa - DeBERTa(He et al., 2021)is a new network architecture proposed by Microsoft. It makes the BERT and RoBERTa models better by using two new techniques. First, the disentangled attention mechanism is applied to represent each word by two vectors, which show their content and relative positions. The attention weights between the word content and position are calculated by disentangled matrices, respectively. Another thing that helps with model pre-training is an "enhanced mask decoder", which adopts the absolute position to predict the masked tokens. In addition, a new virtual adversarial training method is used for fine-tuning to improve models' generalization.

Our system used a series of training techniques. For example, since the general language information and context information obtained by the lower self-attention layer are limited, with the continuous superposition of attention layers, each layer can obtain more language information and context information when encoding. When approaching the last layer, the pre-trained model starts to adjust its embedding information to adapt to different tasks based on different fine-tuning tasks. Therefore, our system set different learning rates in the network to improve the performance of the model. Especially, we set lower learning rates for bottom layers and higher learning rates for top layers. Meanwhile, our system decayed the learning rate with a cosine annealing (Loshchilov and Hutter, 2017) for each batch to improve its overall performance when training deep neural networks.

3.3 Modality Fusion

Multi-modal feature fusion is a useful technique for improving performance in a variety of tasks. According to the order of fusion and prediction, it is divided into early fusion and late fusion. Early fusion is to fuse features before the training model, such as concatenate, add, TFN, MFN, LFN, etc. Late fusion is the fusion of results of different modal predictions, such as maximum fusion, average fusion, etc.

In this scheme, we tried to use different fusion methods for multi-modal fusion, including concatenate, TFN, etc., but finally found that the effect of directly concatenating image features and text features is the best method. Therefore, we concatenate the image features and text features into the fully-connected layer, and then get the fusion features through the normalization layer and multi-sample dropout layer.

3.4 Classification layer

In this work, our system used a two-layer fully-connected neural network as our classification layer. The activation functions for the hidden layer and the output layer are the ReLu and Sigmoid functions, respectively. The loss function is a BCE loss. In addition, we also tried to use SVM as the classification layer, but the performance was not effective.

3.5 Model Fusion

Our system used different pre-trained models to extract text features (RoBERTa and DeBERTa). After fusing image features, we trained a multi-label classification model to obtain the probability value of each category (misogyny, stereotype, shading, objective, and violence). We used weighted voting to fuse the results with two fusion models (ConvNeXt + RoBERTa, and ConvNeXt + DeBERTa). The threshold value selected for the weighted voting method is 0.405 (the classification label returns 1 when the classification probability is greater than 0.405, otherwise it returns 0). Through analysis, it is found that when "shaming", "stereotype", "objectification", and "violence" are positive samples, the "misogynous" must also be positive. In order to improve the results of Task A, the prediction results of "misogynous" are corrected by the prediction results of "shaming", "stereotype", "objectification" and "violence". Experiments show that it is a significant improvement over the result of Task A. Moreover, we also tried to use the results of "shaming", "stereotype", "objectification" and "violence" to correct the results of "misogynous", but found the effect was not satisfying.

4 Experimental setup

4.1 Dataset

The datasets for the MAMI competition(Fersini et al., 2022) are memes collected from the web and manually annotated via crowd sourcing platforms. As summarized in Table 1, the organizers provided 10,000 memes (in jpg format) and a csv file for the training set and 1,000 memes (in jpg format) and a csv file for the testing set. For both Subtask A and B, the memes are released as jpg images.

misogynous: a binary value (1/0) indicating if the meme is misogynous or not. A meme is misogynous if it conceptually describes an offensive, sexist or hateful scene (weak or strong, implicitly or explicitly) having as target a woman or a group of women.

shaming: a binary value (1/0) indicating if the meme is denoting shaming. A shaming meme aims at insulting and offending women because of some characteristics of the body.

stereotype: a binary value (1/0) indicating if the meme is denoting stereotype. A stereotyping meme aims at representing a fixed idea or set of (physically or ideologically) characteristics of women.

objectification: a binary value (1/0) indicating if the meme is denoting objectification. A meme that describes objectification represents a woman like an object through over-appreciation of physical

Task A	Training	Testing	Task B	Training	Testing
Misogynous	5000	500	stereotype	1271	146
			shaming	2810	350
			objectification	2201	348
			violence	953	153
No Misogynous	5000	500	stereotype	3	0
			shaming	0	0
			objectification	1	0
			violence	0	0
Total	10000	1000	Total	7239	997

Table 1: Dataset label distribution

appeal (sexual objectification) or depicting woman as an object (human being without any value as a person).

violence: a binary value (1/0) indicating if the meme is denoting violence. A violent meme describes physical or verbal violence represented by textual or visual content.

The label distribution related to the training and testing datasets is reported in Table1. While the distribution of labels related to the field of misogynous is balanced (for both testing and training datasets), the classes related to the other fields are quite unbalanced. Furthermore, when memes are labeled as "No Misogynous," the classes of "shaming," "stereotype," "objectification," and "violence" are found to be positive in testing datasets. However, there is some error data in training datasets where memes are identified as "No Misogynous".

4.2 Training Details

Image datasets. The public pre-trained model of ConvNeXt_base_22k_1k_384 is adopted in the proposed model. Preprocess the image data through random horizontal and vertical clipping, Random Affine, ColorJitter, Normalize, etc. It is worth mentioning that we set the image size of the training datasets to 384 x 384 and the image size of the verification and testing datasets to (384 + 32) x (384 + 32), which can improve the generalization of the model.

Text datasets. The pre-trained model of deberta-v3-large and roberta-large are adopted for analyzing the text. Models download from HuggingFace[1] are directly used in our model.

Learning rate initialization. Our system sets different learning rates for each layer of text pre-trained model. In particular, the layers of the pre-trained model are divided into three groups with distinct hyper parameters. The learning rates for layer-0 to layer-7 were set to 1e-5/2.6, while layer-8 to layer-15 were set to 1e-5, and layer-16 to layer-23 were set to 1e-5 * 2.6. Setting different learning rates for different layers can make the training more effective and improve the performance of the model.

Learning rate decay. Our system used a method of cosine annealing to decay the learning rates for each batch to avoid falling into a local optimal solution.

multi sample dropout. The four samples dropout were used in our system after fusing the image features and text features. Experiments show that the performance and effects have been significantly improved.

Optimization. Our system applied the AdamW optimizer to optimize the loss function.

Loss Function. Our system applied the BCE loss for multi-label binary classification.

Evaluation Function. Due to our mistakes, we used the incorrect evaluation criteria, which used macro-average F1-Measure instead of weighted-average F1-Measure to train the multi-label classification model. Through offline experiments, we discovered that using the correct evaluation criteria training can result in better and more stable results.

5 Results

In this section, the results of the experiments for our runs will be discussed and compared to the results published in Table 2. We try to only use image or text features for training through different pre-trained models, including Swin Transformers, ConvNeXt, RoBERTa, and DeBERTa. In addition, we also used some other training techniques, such as training a multi-label classification model with

[1]https://huggingface.co/models

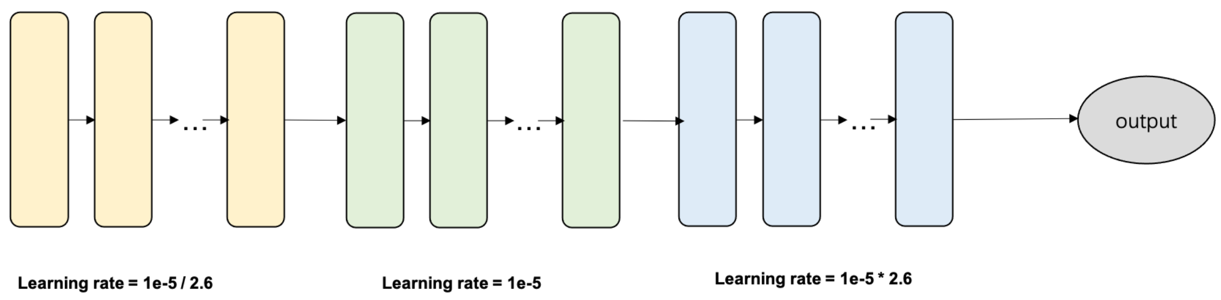

Figure 2: Learning rate initialization

five or four classes, using different classification layers (SVM or full-connected layer), using different fusion methods (concat or LFN), and adjusting the threshold value of fusion prediction results, etc. The specific result of the analysis is shown in Table 2.

V1: Training a image classification model based on a fine-tuned image classification model grounded on swin_large_patch4_window12_384_22k.

V2: Training an image classification model based on a fine-tuned image classification model grounded on ConvNeXt_base_22k_1k_384.

V3: Training a text classification model based on a pre-trained model of roberta-large.

V4: Training a text classification model based on a pre-trained model of deberta-v3-large.

V5: Training a binary classification model for Task A and a multi-label classification model for Task B using four classes (stereotype, humiliation, objectification and violence) after fusing the image features by ConvNeXt_base_22k_1k_384 and the text features by roberta-large, respectively.

V6: Training a multi-label classification model that uses four classes (stereotype, humiliation, objectification and violence) after fusing the image features by ConvNeXt_base_22k_1k_384 and text features by roberta-large (the misogynous results are obtained by the multi-label predictions).

V7: The only difference between this scheme and V6 is that LFN uses feature fusion rather than simply concatenating.

V8: This scheme is the same as the V6. The only difference is that the training labels contain misogynous content (five classes of misogynous, stereotype, humiliation, objectification, and violence).

V9: This scheme is the same as V6. The only difference is that the text features extractor was replaced by deberta-v3-large.

V10: In this scheme, the results of V8 and V9 are fused by a weighted average approach with a threshold set to 0.5.

V11: This scheme is the same as in v10. The only difference is that the threshold is adjusted to 0.4.

V12: This scheme is the same as in v10. The only difference is that the threshold is adjusted to 0.405 (Final results of the leaderboard).

V13: This scheme is the same as in v10. The only difference is that the threshold is adjusted to 0.403 (results not submitted).

Through the experiment, we found the following conclusions:

- The effect of ConvNeXt_base_22k_1k_384 is better than swin_large_patch4_window12_384_22k in our system.
- The effect of multi-modal (text and image) is better than single-modal (text or image) in our system.
- In our system, the effect of multi-task learning is better than individual training.
- According to the results of stereotype, humiliation, objectification and violence to correct misogynous results have a significant improvement effect in our system.
- Adjusting the prediction results also has an improvement for Task B in our system.
- The simple concatenate method is better than the complex feature fusion method in our system.

Version A	Model	Task A	Task B
V1	$swin\_large\_patch4\_window12\_384\_22k$	0.6135	0.5965
V2	$ConvNeXt\_base\_22k\_1k\_384$	0.6431	0.6229
V3	roberta-large	0.656	0.6389
V4	deberta-v3-large	0.6947	0.649
V5	ConvNeXt + RoBERTa + TaskA + TaskB + 4 categories	0.7053	0.7136
V6	ConvNeXt + RoBERTa + TaskB/A + 4 categories	0.7514	0.7136
V7	ConvNeXt + RoBERTa + TaskB/A + 4 categories + LFN	0.7464	0.704
V8	ConvNeXt + RoBERTa + TaskB/A + 5 categories	0.7643	0.7129
V9	ConvNeXt + DeBERTa + TaskB/A + 5 categories	0.7727	0.7240
V10	v8+v9+0.5	0.7785	0.719
V11	v8+v9+0.4	0.7554	0.728
V12	v8+v9+0.405	0.7566	0.7307
V13	v8+v9+0.403	0.7569	0.7319

Table 2: Experimental results of task a and Task B

6 Conclusion

In this paper, we proposed a system to make full use of two modes (image and text) for solving the challenging multi-mode misogynous meme detection task. We extracted the image features and text features using different pre-trained models and weighted averaged the results after fusing the features of image and text. The system performs well in identifying misogynistic memes, achieving 77.85% percent accuracy on TaskA and 73.1% percent accuracy on TaskB.

Abstract

This paper describes our submission for task 5 Multimedia Automatic Misogyny Identification (MAMI) at SemEval-2022. The task is designed to detect and classify misogynous memes. To utilize both textual and visual information presented in a meme, we investigate several of the most recent visual-language transformer-based multimodal models and choose ERNIE-ViL-Large as our base model. For subtask A, with observations of models' overfitting on unimodal patterns, strategies are proposed to mitigate problems of biased words and template memes. For subtask B, we transform this multi-label problem into a multi-class one and experiment with oversampling and complementary techniques. Our approach places 2nd for subtask A and 5th for subtask B in this competition.

1 Introduction

Online misogynous speech has been a worldwide phenomenon spread widely across social media platforms where women are increasingly subjected to offensive content. It has been shown that women are twice as likely as men to encounter online sexual harassment and gender-based violence (Duggan, 2017).

The problem with misogyny detection is that it requires context and external knowledge to understand online speech, which sometimes can be very short and contain subtle meaning (Kiela et al., 2020). Since memes are getting popular as communication tools on social media platforms, misogynous memes have the potential to affect everyone in our society. Automatic multimodal internet memes identification becomes a new challenging type of misogyny detection task that can only be solved by joint reasoning and understanding of visual and textual information (Zhu, 2020).

The proposed task Multimedia Automatic Misogyny Identification (MAMI) (Fersini et al., 2022) at SemEval-2022 requires participants to identify misogynous memes (subtask A) and classify them as certain overlapping categories: stereotype, shaming, objectification, and violence (subtask B).

This paper describes the system developed by the DD-TIG team for SemEval-2022 Task 5 MAMI. This work contributes to the following: for subtask A, solutions to biased words and template memes are proposed to mitigate the effects of overfitting in unimodal information. We also utilize ensemble learning and external knowledge source like Perspective API to boost the performance of our system. For subtask B, we transform the multi-label classification problem into a multi-class classification problem and reach a better result with oversampling and complementary strategy.

2 Background

2.1 Misogynous memes dataset

MAMI task provides participants with a misogynous memes dataset that contains meme images, the transcriptions of texts on memes, and label annotations. For the training set and test set, misogynous and non-misogynous labels are balanced while misogynous category labels are imbalanced (see Table 1).

Label	Trial	Training	Test
Misogynous	44	5000	500
Non-misogynous	57	5000	500
Shaming	0	1274	146
Stereotype	34	2810	350
Objectification	2	2202	348
Violence	9	953	153

Table 1: Summary of the misogynous memes dataset

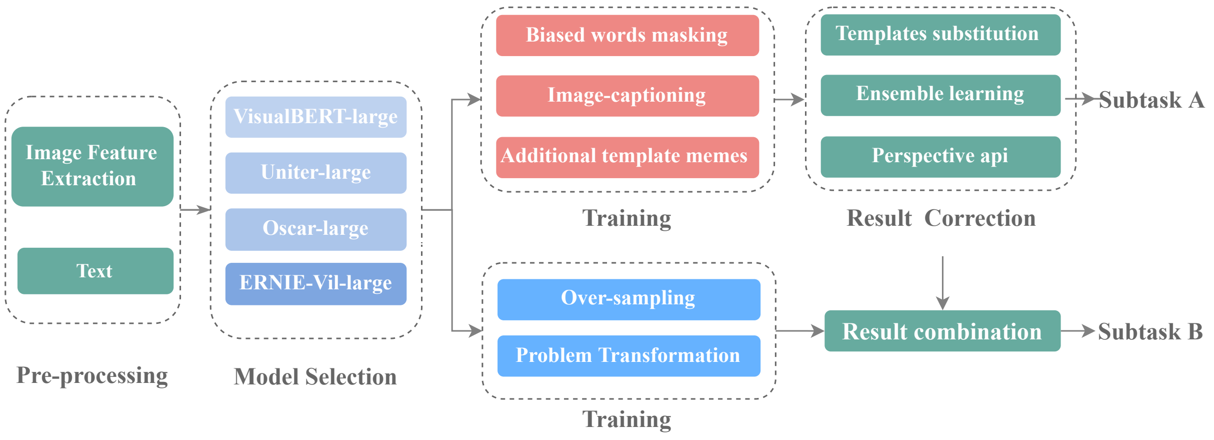

Figure 1: The overall architecture of our proposed system

2.2 Vision and language task

Multimodal misogynous memes identification is a vision and language task. Current state-of-the-art Vision-Language machine learning models are based on the transformer architecture (Vaswani et al., 2017). Among these models, there are two prevalent approaches: single-stream and dual-stream. In single-stream models, such as VisualBERT (Li et al., 2019), UNITER (Chen et al., 2020), OSCAR (Li et al., 2020), image and text features are concatenated and inputted to a standard BERT architecture, which comes under the category of early fusion. In dual-stream models, such as LXMERT (Tan and Bansal, 2019), ERNIE-ViL (Yu et al., 2020a), DeVLBERT (Zhang et al., 2020), VilBERT (Lu et al., 2019), the image and text features are first sent to two independent transformer layers and then into cross-modal transformer layers. Features are combined towards the end of the model as the category of late fusion.

2.3 Vilio: Hateful memes detection framework

The Hateful Memes Challenge (Kiela et al., 2020) is proposed by Facebook AI to leverage machine learning models to solve hateful memes detection problem. Vilio[1] (Muennighoff, 2020) is a code base of 12 different vision+language models and applied to the Hateful Memes Dataset. In our work, we conducted our baseline research on the code of Vilio.

3 System overview

3.1 Preparation

We use the detectron2[2] framework to extract Image features from memes. Detectron2 is provided by Facebook AI with state-of-the-art detection and segmentation algorithms. Specifically, 50 boxes of 2048 dimensions region-based image features are extracted for every meme by Mask-RCNN model. Together with the meme text, which has been extracted using optical character recognition (OCR) and provided in the dataset, features are then fed into the models.

3.2 Vision and language models

We first choose four different base models of VL transformer architectures, namely: VisualBERT, UNITER, OSCAR, and ERNIE-Vil.

We carry out continual pretraining on our dataset with the idea of domain adaptation to reduce the distribution gap between the pretraining dataset and our misogynous memes dataset. MLM pretraining task is taken on pretraining VisualBERT-large, UNITER-large, and OSCAR-large model. However, this does not produce significant performance improvements on our task during the finetuning stage.

Through comparison of results, we found that ERNIE-Vil-large achieves the best performance. In the following steps, we only use the results of ERNIE-Vil-large models.

[1]https://github.com/Muennighoff/vilio

[2]https://github.com/facebookresearch/detectron2

3.3 Strategy for subtask A

3.3.1 Biased words masking

Former research has shown that misogyny detection models can be affected by an unintended bias (Nozza et al., 2019). Some sensitive words, called identity terms, are associated with unreasonably high misogynous scores since they are frequently used in misogynous texts. For example, we observe that the term *kitchen* is frequently used as a stereotypical word against women in our data. Thus, our models tend to associate some non-misogynous texts containing this word with an unreasonably high misogynous score. This situation is known as **unintended bias**, in which models learn usual associations between words (commonly called **identity terms**) which causes them to classify content as misogynous just because it contains one identity word (Godoy and Tommasel, 2021).

Through error analysis on the results of models in the practice stage, we manually collect a list of biased words, including synonyms of woman, dirty words, and controversial words related to feminism. The obtained list of words has been then extended by including their plural form. Refer to Appendix A for the words list.

We propose a novel strategy of biased words masking to mitigate the effects of unintended bias, which also can be regarded as a means of data augmentation. Specifically, when training models, we first use NLTK (Loper and Bird, 2002) to tokenize texts T_i and lemmatize words $w_j \in T_i$ and get $\hat{T_i} = \{w_1, w_2, w_3, \cdots, w_l\}$. Then, for each word w_j in the input text $\hat{T_i}$, with the biased words set $A = \{w_1, w_2, w_3, \cdots, w_k\}$, if $w_j \in A$, it may be masked with a mask token $[mask]$ by a 20 percent probability. We also take strategy with dynamic masking where we generate the masking pattern every time we feed a sequence to the model.

3.3.2 Image captioning

Visual and textual information is semantically aligned in some multimodal tasks, like image-text matching, image-text retrieval, VQA (Yu et al., 2020b). However, for some misogynous memes, image and text are weakly aligned. Thus, there is a semantic gap between visual and textual information. Therefore, we take the strategy of image captioning proposed by previous studies (Das et al., 2020) to enhance model's understanding of visual components. Memes are sent into an image caption model (Xu et al., 2015), which is based on encoder-decoder architecture. This model uses the ResNet-101 as encoder and LSTM as decoder and takes the attention mechanism and beam search when decoding. As a result, this image caption model generates additional descriptions $T_a = \{w_1, w_2, w_3, \cdots, w_i\}$ for visual contents of each meme in the training set; the original text T_o and generated text T_a are concatenated with a separate token $[sep]$.

3.3.3 Templates memes

Through examination of images in the misogyny memes dataset, we notice that many memes are generated by tools of online memes websites. For example, in IMGflip [3], users can choose a meme template from thousands of meme templates and just input their text to caption this template and then get a new meme. In the following part, we refer to memes generated by templates as **template memes**.

In our training set, more than 20 percent of memes are template memes. Some misogynous memes and non-misogynous memes are generated with the same templates and different texts. This may raise a problem that our model associates a high misogynous score or low misogynous score to certain meme templates that actually serve as the medium and contain no misogynous meaning, especially when there is only a few misogynous and non-misogynous sample based on certain templates in the training set. We propose two solutions to mitigate this problem.

Additional template memes: We collect 1,800 memes from memes website. These memes are examples of meme templates and contain no misogynous meaning. Therefore, these memes can be used as the negative sample in our dataset. Without directly adding these memes into the training set, we use our model to make inferences on these memes and only add those false samples (about 90 memes) into the training set.

Templates substitution: we can use an image retrieval model like pre-trained imageNet (Vedaldi and Lenc, 2015) to match memes and templates and find memes that are generated by templates. There are more than 200 memes in the test set are generated with templates. For those memes, original texts and different background pictures are combined to produce K new memes $I_i =$

[3] `https://imgflip.com`

$\{I_1, I_2, I_3, \cdots, I_k\}$. The probability $\hat{p}$ of a sample will be a combination of model's inferential result on the original meme Ia and new memes I_i with a weighted average w.

$$\hat{p} = \frac{p_a + w \cdot \sum_{j=1}^{k} p_j}{K+1} \tag{1}$$

3.3.4 Ensemble learning

The predicted results of our models can be varying since we take the above-mentioned strategy to train different base models. Thus, we continue to improve the whole system's generalizability and robustness with ensemble learning, where predictions of multiple base models are combined with the method of majority Voting (Velioglu and Rose, 2020). In particular, K (K=20) models are selected for ensemble learning, and predictions are collected from each of the models. The label of data is determined by the majority voted class. We hypothesize that some models show a high recall and low precision and vice versa. So a collection of models may balance out individual weaknesses to achieve better performance than any single model used in the ensemble.

$$\hat{y} = \frac{\sum_{j=1}^{K} y_j}{K} \tag{2}$$

3.3.5 Perspective API

Perspective [4] is a free API that uses machine learning to identify toxic comments, making it easier to host better conversations online. We use Perspective API to get a toxic score for the text of our test data. Labels from the previous models' output and probabilities from Perspective API's results are linearly combined with simple linear regression.

3.4 Strategy for subtask B

3.4.1 Transforming a multi-label problem into multi-class problems

A conventional way to solve a multi-label problem is to transform it into binary classification problems where one binary classifier is independently trained for each label. In machine learning implementation, each unit in the output layer uses the sigmoid activation. This will predict a probability of class membership for the label, a value between 0 and 1. Finally, the model would be fit with the binary cross-entropy loss function. However, there are two problems with this approach. On the one hand, it is troublesome to set an optimal threshold for each label. On the other hand, it does not incorporate information about the relationships between labels. For example, label y_a may only occur by itself; labels y_a and y_b may often occur together; labels y_a and y_c may never occur together.

Since the number of labels in subtask B is 4, which is relatively small, we transform this multi-label problem into multi-class problems. Every possible combination of output labels ($[0,0,0,0], [1,0,0,0], \cdots$) will be taken as a class, and the new space of the label set would be 2^4.

[4]https://www.perspectiveapi.com

3.4.2 Over-sampling Technique

label	Positive	Negative
Shaming	12.74%	87.26%
Stereotype	28.10%	71.90%
Objectification	22.02%	77.98%
Violence	9.53%	90.47%

Table 2: Distribution of misogynous categories labels in training set

In subtask B, as shown in table 2 , the number of positive samples and negative samples in all misogynous categories is widely imbalanced. Hence, up-sampling of data is done using over-sampling on the positive sample. Thus our new loss function is defined as follows:

$$J = -\sum_{i=1}^{N} \log p_i \cdot \alpha \tag{3}$$

$$\alpha = \begin{cases} \alpha_{neg} & y_i = [0,0,0,0] \\ \alpha_{pos} & otherwise \end{cases} \tag{4}$$

where N is the size of training set; α_{pos} and α_{neg} are the weights for the misogynous and non-misogynous respectively such that $\alpha_{neg} > \alpha_{pos}$ and $\alpha_{neg} + \alpha_{pos} = 1$.

3.4.3 Combination with subtask A results

We train a binary-classification model for task A and multi-class classification for task B separately. Then, we will use the result of Model A to modify the result of Model B, which means if sample X_i a is predicted as $y_a = 0$ or non-misogynous in Model A, it would not belong to any misogynous category, and its predicted label y_b of Model B would be discarded.

$$\hat{y} = \begin{cases} [0,0,0,0] & y_a = 0 \\ y_b & y_a = 1 \end{cases} \tag{5}$$

4 Experimental setup

In our baseline approaches, VisualBERT-Large, OSCAR-Large, and UNITER-Large provided by Villo are trained for 5 epochs with a batch size of 16. ERNIE-ViL-Large models provided by the original author are trained for 5000 steps with a batch size of 8. In our work, not much time was spent on hyperparameter optimization, and since we notice that there is not much difference when training models with varying hyperparameter settings and we focus more on other strategies. The hyperparameters for finetuning ERNIE-ViL-Large are presented in Appendix B.

5 Results & Discussion

5.1 Subtask A

Table 3 presents the results of our baseline approaches on the test set, where models are evaluated using Accuracy and a macro-average F1-score, while the latter one is the official metrics for system evaluation in this competition.

Model	**Accuracy**	**F1-score**
Oscar-large	69.6	68.9
Uniter-large	69.2	68.4
VisualBERT-large	69.2	68.0
ERNIE-Vil-large	**71.5**	**70.7**

Table 3: The performance of base models on subtask A

ERNIE-Vil has been the STOA model on the multimodal task leaderboard and also achieves competitive performance on our task without any other modification. It is also worth mentioning that continual pretaining with MLM task is conducted on Oscar, Uniter, and VisualBERT, but no improvement is observed. Therefore, ERNIE-Vil is chosen as our base model for further modification with other strategies. Table 4 shows the results of biased word masking, image captioning, and adding false positive samples of template memes into the training set.

Biased word masking experiments have been conducted several times, and the effectiveness is shown by considerable improvement. It is noted that we do not raise scores by only taking the Image captioning technique, but F1-score has a slight increase when image captioning is combined with biased word masking. We hypothesize that image captioning may add noise to our training data since there is a gap between memes in misogynous datasets and the image captioning model's training data. This intuition is confirmed after examining the caption text generated by the Image captioning model, which fails to detect several objects in several images. After we add false-positive samples of template memes into the training set, the performance of our model is boosted. It shows that our model does associate certain normal memes patterns with misogynous or non-misogynous attributes, which can be regarded as biased images.

The results of ensemble learning, templates substitution, and perspective API are shown in Table 4. Ensemble learning obtains a significant improvement where we use different models produced by several times' training of random biased words masking. Since these models are trained with varying texts, we hypothesize their errors will be different, and therefore ensembling may lead to complementary effects and help improve performance. Templates substitution also shows the effectiveness, and this is explained as we find models tend to associate template memes with a high misogynous score, but a majority of them are negative. Perspective API can correct predicted results when sentences contain other malicious words and phrases, but our model does not meet the word or phrase in the training set.

5.2 Subtask B

Table 5 presents the results of our system on the test set for subtask B, where models are evaluated using a weighted-average F1-score, which is the official metric for system evaluation in this competition.

The performance of our model on subtask B is notably improved after the results are modified with the result in subtask A, which has reached a relatively high accuracy score and can be benifical to reduce the number of false positive samples.

5.3 Error analysis

A confusion matrix for subtask A (see Table 6) and a classification report for subtask B (see Table 7) are presented, which will be combined with some bad cases to have both qualitative and quantitative assessments on our system.

	Misogynous	**Non-misogynous**
Misogynous	328	46
Non-misogynous	172	454

Table 6: Confused matrix for subtask A

For subtask A, obviously, the problem with

Model	Accuracy	F1-score
ERNIE-Vil-large	71.5	70.7
ERNIE-Vil-large + WM	72.8	72.1
ERNIE-Vil-large + IC	71.0	70.6
ERNIE-Vil-large + WM + IC	72.7	72.5
ERNIE-Vil-large + WM + IC + AD	73.8	73.7
ERNIE-Vil-large + WM + IC + AD + Emsembling	76.7	76.5
ERNIE-Vil-large + WM + IC + AD + Emsembling + TS	78.1	78.0
ERNIE-Vil-large + WM + IC + AD + Emsembling + TS + PA	**79.4**	**79.3**

Table 4: The performance of our systems on subtask A (WM is biased words masking. IC is image caption. AD is addtional data of template memes. TS is template substitution. PA is the Perspective API.)

Model	F1-score
ERNIE-Vil-large	70.8
ERNIE-Vil-large + Oversampling	71.3
ERNIE-Vil-large + Oversampling + PT	71.7
ERNIE-Vil-large + Oversampling + PT + RC	**72.8**

Table 5: The performance of our systems on subtask B (PT is problems transformation into multi-class classification. RC is results combination with subtask A)

our system is that a considerable number of non-misogynous samples, about 17.2 percent of total and 34.4 percent of the negative sample, is misclassified as misogynous, as the error type false positive. The goal of strategies like biased words masking is to reduce the effects of certain patterns in texts or images and prevent overfitting. Some patterns still are regarded as crucial features of misogyny by our models, but actually, they are biased. Enlarging the size of our dataset may be beneficial to deal with this problem.

The figure in Appendix C shows an example labeled as non-misogynous in the dataset but predicted as misogynous by our model. As mentioned in the previous part, the word kitchen frequently appears in the misogynous sample since misogynists always hold the stereotype to associate women with certain gender roles. We try to mitigate the bias by biased word masking, but it still can not be solved. Moreover, a girl in this image may be associated with the text, but the image and text are not aligned in fact.

label	Precision	Recall	F1-score
Shaming	0.36	0.55	0.43
Stereotype	0.62	0.64	0.63
Objectification	0.69	0.70	0.69
Violence	0.64	0.55	0.59

Table 7: Classification report for subtask B

For subtask B, our model shows relatively poor performance on the label shaming. According to the definition of shaming provided by MAMI organizers, a shaming meme aims at insulting and offending women because of some characteristics of the body. There are two possible reasons to explain this problem. First, we notice that there are some female characters in memes generated by mocking templates, and in truth, the texts on the memes are not targeted towards the female characters in the memes. Second, the definition of shaming is vague and overlaps with other categories of misogyny.

Thus, there is the challenge of this competition: the information from the image and text modalities should not always be treated equally. Sometimes text information should be emphasized if this meme is based on some templates. In multimodal understanding and reasoning tasks, unimodal information can be imbalanced.

6 Conclusion

In this paper, we have presented our work on Multimedia Automatic Misogyny Identification (MAMI) at SemEval-2022. Mainstream vision-language models are applied on misogynous memes dataset in the baseline approach. For subtask A, to better utilize multimodel information and unimodal information, we propose solutions to mitigate the effects of biased words and templates memes. Ensemble learning and external knowledge source like perspective API are used to enhance the performance of our system. For subtask B, training with oversampling strategy, we use a multi-class model to solve this multi-label problem and gain improvement from our subtask A model. In short, this task could never be solved easily since it relies heavily on the context, external knowledge, relations between modalities.

Abstract

Research is progressing in a fast manner in the field of offensive, hate speech, abusive and sarcastic data. Tackling hate speech against women is urgent and really needed to give respect to the lady of our life. This paper describes the system used for identifying misogynous content using images and text. The system developed by the team TECHSSN uses transformer models to detect the misogynous content from text and Convolutional Neural Network model for image data. Various models like BERT, ALBERT, XLNET and CNN are explored and the combination of ALBERT and CNN as an ensemble model provides better results than the rest. This system was developed for the task 5 of the competition, SemEval 2022.

1 Introduction

In our society, women are facing lot of challenges in terms of education, employment, career and life. Eventhough women are better off now-a-days, there are not considered as equal to men in many situations. With the invent and rapid usage of social media platforms, offensive images and texts conveying several forms of hate against women are transmitted and spread online in a fast manner. Although opportunities for women have been increased on the Internet, systematic inequality and discrimination offline is continued in online in the form of offensive contents through MEMEs. A meme is essentially an image characterized by a pictorial content with an overlaying text introduced by human on it.

Most of the memes are created mainly for funniness, still it is used for ironic purpose too. The task 5 by Fersini et al. (2022) in SemEval 2022 mainly focused on identifying the misogynous memes using textual and image contents. There are two subtasks in this. Subtask A is to categorize the memes as misogynous or not misogynous. Subtask B is to classify the misogynous memes into one of the categories like stereotype, shaming, objectification and violence.

2 Related Work

The survey on various techniques used for Automatic Misogyny Identification (AMI) tasks happened in EVALITA 2018 and IBERALEVAL 2018 were discussed in detail by Shushkevich and Cardiff (2019). Machine learning (SVM, Naive Bayes, Logistic Regression) and deep learning techniques (CNN, GRU, RNN, LSTM) are used and achieved an accuracy of 90% in IBERALEVAL task and 70% in EVALITA task.

García-Díaz et al. (2021) uses sentiment analysis and social computing technologies with word embeddings and linguistic features for AMI that achieves better results than traditional machine learning algorithms. Hate speech against women is handled by Frenda et al. (2019). Pamungkas et al. (2020) created models using RNN and BERT for multilingual misogyny detection.

We have performed irony and offensive language detection in earlier SemEval workshop tasks Sivanaiah et al. (2021), Sivanaiah et al. (2020), Sivanaiah et al. (2019) and Sivanaiah et al. (2018). Various machine learning techniques like linear regression, logistic regression, naive Bayes, Random forest, Support Vector Machines and deep learning techniques like Recurrent Neural Networks, Convolutional Neural Networks, Long Short Term Memory Networks, BERT, ColBERT models are used in the above tasks. BERT and ColBERT models perfomed better than other machine learning and deep learning models.

3 System Overview

The proposed system uses the Transformer models to classify the textual content of the memes and Convolutional Neural Network (CNN) to classify

Dataset	Misogynous		Shaming		Stereotype		Objectification		Violence	
	1	0	1	0	1	0	1	0	1	0
Training (10000)	5000	5000	1271	3729	2810	2190	2201	2799	953	4047
Trial (100)	44	56	0	44	34	10	2	42	9	35
Test (1000)	500	500	146	354	350	150	348	152	153	347

Table 1: Data distribution

the visual content. The majority voting ensemble classifier is used to predict the label for the input sample using the output of textual and visual content classifiers. The data is preprocessed to remove the unwanted information before building the model. The architecture of the system is shown in Figure 1.

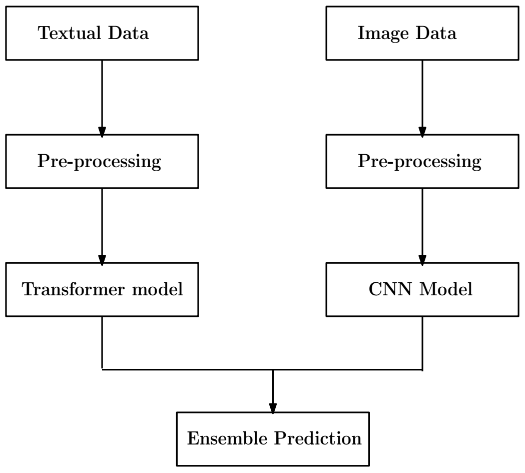

Figure 1: System Architecture

The steps can be summarized as follows:

1. Preprocess the text data and image data separately
2. Separate the image data into folders according to the label category
3. Setup the architecture of the transformer models
4. Train and evaluate the transformer models with text data
5. Use CNN model to train and evaluate the image data
6. Generate the class labels for the test data using transformer model and CNN model
7. Combine the output of both the models using majority voting ensemble classifier

3.1 Dataset

Organizers have provided the data with 10000, 100 and 1000 samples in training, trial and testing datasets. The division of data into various labels are shown in Table 1. Out of 10000 training data, 5000 belongs to misogynous class and 5000 belongs to non-misogynous class. Out of 5000 training misogynous data, 1271 belongs to shaming category and 3729 to not-shaming category. There are 2810 stereotype samples and 2190 non-stereotype samples in 5000 training misogynous data. We have 2201 objectification and 2799 non-objectification samples in misogynous type in training dataset. There are 953 violence and 4047 non-violence samples in misogynous training data.

3.2 Data Pre-processing

Data preprocessing is critical for the success of any machine learning solution to remove the irregularities in the data. Normalization is done to flatten the dimensions of data in textual form. The text data is cleaned and processed to remove URLs, annotate emojis, emoticons, convert uppercase to lowercase, remove stopwords, remove special characters, remove accented characters, lemmatize text, and remove extra whitespace. The images are categorized into their corresponding label folders for further processing. Noise in the image data is removed and converted into pixel values of size 128x128.

3.3 Classification with Transformer models

A transformer is a deep learning model that uses self-attention with weights. Transformer models are used in natural language processing and computer vision. It uses encoder-decoder mechanism to learn features from the sequential input data. Encoder learns the relevant features in the input and pass them to next layer. Decoder does the opposite by taking the output of encoder and incorporate the contextual information to generate the output sequence. Both encoder and decoder layer uses attention mechanism to perform these operations. While Recurrent Neural Networks (RNN) process the data in the sequential order, transformers does not require this. Bidirectional Encoder Representations from Transformers (BERT) is a popular model developed by Google for language modelling (Devlin et al., 2018). Variants of BERT like A Lite BERT (ALBERT) (Lan et al., 2019), XLNET (Yang et al., 2019), Robustly optimized BERT approach (ROBERTa) and COntextualized Late interaction over BERT (ColBERT) are used to perform the learning on text data. XLnet is an extension of the Transformer-XL model pre-trained using an autoregressive method to learn bidirectional contexts.

BERT model works in a better manner for sparse data representations. Instead of training the model from the base, we can take a pretrained model and tune the model to suit our need. The drawback of BERT model is that it generates many parameters for learning which makes the model complex and time consuming. ALBERT model is a lighter version of BERT that reduces the parameters size without much reduction in performance. ALBERT model uses the multi-headed, multi-layer transformer architecture. The number of epochs used to train the models is 5. The embeddings used are albert-base-v2, xlnet-base-uncased and bert-base-uncased.

3.4 Classification using CNN model

Convolutional Neural Network (CNN) (Albawi et al., 2017) is a deep learning technique that takes the image as input, assign importance in the form of learnable weights, learn the various aspects in the input and classify the data. It uses convolutional, maxpooling and dropout layers to learn the features. CNNs have wide applications in computer vision, medical image processing, NLP and recommender systems. We have used 3 convolutional layer with ReLU activation function, maxpooling layer after each convolutional layer, fully connected layer with ReLU activation function and final output layer with softmax activation. Adam optimizer is used with learning rate 0.001 for 30 epochs.

3.5 Ensemble Prediction

Performance of text model and image model are analyzed with the ensemble technique. Majority voting is done with the output of transformer models and CNN to predict the final output class label. Ensemble method will predict the output class label as misogynous if both transformer and CNN models predict the label as misogynous.

4 Results and Discussions

We have used variants of BERT models for analyzing text data and CNN for image data. The results are tabulated in Table 2. The models are executed for various epochs and the results are listed for 5 epochs.

Models	Subtask A	Subtask B
AlBERT	0.5128	-
XLNet	0.3524	-
BERT	0.4584	0.4137
CNN Model	0.4756	-
Ensemble model	0.5223	0.4673

Table 2: F1-measure Results

In subtask A, we have used AlBERT, XLNet and basic BERT techniques to classify the given sample as misogynous or non-misogynous using the text data. Albert model gives better results than other BERT variants. CNN model is used for the classification of image data. The combined ensemble model (AlBERT + CNN) gives better F1 score than using them separately. For the subtask B, we have worked on two models BERT and ensemble model. Ensemble model with multi-label classification model in transformers and CNN is used for predicting the subcategories. The ensemble model (image and text) achieved better score than the BERT model (text alone) and the performance can be increased by tweaking the hyper parameters.

5 Conclusion

User generated content in social media is rapidly increasing day by day that detecting and limiting the diffusion of sarcastic and hate speech content against women is tedious. Automatic identification and removal of these contents is the current topic of research. Many shared tasks are conducted in various conferences for Automatic Misogyny Identification (AMI).

Task 5 in SemEval 2022 focuses on Multimedia Automatic Misogyny Identification (MAMI) with the help of image and text data. Transformer models are used to identify the misogynous content from the text and CNN model is used to detect from the image content. Performance of the system can be increased by tweeking the parameters in the transformer models. The current system trains the text and visual modalities independently on the labels. However, memes portray misogynistic content though a combination of text and image cues, and training these models independently might miss out on the context provided by the other modality, which might be crucial to further improve the performance of this system.

radhika.mamidi@iiit.ac.in

Abstract

In current times, memes have become one of the most popular mediums to share jokes and information with the masses over the internet. Memes can also be used as tools to spread hatred and target women through degrading content disguised as humour. The task, Multimedia Automatic Misogyny Identification (MAMI), is to detect misogyny in these memes. This task is further divided into two sub-tasks: (A) Misogynous meme identification, where a meme should be categorized either as misogynous or not misogynous and (B) Categorizing these misogynous memes into potential overlapping subcategories. In this paper, we propose models leveraging task-specific pretraining with transfer learning on Visual Linguistic models. With our best performing models, we were able to achieve rank 5 th and 10 th on sub-tasks A and B respectively.

Figure 1: Example memes from the dataset showing the multimodal nature

1 Introduction

The term "misogyny" means hatred towards women. Misogyny can be interpreted through multiple forms such as male privilege, sexual harassment, violence against women, objectification. Memes that targeted women focus on appearance, intellect, their traditional gender roles and capabilities of women (Siddiqi et al., 2018).

For this, SemEval 2022 Task 5 (Fersini et al., 2022) focuses on identifying such behaviour in a multimodal setting (text + image). The textual cues to this task are given in the English language. The task is divided into two sub-tasks. The first subtask is modelled as a binary classification problem. The second sub-task focuses on identifying type of misogyny from a set of overlapping categories, making it a multi-label classification problem.

A meme contains text superimposed on an image. The image's aim in a meme is generally to reinforce a technique in the text, thus making its classification a multimodal problem. Both the modes of information are crucial to establishing the message conveyed by the meme, which can be very different from when the two modalities are evaluated separately.

We experiment with Visual Linguistic (VL) Models like OSCAR (Li et al., 2020) and UNITER (Chen et al., 2020) to understand the memes through both modalities. We employ transfer learning to use a model trained on another similar dataset and then finetune it on our dataset.

As task-specific pretraining has shown to improve results on several NLP tasks (Gururangan et al. (2020)), We experiment with task-specific pretraining our VL models before finetuning it and also finetune it on models task-specifically pretrained for other similar task like hateful memes detection (Kiela et al. (2021)).

We also train BERT (Devlin et al., 2019) based models on only the textual data, thus comparing the performances of multimodal setting vs unimodal settings. This comparison helps us understand how vital each modality is and how much using both together makes a difference.

We discover that even though detecting misogyny in memes can be modelled as a multi-modal task, it can, to a very good extent be done through working with just the textual cues but when it comes to detecting more subtle forms of misogyny, the visual cues play an important role as well. Our system ranked 38th and 19th for sub-taskA and sub-taskB respectively.

The paper is structured as follows: Section 2 describes the dataset along with related work. Section 3 describes our system and model architecture. Section 4 has information regarding the dataset size and splits with libraries used to implement our system. Section 5 has the discussion about the findings from our experiments and section 6 concludes our paper.

2 Background

Nowadays, the internet and various social media platforms have become an intrinsic part of more and more people's lives. With its growth, the problems associated with it have also increased exceedingly, like the increase in hate speech against certain groups including women.

Detecting misogyny and sexist slurs in general over social media can be challenging as its overall meaning can depend on its context and the user it is shown. (Fasoli et al., 2015). For this, look at the few examples in Figure 1 to exhibit the importance of visual and textual cues.

Memes can be defined as an image, video, or text, typically humorous in nature, that is copied and spread rapidly by internet users, often with slight variations. Memes in online culture have been seen to push potential instances of misogyny as a form of "joke" and "irony" while disguising itself as a harmless form of humour. (Drakett et al., 2018).

There has been previous work done to detect hate speech and misogyny. (Pamungkas et al., 2018) Employed Support Vector Machine(SVM) based architectures with a novel lexicon of abusive words to detect misogyny in English and Spanish tweets. (Gasparini et al., 2018) compared unimodal textual classifiers to multimodal classifiers trained with both visual and textual features using early fusion on a dataset of advertisements consisting of image and text marked for being sexist.

The meme classification task is primarily a Visual-linguistic(VL) task where we are trying to classify data where the image can be semantically correlated with the text. Traditional VL approaches are based on primary fusion techniques like early or late fusion, where each modality is learned separately. However, a multimodal pre-trained model might perform better at memes classification (Afridi et al., 2020).

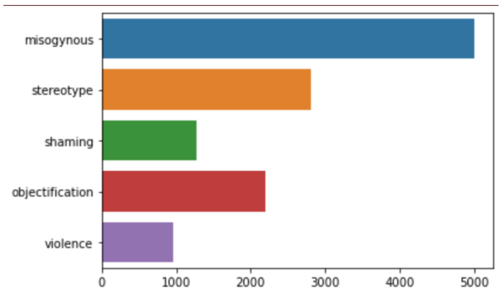

Figure 2: Data Distribution of labels in the training set.

Dataset Description

The dataset (Fersini et al., 2022) contains 10,000 memes.It is furthere divided into train and dev splits. Both tasks require the same dataset, but each task's final labels are different. Half of the 10,000 data points are marked positive and half negative. Of these half marked positive, the data is further annotated for potential overlapping categories of misogyny, namely: stereotype, shaming, objectification and violence.

3 System Overview

We use transformer based models for both the tasks with task specific modifications.

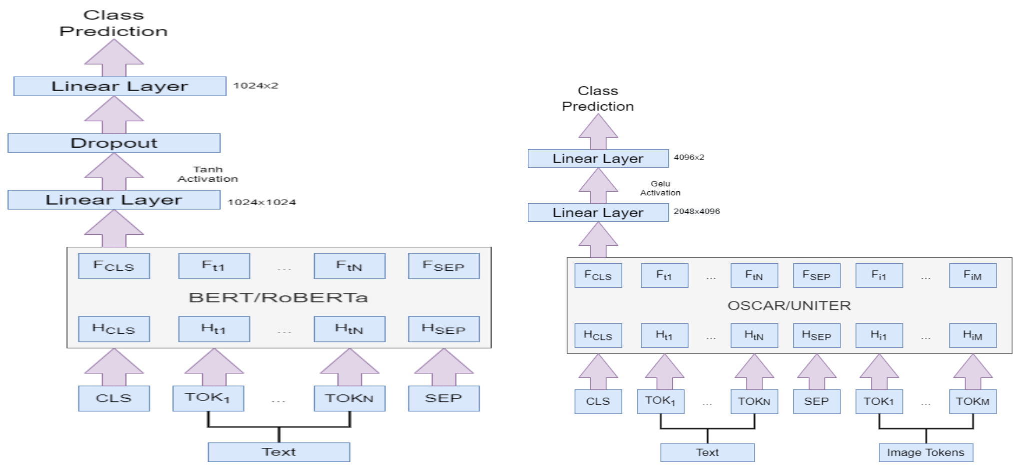
3.1 Pre Processing

Our text is tokenized into subwords to lookup the embedding. For our images, features were extracted using Faster-RCNN (Ren et al., 2016) pre-trained on the VisualGenome dataset(Krishna et al., 2017) trained with and & without object attributes (Anderson et al., 2018).We extract features with object attributes of fixed box sizes 36(OSCAR36) and 50(OSCAR50) and features without object attributes of fixed box size 50 (OSCARV50).

The final input embeddings is a concatenation of both textual and image features represented as

$$h_{[CLS]}, h_{t_1}, \cdots, h_{t_n}, h_{[SEP]}, h_{i_1}, \cdots, h_{i_m}$$

Here $h_{[CLS]}$ and $h_{[SEP]}$ are the vector representations of the special [CLS] and [SEP] tokens respectively. $h_{t_1}, \cdots, h_{t_n}$ represents the text embeddings and $h_{i_1}, \cdots, h_{i_m}$ represents the vision embeddings.



(a) Text Only Models (b) VL Models

Figure 3: Proposed architectures

3.2 Task-specific Pretraining

For both the tasks, We experiment with task-specific pretraining. Every task-specifically pre-trained models were pretrained on two pretraining objectives, namely Masked language Modelling (MLM) and Image Text Matching (ITM). We also make use of models trained on the hateful-memes dataset (Kiela et al., 2021). We use checkpoints from models that were:

1. Task-specifically pretrained on our dataset.
2. Task-specifically pretrained on hateful memes dataset.
3. Task-specifically pretrained and finetuned on hateful memes dataset.

The checkpoints for models pre-trained, fine-tuned on hateful memes dataset were taken from the vilio repository. [1]

3.3 Sub-task A

We used OSCAR as our primary VL model, we also experiemnt with another VL model named UNITER.The UNITER and OSCAR pre-trained weights are based on the BERT transformer. We used Binary Cross Entropy as our loss function to train our models. We trained 3 separate models on the 3 different visual features extracted but use the same textual features. We also experimented with ensembling these models using simple average as our ensembling technique.

We also train transformer-based models like BERT and RoBERTa (Liu et al., 2019) using just the textual cues. We use Binary Cross entropy as our loss function to train our models.

We use the CLS token embeddings from our transformer models and apply classification on top of it. The complete architecture for both text only and VL models can be seen in Figure 3.

3.4 Sub-task B

Here, instead of treating this problem as a multilabel classification problem, we treat it as a binary classification problem just like sub-taskA. We train VL models separately for each of the four labels, namely stereotype, shaming, objectification and violence, rather than training a single model for all labels. We also use an ensemble of models trained on different visual features like we did for sub-taskA.

For our textual models, we trained BERT-based multilabel classification models. We use cross-entropy loss to train our models. Since there is a significant class imbalance, we add weights to our positive data samples while calculating the loss function as done by researchers at (Gupta et al., 2021).The formula is given below:

$$\ell(\mathbf{x},\mathbf{y}) = -\frac{1}{Nd}\sum_{n=1}^{N}\sum_{k=1}^{d}\left[p^k y_n^k \log x_n^k + (1-y_n^k)\log(1-x_n^k)\right]$$
$$p^k = \frac{1}{f^k}(|K| - f^k) \tag{1}$$

Where N is the batch size, n index denotes n^{th} batch element, d is the number of classes, f stands for a vector of class absolute frequencies calculated on the train set, $\mathbf{x}$ is the output vector from the last sigmoid layer, $\mathbf{y}$ is a vector of multi-hot encoded ground truth labels and $|K|$ is the size of the train

[1] vilio-repository,https://github.com/Muennighoff/vilio/blob/master/SCORE_REPRO.md

set.

4 Experimental setup

Parameter	Text Only	VL
Dropout	0.3	-
BatchSize	8	4
Epochs	5	3
Learning Rate	1e-05	1e-05
Warmup	-	0.1
Optimizer	Adam	AdamW

Table 1: Hyperparameters

The dataset contained 10,000 images along with the corresponding texts. Half of the data is marked positive for being misogynous. 85% of the dataset was used to train the model, and the rest was used to validate the model for both subtasks.

We use the VL model implementations of OSCAR and UNITER from the library vilio and for image feature extraction. [2]. We use huggingface [3] library for our transformers trained on just text.

The information about the hyperparameters can be found in Table 1. All models were trained on a GeForce RTX 2080 Ti GPU.

4.1 Evaluation Metrics

We use f1-macro scores as our primary evaluation metrics for both the tasks. We also calculate the accuracy scores for both tasks.

Model	Accuracy	F1-Macro
RoBERTa$_{large}$	68.4	68.3
BERT$_{large}$	64.7	63.7
OSCAR$_{ens}$	68.7	67.2
OSCAR $_{pretrained\_ens}$	69.5	67.8
OSCAR $_{hm\_pretrained\_ens}$	**70**	**68.5**
OSCAR $_{hm\_finteuned\_ens}$	59.9	59.3
UNITER $_{ens}$	65.8	63.3
OSCAR + UNITER $_{ens}$	68.1	66.5
OCSAR36	69.5	67.9
OSCAR50	68.2	66.3
OSCARV50	67.1	64.7

Table 2: Results: Sub-TaskA

[3]Transformers,v4.16.2,https://huggingface.co/docs/transformers/index

5 Results And Discussion

The detailed results from all our experiments conducted can be seen in Table 2 and 3.

We here use the F1 macro scores to judge our models. For subtaskA, We see that OSCAR ensemble models, task-specifically pre-trained on hateful memes dataset perform the best. Another interesting thing to notice is the textual only RoBERTa large model performs almost as good as our best performing VL model and better than all other VL models and is significantly better than BERT large.

We also see that simple average ensemble models for OSCAR perform better than each of its constituent models, and using transfer learning methods with model fine-tuned on hateful memes dataset performed unexpectedly worse. It means that even though hateful memes detection and detecting misogyny in memes are closely related in their idea, they are still not necessarily similar to predict.

In sub-taskB, we see that the ensemble of models with task-specific pretraining on our dataset worked the best and slightly better than the ensemble with task-specific pretraining on the hateful memes dataset. We also see that our OSCAR VL models worked significantly better here than text-only models like BERT and RoBERTa, which is unexpected since the text-only models worked very well compared to VL models in sub-taskA.

Model	Accuracy	F1-Macro
BERT $_{large}$	31.9	45.8
RoBERTa $_{large}$	35.8	45.7
OSCAR $_{ens}$	41.4	**52.6**
OSCAR $_{hm\_pretrained\_ens}$	42.3	52
OSCAR $_{pretrained\_ens}$	**45.5**	31.3
RoBERTa $_{large\_misogynous\_labels}$	12.5	41

Table 3: Results: Sub-TaskB

As we observe that BERT Based models give comparable, and in the case of RoBERTa, better performance than almost all the VL models, it indicates that detecting misogyny might not be an utterly multimodal problem, and just the textual cues are enough in identifying the misogyny.

We also observe that even though text-only models performed very well on misogyny detection, they performed poorly on more fine grained classification tasks, showcasing that the visual cues mattered as well to figure out the subtleties in the classification of the type of misogyny.

We also trained both textual, and VL models on just the data points marked for misogyny as those are the only ones where at least one of the sub-categories of misogyny will be marked positively. However, in this case, the models performed much more poorly. It is because they are not trained on examples that are not misogynous in nature and thus perform poorly on them in the test dataset.

The scores according to the official metrics for our best performing unimodal and multimodal models were as follows: Sub-taskA: RoBERTa $_{\text{large}}$: 68.3; OSCAR $_{\text{hm\_pretrained\_ens}}$: 68.6; Sub-taskB: RoBERTa $_{\text{large}}$: 63.6; OSCAR $_{\text{hm\_pretrained\_ens}}$: 69.1

6 Conclusion

In this paper, our experiments indicate that although misogyny detection in memes is designed as a multi-modal setting, the textual cues also perform very well and, in some instances, better than Visual Linguistic models. We also found out that when it comes to detecting more subtle forms of misogyny, visual cues seem to help in the classification task and perform better than transformer models with just textual cues. More work can be done to improve the results. Future work like experimenting with more upcoming VL models, employing better techniques to address the class imbalance, and using more advanced ensembling techniques like Rank Averaging, Power Averaging & Simplex Optimization can improve results.

{aarango,jperez,alabrada}@dcc.uchile.cl

Abstract

Hate speech expressions in social media are not limited to textual messages; they can appear in videos, images, or multimodal formats like memes. Existing work towards detecting such expressions has been conducted almost exclusively over textual content, and the analysis of pictures and videos has been very scarce. This paper describes our team proposal in the Multimedia Automatic Misogyny Identification (MAMI) task at SemEval 2022. The challenge consisted of identifying misogynous memes from a dataset where images and text transcriptions were provided. We reported a 71% of F-score using a multimodal system based on the CLIP model.

1 Introduction

Expressions of hate are common in online environments, and they can appear in different types of multimedia content (Bhattacharya et al., 2020). However, the related work on hate-speech and offensive language detection is primarily focused on textual English content (Agrawal and Awekar, 2018; Hosseinmardi et al., 2015). But, even for the English language, the task is still not solved. Evidence of that is recent reports of the increasing amount of hateful content in social media[1] following the occurrence of social or political events. Recent events like the COVID pandemic have brought a new wave of hate (Vishwamitra et al., 2020), with new targets and expressions including hateful memes (Pramanick et al., 2021). Therefore, the techniques for hate speech detection need to evolve towards new types of hate, representations, and languages.

The lack of generality of existing resources along with the emergence of new nets of hate makes current systems quickly outdated[2].

Most of the available datasets contain tweets (Waseem, 2016; Basile et al., 2019), Facebook and Youtube comments (Bosco et al., 2018) and, in general, textual content. Similar to The Hateful Memes Challenge [3] hosted by Facebook in 2020, The Multimedia Automatic Misogyny Identification (MAMI) challenge (Elisabetta Fersini, 2022) is an excellent opportunity for covering the hate speech detection task beyond written expressions.

In this competition, the organizers provided a training set of 10,000 memes labeled as hate speech in two different forms: binary (misogynous, not misogynous) and multi-class (stereotype, shaming, objectification, and violence). The competition comprises two tasks: Task A, for binary identification of misogyny, and Task B, for fine-grained classification of misogynous memes. For final system evaluation, the organizers published a set of 1000 extra unlabeled memes. Each meme in training and testing sets consists of an image with an overlay text. Each object in the dataset consists of an image and a transcription of the overlay text.

This paper describes our team participation in Task A of the MAMI challenge. We encoded images and texts using a pre-trained multi-modal model based on the CLIP model (Radford et al., 2021). We combined the encoded vectors in different ways to obtain a final classification output. Our best result reported was 71% of *f-score*.

In Section 2 we describe the work that has been done on hate speech detection using multi-modal content. In Section 3 we described the training dataset provided in the competition. Then, in Section 4 we describe our system and experiments. Our conclusions can be read in Section 6.

2 Background

Most of the research in hate speech detection has been conducted over textual datasets (Davidson

[1]https://www.channel4.com/news/george-floyd-death-has-led-to-increasing-online-hate-speech-report-claims

[2]https://whatsnewinpublishing.com/the-rise-of-hate-speech-and-what-the-media-can-do-about-it/

[3]https://www.drivendata.org/competitions/64/hateful-memes/page/205/

et al., 2017; Agrawal and Awekar, 2018; Founta et al., 2018). Several strategies based on machine learning models and Natural Language Processing have been used to solve the task, though without success.

On the other hand, the identification of hate other than text formats of multimedia content has been treated only in a few works. Hosseinmardi et al. in 2015 and Singh et al. in 2017 have took advantages of the multi-modal information they could extract from *Instagram*[4] for they work on cyberbullying detection. While Perez-Martin et al. (2020) used the multi-modal representations for retrieving *Twitter* memes from textual queries.

Fortunately, in recent years the multi-modal detection of hateful content has gained popularity due to competitions like "*The Hateful Memes Challenge*" (Velioglu and Rose, 2020) hosted by *Facebook* where different models were proposed to detect hateful content on memes.

The proposed approaches encompass different visual state of the art models like VisualBert (Li et al., 2019), LXMERT (Tan and Bansal, 2019), VilBert (Lu et al., 2019) among others. The winning system combined some of these models with predefined rules (Zhong, 2020) for improving the classification accuracy of difficult samples.

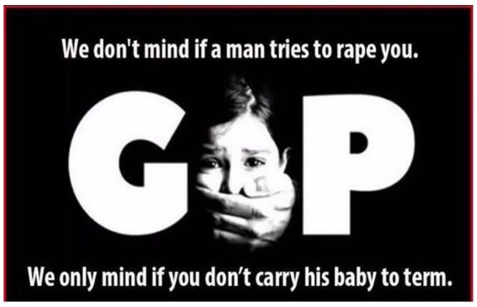
Another recent result on multimodal detection of offensive content has addressed the detection of harmful memes related to the COVID pandemic, also contributing with a new meme dataset (Pramanick et al., 2021).

There is much to do in the multimedia offensive language detection in images and video, considering the popularity of social networks like *Instagram* and *Tik Tok*[5].

3 Dataset Description

The dataset is composed of 10 000 memes, 5000 of which are labeled as *misogynous* and 5000 as *not misogynous*. For each meme is provided the corresponding image in *jpg* format and meme text transcription. All texts are in English; the most extensive text transcription found in the dataset contains 252 words, while the shortest contains one word. A characteristic of this dataset is that in some examples, only the text is enough for determining the nature of the comment (see Figure 1). We do not have evidence of an example where only the image would be necessary for identifying the nature of the meme. This characteristic may be detrimental to the multi-modal intention of the competition.

Figure 1: Meme example 17082. In this example only the texts is necessary for identifying the nature of the meme. The text transcription is: "We don't mind if a man tries to rape you. We only mind you don't carry his baby to term."



We don't mind if a man tries to rape you.
GOP
We only mind if you don't carry his baby to term.

System	F-Score
Text_Only	69.23
Image_Only	65.37
CLIP_concat	70.50
CLIP_sum	**71.20**

Table 1: The results obtained in our experimentation. The details of each system is described in Section 4.

4 Experiments and results

Though we experimented with several models for texts and images, our best result was obtained using the CLIP model as the core of our system.

CLIP model: The CLIP model proposed by Radford et al. 2021 exploits the state-of-the-art textual and visual approaches for learning about images from texts. The general idea of the CLIP training strategy is to jointly learn image and text representations and predict the most similar pairs (image, text). According to the authors, the model can competitive transfer to different vision tasks.

CLIP based systems: We use a pre-trained CLIP model[6] for learning text ($text\_clip$) and image ($text\_clip$) representations from the texts transcriptions and images provided for the competition. We combined these outputs in different ways to obtained a vector x used as input for a classification final classification.

$$output = FFN(x)$$

[4]https://www.instagram.com/

[5]https://www.tiktok.com/

[6]https://github.com/OpenAI/CLIP

The different results can be found in Table 1.

Text_Only: Based on the characteristic of the dataset spotted in Section 3, we investigated if only the text transcriptions were enough for successfully detecting misogyny using this dataset.

$$x = text\_clip$$

With this system, we obtain a 69% of f-score after three epochs. This result is very close to our best result using both types of information (71%). One of the reasons could be the percentage of memes that can be classified by only using the texts, but more need to be studied to obtain a conclusive explanation.

Image_Only: Similar to the *Text_Only* system, we investigated if only the images were enough for successfully detecting misogyny using this dataset. The f-score obtained after five epochs is 65%, a lower result than the *Text_Only* system.

$$x = image\_clip$$

CLIP_concat: This system considered both image and text representations by concatenating them into a single vector in one single vector.

$$x = concat(image\_clip, text\_clip)$$

The results improved by using both representations to a 70% of f-score.

CLIP_sum_system: In this variant of the system, we sum both image and text representation in one single vector. This sum was pondered by a trainable parameter of the model a. The idea of this combination is to give the possibility to the model of using the necessary weights for image and text.

$$x = sum(a * image\_clip, (1 - a) * text\_clip)$$

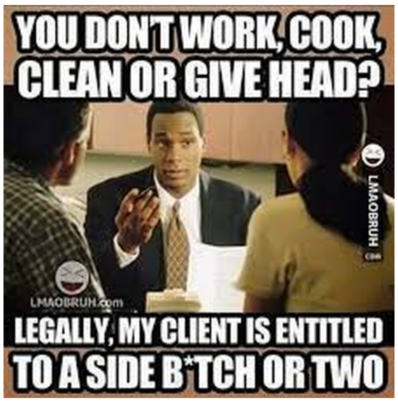
With this combination we obtained our best reported result for the competition.

5 Error Analysis

We observed the memes miss classified by our best model (*CLIP_sum*). The most common type of error was the *false negative* error, examples wrongly classified as *not misogynist*, we noticed that most of them represent male figures or inanimate objects. Only a small number of memes picture a woman as the central figure (see Figure 2).

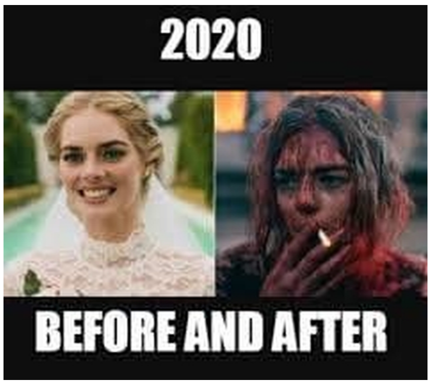
On the other hand, the female figures in the *false positive* examples is very common (see Figure 3).

Figure 2: Meme example 15115 from the testing set. Our model *CLIP_sum* wrongly classified it as a *not misogynist* meme. The text transcription is: "YOU DON'T WORK,COOK, CLEAN OR GIVE HEAD? LMAOBRUH LMAOBRUH.com LEGALLY, MY CLIENT IS ENTITLED TO A SIDE B*TCH OR TWO"



YOU DON'T WORK, COOK, CLEAN OR GIVE HEAD?
LMAOBRUH.com
LMAOBRUH.com
LEGALLY, MY CLIENT IS ENTITLED TO A SIDE B*TCH OR TWO

Figure 3: Meme example 15977 from the testing set. Our model *CLIP_sum* wrongly classified it as a *misogynist* meme. The text transcription is: "2020 BEFORE AND AFTER"



This phenomenon could be caused by a particular bias in the training set that relates misogyny memes with the images of women. But a deeper analysis has to be conducted in this regard.

6 Conclusions

This paper describes our team participation in Task 1 of the Multimedia Automatic Misogyny Identification (MAMI) at SemEval 2022. The purpose of this task was to identify memes as misogynists or not. Images and texts were provided in a training set of 10000 examples. Our team implemented a system based on the pre-trained CLIP approach and reported a 71% of f-score.

The multimodal hate speech detection has been under-addressed through the years and recently is gaining popularity, though there is still much for research in this regard. Moreover, other types of multimedia, like videos, need to be analyzed since they are popular ways of communicating on social networks.

Abstract

Online misogyny meme detection is an image/text multimodal classification task, the complicated relation of image and text challenges the intelligent system's modality fusion learning capability. In this paper, we investigate the single-stream UNITER and dual-stream CLIP multimodal pretrained models on their capability to handle strong and weakly correlated image/text pairs. The XGBoost classifier with image features extracted by the CLIP model has the highest performance and being robust on domain shift. Based on this, we propose the PBR system, an ensemble system of Pretraining models, Boosting method and Rule-based adjustment, text information is fused into the system using our late sequential fusion scheme. Our system ranks 1st place on both sub-task A and sub-task B of the SemEval-2022 Task 5 Multimedia Automatic Misogyny Identification, with 0.834/0.731 macro F1 scores for sub-task A/B correspondingly.

1 Introduction

Much of the real world's information comes in multimodality, a combination of images, texts, audios and so on. Multimodal understanding aims to utilize different modal of information to improve the overall system recognition intelligence or robustness (Gadzicki et al., 2020), which plays a key foundation role in cognitive AI and embodied AI.

With transfer learning by large deep models and colossal corpus achieving remarkable success in vision and language domain, there is a rising interest in combining both sides' advances to push the multimodality understanding further (Lu et al., 2019; Tan and Bansal, 2019; Chen et al., 2019; Li et al., 2020; Yu et al., 2020; Huo et al., 2021; Kim et al., 2021; Radford et al., 2021). We will limit the discussion scope of multimodal to vision and language in this paper. There are two kinds of representative architecture of multimodal learning models, single-stream models and dual-stream models. Single-stream model fuses the image and text data at an early stage, and then feed into the model. Dual-stream models design separated structure as image encoder and text encoder, and a further module is stacked on top of the unimodel encoders for cross-modal learning objectives (Tan and Bansal, 2019; Yu et al., 2020; Radford et al., 2021; Huo et al., 2021). Usually per-unimodal objectives and multimodal objectives are designed to ensure that the model learns unimodal and crossmodal knowledge, like masked image prediction, masked token prediction, and text-image pairing (Chen et al., 2019; Kim et al., 2021). Two kinds of data distributions are explored for the large-scale pretraining, strongly paired data (Chen et al., 2019; Radford et al., 2021; Li et al., 2020; Kim et al., 2021) and weakly paired data (Huo et al., 2021). The different distributions would directly affect the correlations learned by the model, yet each pretraining corpus only falls in one pattern.

The SemEval-2022 Task 5 (Fersini et al., 2022) Multimedia Automatic Misogyny Identification (MAMI) is a multimodal classification task in English. It targets the identification of misogynous memes (characterized by a pictorial content with an overlaying text a posteriori introduced by human), using the image and text from the meme as input data. It has two sub-tasks: sub-task A: 2-fold classification, to identify whether a meme is misogynous or not; sub-task B: 4-fold fine-grained classification, to further recognize the misogynous meme among potential overlapping categories of stereotype, shaming, objectification and violence.

The relationship of the MAMI paired meme image/text data can vary from highly correlated to weakly correlated or not correlated at all. The semantic logical relationship between the meme's image and text can be: 1) align with each other, containing the same semantic, 2) independent but

[*]Contribution during Intership in Samsung Research China-Beijing.

connected to form a complete semantic, 3) irrelevant with each other, only one modality decides the meme's semantic (refer to the appendix for illustrations). In summary this task demands both understanding the image and text, as well as setting up the correct semantic logic between the image/text modalities.

In this paper, we want to investigate either the multimodal pretrained models of different design architecture are capable of handling such complex relationship between vision and language, and whether the pretrain-and-fine-tuning paradigm is advantageous over the feature-extraction-and-machine-learning-classification paradigm. We choose two strong baseline pretrained models, UNITER (Chen et al., 2019) as the single-stream model, and CLIP (Radford et al., 2021) as the dual-stream model, and fine-tuning with cross-entropy softmax is compared against the widely adopted XGBoost (Chen and Guestrin, 2016) classifier. Domain shift is discovered between the train (dev) and test dataset, and the above two paradigm is explored for both in-domain situation and domain shift situation. An adversarial discrimination loss (Tzeng et al., 2015) is added to the fine-tuning deep neural network for domain shift, while the XGBoost classifier is tuned with its hyper-parameters.

Our results show that 1) for both pretrained models, multimodal fine-tuning performs better than unimodal. The CLIP dual-stream model performs sightly better than the UNITER single-stream model on in-domain data, given the much greater pretraining corpus CLIP has than UNITER. On data with domain shift, the CLIP fine-tuning is much more stable than the UNITER model, but both models suffer from great performance degradation. 2) the performance of feature-extraction-and-machine-learning-classification by XGBoost classifier is no weaker than that of fine-tuning on top of pretrained models, the XGBoost classifier utilizing only image features from CLIP hits best performance on the test dataset among all modality combinations, plus that the XGBoost is cheaper to train. 3) for domain shift, the XGBoost classifier is more robust, the domain adversarial loss for fine-tuning brings a small rise, but still falling behind the XGBoost classifier.

Our final winning system is a combination of machine learning and deep neural network, by Pretraining models, Boosting method and Rule-based adjustment, which we name PBR, based on the XGBoost classifier of CLIP image features, and a late sequential fusion of multimodal/text information into the classifier's prediction, followed by rule-based adjustment. The details will be stated in Section 2. Our system gets 0.834 macro F1 score on sub-task A and 0.731 macro F1 score on sub-task B, ranking 1st place in both the tasks in the leaderboard.

2 System Overview

2.1 Overall Architecture

Our 3-stage ensemble system showed in Figure 1 works as following:

- stage 1, the image feature extracted by the CLIP model is learned by the XGBoost classifier, to form a image only prediction. The image/text paired data is used to fine-tune the UNITER model on the MAMI task. And external text datasets together with the MAMI text data is fed into the BERT model to train a text only model on the MAMI task.

- stage 2, the UNITER fine-tuning predictions and the BERT fine-tuning predictions are used to adjust the medium confidence zone of the XGBoost prediction, by our late sequential fusion scheme.

- stage 3, the sub-task A and sub-task B predictions are mutually adjusted, taking advantage of the two sub-tasks' logical inference relationship with each other.

2.2 Deep Pretrained Model for Image and Text Representation

The multi-head attention of transformer architecture modelling the interaction between any two tokens within a sequence by constant $\mathcal{O}(\infty)$ distance, has proved to be powerful in learning deep bidirectional interactions in language and vision (Lu et al., 2019; Dosovitskiy et al., 2020). We choose two transformer based pretrained model to get the image and text representations.

1) **single-stream model UNITER.** UNITER (Chen et al., 2019) is a large-scale pre-trained model for UNiversal Image-TExt Representation. The image and text input are fused early by concatenation, and fed into the transformer module to learn contextualized representations. The pretraining includes unimodal and multimodal tasks. The

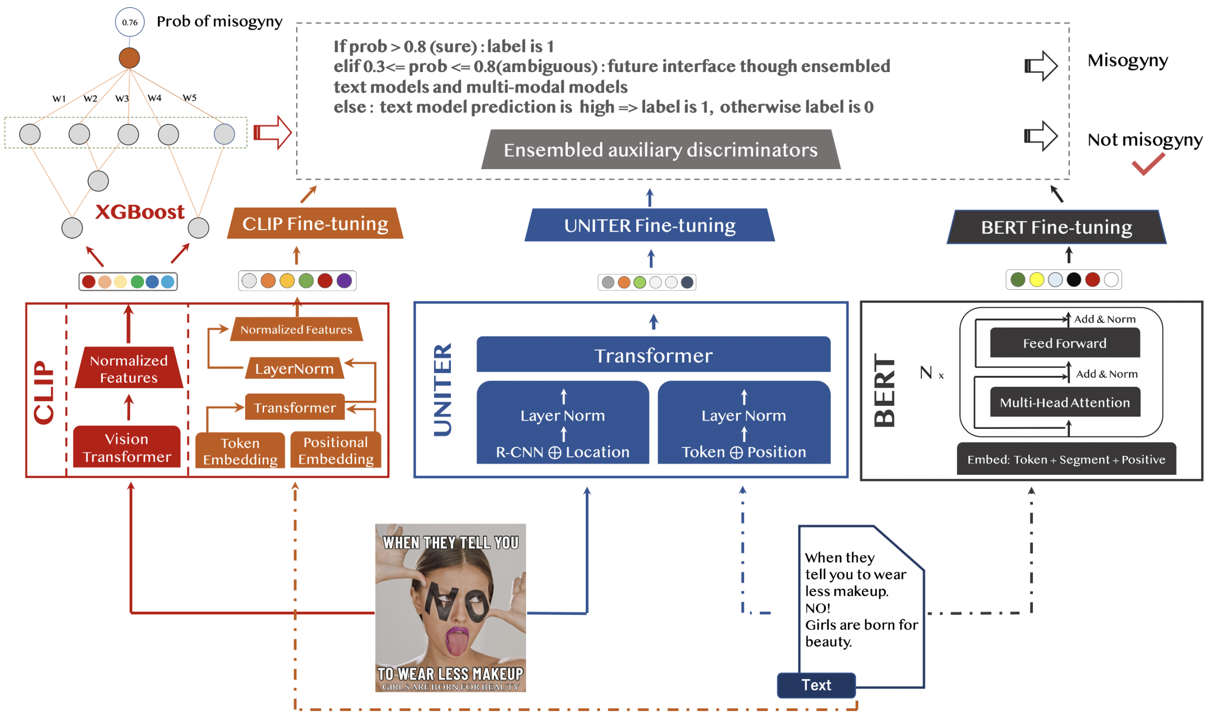

Figure 1: The overall architecture of our ensembled system.

model outputs a fused text and image representation. The pretraining dataset has about 8.4 million image/text pairs.

2) **dual-stream model CLIP.** CLIP (Radford et al., 2021), the Contrastive Language-Image Pretraining model, has separate image transformer encoder and text transformer encoder. The two are joined by a contrastive loss to learn the multi-modal embedding space. The model is pretrained on a dataset of 400 million (image, text) pairs collected from the internet. The simple pretraining task only involves multimodal alignment, predicting which text as a whole is paired with which image, unimodal learning task is not applied. whereas the natural language performs well in enabling zero-shot transfer of the model to downstream tasks when used to reference visual concepts and functioning as prompt text.

2.3 Classification on Downstream Task

2.3.1 Fine-tuning with Pretrained Models

As illustrated in Figure 2, for the UNITER model, the fine-tuning head is a feed forward neural layer (ffn) followed by the cross-entropy softmax classifier. And for the CLIP model, the encoded image and text representations are linearly transformed separately, and then concatenated to be passed forward to a ffn layer and a cross-entropy softmax classifier. The fine-tuning structure of BERT model is the same as the UNITER model. The fine-tuning is used to select the base pretrained model for MAMI, and the fine-tuned UNITER model is utilized as a multimodal voter and the fine-tuned BERT as a text unimodal voter for the model ensemble.

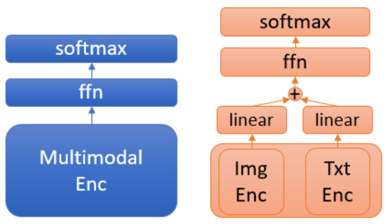

Figure 2: Fine-tuning head structure for UNITER(left) and CLIP(right).

2.3.2 XGBoost Classifier

XGBoost (Chen and Guestrin, 2016) classifier is a tree boosting ensemble model that uses additive functions to predict the output. The boosting ensemble learning algorithm combines multiple weak learners in a sequential method, iteratively improving upon observations. XGBoost borrows from random forests and supports column sampling as well as data sampling. The benefits of the XGBoost classifier is its capability to reduce bias and the low training cost.

In Eq. 1 , the f_k stands for the kth regression

Dataset	**Modality**	**# Samples**	**# Labels**

Table 1: MAMI task and augmented datasets statistics.

tree with K trees in total, $\hat{y}_i$ is the prediction of sample i formed by the sum of K regression trees. In Eq. 2, L is the training objective, l a differentiable convex loss function that measures the difference between the prediction $\hat{y}_i$ and the target y_i, and Ω is the penalty function to avoid over-fitting. The Eq. 3 describes the iterative update of object function L, y_i^t is the prediction of the i-th instance at the t-th interation. At each iteration t, a new tree f_t is added to optimize the objective, the selection of f_t is by a greedy algorithm that most improves the model according to Eq. 2.

$$\hat{y}_i = \sum_{k=1}^{K} f_k(x_i) \tag{1}$$

$$L(\phi) = \sum_i l(y_i, \hat{y}_i) + \sum_k \Omega(f_k) \tag{2}$$

$$L^t(\phi) = \sum_i l(y_i, \hat{y}_i^{t-1} + f_t(x_i)) + \sum_k \Omega(f_k) \tag{3}$$

2.4 Post-adjustification

2.4.1 Late Sequential Fusion

The XGBoost classifier with image features extracted by CLIP stands out among all modality combinations by a large margin, including the multimodal fusion pattern of both CLIP and UNIER, thus it is chosen as our basis. While the information in text is non-negligible, we make use of it in a late sequential fusion fashion, with image going first and text catching up. We treat the XGBoost prediction score ranging [0,1] as the prediction confidence, denoted as $\hat{p}$, and the whole XGBoost predicted confidence on the MAMI test cases are denoted as $\hat{P}$. We rank $\hat{P}$ in decreasing order, and divide it into three intervals, the high, medium and low confidence intervals. The prediction confidence score from the BERT fine-tuning (text modality) and UNITER fine-tuning (multimodality) are denoted as $\hat{p}_b$ and $\hat{p}_u$.

$$\hat{p} = \begin{cases} \hat{p}, & \text{if } \hat{p} \in [\hat{P}_{hi}, \hat{P}_{t_1}] \\ vote(\hat{p}, \hat{p}_u, \hat{p}_b), & \text{if } \hat{p} \in (\hat{P}_{t_1}, \hat{P}_{t_2}] \\ vote(\hat{p}, \hat{p}_b), & \text{if } \hat{p} \in (\hat{P}_{t_2}, \hat{P}_{lo}] \end{cases} \tag{4}$$

The medium confidence interval reflects the model's uncertainty for classification based on image solely. In the low confidence interval, when the image is highly non-misogynous, while the text is highly misogynous, the whole semantic of the meme would be positive. Thus we fuse the text and image modality in a late sequential way by the scheme in Eq. 4. The high confidence interval take the XGBoost classifier prediction as the result directly, and the medium interval combines the text ($\hat{p}_b$) and multimodal ($\hat{p}_u$) information by voting, while the low interval takes advantage of the text information to adjust the image-only prediction. $\hat{P}_{hi}$ and $\hat{P}_{lo}$ refer to the highest and lowest probability, by experience we choose the endpoints of the medium interval t_1 to be 300, and t_2 be 700 in the descending ranked $\hat{P}$ sequence (eg. $\hat{P}_{t_1}$ equals the probability value of the 300th $\hat{P}$).

2.4.2 Mutual Adjustment of the Sub-task A/B

This step is the final adjustment towards our final results. By task definition, when the MAMI subtask A is non-misogynous, all labels in sub-task B should be 0, vice visa. If any of sub-task B is labelled as 1, sub-task A should be misogynous. Therefore, we design the following rules to increase performance.

1) If the prediction of "misogynous" in sub-task A has high confidence for label 0, while some of the four sub-classes in sub-task B are labelled as 1 , we ignore them and set all the labels to 0s due to the high confidence of the misogyny binary classification.

2) If multiple 1-labels appear in sub-task B, it suggests the sample meme probably being misogyny. Meantime if the confidence level of "misogynous" for sub-task A is in the medium interval and the text and visual combination are also very ambiguous, we set the label to be 1 in sub-task A.

2.5 Data Augmentation

Data augmentation is applied to enrich the data distribution and enhance the system's generalization capability (Perez and Wang, 2017) in the downstream task classification phase (applied both in fine-tuning and XGBoost classification).

Our data augmentation strategy includes 3 aspects: 1) collecting memes of the misogyny topic from search engines with a set of misogynous keywords and neutral keywords. 2) collecting public dataset on misogyny and related topics, to help provide more knowledge on the topic. 3) self-augmentation from the task dataset. For image self-augmentation, we used geometric-based augmentations, including flipping horizontally and vertically with cutout (DeVries and Taylor, 2017), randomly resized cropping and 30-degree rotation, as well as color-based transformation, color jittering. For text self-augmentation, back-translation is used. Details of 1) and 2) can be referred in Section 3.1

3 Experimental Setup

3.1 Training Datasets

The MAMI task dataset and augmented datasets are used for training.

MAMI. Dataset for the SemEval-2022 Task 5 (Fersini et al., 2022), the labels of sub-task A is evenly distributed (1:1 for misogyny and non-misogyny samples), and the labels for sub-task B are distributed unevenly, the shaming/stereotype/objectification/violence have 1271/2810/2201/953 labels correspondingly.

searched-meme. Memes crawled from commercial search engines. Searching by keywords in commercial search engines, and an in-house OCR tool is applied to get the paired text for each meme. The final dataset contains 3447 image-text pairs. The searching keywords is listed in the appendix.

misogynistic-meme. An expert-labeled open misogynistic dataset (Gasparini et al., 2021), it contains 800 memes with manually transcribed text, the misogynisticDE field is used as the label for misogyny.

sexist-detection. A text dataset of sexist statements at workplace (Grosz and Conde-Cespedes, 2020), the label for sexism or not is mapped to misogyny or not for the SemEval-2022 Task 5.

online-misogyny-eacl2021. A text dataset of 6567 labels for Reddit posts and comments for online misogyny detection (Guest et al., 2021).

3.2 Training Details

For the fine-tuning of UNITER and CILP, we mainly follow the original paper, detailed hyper-parameters can be referred in the appendix. The hyper-parameters of the XGBoost classifier is listed in Table 5 in the appendix. We treat the sub-task B as four independent binary classification tasks with four independent XGBoost classifiers. Dealing with the label imbalance, we adjust the XGBoost parameter "scale_pos_weight" to achieve good performance. The sub-task A is evaluated using macro-average F1-Measure, the sub-task B is evaluated using weighted-average F1-Measure (Fersini et al., 2022). A point worth noting is that when there is data imbalance of positive (label-1) and negative (label-0) samples, it is more profitable to predict the less labelled ones in the measure of macro F1. So we try to find label-1 in each category of sub-task B as much as possible by tuning the hyper-parameters since label-1 samples are much less than label-0.

4 Results and Discussion

4.1 Multimodal Pretrained Model Selection

We take the BERT text model as the baseline for text modality and the CLIP image model as the baseline for image modality (the image features of CLIP model outperforms state-of-art image pre-trained models in image classification tasks (Radford et al., 2021)), which we will denote as TB and IB below. We randomly split the 10000 training data into train/dev/inner-test data by 8:1:1, and the test data is released by the task organizer. The UNITER image model and text model are tested by putting the unimodal-only data into the model.

As shown in Table 2, the UNITER image model is well below the IB and the UNITER text model is well below the TB on dev dataset. The UNITER image-text multimodal fine-tuning dev results gains large increase compared to its unitmodal implementations, while slightly better than the TB/IB. This suggests that the unimodal pretraining objectives in UNITER is not as well learned as the unimodal

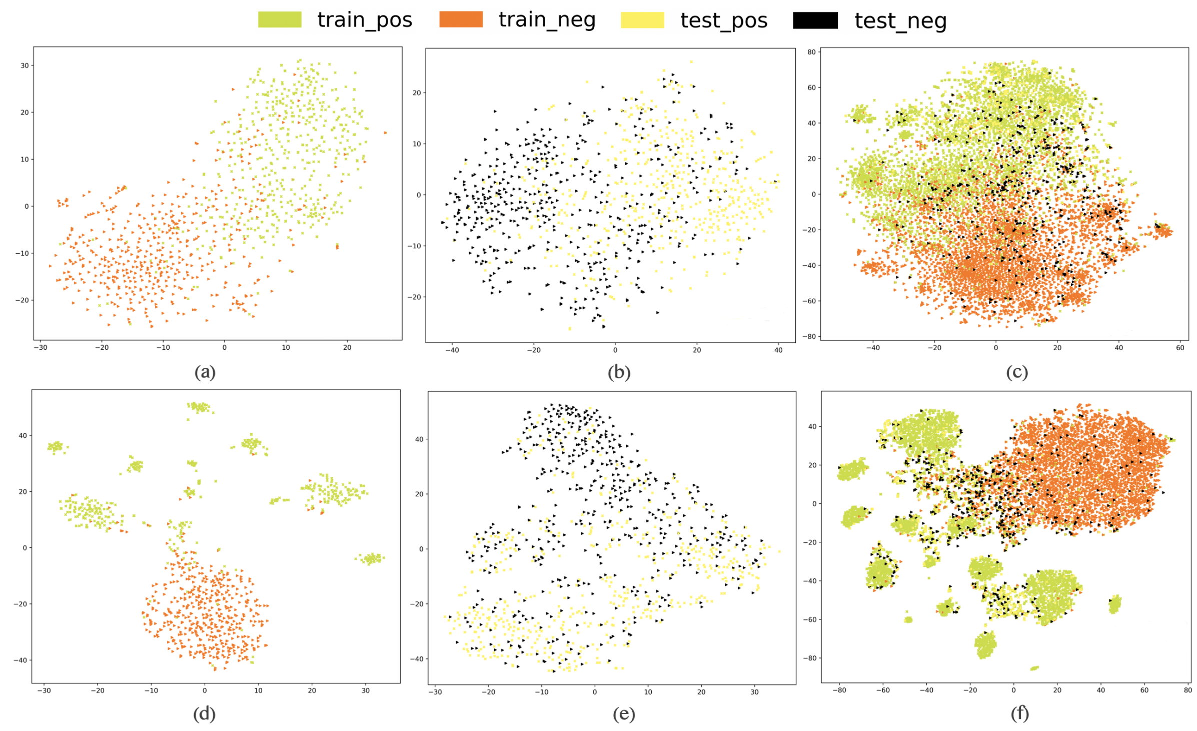

Figure 3: Visualization of t-SNE data distribution under CLIP(a,b,c) and UNITER(d,e,f) models.

Pre-trained model	**Fine-tuning**	
	dev	**test**
BERT txt (TB)	82.6	65.9
UNITER img	70.2	60.3
UNITER txt	76.8	60.7
UNITER img+txt	82.8	67.1
CLIP img (IB)	82.1	68.1
CLIP txt	82.0	66.8
CLIP img+txt	84.3	72.1

Table 2: Baseline performance of single-stream and dual-stream pre-trained models.

benchmarks, and the cross-modal learning objective is better learned through its pretraining given the improvement over the unimodality UNITER models.

The CLIP text model has a comparative performance with the TB, noting that there is no specified text pretraining objective in CLIP. With the well learned image and text unimodal semantics, the CLIP multimodal fine-tuning brings a marinal improvement, leading to 84.3 macro F1 score on dev dataset.

Overall the CLIP multi-modal fine-tuning performs better than the UNITER multimodal fine-tuning, both on dev and test dataset, with comparative unimodal performance at the same time.Thus CLIP is chosen as the pretrained model to provide image/text representations.

4.2 Domain Shift

The big performance gap between the dev and test set in Table 2 suggests domain shift between the train (dev) and test data. Domain shift can be simply expressed as Eq. 5, p_s denotes source data distribution and p_t denotes target data distribution.

$$p_s(x, y) \neq p_t(x, y) \tag{5}$$

$$p(x, y) = p(x|y)p(y) = p(y|x)p(x) \tag{6}$$

According to Bayesian joint probability distribution formula in Eq. 6, the analysis of inconsistent data distributions can be turned to the analysis of marginal probability distributions and conditional probability distributions.

1) $p_s(x) \neq p_t(x), p_s(y|x) = p_t(y|x)$
We consider the training set as the source domain and the test set as the target domain. The distribution of positive and negative samples in the training set is more separable, as shown in Figure 3-a and 3-d. However, the distribution of two classes in test set is mixed, especially the distribution of negative

samples drawn in black triangle shows a significant domain shift,the black triangle, as shown in Figure 3-b and 3-e. Therefore, we regard this as $p_s(x) \neq p_t(x)$ case.

2) $p_s(x) = p_t(x), p_s(y|x) \neq p_t(y|x)$
Another way is to observe the overall distribution in the data set clusters together, as shown in Figure 3-c and 3-f. It is indicated that the distribution of the training set and the test set have relatively low difference. $p_s(x) = p_t(x)$. Generally, the training and test sets are composed of easy samples and hard samples. A hard sample in terms of visualization is a positive sample running into the domain of a negative sample, or a negative sample distributed in the domain of a positive sample. The test set of this competition has a large number of ambiguous samples and difficult samples. This causes the deep learning model to crash, while the more interpretable XGBoost performs better.

To alleviate the problem, we exploit data augmentation and explored further with the XGBoost hyper-parameters

4.2.1 Extra Data for Better Generalization

The external searched-meme dataset and the misogynistic-meme dataset is added for training and the macro F1 score was improved by 2.1 points. This improvement is shown in Figure 4.

4.2.2 XGBoost on Domain Shift

XGBoost has many design parameters to prevent overfitting. These include the number of trees, tree depth, subsampling and colsampling, etc. In addition, there are two penalty terms in XGBoost. $\Omega(f)$ corresponds to Ω in Eq. 2. γ and λ denote the penalty factor, T is the number of leaf nodes. $||w||^2$ is equivalent to the L2 norm in Eq. 7 .

$$\Omega(f) = \gamma T + \frac{1}{2}\lambda||w||^2 \tag{7}$$

As shown in Table 3, the XGBoost classifier shows advantage over fine-tuning on the CLIP model. Different from the fine-tuning paradigm, the image-text CLIP feature performs worst on the XGBoost classifier, with 82.4 macro F1 score. The CLIP text model with XGBoost classifier achieves the best results on dev data, 90.1 macro F1 score, and CLIP image model with XGBoost achieves 85.2 on dev data, but achieves the highest macro F1 score on test data, both of them outperforms the CLIP multimodal fine-tuning. The CLIP image model with XGBoost classifier is chosen as our basis.

Pre-trained	**Fine-tuning**		**XGBoost**	
model	**dev**	**test**	**dev**	**test**
CLIP img	82.1	68.1	85.2	**77.6**
CLIP txt	82.0	66.8	90.1	65.4
CLIP img+txt	84.3	**72.1**	82.4	75.1

Table 3: XGBoost Performance on dev and test data compared with pretrained model fine-tuning.

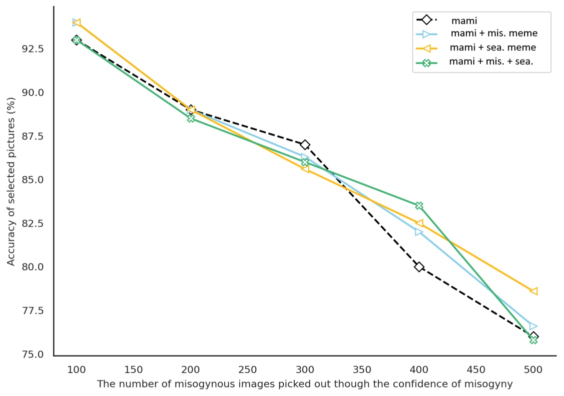

Figure 4: Accuracy of XGBoost classifier trained by different datasets. mis. meme is the misogynistic-meme datase and sea. meme is the searched-meme dataset.

4.2.3 Fine-tuning with Domain Adaptation Compared to the XGBoost Classifier

We apply domain adaption to the CLIP fine-tuning model by an adversarial loss between the source and the target domain following (Tzeng et al., 2015). The core concept is to fuse the distributions of source and target data by a domain classifier together with a domain confusion loss. Besides the standard cross-entropy loss for misogyny classification, the domain classifier (with loss L_{dm}) is on top of CLIP pretrained model to discriminate the source and target data, and the domain confusion loss L_{conf} forces the output of the domain classifier to be a uniform distribution, thus achieving the goal of fusing the source and target domain. By minimising two adversarial losses L_{dm} and L_{conf}, the performance of CLIP model improves by 1.5 on the macro F1 score of testing dataset (72.1->73.6) while it still falls behind the XGBoost.

4.3 Late Sequential Fusion and Mutual Adjustment

The confidence statistics of the XGBoost image (CLIP feature) and BERT text models are shown in Figure 5. It illustrates our intuition of the late sequential fusion. The upper left and lower right

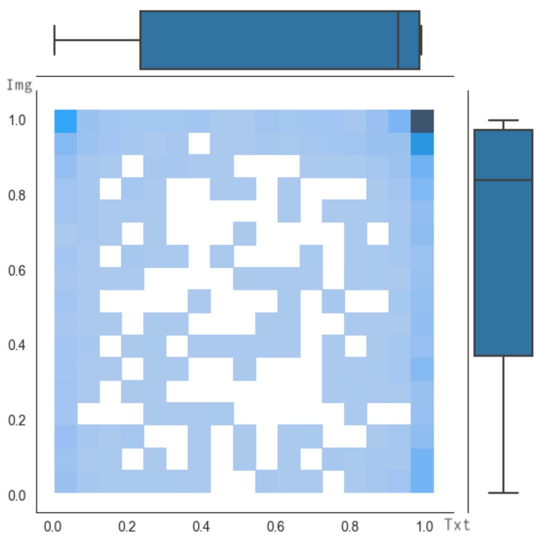

Figure 5: The joint density plot of visual and text modalities on test data.

Task	XG-Boost	Aug. data	Seq. fus.	Mut. adj.
sub-task A	77.6	79.5	81.9	83.4
sub-task B	71.1	-	71.9	73.1

Table 4: Ensemble performance of the system.

corner in the figure shows the disagreement of the image model and the text model. In the medium confidence interval of the XGBoost image prediction, the BERT text prediction can sometimes provide high confidence positive prediction. In addition, the box plot shows the positive skewness distribution in the BERT text model is more obvious than the CLIP-image XGBoost classifier, which means more negative samples are misjudged as positive by the BERT text model. The late sequential fusion boosts the macro F1 score of sub-task A (79.5->81.9) and sub-task B (71.1->71.9). And we get the leading score of 83.4 in sub-task A and 73.1 in sub-task B by the mutual adjustment of the two sub-tasks.

5 Conclusion

In this paper, we investigated the single-steam model UNITER and dual-stream model CLIP's performance on the downstream multimodal classification task, and compared the pretrain-and-fine-tuning paradigm over the feature-extraction-and-machine-learning-classification paradigm.

The experiment results show that the CLIP performs better than UNITER on the MAMI task, and is more robust on domain shift. The UNITER unimodal fine-tuning results are significantly worse than the unimodal pretrain model benchmark, suggesting its weakness in handling the complicated semantic logical relationship in the MAMI task. Wheras the structure of CLIP image feature extraction and XGBoost classificatin achieves the highest baseline performance.

We proposed the late sequential fusion scheme to fuse text information into our system PBR, and exploited extra data and mutual adjustment of the two sub-tasks to further improve the system performance. Our system ranks 1st place in both the sub-tasks in the leaderboard of the SemEval-2022 Task 5 MAMI.

A Task Data Analysis

The 3 kind of semantic logical relationships between the meme image and meme text in the Introduction Section is illustrated in Figure 9. The subfigures a-c are the cases only text decide the meme's semantic, and d-f are cases that only image decide the semantic, lastly e-g are cases the image and text together form the complete semantic of the meme. Figure 8 shows the high frequency uni- and bigram text distribution. We analyse the top 30 frequent unigram and bigram features of the text input over training and testing distribution (with stop words filtering and ubiquitous words filtering such as "come, "makeameme", "org" which indicate sources of memes). These plots show significant bias, in terms of content and frequency, between train and test distributions.

B Hyper-parameter settings

XGBoost classifier hyper-parameters is shown in Table 5, the BERT fine-tuning hyper-parameters is in Table 6, and the UNITER fine-tuning hyper-parameters shown in Table 7.

Hyper-parameters	Value
objective	binary:logistic
n_estimator	800
learning_rate	0.03
subsample	0.90
max_depth	7
lambda	10
colsample_bytree	0.85
reg_alpha	10
reg_lamba	10
scale_pos_weight	15

Table 5: Hyper-parameters of XGBoost classifier

C keywords for crawling meme data from search engines

The keywords for misogynous memes are {'meme misogyny','meme anti-feminist', 'meme chauvinism woman', 'meme shaming/objectification/stereotype/violence/insult women/woman/girl/female/feminine', 'meme sexist' , 'woman/women/female/feminine hater' }. The keywords for non-misogynous memes are randomly selected neural words like {'meme happy girl', 'meme plants', 'meme school', 'meme actress'} etc.

Hyper-parameter	Value
learning rate	1e-5
learning rate decay	linear
warmup fraction	0.1
Adam ϵ	1e-6
Adam $beta_1$	0.9
Adam $beta_2$	0.98
gradient clip norm	1.0
Weight Decay	0.01
Dropout	0.1
Batch Size	32
Train Epochs	10

Table 6: Hyper-parameters for BERT fine-tuning

Hyper-parameter	Value

Abstract

Women are frequently targeted online with hate speech and misogyny using tweets, memes, and other forms of communication. This paper describes our system for Task 5 of SemEval-2022: Multimedia Automatic Misogyny Identification (MAMI). We participated in both the sub-tasks, where we used transformer-based architecture to combine features of images and text. We explore models with multi-modal pre-training (VisualBERT) and text-based pre-training (MMBT) while drawing comparative results. We also show how additional training with task-related external data can improve the model performance. We achieved sizable improvements over baseline models and the official evaluation ranked our system 3rd out of 83 teams on the binary classification task (Sub-task A) with an F1 score of 0.761, and 7th out of 48 teams on the multi-label classification task (Sub-task B) with an F1 score of 0.705.

1 Introduction

Despite its unique advantages, social media is considered to be one of the harmful elements of society, if not monitored properly. It has become a medium to express hatred towards particular groups, especially women. Women have a strong presence online and have become victims of systematic inequality and discrimination which is reflected from the behavior offline. Violence has increased to the point where for many girls, abuse is a day-to-day reality. A landmark survey conducted by Plan International in more than 20 countries has revealed shocking accounts of escalating online violence against girls and women, with respondents exposed to explicit messages, pornographic photos, cyberstalking, and other forms of internet abuse. The most common type of online harm includes using abusive and insulting language, followed by deliberate embarrassment, body shaming, and threats of sexual violence.

One of the most popular communication tools in social media is a *meme*. It is a combination of image and text, created typically for humor. SemEval 2022 Task 5 is the first misogynistic meme detection challenge that incorporates several categories such as stereotyping, shaming, objectification and violence.

Pre-trained language models such as BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), etc., have emerged as the state-of-the-art models for many NLP tasks such as text classification, machine translation, sequence tagging, etc., mainly due to their rich contextual embeddings. Hence, we chose a transformer-based architecture to fuse both visual and textual features. Two types of pre-training techniques are explored in this paper: text-based and multi-modal-based. Instead of directly using a pre-trained text transformer, we further train RoBERTa on task-related data and fine-tune the model with extended visual features extracted from a image classification network (e.g. ResNet). We also use ensemble learning to combine the results of the two pre-training techniques.

We achieved significant improvement over baselines in both the sub-tasks. We were ranked (1) 3rd with an F1-macro score of 0.761 in sub-task A and (2) 7th with a weighted F1 score of 0.705 in sub-task B among 83 teams. We release the code for models and experiments via GitHub [1]

The rest of the paper is organized as follows: Section 2 describes the challenge, followed by a brief literature survey. Section 3 explains the proposed approach in detail while section 4 presents the experimental details required to reproduce the results. Results and analysis are shown in section 5. Finally, conclusions are drawn in section 7.

Label	No. of samples
Misogynous	5044
Shaming	1274
Objectification	2204
Violence	962
Stereotype	2844

Table 1: Distribution of training data.

2 Background

2.1 Problem Description

SemEval 2022 Task 5: MAMI: Multimedia Automatic Misogyny Identification (Fersini et al., 2022) consists of two sub-tasks: **Sub-task A** is a simple binary classification task to identify whether a meme is misogynous or not. **Sub-task B** is an advanced multi-label classification task, where memes are further classified among four categories namely *stereotype*, *shaming*, *objectification*, and *violence*.

2.2 Related Work

Multimodal data classification There are two types of approaches to multimodal data classification: late fusion and early fusion. Early works on multimodal data employed late fusion techniques such as combining major image features with bag-of-words-based text features (Tian et al., 2013). In this approach, two separate models are trained with images and text and their outputs are combined at a later stage. (Zhang and Pan, 2019) used a late fusion of CNN-based image features and RNN-based text features. The late fusion approach can be used even if one of the modalities is missing in the input. The disadvantage of this approach is, it fails to learn the interactions between different modalities. On the other hand, early fusion approaches use joint representations of images and text, thereby training a single model to learn within and across both modalities. With the development of pre-trained language models such as BERT, early fusion models like VisualBERT (Li et al., 2019), Vision and Language BERT (Lu et al., 2019), Visual-Linguistic BERT (Su et al., 2019), Multimodal Bitransformers (MMBT) (Kiela et al., 2019) and Learning Cross-Modality Encoder Representations from Transformers (Tan and Bansal, 2019) have quickly risen in popularity. However, early fusion models may perform poorly because using a single optimization strategy is sub-optimal for a model dealing with multiple modalities as explained in (Wang et al., 2019).

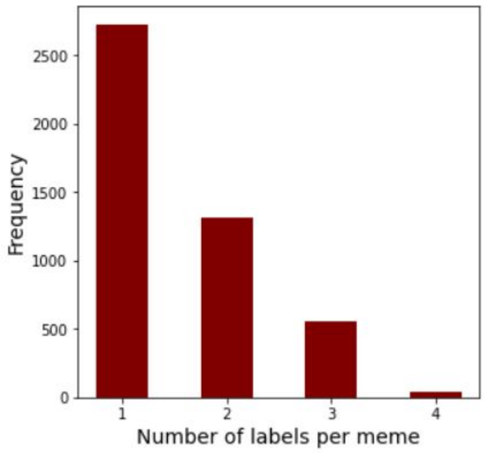

Figure 1: Frequency distribution of #labels per meme.

Multi-label classification There are mainly three different techniques to solve a multi-label classification problem (sub-task B) : Binary Relevance, Classifier Chains (Dembczyński et al., 2010) and Label Powerset method (Boutell et al., 2004). Binary Relevance treats each class independently and ignores label dependence. The Label Powerset method considers each combination of labels as a distinct class, thereby transforming a multi-label classification problem into a single-label problem. Classifier Chains connects binary classifiers in a chain such that the output of one classifier is treated as the input feature for the subsequent classifier.

3 System Overview

We explored models using both single-task and multi-task learning approaches. Since multi-task learning did not provide any significant improvement, our final model was trained using single-task learning. Consequently, we trained models using one modality (either text or image) and both modalities for the sake of comparison. We also compared the performance of models with and without multimodal pre-training.

3.1 Data

The training data provided for this task consists of 10,00 memes. The text transcription of memes along with the annotated labels for each image file is provided in a .csv file. Memes in the dataset are of random size. The distribution of different labels in the public training data is shown in Table 1. The frequency distribution of the number of labels per meme is shown in Figure 1. Each meme is labeled as either misogynous or non-misogynous

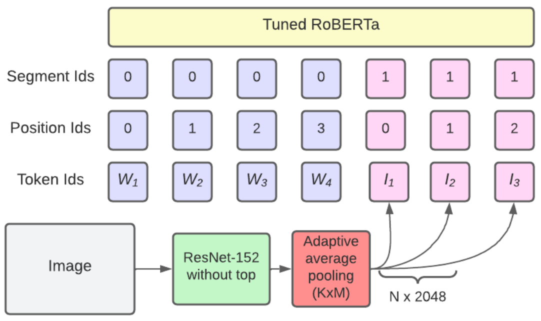

Figure 2: Architecture of the proposed model.

and in turn, misogynous memes are further classified among potential overlapping categories. 20% of data is randomly sampled from the training data for validation. The final test data provided for evaluation consists of 1000 memes.

3.2 Single modality approach

3.2.1 Text-based approach

We tested the following text-based models: i) A bidirectional LSTM model with Glove embeddings. ii) Pre-trained RoBERTa-base model fine-tuned with a classification head. iii) Ernie-2.0 (Sun et al., 2019), fine-tuned in the same way as RoBERTa-base model. RoBERTa model is further trained with external data and fine-tuned with training data for classification.

3.2.2 Leveraging External data

RoBERTa (Liu et al., 2019) has 12 layers, 12 heads, and a hidden layer dimension of 768. It is trained with masked language modeling on five datasets: BookCorpus, English Wikipedia, CC-News, OpenWebText, and Stories. We initiated it with pre-trained weights and trained on sexism-based datasets using the HuggingFace library. Sexism-based datasets are used since the language and content present is similar to our training dataset. (Grosz and CONDE-CESPEDES, 2020) introduced a labeled dataset consisting of sexist comments made in the workplace. We took 624 comments labeled 'sexist' out of 1137 comments present in this dataset. (Singh et al., 2021) presented a dataset to determine the use of sexism in English sitcoms from which, we extracted 1631 sexist text instances. From EXIST2021 dataset (Rodríguez-Sánchez et al., 2021-09), sexist text instances in English language are extracted. Altogether, we curated 5049 sexist text instances for training. Since the acquired dataset is small, we did not train the RoBERTa model from scratch. We call this model *tuned* RoBERTa (tRoBERTa) for the entirety of this paper.

3.2.3 Image-based approach

We fine-tuned several large-scale image feature extraction networks such as VGG-16 (Liu and Deng, 2015), ResNet-50, ResNet-152 (He et al., 2015) and Vision transformer (Dosovitskiy et al., 2021) for both the sub-tasks.

3.3 Multimodal input

We implemented the late fusion approach mentioned in section 3.2.1 by combining image features from VGG-16 and text features from a BiLSTM model. Besides, we also trained the state-of-the-art multimodal models such as VisualBERT and MMBT described in section 2.2.

VisualBERT is an integration of BERT and pre-trained object proposal system, Faster-RCNN. Similar to BERT, VisualBERT is pre-trained using two language model objectives: 1) Masked language modeling, where part of the input text is masked and predicted using contextual visual and text tokens. 2) Sentence-image prediction where the model determines if the text data matches the image or not. By combining image and text regions through a transformer, VisualBERT aims to learn useful alignments between them. For this purpose, it uses unordered visual embeddings extracted from an object detector, each corresponding to a bounded region in the image. In addition to BERT inputs, VisualBERT takes visual embeddings, visual token type ids, and visual attention masks as input. We fine-tuned VisualBERT for the task which is pre-trained on the VQA task with COCO dataset. Image features are extracted from a ResNeXt-based Faster RCNN, pre-trained on Visual Genome dataset.

MMBT combines representations from large language models and state-of-the-art convolutional neural networks in a straightforward way. It employs a BERT-base uncased model (12-layer 768-dim) trained on English Wikipedia. It uses N separate image embeddings extracted from the ResNet-152 network with average pooling over K x M grids (N = K x M). The dimension of each embedding is 2048. MMBT maps these image embeddings to BERT's token space using a set of randomly initialized mappings. The output of the [CLS] token in the last layer of BERT is given to a dense layer for classification. In our system, we

Model	Task A	Task B

use the tuned RoBERTa (tRoBERTa) described in section 3.2.2 instead of the BERT model used in the original implementation. The architecture of our proposed model is shown in Figure 2. This model is fine-tuned with a classification head on top by optimizing focal binary cross-entropy loss for multi-label classification.

3.4 Ensemble Learning

Multimodal models such as VisualBERT and MMBT differ in their training procedures and the datasets on which they are trained. Hence, they may focus on different aspects of the input. So, it is a good practice to combine the results of these two models to learn accurate representations. There are several ways to combine them: we can concatenate embeddings of different models and project them to a low dimensional space for prediction, but this will require high computational power. Instead, we can train these models independently and later combine their predictions. In a Weighted-Average Ensemble, results are obtained by taking a weighted average of the predictions. In this case, the weights are obtained by grid search on the validation dataset. Another way to combine the predictions is the Voting Ensemble method, where the class predicted by the majority of the models is considered as the final output. We experimented with both approaches and found that the weighted average method yields better results than the voting ensemble method.

4 Experimental Setup

We used pytorch (Paszke et al., 2019) and HuggingFace library (Wolf et al., 2019) for training and inference. All the models are trained on Google Colab. AdamW (Loshchilov and Hutter, 2019) optimizers with learning rates of 2e-5 and 5e-5 are used for training Visualbert and MMBT models respectively. Other text models such as RoBERTa and Ernie-2.0 also use AdamW optimizer with a learning rate of 2e-5. The maximum length of the text is limited to 50. We chose a batch size of 32 for training all the models. All the hyperparameters are tuned on the validation set which is 20% of the training data.

4.1 Data prepocessing

An input image is resized to 256 x 256 and then center-cropped to 224 x 224, followed by normalization before passing into MMBT. Text transcriptions of memes are cleaned to get rid of any URLs, HTML tags, and punctuation. Subsequently, they

are annotated with the [CLS] token in the beginning before passing to the model. Removing stopwords showed a slight deterioration in the performance. Hence, we did not remove them.

4.2 Data Augmentation

Data augmentation is widely used to generate slightly variant larger datasets from the existing smaller ones. Since one recurring issue among all the models we trained is overfitting, three types of data augmentation techniques are tested to address this issue. We applied contextual augmentation for labeled sentences as proposed in (Kobayashi, 2018). In this method, we replace the words in a sentence with words predicted by a bi-directional language model. We also tested the back-translation approach proposed in (Sennrich et al., 2016) and easy data augmentation (EDA) techniques described in (Wei and Zou, 2019). We observed that while back-translation and contextual augmentation slightly improved the performance of the model, the use of EDA degraded it.

4.3 Loss functions

We trained our model for sub-task A with binary cross-entropy loss, whereas for sub-task B we used focal loss. Focal loss (Lin et al., 2020) is a form of cross-entropy loss, but it is dynamically scaled. It is computed as:

$$FL\left(p_t\right) = \left(1 - p_t\right)^{\gamma} \log\left(p_t\right)$$

By setting $\gamma > 0$, we are reducing the relative loss for easy, well-classified examples ($p_t > 0.5$). For prediction, we used a threshold of 0.35 as it produced better results on the validation set.

5 Results and Analysis

We have tested transformer and non-transformer-based models with features extracted from text, images, and a combination of text and images as input. We experimented with models that employ text and multimodal pre-training like MMBT and VisualBERT respectively. The results of these experiments are summarized in Table 2. We can infer from the results that pre-training transformer-based language models give better results compared to LSTM-based text models. This performance can be attributed to their rich contextual embeddings.

System	F1
MMBT with RoBERTa	0.682

1	0.751
3	0.743
4	0.739
5	0.740

Table 5: Comparison of results of sub-task A with different number of image embeddings.

Our model (MMBT with tuned RoBERTa) performs slightly better than VisualBERT without any multimodal pre-training. This is because VisualBERT is pre-trained on Microsoft's image annotation dataset COCO and most real-world multimodal inputs are not as straightforward as a caption describing an image. For the model to adapt to the target domain, we need additional pre-training with the data of interest. In our case, instead of extra multimodal pre-training, we just trained the text model (RoBERTa) for a few epochs using external data. This is computationally more efficient and flexible. Furthermore, this approach can be easily applied to inputs with missing modalities.

The performance of our model on the development set with a different number of image embeddings is shown in Table 5. Using a single image embedding gave better results than using multiple ones. Also, an incremental analysis of our system is shown in Table 6. This shows the importance of further training RoBERTa and focal loss. Besides, combining VisualBERT and our model in an ensemble gave an additional performance boost of around 1% (F1 score) in sub-task A and 0.5% in sub-task B.

Meme			 SHE'S A NICE GIRL BUT SHE IS NOT A SEX OBJECT, SO MEME MAKERS, PLEASE SHOW SOME CLASS AND STOP THINKING WOMEN OWE YOU SEX AND FOOD. Pred. label	stereotype, violence	stereotype, objectification	shaming, stereotype, objectification	objectification
Org. label	stereotype, violence	stereotype, objectification	non-misogynous	shaming, stereotype

Table 7: Sample test predictions of our model.

Comparison of the results of our model with the top submissions on the leaderboard for sub-task A and sub-task B are reported in Table 3 and 4 respectively. The official baselines for sub-task A are fine-tuned USE sentence embeddings (only text as input), fine-tuned VGG-16 model pre-trained on ImageNet dataset (only image as input), and concatenation of the above two models (image plus text as input). Baselines for sub-task B are: i) flat multi-label classification model with the concatenation of USE sentence embeddings and VGG-16 model features. ii) a hierarchical multi-label model based on USE sentence embeddings. Our model outperforms the best baseline model by 12% in sub-task A and 8.4% in sub-task B.

Error analysis of our model is shown in Table 7. The first two columns are examples of correctly classified memes whereas the last two columns are the incorrectly classified ones. The Model fails to classify the third meme as non-misogynous because it overlooks the word 'not'. This has been a common problem in language models such as BERT since they don't understand negation well, resulting in incomplete syntactic knowledge. In the last meme, the usage of the words *sexual objects* most likely misled the model into classifying it as *objectification* without taking into account 'not'. As this is a common error, in future, special methods should be devised to help models overcome it.

6 Conclusion and Future Work

We conducted experiments with models trained on features extracted from text, images, and both modalities combined for meme classification. To evaluate the text-based approach, we trained language models such as RoBERTa, Ernie-2.0, etc., and RNN-based models. Subsequently, we concluded that the transformer-based models produced best results. We showed that further training the RoBERTa model (tuned RoBERTa) with task-related data improves the performance. This tuned RoBERTa model combined with the features from ResNet-152 without multimodal pretraining performs slightly better than VisualBERT. Furthermore, an ensemble of these two models gave an additional performance boost. In the future, we plan to test other problem transformation approaches such as Classifier Chains and their variants for multi-label classification in order to accurately model label dependence and hierarchy. Additionally, we plan to train VisualBERT from scratch on meme datasets to see if there is an improvement in its performance.

Abstract

In the context of the Multimedia Automatic Misogyny Identification (MAMI) competition 2022, we developed a framework for extracting lexical-semantic features from text and combine them with semantic descriptions of images, together with image content representation. We enriched the text modality description by incorporating word representations for each object present within the images. Images and text are then described at two levels of detail, globally and locally, using standard dimensionality reduction techniques for images in order to obtain 4 embeddings for each meme. These embeddings are finally concatenated and passed to a classifier. Our results overcome the baseline by 4%, falling behind the best performance by 12% for Sub-task B.

1 Introduction

The Multimedia Automatic Misogyny Identification (MAMI) competition (Fersini et al., 2022) consists in the identification of misogynous memes, taking advantage of both text and images available as source of information. The task was organized around two main sub-tasks. Sub-task A: a basic task about misogynous meme identification, where a meme should be categorized either as misogynous or not misogynous; Sub-task B: an advanced task, where the type of misogyny should be recognized among potential overlapping categories such as stereotype, shaming, objectification, and violence.

In this paper, we present a proposed solution for Sub-task B only, which consists of a framework for extracting lexical-semantic features from text and combine them with semantic descriptions of images, together with image content representation. We propose to use a pre-trained BERT model (Devlin et al., 2019) as lexical feature enhancer, and to use a vision-language model (Zhang et al., 2021) as visual descriptor.

The rest of this paper is organized as follows. We introduce our multimodal framework in Section 2. In Section 3 we present and discuss our results. We conclude the paper in Section 4.

2 Methods

Fig. 1 shows a diagram of the method that we propose to describe memes using both visual and text inputs. It is known that local descriptors can provide rich representations, as they can extract fine details from local areas within documents (Lowe, 2004). Therefore, we compute two types of description for each modality -visual or text-. Namely, global and local descriptors, and then concatenate the resulting four descriptors into a single vector that we use for classification.

More specifically, we relied on transfer learning coupled with fine tuning procedures, in which one pre-trained model was further adjusted for each of the four input modalities, and for the five classes problem presented by the MAMI competition.

2.1 Image descriptors

We describe images at two levels of detail. First globally using a pre-trained CNN, and also locally by detecting and describing individual objects within the images.

2.1.1 Global descriptors

In order to generate a global visual description of the image, we use the InceptionV3 (Szegedy et al., 2016) network pretrained on ImageNet (Russakovsky et al., 2015) to perform a fine tuning on the MAMI dataset. The classification head is replaced with a global average pooling, a dropout layer, and 4 dense layers with weights randomly initialized. The first three dense layers have 1024, 512, and 64 units. The last dense layer has five units with sigmoid activations.

To train the network, first the convolutional basis is frozen and the parameters of the classification head are optimized for ten epochs using a learning rate of $1e^{-3}$. Next, all parameters are unfrozen and retrained with a smaller learning rate ($1e^{-5}$). The training is stopped by using the regularization strategy of Early Stopping to avoid overfitting. Once the training process is completed, a 64-vector of floating-point values is generated for each image. This descriptor is obtained in inference mode from the output of the penultimate dense layer.

2.1.2 Local descriptors

We detect and describe each of the objects contained in the images by means of the pre-trained VinVL model (ResNeXt-152 C4 architecture) (Zhang et al., 2021). VinVL was pre-trained on four public datasets specialized in object localization, so it considers up to 1848 object categories and 524 attribute categories (nouns and adjectives respectively).

This stage generates a feature vector of length 2048 for each object within the image. More precisely, this step produces a matrix of varying length according to the number of objects detected in an image, where each component is a fixed-length vector of size 2048. We post-process this matrix using Principal Component Analysis (PCA) on both of its axes, and recovering the eighth principal components for each axis. This is, we identify features corresponding to the eighth most relevant objects in a given image, as well as those corresponding to the eighth most relevant variables describing each object representation, both of them in an orthogonal space of PCA that is independent across images.

This PCA processing results in a 64-D representation of the visual features for all object detected within an image.

2.2 Text representations

Analogous to the image processing stage, we also describe the meme's text transcriptions at two levels of granularity. First, generating an embedding for the whole sentence, and then incorporating individual word representations.

2.2.1 Contextual embeddings

We generated a global sentence embedding for each meme transcription. This was performed using a pre-trained BERT model (Devlin et al., 2019). Namely, the small uncased BERT "L-4_H-512_A-8" for English language (Turc et al., 2019). This model was used up to the layer that produces its so-called pooled output, which provides a sentence embedding vector of 512 elements. We connected such output to a classification multi-layer perceptron (MLP) for fine tuning the model.

The classification MLP, added to BERT for fine tuning, consists of two fully-connected hidden layers of 512 and 64 perceptrons, and a final 5 units layer that performs multi-class multi-label classification for the five possible labels defined for this challenge. Both hidden layers contain 'swish' activation functions, while the output layer implements 'sigmoid' non-linearities to ensure that it outputs values bounded between 0 and 1. We chose 'swish' as activation function to obtain a smooth transition between the positive and negative sides of the response space of the non-linear projection (Ramachandran et al., 2017). Dropout layers with rate equal to 0.1 were added in between fully-connected layers.

We performed fine tuning of this model on the training set of the MAMI challenge. First, warming up only on the added MLP during 8 epochs. Then, on the full model during 8 more epochs. Both training stages made use of the Adam optimizer (Kingma and Ba, 2014), the first one with initial learning rate of $3e^{-3}$ and the latter with $3e^{-5}$.

2.2.2 Enhanced vocabulary representations

We enriched the text modality description by incorporating word representations for each object present within the images. To this end, we relied on

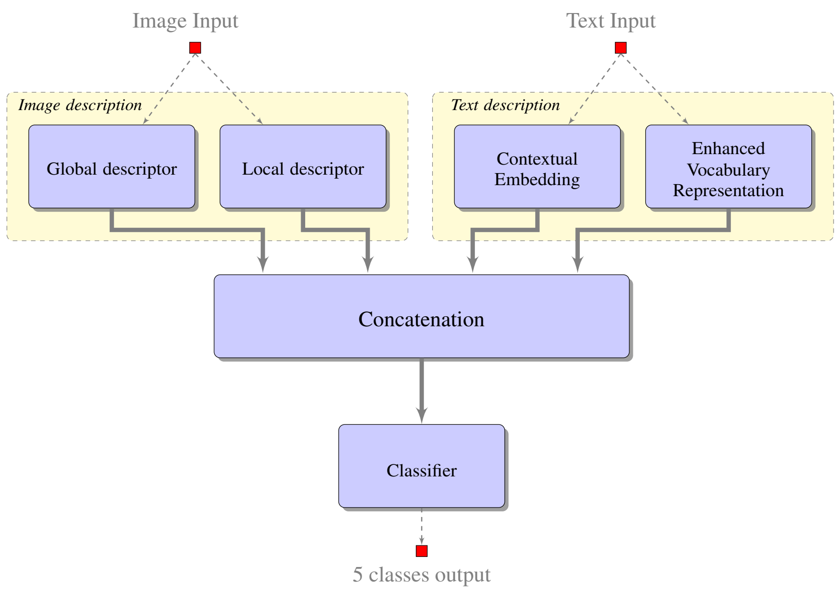

Figure 1: Architecture proposed

the pre-trained VinVL model (Zhang et al., 2021), which is used to segment objects, and provides a list of nouns and adjectives for each segmented object. Some examples of words generated in this stage are: woman, man, red, blue, thin, tall, etc.

This process produces as many lists as there are objects detected within the image. We concatenated all individual words discovered for the same image into a single vector. Then, we used this vector of nouns and adjectives to train a classification network with the same architecture and process as the one explained in sec. 2.2.1, i.e., the architecture and training process are repeated on a different set of parameters.

2.3 Classifier

After the individual training of each of the models described through sections 2.2 and 2.1, we used them in inference mode to process their corresponding inputs, and obtained their respective outputs up to their next-to-last layers. This step produces a 64-D vector for each of the four models.

By concatenating these four representations into a single vector, we produced a multi-modal feature vector of length 256. This resulting vector is used as input for a final MLP classification model, which consists of nine fully-connected layers as shown in Fig. 2.

This final model also uses ‘swish’ activation functions for all hidden layers, and the ‘sigmoid’ activation function for its output layer. As shown in Fig. 2, this model is organized in four blocks, each of which is composed by: a regularization process plus two consecutive fully-connected layers. Regularizers are either dropout or batch normalization. Dropout regularizers use a dropout rate of 0.3. Similarly to the previous individual models, this one also uses an output layer of five perceptrons corresponding to each of the five possible classes in the classification task.

2.4 Training

The final classification model was trained using binary cross entropy as loss function, and the Adam optimizer (Kingma and Ba, 2014) with default parameters as implemented in tensorflow: learning rate $\eta = 0.001$, decay for the smoothing of first and second order moments $\beta 1 = 0.9$ and $\beta 2 = 0.999$, and minimum tolerance $\epsilon = 1e{-}7$. We trained this model during 50 epochs with batches of size 64.

We decided to stop training at 50 epoch, as we observed after several attempts that the loss function has consistently converged by then, for both training and validations sets, i.e., no overfitting was observed.

3 Results and discussion

Table 1 shows the accuracy obtained by our model during training and validation, as well as the F1 score obtained on the test set as reported by the server of the MAMI challenge. These scores are presented for Task B (multi-class - multi-label classification) and for three models: the baseline as reported by the organizers of the challenge; our

proposed model; and the best model submitted to the leader board of the competition.

Model	Training	Validation	Test (F1)
Baseline	–	–	0.621
Ours	0.937	0.895	0.646
Best	–	–	0.731

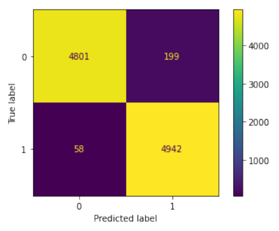
Table 1: Performance on Sub-task B from the baseline model, our proposed model, and the top model reported on the leader board. Columns Training and Validation report accuracy, while column Test reports the F1 score.

Fig. 3 shows the confusion matrices produced by our model on the instances of the MAMI challenge, computed on the joined training and validation sets. We show five confusion matrices because the categories are not mutually exclusive. Each of the matrices contains true negatives [0,0], false positives [0,1], false negatives [1,0], and true positives [1,1]. In all cases, the accuracy is greater than 0.90, with the "misogynous" class having the highest score (0.97) and the stereotyped class the lowest (0.90). Using the F1 measure, the "shaming" and "violence" (the most unbalanced) classes have the worst performance with 0.68 and 0.71 respectively. This situation is due to the small number of true positive instances in these two classes, which might bias the model towards the prediction of the negative label. Meanwhile, the "misogynous", "stereotype" and "objectification" (the most balanced) classes have a similar performance with an F1 score above 0.82. Moreover, the classes with the lowest performance, have a proportionally much lower number of training examples. This fact limits the fine tuning of the model parameters in the overall training process.

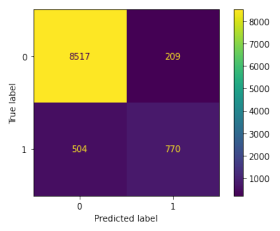
Fig. 4 visualizes the ROC curve, which represents the rate of true positives versus the rate of false positives. As in the confusion matrices, it can be observed that the best performance is obtained in the class "misogynous", while the worst occurs with the classes "shaming" and "violence".

4 Conclusions

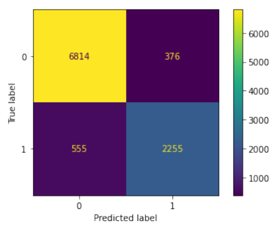
In this paper, we proposed a framework for extracting lexical-semantic features from text and combine them with semantic descriptions of images in the context of the Multimedia Automatic Misogyny Identification (MAMI) competition 2022. Our results overcame the baseline by 4%, but fell behind the best performance by 12% for Sub-task B. Our model's performance could be explained by the un-



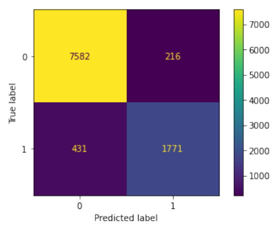
(a) Misogynous.



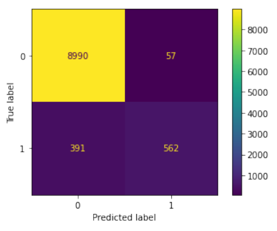
(b) Shaming.



(c) Stereotype.



(d) Objectification.



(e) Violence.

Figure 3: Confusion matrices for the 5 classes in the challenge.

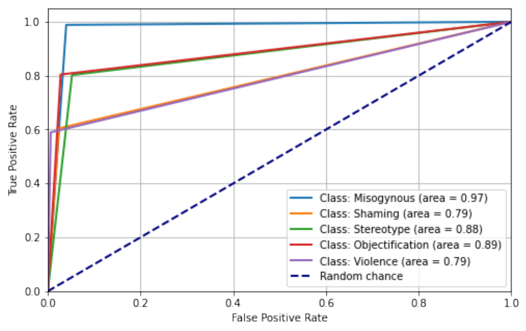


Figure 4: ROC curve for the five classes in the MAMI challenge: "misogynous", "shaming", "stereotype", "objectification", and "violence". "Shaming" and "violence" curves are overlapped.

balanced classes and low number of examples, and, therefore, is limited in this sense, achieving a performance below 0.9 and around 0.7, for accuracy and F1 measure, respectively. Still, for balanced classes we obtained a performance above 0.9 and 0.8, in terms of accuracy and F1 score respectively. As future work we propose three alternatives: 1) To fine tune the classification threshold of the sigmoid output layer of the model, independently for each class, i.e., not all classes need to have 0.5 as classification threshold; 2) Optimize the loss function directly on the F1 score; and, 3) Weight the contribution of each class in the overall loss function during backpropagation.

Aknowledgements

Abstract

Gender discrimination is a serious and widespread problem on social media and online in general. Besides offensive messages, memes are one of the main means of dissemination for such content. With these premises, the MAMI task was proposed at the SemEval-2022, which consists of identifying memes with misogynous characteristics. In this work, we propose a solution to this problem based on Mask R-CNN and VisualBERT that leverages the multimodal nature of the task. Our study focuses on observing how the two sources of data in memes (text and image) and their possible combinations impact performances. Our best result slightly exceeds the higher baseline, but the experiments allowed us to draw important considerations regarding the importance of correctly exploiting the visual information and the relevance of the elements present in the memes images.

1 Introduction

Even though many advances and initiatives have been carried on in the last decades, misogyny and gender discrimination still represent a serious social problem. Comments and posts with hate messages or bad jokes having the female gender as the target are published every day on social networks. Memes are the most popular means of communication on the internet. A meme basically is an image with overlayed text. The combination of image and text should transmit in a clear and direct way a message, which is often funny or ironic. However, many users use them to spread hate or discriminatory messages against certain categories of people. Considering the number of contents that are published online every moment, social network administrators require automatic tools to identify and remove this type of memes. Such tools can be an effective way to fight and stop sexist and misogynous manifestations online.

For the SemEval-2022 it has been proposed the Multimedia Automatic Misogyny Identification (MAMI) task (Fersini et al., 2022), which consists of identifying misogynous memes.

In this work, we present our proposed solution for subtask A of MAMI, which is a binary classification problem where a meme must be categorized as misogynous or non-misogynous. Our solution exploits the multimodal nature of the available data (a meme is represented by a pair image - overlayed text) by using a VisualBERT model together with a Mask R-CNN. Our solution classified 35^{th} out of 69 participants, getting an F1 score 2% higher than the best baseline. Beyond metric values, our work highlights the different importance of various visual elements and how their usage can affect the performances.

2 Task Overview

The purpose of MAMI is identifying misogyny contents and messages within memes through the use of visual and textual information. Organizers set up this task as a competition, providing an annotated dataset and proposing two different sub tasks.

2.1 Dataset

The training dataset contains 10000 memes. Each sample is composed of a pair (image, text) corresponding to the visual and textual information inside the meme.All texts transcripts are already extracted from pictures and available in English language. Data samples are labeled with five different binary tags, each aimed at identifying a different type of hate content: misogyny, objectification, violence, stereotype and shaming. More than one class can characterize a single data sample.

During the final phase of the MAMI challenge, task organizers released a test dataset, made by 1000 elements, which labels were released at the end of the competition only. Therefore, we decided to reserve 25% of the labeled training samples for the validation set to perform our experiments.

In addition to general information, we compute some image-related statistics to analyze and compare all dataset splits. In particular, we use Mask R-CNN (He et al., 2018) classification and bounding-box regression branches to identify which, how many and how large are the most frequent elements within the images. We try two different Mask R-CNN pretraining: the former trained on COCO (Lin et al., 2015) (91 classes) while the latter trained on LVIS version 0.5 (Gupta et al., 2019) (1230 classes).

Computed statistics for both mask R-CNN pretrainings are reported in Table 1. Comparing the two, it is possible to observe how the COCO pretraining allows identifying elements in greater quantity and of greater dimensions than the LVIS one. This is a strange result considering the higher number of classes contained in LVIS. Looking in detail at the detected objects we noticed that the majority of elements identified by the COCO-pretrained network belong to the class "person" ($\sim 63\%$ for train and validation, $\sim 68\%$ for test). This category is not present among those of LVIS, which instead detects as most popular categories some types of clothing and jewelry, such as swim suits, dresses, necklaces and earrings (each appearing at most in $\sim 8\%$ of predicted classes). Moreover, COCO pretraining performs better also in other domains different from photos, such as drawings and cartoons, where LVIS pretraining is often not able to detect and extract any relevant patch. A last noteworthy fact is the dimensional discrepancy between the test and the other splits when using the COCO pretraining. Even though the detected object ratio is lower on the test set, the percentage of covered picture is higher, implying that elements in test images are larger but in less quantity than in the other splits.

2.2 Sub-tasks

Regarding the goals of the challenge, the MAMI task is split up into two sub-tasks:

- Sub-task A consists of a binary classification problem, where each sample/meme must be categorized as misogynous or non-misogynous. The two classes are balanced.

- Sub-task B is a multi-class and multi-label classification problem, where each meme/sample must be assigned labels belonging to 5 different classes: misogynous, stereotype, shaming, objectification, and violence. It is an advanced task since the labels identify more in-depth the type of offensive content and the classes are unbalanced.

Our team worked on a solution for sub-task A only.

3 Related Works

Hate speech detection in text data has been deeply studied in the last few years. State-of-the-art approaches usually apply transformers-based methods achieving impressive results. (Mozafari et al., 2020) for example proposed different hybrid architectures to fine-tune a BERT model (Devlin et al., 2019) for detecting offensive tweets. However, identifying hate content in multimodal data requires correlating visual and textual information and introduces an additional challenge. Multimodal transformers, such as VisualBERT (Li et al., 2019) and ViLBERT (Lu et al., 2019), are currently the state-of-the-art models for these types of problems.

In 2020 Facebook AI organized the Hateful Memes Challenge (Kiela et al., 2021). The competition was similar to MAMI and consisted of categorizing a meme as hateful or non-hateful. The dataset contained memes with various types of hate messages (e.g. targeting an ethnicity, a religion, or the sexual orientation of people). Winning solutions all used ensembles of multimodal transformers-based networks. (Zhu, 2020) won the competition using a complex and task-specific pipeline to extract additional information from the data with which to fine-tune multimodal transformers networks. (Muennighoff, 2020) and (Velioglu and Rose, 2020), who ranked respectively second and third, proposed simpler ensemble methods based on VisualBERT and VilBERT-derived architectures.

Many other works regarding meme analysis for hate speech detection can be found in the literature. Each has its own peculiarities, often related to information extraction techniques, especially from the visual content. Among them, the most used are text removal, object detection, image captioning, and entity recognition, such as in (Deshpande and Mani, 2021), (Pramanick et al., 2021) and (Lee et al., 2021).

4 Method

In this section, we present architectures and preprocessing steps used to address sub-task A of MAMI.

		COCO			LVIS		
Split	Size	Detected Objects	Objects Ratio	Selected Area	Detected Objects	Objects Ratio	Selected Area
Train	7500	21480	2.86	51.55%	13665	1.82	13.20%
Validation	2500	7174	2.87	52.31%	4460	1.78	12.79%
Test	1000	2490	2.49	60.89%	1439	1.44	12.29%

Table 1: dataset statistics related to image content. For each split and for each pretraining version of Mask R-CNN are reported the total number of detected objects, the average number of elements per image and the average percentage of pixels per image contained in all the selected boxes .

First of all, we exploit single modalities separately, through state-of-the-art deep models, to investigate their relevance and the quantity of information they carry on. Subsequently, we combine image and text embeddings to estimate the performance of a multimodal approach.

The strategies mentioned above can be considered as three baseline models in which the information from each modality is retrieved without taking into account the other one and then used both alone or together. Afterward, we adopt early fusion methods to create a more informative embedding of a whole meme, extracting information jointly from both modalities with the same model. This allows to directly obtain a final representation depending on both text and image, thus removing the need for a fusion point between unimodal embeddings.

4.1 Text Encoding

Transformer architectures (Vaswani et al., 2017) are currently the state-of-the-art models in NLP as regards the generation of textual embedding. Among them, BERT (Devlin et al., 2019) is the most renowned sentence encoder, with top-level performances in encoding sentence semantics.

Our text-based baseline model exploits BERT encoder to convert the input sentence into a 768-dimensional embedding vector, obtained with a mean pooling operation over all the output tokens. The classification is accomplished by a single fully connected layer. Both sentence encoder and classification head are trained end-to-end.

4.2 Image Encoding

Convolutional Neural Networks (LeCun et al., 1999) are the type of model most commonly employed in image analysis. CNNs consist of a stack of convolutional layers that extract visual elements from the image, assigning each an appropriate relevance. Among all CNNs, VGG16 (Simonyan and Zisserman, 2015) is one of the most known and used.

Our image-based baseline end-to-end model uses the VGG16 feature extractor along with a multi layer perceptron to obtain a 2048-dimensional embedding vector from the entire original input image. Once again, the classification is accomplished by an additional fully connected layer, as happens for the text, and the two pieces of architecture are trained end-to-end.

4.3 Multimodal Fusion

As a naive multimodal solution, we combine each modality embedding extracted with the previously described techniques. Adopting this implementation we build an end-to-end architecture with two input branches, one for each modality, and a single classification head that takes as input the concatenation of text and image representation vectors, thus setting a late fusion point in the system.

4.4 Multimodal Extraction

Baseline architectures presented in previous subsections suffer from several disadvantages. First and foremost, the choice of fusion point is a critical decision during the construction of multimodal architectures. A late fusion point does not allow information contained in one modality to affect the embedding creation of the others, limiting the influence between modalities only through the back-propagation steps along with the end-to-end architecture. On the other hand, an early fusion has proven to be the best choice for a wide range of other tasks, such as in (Barnum et al., 2020) and (Peinelt et al., 2020).

Another weakness is the usage of the entire input image. The overlayed text in memes is often characterized by a showy style. Since transcriptions are available and typography is unlikely to bring any useful information about hate content, the text should be removed from the pictures, or simply not considered, to avoid affecting the image representations with noise data.

VisualBERT (Li et al., 2019) is a novel transformer designed to address vision-and-language tasks. It reuses self-attention mechanism to align elements of the input text and regions in the input image. VisualBERT is able to address all the weaknesses highlighted above. Input tokens originate from both text and image concurrently, implicitly setting an early fusion point at the model input stage. Furthermore, image input tokens are typically extracted from the original picture as small patch representations, instead of using the whole figure, allowing to focus on important details and ignoring text, background and noise elements. This architecture has been successfully applied to other tasks involving memes (Velioglu and Rose, 2020).

The criterion adopted to select the input patches is based on Mask R-CNN. The same pretrainings mentioned in the dataset sections are used to retrieve multiple Region Of Interest (ROI) in the picture. Then, if a ROI overcomes a fixed confidence threshold, it is select as input token for VisulBERT.

Similarly to BERT, VisualBERT provides a 768-dimensional vector for each input tokens, based on both image and text information, that is finally fed as input for the fully connected classification layer.

5 Experimental Results

5.1 Experimental Design

We try several configuration of the proposed architecture. During the ROIs identification step we exploit both COCO and LVIS pretraining, feeding the model with the patches coming from both Mask R-CNN versions, both separately and simultaneously. Another setting of our architecture concerns the use of transformer output embeddings as input for the classification head: we feed the final fully connected layer with both the CLS token embedding only and the average of all input token embeddings. During our experiments, one of the major issues we faced was the small dimension of the dataset and, consequently, the risk of overfitting. Thus, we used our validation set, obtained with an hold-out splitting as described in 2.1, to monitor the model performance during training. Then, the test set is evaluated selecting the best model according to the results obtained on validation set. Task organizers designated the F1 score as the official metric for the competition, so we used it for model selection.

Algorithms' configuration. We train our models for 25 epochs to minimize BCE loss with AdamW (Loshchilov and Hutter, 2019), using a batch size of 32 and 10^{-5} as learning rate. Many of the best models were obtained within of the first 10 epochs, so there were no need for longer training sessions. For the sake of reproducibility, the code is publicly available in the project repository [1].

Hardware Settings. Experiments were perfomed on a machine equipped with AMD® Ryzen 9® 3950X CPU, Nvidia® RTX 3090 GPU, and 128 GB of RAM running Ubuntu 21.10.

5.2 Results

Table 2 shows F1 scores on validation and test set of our baselines and proposed methods. We also report the best organizers baseline result, which was released at the end of competition.

As we can see, VisualBERT methods perform slightly better than our baseline approaches. Among them, the unimodal BERT and the multimodal fusion method turn out to be our best baselines on the validation and test sets respectively, while exploiting visual information only gives unsatisfactory results. This leads us to formulate some considerations about the nature of the task. First of all, not in all memes the quantity of relevant information is equally distributed between the two data sources (image and text). Indeed, some memes can be formed by a neutral image but a very offensive text or by a neutral or ironic test and a tacky image. The former can be successfully recognized by a text-only approach, which can manage to classify also the latter if correctly trained on identifying malicious messages in ironic texts. On the contrary, image-only methods can only spot misogyny in memes with explicit offensive images. Furthermore, simple approaches that focus on whole images like our VGG16 will fail to link different objects in the image scene and to understand the context depicted in it. As a result, the network will work properly only if the meme image clearly contains the target of the hate message (e.g. a woman on the foreground).

However, in some misogynous memes the hate message is formed by the combination of an apparently innocent meme and a neutral text. VisualBERT should be capable of merging the two

[1]The GitHub project repository is available at `https://github.com/VaianiLorenzo/SemEval-2022-MAMI`

sources of information and putting them into context, identifying these subtle cases. Indeed, it significantly outperforms baseline methods in both validation and test set.

Focusing on the VisualBERT-based methods, we found that using the CLS token over the average of the output embeddings for the classification gave better results in general. We can see from Table 2 that all the three pretraining modalities for Mask R-CNN led to similar results on the validation set, with the LVIS one performing slightly better and achieving an F1 score of 0.823. However, when evaluating on the test set, VisualBERT with Mask R-CNN pretrained on the COCO dataset performed the best, with an F1 score of 0.67 and an improvement of 4% over the other two methods and 2% compared with task organizers baseline. According to the results, giving VisualBERT features from both pretrained modalities gave no improvement. The motivation behind this can be the high overlap probability between patches: combining them brings no additional information and introduce redundancy.

The performance gap between the COCO-pretrained model and the LVIS one on the test set compared to the validation can be explained by the statistics described in Section 2.1. The pretraining on COCO allows the Mask R-CNN to detect ROIs containing whole people, that is, it allows to provide to VisualBERT features regarding the potential targets of the misogynous messages. Since more people are found in the test set images, VisualBERT can exploit the visual information in a more effective way in those memes. Some examples of critical types of memes discussed in this section and their analysis can be found in the Appendix A.

Due to the limited number of examples, our models showed signs of overfitting after a few epochs. Using the whole available training set brought no improvements. Hence, we tried some solutions to help the model to generalize better on unseen data. We did a pre-train phase where we applied our VisualBERT to the Hateful Memes task before fine-tuning it on the MAMI one with a lower learning rate. Unfortunately, this did not bring any improvement. The model only converged faster on the MAMI training set, maybe due to a similarity between the data of the two competitions. Afterward, we tried to keep the VisualBERT layers frozen and gradually unfreezing them during training, but also in this case we got no improvements.

Model	**Val F1 score**	**Test F1 score**
Task Baseline	-	0.650
BERT	0.786	0.607
VGG16	0.696	0.571
BERT + VGG16	0.756	0.628
VB (COCO)	0.811	**0.670**
VB (LVIS)	<u>0.823</u>	0.631
VB (LVIS + COCO)	0.818	0.632

Table 2: F1 scores of our VisualBERT-based architectures compared with both our and organizers baselines. Best results obtained for validation and tests splits are underlined and highlighted in bold respectively.

6 Conclusions and Discussion

In this work we demonstrate how leveraging the multimodal nature of data allows to achieve a significant boost in performance when facing tasks involving memes. Moreover, we confirm that an early fusion point between modalities implemented using VisualBERT, the current state-of-the-art architecture for vision-and-language tasks, can lead to satisfactory results to the MAMI task. The reliability of this model allows us to focus on other crucial aspects of the problem, such as the data to use as input to the network. While unimodal transformers successfully identify offensive content in textual data, state-of-the-art computer vision models obtain lower results on this task when analyzing visual information only. Catching the message of a meme requires understanding the context created by the text and the various elements depicted in the image. A deep learning model will struggle to form this context if the visual data are analyzed as a whole. Therefore, we have to first extract the relevant parts from the image and use their features separately as input to our multimodal network. By doing this, VisualBERT is capable of correlating text and visual scene to create the aforementioned context. Our experiments showed that the most relevant elements in the images are people, likely the target or the offender mentioned in the text.

Despite these discoveries, the extraction of information from the pictures remains the main obstacle of this task. As a future work, we plan to thoroughly investigate the content analysis of images. In particular we would like to enrich the preprocessing stage, performing captioning and entity detection of the image, in order to transpose some visual information in textual format.

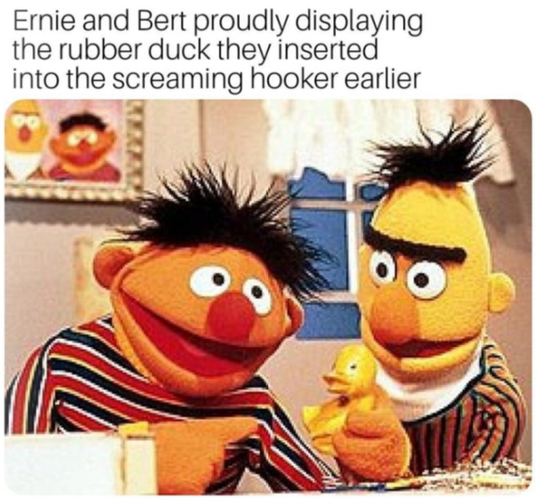
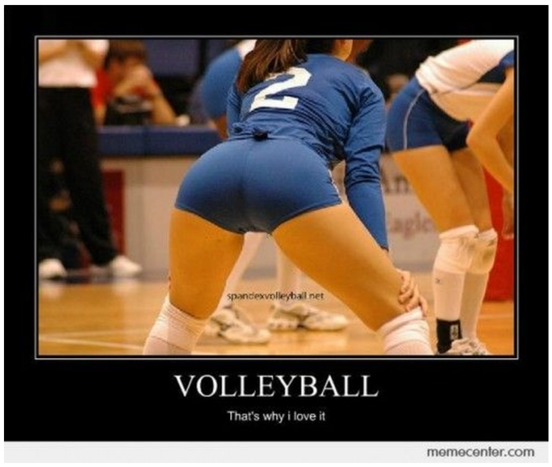
A Memes Examples



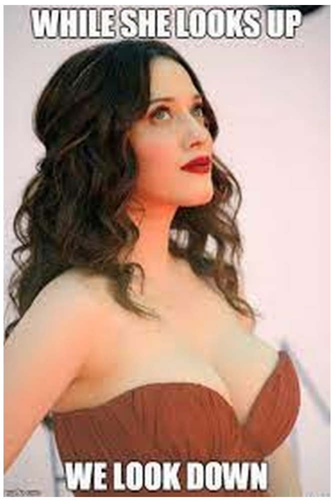
Ernie and Bert proudly displaying the rubber duck they inserted into the screaming hooker earlier

(a) Meme with a neutral image and offensive text.

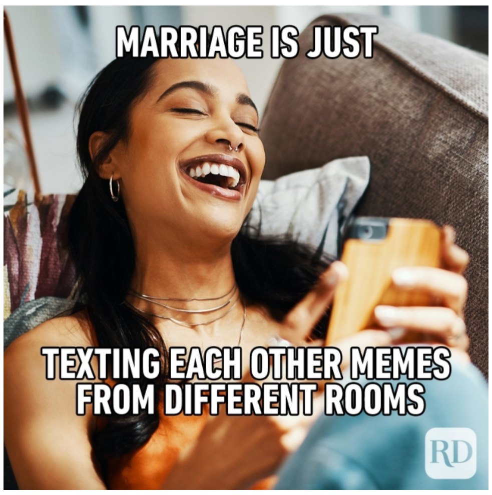


(b) Meme with neutral/ironic text and tacky image.

Figure 1: two example of misogynous memes where one of the two modalities, image in (a) and text in (b), contains neutral and /or not useful information according to the task goal. These memes highlight the importance of a multimodal approach.



(a) misogynous meme.



(b) not misogynous meme.

Figure 2: Two memes from test set depicting a woman in the foreground. The image-only baseline model classifies both memes as misogynous, probably due to the presence of a woman as main element in the picture. On the other hand, our best performing model predicts the appropriate label, demonstrating that the text is definitely needed to correctly classify these type of memes.

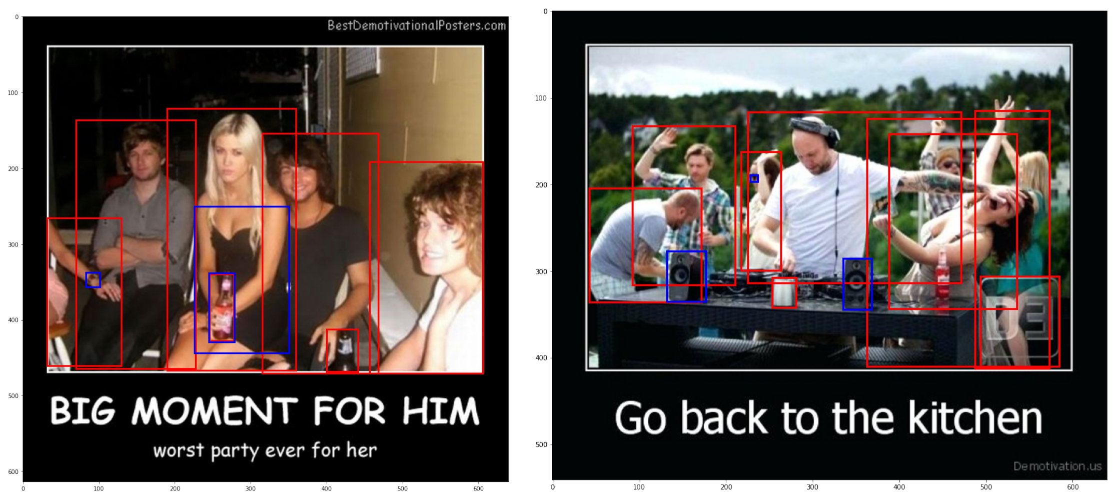


Figure 3: Two misogynous memes depicting several people. The highlighted boxes are the Mask R-CNN ROIs: red ones from the COCO pretraining and blue ones from the LVIS pretraining. As we can see, people are detected only by the former, while the latter retrieves mainly small objects. Moreover, it is possible to notice blue boxes are often contained in red ones, justifying why using COCO and LVIS pretraining jointly there is no improvement in performances.

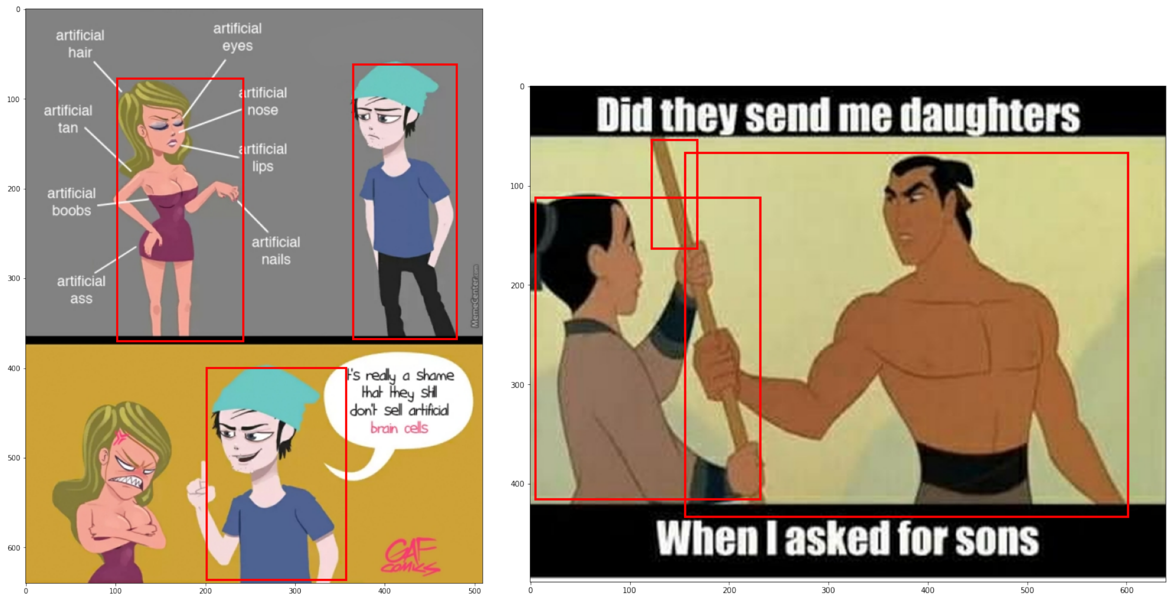

Figure 4: Two misogynous memes with cartoon style. The bounding boxes are all retrieved with Mask-R CNN pretrained on COCO, which is able to detect people also in images other than photos. On the contrary, the LVIS-pretrained model is often not able to identify any details in these kind of pictures.

UPB at SemEval-2022 Task 5: Enhancing UNITER with Image Sentiment and Graph Convolutional Networks for Multimedia Automatic Misogyny Identification

{andrei.paraschiv74, mihai.dascalu, dumitru.cercel}@upb.ro

Abstract

In recent times, the detection of hate-speech, offensive, or abusive language in online media has become an important topic in NLP research due to the exponential growth of social media and the propagation of such messages, as well as their impact. Misogyny detection, even though it plays an important part in hate-speech detection, has not received the same attention. In this paper, we describe our classification systems submitted to the SemEval-2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification. The shared task aimed to identify misogynous content in a multi-modal setting by analysing meme images together with their textual captions. To this end, we propose two models based on the pre-trained UNITER model, one enhanced with an image sentiment classifier, whereas the second leverages a Vocabulary Graph Convolutional Network (VGCN). Additionally, we explore an ensemble using the aforementioned models. Our best model reaches an F1-score of 71.4% in Sub-task A and 67.3% for Sub-task B positioning our team in the upper third of the leaderboard. We release the code and experiments for our models on GitHub[1].

1 Introduction

The web and social network platforms, in particular, have become a significant part of our modern social lives. Sharing information, opinions, news, and jokes through these platforms with friends and family are now daily routines. One of the most prevalent forms of jokes in social networks are memes. Internet memes are small cultural units that are transformed, mixed, and shared using online platforms, often spreading in a viral manner (Milner, 2013). A prolific part are image-based memes, often available as templates that are accompanied by humorous or witty text. Unfortunately, a considerable proportion of the memes shared by Internet users are offensive or even hateful messages[2].

Detecting hate and offensive speech is a significant task for any online platform. Not only companies have this legal obligation in most countries, but also such language establishes a toxic environment that is detrimental to any online community on the long run. Hate speech can take multiple forms, but it is most frequently encountered as a disparaging message on the basis of a characteristic as race, gender, religion, and other criteria; Misogyny is one such frequent form specific to meme culture (Drakett et al., 2018; Phillips, 2012). Detecting hate speech is often a hard problem, even in an unimodal setting since the message often relies on the context, addresses current events, and incorporates cultural knowledge that cannot be easily incorporated into an automated model. The multi-modality of Internet memes increases the difficulty of the task since many memes can have a seemingly benign text that, contextualized with the associated image, becomes offensive or hateful.

Multi-modal hate speech detection had less attention in the research literature than traditional text-only methods. In the past two years, several datasets and challenges have addressed this by proposing detection tasks on meme-based data (Kiela et al., 2020; Gasparini et al., 2021; Miliani et al., 2020). Misogyny detection, as a subgroup of hate speech detection tasks, has also been more frequently encountered in research in recent years. The series of Automatic Misogyny Identification tasks proposed at IberEval 2018, EVALITA 2018, EVALITA 2020, and TRAC-2020 (Fersini et al., 2018a,b, 2020; Kumar et al., 2020; Bhattacharya et al., 2020) focused on the classification of tweets in English, Spanish, Italian, Bangla, and Hindi languages. In these tasks, researchers identified misogynous tweets and classified them as aggressive/non-aggressive or active/passive.

[2] https://www.hmc.org.uk/blog/third-teenage-boys-admit-sending-receiving-racist-homophobic-content-online/

Semeval-2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification (Fersini et al., 2022) is a multi-modal classification task, aiming to detect misogynous memes by leveraging both image and text information. The task includes two sub-tasks: a binary identification of misogynous/non-misogynous memes (Sub-task A), and a multi-label classification distinguishing between the types of misogyny, namely: stereotype, shaming, objectification, and violence (Sub-task B).

In this paper, we present our contribution to this task by proposing two architectures based on the pre-trained multimodal UNITER (UNiversal Image-TExt Representation) model (Chen et al., 2020), as well as an ensemble from these two models. UNITER is an early fusion model pre-trained on large text-image datasets. UNITER leverages visual and location features extracted with Faster R-CNN (Ren et al., 2016), together with WordPiece encodings (Wu et al., 2016) derived from text tokens using a Transformer-based model (Vaswani et al., 2017). UNITER learns a generalizing representation for the text-image context by bringing the visual and text representations in a common embedding space. We use UNITER at the core of our two architectures: the first one enhances the pre-trained model with image sentiment features using a VGG-19 model (Vadicamo et al., 2017), while the second leverages graph convolutions on a co-occurrence graph (Kipf and Welling, 2016) built from an external dataset.

2 Background

Multi-modal tasks were traditionally associated with visual question answering (Goyal et al., 2017), image captioning (Gurari et al., 2020), audio-visual speech recognition (Paraskevopoulos et al., 2020), or cross-modal retrieval (Wang et al., 2016). With success of competitions like the Hateful Memes Challenge (Kiela et al., 2020), more research focused on multi-modal offensive classification. Pre-trained transformer models such as ViLBERT (Lu et al., 2019), VisualBERT (Li et al., 2019), LXMERT (Tan and Bansal, 2019), Oscar (Li et al., 2020), and others, dominated the competition leaderboard, either as stand-alone models or in large ensembles. While considering UNITER, Lippe et al. (2020) used an ensemble that placed them in the top 5 teams.

3 Method

We explored two ways of enhancing UNITER, first by adding a unimodal late fusion with a visual sentiment classifier, and second by using a multimodal early fusion with a modified Vocabulary Graph Convolutional Network (VGCN) (Lu et al., 2020; Paraschiv et al., 2021).

Dataset analysis and preprocessing

The training dataset contains 10,000 records, half of them misogynous. One misogynous record can have one or more of the four labels. The class distribution among the types of misogyny is as follows: shaming - 1,274, stereotype - 2,810, objectification - 2,208 and violence - 953 samples.

The text modality from the dataset was obtained, as far as we can tell, through OCR without any manual cleaning. This lead to the inclusion of date, times, mobile carrier names, Facebook user names or words on some unrelated objects in the image like *"Verizon LTE 4:41 PM Bikram Dec 11 at 12:31 AM"*. Additionally, many memes contain the watermark of the publishing website: "imgflip.com", "makeameme.org", "memez.com". Since most memes use full uppercase fonts, the letter casing was not reliable throughout the dataset and we choose to lowercase all training entries.

In our experiments, we tried two types of data cleaning techniques: one where we remove all timestamps and date mentions using the SUTime library (Chang and Manning, 2012) and a second with the supplementary step of removing all website mentions and Twitter usernames from the text.

Visual Sentiment-enhanced UNITER

Offensive texts, hate speech, and misogynous language are often correlated with negative sentiments, whereas the tone, context, and content is often highly loaded with polarized language (Ali et al., 2021; Gitari et al., 2015); as such, our intuition to enhance the UNITER model with a sentiment classifier. We focused only on image modality since large language models often already capture features required for text sentiment analysis. All images were classified using a pre-trained VGG-19 model (Simonyan and Zisserman, 2014) fine-tuned on the T4SA dataset (Vadicamo et al., 2017). The resulting 4,096 sized feature vectors were fused by concatenation with the UNITER's pooled output and classified through a fully connected layer in

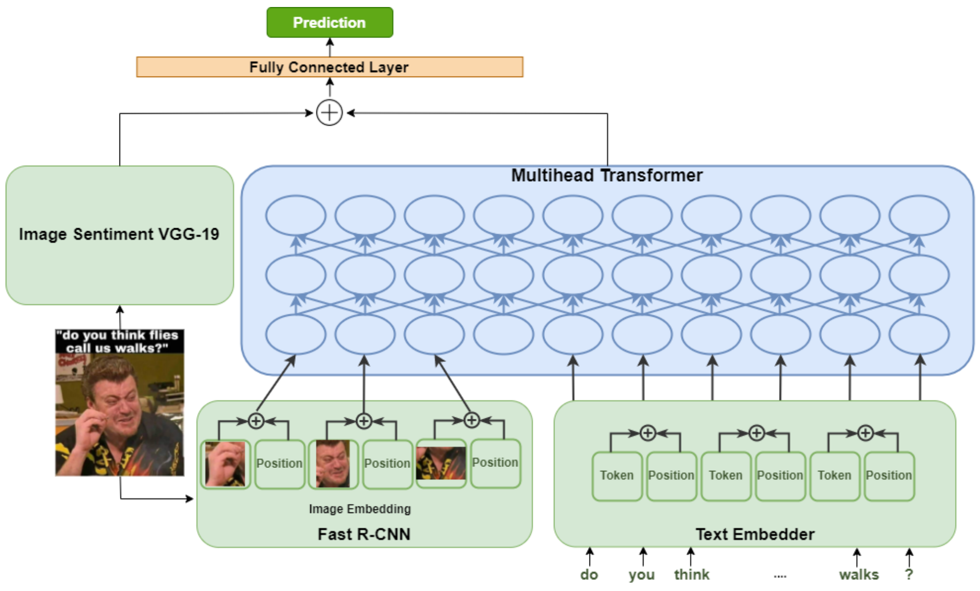

Figure 1: Illustration of the proposed UNITER-Sentiment model.

the classes for each sub-task (see Figure 1).

VGCN-enhanced UNITER

Graph enhanced BERT models have proven to be powerful for text classification (Mamani-Condori and Ochoa-Luna, 2021), even in multimodal tasks (Vlad et al., 2020). Using a GCN on a vocabulary graph (Kipf and Welling, 2016), the model can train an embedding layer to be fused with the Transformer embedding, before being processed by the multi-head attention layers. For our architecture, we employ a novel approach, namely to create a heterogeneous graph with nodes that represent text tokens and objects detected by the R-CNN layer, in the corresponding image.

A Kaggle dataset[3] containing 3,000 meme templates and their various possible text captions, totaling 533,827 text records, was used to build the aforementioned graph. The same R-CNN layer and object-token encoding as the UNITER model were considered to create a co-occurrence graph, having nodes as BERT-token-IDs and detected object-IDs, while edge values were computed using Point-wise Mutual Information (PMI). In contrast to (Lu et al., 2020), the obtained graph is independent of the training dataset and can be used for several tasks in the same domain.

In the training step, the UNITER image and text embeddings are fed through a GCN layer on top of the pre-built graph, thus generating a new embedding vector. The concatenated text, image, and graph embeddings are then processed by multi-head attention layers, while the pooled outputs are classified using a fully connected layer (see Figure 2).

[3]https://www.kaggle.com/zacchaeus/meme-project-raw

Ensemble model

In order to leverage the learning of both proposed models, we also utilize an ensemble formed from multiple versions of both models, trained on different train/dev/validation splits, that are then combined via a soft voting scheme. The best performing trained versions evaluated on our test set were picked in the ensemble. For our final submission, we used the votes from 2 UNITER-Sentiment with UNITER-base, 2 with UNITER-large, and 7 UNITER-VGCN with UNITER-large. We chose these components of the ensemble based on the results for Sub-task B on our validation set, as seen in Table 1. Details on general hyper-parameters across all models are presented in the subsequent section. For UNITER-Sentiment models, we used 150 warm-up steps with a weight decay of 0.01, in contrast to only 120 warmup steps with a weight decay of 0.1 for UNITER-VGCN models. All UNITER-VGCN models in our ensemble had a graph embedding size of 16 and the edges had a minimum normalized PMI (Bouma, 2009) of 0.3. Since we trained each of the 11 ensemble components on a different train/dev/validation partition with the same seed, each configuration converged on different weights, with different performances. The results of all 11 models were combined through

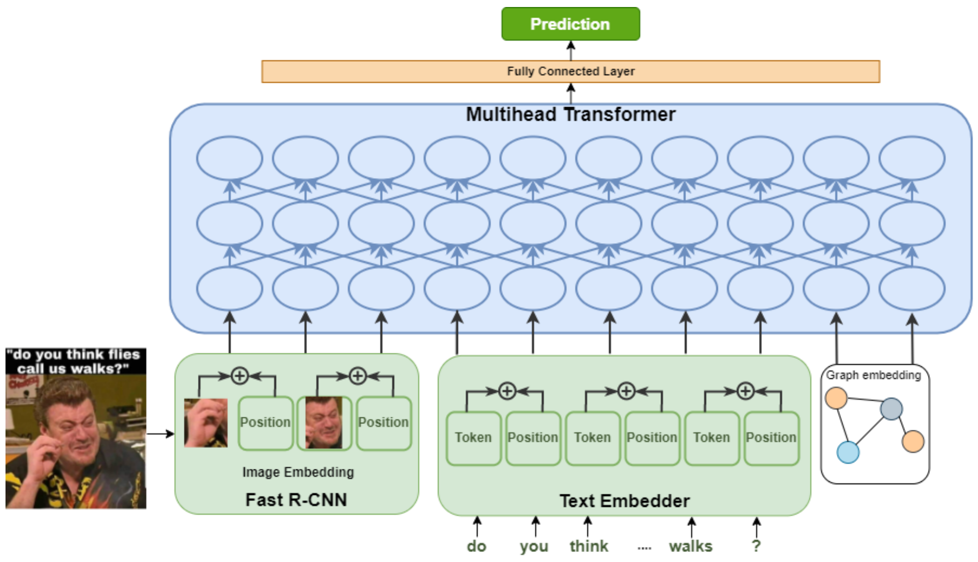

Figure 2: Illustration of the proposed UNITER-VGCN model.

a soft-voting scheme based on the average predicted probability for each label. Additional configurations were trained, but overall this ensemble had the best test performance among our submissions to SemEval-2022 Task 5.

3.1 Experimental Setup

Since the regions of interest (ROI) detection in the R-CNN layer[4] returns the probability for each rectangle, in our experiments, we use the minimum threshold for a ROI to be included in the dataset as an input hyperparameter. We experimented with both versions of UNITER: *UNITER-base* with 12 attention heads and 768 output dimensions, and *UNITER-large* with 24 attention heads and 1024 dimensions[5]. In order to mitigate class imbalance from Sub-task B, we used a weighted binary cross entropy loss using the class distribution in the training set. Other hyperparameter values were determined through grid search. Thus, the minimum confidence level for ROIs was set at 0.7, the learning rate at 1e^{-4} using an AdamW optimizer (Loshchilov and Hutter, 2017), and the maximum text length at 64 tokens. We experiment with GCN embedding sizes between 8 and 32, and selected 16 as the optimum value.

In order to further address the class imbalance between the misogyny sub-types, we experimented with oversampling from the minority classes, as an alternative to the loss re-weighting technique. Also, from our experiments, we learned that using an additional "non-misogynous" class besides the four misogyny types improved the model performance.

During training, we optimize the weighted-average F1-score (i.e., the F1-scores computed for each label, afterwards weighted by the label support) using early-stopping with a patience of 2 epochs.

[5]https://github.com/ChenRocks/UNITER

4 Results

While considering the two proposed data preprocessing techniques, removing the websites from the textual information proved to decrease the performance of the models. Even though removing the source from the texts would provide a better generalization in a production setting, this information turned out to be a clue on misogyny content in this dataset.

Compensating for the unbalanced classes with oversampling from the minority classes proved to be less impactful than weighting the loss of the positive classes. Also, we noticed a strong tendency to overfit during our experiments. A common used mitigation technique is to augment the training data with small variations - e.g., data augmentation using similar words in the embedding space (Wang and Yang, 2015), as well as simpler replacement, swap, and deletion methods (Wei and Zou, 2019). None of the applied augmentation methods improved performance. We thus hypothesize that although these augmentations create similar meanings, innuendos get lost. For example, the phrase *"Her: Excuse me, I'm trying to put a* ***load*** *in the*

	Baseline	65.0%	Baseline	62.1%

Table 4: Comparison for Sub-tasks A and B between the top 3 team results, our scores, and the competition baseline.

dishwasher Him: Same @gogomeme" would get an augmented counterpart *"Her: Excuse me, I'm trying to put a **burdened** in the dishwasher Him: Same @gogomeme"*. Changing the word "load", which in the context has a double meaning, loses the implicit misogynistic comparison of the woman to a dishwasher. Similarly, a text like *"my horny girlfriend on her period me"* augmented as *"my horny girlfriend on her deadline me"* would not improve the training.

Tables 2 and 3 are the best performances on the official competition test set for the models we trained. All modes were trained using the hyperparameters specified in the previous section.

Even though the performance on the binary classification from Sub-task A was comparable with

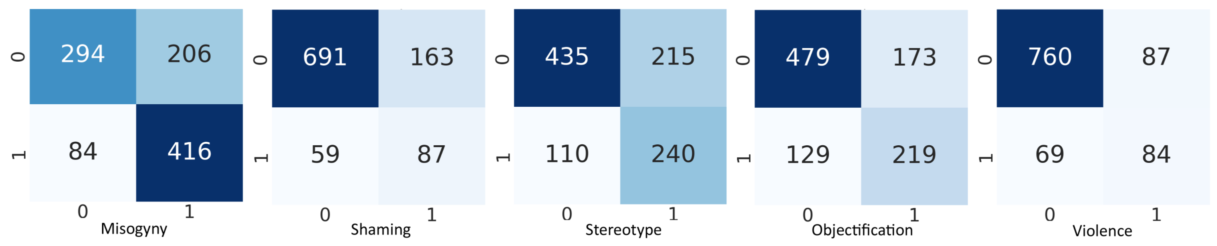

Figure 3: Per class confusion matrices for the ensemble model.

the best single model (UNITER-VGCN), it was slightly lower. As seen in Figure 3, our best system - the ensemble model - has the tendency to over-predict misogyny. Some erroneous predictions were driven by their aggressive language, for instance *"IF YOU'RE DATING MY DAUGHTER AND YOUR STUPID ENOUGH TO DO THIS I'M GOING TO KILL YOU!" depicting also that a domestic abuse victim was understandably detected as misogynous type "violence"*. Records 15566 and 15311 depict a face close up of a famous woman and were incorrectly labeled as misogynous, even if the text is replaced with a neutral or even positive one like "woman" or "best". This can be explained by the off-balance in the training data where the visual object "woman" is detected 2,262 times in the misogynous entries, and only 639 times in non-misogynous memes; similarly, "eyebrows" are four times more likely to appear in the misogynous class. However, memes like *"When you know it's a trap but you can't wait to take the bait"* that depict a woman body are not detected as misogyny since these memes require additional background knowledge in order to understand the real intent.

5 Conclusion

In this paper, we describe the architectures used in our submission at Semeval-2022, Task 5: MAMI - Multimedia Automatic Misogyny Identification. Our proposed models took the pre-trained UNITER-base and UNITER-large models and enhanced them with image sentiment features or, by using a GCN, with additional domain information from an external dataset. Our best model achieved an F1-score of 71.4 for Sub-task A and 67.3 in Sub-task B, seen in Table 4 in comparison to the top three results on each sub-task, arguing that these models can perform reasonable well in a multi-modal setting and that the generalization power of the UNITER pre-trained model was enhanced by integrating image object nodes in the co-occurrence graph. Also, we showed that our ensemble smoothed out the uneven performance caused by different train/dev data splits and improved the overall performance.

In terms of future work, we plan to continue our research into the automatic detection of abusive and hateful online content, and extend the experiments onto other pre-trained multi-modal models, as well as to attempt to improve their performance through task-adaptive pre-training (Gururangan et al., 2020). Even though Internet memes provide an interesting combination of textual message and image, they represent only one medium that can spread toxic messages. Studying other modalities like video or audio would help widen the understanding on how to detect and limit the spread of these undesired messages.

Abstract

This work presents an ensemble system based on various uni-modal and bi-modal model architectures developed for the SemEval 2022 Task 5: MAMI-Multimedia Automatic Misogyny Identification. The challenge organizers provide an English meme dataset to develop and train systems for identifying and classifying misogynous memes. More precisely, the competition is separated into two sub-tasks: sub-task A asks for a binary decision as to whether a meme expresses misogyny, while sub-task B is to classify misogynous memes into the potentially overlapping sub-categories of stereotype, shaming, objectification, and violence. For our submission, we implement a new model fusion network and employ an ensemble learning approach for better performance. With this structure, we achieve a 0.755 macro-average F1-score (11th) in sub-task A and a 0.709 weighted-average F1-score (10th) in sub-task B. [1]

1 Introduction

Hate speech against women remains rampant despite many efforts at education, prevention and blocking. Misogyny takes place online and offline. Especially on social media platforms, misogyny appears in different forms and has serious implications (Chetty and Alathur, 2018). Currently, automated detection and filtering seem to be the most effective way to prevent hate speech online. However, over the past few years, the rising popularity of memes brought misogyny to a new multi-modal form, which may be more likely to go viral due to their often surprising combinations of text and image that may strike viewers as funny and hence, as eminently shareable.

The multi-modality of memes also makes automatic detection more challenging. Some memes express their hatred implicitly or through juxtaposition, so they may even appear harmless when considering the text or the image in isolation. SemEval-5 2022 Multimedia Automatic Misogyny Identification (MAMI) (Fersini et al., 2022) aims to identify and classify English misogynous memes.

In recent years, the Transformer model (Vaswani et al., 2017) has been widely used in natural language processing (NLP) and image processing. Transfer learning (Torrey and Shavlik, 2010) with a pre-trained Transformer model can save training resources and increase efficiency with less training data (Wang et al., 2020).

Therefore, in this work, we consider transfer learning to customize three uni-modal models based on the Transformer model: i) fine-tuning a pre-trained RoBERTa model for classification (BERTC) (Liu et al., 2019); ii) training a graph convolutional attention network (GCAN) using the pre-trained RoBERTa model for word embedding; iii) fine-tuning a pre-trained image model, the Vision Transformer (ViT) (Dosovitskiy et al., 2020). Based on these three uni-modal models, four bi-modal models are trained through our proposed model fusion network, namely BERTC-ViT, GCAN-ViT, BERTC-GCAN, and BERTC-GCAN-ViT. All models are evaluated with 10-fold cross-validation. The macro-average and weighted-average F1-scores are employed as the metrics for the sub-tasks. Ultimately, the ensemble strategy is applied on both the dataset- and the model-level (detailed in Section 3.3) for better performance.

The remainder of the paper is structured as follows: Section 2 introduces the MAMI challenge and related solutions to the task. Our ensemble model is described in Section 3, followed by the experimental setup in Section 4. Finally, our results are shown and conclusions are drawn in Sections 5 and 6.

[1]Code available at: https://github.com/rub-ksv/SemEval-Task5-MAMI.

2 Background

The MAMI dataset contains 10,000 memes as the training and 1,000 memes as the test set; all of these are given together with the text transcription as obtained through optical character recognition (OCR). The reference labels are obtained by manual annotation via a crowdsourcing platform.

The challenge is composed of two sub-tasks: Sub-task A represents a binary classification task and focuses on the identification of misogynous memes, so each meme should be classified as not misogynous (noMis) or misogynous (Mis). Sub-task B, in contrast, presents a multi-label classification task, where the misogynous memes should be grouped further, into four potentially overlapping categories. The dataset class distribution is illustrated in Table 1.

Table 1: MAMI-22 dataset class distribution. **Mis**: misogynous; **Shm**: shaming; **Ste**: stereotype; **Obj**: objectification; **Vio**: violence.

Sets	**Mis**	**Shm**	**Ste**	**Obj**	**Vio**
training set	5000	1274	2810	2202	953
test set	500	146	350	348	153

Since the provided dataset contains two modalities (namely, images and texts), an automated approach requires integrating the information from the images with the textual information. However, the OCR-based transcriptions are quite error prone, while the images are often hard to recognize for automatic systems, due, among other reasons, to overlaid text and to the popularity of further changes, such as the composition of multiple sub-images. Consequently, it is challenging to identify the pertinent information of the respective modalities, in order to merge it into a joint classification decision.

Some researchers have already worked on meme datasets. For example, (Sabat et al., 2019) created a hateful memes database, using the BERT model to extract a contextual text representation and the VGG-16 convolutional neural network (Simonyan and Zisserman, 2014) for image features. Then, text and image representations are concatenated to obtain a multi-modal representation. Facebook also organized a challenge for the identification of hateful memes in 2020 (Kiela et al., 2020). The winner of this challenge adopted an ensemble system with four different visual-linguistic transformer architectures (Zhu, 2020).

The Transformer model has shown excellent performance in many tasks, and it also shows promising results in the above studies, based on its use of the attention mechanism to extract the contextual information within a text. However, its ability to capture global information about the vocabulary of a language remains limited (Lu et al., 2020), and we hypothesize that this is even more of an issue in the task at hand, due to the very short texts in the given challenge.

For this reason, we combine a Transformer model with a graph convolutional network (GCN) (Yao et al., 2019), which may help to address this issue. GCNs can be understood as a generalization of CNNs, where the data has graph structure and locality is defined by the connectivity of the graph. As input, a GCN receives features that connect to a set of nodes. From layer to layer, the features of a node are updated as weighted combinations of its neighbors' features. In our case, the graph is defined as follows: There is a node for every word in the vocabulary and for every document. The collection of nodes is $V = \{D_1, D_2 \cdots D_{n_D}, W_1, W_2, \cdots W_{n_w}\}$, where D_i and W_i indicate the document and word nodes, respectively. n_D is the number of documents and n_W is the number of unique words in the corpus. The edges between word nodes are weighted with the word co-occurrence, the edges between document-word pairs are weighted with the term frequency-inverse document frequency (TF-IDF).

A fixed-size sliding window with step size 1 is used to gather the word co-occurrence information through the entire dataset. The point-wise mutual information (PMI) is employed to measure the relationship between the words i and j as follows:

$$\begin{aligned} \text{PMI}(i,j) &= \log\tfrac{p(i,j)}{p(i)p(j)}, \\ p(i,j) &= \tfrac{N(i,j)}{N}, \\ p(i) &= \tfrac{N(i)}{N}, \end{aligned} \tag{1}$$

where $N(i)$ counts the sliding windows in the training set that contain word i, $N(i,j)$ is the number of sliding windows that carry both words i and j, and N is the total number of sliding windows in the corpus. As described in (Yao et al., 2019), a positive PMI value indicates a high semantic correlation of words in corpus and vice versa.

The adjacency matrix $\boldsymbol{A}$ of the graph is then computed elementwise, as follows:

$$A_{i,j} = \begin{cases} \mathrm{PMI}(i,j) & i,j \text{ are word nodes, } \mathrm{PMI}(i,j) > 0; \\ & n_D < i,j \leqslant n_D + n_W \\ \text{TF-IDF}_{i,j} & \text{document node } i \text{ and word node } j; \\ & i \leqslant n_D; n_D < j \leqslant n_D + n_W \\ 1 & i = j \\ 0 & \text{otherwise} \end{cases} \tag{2}$$

Since the graph is undirected, the adjacency matrix is symmetric. Finally, the adjacency matrix is normalized by $\widetilde{\boldsymbol{A}} = \boldsymbol{D}^{-\frac{1}{2}}\boldsymbol{A}\boldsymbol{D}^{-\frac{1}{2}}$, where $\boldsymbol{D}$ is the degree matrix of $\boldsymbol{A}$. The normalized adjacency matrix $\widetilde{\boldsymbol{A}}$ is used to weight the graph node features, cf. Section 3.1. A PyTorch implementation based on Text-GCN (Yao et al., 2019), as provided on GitHub[2], was used for the implementation.

3 System Overview

In this section, we specify our uni- and bi-modal models.

Figure 1: Uni-modal models, where L_S is the sequence length, which depends on the RoBERTa tokenizer.

Figure 1 depicts the three uni-modal models BERTC (1a), GCAN (1b), and ViT (1c), which form the basis of our further experiments. The bi-modal models are constructed based on trained uni-modal models and our proposed model fusion network, which is further detailed in Section 3.2. Finally, we apply soft and hard voting ensembles on the trained candidate models.

3.1 Uni-modal models

As illustrated in Figure 1, every uni-modal model has two outputs: the classification probabilities $\boldsymbol{p}_{\text{i}}$ and the classification features $\mathbf{f}_{\text{i}}$. All classifier blocks in our models have the following, identical structure: a fully connected layer reduces the feature dimension to half the input dimension, followed by a ReLU activation and a dropout layer. Ultimately, an output layer projects the features to the output dimension n, and a sigmoid function squashes the range of the output vector components to $(0, 1)$, allowing for an interpretation as a vector of label probabilities, with possible overlap in categories.

BERTC: We fine-tune a pre-trained large RoBERTa language model (`roberta-large`) for classification. The text input is encoded by the RoBERTa model with the embedding dimension 1024. The Pooler layer returns the first classification token `[cls]` embedding $\mathbf{f}_{\text{BERTC}}$ and feeds it into the classifier to obtain the probabilities $\boldsymbol{p}_{\text{BERTC}}$.

GCAN: Again, a pre-trained RoBERTa model extracts contextual text information. Each token is considered as a word node and each meme is a document node. Thus the word node representation is given by the corresponding RoBERTa word embedding vector. We denote the input embedding sequence of document k as $\boldsymbol{x}^k = [\boldsymbol{x}_1^k, \boldsymbol{x}_2^k, \cdots \boldsymbol{x}_{\mathrm{L}_S}^k]$, where $\boldsymbol{x}_i^k$, $i \in \{1, \ldots, \mathrm{L}_S\}$ is a 1024-dimensional embedding vector of the i-th token. As depicted in Figure 1b, $\boldsymbol{x}^k$ is an $\mathrm{L}_S\times1024$ matrix. The first classification token `[cls]` embedding represents the document classification information. Thus, we use the document-word co-occurrence information TF-IDF as the edge weights for the `[cls]` embedding. All other token embeddings are weighted with the word co-occurrence information PMI.

For each document k, we extract its specific adjacency matrix $\widetilde{\boldsymbol{A}}_k$ from the complete adjacency matrix $\widetilde{\boldsymbol{A}}$ by reducing it to rows and columns of all the document and word nodes (i and j in Equation 2) that are present in this document. The extracted document adjacency matrix $\widetilde{\boldsymbol{A}}_k$ is an $\mathrm{L}_S \times \mathrm{L}_S$ matrix.

The GCAN block in Figure 1b adopts the multi-head self-attention mechanism in 3 successive GCAN layers to embed the node representations. The queries $\mathbf{Q}$, keys $\mathbf{K}$ and values $\mathbf{V}$ are identical and set to the respective layer input. The first layer input is given by the RoBERTa word embeddings $\boldsymbol{x}^k$ of the input text. The attention of head j is obtained by

[2]https://github.com/codeKgu/Text-GCN

$$\boldsymbol{\alpha}_j = \text{softmax}\left(\frac{\left(\mathbf{W}_j^Q\mathbf{Q}^T\right)^T\left(\mathbf{W}_j^K\mathbf{K}^T\right)}{\sqrt{d_k}}\right)\left(\mathbf{W}_j^V\mathbf{V}^T\right)^T \tag{3}$$

where $\mathbf{W}_j^*$ are learned parameters for the queries $\mathbf{Q}$, keys $\mathbf{K}$, and values $\mathbf{V}$, respectively. A superscript T denotes the transpose; $d_k = \frac{d_{att}}{h}$, d_{att} is the attention dimension and h is the number of attention heads. Having computed the multi-head self-attention, each attention head output is multiplied by the document adjacency matrix $\widetilde{\boldsymbol{A}}_k$

$$\widetilde{\boldsymbol{\alpha}}_j = \widetilde{\boldsymbol{A}}_k\boldsymbol{\alpha}_j. \tag{4}$$

Equation 5 describes the output $\boldsymbol{\alpha}$ of the GCAN layer: The weighted outcomes all heads are concatenated (concat), and a fully connected layer (FC) projects the representation to the attention dimension. Inspired by (Veličković et al., 2017), instead of concatenating the weighted attention head outputs, we employ averaging (avg) to fuse these weighted outputs in the last GCAN layer. A fully connected layer again projects the final representation to the attention dimension. Thus, after the GCAN block, the text representation is still an $\text{L}_S \times 1024$ matrix. The document classification feature vector $\mathbf{f}_{\text{GCAN}}$ is obtained by summing all node representations.

$$\boldsymbol{\alpha} = \begin{cases} \text{FC}\left(\text{concat}\left(\widetilde{\boldsymbol{\alpha}}_1, \cdots \widetilde{\boldsymbol{\alpha}}_h\right)\right) & \text{not in last layer} \\ \text{FC}\left(\text{avg}\left(\widetilde{\boldsymbol{\alpha}}_1, \cdots \widetilde{\boldsymbol{\alpha}}_h\right)\right) & \text{in last layer} \end{cases} \tag{5}$$

ViT: To extract the visual contextual information, we utilize the pre-trained ViT model `vit-large-patch16-224` to encode the input image. For this purpose, the input image is split into fixed-size patches, and a linear projection of the flattened patches is used to obtain the patch embedding vectors. The Transformer encoder transforms the embedding vectors. Finally, the embedding $\mathbf{f}_{\text{ViT}}$ of the first classification token, `[cls]`, is fed to the classifier to obtain the prediction probabilities $\boldsymbol{p}_{\text{ViT}}$.

3.2 Bi-modal models

Figure 2 shows our fusion model structure.

Each model M_i has two outputs: the vector of its classification probabilities $\boldsymbol{p}_i$ and the classification features $\mathbf{f}_i$. We concatenate the model classification probabilities and features as a multi-modal representation to make the final decision.

Two fusion strategies—stream-weighting-based decision fusion and representation fusion—are considered. The weight predictor and the classifier in

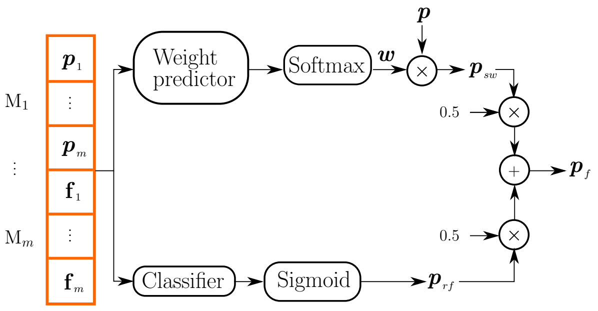

Figure 2: Fusion model structure

Figure 2 both have the same structure as the classifier block in Figure 1. The weight predictor output dimension is the number m of candidate models for fusion. The stream weighting probability $\boldsymbol{p}_{sw}$ is obtained through a weighted combination of the class probability vectors of all uni-modal model outcome probabilities, i.e.

$$\boldsymbol{p}_{sw} = \sum_i \boldsymbol{p}_i \cdot w_i. \tag{6}$$

The classifier output dimension is the same as the number of classes n. A sigmoid function computes the representation fusion probabilities $\boldsymbol{p}_{rf}$ from the combined multi-modal representation. Finally, we average the stream weighting and the representation fusion probabilities. The following model combinations are attempted, where M_i, $i \in \{1, 2, 3\}$ is the i-th pre-trained uni-modal model.

Bi-modal model	M_1	M_2	M_3
BERTC-ViT	BERTC	ViT	-
GCAN-ViT	GCAN	ViT	-
BERTC-GCAN	BERTC	GCAN	-
BERTC-GCAN-ViT	BERTC	GCAN	ViT

3.3 Ensemble learning

Having established a number of possible uni-modal and bi-modal models, we now combine these trained models into ensembles. It has been reported in many studies that ensemble learning can enhance performance in comparison to single learners (Onan et al., 2016; Zhu, 2020; Gomes et al., 2017). Therefore, we consider soft and hard voting ensemble approaches.

We use the Python `sklearn` package[3] for 10-fold cross-validation. Thus, each model structure

[3]`https://github.com/scikit-learn/scikit-learn`

was trained ten times with different inner test sets. Finally, these ten models are used to evaluate the official test set and deliver ten predictions for every sample. The soft voting ensemble method is implemented as follows: $\boldsymbol{p}_{\mathrm{M}_i}$, the ensemble probabilities that are used in the overall class decisions, are computed via

$$\boldsymbol{p}_{\mathrm{M}_i} = \sum_{j=0}^{9} w^j_{\mathrm{M}_i} \cdot \boldsymbol{p}^j_{\mathrm{M}_i}. \tag{7}$$

Here, $\boldsymbol{p}^j_{\mathrm{M}_i}$ denotes the probabilities of model M_i in the j-th fold. The weights $w^j_{\mathrm{M}_i}$ are computed by

$$w^j_{\mathrm{M}_i} = \frac{\mathrm{F1}^j_{\mathrm{M}_i}}{\sum_f \mathrm{F1}^f_{\mathrm{M}_i}}. \tag{8}$$

$\mathrm{F1}^j_{\mathrm{M}_i}$ corresponds with the best F1-score of model M_i over all epochs, computed on the inner test set in fold j. This soft voting ensemble, using the same model structure, but with the multiple outcomes from 10-fold cross-validation, is referred to as a *dataset-level ensemble* in the following.

The second type of ensemble—the *model-level ensemble*—is constructed from the *dataset-level ensemble* results of each model. We use a hard voting strategy with seven candidate models (BERTC, GCAN, ViT, BERTC-ViT, GCAN-ViT, BERTC-GCAN, and BERTC-GCAN-ViT). In this approach, we set the final prediction for a data point to one, if at least half of the considered models vote one, making it a simple majority-voting strategy.

4 Experimental Setup

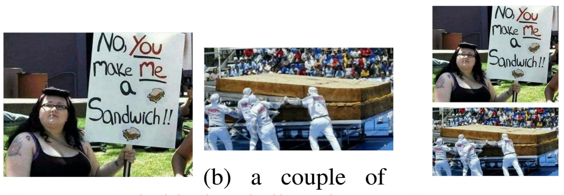
In the following, we describe our data processing and training pipeline in more detail.

4.1 Data pre-processing

The challenge dataset provides a transcription text stream that was obtained via OCR. Via image captioning, we derive a second text stream that contains a description of the image in a few words.

For the OCR text, we first use the Python `ftfy` package[4] to fix the garbled sequences that result from unexpected encodings (the *mojibake*) like "à¶´à¶§à·". Next, all "@", "#" symbols and website addresses are removed from the text. The emojis are converted to text form by the Python `emoji` package[5]. Finally, we remove non-English characters and convert the text to lowercase.

For image captioning, we utilize a pre-trained encoder-decoder attention model (Xu et al., 2016)[6]. Although the translation from image to text is not very accurate, most likely owing to issues like the overlaid meme text, it was nonetheless beneficial for our classification task. We found that the description becomes more precise, when we split the memes into their constituent sub-images where applicable. In that case, the image caption is extracted over every sub-image as well as the entire meme. Finally, the image captions are combined with the word "and" and then concatenated with the OCR text, separated by ". ". With this rule, the final text of the meme in Figure 3 is: "*mgo ci aindo make make me sandwich!!. a couple of baseball players standing next to each other and a woman holding a sign in front of a sign and a woman standing next to a group of people.*"



(a) a woman holding a sign in front of a sign

(b) a couple of baseball players standing next to each other

(c) a woman standing next to a group of people

Figure 3: In (a) and (b), we see "sub-images" and corresponding captions. (c) shows the meme and its caption (when not considering the sub-image structure).

We use the entire meme as the image input for ViT. All memes are first resized to 256×256 and center-cropped to 224×224 dimensions. The ViT model uses all 3 RGB channels, so we retain the RGB structure, thus the input image dimension is 3×224×224. We regularize the entire image database to range 0 to 1, then normalize each individual image to have zero mean and unit variance.

4.2 Loss function

We decided to use the binary cross-entropy (BCE) loss for both subtasks.

Due to the imbalance in the class distributions (see Table 1), in sub-task B, we weighted the class-

[4]https://github.com/rspeer/python-ftfy

[5]https://github.com/carpedm20/emoji

[6]https://github.com/sgrvinod/a-PyTorch-Tutorial-to-Image-Captioning

specific loss terms by their support as follows:

$$w_c = \frac{\frac{\text{NoS}}{\text{NoS}(c)}}{\sum_{c'} \frac{\text{NoS}}{\text{NoS}(c')}}, c \in [\text{Shm}, \text{Ste}, \text{Obj}, \text{Vio}] \quad (9)$$

where NoS is the total number of samples in the training set and NoS(c) represents the number of true instances for class c. The loss is then computed through the weighted combination of the single BCE terms:

$$\mathcal{L}_1 = \sum_c w_c \cdot \text{BCE}(\boldsymbol{p}_c^B, \boldsymbol{y}_c^B). \quad (10)$$

Here, $\boldsymbol{p}_c^B$ represents the system's output probability of class c and $\boldsymbol{y}_c^B$ is the binary ground truth for sub-task B.

Additionally, we employ a teacher forcing loss to connect both subtasks. The idea is that an instance should be identified as misogynous and possibly grouped into sub-categories simultaneously. The teacher forcing loss is defined as:

$$\mathcal{L}_2 = \|\boldsymbol{p}^A - \boldsymbol{y}^A\|, \quad (11)$$

where the system's output probability for sub-task A is determined as:

$$\boldsymbol{p}^A = \max\left(\boldsymbol{p}_{\text{Shm}}^B, \boldsymbol{p}_{\text{Ste}}^B, \boldsymbol{p}_{\text{Obj}}^B, \boldsymbol{p}_{\text{Vio}}^B\right). \quad (12)$$

The final loss is computed by

$$\mathcal{L} = 0.7 \cdot \mathcal{L}_1 + 0.3 \cdot \mathcal{L}_2. \quad (13)$$

4.3 Model training

All models are trained using the PyTorch library (Paszke et al., 2019) for 50 epochs. The AdamW optimizer (Loshchilov and Hutter, 2017) is used for backpropagation, using a linear learning rate scheduler with a warm-up to adapt the learning rate during the first four epochs in the training stage. The dropout rate is 0.5. The RoBERTa model parameters in the BERTC and the GCAN model are optimized separately.

In our GCAN model, the adjacency matrix is computed with a sliding window of length 10. An 8-head self-attention is applied over 3 GCAN layers with an attention dimension of 1024.

For all uni-modal models, the batch size is 16 and the initial learning rate is $2 \cdot 10^{-5}$. The RoBERTa and ViT block parameters in Figure 1 are also fine-tuned. The bi-modal models are trained based on the pre-trained uni-modal models. Here, we choose the batch size as 32, the initial learning rate is $5 \cdot 10^{-6}$. As the RoBERTa and ViT block parameters in Figure 1 are already updated during the uni-modal training stage, we froze these parameters in bi-modal re-training.

To avoid overfitting, we adopt early stopping to exit the training process when the computed F1-score on the inner test set does not increase over 4 epochs. Inspired by (Huang et al., 2017), we finally averaged those two epoch-wise model parameters, which had the highest validation F1-score during the training stage.

The models have the same structure for sub-tasks A and B. The only differences are that in sub-task A, the classifier output dimension n is 1, and the BCE is used as the loss function (*Setup A*), whereas in sub-task B, the classifier output dimension n equals 4 and training uses the weighted BCE with teacher forcing (Equation 13) as the loss function (*Setup B*). All models are trained using NVIDIA's Volta-based DGX-1 multi-GPU system, using 3 Tesla V100 GPUs with 32 GB memory each.

5 Results

In summary, we investigated two configurations, displayed in Table 2. *Setup A* represents the binary classification for sub-task A, resulting in an output dimension $n = 1$. *Setup B* additionally deals with the multi-label classification of sub-task B, returning an output of dimension $n = 4$. All results are evaluated on the official test set.

Setup	**Task**	**Dimension**	**Loss**
Setup A	sub-task A	$n = 1$	BCE
Setup B	sub-tasks A/B	$n = 4$	Weighted BCE & Teacher Forcing

Table 2: Summary of the considered configurations.

5.1 Results for *Setup A* (Sub-task A)

In the first stage, we trained three different uni-modal models (i.e., BERTC, GCAN, and ViT). In the second stage, we optimized the bi-modal models (i.e., BERTC-ViT, GCAN-ViT, BERTC-GCAN, and BERTC-GCAN-ViT). The evaluation results in terms of the macro-average F1-score are displayed in Figure 4 and Table 3, showing the performance in identifying misogynous memes. To assess the statistical significance of performance differences, we applied a 10-fold cross validation and computed the Mann-Whitney-U test (Mann and Whitney, 1947).

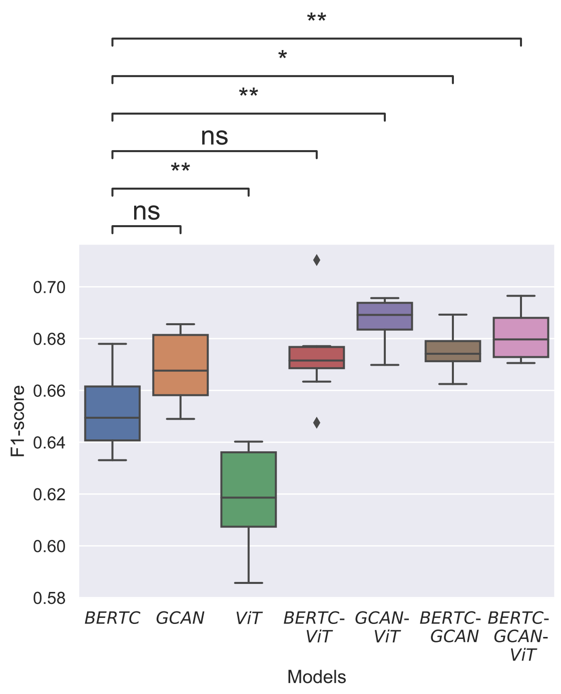


Figure 4: Macro-average F1-scores for sub-task A based on 10-fold cross validation. Asterisks indicate a statistically significant difference, where ** denotes 1e-04 < p <= 1e-03, * corresponds to 1e-02 < p <= 5e-02, and ns indicates results where p > 5e-02.

As we can see, the text-only models (BERTC and GCAN) generally show a superior performance compared to the image-only model (ViT). The results in Figure 4 clearly indicate robust performance for our bi-modal models. They are more accurate and robust. In summary, the GCAN-ViT model yields the best results w.r.t. the reported median F1-score.

Model	Ensemble	Model	Ensemble
BERTC	0.663	GCAN-ViT	**0.707**
GCAN	0.674	BERTC-GCAN	0.677
ViT	0.619	BERTC-GCAN-ViT	0.689
BERTC-ViT	0.697	-	-

Table 3: Macro-average F1-scores of soft voting ensembles for sub-task A.

Table 3 lists the averaged F1-scores for soft voting ensembles, obtained by combining all learned models from the 10-fold cross-validations. The results show that our GCAN-ViT model outperforms all other models, achieving an F1-score of 0.707.

5.2 Results for *Setup B* (Sub-tasks A/B)

Next, we addressed sub-task B, i.e. to classify the misogynous memes into four, potentially overlapping, categories. Similar to *Setup A*, we trained the same uni- and bi-modal models, but incorporating a different loss (see Table 2). For sub-task B, the weighted-average F1-score is applied. The results are presented in Figure 5.

Interestingly, the models optimized for sub-task B also perform better for sub-task A. In this case, we set the estimated label "misogynous" to 1 if at least one of the labels for "shaming", "stereotype", "objectification", or "violence" is 1.

Figure 5a depicts the sub-task A results while Figure 5b shows the corresponding performance for sub-task B. Again, we see that the bi-modal model GCAN-ViT outperforms all other models.

In addition, Tables 4 and 5 show the results for soft and hard voting ensembles. By comparing Table 4 with Table 3 (both tables represent soft voting results), we observe significantly improved F1-scores for *Setup B*.

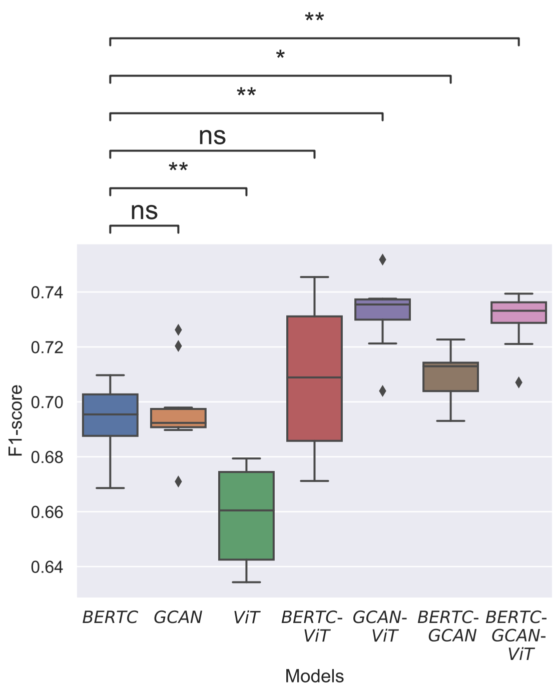
Model	Sub-task A	Sub-task B
BERTC	0.714	0.684
GCAN	0.725	0.695
ViT	0.666	0.641
BERTC-ViT	0.746	0.692
GCAN-ViT	**0.758**	**0.704**
BERTC-GCAN	0.724	0.696
BERTC-GCAN-ViT	0.755	0.704

Table 4: F1-scores of soft voting ensembles for *Setup B* (sub-tasks A and B).

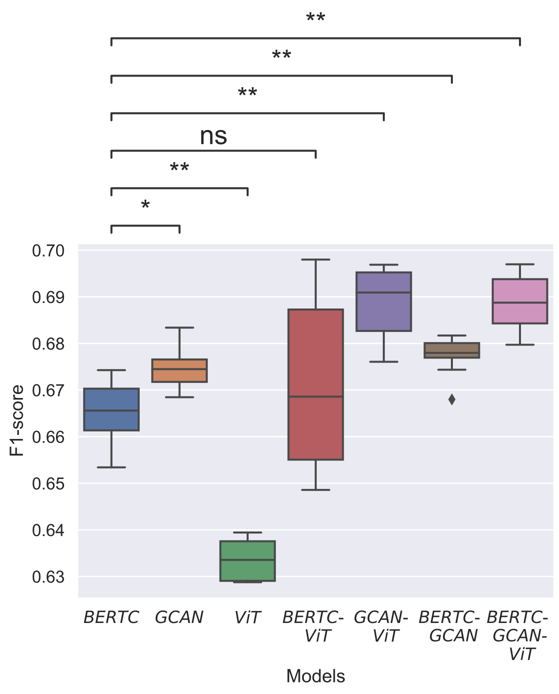
Combination	Sub-task A	Sub-task B
Three uni-modal models	0.728	0.698
Four bi-modal models	0.752	**0.709**
All seven models	**0.755**	0.706
Oracle model combination	0.762	0.716

Table 5: Model-level hard voting ensemble performance with *Setup B* for sub-task A and B.

As a last experiment, we applied hard voting on the ensembles. Again, sub-task A results are derived from sub-task B.



(a) Results for sub-task A.



(b) Results for sub-task B.

Figure 5: Performance for *Setup B*. The notation is defined in Figure 4.

Table 5 shows the results of different combinations. Generally, the combination of the four bi-modal models in the 2nd row outperforms a combination of three uni-modal models in the 1st row. If we combine all uni- and bi-modal models (3rd row), the F1-score is 0.755 for sub-task A, and 0.706 for sub-task B.

The results in bold print represent our submitted approaches for both sub-tasks, showing an F1-score of 0.755 for sub-task A and 0.709 for sub-task B.

After the challenge ended, we again evaluated all possible subset combinations of the seven candidate models. The followed combinations give the best achievable results by knowing the official test set reference labels: ViT, BERTC-GCAN-ViT, BERTC-ViT, GCAN-ViT achieves an F1-score of 0.762 for sub-task A, while an ensemble consisting of BERTC-ViT and BERTC-GCAN-ViT yields an F1-score 0.716 on sub-task B. These results are shown for comparison in the final row of Table 5 as oracle results.

6 Conclusion

This paper presents our ensemble-based approach to address two sub-tasks of the SemEval-2022 MAMI competition. The challenge aims to identify misogynous memes and classify them into—potentially overlapping—categories. We train different text models, an image model, and via our proposed fusion network, we combine these in a number of different bi-modal models.

Among the uni-modal systems, all text models show a far better performance than the image model. As expected, our proposed graph convolutional attention network (GCAN), which also considers the graph structure of the input data while using pre-trained RoBERTa word embeddings as node features, consistently outperforms the pre-trained RoBERTa model.

The proposed fusion network further improves the performance by combining the ideas of stream-weighting and representation fusion. We additionally adopt 10-fold cross-validation and use a dataset-level soft voting ensemble to obtain better and more robust results. Finally, our model-level hard voting ensemble integrates the soft voting ensemble predictions of our best uni- and bi-modal models. Our experiments indicate that this layered ensemble approach can significantly improve the model accuracy. Ultimately, our submitted system results in an F1-score of 0.755 for sub-task A and 0.709 for sub-task B.

Overall, we believe that the identification of misogyny in memes is best addressed through bi-modal recognition, considering both textual and image information. Concerning the text-based classification, we found a graph convolutional attention neural network to be beneficial as an integrative model for Transformer embeddings. This helps in the text classification, when the documents are short, as for the given meme classification task.

To cope with the bi-modality of the task at hand, we have implemented a range of systems for integrating the information from both streams. An idea that proved to be effective here was that of bringing together the strengths of early fusion and decision fusion in a joint framework. This allowed us to dynamically adjust the contributions of the two modalities through dynamic stream weighting, while still being able to combine information at the feature level across the streams, thanks to the representation fusion branch of our bi-modal systems.

Abstract

Detecting MEME images to be misogynous or not is an application useful on curbing online hateful information against women. In the SemEval-2022 Multimedia Automatic Misogyny Identification (MAMI) challenge, we designed a system using two simple but effective principles. First, we leverage on recently emerging Transformer models pre-trained (mostly in a self-supervised learning way) on massive data sets to obtain very effective visual (V) and language (L) features. In particular, we used the CLIP (Radford et al., 2021) model provided by OpenAI to obtain coherent V and L features and then simply used a logistic regression model to make binary predictions. Second, we emphasized more on data rather than tweaking models by following the data-centric AI principle. These principles were proven to be useful and our final macro-F1 is 0.778 for the MAMI task A and ranked the third place among participant teams.

1 Introduction

Systematic inequality and discrimination to women does not appear offline but also in online communication. MEME is an image characterized by a visual content with an overlaying text added MEME creators. Although most of MEMEs are created with the intention of making funny jokes, some of MEMEs are created as a form against women. Therefore, identifying misogynous MEMEs is important for curbing such misuse.

In the SemEval-2022, the task 5, Multimedia Automatic Misogyny Identification (MAMI) (Fersini et al., 2022), was organized for this purpose. The challenge consists of two sub-tasks, including the task A, which is determining a MEME be misogynous or not, and the task B which distinguishes non-misogynous and 4 overlapped misogyny subtypes.

*Equal contributor

We participated in the MAMI challenge and focused on the task A. Our solutions focused on exploring various pre-trained Transformer models for extracting textual and visual features and utilizing a simple logistic regression (LR) model to make binary predictions. In addition, following a new trend in AI research, which is relying on the power provided by data more, i.e., data-centric AI (Ng, 2021b,a), we expanded available training data by manually marking more samples from the evaluation set. As a result, by jointly utilizing these methods, our team ended up on obtaining the third rank in the task A.

2 Related work

Automatic Misogyny Identification (AMI) has become an active research topic in natural language processing (NLP). For example, in the IberEval-2018, the AMI task was introduced as a new task (Fersini et al., 2018). The task consists of the three sub-tasks, i.e., misogyny identification, misogynistic behavior categorization, and target classification. The misogyny related annotations are made on both Spanish and English tweets. Among 11 different teams from 5 countries, (Pamungkas et al., 2018) ranked first in the misogyny identification task on both languages. It proposed an SVM-based architecture and explored several sets of features, including lexical features relying on the lexicon of abusive words.

Another AMI challenge (Fersini et al., 2020) was organized at the Evalita-2020 evaluation campaign and used Italian tweets. Its sub-task A is about misogyny and aggressiveness identification (4 class labels). A total 8 teams from 6 different countries participated in the challenge. Though a few teams used traditional word embedding to be textual features, most of the participants explored richer sentence embedding such as BERT (Devlin et al., 2019) or Roberta. Regarding modeling, the used methods are diverse, ranging from simple logistic regression (LR), to Convolutional Neural Network (CNN), even to fine-tuning pre-trained models.

Data plays an important role on AMI research development. How to organize misogyny labels is an important research question. (Guest et al., 2021) created a new dataset for tackling online misogyny. Its dataset consists of $6,567$ labels for Reddit posts and comments. A new hierarchical taxonomy has been proposed and a careful training was provided to annotators for obtain high-quality labels.

In the misogyny detection works described above, only textual clues are utilized. In a related topic, detecting hateful speech, image clues have been widely used to better reflect the fact that human communication is naturally multimodal. A Hateful Memes Challenge competition was held at NeurIPS 2020 (Kiela et al., 2020). The task is to classify a meme (i.e., an image and associated texts) to be hateful or not. In the challenge, a set of language-visual pre-trained models, such as UNITER, VILLA, and ERNIE-ViL, have been widely used for extracting semantically coupled textual and visual features. For example, the winning solution utilized four types of VL transformers (Zhu, 2020). The multimodal hateful meme detection prompts more follow-up research. For example, (Zhou et al., 2021) proposes using a triplet-relation network to improve encoding on texts, images, and captions generated on images. The improved encoding helps final prediction performance. (Pramanick et al., 2021) propose MOMENTA (multimodal framework for detecting harmful memes and their targets) that uses both global and local perspective to detect all kind of hateful memes. In addition, this framework can be easily explainable and can generalize to unseen contexts.

3 Task and Data

The MAMI challenge consists of the two sub-tasks. The task A is a binary classification task on identifying a MEME to be misogynous (labeled as 1) or not (labeled as 0). The task B is a multi-label classification task on identifying a MEME to be non-misogynous or misogyny sub-types that can be overlapped, i.e., *shaming, stereotype, objectification, and violence*. Table 1 reports on counts of 0/1 labels on the five types of labels. Note that on the misogyny label that is the task A's prediction goal, half of MEMEs in the training data are misogynous ($label = 1$). Among four types of misogyny sub-types, we can find that their distributions are not balanced. For example, most frequent sub-type is stereotype with 2810 positive MEMEs while the least frequent label is the violence with only 953 positive MEMEs. For the task A, the evaluation metric is macro-F1. For the task B, the evaluation metric is micro-F1 among five sub-types.

4 Methods

Regarding extracting features from MEME posts' text and image parts, we chose using pre-trained Transformer models to utilize their highly effective feature representations. On texts, we considered two ways, including fine-tuning BERT (Devlin et al., 2019) model and using sentence representations based on BERT, such as Universal Sentence Encoding (USE) embedding (Cer et al., 2018) and SBERT (Reimers and Gurevych, 2019). A major difference between these two ways is that pre-trained BERT model weights are updated in the fine-tuning process. In a contrast, when using USE or SBERT embedding features, these pre-trained models are kept intact.

Regarding the visual encoder processing MEME images to visual representations, we chose a newly emerging Transformer model similar to the BERT model on texts. In recent years, Transformer based visual models have become popular (Han et al., 2020). Among the many visual Transformer models, we selected the ViT model (Dosovitskiy et al., 2020), which is a pure Transformer that is applied directly on an image's $P \times P$ patch sequence. In the implementation, it follows the original Transformer's design as much as possible. ViT utilizes the standard Transformer's encoder part as an image classification feature extractor and adds a MLP head to determine the image labels. The ViT model is pre-trained using a supervised learning task on a massive image data set. The size of the supervised training data set impacts ViT performance significantly. When using Google's in-house JFT 300M image set, ViT can reach a performance superior to other competitive ResNet (He et al., 2016) models. We used the open-sourced pre-trained models on the ImageNet 21K dataset.[1] After converting a MEME image to $P \times P$ patches, ViT converts these patches to visual tokens. After adding a special [CLS] visual token to represent the en-

tire image, the $M = P \times P + 1$ long sequence is fed into a ViT model to output an encoding as $\mathbf{v} = (v_0, v_1, v_2, ...v_M)$, where $M = P \times P$.

CLIP model (Radford et al., 2021) is a seminal work from OpenAI. As shown in Figure 1, on a massive set of image-text pairs, about 350 million, CLIP can pre-train a quite powerful vision-language (VL) joint model by using a simple cross-modal contrastive learning. The trained model shows many impressive applications, like superior performance on many zero-shot image classification tasks. Note that the advantage of using the CLIP model is that the extracted visual and language features have been mapped into a unified embedding space. This will facilitate the next step that combines the two types of features (V for visual features and L for language features) and then uses a simple LR model for predicting misogyny.

After obtaining visual (V) and language (L) features, one solution could be using sophisticated multimodal fusion methods as shown in (Chou et al., 2020) to consider inter-actions between the two types of features. However, after our pilot experiments, we did not find noticeable gains by using such advanced fusion methods compared to the simple *early fusion*, i.e., simply concatenating both V and L features. Therefore, we focused on utilizing the early fusion method in this challenge. Figure 2 depicts our proposed model. The image and text part of a MEME post are sent into the CLIP model to extract both V and L features. Then, the V and L features are combined and fed into a LR model to make a binary prediction on misogyny.

Besides the LR model, we also considered another novel way, DeepInsight (Sharma et al., 2019) that is suggested recently. People were impressed by Convolution Neural Network (CNN) on its universal ability on extracting useful image features. Therefore, DeepInsight was proposed for converting a tabular feature vector into a 2D image and using a CNN model to do classification. On some tasks, such method shows its effectiveness on extracting features from complicate tabular data. In

Model	macro F1

USE embedding + LR	0.671
ViT fine-tuning	0.633
visualBERT fine-tuning	0.642
USE,ViT + LR	0.720
CLIP VL features + LR	0.765

Table 2: Macro-F1 on misogyny detection from various models that are based on using pre-trained Transformer models to extract features.

addition, a set of techniques that have shown to be useful for improving image classification performance, such as data augmentation in the training stage, i.e., mix-up (Zhang et al., 2017), or in inference stage, testing time augmentation (TTA), are already developed on the image classification task and can be easily applied.

In recent years, a new trend in AI research has emerged and it emphasizes the power brought by data sets (Ng, 2021a). On some AI tasks, the performance increase can be achieved by adding a set of labeled samples and sometimes such new data set could be small. In a contrast, performance increases could be hard to achieve when trying different models. For example, in the challenge (Ng, 2021b), all participants were required to solve the problem by only using data-related methods while keeping using one identical model. We also explored this new approach. In this challenge, we explored the data-centric AI approach by manually annotating more samples in the evaluation set. Although we don't have an access to the coding manual used in the MAMI challenge, we checked the training and trial data that were provided with manual labels. After learning the how-to, we annotated a subset of testing samples and then added these labeled samples into our model's training.

Figure 1: CLIP model is pre-trained on a large number of text-image pairs in a contrastive learning way

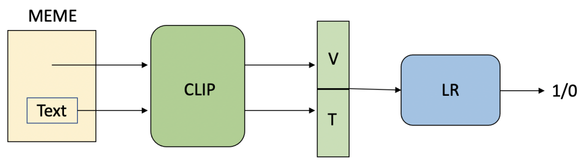

Figure 2: Our model is based on using a logistic regression to detect misogyny by using VL features extracted by the CLIP model

When using BERT fine-tuning, i.e., adding a fully-connected layer on the [CLS] token after BERT model's output layer and fine-tuning two models together by using the cross-entropy (CE) loss, the macro-F1 is 0.608. A different way is obtaining sentence level representations and then feeding these dense features into a LR model implemented in the scikit-learn Python package. We tried both SBERT and USE sentence level representations. This way of using sentence level representations in fact shows improved performance. The macro-F1 can be improved to 0.605 for using the SBERT features and 0.671 for using the USE features.

On image features, we explored ViT model fine-tuning and observed that images play an important role on the misogyny detection. The performance simply using images is 0.633, which is higher than using texts by fine-tuning a BERT model.

Regarding fusing both textual and image features for making a multimodal classification, we tried two methods. The first is fine-tuning a joint Visual-Language (VL) model, visualBERT (Li et al., 2019). However, the performance is not very impressive. Its performance is 0.642, only a slight gain on top of either of uni-modal's performance. The second method is using an *early fusion* by concatenating textual (USE embedding) and image features (ViT embedding) and then fed into a logistic regression (LR) for predicting misogyny. By doing so, the performance can be improved to 0.720.

However, the USE and ViT embeddings are learned from separate models and may not exist in a unified space. To address this issue, We tried the CLIP model for the two attractions, i.e., (1) having coherent textual and visual features in an unified space and (2) image encoder training is on a massive image set with about 350 million images. Consistent to our prediction, after switching to CLIP features, the misogyny prediction's macro-F1 value immediately increased to 0.765.

To explore other possible sophisticated models besides using an LR model, we explored the DeepInsight (Sharma et al., 2019). After converting the dense VL features output from the CLIP model into 2D images, we use a ResNet34 CNN model pre-trained on the ImageNet dataset and converted the misogyny detection into a CNN-based image classification. However, as shown in Table 3, the performance, i.e., 0.751, is worse than using an

Model	macro F1
DeepInsight + CNN	0.751
+ mixup	0.758
+ TTA	0.726

Table 3: Macro-F1 on misogyny detection by using the method converting visual and textual embeddings to 2D images and then using CNN model to do a classification.

Model	macro F1
CLIP VL features + LR	0.765
+ 50 labeled samples	0.767
+ 150 labeled samples	0.772
+ 250 labeled samples.	0.777
using semi-supervised learning	0.778

Table 4: Macro-F1 on misogyny detection by introducing more labeled samples annotated on the test set.

LR model directly. When using the mix-up augmentation, we observed a further performance gain to 0.728. Surprisingly, The TTA method did not show any help. One possible explanation is that we used dense vectors rather than regular tabular data whose feature columns represent some real physical values.

Table 4 reports on the results of utilizing the data-centric AI principle. We can find that by adding increasing number of labeled samples (from the evaluation set), we can keep increasing macro-F1 values. When using labels created by us on 25% of the evaluation set, we can reach a macro-F1 to 0.777. We also used a simple pseudo-label semi-supervised method that is provided by the sci-kit learn Python package and treated all evaluation set ($n = 1,000$) to be unlabeled data. This gave us another small gain to reach our final result of 0.778.

6 Discussions

Multimedia misogyny detection is an important natural language processing application. It uses powerful AI technologies to against misinformation or even harmful information appearing in online communication. For a world emphasizing equal roles between genders, finding misogyny information and removing them is critical for a healthy online communication platform. In this challenge, our methods have been focusing on (a) relying on various pre-trained Transformer models to provide high quality multimodal features and (b) applying the data-centric AI principle to rapidly improve model performances with controllable human efforts. Regarding text encoding, we found that running a simple LR model on top of sentence level representations works consistently better than fine-tuning BERT models. Joint VL model, e.g., visualBERT, does not work quite well in this challenge. However, CLIP, which is trained on a large-sized text-image pair data set in a self-supervised learning approach, can provide high-quality multimodal features and these features can be conveniently used in down-stream classification tasks. On top of highly effective multimodal features, utilizing sophisticated models becomes secondary. In our experiments, simply using an LR model gave us better result than using other complicate models, e.g., DeepInsight. At last, the data-centric AI principle is worth noting. By focusing on our efforts on expanding labeled training data, we can consistently improve our misogyny prediction performance.

Abstract

We describe our system for the SemEval 2022 task on detecting misogynous content in memes. This is a pressing problem and we explore various methods ranging from traditional machine learning to deep learning models such as multimodal transformers. We propose a multimodal BERT architecture that uses information from both image and text. We further incorporate common world knowledge from pretrained CLIP and Urban dictionary. We also provide qualitative analysis to support out model. Our best performing model achieves an F1 score of 0.679 on Task A (Rank 5) and 0.680 on Task B (Rank 13) of the hidden test set. Our code is available at https://github.com/paridhimaheshwari2708/MAMI.

1 Introduction

In this era of the internet, memes have become a new form of communication, which predominantly contain an image and a small caption. While their general purpose is to invoke humour or irony, they are also increasingly being used as a source of harmful, offensive and misogynistic content. Detecting such content in an automated manner is an important problem to avoid the spread of hate.

Memes pose a unique multimodal challenge as their underlying implication is not just a simple combination of the image and text, but a subtle inference that comes naturally to humans. Another complexity is that memes are highly contextual and the component image and text pieces might be completely uncorrelated. Understanding this fusion of modalities is a challenging task for machines. Our aim is to automatically identify misogynistic multimodal memes using machine learning.

2 Related Work

The task of identifying misogyny in memes is a relatively new area and is closely related to hate detection. While there has been a lot of work on identifying hateful content in unimodal data (Gandhi et al., 2019; Fortuna and Nunes, 2018), there is little work on multimodal hate detection. Recently, Facebook Hateful Memes Challenge (Kiela et al., 2020) explored fusion of text and vision models along with advanced architectures like cross-modal BERT (Lu et al., 2019). A major problem with these large pretrained models is the domain gap between memes and training data. Some works try to solve this with better pretraining (Zhu, 2020) and disentangling hate from meme representations (Lee et al., 2021). In this work, we build on these technologies for our specific use-case of misogyny detection and incorporate common world knowledge from Urban Dictionary (Wilson et al., 2020) and CLIP (Radford et al., 2021) to address the domain gap.

3 Method

3.1 Baselines

The task of detecting misogynistic content in memes can be posed as a classification task based on visual and textual features. We start with simple baselines, namely SVM, Naive Bayes and Logistic Regression, and also experiment with *unimodal* feature space, i.e, training classifiers with *text only* and *image only* features. For text only models, we incorporate the TF-IDF technique with bag-of-words concepts to compute features. To capture visual cues from images, we leverage pretrained VGG-16 (Simonyan and Zisserman, 2014) for feature extraction. Since memes are a complex combination of text and image, we require cues from both modalities and we therefore, move towards *multimodal* methods for classification.

3.2 Deep Learning Architectures

We leverage various Deep Learning (DL) techniques for this task. We first start with unimodal techniques, namely LSTM and CNN architectures.

Table 1: Evaluation of various baselines.

For text, we use the GloVe (Pennington et al., 2014) embeddings to initialize individual words and pass this sequence through an LSTM layer. Finally, this embedding is fed to FC layers that outputs a score for each class. For image, we extract the feature representations from a pretrained VGG-16 (Simonyan and Zisserman, 2014) model and pass through a classifier head which is composed of FC layers. All models are trained end-to-end using binary cross entropy loss for every class independently. Note that we do not pose this as softmax classification as each meme can belong to multiple classes simultaneously, i.e., multi-label classification. To handle class imbalance in the dataset, we give more importance to the positive examples. Specifically, we weigh the positive component of the binary cross entropy loss with the ratio of negative to positive occurrences per class.

Since our data is inherently multimodal, we propose advanced DL methods that incorporate both textual and visual features. This is important because memes are complex entities and the fusion of both modalities is necessary to understand the full meaning of the meme (which might not be apparent from a single modality alone). We experiment with the following mulitmodal networks:

1. **CNN + LSTM**: This architecture does a simple late-fusion of the two unimodal designs. We concatenate image and text features and pass through a FC classifier for prediction.
2. **VQA**: There has been significant work in multimodal learning on Visual Question Answering, which requires subtle reasoning around both modalities to answer complex queries. Given similar reasoning in memes, we experiment with the VQA model (Antol et al., 2015). Both image and text (question) features are transformed to a common space and fused via element-wise product, which is then passed to a FC layer to get class scores (answers).
3. **MUTAN**: This model (Ben-Younes et al., 2017) tries to effectively mix and merge information from the two modalities. It uses a multimodal Tucker decomposition to efficiently parametrize bilinear interactions between visual and textual representations. It demonstrates improved performance on the visual question-answering task by learning interpretable embedding spaces.

Recently, Bidirectional Encoder Representations from Transformers (BERT) models (Devlin et al., 2019) trained on large-corpus have proven to provide state-of-the-art results for diverse NLP applications. Given an input sentence, a pretrained BERT model gives a hidden representation for each token in the sentence along a pooled output for the entire sentence. These representations are rich in contextual knowledge and we explore different ways to use this information as follows:

4. **Concat BERT**: The pooled output for text is concatenated with the image feature, and passed through a FC classifier.
5. **Average BERT**: Similar to the previous setting, but the average of the final hidden state is taken as the text feature.
6. **Gated BERT**: The final hidden state is averaged to get text feature. We combine the text and image feature using a Multimodal Gated Layer (Ovalle et al., 2017), which weights relevance of each modality and combines them to output prediction classes.

3.3 Common World Knowledge

Language in memes is informal and often contains slang words. We propose to use the Urban dictionary which is a crowd-sourced repository of common slangs along with their definitions. Particularly, we initialize our constituent words with embeddings pretrained on the Urban Dictionary (Wilson et al., 2020) instead of GloVe vectors. These features perform well on extrinsic tasks such as sentiment analysis and sarcasm detection where some knowledge of colloquial language is required.

Popular vision algorithms (such as VGG-16) are trained on object detection tasks and they require explicit supervision from labels. This limits their usability. More recently, pretraining on image-text matching (Radford et al., 2021) has gained traction by outperforming other methods. Since the images are crawled from the internet, we believe that the distribution captured by CLIP (Radford et al., 2021) are more relevant and representative of the online media today, and hence, more suitable for our task.

3.4 Joint Learning

In the previous sections, we were considering the two tasks independently and training separate models. Given the synergy between the two tasks, we propose a joint learning framework where we use weight sharing between networks to exploit the commonalities and learn improved features. We propose two approaches to achieve this:

1. **Multi-Task Learning**: We start with a multimodal deep network as a shared embedding layer for both modalities, and followed by two different classifier heads, one for each task.
2. **Hierarchical Learning**: We utilize the inherent hierarchy between the two tasks where the second classifier kicks in only when the probability for "misogynous" class from first classifier is greater than 0.5. The model architecture is same as the multi-task setup, but now the second classifier head for finer categorization is only trained on misogynous items.

4 Experiments and Results

4.1 Task and Dataset

We work on the "*Multimedia Automatic Misogyny Identification*" task (Fersini et al., 2022) at SemEval 2022. The problem comprises of two sub-tasks: (i) *Binary Classification* to categorize a given meme as misogynous or not; (ii) *Multi-class Multi-label Classification* to further classify misogynous memes into fine-grained, overlapping categories (shaming, stereotype, objectification, violence). Our dataset consists of 10,000 memes and we partition them into 70% / 20% / 10% for train, validation and test respectively. We only report metrics on this data split as we do not have the ground truth labels for the competition's hidden test set. We measure the performance using these metrics: average accuracy per class, and weighted-average precision, recall and F1 scores where the weights are determined by the support of that class.

4.2 Textual and Visual Cues

Prior work on detecting sexism in memes (Fersini et al., 2019) use specially curated textual and visual cues. We curated the profanity scores for text using a pretrained model on toxic comment classification (Pearson coeff. -0.05), sentiment polarity from Textblob (Pearson coeff. -0.012), and percentage of skin in images (Pearson coeff. 0.125). Thus, many intuitive cues showed no correlation with misogyny, exemplifying the difficulty of our task.

4.3 Baselines

Table 1 presents the baseline results. We extend these linear models to the multi-label setting as a *one-vs-all* task, where separate classifier are trained for each class. We observe the following: (i) Textual models perform better than image only models. (ii) Performance of text + image models is similar to text only methods, implying that TF-IDF vectors are a strong indicator for meme classification.

4.4 Deep Learning Architectures

The results are tabulated in Table 2 and we make the following observations: (i) Using both image and text significantly improves performance over the unimodal variants. We further provide qualitative comparison of unimodal and multimodal methods in Figure 1, which also illustrates the complexity of the task and the subtle relations between the two modalities. (ii) Similar to the baselines, text only methods give better results than image only methods. (iii) BERT-based models show significant improvement in performance for multi-label classification task. (iv) For the multi-class, multi-label classification problem, there is a skewed distribution of positive and negative examples within a class. Hence, performance varies across different classes, as shown in Figure 2. Here, training the

models with weighted cross entropy plays an important role in the precision-recall trade off. Note that F1 score is a better measure than accuracy because of the class imbalance.

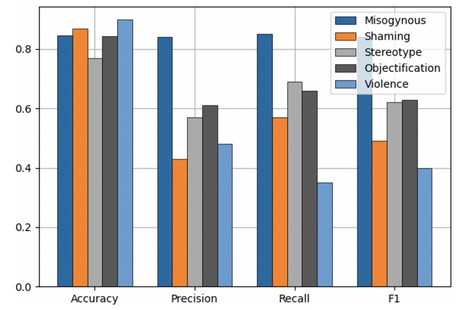

Figure 2: Class-wise performance across metrics.

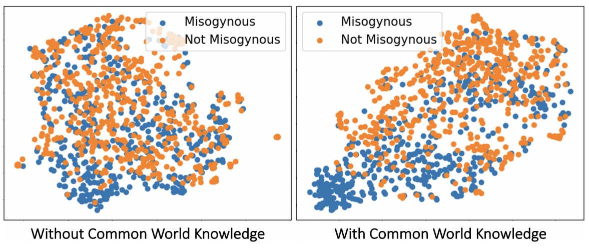

Figure 3: Multimodal features projected into two dimensional space along with misogynous-or-not labels.

4.5 Common World Knowledge

Incorporating Common World Knowledge (CWK) from Urban Dictionary and CLIP provides a substantial boost in performance across all models, and this is because visiolinguistic models are able to learn more discriminative features. To illustrate this, we consider two set of multimodal features (with and without CWK) and run dimensionality reduction using Uniform Manifold Approximation and Projection (McInnes et al., 2018). We visualize the feature space in lesser variables and plot the misogynous-or-not class in Figure 3. It can be seen that the features without CWK are not able to differentiate between the classes, whereas features with CWK result in better separation, and are therefore, more effective for our task. We provide further qualitative evidence in Figure 4.

4.6 Joint Learning

The results for multi-task and hierarchical learning are presented in Table 3. We observe that there is an improvement in the binary classification task, and we reason that the joint learning paradigm provides significantly new information about subclasses from the multi-class setting to the binary task. However, results for the multi-class setting are comparable to the independent models.

5 Conclusion and Future Work

Our work focused on the task of misogyny detection in multimodal memes. We demonstrated that using a combination of visual and textual, i.e, multimodal features outperforms the unimodal counterparts. In addition to simple baselines, we have also experimented with advanced DL architectures inspired from VQA and multimodal transformers. Further, we have shown how incorporating common world knowledge from Urban dictionary and pretrained CLIP can significantly help in identifying misogynistic content, along with qualitative evidence. Finally, the proposed joint learning paradigm can exploit the synergy between the two tasks, instead of training models independently.

Abstract

We present a multi-modal deep learning system for the Multimedia Automatic Misogyny Identification (MAMI) challenge, a SemEval task of identifying and classifying misogynistic messages in online memes. We adapt multi-task learning for the multimodal subtasks of the MAMI challenge to transfer knowledge among the correlated subtasks. We also leverage on ensemble learning for synergistic integration of models individually trained for the subtasks. We finally discuss about errors of the system to provide useful insights for future work.

1 Introduction

Multimodal machine learning processes data from different modalities (e.g. visual, auditory, lingual) to infer their combined meaning. This topic has seen tremendous development, encompassing visual question answering (VQA) (Stanislaw Antol, 2015), image captioning (Chen et al., 2015), multimodal classification and beyond. SemEval 2022 Task 5 "Multimedia Automatic Misogyny Identification" (MAMI) (Fersini et al., 2022) also requires multimodal machine learning to analyze both visual and textual information from memes (image, caption) in order to identify and classify misogynistic memes. The MAMI challenge has the following two subtasks:

- Subtask A: Classification of a meme as either misogynistic or not
- Subtask B: Categorisation of the type of misogyny if the meme is identified as misogynistic in Subtask A. There are 4 types (or sub-categories) of misogyny: shaming, stereotype, objectification and violence

As introduced by a multimodal research survey (Baltrušaitis et al., 2019), data representation, fusion, and co-learning are the primary challenges in multimodal classification problems. To address those challenges, we explore the following relevant topics: data augmentation, multimodal pre-training, multi-task learning and ensemble learning. Data augmentation helps enrich under-represented features in data. Multimodal pre-trained models may represent multimodal data like those of the MAMI challenge better than unimodal pre-trained models. We also adapt multi-task learning to transfer knowledge in training data among related tasks. As the misogyny sub-categories are correlated to each other, this approach is especially useful in Subtask B. Our final predictions are determined by majority voting among the top performing models.

This paper is structured as follows: In Section 2, we describe the task description and dataset. Section 3 explains in details the models and methods we incorporate into the final system architecture. Section 4 discusses the evaluation results of the models and methods, including multi-task learning and ensemble learning. We conduct error analysis in Section 5 and conclude our findings in Section 6.

2 Task Description and Dataset

SemEval 2022 Task 5 "Multimedia Automatic Misogyny Identification" (MAMI) (Fersini et al., 2022) is a classification task that aims at identifying and classifying misogynistic memes in social media. While most memes are funny and harmless, some deliver misogynistic content and have strong, negative influence due to their high speed of spread. Such memes need to be detected and removed from online sites to avoid gender-related hate. In particular, the MAMI task targets memes, each of which is essentially an image characterized by a pictorial content with an overlaying text a posteriori introduced by human, thus a multi-modal (image+text) analytics task.

The MAMI task has two subtasks. In Subtask A, participants must classify memes into misogynistic and non-misogynistic. The evaluation metric is

[*]Corresponding Author

macro-average F1 score. Subtask B is to identify the type of misogyny from the possibly overlapping categories: shaming, stereotype, objectification, and violence if the meme is misogynistic. The evaluation metric is weighted-average F1-Measure, where the F1 scores of the four categories are averaged with weights by support, i.e. the number of true instances for each label.

The training dataset contains 10,000 memes with English captions, assembled from social media platforms. Another 1,000 memes are given as the test dataset. Besides memes in JPEG file format, the task also provides transcriptions of memes captions in a separate text file. Parts of the data are collected and evaluated as described in (Gasparini et al., 2021).

3 Methods

We present a system that utilizes a multi-task learning method to deal with dependencies between the subtasks, fills in the lacking parts of the training dataset by using data augmentation methods, and combines the outputs of multiple base models with ensemble methods.

3.1 Multimodal Base Models

The Hateful Memes Challenge (Kiela et al., 2020b), calling for state-of-the-art models for hate speech detection in multimodal memes, published baseline codes called MMF, which are modular and highly scalable. We thus chose MMF as the codebase of our base models. We extracted 100 features from each meme with the image feature extraction function of MMF and the configurative specifications produced by HateDetectron (Kiela et al., 2020b), the second runner-up of the Hateful Memes Challenge. The feature extractor is backboned by Faster-RCNN (Ren et al., 2015) and ResNet-152 (He et al., 2016).

Below are detailed descriptions of all the base models offered in MMF that we used.

Unimodal (text): We included a unimodal model as a control group. The modality for this model is configurable. After experimentation, we decided to go for text as the single modality for prediction, as it rendered better results than using only images or feature vectors.

ConcatBOW/BERT/MMF: MMF has baseline models for multimodal classification tasks. We obtain text representations from bag-of-word (BOW), BERT, and MMF models and image representations as feature vectors. The "Concat" models concatenate the two representations (text+image) as fusion, and the fusion results are then passed through a Multi-Layer Perceptron (MLP) to output predictions.

LateFusionMMF: The Late fusion model takes the mean between the text and image representations, instead of concatenation.

ViLBERT: Vision-and-Language BERT (ViLBERT) (Lu et al., 2019) is a BERT-based multimodal model pre-trained on the Conceptual Captions (Sharma et al., 2018) dataset, comprising captioned images. It uses two pre-trained strategies: (1) reconstructing image regions or words for masked inputs based on the unmasked portions and (2) prediction of multimodal image-text alignment.

The fundamental difference from the original BERT architecture lies in the attention mechanism, with co-attention used in place of self-attention. By exchanging key-value pairs in multi-headed attention, ViLBERT conducts vision-attended language attention in the visual stream and language-attended vision attention in the linguistic stream. ViLBERT has shown state-of-the-art performance on multiple vision-and-language tasks.

Visual BERT: Like ViLBERT (Li et al., 2019), Visual BERT is another BERT-based multimodal model. It reuses the self-attention system in transformers to implicitly match image regions with texts. The visual embeddings comprise segment embeddings, positional embeddings, and feature vectors of bounding boxes, generated by Faster-RCNN (Ren et al., 2015). They are then fed into the transformer together with text embeddings. With visual and linguistic inputs pre-trained together, the model can discover interesting alignments and implicitly construct effective joint representations.

Visual BERT was pre-trained task-agnostically on the COCO (Chen et al., 2015) dataset for two tasks: masked language modelling and sentence-image prediction. For better adaptation to a particular domain, Visual BERT is usually fine-tuned using masked language modelling on task data before it is applied to downstream tasks.

MMBT: The basic idea of Multimodal Bitransformers (MMBT) (Kiela et al., 2020a) is to apply self-attention to both modalities (i.e. text and image) all at once. This is achieved by utilizing segment embeddings to differentiate between the two modalities, the same method for typical question answering tasks to separate question from paragraph.

A fundamental difference between MMBT and other self-supervised architectures like ViLBERT and VisualBERT is that MMBT only pre-trains individual modalities unimodally. Such design has the plug-and-go advantage if a better vision or language model emerges. It is trivial to replace the pre-trained models for different modalities since they are pre-trained separately. On the other hand, MMBT cannot fully gauge the powerful attention mechanism on multimodal data during pre-training.

3.2 Multi-task Learning

Our baseline models' results (see Section 4) show a significant gap between Subtasks A and B and also uneven performance among the misogynistic sub-categories of Subtask B. This means the models fall short of generalizing the meaning of misogyny. Therefore, we adapted multi-task learning (MTL) to uncover the shared knowledge among all the misogynistic sub-categories.

A MTL learns multiple tasks simultaneously by constructing a generalized representation for the data in different yet related contexts. It is suitable for our dataset since we have five inter-correlated outputs (1 from Subtask A and 4 from Subtask B). To realize multi-task learning, we altered the architecture of the Visual BERT baseline model. While the encoder portion was kept unchanged, we duplicate the classification layer of the decoder into five, each associated with a sigmoid layer for prediction of one of the five outputs. We used binary cross-entropy (BCE) loss combined with Kullback–Leibler divergence loss (KL) as the loss function and summed all the losses generated by individual classification layers. For comparison purpose, we also tried MTL on only the four misogyny types of Subtask B, but the five layers configuration yielded better results.

In fact, we tried to fine-tune Visual BERT on Subtask A first before further fine-tuning it on Subtask B, because we view the misogynistic classification as the main task, and the type categorization task stems from it. Contrary to our expectations, we observed a decrease in model performance. Instead of the misogyny classification inferring the types of misogyny, the results could indicate that the types of misogyny dictate the misogyny classification.

3.3 Data Augmentation

Upon inspection of the validation dataset errors, we found that around 30% of them are blurry or have low resolution, and that about 17% of them express sarcasm against men but are misclassified as misogyny. To address this issue, we created new data by augmenting 10% of the original training set that compare males with females. We augmented them with nine transformations: (1) rotation, (2) Gaussian noise, (3) blurring, (4) horizontal flip, (5) contrast, (6) Affine transformation, (7) distortion, (8) elastic transformation, and (9) change in hue and saturation, with 100 memes per transformation. This boosted the robustness of our model to deal with various data qualities. The data augmentation library we used is *imgaug* (Jung et al., 2020).

3.4 Ensemble Learning

Ensemble learning (Opitz and Maclin, 1999) is an effective method that makes better achievements by combining multiple models' outputs. Taking advantage of the "wisdom of the crowd", an ensemble model can outperform a single contributing model.

Based on our baseline results (see Section 4), all the baseline models except Concat BOW and Unimodal Text have competency on at least one subtask. Thus, the ensemble model pool only excludes the two underperforming models. We experimented with two ensemble strategies, 1) an Multi-layer Perceptron (MLP) and 2) a majority voting layer that averages output probabilities, and compared their results, where both take as input the concatenation of the outputs of the selected baseline models and predict the final outputs per subtask[1].

4 Results

We show the evaluation results of the baseline models, multi-task learning and ensemble methods, and then based on the results, present the overall architecture of the final system we used for our official submission of the MAMI challenge in Section 4.4.

4.1 Baseline comparison

The baseline models serve as the starting point for our experimentation. We trained and evaluated all models included in Section 3.1 individually on all subtasks (misogyny, shaming, stereotype, objectification, violence). Table 1 summarizes the evaluation results.

[1]We refer to the lowercase "subtask" as the misogyny type columns (misogyny, shaming, stereotype, objectification, and violence), in comparison to the capitalized "Subtask" (Subtasks A and B) in the MAMI challenge.

Model	Misogyny	Shaming	Sterotype	Objectification	Violence
Unimodal (text)	80.9%	68.8%	72.2%	74.7%	65.3%
ConcatBOW	74.9%	67.2%	63.5%	73.3%	64.0%
ConcatBERT	**83.7%**	68.0%	71.6%	**77.5%**	**72.0%**
ConcatMMF	**84.4%**	69.6%	**72.7%**	**77.1%**	**74.0%**
Late Fusion	82.8%	**70.9%**	**72.3%**	76.1%	69.1%
ViLBERT	83.4%	69.8%	72.1%	**79.7%**	**75.2%**
VisualBERT	**84.4%**	**72.0%**	**73.8%**	75.5%	71.5%
MMBT	82.3%	**71.4%**	70.9%	73.6%	67.2%

Table 1: Baseline performance evaluated on the validation set. Scores in this table are macro-averaged F1-scores. The best **three** performance for each subtask are highlighted in bold.

Since there was no noticeable change in model performance after we tuned the hyperparameters, we set them as fixed values specified as follows: Enabled early stopping, learning rate of 2e-05, epsilon of 1e-05, batch size of 16, learning rate ratio of 0.6, and warm-up steps of 500.

As seen in Table 1, model performance varies significantly from task to task. Among all the subtasks, Shaming and Violence are the hardest to learn, carrying a non-negligible difference of more than 10% from the Misogyny subtask. This difference in performance will be addressed in the next section.

An interesting note is that early fusion (Snoek et al., 2005) models like Visual BERT are comparable to late fusion (Gunes and Piccardi, 2005) models such as Concat BERT and MMBT. Based on this finding, modal correlations may be picked up at both the decision level as well as the low-dimensional feature level, although the learnt correlations could be different.

Concat BOW performs the worst since it uses simple bags of words as text representation. Its performance is even worse than the unimodal text model. All other multimodal models achieved better results than the unimodal model, showing the involvement of visual information contributes to the overall understanding of the meme contents. We selected the best three models for each subtask for later experiments.

4.2 Multi-task learning evaluation

The alteration of Visual BERT for multi-task learning resulted in an overall advancement of 2.6% for Subtask B and a slight improvement of 1.3% for Subtask A. We also explored different specifications of the classification layers, adjusting the number of hidden layers and activation functions. However, none of them showed significant influence on model's performance.

Method	Subtask A	Subtask B
Top-3 models + MLP	**71.6%**	68.2%
Top-3 models + majority voting	66.1%	**69.5%**
Top-6 models + MLP	70.2%	67.9%
Top-6 models + majority voting	67.4%	69.2%

Table 2: Performance comparison between ensemble learning methods. Scores in this table are of the metrics used for Subtasks A and B, and evaluated on the test set.

4.3 Ensemble evaluation

Table 2 summarizes the evaluation results of two ensemble methods (MLP, majority voting) with the top-*k* models (*k*=3,6)[2]. For each subtask, the top-3 models used are highlighted in bold face in Table 1, and all models except Concat BOW and Unimodal Text are selected as the top-6 models. Refer to Table 1 for the top-3 models selected for each subtask.

The evaluation results of the ensemble methods do not identify a single best method. The majority voting with top-3 models shows the best performance for Subtask B, while MLP is the best for Subtask A. Based on these mixed results, we select different models and ensemble methods for the two Subtasks A and B, which is illustrated in the next section.

4.4 Overall system architecture and evaluation

After considering the evaluation results above, we selected the following three models as parts of the final system architecture:

[2]We refer to the lowercase "subtask" as the misogyny type columns (misogyny, shaming, stereotype, objectification, and violence), in comparison to the capitalized "Subtask" (Subtasks A and B) in the MAMI challenge.

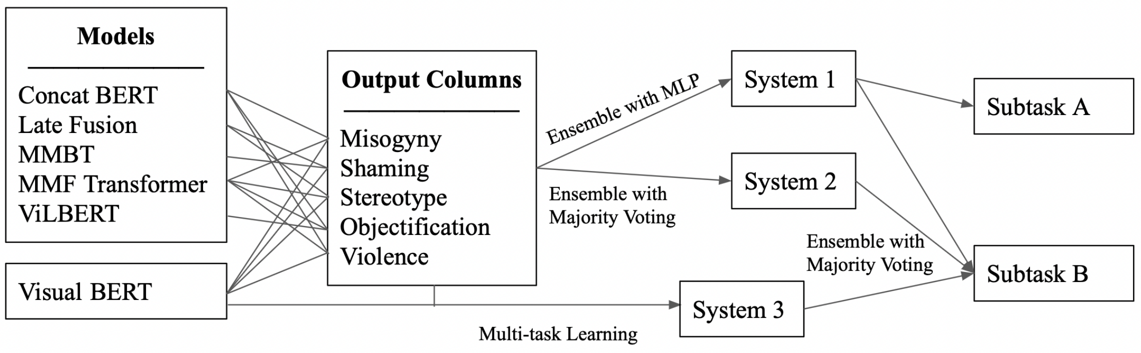

Figure 1: The high-level architecture of the multimodal multitask learning and ensemble learning framework

1. A Visual BERT based multi-task learning model
2. An ensemble learning model that feeds the output probabilities from the top-3 models individually trained on each subtask to a Multilayer Perceptron (MLP)
3. An ensemble learning model that does majority voting among the top-3 models individually trained on each subtask

In Subtask B, results are generated by applying yet another majority voting layer to these three models. In Subtask A, results are directly taken from the outputs of the ensemble model with MLP (the second model on the list), since we found applying majority voting to Subtask A produced suboptimal results. During the evaluation phase of the competition, we achieved 71.6% in Subtask A and 70.6% in Subtask B, ranked 4th and 6th on the leaderboard, respectively. Figure 1 illustrates how the models are integrated into the final system architecture.

5 Error Analysis

5.1 Analysis on Subtask A

Despite the competitiveness of our system, it still misinterprets the misogyny of some memes in Subtask A. A deeper examination reveals the most common error clusters as discussed below.

First, memes often include references to news, celebrities and cultural practices, e.g. those containing members of "the squad" in the 2019 US House election. This issue may be addressed by detecting entities in memes and collecting their details from the Web to better represent the entities.

Second, the current system falls short of extracting meaning from text positions in memes and the order of sentences (e.g. four-frame mangas). This issue may be addressed by correcting the sentence order and learning their alignment to meme frames.

Third, memes of anti-violence propaganda are often misclassified into the violence category since they include violent-looking images, while the caption is about fighting against violence. In contrast, other misogynistic memes portray violent acts against women in the caption and praise their actions in the image, e.g. with a thumbs-up icon or trophies.

Fourth, memes about comparison between men and women are often confusing. We noticed that these memes either mock males by comparing them to females or describe the real difference between males and females in a funny way. This issue may be addressed by using data augmentation of switching gender-referring words (e.g. man, woman, boy, girl) in the captions of those memes.

5.2 Analysis on Multi-task Learning

In the hold-out set from the training data, our model achieved 83% for Subtask A and 73% for Subtask B. Nevertheless, the same model only yielded 69.7% and 67.5% on the test data. This discrepancy may indicate that training and test data come from different distributions. Conventional multi-task learning is vulnerable to out-of-distribution because it assumes the predicted targets are independent given the input. Unfortunately, the target sub-categories are dependent on each other. This issue might be addressed by adapting, e.g. generative multi-task learning (Makino et al., 2022), which considers the dependency between targets.

6 Conclusion

In this paper, we presented our system for the Multimedia Automatic Misogyny Identification (MAMI) task in SemEval 2022. We augmented the data with visual transformation techniques and extracted features from memes by using multimodal baseline models. We further enhanced the system by adapting multi-task learning and ensemble learning methods. We leave issues such as incorporating external information about entities, frame layout in memes, gender-related text data augmentation and cross-subtask dependency in multi-task learning as future works.

Abstract

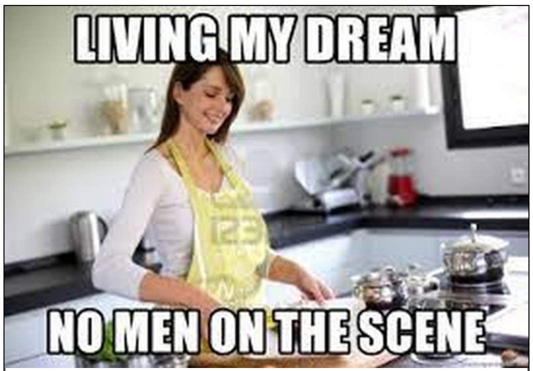
Warning: This paper contains examples of language that some people may find offensive or upsetting.

In this paper, we describe the system proposed by the *MilaNLP* team for the Multimedia Automatic Misogyny Identification (MAMI) challenge. We use Perceiver IO as a multimodal late fusion over unimodal streams to address both sub-tasks A and B. We build unimodal embeddings using Vision Transformer (image) and RoBERTa (text transcript). We enrich the input representation using face and demographic recognition, image captioning, and detection of adult content and web entities. To the best of our knowledge, this work is the first to use Perceiver IO combining text and image modalities. The proposed approach outperforms unimodal and multimodal baselines.

1 Introduction

Monitoring and detecting hateful content online is of paramount importance to limit the spread of hate, misconception, and prejudice. Content on social media platforms poses several challenges, from fast-paced, large-scale generation requiring automatic solutions, to ever-changing information mediums, like internet memes.

Misogynous memes are an unfortunately common phenomenon. Based on sexist preconceptions, these memes target and degrade women for humor. This intricate nature makes them hard to detect with classical computational models as hate is conveyed by associating known visual concepts with specific textual wording. In the Multimedia Automatic Misogyny Identification task (Fersini et al., 2022) novel systems are required to detect misogynous memes in English. The task is divided into two sub-tasks. Sub-task A requires solving the sole misogynous meme identification (i.e., a binary task). Sub-task B requires recognizing more specific categories, namely *stereotype*, *shaming*, *objectification*, and *violence*. Figure 1 (top) shows an example from the dataset.



F: White, 20-29, Female - Count: 1
W: "No men meme"
C: "A poster of a woman in a kitchen"
A: False

Figure 1: Sample from the training set (top) annotated with *Misogynous* and *Stereotype* labels. We enriched the meme with additional information (bottom), namely detected faces (F), web entities (W), caption (C), and adult content (A).

We propose a novel architecture where unimodal[1] components extract salient information from the meme. We present all information to a late fusion layer that distills it into a latent representation. We use renowned unimodal encoders networks and Perceiver IO (Jaegle et al., 2022) as the late fusion layer. Notably, while jointly learning from all modalities, Perceiver IO easily extends to multi-task learning. To the best of our knowledge, this work is the first to use Perceiver IO combining text and image modalities. We hence effectively address, with the same architecture, both sub-tasks A and B.

[1]We use *unimodal* whenever a single modality is involved, e.g., when dealing with Image content only. By extension, *multimodal* refers to a mixture of unimodals, e.g., Image and Text.

The proposed system outperforms both unimodal and multimodal baselines. The results show that Perceiver IO is an effective and efficient method to jointly fuse input representations from different modalities in multi-task setups. However, we achieved sub-par performance against other competing solutions. We ranked 25th (13 F1 points worse than the best system) out of 69 competing teams on sub-task A and 15th (4 F1 points worse than the best system) out of 42 competing teams on sub-task B. Our system is not specialized in either of the sub-tasks and hence it under-performs against task-engineered solutions. We report a brief error analysis in Section 5.

We release the code to replicate our experiments at `https://github.com/MilaNLProc/milanlp-at-mami`.

2 Background

In the last years, the task of hate speech detection has attracted considerable attention from the Natural Language Processing and Computer Vision communities. Among the research work in this area, only a limited number of approaches have focused on the problem of misogyny detection, which is a concrete problem in social media platforms. Nozza (2021) shows that hate speech detection models do not transfer across different hate speech targets, further demonstrating the need for ad-hoc misogyny detection approaches and datasets. Indeed, the corpora made available as part of shared tasks (Fersini et al., 2018, 2020b; Basile et al., 2019; Mulki and Ghanem, 2021) enabled a variety of NLP approaches to the problem of automatic misogyny detection on Twitter posts (Indurthi et al., 2019; Fersini et al., 2020a; Attanasio and Pastor, 2020; Lees et al., 2020, inter alia).

The Multimedia Automatic Misogyny Identification task focuses on the problem of misogyny detection with the new perspective of multimodality. The most similar research effort in the direction of hateful memes detection is the Hateful Memes Challenge (Kiela et al., 2020) and the MMHS150K corpus (Gomez et al., 2020).

On the other hand, multi-modal models that combine image and text are now becoming incredibly popular in Natural Language Processing (Cao et al., 2020; Lu et al., 2019; Tan and Bansal, 2019; Radford et al., 2021; Bianchi et al., 2021; Su et al., 2020, inter alia) due to their capabilities to solve zero-shot tasks.[2]

In this paper, we focus on the use of Perceiver IO (Jaegle et al., 2022) to combine the information coming from different sources such as the meme image, the text, and other features.

3 System overview

Following recent work addressing similar tasks (Pramanick et al., 2021; Zhu, 2020; Lee et al., 2021, inter-alia), we decompose the multimodal learning of hateful memes into two stages. First, we embed with unimodal encoders different input sources. Next, we adopt a multimodal late fusion to jointly learn from different modalities. With this setup, we tackle both sub-tasks A and B with no additional data other than the one provided for the task.

We build unimodal streams using pretrained, modality-specific encoder networks. Each encoder contributes an input representation to the subsequent fusion layer. We then use Perceiver IO (Jaegle et al., 2022) as a late fusion approach over the concatenation of modality-specific representations. Perceiver IO produces a structured, multidimensional output. We leverage this ability to jointly learn misogyny and other relevant aspects (e.g., aggressiveness, objectification, etc.) from the input. With that, we effectively solve both sub-tasks A and B of the challenge using a single model in a multi-task learning setting.

The system architecture is shown in Figure 2. To the best of our knowledge, this is the first attempt to use Perceiver IO as a multimodal late fusion layer for multi-task learning.

In the following sections, we further describe what type of unimodal source we considered (Section 3.1) and how we adapted Perceiver IO to multimodal, multi-task learning (Section 3.2).

3.1 Unimodal streams

The provided memes are characterized by two features: the meme image and the transcription of the over-imposed text. Building on ideas from recent work (Blaier et al., 2021; Pramanick et al., 2021), we enrich the meme with semantic information including image caption, face and demographics, detection of adult content, and web entities. We report a sample in Figure 1.

[2]See also Frank et al. (2021) for a detailed study and ablation analysis on the capabilities of these models.

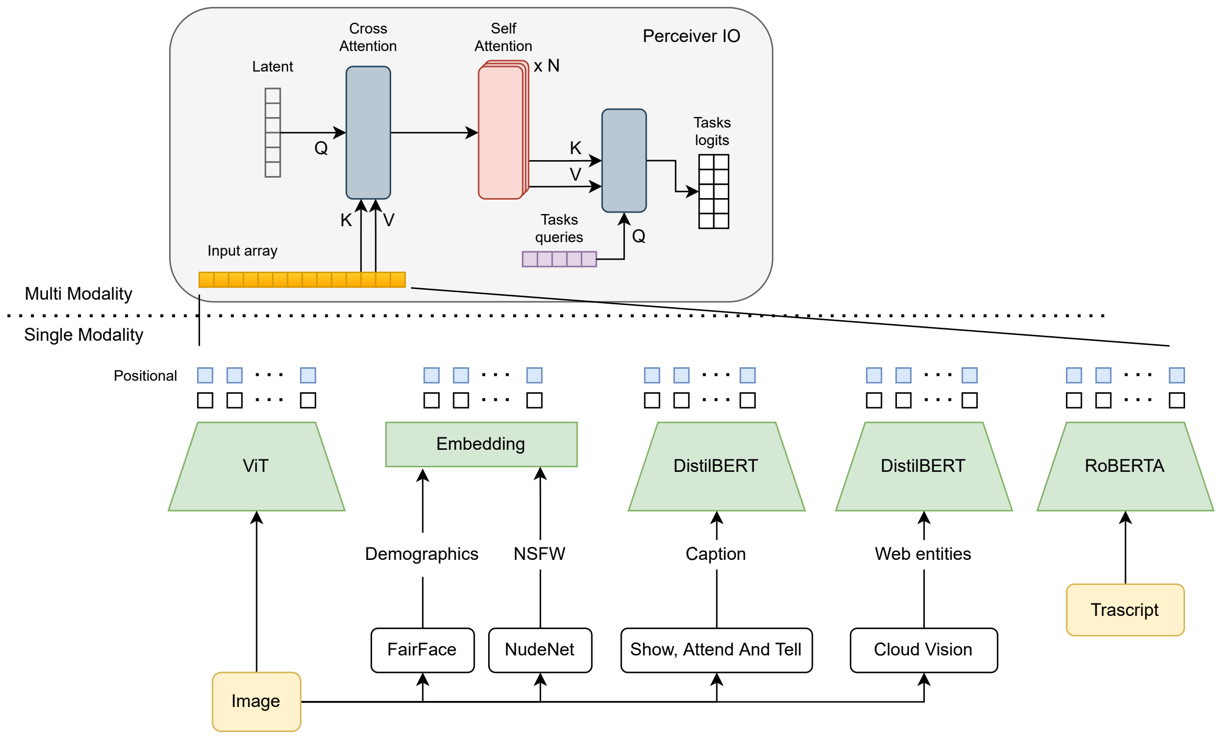


Figure 2: System overview. Light yellow boxes are the raw meme components. Green shapes are unimodal encoders. White boxes are external models used to enrich the meme. The darker yellow array represents the input array to the Perceiver IO fusion layer.

We derive a different input stream from each of the features of the semantically-augmented meme (Figure 2, bottom).

Image We encode raw images using a pretrained Vision Transformer (Dosovitskiy et al., 2021) (ViT). In this stream, the input image is divided into patches of 16x16 pixels and fed through a stacked transformer architecture. We use the last hidden token embeddings as the output of the stream.

Text Transcript We encode the text transcript using a pretrained RoBERTa (Liu et al., 2019) and use the last hidden token embeddings as the output of the stream. We choose RoBERTa based on its performance and its hurtful sentence completion (HONEST) score (Nozza et al., 2021, 2022b).

Face and Demographics Some images contain one or more faces. We use a pretrained Fair-Face (Karkkainen and Joo, 2021) model to detect faces and demographics. For each face found, we extract three categorical attributes, namely *Age*[3], *Gender*, and *Ethnicity*. Figure 1 (bottom, F) reports an example of face and demographics extracted with FairFace from a training sample. We encode face demographics with a simple embedding layer.

[3]FairFace produces age ranges, e.g., *60-75*, *75+*.

Adult Content We use NudeNet[4], a pretrained classification and detection model for nudity detection and censoring, to detect if the image contains adult content. We encode this information with additional embeddings.

Image caption We include an automatically generated image caption to have a textual description of the meme content. We use a pretrained Show, Attend and Tell model (Xu et al., 2015) to generate the caption for both training and test memes. Figure 1 (bottom, C) reports an example of an automatically generated caption. We encode the caption using a pretrained DistilBERT (Sanh et al., 2019).

Web Entities We use Google Cloud Vision API to detect web entities starting from the meme image.[5] As a summary of the extracted entities, we use the textual field `best guess labels` provided by the API. We encode this text using a pretrained DistilBERT. Note that this is a different model than the one used for captions.

3.2 Late fusion with Perceiver IO

We concatenate all the information extracted by unimodal streams into a single input array (Figure 2, top). Ideally, this array contains all the raw unrouted information necessary for the task. We use a Perceiver IO-based late fusion layer for information distillation and multi-task learning.

Perceiver IO builds on Perceiver (Jaegle et al., 2021) a modality-independent neural architecture with two crucial advantages over unimodal models. First, it is designed not to leverage inductive biases as in modality-specific architectures. Because of that, it effectively learns from the input of any shape and nature. Second, Perceiver distills inputs in a much smaller latent representation for memory efficiency. On top of that, Perceiver IO (Jaegle et al., 2022) adds a decoding step to produce a structured output of arbitrary size and semantics. The output is generated using decoder queries cross-attending the latent representation. The number of queries and their dimension defines the output shape.

We use this feature of Perceiver IO to address both sub-tasks A and B at once. Specifically, we define five different *task queries*, one per characteristic of the misogynous meme identification problem, i.e., *misogyny*, *shaming*, *aggressiveness*, *objectification*, and *violence*. In this multi-task setup, we generate logits and extract probability distributions for each of the five aspects.

4 Experimental setup

The provided training set counts 10,000 samples. Class labels are balanced on misogyny ($p_1 = 0.5$) but unbalanced on *shaming* ($p_1 = 0.18$), *stereotype* ($p_1 = 0.28$), *objectification* ($p_1 = 0.22$), and *violence* ($p_1 = 0.095$). We validated our models and baselines using three-fold cross-validation over the training set. We measure performance with F1 Macro on the binary misogyny detection task.

For ViT, RoBERTa, and DistilBERT, we use implementations and checkpoints from the transformers library (Wolf et al., 2020) and HuggingFace Hub. We use monolingual English checkpoints for text models. For Perceiver IO, we use the lucidrains's PyTorch implementation.[6]

Unimodal encoders For ViT, we used the `google/vit-base-patch16-224-in21k` checkpoint. We used the standard feature processor which entails 1) resizing to a maximum shape of 224x224 and channel normalization. We also augmented the image using color jitter ($hue = 0.1$), random horizontal flip ($p = 0.5$), affine transformations,[7] contrast ($p = 0.3$) and equalization ($p = 0.3$) variations. We discard the CLS last token embedding and use the sequence of the remaining 196 tokens as the image representation.

For RoBERTa, we used the `roberta-base` checkpoint and its standard tokenizer padding and truncating up to a maximum of 32 tokens. We performed text augmentation via token removal ($p = 0.15$).

For DistilBERT, we used the `distilbert-base-uncased` checkpoint and its standard tokenizer padding and truncating up to a maximum of 32 tokens. Note that this configuration is duplicated for both the text transcript and web entity streams.

Perceiver IO We did not use a Perceiver IO pretrained checkpoint. We manually fine-tuned the number of latent variables in $\{64, 128, 256, 512, 1024\}$, latent dimension in $\{128, 256, 512, 1024\}$, and number of self-attention layers in $\{6, 12\}$, and settled on the configuration `[265, 512, 6]`. Self-attention layers are applied sequentially and do not share weights. We use 5 decoder queries to produce a structured output of shape $(5, 2)$. We project the output using a final linear layer and consider the result as the tasks logits. We also tried to use a different linear projection layer per task but with no measurable improvement in performance.

Training setup We trained the entire system end-to-end, i.e., we jointly optimized all unimodal encoders *and* Perceiver IO. Following Bianchi et al. (2021), we tried to freeze the encoders for an arbitrary number of steps and then unfreeze them, with no significant improvement.

We manually tuned the learning rate in the range $[10^{-5}, 10^{-6}]$. We then used 10^{-5} with linear decay and 10% of total steps as warmup steps. We set weight decay to 10^{-2}. We trained the system for four epochs using Focal Loss (Lin et al., 2020) to account for class imbalance. We set alpha to 0.25 and gamma to 2.

Model	F1
Lexicon BoW + LR	66.4
RoBERTa	77.4
Vision Transformer	73.1
Perceiver IO	82.9
Perceiver IO (FWCA)	**83.3**

Table 1: F1 performance (%) on our three-fold cross-validation setup of unimodal (top) and multimodal (bottom) models in the misogyny identification task (sub-task A).

Model	F1
Best system	**83.4**
Perceiver IO (FWCA)	69.9
Provided baseline	64.0
Best system	**73.1**
Perceiver IO (FWCA)	69.3
Provided baseline	62.1

Table 2: Performance on sub-task A (top) and sub-task B (bottom) compared to best systems and *baselines* provided by task organizers.

5 Results

The provided test set counts 1,000 samples. Target labels are balanced in terms of misogyny but imbalanced for the rest of the categories. Unbalancing is slightly more marked than the training set. We report the prior frequency of the positive class as p_1 in Table 3.

In the following, we compare the performance of the proposed system which encodes detected faces (F), web entities (W), the image caption (C), and adult content detection (A). We refer to the system as Perceiver IO (FCWA). It achieves an overall F1 (macro) score of 69.9% in sub-task A and an F1 (weighted) score of 69.3% in sub-task B. We rank 31th (13 F1 points worse than the best system) on sub-task A and 18th (4 F1 points worse than the best system) on sub-task B. The system outperforms several baselines provided by the task organizers. On sub-task A, we outperform 1) sentence embeddings from a pretrained Universal Sentence Embedding model, 2) an image classifier fine-tuned from a VGG model, and 3) a classifier based on the concatenation of the first two representations plus a single layer neural network. On sub-task B, we outperform 1) a multi-label model based on the concatenation of deep image and text embeddings and 2) a hierarchical multi-label model based on text representations. Results are reported in Table 2.

Category	F1	P	R	p_1
misogynous	69.91	75.07	71.10	0.50
shaming	65.98	65.69	66.31	0.15
stereotype	67.79	68.58	67.34	0.35
objectification	70.06	71.72	69.30	0.35
violence	74.29	82.73	70.27	0.15

Table 3: Performance on the test set in terms of F1 (%), Precision (P), and Recall (R) with macro averaging. Prior frequency (p_1) of the positive class in the training set.

5.1 Quantitative analysis

In the proposed dataset, misogyny characteristics (e.g., *shaming* or *objectification*) apply only to misogynous content. Hence, we consider performance on sub-task A (binary misogyny detection) as a proxy for the overall quality of the model configuration. We report performance on our cross-validation over the training set in Table 1.

We compared our system with internal unimodal baselines. For the textual modality, we tested a Bag-of-Word (BoW) representation[8] extracted from the HurtLex lexicon (Bassignana et al., 2018) fed to a Logistic classifier and RoBERTa. For the visual modality, we tested Vision Transformer. Our system outperforms by a large margin these unimodal baselines.

Further, we validated the intuition of semantically enriched memes with input ablation. Results are reported in Table 1. Specifically, we removed all streams but the encoders of the raw image and the transcript (Perceiver IO). Cross-validation results show that our enriched input (Perceiver IO (FWCA)) improves classification performance.

5.2 Error analysis

In the post-evaluation phase of the task, we studied the labels predicted by our system on the 1,000 test memes. Results are reported in Table 3 separately by category.

The system effectively learned all categories (F1 is always greater than 65%) but with differences. The misogynous identification task has a 70% F1

[8]We use a binary presence matrix, i.e., the rows are the transcript of the meme, the columns each of the terms of the lexicon, and the cell is 1 if the transcript contains the term at least once or 0 otherwise.

Figure 4: A sample of false negatives from the test set on the misogyny identification task.

score composed of a promising 75% in precision and 71% recall. While performance between *stereotype* and *objectification* are close, the system underperformed in the *shaming* category. We think this behavior is due to the broad kind of both visual and textual content that can convey *shameful* messages and is hence more difficult to learn. Finally, the model performed best in *violence*, where it is probably simpler to identify visual clues that let intend a violent message.

We also manually inspected the errors of our model. We conducted the analysis separately by false positives (Figure 3) and false negatives (Figure 4). In the following, we speculate on the possible causes of these errors.

Weak Adult Content detection We noticed several wrong annotations extracted by NudeNet in both false positives and false negatives (e.g., all memes in Figure 3 are labeled as NSFW). We believe this might have introduced noise in our training that further propagated in classifying test memes.

Bias towards composite memes Several memes have a composite nature. They contrast some behavior or reaction of two groups (e.g., boys and girls) using a predefined structure. A typical example is achieved by organizing one group on top of another (Figure 3b and 3c).

We noticed several composite memes among false positives. We argue this kind of meme has a strong association bias with the positive class (*misogynous = 1*). Indeed, we believe that, in absence of relevant information, the system leverages the structure of the memes and wrongly produces a positive prediction.

Hard stereotypes Several memes contain non-hateful wording and image content. However, they convey misogynous messages because the combination of image and text leverages a well-known stereotype about women. We argue that the correct classification of these memes must involve either a solution explicitly modeling the stereotype or sufficient training data to become *aware* of it. We call "hard stereotypes" those memes whose stereotypical message is not backed by sufficient training data. We noticed several hard stereotypes in our misclassified memes. Figure 4 shows four examples of those.

Gender Bias We noticed several memes misclassified as false negatives depicting only a man in the scene. We believe the system might have learned a spurious bias associating the presence of men in the image with the negative class (*misogynous = 0*).

5.3 Further considerations

Quality of generated information In our experiments, automatically generated image captions often describe coherently the content of the image, although we do not expect them to generalize well to complex and diverse concepts.

Instead, FairFace extracts almost always precise face counts and age, ethnicity, and gender for each face even in crowded images (there are cases of 14 people in a single image). Web entities are often significant but provide coarse-grained information (e.g., "internet cat meme").

Unconditioned prediction During the post-evaluation phase, we identified a potential weakness in the proposed architecture.

Decoding queries in Perceiver IO are independent by design. This behavior enhances the model's generalization capabilities as it needs to learn internal representations useful for all outputs. However, it also prevents any conditioning between them. In our task, the *misogynous* aspect influences the remaining ones in the sense that only misogynous memes are characterized by one or more categories for sub-task B. We are not explicitly modeling this condition and hence probably hindering the performance.

6 Conclusion

We addressed both sub-tasks A and B of the Multimedia Automatic Misogyny Identification shared task with a novel Perceiver IO-based system. We take advantage of pretrained encoders and external services to extract and enrich with salient information the input meme. Then, we use Perceiver IO as a multimodal, multi-task late fusion layer of several unimodal streams. To our knowledge, this is the first time Perceiver IO has been used to combine text and image modalities.

The proposed system outperforms unimodal and multimodal baselines but underperforms against more specialized, task-specific competitor systems. We ranked 25th out of 69 competing teams on sub-task A and 15th out of 42 competing teams on sub-task B. In future work, we will explore improved input preprocessing (e.g., for the OCR-based text provided), and model ensembling. Additional effort should be put into identifying and mitigating unintended bias that may be present in our multimodal misogyny detection model following approaches proposed for text modality (Nozza et al., 2019; Attanasio et al., 2022a,b). The development of these multi-modal hate speech classifiers can be useful for the automatic evaluation of large pre-trained models (Nozza et al., 2022a).

Abstract

We present our submission to SemEval 2022 Task 5 on Multimedia Automatic Misogyny Identification. We address the two tasks: Task A consists of identifying whether a meme is misogynous. If so, Task B attempts to identify its kind among shaming, stereotyping, objectification, and violence. Our approach combines a BERT Transformer with CLIP for the textual and visual representations. Both textual and visual encoders are fused in an early-fusion fashion through a Multimodal Bidirectional Transformer with unimodally pretrained components. Our official submissions obtain macro-averaged F_1=0.727 in Task A (4th position out of 69 participants) and weighted F_1=0.710 in Task B (4th position out of 42 participants).

1 Introduction

Evolving from the two previous editions of the Automatic Misogyny Identification initiatives (Fersini et al., 2018, 2020), the Multimedia Automatic Misogyny Identification shared task at SemEval 2022 (MAMI) targets multimodal data for the first time. Within MAMI, Fersini et al. (2022) propose two classification tasks:

Task A A basic task about misogynous meme identification, where a meme should be categorized either as misogynous or not.

Task B An advanced task, where the type of misogyny should be recognized among potentially overlapping categories: stereotyping, shaming, objectification and violence.

The increasing volume of meme posts on social media renders the development of models able to identify malicious instances timely. The task is more challenging than when dealing with text alone because, in general, both the textual and the visual channels play an indivisible role in conveying the desired message.[1]

We build upon our previous experience in identifying misogyny and aggressiveness in text (Muti and Barrón-Cedeño, 2020) and approach both multimodal tasks with a supervised multi-modal bi-transformer model (MMBT) (Kiela et al., 2020a). We use *bert-base-uncased-hatexplain* (Mathew et al., 2020) and *bert-base-uncased* (Devlin et al., 2019) for the textual embeddings, and CLIP (Radford et al., 2021) for the visual ones. We also build two unimodal baselines to compare against.[2]

Our experiments aim at understanding if and to what extent our multimodal model outperforms the two unimodal ones that address the problem separately. Since meme classification is a challenging task due to its multimodal nature, we shed some light on which component should weigh more in the decision process —text or image— by observing the impact of both modalities in the predictions.

Our official submission for Task A achieved a macro-averaged F_1 score of 0.727, whereas that for Task B obtained a weighted F_1 score of 0.710, positioning our team in the 4th position in the task, for both tasks.

In addition, we identify the linguistic and visual elements which are potentially responsible for the misclassification. We perform an error analysis to check whether misclassified memes rely heavily on external world knowledge and/or are subtle and implicit, as we believe that those two aspects cause struggle to the models.

The rest of the paper is structured as follows. Section 2 provides essential definitions for this task, such as misogyny and memes. We then move on to dataset description as well as a summary of related work. Section 3 describes our models for both tasks.

[1]This is different from other multimodal scenarios, such as visual question answering or image captioning, where one of the two modalities tends to be the dominant one (Zhu, 2020).

[2]Our model is publicly available at https://github.com/TinfFoil/Unibo-at-SemEval-2022-MAMI.

	train	test
Not Misogynous	5,000	500
Misogynous	5,000	500

Table 1: Class distribution for the binary Task A misogynous or not.

Section 4 describes the experimental setup. Our results are presented and discussed in Section 5. Section 6 presents our error analysis. Section 7 concludes with a summary of our findings.

2 Background

2.1 Definitions

Memes are relatable acts of communication made of visual and textual artifacts, where often an image is superimposed with text with a humorous purpose (MacDonald and Wiens, 2022). To be fully understood, memes require context and real-world knowledge. They are often satirical, implying humour and sarcasm in a subtle way (Sharma and Pulabaigari, 2020). These factors cause the identification of phenomena in them —such as expressions of misogyny— difficult.

Humour does not always come as harmless fun and that is the case with misogynous memes. Such memes contribute to the establishment of a rape culture (Ridgeway, 2014), where violence and sexual harassment are tolerated, belittled, normalized, excused and transformed into jokes. Therefore, developing automatic approaches to tackle misogyny has both technological and social value.

According to the MAMI guidelines (Fersini et al., 2022), a meme is misogynous when it conveys an offensive, sexist or hateful message (be it weak or strong, implicitly or explicitly) targeting a woman or a group of women. Four kinds of misogyny are considered for this task:

Shaming occurs when memes insult or offend women because of their physical aspect.

Stereotyping represents a fixed idea or set of characteristics; physically or ideological.

Objectification represents a woman like an object through the over-appreciation of her physical appeal (sexual objectification) or by depicting her as an object (a human being without any value as a person).

Violence shows physical or verbal violence toward women.

	train	test	preds

Table 2: Number of instances per class for the multi-label Task B (top). Class distribution (bottom). Column **preds** shows the predictions of our best submitted model (Multi; cf. Section 5).

2.2 Datasets

The datasets are balanced with respect to Task A (see Table 1). The same instances include the multi-label annotation for Task B. Table 2 shows the number of instances for each label combination.

Stereotyping is the most represented class, with $3.2k$ instances overall, followed by objectification ($2.2k$) and shaming ($1.2k$); violence is the least represented, with less than $1k$. The label overlapping plays an important role in our results analysis (c.f., Section 6). As Table 2 shows, stereotyping and objectification tend to come together, whereas shaming and violence do not. We will explore whether our models capture this intersection in Section 6.

2.3 Related Work

The identification of misogyny in textual form was explored in the series of shared tasks on Automatic Misogyny Identification (AMI), held at IberEval (Anzovino et al., 2018) and EVALITA (Fersini et al., 2018, 2020). AMI at IberEval 2018 focused on identifying misogyny on English and Spanish tweets and on classifying the misogynous tweets into seven categories: discredit, stereotype, objectification, sexual harassment, threats of violence, dominance, and derailing. AMI at EVALITA 2018 targeted the analysis of Italian and English tweets. Task A addressed misogyny identification as well. Task B aimed at recognizing whether the target of a misogynous post was a specific person or women in general, and at classifying the positive instances in the aforementioned categories. AMI at EVALITA 2020 targeted the detection of misogyny and aggressiveness in Italian tweets (Task A) and the identification of unintended bias (Task B).

Multimodality has been explored for the automatic analysis of memes. Sharma and Pulabaigari (2020) worked in the task of identifying whether an image is a meme or not. Two recent SemEval tasks have targeted memes as well. Sharma et al. (2020) proposed an emotion identification task. The best performing system consisted of a text-only approach, a feed-forward neural network (FFNN) wth word2vec embeddings (Keswani et al., 2020). Dimitrov et al. (2021) proposed a shared task on the identification of propaganda techniques. Feng et al. (2021) approached it with a pre-trained transformer using text with visual features. They extracted grid features using ResNet50 (He et al., 2016) and salient region features using BUTD (Anderson et al., 2018). They further used these grid features to capture the high-level semantic information in the images. Moreover, they used salient region features to describe objects and to caption the event present in a meme. They built an ensemble of fine-tuned DeBERTA+ResNet, DeBERTA+BUTD, and ERNIEVIL (Yu et al., 2021) models.

Multimodal hate speech has attracted the interest of the research community only recently. In 2019, Facebook AI launched the Hateful Memes Challenge (Kiela et al., 2021b), which consisted in identifying hate speech in memes: hateful vs not. It is constructed such that unimodal models struggle and only multimodal models can succeed: difficult examples ("benign confounders") are added to the dataset to make it hard to rely on unimodal signals. The most successful approaches used both *early fusion* and *late fusion* (Kiela et al., 2021a), with the former achieving the best results. Those include VilBERT (Lu et al., 2019), VisualBERT (Li et al., 2019), MMF (Singh et al., 2020), MMBT (Kiela et al., 2020a) and CLIP (Radford et al., 2021). In late fusion approaches, systems for each modality are trained independently. The scores produced by each model are joined during inference to produce the final prediction (Kiela et al., 2020b).

In early fusion the different modalities are combined at an early stage to learn one single classification model (Kiela et al., 2020b). The top-performing model applied optical character recognition to find and remove the text from the input images in order to improve the quality of object detection, named entity identification and human race detection, using all these tags as input for different transformer models (Zhu, 2020).

Although MAMI is the first shared task on misogyny detection on memes, there has been preliminary work on automatic detection of sexist memes. Fersini et al. (2019) explored unimodal and multimodal approaches both with late and early fusion to understand the contribution of textual and visual cues on the MEME dataset, a dataset containing 800 sexist and not sexist memes. The sexist memes were also annotated according to aggressiveness and irony. From their work emerged that a unimodal textual model performs better than image-based ones. Concerning multimodality, late-fusion worked better.

3 System Overview

Our approach is based on the multimodal bi-transformer model (MMBT) (Kiela et al., 2020a). MMBT fuses image and text embeddings in an early fashion. MMBT jointly finetunes unimodally pretrained text and image encoders by projecting image embeddings to the text token space. Figure 1 represents the model architecture. MMBT combines two segments: segment 0 corresponds to the text, whereas segment 1 corresponds to the picture. They are fed together to use attention over both modalities at the same time. Each token is indexed according to its position from 0 to the maximum text length, which we set to 80. Each image representation is indexed from 0 to 640.

The original MMBT combines BERT (Devlin et al., 2019) and ResNet (He et al., 2016). We con-

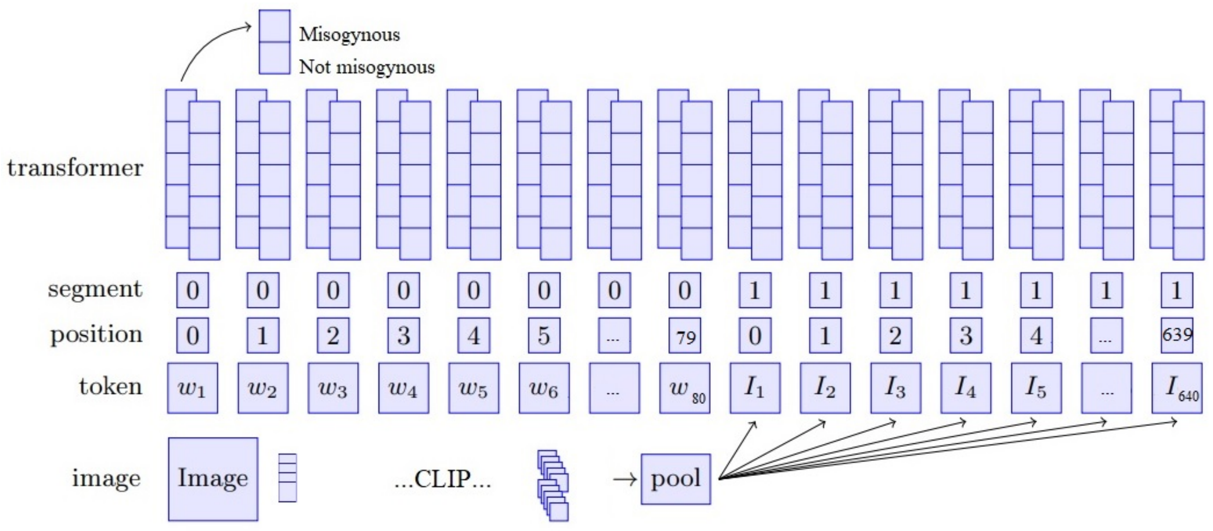

Figure 1: Representation of the MMBT model architecture combining CLIP and BERT; adapted from (Kiela et al., 2020a).

sider other models. For the textual embedding we tried with *bert-base-uncased-hatexplain* (Mathew et al., 2020), a version of BERT trained on identifying hate speech. For the image embedding we used CLIP, since it has outperformed all alternative models in a large variety of multimodal tasks, including OCR, action recognition in videos, geo-localization, and various types of fine-grained object classification (Radford et al., 2021). CLIP is pre-trained on the task of predicting which caption should be tied together with a given image. In this way it learns state-of-the-art image representations from scratch, enabling zero-shot transfer of the model to downstream tasks.

The two embeddings are fused through MMBT. For Task A we use the sigmoid activation function for the output layer and threshold at 0.5 to discriminate between misogynous or not. For Task B we adopt a binary relevance approach (Zhang et al., 2017), combining four binary classification models. The output for each classifier is a sigmoid function too. We opt for this approach after observing that treating the classes separately increased the performance in a multi-class model predicting misogynous, misogynous-aggressive or none (Muti and Barrón-Cedeño, 2020). This approach allows us to predict multiple mutually non-exclusive classes.

We apply a heuristic to refine the multi-label decisions in Task B. All four decisions are turned off if an instance had not been predicted as misogynous by our Task-A model.

Pre-processing Since CLIP requires square images, following Neskorozhenyi (2021) we produce 288×288 pixel versions of all memes. The memes come in different sizes and orientations, hence we rescale them until the largest side reaches 288 pixels respecting the aspect ratio and pad to fill the empty pixels in the square. Then, we slice the resized images into three equal parts horizontally if the image orientation is landscape and vertically if it is portrait to obtain both global and local image features. We extracted four vectors for each image: a vector for each part encoding spatial information and one for the whole image. We used the Pillow library (Clark, 2015) to perform these operations.

No preprocessing is applied to the text, other than applying the BertTokenizer (Devlin et al., 2019).

4 Experimental Setup

We shuffled the training set and take 10% of the data for development preserving the class distribution through stratified random sampling (Pedregosa et al., 2011).

We trained three alternative models to identify the best possible configuration. **Uni$_{\textbf{txt}}$** is a BERT-based unimodal system that considers the text alone. **Uni$_{\textbf{img}}$** is a CLIP-based unimodal system that considers the image alone. **Multi** is a multimodal system, fusing BERT and CLIP embeddings through MMBT.[3]

[3]We tried a variation of **Uni$_{\textbf{txt}}$** for Task A. We augmented the training data with the tweets corpus from AMI at Evalita

model	**variation**	**macro F_1**
Multi_5	after 5 epochs	0.703
Multi_6	after 6 epochs	**0.727**
Uni_{txt}	bert-base-uncased	0.656
Uni_{txt}	bert-Hatexplain	0.569
Uni_{img}	with fine tuning	0.703
Uni_{img}	zero-shot	0.417

Table 3: Official macro-averaged F_1-measures for our submissions to Task A.

Hyperparameters For Multi, we tried learning with different numbers of learning epochs, in range [3, 6]. The best validation performance was obtained after 5 epochs in Task A in the development set. We trained over 5 epochs in Task B. For both Uni_{txt}we train over 4 epochs. For the Uni_{img}we train over 5 epochs. In all cases we saved the model only when an increase in the performance was obtained. Since we also aimed at assessing how CLIP performs in making zero-shot predictions in this task, we used CLIP without fine-tuning on the training set, to check whether it could be effectively used to detect misogyny without prior annotation. We considered batch sizes of 16 and 32, with the former consistently performing better. We used a learning rate of 2e-4, the MADGRAD optimizer (Defazio and Jelassi, 2021), and a binary cross-entropy loss function.

The results reported in Section 5 are obtained with a model trained during 5 epochs for Task B and 6 epochs for Task A with 16 as the batch size.

Evaluation metrics We stick to the official MAMI evaluation metrics: macro-averaged F_1-measure for the binary Task A and weighted-averaged F_1-measure for the multi-label Task B.

5 Results

In this section we present the results obtained by our submissions to both Task A and Task B.

5.1 Task A

Table 3 shows the results of our submitted runs for Task A. The highest score is obtained after training the multimodal model Multi during 6 epochs: F_1=0.727. Considering the textual information alone runs short; the highest performance being obtained when the Uni_{txt} model is trained upon a *generic* BERT: 0.656. As expected, the zero-shot Uni_{img}model performs the worst, with a performance lower than that of a random model. A proper fine-tuning of the Uni_{img} model turns into the runner-up performance with F_1=0.703. The improvement of the Uni_{img}over the Uni_{txt}model by five points suggests that the visual information is captured better than the textual one. The reason might be that the text is too short and out of context to be captured effectively by BERT.

2018 (Fersini et al., 2018). Since no improvement was observed in the model, the results are neglected.

model	**masked with**	**weighted F_1**
Multi	Multi_5	**0.710**
Multi	Multi_6	0.588
Uni_{txt}	Uni_{txt} bert-base-uncased	0.660

Table 4: Official weighted F_1-measures for our three submissions to Task B. Column *masked with* specifies the model from Task A used to mask the output labels.

5.2 Task B

Table 4 shows the results of our submitted runs for Task B. In this case, we trained one single Multi model during 5 epochs. The difference between the two configurations is in the masking of the multi-label classification. The most successful multimodal model gets F_1=0.710, after masking with respect to Task A's Multi_5 model. Masking on the basis of Task A's Multi_6 model causes a performance drop of twelve points. Multi_5 predicts more misogynous instances than Multi_6 (678 vs 653). Multi_6 blacks out more predictions which are false positives and hence a potentially correct decision by the multi-label model gets ignored. The text-alone approach, masked by the corresponding Task A model, runs short by five points.

In Table 5 we zoom into the performance of our Task B Multi model for each of the four classes. The model struggles the most when trying to spot stereotyping and shaming. This reflects the nature of misogyny. Stereotyping and shaming tend to be less explicit, and hence harder to spot —even for human beings. On the contrary, violence, which is the most explicit, is more likely to be identified. Stereotyping is the class that has been overpredicted the most (cf. Table 2).

6 Qualitative Analysis

In this section we present a qualitative analysis of the results to further examine the strengths and weaknesses of our approach.

	prec	recall	F$_1$
Shaming	0.52	0.46	0.49
Stereotype	0.54	0.58	0.56
Objectification	0.69	0.66	0.67
Violence	0.73	0.48	0.58

Table 5: Per-class performance on the positive class for model Multi; our best submission to Task B.

	Uni$_{\text{txt}}$	Uni$_{\text{img}}$	Multi
false positives	0.20	0.23	0.21
false negatives	0.14	0.06	0.06
true positives	0.36	0.44	0.44
true negatives	0.30	0.27	0.29

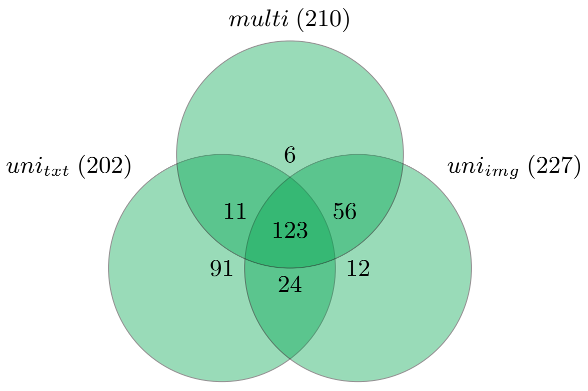
Table 6: Error analysis across all models for Task A showing relative frequencies.

6.1 Analysis on Task A

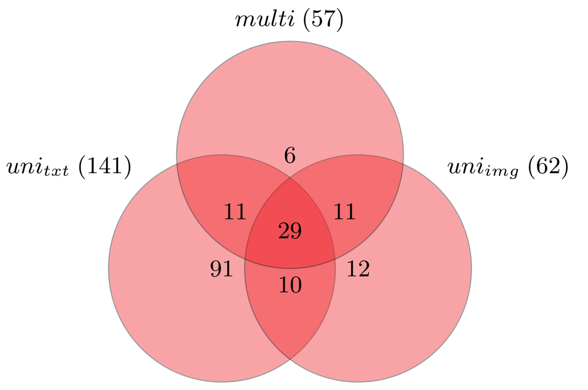
To address the question of which component for detecting misogyny in multimodal settings is more important, we looked at the distribution of the kind of errors made by the different models, as well as the overlapping instances among the four categories. Table 6 shows the relative frequencies. The amount of false negatives is much lower than that of false positives across all models. Considering a practical application, false negatives could have a greater impact as they are the misogynous instances that could not be detected, and could therefore lead to harm. On the other hand, blocking instances that were not misogynous but were classified as such could be considered censorship.

Table 6 shows the prediction analysis of the best runs for each modality. Looking at each model individually, Uni$_{\text{txt}}$ has less false positives but more false negatives than the other two models. Uni$_{\text{img}}$ has the highest number of false positives, and the same number of false negatives as the Multi model. This means that the textual model performs worse than the others in capturing misogyny, while the visual one tends to overpredict misogyny more than the other two models.

Figure 2 shows the intersections and differences in both false positives and false negatives by the three models. There are more false positive than false negative instances across all models, as observed in Table 6. Indeed, the number of common false positives by all models is almost 4 times as high as the number of common false negative values. This indicates that the models tend towards over-predicting misogyny. Taking into account the differences among the sets, Uni$_{\text{txt}}$ accounts for the fewest false positive instances (Figure 2a), while it accounts for the most false negative instances (Figure 2b). Therefore, in this specific multimodal task, where we can be more lenient with false positives than false negatives, a textual model does not seem to be an optimal alternative.



(a) False positives.



(b) False negatives.

Figure 2: Venn diagrams representing the false positive and false negative errors by the three top Multi, Uni$_{\text{txt}}$ and Uni$_{\text{img}}$ models during the testing stage.

Since the model does not allow for a great interpretability of the results, we performed a manual inspection of some interesting instances and the potential reasons behind the errors when classifying them. As Figure 2 shows, 132 instances are misclassified by all three models: 123 are false positives and 29 are false negatives. We observe the following trends after looking at the false negatives:

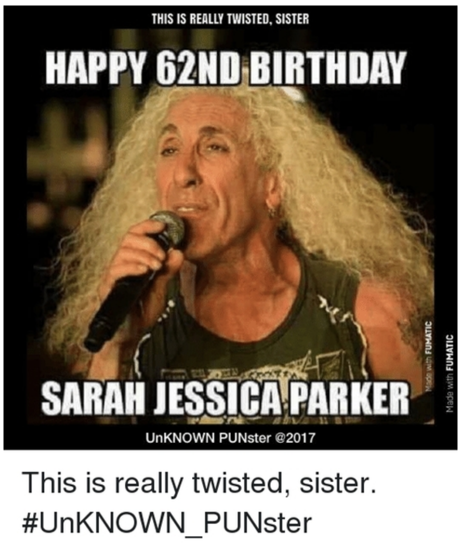
1. The level of misogyny is low or subjective, as the meme is not directly referred to women (e.g., Figure 3a) or misogyny is expressed in a subtle way (e.g., Figure 3b implies the stereotype that women are complicated);

2. Real-world knowledge is required to under-

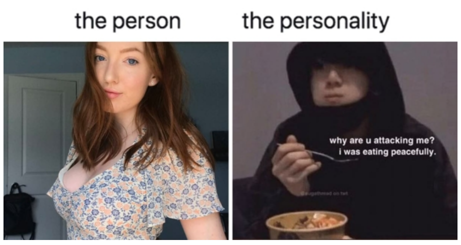
(a) Instance 15846.

My angry girlfriend: "I'm fine"
Me:
I am trying to solve a puzzle.

(b) Instance 16132.



(c) Instance 17028.



(d) Instance 16232.

Figure 3: Instances of Task A false negatives by all three models

stand the meme (Figure 3c can be better understood if we know Sarah Jessica Parker and the Twisted Sister band).

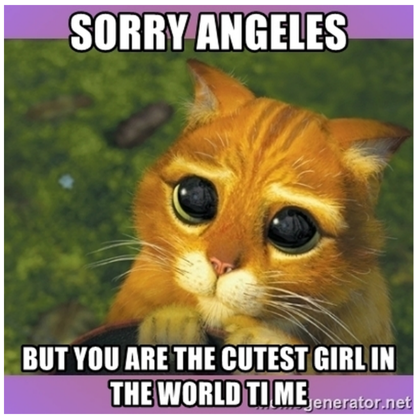


Figure 4: An example of false positive (instance 15094).

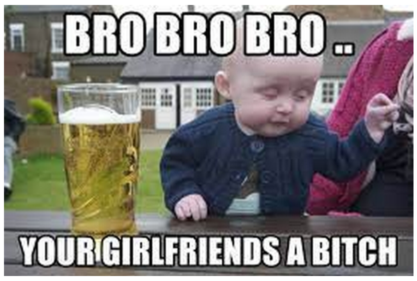

Figure 5: An example of meme properly labeled by text models only (instance 15802).

3. The stance of the text with respect to the image is relevant in order to convey the general meaning (see Figure 3d);

Among the false positives, memes mostly contain:

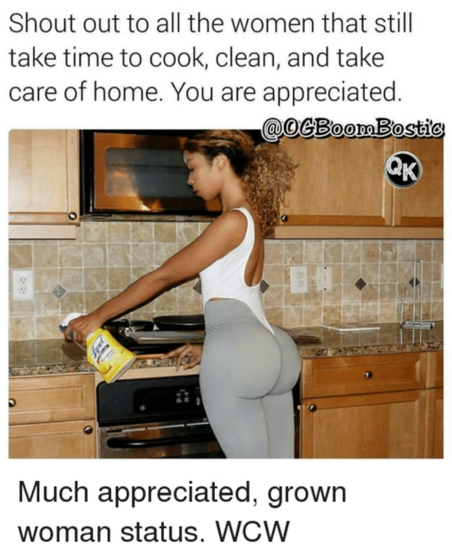
1. Compliments, which are often associated to objectification (e.g. Fig. 4).

2. Images or phrases that often occur in misogynous contents (e.g., women in underwear, kitchen-related terms).

3. Identity terms (e.g., *wife, women, girls*), that tend to co-occur with misogynous contents in the training set.

We also performed an analysis on memes that have been correctly classified by only one model. Among the instances that only the textual model got right, 11 were true positives and 56 true negatives. True positive cases mostly share a strong textual component in conveying misogyny, while the image is either irrelevant, or it is used only to make the sentence ironic (Fig. 5).

Among instances that only the visual model got right, both true positives and true negatives are 11.



Shout out to all the women that still take time to cook, clean, and take care of home. You are appreciated.

Much appreciated, grown woman status. WCW

Figure 6: An example of benevolent sexism that tends to confuse the classifier.

Most true positives have a explicit visual component. For instance, beaten women and texts justifying an aggression or glorifying violence. Among instances that only the multimodal model got right, 10 are true positive and 24 true negative. By observing the true positive instances, contrarily to what is expected, misogyny is not always conveyed by the integration of text and image, as in most of the cases the text is actually dominant.

6.2 Analysis on Task B

We performed a manual inspection focusing on the errors in predicting stereotyping and observed a relatively large amount of compliments toward women, which tend to confuse the classifier. In particular, false negatives are often caused by the presence of *benevolent sexism* (Glick and Fiske, 1997), which shows a subjectively positive attitude towards women that conceals inferiority compared to men, and it is often disguised as a compliment. Figure 6 shows an example.

Now we analyse the label overlaps to determine if our model captured the intersection of the classes. We compare our predictions to the gold labels in Table 2. The size of the intersection between stereotype and objectification is in the same order for gold and predictions: 152 vs 118. The intersection between cases of shaming and violence is practically null, which is well reflected in the model (2 vs 0). Less cases of both shaming and stereotyping than expected are identified (32 vs 20). The same applies to the combinations stereotyping–violence (40 vs 31) and objectification–violence (38 vs 23). The pair shaming–objectification tends to be overpredicted (25 vs 40).

7 Conclusions

We presented our participation to the Multimedia Automatic Misogyny Identification shared task. We addressed two problems: spotting whether a meme is misogynous and, if it is, what kind of misogyny it expresses. We compared unimodal models (text only and image only) with a multimodal model based on Multimodal bi-Transformers. Our image-only model performs better than the text-only one, suggesting that the visual information might be easier to capture than the textual one. Our multimodal approach performs the best in both tasks. The errors come from more false positives than false negatives.

From our error analysis we observed that stereotyping and shaming are the most misclassified categories. This proves that more focus on subtle and implicit forms of misogyny and sexism is needed.

Abstract

This paper provides a comparison of different deep learning methods for identifying misogynous memes for SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification. In this task, we experiment with architectures in the identification of misogynous content in memes by making use of text and image-based information. The different deep learning methods compared in this paper are: (i) unimodal image or text models (ii) fusion of unimodal models (iii) multimodal transformers models and (iv) transformers further pretrained on a multimodal task. From our experiments, we found pretrained multimodal transformer architectures to strongly outperform the models involving fusion of representation from both the modalities.

1 Introduction

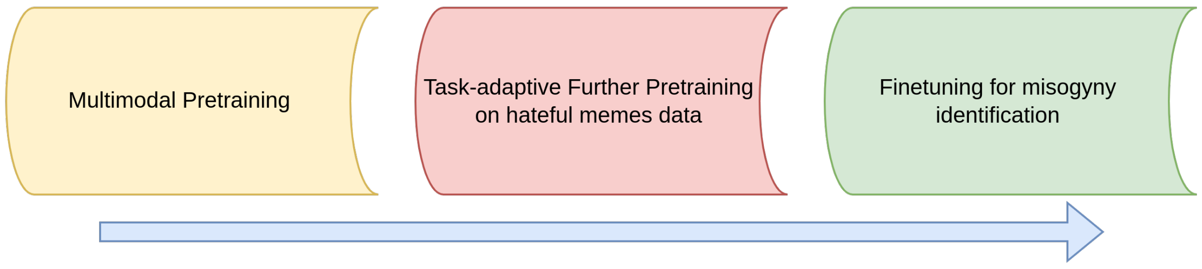
With the social media turning out to be a medium for propagation of hate speech and other perils, misogyny and sexism is incident upon women in explicit and implicit ways. Although memes have turned out to be a potent mechanism for exchanging humorous messages, they have been turning out to also be bearers of such malicious content. With this motivation, the task of Multimedia Automatic Misogyny Identification (MAMI) (Fersini et al., 2022) was proposed with two subtasks: (1) determining whether a meme is misogynous as a binary classification problem (2) finegrained misogyny classification into categories of stereotype, shaming, objectification and violence as a multilabel problem. In our work, we have compared different deep learning approaches for identifying misogyny in memes and also further classifying them into different kinds of misogyny.

We base our experiments on unimodal architectures making use of only either the textual or the image content in memes. The unimodal architectures were naturally superseded by their multimodal counterparts, since they made use of both the modalities in misogyny identification. Among the multimodal architectures, we initially experimented with simple fusion-based approaches which involved combining the image and text representations. These experiments were followed by trying out multimodal transformer architectures in which we made use of MMBT (Kiela et al., 2019), ViLBERT (Lu et al., 2019) and VisualBERT (Li et al., 2019). We used these architectures pretrained on unimodal as well multimodal objectives. We found VisualBERT and ViLBERT trained using multimodal objectives to perform competitively on the task. In order to further improve the capability of the models for misogynous content identification, we tried out further pretraining the models on a dataset for classifying hateful memes. This strategy involving a task-adaptive further pretraining stage turned out to further boost the performance of the models showing the benefit obtained from larger datasets for adapting models to a finegrained downstream task. Figure 1 shows the training stages of such an architecture.

Our best model achieved a macro-F1 score of 0.712 for Subtask 1, while the best performing model for Subtask 2 gave a weighted F1 of 0.706.

2 Related Work

Misogyny detection. Sexism and misogyny has been a long-studied problem, with (Barreto and Ellemers, 2005) and (Dardenne et al., 2007) bringing out the differences in explicit (hostile) and vieled (ambivalent) sexism, with the latter being observed to be subtly undermining and perilous to women. With misogynist remarks - a category of hate speech - being prevalent on social media, the dataset introduced by (Waseem and Hovy, 2016) for hate speech detection on tweets includes sexism as one of the categories in a multiclass problem. In a dataset introduced specifically for misogyny identification on tweets, (Anzovino et al., 2018) also design a taxonomy identifying different manifes-



Multimodal Pretraining
Task-adaptive Further Pretraining on hateful memes data
Finetuning for misogyny identification

Figure 1: Stages of training for the model with best performance on misogyny identification

tations of sexism. Focusing on the differences in hostile and benevolent sexism, (Jha and Mamidi, 2017) curated a dataset for classifying the misogyny content in a tweet between the two categories, if the tweet is sexist in nature. Apart from detection of directed hateful content from tweets, there has been work on identifying categories of sexism from personal accounts such as (Karlekar and Bansal, 2018). (Parikh et al., 2019) created a dataset having 23 labeled categories of sexism from sexism accounts without maintaining mutual exclusivity in the categories and proposed a multi-task approach involving three auxiliary tasks for the multilabel classification in (Abburi et al., 2020).

Meme classification. The ubiquity of memes on internet, presence of malicious / hateful content in memes and the challenges involved in meme understanding were discussed in (Sharma et al., 2020). The work presented a new dataset and a challenge for understanding emotions in memes which involved subtasks for identifying the sentiment, humour category and scale (or intensity) of the detected class. (Suryawanshi et al., 2020) introduced a dataset for detection of offensive content in memes. A larger, challenging dataset was introduced in (Kiela et al., 2020) by involving 'benign confounders' to force the multimodal architectures to learn robust representations using both the modalities. The work also introduces formidable baselines with multimodally pretrained transformer encoders. Among the top performing models on this dataset, (Velioglu and Rose, 2020) perform an ensemble of multiple trained VisualBERT models, while ensembling was done in (Muennighoff, 2020) on a set of five predictions from different trained models, with the predictions for each model averaged from 3-5 different runs.

3 Task and dataset overview

The task consists of two subtasks:

- **Course-grained misogyny identification:** For this task, given a meme, we have to predict if a meme is misogynous in nature or not.
- **Fine-grained misogyny identification:** Given that a meme is misogynous, this task further identifies the kinds of misogyny among potential overlapping categories such as stereotype, shaming, objectification, and violence.

The dataset for the task was provided by the workshop organizers. The training set consisted of 10000 memes, whereas the hidden test consisted of 1000 memes. Each row in the dataset contained a unique identifier, the path to the image file for a corresponding meme, the text in the meme, and the label values of misogyny, stereotype, shaming, objectification, and violence.

4 Methodology

In the following section, we discuss our approaches for misogyny detection. We discuss our models in detail and provide a comparison between the models. We have explored unimodal models which use just the text or image as the input. The unimodal fusion models take the representation of the image part of the textual part separately and combine them to give the output. We have also exploited different pretrained multimodal transformers models. We have also experimented with how to further pretraining of these multimodal transformers models affect the quality of the predictions.

4.1 Unimodal models

For unimodal models, we experimented with the following models:

- **Image-Grid:** This is a unimodal image-based classifier that uses convolutional features with average pooling from ResNet-152 (He et al., 2016) architecture.

Setting	Subtask 1 (Macro F1-Score)	Subtask 2 (Weighted F1-Score)
Unimodal-Image-Grid	0.601	0.557
Unimodal-Image-Region	0.606	0.582
Unimodal-Text-BERT	**0.621**	**0.590**
Unimodal-Text-RoBERTa	0.619	0.585
Concat-BERT	**0.648**	**0.611**
Late-Fusion	0.626	0.608
MMBT-Grid	0.651	0.625
MMBT-Region	0.657	0.642
VilBERT	**0.687**	0.671
VisualBERT	0.684	**0.679**
VilBERT CC	0.693	0.683
VisualBERT COCO	0.685	0.689
VilBERT HM	**0.712**	0.698
Visual BERT HM	0.706	**0.702**

Table 1: Results on the testing split for each subtask. Task 1 refers to course-grained identification of misogyny and task 2 refers to the fine-grained identification ofthe types of misogyny.

- **Image-Region** In this unimodal image-based classifier, features from Faster-RCNN (Ren et al., 2015) with ResNeXt-152 (Xie et al., 2016) are used as the backbone network and are pretrained on the Visual Genome dataset (Krishna et al., 2017).

- **Text BERT:** This unimodal text-based approach uses BERT embeddings (Devlin et al., 2018) on the text given as part of the dataset.

- **Text RoBERTa:** Similar to the previous model but it used RoBERTa embeddings (Liu et al., 2019) instead of BERT.

4.2 Unimodal fusions

After taking unimodal representations, we have used the following techniques to fuse the representations to get the final representations before passing to the classifier:

- **Concat-BERT:** In this multimodal approach, an earlier fusion of the output of the unimodal ResNet-152 and BERT embeddings is performed by concatenation, and an MLP is trained for classification.

- **Late Fusion:** This is a simple multimodal approach where the output of ResNet-152 as in Image-Grid and BERT-based models is taken unimodally, and their mean is taken as the final model representation.

4.3 Multimodal transformers

For more advanced models, we have used the following multimodal transformers models:

- **MMBT-Grid:** MMBT (Kiela et al., 2019) is a multimodal supervised bitransformer architecture consisting of individual unimodally pretrained components trained to map multimodal image embeddings to text token space. MMBT-Grid uses features from ResNet-152 for image embeddings.

- **MMBT-Region:** In this approach, the MMBT transformer uses features from Faster-RCNN as in Image-Region for image embeddings.

- **ViLBERT:** ViLBERT (Lu et al., 2019) is a dual-stream multimodal transformer architecture. Here, the VilBERT model without any multimodal pretraining is used. It has BERT initializations for the text stream and uses Faster-RCNN pretrained on Visual Genome dataset to extract image region features.

- **Visual BERT:** Visual BERT (Li et al., 2019) is a multimodal single stream transformer architecture in which the text and image inputs are jointly processed by a stack of BERT-based transformer layers. It uses Faster RCNN for extracting image features.

4.4 Further pretrained models

From the models mentioned in the previous subsection, we have seen VilBERT and VisualBERT perform the best. We move forward with these models to further pretrain them on relevant datasets in a multimodal setting.

- **ViLBERT CC:** ViLBERT architecture used here is pretrained multimodally on the Conceptual Captions (CC) dataset (Sharma et al., 2018) using two pretraining tasks - masked multi-modal modelling (masking 15% of text and image region inputs and reconstructing them with unmasked inputs) and multi-modal alignment prediction (given a pair of image and text, determine if the text describes the image).

- **Visual BERT COCO:** Visual BERT architecture is pretrained multimodally on the Common Objects in Context (COCO) dataset (Lin et al., 2014). The two tasks the model is pretrained on are masked language modeling with an image (some part of the text is masked and is to be predicted using image regions and unmasked text) and sentence-image prediction (given two captions for an image, while one of them is the proper caption for the image, determine if the same holds for the remaining caption as well).

- **VilBERT HM:** For this architecture, we have pretrained the VilBERT architecture on the Hateful Memes dataset (Kiela et al., 2021) with the hypothesis that it will provide better representations given that it has been trained on memes that are hateful in nature. It has been pretrained on masked multi-modal modeling and a new task of meme-caption prediction(where given the image of the meme, the task is to choose the correct text from a given set of options).

- **Visual BERT HM:** Similar to the previous architecture, we have pretrained the Visual BERT model on the Hateful Memes dataset on masked multi-modal modeling task and meme caption prediction.

4.5 Final Setup

After the representation is obtained from any models above, it is passed through a multilayer perceptron classifier to predict the final label. For the second subtask, we used a hierarchical level modeling where the model would predict at first if a meme is misogynous or not, and if it is misogynous, it will perform further fine-grained classification.

4.6 Experimental details

We have used the pretrained models from the MMF framework (Singh et al., 2020) by Facebook AI Research for all of our experiments. We used an 80-20 split to split the dataset into training and validation datasets with a random seed of 42 using sklearn's (Pedregosa et al., 2011) train_test_split functionality. For the hyperparameters, we have used the default hyperparameters of MMF. For subtask 1, we have reported macro F1 score and for subtask 2, we have reported weighted F1.

5 Results

Table 1 contains all the results of our experiment. It can be noted that we mostly used the default hyperparameters from the MMF framework and did not perform rigorous hyperparameter tuning for our experiments, so the model performances still be improved with the search for optimal hyperparameters using cross-validation. We analyze the results of the approaches tried for each subtask. Among the baselines, we saw the unimodal-text models perform better for both the subtasks than the unimodal-image models. Among the unimodal-text models, BERT performed better than RoBERTa. The fusion models performed a bit better than the unimodal models for both the subtasks, with BERT Concatenation performing significantly better than late fusion in the first subtask. The multimodal transformers models give a performance increase over the fusion models, with VilBERT performing the best for Subtask 1 and VisualBERT giving the best performance for the second subtask. Among the multimodal transformer architectures, the ones pretrained with multimodal objectives turned out to be better in performance than those trained using unimodal objectives. Given that VisualBERT and VilBERT performed the best, we further pretrained them in a multimodal task-adaptive setting. VilBERT pretrained on the HatefulMemes dataset gave the best results for the first subtask, whereas VisualBERT pretrained on the HatefulMemes dataset was our best model for the second subtask.

6 Conclusion

In our worked, we have provided a comparative analysis of architectures for solving the task of misogyny identification. Although our best-performing model did achieve a substantial improvement over the baselines, the scores still indicate scope for further improvement. This also brings forth the challenging nature of the task in itself. Furthermore, using ensemble models like Vilio (Muennighoff, 2020) can result in better-performing models which can be tried out in future scope.

Abstract

In this paper we describe our work towards building a generic framework for both multi-modal embedding and multi-label binary classification tasks, while participating in task 5 (Multimedia Automatic Misogyny Identification) of SemEval 2022 competition.

Since pretraining deep models from scratch is a resource and data hungry task, our approach is based on three main strategies. We combine different state-of-the-art architectures to capture a wide spectrum of semantic signals from the multi-modal input. We employ a multi-task learning scheme to be able to use multiple datasets from the same knowledge domain to help increase the model's performance. We also use multiple objectives to regularize and fine tune different system components.

1 Introduction

In this paper, we present the system that we have built to participate in SemEval 2022 task 5 (Fersini et al., 2022), Multimedia Automatic Misogyny Identification (MAMI) challenge. The task is targeted at identification of misogynous memes by basically using the meme's image and pre-extracted English text content as input sources. The task is divided into two main sub-tasks: Sub-task A is a binary classification task where a meme should be categorized either as misogynous or not misogynous, Sub-task B is a multi-label binary classification task, where the type of misogyny should be recognized among the potential overlapping categories: stereotype, shaming, objectification and violence. Generally, meme classification is a challenging task as memes are multi-modal, rely heavily on implicit knowledge, and are subject to human misinterpretation especially among different backgrounds and cultures.

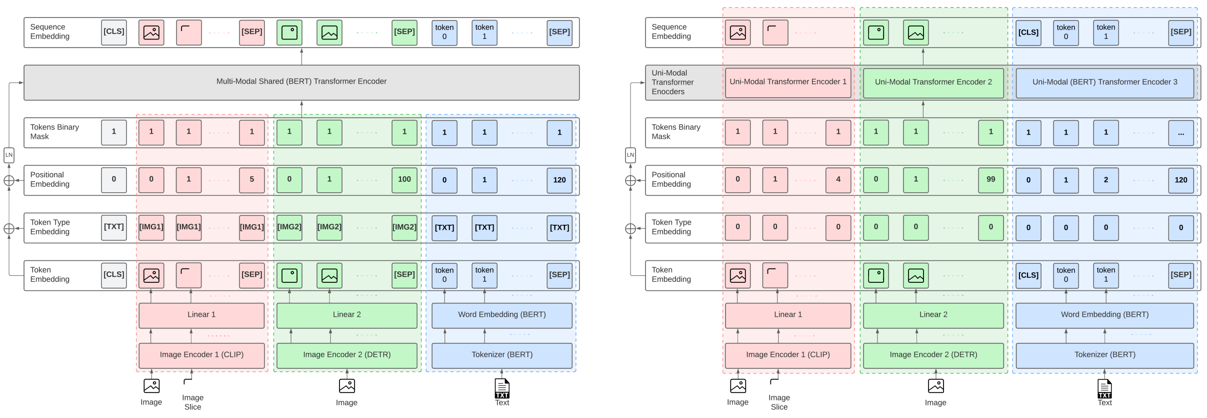
We have used transformer (Vaswani et al., 2017) based architectures and took a transformer based approach to combine them. Transformer based architectures are achieving state-of-the-art performance for Natural Language Processing and Computer Vision related tasks. There are architectures for language, vision, and language and vision combined. There are also architectures for other modalities however in MAMI's scope, we are interested in images and text only.

Pretraining a deep neural network and a transformer based architecture from scratch is a data hungry and computation resources demanding task. Especially in a multi-modal domain where input can have multiple image and text modalities. The literature is rich in a variety of architectures which achieve competitive performance in different tasks for different modalities. In our work, we took an approach towards building a framework that would allow us to combine different pretrained architectures. With relatively few epochs and using relatively less compute resources, our goal was to build and train a classifier framework that could harness the power of pretrained architectures as backbones, using relatively limited resources: no multiple GPUs for training and constrain the cost to be relatively small, in the range of hundred dollars in total.

We have assumed that using as many different backbone architectures which are trained on different tasks for different modalities can allow us to capture a wide spectrum of semantic signals from the input modalities. Then we just need to build a classifier to learn the relationship between these signals and the target classes.

We have also found and discuss below that there are available text and image datasets for hate speech, sexism and hateful memes which sound related to this task and could be used to augment MAMI's dataset. Eventually, our goal was to combine different datasets in a multi-task classifier.

In order to guide the model during training towards the main objective, which is to minimize



(a) Multi-modal shared transformer encoder

(b) Uni-modal multi transformer encoders

Figure 1: Sequence embedding

the classification loss, we have employed different auxiliary objectives. Breaking down the whole architecture into components, each component has a sub-target. We have assumed that if we could assure that each component performs well on the sub-target, then the whole system would perform better on the main target. A component producing a clear signal can facilitate the learning of the downstream dependent components. This could increase model performance in terms of either accuracy or convergence speed. So, if we could formulate an objective function for each component, we can linearly combine them with the main objective function. This helps fine tuning and regularizing the components of the system.

We have built a generic classification framework and applied it to both sub-tasks A and B. During the evaluation phase of the competition, we have achieved, for sub-task A, a macro-average F1-Measure of 0.715, and for sub-task B, a weighted-average F1-Measure of 0.698. During post-evaluation phase we have achieved higher score for sub-task A of 0.761. Our code is available at `https://github.com/ahmed-mahran/MAMI2022`.

2 Background

Datasets: Besides MAMI dataset, there are many datasets that could be used to train our model. The input could be uni-modal as text only or image only, or bi-modal as pairs of image and text. (Vidgen and Derczynski, 2020) reviews 63 publicly available training datasets and they have published a dataset catalogue on a dedicated website [1]. We have used the hateful meme dataset created by Facebook AI (Kiela et al., 2020) which consists of $10K$ memes labeled hateful or not.

Multi-modal frameworks: MMBT (Kiela et al., 2019) concatenates, into a single sequence, linear projection of ResNet (He et al., 2016) output for image pooled to N different vectors, with BERT (Devlin et al., 2018) tokens embeddings for text. The sequence is fed into a transformer encoder, they call it a bi-transformer, after adding positional embeddings and segment embeddings to distinguish which part is image and which part is text. The architecture is generic enough to use different image encoders. As a variant of how we combine signals from image and text, we extend the MMBT architecture to combine more than two encoders however that wasn't our top performing variant. MMCA (Wei et al., 2020) combines Faster R-CNN (Ren et al., 2015) with BERT to compute two embedding types for each modality: self-attention embedding to capture intra-modality interactions, and cross-attention embedding to capture both intra- and inter-modality interactions.

3 System overview

3.1 Tokens embedding

At this stage, we encode each input modality into a sequence of vectors in a unified dimension space. We also generate a binary mask vector with length equal to the sequence's length to indicate which part of the sequence the model should consider. This produces the output at "Token Embedding" and "Tokens Binary Mask" layers illustrated in figure 1. We can use different encoders per modality and generate different sequence types to capture as

many semantic signals as possible. For our setup, we have tested CLIP (Radford et al., 2021) and DETR (Carion et al., 2020) encoders for image modality and BERT (Devlin et al., 2018) encoder for text modality.

CLIP image embedding: We split the image into 4 equal size patches (2×2) then we use CLIP (Radford et al., 2021) to encode the whole image along with its 4 slices into a sequence of 5 vectors. Then we project each vector into the model hidden dimension space. In our experiments, we have used CLIP model named "RN50x4" (which uses as backbone ResNet-50 scaled up 4x using the EfficientNet scaling rule (Tan and Le, 2019))[2].

DETR image objects embedding: We use DETR (Carion et al., 2020) [3] to encode the image into a sequence of 100 image objects representations. DETR's transformer decoder produces a sequence of 100 possible object boxes representations that we use as objects embeddings. However, not all of the objects are real objects as DETR can produce a no-object prediction. So, we use DETR's classifier which is trained on the object detection task to generate masks for no-objects. For each box from the 100, the classifier produces 92 logits which correspond to 92 possible object labels. We take the softmax of the 92 logits and mask out the corresponding object box if the label with the highest softmax probability is the no-object label. We fallback to another masking strategy if all the 100 boxes are masked out; we ignore the logit of the no-object label and then take the softmax of the rest labels to select 4 out of 100 boxes with highest softmax probabilities. Similarly with CLIP output, we project each vector into the model hidden dimension space.

BERT text embedding: We use BERT (Devlin et al., 2018) [4] pre-trained on hate speech (Mathew et al., 2020) to tokenize input text and generate tokens embeddings (for a maximum of 120 tokens). We don't project BERT's embeddings as we use its output space as the model's hidden dimension space (which has length of 768 dimensions).

3.2 Sequence embedding

At this stage, the model generates one combined sequence of vectors using tokens embedding from the tokens' embedding stage. This is the output in the "Sequence Embedding" layer illustrated in figure 1. For the token embedding output, we add token type embedding and positional embeddings that encode the position of each token in the corresponding input sequence per type then we apply a layer normalization (Ba et al., 2016). Along with input masks, the layer normalized sum of embeddings is fed to a multi-layer transformer encoder stage to produce the final sequence embedding at the "Sequence Embedding" layer in figure 1. The output sequence has the same number and dimen-

[2]We have used OpenAI implemantion on `https://github.com/openai/CLIP`

[3]We have used Huggingface Transformers implementation of DETR

[4]We have used Huggingface Transformers implementation of BERT with weights from "Hate-speech-CNERG/bert-base-uncased-hatexplain"

sionality of the input tokens. We have two variants for the transformer encoder stage:

Shared transformer encoder: The general architecture of the shared transformer encoder variant is illustrated in Figure 1a. What distinguishes this variant is that we use a shared multi-layer transformer encoder to capture the intra- and inter-modality interactions. Because of this, for each input embedding type, we add token type embedding which is the same for each input encoder to distinguish which tokens are from which input encoder. In our setup, we have three token types; that is one for each of: CLIP, DETR and BERT encoders. We also append a special [SEP] token at the end of each sequence type and we prepend to the whole combined sequence a global and special [CLS] token. We use the pre-trained BERT transformer encoder as the shared transformer encoder.

Multiple transformer encoders: The general architecture of this variant is illustrated in Figure 1b. The difference here is that instead of using one shared transformer encoder, we use a multi-layer transformer encoder per token type. We still add a token type embedding such that each transformer encoder learns its own token type parameters. We think we can remove this step however we have not tested this. Also, in this variant we don't need to add the extra [SEP] token per type and the global [CLS] token however we add a local [CLS] and [SEP] tokens for BERT only. For CLIP and DETR, we use PyTorch's implementation of the transformer encoder which is described in (Vaswani et al., 2017) with 8 heads and 6 layers but for BERT we keep it as in (Devlin et al., 2018). Then the final output sequence is just the concatenation of all sequences from each transformer encoder.

3.3 Classification

We have two modes of classification depending on the sequence length of the output of the transformer encoder stage. As shown in figure 2, we either use the whole sequence of vectors or pool it to one vector.

Multi-head MLP classifier: We use the pooled sequence embedding as classifier input. In our setup, we have used the first [CLS] token in the shared transformer encoder variant. The classifier is a two feed forward linear layers with a GELU activation in between and a hidden size of 768. The final layer produces number of logits equals to number of classes and we apply a sigmoid activation to compute each binary label probability.

Transformer decoder with single-head shared MLP classifier: Here the whole sequence embedding along with the binary mask is fed into a multi-head transformer decoder as a source sequence. Then the target sequence is formed by a learnable target class query embedding for each class in the target classes. The transformer decoder learns how each class interacts with each input modality signal through the cross-attention mechanism between the source and target sequences. Moreover, the decoder learns the dependency among the target classes through the self-attention mechanism for the target sequence. The decoder output is then fed into a single-head MLP classifier that shares parameters for all classes such that $MLP(q_i)$ is the logit of label i using the corresponding class query embedding, q_i, from the decoder output. The MLP classifier has the same architecture as the previous one in terms of number of layers, type of activation and hidden size, and similarly as well we compute the binary label probability for each class. We use PyTorch's implementation of the transformer decoder which is described in (Vaswani et al., 2017) with 8 heads and 6 layers.

3.4 Multi-task learning

In order to use more training data from other but similar datasets, we have followed a multi-task learning approach. For each dataset $\mathcal{D}$, there is a set of target labels $\mathcal{L}$, we can define as many tasks as the sets of labels in the power set $\mathcal{P}^+(\mathcal{L})$ (excluding the empty set) such that it is possible to use the same label in more than one task. Each task has a separate MLP classifier while all tasks across the datasets share the rest of the parameters including the learnable classes queries. During training, each mini-batch contains data from only one dataset and we compute the targets per task for all the tasks of the dataset.

3.5 Multi-objective

For a training instance i, we use x_i to refer to the input regardless from its actual representation, $y_{i,c} \in \{0, 1\}$ is the value of the target binary label c, and θ is the set of learnable parameters.

Main objective: We use a binary cross entropy to minimize the loss per label.

$$\begin{aligned} \mathcal{L}_0(i,c) = \; & y_{i,c}. \log p(c|x_i,\theta) \\ +(1-y_{i,c}). & \log(1-p(c|x_i,\theta)) \end{aligned} \tag{1}$$

Algorithm 1 Multi-task learning

```
$datasets \leftarrow \{D_1, D_2, ...\}$
$tasksPerD \leftarrow \{(D_1, \{T_1, T_2, ...\}), ...\}$
$labelsPerT \leftarrow \{(T_1, \{l_1, l_2, ...\})\}$
for $epoch \in epochs$ do
    for $b \in mini\text{-}batches$ do
        $dataset \leftarrow$ sample $1$ from $datasets$
        $tasks \leftarrow tasksPerD[dataset]$
        for $task \in tasks$ do
            learn $b$, $task$, $labelsPerT[task]$
        end for
    end for
end for
```

Token encoding projection alignment: We linearly project modal encoding into the hidden model space (as described in section 3.1). In order to preserve a similar structure of data points across spaces, we impose a cosine similarity constraint such that for any two input instances, x_i and x_j, the similarity, $s(.,.)$, between their encoding, $f(.)$, is the same as the similarity between the projection, $g(.)$, of their encoding. We apply this to all pairs in each batch.

$$\begin{aligned}\mathcal{L}_1(i,j) = \ & |s(f(x_i), f(x_j)) \\ & -s(g(f(x_i)), g(f(x_j)))|\end{aligned} \tag{2}$$

Contrastive embedding loss: This is intended at regularizing the embedding space of the MLP classifier to make instances of dissimilar labels more separable. For any two input instances, x_i and x_j, we apply the embedding loss per class c on the input, h^{l-1}, of each layer l of the MLP classifier.

$$\begin{aligned}\mathcal{L}_2(i,j,c) = \\ \frac{1}{2}\sum_l 1 - s_c(y_i, y_j) s_h(h^{l-1}_{i,c}, h^{l-1}_{j,c})\end{aligned} \tag{3}$$

$$s_c(y_i, y_j) = (2y_{i,c} - 1)(2y_{j,c} - 1) \tag{4}$$

$s_c(.,.) \in \{-1, 1\}$ is the labels similarity for class c of two instances; -1 indicates dissimilar labels while 1 indicates similar labels. $s_h(.,.) \in [-1, 1]$ is the cosine similarity of layer input when comparing two instances. It is worth noting that in case of the multi-head MLP classifier, $h^{l-1}_{i,c}$ is the same for all classes. We also apply this loss to all pairs in each batch. This loss encourages the transformer encoder in case of the multi-head MLP classifier, the decoder in case of the shared single head MLP classifier, as well as the hidden layers of the MLP classifier to produce embeddings with structures that capture labels similarity such that instances with the same label value get closer embeddings than instances with different label value.

The overall loss per batch and task given a dataset d:

$$\begin{aligned}\mathcal{L}^d_t = & \frac{1}{N_i N^t_c}\sum_{i,c}\mathcal{L}_0(i,c) \\ & + \frac{1}{N_i(N_i-1)}\sum_{i \neq j}\mathcal{L}_1(i,j) \\ & + \frac{1}{N_i(N_i-1)N^t_c}\sum_{i \neq j, c}\mathcal{L}_2(i,j,c)\end{aligned} \tag{5}$$

The overall loss per batch for all tasks of the dataset is the average task loss:

$$\mathcal{L}^d = \frac{1}{N^d_t}\sum_t \mathcal{L}^d_t \tag{6}$$

N_i is the batch size, N^d_t is the number of tasks for dataset d, and N^t_c is the number of classes for task t.

4 Experimental setup

In addition to MAMI's dataset, we have used Facebook's hateful memes dataset. We have set the tasks configurations as shown in table 1.

Dataset	Task	Labels
MAMI	MAMI	{misogynous, shaming , stereotype , objectification, violence}
	Task_A	{misogynous}
	Task_B	{shaming, stereotype , objectification, violence}
FBHM	Hateful	{hateful}

Table 1: Tasks labels configurations per dataset. FBHM is short for Facebook Hateful Meme.

We have added the redundant task MAMI for the MAMI dataset to make sure that the decoder learns the dependency among all labels as Task_B's labels depend on Task_A's label we wanted to make sure that the model captures this dependency.

We have split both datasets into 80% train and 20% dev sets using stratified sampling. We have used the data provided at post-evaluation period of the competition as the test set. We have used a batch size of 16 and number of epochs as 15. We have used MADGRAD (Defazio and Jelassi, 2021) for optimization. Learning rate was set to 2×10^{-4} and we used a learning rate linear scheduler with a warmup period [5]. Gradients are accumulated every 20 batches so there was a total gradient accumulation steps of: total number of batches$/20 \times$ number of epochs. We have set the warmup period to: total gradient accumulation steps$/10$. For all parameters except biases and layer normalization weights, we have used a weight decay of 5×10^{-4}. We clip gradients to overall norm of 0.5. Our implementation is PyTorch based and we have used HuggingFace Transfomers implementation for both BERT and DETR. We have run our experiments on Google Colab Pro plus using one Tesla P100 GPU. We didn't perform any special data preprocessing, just the requirements for each backbone. Also, to make experiments quicker, we didn't perform any fine tuning for any of the backbones and we pre-generated and stored each backbone output instead of re-evaluating the same data across epochs and experiments.

We used the official accuracy measures to score how the model performs on each task. For the single class tasks, we have used macro-average F1-Measure and we called it scoreA. In particular, for each class label (i.e. true and false) the corresponding F1-Measure will be computed, and the final score will be estimated as the arithmetic mean of the two F1-Measures. For the multi class tasks, we have used weighted-average F1-Measure and we called it scoreB. In particular, the F1-Measure will be computed for each label and then their average will be weighted by support, i.e. the number of true instances for each label.

5 Results

5.1 Ablations

We have the following system configurations [6] which would result in different architecture variations.

Transformer encoder (Xformer Enc) whether to use shared transformer (**Shared**) or multi transformers (**Multi**).

Encoder output pooling (Pooling) whether the whole sequence is pooled using [CLS] embedding (**[CLS]**), this means we use the multi-head MLP classifier and no decoder), or no pooling (**No**) or only text tokens are pooled using text's [CLS] token (**txt [CLS]**), this means we use the decoder with the shared single head MLP classifier.

Token encoding projection alignment (Proj Align) whether to enable it (**Yes**) or not (**No**).

Contrastive embedding loss (Contrastive) whether to enable it (**Yes**) or not (**No**).

Multi-task learning (Multi-task) whether to use Facebook's hateful meme dataset (**Yes**) or not (**No**).

Image encoders (Backbones) whether to use CLIP only (**CLIP**), DETR only (**DETR**), or both together (**CLIP and DETR**).

We plan experiments as tournament of rounds such that in each round we test subset of the configurations fixing the rest. Then we use the winning configuration values for subsequent rounds. For each experiment, we report the max score for Task_A and Task_B on all splits. Appendix A contains more details on scores distributions.

5.1.1 Round 1

At this round we compare transformer encoder and encoder output pooling methods. We perform four experiments with configurations and results sumaized in table 2. The winner of this round is the multi-transformers encoders without output pooling architecture variant.

Experiment	00	01	02	03
Xformer Enc	Shared	Shared	Multi	Multi
Pooling	[CLS]	No	No	txt [CLS]
Proj Algn	No			
Contrastive	No			
Multi-task	No			
Backbones	CLIP and DETR			
Score				
Test - Task_A	0.6819	0.7226	**0.7436**	0.7329
Test - Task_B	0.5886	0.6422	**0.6785**	0.6772
Dev - Task_A	0.8395	0.8355	**0.8564**	0.8519
Dev - Task_B	0.6650	0.6933	**0.7420**	0.7310
Train-Task_A	**0.9253**	0.9121	0.9066	0.8998
Train-Task_B	0.7006	0.7242	**0.7782**	0.7647

Table 2: Experiments configurations for round 1 and corresponding results.

5.1.2 Round 2

At this round, we test the significance of the multi-objective approach. The configurations and corresponding results are summarized in table 3. To-

[5]We used get_linear_schedule_with_warmup from Huggingface Transformers.

[6]We give each item a short name in parenthesis to be able to refer to corresponding items in experiments results tables compactly.

ken encoding projection alignment makes improvements on both tasks on the test split when enabled alone. Also, contrastive embedding loss seems to slightly improve Task_B. After performing statistical tests and comparing distributions of the scores, we pick experiment 10 as the winner variant.

Experiment	02	10	12	13
Xformer Enc	Multi			
Pooling	No

Test - Task_A	0.7436	**0.7504**	0.7358	0.7467
Test - Task_B	0.6785	0.6798	**0.6823**	0.6777
Dev - Task_A	**0.8564**	0.8535	0.8515	0.8535
Dev - Task_B	**0.7420**	0.7387	0.7371	0.7313
Train-Task_A	0.9066	0.8983	**0.9090**	0.8988
Train-Task_B	**0.7782**	0.7679	0.7676	0.7573

Table 3: Experiments configurations for round 2 and corresponding results compared to best configurations from round 1.

5.1.3 Round 3

At this round, we test the significance of the image encoders backbones, namely: CLIP and DETR. The configurations and corresponding results are summarized in table 4. It seems that our use of DETR was incompetent to CLIP.

Experiment	10	20	21
Xformer Enc	Multi		
Pooling	No		
Proj Algn	Yes		
Contrastive	No		
Multi-task	No		
Backbones	CLIP and DETR	CLIP	DETR

Dev - Task_B	0.7387	**0.7429**
Train-Task_A	0.8983	**0.9127**
Train-Task_B	0.7679	**0.7815**

Table 5: Experiments configurations for round 4 and corresponding results compared to best configurations from round 2.

5.2 Visualizations

In figure 3, we show t-SNE projections of the transformer decoder output per class and the corresponding class learnt input query embedding. We use data from experiment 30 in section 5.1.4. It is interesting that, for all classes, the class learnt query embedding is positioned on the side with denser positive labels. This indicates that the learnt class queries can be thought of as centers of positive labels.

In figure 4, we show average attention weights per transformer decoder layer. Figure 4a illustrates the dependencies between each class and other classes. As shown in the figure, numbers are very close which indicates that each class depends uniformly on other classes. Figure 4b shows the average cross-attention weights between the source and target sequences from the transformer decoder layers and aggregated per input encoder. Clearly, the model pays more attention to CLIP features, and less attention to BERT text features, and the least attention to DETR objects features. This conforms with results from round 3 in section 5.1.3.

6 Conclusion

In this paper, we propose a generic framework for both multi-modal embedding and multi-label binary classification tasks. We combine and use as backbones different architectures achieving state-of-the-art in different or similar tasks on different modalities to capture a wide spectrum of semantic signals from the multi-modal input. By employing a multi-task learning scheme, we are able to use

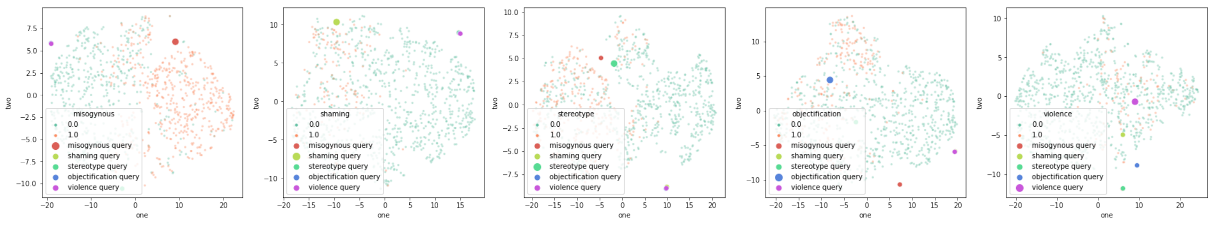

Figure 3: t-SNE projections of transformer decoder output per class (small dots) and the corresponding class query embedding (the biggest dot).

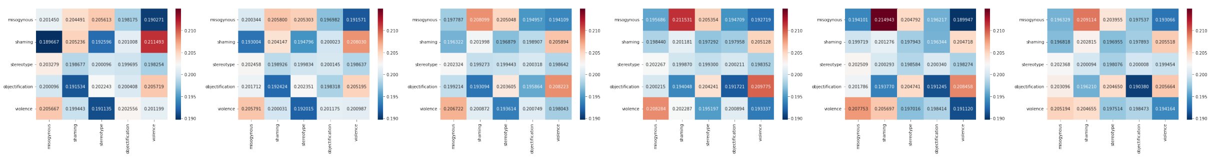
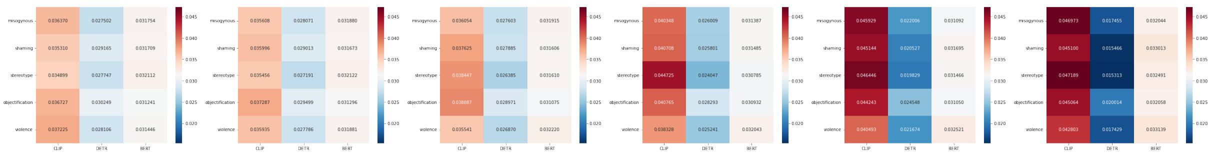


(a) Transformer decoder average self-attention weights



(b) Transformer decoder average source $\times$ target cross-attention weights. Source weights are aggregated per input encoder.

Figure 4: Attention weights visualization per transformer decoder layer. First input layer is on the left while last output layer is on the right.

multiple datasets from the same knowledge domain and increase the model's performance. In addition to that, we use multiple objectives to regularize and fine tune the system components. We have carried out experiments to verify our ideas and the results show the significance of some of the ideas. As a future work, we need to do more experiments with different backbone architectures and more datasets. We can also try more objectives and regularizations; for instance, we can use our observation from figure 3 to make the decoder output for a positive instance closer to the corresponding class query embedding.

Abstract

In this paper we present our approach and system description on *Task 5 A in MAMI: Multimedia Automatic Misogyny Identification.* In our experiments we compared several architectures based on deep learning algorithms with various other approaches to binary classification using Transformers, combined with a nudity image detection algorithm to provide better results. With this approach, we achieved a test accuracy of 0.665.

1 Introduction

Misogyny is hatred or contempt for women. It is a form of sexism used to keep women at a lower social status than men, thus maintaining the societal roles of patriarchy. Misogyny has been widely practiced for thousands of years. It is reflected in art, literature, human societal structures, historical events, mythology, philosophy, and religion worldwide (Manne, 2017).

The Internet represents for many an extension of our offline interactions, and seemingly mundane everyday practices (e.g. participating in social media) form a significant part of our everyday experiences. Unfortunately, it is too common to see examples of harassment towards women and marginalized groups online within these experiences and practices (Drakett et al., 2018).

Women have a solid presence on the web, especially in picture-based web media like Twitter and Instagram: 78% of females utilize online media on numerous occasions each day, in contrast with 65% of men.

A popular way of communicating via social media platforms are MEMEs. A meme is an image portrayed through pictorial content with overlaid text which is written a posteriori, with the fundamental objective of being entertaining and/or ironic. Even though most of memes are created with the goal of making amusing jokes, shortly after their standardization individuals began to use them to disseminate hate against women, leading to sexist and aggressive messages in internet environments that allow people to freely express sexism without the fear of retaliation.

The detection of this disrespectful content is essential to eliminate it as soon as possible and stop spreading misogyny as a "joke".

In MAMI: Task 5, Track A (meme binary classification) (Fersini et al., 2022), participants must determine whether a meme (text + image) is misogynist or not.

Meme sentiment-related tasks analysis is challenging, as memes are used created for various purposes, they are always evolving and often use sarcasm and humour. While misogyny and hate speech detection in text has been widely explored by the NLP community (Badjatiya et al., 2017). Its detection in images and text and how they correlate has not been explored in depth.
In this field we used BERT (Devlin et al., 2018), RoBERTa (Liu et al., 2021) for training and classifying text, and nudenet tool for image classification (https://github.com/notAI-tech/NudeNet).

Our results show that combining text and image classification results are slightly better than using only one of the two methods.

The rest of the paper is organized as follows. Section 2 contains a briefly description of the dataset and its structure, Section 3 features the analysis of some of the previous works related to our task. In section 4 we describe the different models and algorithm used, and their configurations. Section 5 provides details about data and models setup, while Section 6 reports experimental results and the paper is concluded in Section 7.

2 Background

This paper is focused on subtask A: Binary classification. The corpus provided is composed of 5000 1-value rows (misogyny) and 5000 0-value rows (not misogyny), so it is already well-balanced. Each row has the following format:

file_name | misogynous | shaming | stereotype | objectification | violence | text transcription

Where "file_name" is the .jpg link to the image, and "text transcription" is the text extracted from the image.

For our binary classification task, we only need the fields "file_name", "misogynous" and "text transcription" to train the models presented. For models that also used nudity recognition, a column "unsafe" was added later.

The csv file used follows this structure:

- file_name: *"10.jpg"*
- misogynous: "*1*"
- text transcription: "*ROSES ARE RED, VIOLETS ARE BLUE IF YOU DON'T SAY YES, I'LL JUST RAPE YOU quickmeme.com*"

3 Related work

Sentiment analysis of text is a very active research area that still faces multiple challenges such as irony and humour detection (Farías et al., 2016). In this area, the focus of the NLP community has increased towards detection of offensive language, aggression, hate-speech detection (Wei et al., 2021) and specifically misogyny, taking into account it can be expressed in a direct, explicit manner or an indirect, sarcastic manner, and even if this message is genered or not-gendered (Samghabadi et al., 2020).

The analysis of misogyny in memes has already been done in a psychologic point of view (Drakett et al., 2018), but never in computational models. Multimodal analysis research has been extended during the last years, but the focus was mostly on Video and text or speech and text (Pozzi et al., 2016). The specific multi-modality of memes in sentiment analysis has only been addressed recently by investigating their correlation with other comments in online discussions (French, 2017).

The growing usage of memes as an alternative medium of communication on social media has also recently drawn the attention of the online abuse research community.

However, memes completely make sense only if one takes both text and image content into account. These modalities can also lead to totally different perceived sentiment when recombined. For example, a meme whose image is a scary clown and the text is "happy birthday" will have a very different sentiment from a meme with the same text but with an image of a funny clown.

Sabat et al. (2019) performed hate speech detection on memes and showed that images were more important than text for the prediction.

In the other hand, Bonheme and Grzes (2020), investigated the relationship of text and image in sentiment analysis of memes, and found that images and text were uncorrelated. Fusion-based strategies did not show significant improvements and using one modality only (text or image) tends to lead to better results.

4 System overview

We focus on exploring different training techniques for text using BERT and RoBERTa, given their superior performance on a wide range of NLP tasks, while for image we used the python module *nudenet*.

Each text encoder, image classifier and training method used in our model are detailed below.

4.1 Text Encoders

BERT (Devlin et al., 2018): pretrained model BERT-base uncased, released by the authors, was used as embedding layer, tokenizer and classifier. It consists of 12 transformer layers, 12 self-attention heads per layer, and a hidden size of 768.

RoBERTa (Liu et al., 2021): We use the RoBERTa-base model released by the authors. Like BERT, RoBERTa-base consists of 12 transformer layers, 12 self-attention heads per layer, and a hidden size of 768.

4.2 Image nudity classification

As memes are mostly done as "joke" and tend to be ironical and use a very refined and deep text-image relationship.

A similar approach to the one used by Messina et al. (2021) was applied, where one of the two modalities acts as the main one and the second intervenes to enrich the first (in our case, text will act as the main modality and image will be used just to enrich the results from the first one).

The goal of this task was to detect misogyny, and we decided to use a Not Safe For Work (NSFW) image classifier.

Nudenet is the classifier used for this task. It gives each image of our dataset an "unsafe" value from 0 (safe) to 1 (unsafe). The Neural Net for Nudity Classification is trained on 160,000 entirely auto-labelled (using classification heat maps and various other hybrid techniques) images.

A NSFW image classifier was used for two main reasons. First, because image-only classification using Convolutional Neural Networks did not reached good results using the training data. We only obtained an accuracy of 0.52. Second, because most of NSFW images are misogynous, as it could be demonstrated by using only the *Nudenet* classifier, obtaining a value of 0.83 for precision in the positive (misogynous) class.

4.3 Models

Based on Convolutional Neural Networks (Konda et al., 2019), BiLSTM Neural Networks (Zhou et al., 2016), and BERT Transformers (Devlin et al., 2018), several models have been developed: (1) BiLSTM Neural Network with RoBERTa as embedding, (2) BiLSTM Neural Network with BERT as embedding, (3) BiLSTM Neural Network with BERT as embedding and nude detection, (4) 1- Dimensional Convolutional Neural Network with BERT Tokenizer, and (5) BERT Transformer with nude detection.

In our models, RoBERTa and BERT were used with word-embedding strategies, as they have an advantage over models like Word2Vec. Each word, under Word2Vec, has a fixed representation regardless of the context within which the word appears. Nevertheless, BERT produces word representations that are dynamically informed by the words around them (Shi and Lin 2019a).

For example, given the two sentences *"The man was director of a bank in his hometown."* and *"The man went fishing by the bank of the river."*, Word2Vec would produce the same word embedding for the word "bank" in both sentences. However, BERT will create different word embedding for "bank" for each sentence.

4.3.1 BiLSTM Neural Network with RoBERTa as embedding

Long Short-Term Memory (LSTM), (Hochreiter and Schmidhuber, 1997) is a widely known recurrent neural network (RNN) architecture. We used Bidirectional LSTM (Schuster and Paliwal, 1997) models for our experiments. A Bidirectional LSTM (BiLSTM) layer processes the text both in the forward as well as backward direction and hence is known to provide better context understanding.

Introduced by Facebook, the Robustly optimized BERT approach RoBERTa, is a retraining of BERT with an improved training methodology, 1000% more data and compute power (Shi and Lin, 2019b).

The RoBERTa model used to extract the word embedding layer for the BiLSTM Neural Network was RoBERTa-base uncased.

4.3.2 BiLSTM Neural Network with BERT as embedding

For this approach, a BERT-based model was used. In particular, we implemented the BERT-base uncased model.

4.3.3 BiLSTM Neural Network with BERT as embedding + nude detection

Python's Nudenet module was used in every image of the given dataset to assign it a value of "unsafety" from 0 (safe) to 1 (unsafe). Then, if the text prediction is 1, the final prediction is set as 1, otherwise if the text prediction is 0 and the image unsafe value is greater than a threshold value, final prediction is set to 1.

The best values for this threshold were the ones with the best accuracy classifying using with nudity in images. These threshold values were 0.45 and 0.60.

4.3.4 1-Dimensional Convolutional Neural Network with BERT as embedding + nude detection

Convolutional neural networks (CNN) (Lecun et al., 1998) are originally designed to process and learn information from image features by applying convolution kernels and pooling techniques which are widely adopted for extracting stationary features; for instance, CNN has shown its adaptability in the field of text mining and NLP tasks. (Kim, 2014) reported series of experiments with CNNs that achieve good results on sentence classification and sentiment analysis tasks.

To improve this model classification, BERT-base uncased model was used to create the word embedding layer. The nudity classification algorithm with a threshold of 0.45. was used to achieve better results.

4.3.5 BERT Transformer with nude detection

Bidirectional Encoder Representations from Transformers (BERT) is a transformer-based machine learning technique for natural language processing (NLP) pre-training developed by Devlin et al. (2018). BERT model is pre-trained from unlabeled data extracted from the BooksCorpus with 800M words and English Wikipedia with 2,500M words.

It uses Transformer, (Vaswani et al., 2017) an attention mechanism that learns contextual relations between words (or sub-words) in a text. In its vanilla form, Transformer includes two separate mechanisms — an encoder that reads the text input and a decoder that produces a prediction for the task. Since BERT's goal is to generate a language model, only the encoder mechanism is necessary.

Also, the nudity classification algorithm with a threshold of 0.45. was used to achieve better results.

5 Experimental setup

For each text transcription row in the corpus, a small preprocessing was applied. Every word was undercased, web pages' links, hashtags, usernames, emojis, punctuation symbols, numbers, and words with length less than 2 characters were removed, as well as English stop words using nltk.corpus module (Sarica, 2021).

For all the experiments, we split the training dataset in two parts: 80% for training and 20% for validation using a stratify approach.

The parameters used in the training phase were: batch size of 32 and 5 epochs.

6 Results

Table 1 shows a summarization of the training and test results obtained for each one of the models in the evaluation phase.

According to the official metrics (F1-score for the positive class), our results are all around 0.60 – 0.65, being the best model BiLSTM Neural Network with BERT as embedding + nude detection, with a 0.665 F1-score. With this result, we obtained the 43 place in the ranking.

As we expected, the model that obtained the best results during the training phase also obtained the best result in the evaluation phase.

7 Conclusions

In this paper, several approaches and systems descriptions on Task 5 (Subtask A) in SemEval 2022: Multimedia Automatic Misogyny Identification are detailed. The main aim was to develop various deep learning models and check how multi-modality of text and image could help achieve better classification results.

Six different models were developed and BiLSTM Neural Network with BERT as embedding + nude detection (0.45 threshold) was the definitive one. After training and analyzing each model, we achieved an F1-score of 0.665 in

Model	**Training phase**		**Evaluation phase**
	Accuracy	**F1 - Score**	**F1 - Score**
BiLSTM Neural Network with RoBERTa as embedding	0.793	0.799	0.607
BiLSTM Neural Network with BERT as embedding	0.810	0.832	0.652
BiLSTM Neural Network with BERT as embedding + nude detection threshold 0.45	**0.837**	**0.840**	**0.665**
BiLSTM Neural Network with BERT as embedding + nude detection threshold 0.6	0.835	0.838	0.663
1-D Convolutional Neural Network with BERT as embedding + nude detection	0.813	0.825	0.649
BERT Transformers + nude detection	0.806	0.812	0.639

Table 1: Results obtained with the different models

the evaluation phase for class “1”. We can conclude that merging text and image classifiers improves the results in the task of misogyny detection in memes.

In future works, we intend to improve our image classifiers models. Also, we want to use other pretrained models based on transformers.

galorentz@inf.ufrgs.br

Viviane P. Moreira
Inst. of Informatics / UFRGS – Brazil
viviane@inf.ufrgs.br

Abstract

This paper describes INF-UFRGS submission for SemEval-2022 Task 5 Multimodal Automatic Misogyny Identification (MAMI). Unprecedented levels of harassment came with the ever-growing internet usage as a means of worldwide communication. The goal of MAMI is to improve the quality of existing methods for misogyny identification, many of which require dedicated personnel, hence the need for automation. We experimented with five existing models, including ViLBERT and VisualBERT - both uni and multimodally pretrained - and MMBT. The datasets consist of memes with captions in English. The results show that all models achieved Macro-F1 scores above 0.64. ViLBERT was the best performer with a score of 0.698.

1 Introduction

Social media and anonymity enable the spread of hateful speech, which explains why misogyny is prevalent and abundant on the internet. Not only is it present, but also increasingly so, as confirmed by Farrell et al. (2019). The platforms that contribute to the sharing of hateful content dedicate a considerable amount of human effort in detecting, analyzing, and eventually removing these contents. The task is demanding due to the nature of the posts, which are frequently not straightforward – they often contain irony and slang. Additionally, the textual information needed to automatically classify a post as misogynistic might be part of an image, in the form of a meme. That prevents sexist posts from being immediately detected by algorithms that rely solely on textual input.

In this paper, we describe the training and usage of five different multimodal models applied to detecting misogynistic memes in the scope of SemEval-2022 Task 5 Multimodal Automatic Misogyny Identification (MAMI) (Fersini et al., 2022). We explain the distinction between the models and compare their performances in light of differences in pretraining (unimodal or multimodal).

Among the five models, the one which achieved the highest score was ViLBERT, reaching the 32nd position on the leaderboard (out of 83 participants), with a score of 0.698. The one which performed the worst was MMBT-Grid, with a score of 0.649.

The remainder of this paper is organized as follows: Section 2 covers background and related work. Section 3 presents an overview of our system. The experimental setup is described in Section 4. Section 5 presents our results. Then, Section 6 concludes the paper.

2 Background and Related Work

One crucial aspect of this task is the multimodality of inputs. Most of the time, a meme requires both textual and visual information to be correctly understood. Not only because the punch line usually comes in written form, but also because texts and images often contradict each other for humouristic purposes. Take for example Figure 1. The text alone indicates a positive feeling towards an object that makes sandwiches. The image, if one would remove the caption, would show a woman. But when taken into consideration simultaneously, it is a sexist meme implying that women exist to make men sandwiches.

We took part only in Subtask A, in which the goal of the model is to take a meme such as the one in Figure 1 as input and indicate whether it is misogynistic or not.

The Hateful Memes Challenge (Kiela et al., 2021) is similar to MAMI since both address hateful multimodal contents. Participants in the Hateful Memes Challenge received a dataset of memes with visual as well as textual inputs and had to predict whether the memes were hateful.

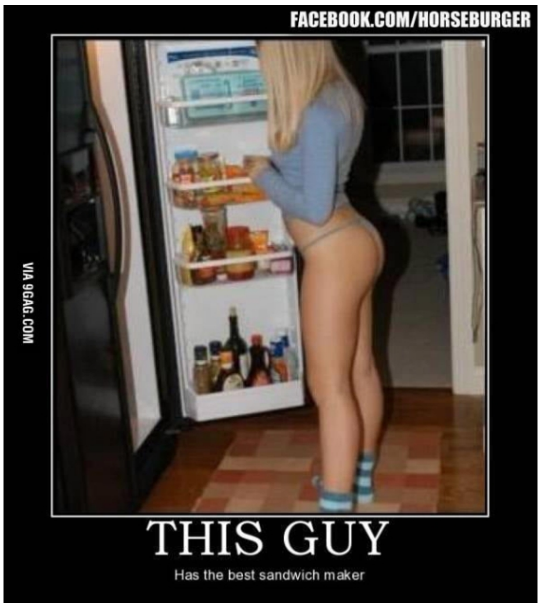

Figure 1: Example of a meme from the MAMI dataset

MMF (Singh et al., 2020) is a multimodal framework from Facebook AI Research and it implements state-of-the-art visual and language models, such as VisualBERT (Li et al., 2019), ViLBERT (Lu et al., 2019), M4C (Hu et al., 2020), and Pythia (Jiang et al., 2018), among others. MMF provides code and model implementations for The Hateful Memes Challenge. Their work served as the primary inspiration for our experiments, in which we apply many of the same models to the Multimedia Automatic Misogyny Identification (MAMI) dataset.

3 System Overview

We used MMF (Singh et al., 2020) to train five models on the MAMI dataset. These models can be briefly described as follows.

1. **MMBT-Grid** is a supervised multimodal bitransformer that jointly finetunes unimodally pretrained text and image encoders by projecting image embeddings to text token space. Its inputs are the concatenation of textual embeddings and the final activations of a ResNet after pooling – the downsampling of dimensions – and positional and segment encodings. The final activations are transformed so that they fit the dimensions of the transformers' hidden layers.

2. **ViLBERT and ViLBERT CC** ViLBERT (Lu et al., 2019) consist of two parallel models, one that operates over visual inputs, and another that operates over textual inputs. Both models operate similarly to BERT, *i.e.*, they are a series of transformer blocks. The difference lies in the *Co-attentional Transformer Layers* introduced by the researchers. During the attention calculation, they compute the usual Q, K, and V matrices. However, the textual K and V are passed to the visual multi-headed attention block, and the visual K and V are passed to the textual multi-headed attention block. The rest of the transformer operations proceed normally, causing multi-modal features since each modality pays attention to the other.

3. **VisualBERT and VisualBERT COCO** - VisualBERT extends BERT by modifying the input it processes. Making use of features extracted from Object Proposals – a set of image regions likely to contain objects – the model can capture the interaction between text and image. The model does that by treating these features as usual BERT input tokens, appending them to the textual tokens. That is, VisualBERT uses the self-attention mechanism to align textual and visual elements implicitly.

Two versions of ViLBERT and VisualBERT were used. The distinction between these two versions lies not in the architecture, but rather in how they were pretrained. The multimodally pretrained versions, ViLBERT CC and VisualBERT COCO, are the official ones published by Lu et al. (2019) and Li et al. (2019), respectively. The unimodally pretrained versions are, as explained by Kiela et al. (2021), *multimodal models that were unimodally pretrained (where, for example, a pretrained BERT model and a pretrained ResNet model are combined in some way).*

4 Experimental Setup

The dataset used to train all models was the one provided by the organization team. The data has not been augmented or modified in any way. Training data consists of 10,000 memes, trial data has 100 memes, and validation data has 1,000 memes.

The MMF framework comes with implementations of state-of-the-art models, preconfigured with hyperparameters. In our experiments, the default configurations of the models were used. All models share the same values for the main configurations, such as 1e-5 for learning rate, 22,000 for maximum number of steps, 128 tokens at most for text processing and, due to memory limitations, one hyperparameter was set to a fixed value, that is, models used batch sizes of 16 for training. Hyperparameter optimization could, therefore, be applied to the models to obtain better results. The configuration files are open to inspection and change, given that they are publicly available at Facebook Research's Github repository[1]. The specific commit that was used for this work is available here[2]. The training process of all models, excluding MMBT-Grid, uses image features, which were not included with the dataset supplied by the organization team. We relied on a script included in MMF to extract these features, using ResNet-152.

The main evaluation metric used in the task and during training is macro-F1. Here we also report True Positive (TP), True Negative (TN), False Positive (FP), and False Negative (FN) Rates.

5 Results

In this section, we report on our experimental results organized around four questions.

5.1 What are the best and worst models?

The results obtained by each model can be seen in Table 1. The best and worst-performing models were, respectively, ViLBERT and MMBT-Grid, with macro-F1 scores of 0.698 and 0.649. With this score, ViLBERT ranked 32nd on Subtask A. It is worth pointing out that they had very similar values for TP-rate. MMBT-Grid achieved a value of 0.866, despite being the worst-ranked among all five models. That means it had a good performance in identifying misogynistic memes. The problem is evidenced by the TN and FP rates. MMBT-Grid was the worst at classifying memes that are not misogynistic, with a TN-rate of 0.463, the lowest of all. It also has the highest FP rate of 0.537. Analyzing ViLBERT's metrics, we can see that what guaranteed it the first place among the five models was the TP and FN rate, which were, respectively, the highest and the lowest. VisualBERT COCO was the best at correctly classifying the negative class (TN rate = 0.581), but it also had, by far, the highest FN rate (0.21).

The differences in performance can not be explained by the usage of uni or multimodal pretraining. This is evidenced by the similarity between scores obtained by unimodally pretrained models (VisualBERT and ViLBERT) and that by multimodally pretrained models (VisualBERT COCO and ViLBERT CC). Additionally, the mentioned models share the same architecture (ViLBERT with ViLBERT CC and VisualBERT with VisualBERT COCO), and so it can not be the explanation for the differences in performance. However, what seems to have impacted scores the most is the use of image features during training, since MMBT-Grid performs the worst.

5.2 Do multimodally pretrained models perform better?

It is interesting to notice that there was no great difference in performance between unimodally and multimodally pretrained models, such as VisualBERT vs. VisualBERT COCO and ViLBERT vs. ViLBERT CC. This finding is in line with Kiela et al. (2021), who worked on the Hateful Memes dataset. Nevertheless, while multimodally pretrained models were slightly better on Hateful Memes, here the unimodally pretrained version of ViLBERT yielded slightly better results, but the difference was not statistically significant (according to a Wilcoxon signed-rank test).

5.3 Can combining classifiers improve classification performance?

To answer this question we analyzed the predictions of the five models for each instance on the evaluation dataset. Our results have shown that:

- 86.89% of the instances were correctly predicted by at least one model;
- 77.58% of the instances were correctly predicted by at least two models;
- 69.67% of the instances were correctly predicted by at least three models;
- 61.76% of the instances were correctly predicted by at least four models;
- 47.95% of the instances were correctly predicted by all models.

[2]https://github.com/facebookresearch/mmf/tree/d31f8776f3bee53e7be722cb6d6c7ecf0827cc30/mmf/configs

Model	Macro-F1	TP	TN	FP	FN
MMBT-Grid	0.649	0.866	0.463	0.537	0.134
VisualBERT	0.666	0.874	0.483	0.517	0.126
VisualBERT COCO	0.679	0.786	0.581	0.419	0.214
ViLBERT CC	0.697	0.836	0.571	0.429	0.164
ViLBERT	0.698	0.874	0.541	0.459	0.126

Table 1: Macro-F1 scores, true positive and negative rates, and false positives and negative rates for our models

This analysis suggests that, if we were to use a simple majority voting system to determine the predicted label for images, the obtained accuracy score would be 69.67%, which does not surpass the score achieved by ViLBERT alone. Additionally, we tried combining the predictions of the classifiers by averaging their output probabilities. Similar to what we found with majority voting, there were no performance improvements in relation to ViLBERT on its own.

5.4 How correlated are the models?

Table 2 shows the Pearson correlation coefficient calculated for all pairs of models to measure their level of agreement, *i.e.,* how many images they classified with the same label. We can see that ViLBERT and ViLBERT CC have the highest correlation coefficient, 0.78. We initially supposed that the reason for their high similarity was that they share the same architecture, but further analysis showed that VisualBERT and VisualBERT COCO, the other models that also share architectures, have low similarities. Therefore, the initial hypothesis was wrong and we can assert that the reason for the difference in similarity resides in the pretraining modality, since that is the only distinction between the models. We see that MMBT-Grid and ViLBERT have a correlation score of 0.61, while the lowest score is between MMBT-Grid and VisualBERT, 0.56. The fact that all correlation scores can be classified between strong and moderate explains why there were no gains in combining the models in an ensemble.

5.5 Is there any pattern in memes that were erroneously classified?

We analyzed images that were wrongly classified by all five models. They were, in total, 131 images. Through visual inspection, we were able to identify a pattern in the captions. We noticed that most false positives contained words like "girl", "girls", "woman", and "women", while false negatives did not present these words. To confirm this, we examined the frequency of these words in training and test datasets. The term "girl" appeared in approximately 4.57% of not misogynous memes in the training dataset, and in 6.37% of misogynous memes, that is, 1.39 times more often. This proportion, however, is almost reversed in the test dataset, in which the term appears in 11.1% of *not* misogynous memes, and only in 7.1% of misogynous memes, that is, 1.56 times *less* frequently. This might explain the high number of wrong classifications for memes that contain this word. For the term "women", training dataset analysis shows that 8.27% of misogynous memes had this word, while appearing in only 2% of not misogynous memes, about 4.13 times less often, while in the test dataset, 5.8% of misogynous memes had it, and 2.4% of not misogynous memes, that is, 2 times less. The change in word frequency for this term might also have contributed to misclassification.

6 Conclusion

In this paper, we described our submission to SemEval-2022 Task 5. Using Hateful Memes and MMF as inspiration, we wanted to replicate their methods in a similar context. Although hateful and misogynistic memes share some overlap, there are important distinctions between them, regarding different vocabulary, context, and targets (*i.e.,* hate can be directed towards anyone, while misogyny cannot).

In our experiments, we trained five models and confirmed that they reach similar performances in this dataset as they do in Hateful Memes. Our best model, ViLBERT, reached a F1 score of 0.698 and ranked 32nd out of 83 on the leaderboard. We showed that using a majority voting system with all models would not be beneficial. The models could be further improved by hyper-parameter

	ViLBERT CC	VisualBERT	VisualBERT COCO	MMBT-Grid	ViLBERT
ViLBERT CC	1.00	0.66	0.58	0.61	0.78
VisualBERT		1.00	0.57	0.56	0.69
VisualBERT COCO			1.00	0.58	0.59
MMBT-Grid				1.00	0.61
ViLBERT					1.00

Table 2: Pearson correlation for each pair of models

tuning. We could also have experimented with late/early fusion, which, as suggested by Hateful Memes (Kiela et al., 2021), has an impact on performance, and we leave this as future work.

Acknowledgments. This work was partially supported by CAPES Finance Code 001.

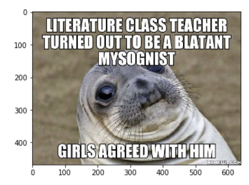
Abstract

Memes have become quite common in day-to-day communications on social media platforms. They often appear to be amusing, evoking and attractive to audiences. However, some memes containing malicious content can be harmful to targeted groups. In this paper, we study misogynous meme detection, a shared task in SemEval 2022 - Multimedia Automatic Misogyny Identification (MAMI). The challenge of misogynous meme detection is to co-represent multi-modal features. To tackle with this challenge, we propose a Multi-modal Multi-task Variational AutoEncoder (MMVAE) to learn an effective co-representation of visual and textual features in the latent space. Our goal is to automatically determine if a meme contains misogynous information and then identify its fine-grained category. Our model achieves F_1 scores of 0.723 on the MAMI sub-task A and 0.634 on sub-task B. We carry out comprehensive experiments on our model's architecture and show that our approach significantly outperforms several strong uni-modal and multi-modal approaches. Our code is released on github[1].

1 Introduction

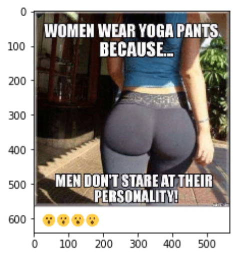
With the rapid development of social media, the use of image-based memes has been growing. People use memes for various purposes, such as to express humor (Velioglu and Rose, 2020), or to attract greater attention. Enabling this, simple websites that allow people to easily create new memes have further seen their proliferation.

However, this easy composition has allowed people to easily embed harmful messages within memes, often circumventing more traditional text-based moderation tools (Malmasi and Zampieri, 2017). This paper particularly focuses on misogynous memes (*i.e.* hatred towards women) — see Figure 1 for two examples. As some platforms may choose to limit the sharing of such material, we argue it is vital to build tools that can automatically identify misogynous memes at scale.



LITERATURE CLASS TEACHER TURNED OUT TO BE A BLATANT MYSOGNIST
GIRLS AGREED WITH HIM

(a) A misogynous meme with an uncorrelated image.



WOMEN WEAR YOGA PANTS BECAUSE...
MEN DON'T STARE AT THEIR PERSONALITY!

(b) A misogynous meme with a correlated image.

Figure 1: Examples of misogynous memes. In (a), the embedded text is misogynous. In (b), both the image and the embedded text are misogynous.

Many prior works have sought to analyze the content of memes. Some have looked into meme emotion analysis (Sharma et al., 2020; Smitha et al., 2018), meme ecosystem measurements (Zannettou et al., 2018) and meme auto-generation (Vyalla and Udandarao, 2020). Past efforts have also shed light on hateful meme detection (Kiela et al., 2020) or offensive meme detection (Sabat et al., 2019) more generally.

This paper builds on these prior works to automatically detect *misogynous* meme content (Fersini et al., 2022). This comes with several key challenges. First, a meme usually comes with both a visual and a textual part. Sometimes the standalone image or text is not necessarily hateful or toxic, but when combined together, the semantic meaning becomes harmful. To effectively understand the semantic meaning of a meme, information encoded in both modalities should be considered. Second, different memes frequently have the same image, but are embedded with different text (and thus have different and even opposite meanings). This makes reliance on image-hash lists ineffective. It is also common that the image and text of a meme are unrelated, as in Figure 1a. In this case, finding an

[1]https://github.com/MMVAE-project/MMVAE

accurate co-representation of both visual and textual features is vital. Finally, malicious information contained in a meme can have granular labels and even belong to multiple categories. Thus, it is often necessary to devise a more nuanced taxonomy.

With the above challenges in mind, we propose MMVAE: a pipeline to determine if a meme contains misogynous information, and to identify its fine-grained hateful labels accordingly. Specifically, our contributions are as follows:

1. We propose a Multi-modal Multi-task Variational AutoEncoder (MMVAE) that effectively co-represents the textual and visual features of the meme. We use this to predict if a meme is misogynous/non-misogynous. We further expand our model to predict more fine-grained labels, *e.g.* shaming, violence, objectification.

2. We evaluate our model on SemEval competition Task 5: Multimedia Automatic Misogyny Identification (Fersini et al., 2022). We achieve an F_1 score of 0.723 on sub-task A and 0.634 on sub-task B.

3. We analyze the strengths and weaknesses of our multi-modal approach by presenting a text-based error analysis and case study. Our model is better at identifying misogynous memes with a high precision, yet less effective in determining the correct label for non-misogynous memes.

2 Background

Our approach leverages multi-modal learning, pre-trained model, variational autoencoder and multi-task learning. Below, we provide a brief overview of these concepts.

2.1 Multi-modal Feature Representation

We leverage multi-modal learning to co-represent features from both image and text. Common multi-modal features co-representation techniques (Zeng et al., 2021) include fusion mechanism (early at feature level (Su et al., 2020), or late at decision/scoring level (Poria et al., 2016)), tensor factorization (Zadeh et al., 2017; Mai et al., 2019) and complex attention mechanisms which can be further classified as dot-product attention (Yu et al., 2021), multi-head attention (Cao et al., 2021; Wu et al., 2021), hierarchical attention (Pramanick et al., 2021), attention on attention (Liu et al., 2021) among others. These techniques have proven to be effective in encoding multi-modal features. However, leveraging multi-modal features doesn't always enhance the task performance. Hence, another topic that has raised concern in multi-modal learning is the uni-modal contribution analysis. A straightforward approach (Hessel and Lee, 2020; Frank et al., 2021) is to ablate cross-modal inputs or interactions in order to evaluate the model's performance on uni-modal data. Zeng et al. (2021) demonstrated that multi-modal models might not achieve optimal performance because there are noises contained in each modality.

2.2 Pre-trained Model

We adopt pre-trained models to embed the text and image of a meme.

Usually trained on large dataset corpus, pre-trained models have achieved state-of-the-art (SOTA) performances on various Natural Language Processing (NLP) and Computer Vision (CV) benchmark tasks. Thus, they can be used as a powerful embedding tool or be easily fine-tuned on downstream tasks. Popular language pre-trained models such as BERT (Devlin et al., 2019), LASER (Artetxe and Schwenk, 2019) and LaBSE (Feng et al., 2020) have constantly updated the SOTA performance on downstream NLP tasks. Similarly, image pre-trained models including ResNet (He et al., 2016), VGG (Simonyan and Zisserman, 2015), and Inception (Szegedy et al., 2016) have proved their effectiveness in multiple tasks. Recently, there has been increasing interest in pre-training multi-modal models. Lu et al. (2019) proposed ViLBert, which extends BERT to multi-modal two-stream models that interacts through co-attentional transformer layers and can be easily transferred into performing multiple visual-and-language tasks. Similarly, LXMERT (Tan and Bansal, 2019) further included a cross-modality encoder that captures cross-modality relationships. Instead of implementing two stream models, Su et al. (2020) input the caption and image regions all together to the modified BERT model named VL-BERT. Radford et al. (2021) jointly trained an image encoder and a text encoder known as CLIP to match the image and its corresponding caption by contrastive learning.

2.3 VAE Overview

We later use Variational AutoEncoder (VAE) to fuse multi-modal features. Thus, here we introduce the basic structure and loss calculation of a VAE. A VAE is an unsupervised approach for learning a lower-dimensional feature representation from unlabeled training data (Li et al., 2019a). The aim of finding a representation in the latent space is to capture meaningful factors of variation in the data (Li et al., 2019a). Typically, a VAE consists of an encoder and a decoder, which look "symmetrical" in the model's architecture. The encoder learns a latent variable space where a latent variable z is sampled from and input to the decoder for original data reconstruction. Figure 2 shows the structure of a simple VAE.

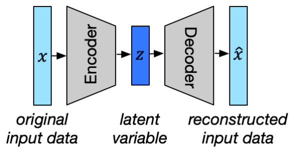


Figure 2: A simple VAE example.

Encoder. The encoder network of a VAE can have various structures. For textual input, the common structure is the Recurrent Neural Networks (RNN), *e.g.* Bi-LSTM (Cheng et al., 2020). For image input, the common encoder structure is the Convolutional Neural Networks (CNN). Mathematically, the encoder can be described as $q_\phi(\mathbf{z}|\mathbf{x})$, where ϕ is the parameters of the encoder network. $q_\phi(\mathbf{z}|\mathbf{x})$ stands for the probability distribution of latent variable z given x.

Decoder. Generally, the decoder network of a VAE is symmetrical to the encoder. It reconstructs the input by sampling from the learned latent variable space subject to a Gaussian distribution. The decoder can be described as $p_{\boldsymbol{\theta}}(\mathbf{x}|\mathbf{z})$, where $\boldsymbol{\theta}$ is the parameters of the decoder network. $p_{\boldsymbol{\theta}}(\mathbf{x}|\mathbf{z})$ stands for the probability distribution of reconstructed x given z.

Loss. In order to compute the loss of VAE in our model, we first introduce how to compute the loss of a general VAE. Since VAE models the probabilistic generation of data $\{x^{(i)}\}$, the goal is to maximize the (log) data likelihood (Kingma and Welling, 2014):

$$\begin{aligned}\log p_{\boldsymbol{\theta}}(\mathbf{x}^{(i)}) = D_{KL}(q_\phi(\mathbf{z}|\mathbf{x}^{(i)})||p_{\boldsymbol{\theta}}(\mathbf{z}|\mathbf{x}^{(i)})) \\ +\mathcal{L}(\boldsymbol{\theta}, \boldsymbol{\phi}; \mathbf{x}^{(i)})\end{aligned} \tag{1}$$

where $\boldsymbol{\theta}$ and $\boldsymbol{\phi}$ are parameters of the decoder and encoder network respectively. The first KL divergence term on the right hand side can't be computed explicitly but it is non-negative. The second term is called the *lower bound* on the marginal likelihood of datapoint i and can be rewritten as (Kingma and Welling, 2014):

$$\begin{aligned}\mathcal{L}(\boldsymbol{\theta}, \boldsymbol{\phi}; \mathbf{x}^{(i)}) = -D_{KL}(q_\phi(\mathbf{z}|\mathbf{x}^{(i)})||p_{\boldsymbol{\theta}}(\mathbf{z})) \\ +\mathbf{E}_{q_\phi(\mathbf{z}|\mathbf{x}^{(i)})}\left[\log p_{\boldsymbol{\theta}}(\mathbf{x}^{(i)}|\mathbf{z})\right]\end{aligned} \tag{2}$$

Hence, to maximize the log likelihood, we only need to maximize $\mathcal{L}(\boldsymbol{\theta}, \boldsymbol{\phi}; \mathbf{x}^{(i)})$. To achieve that, the KL divergence term in eq. 2 should be minimized and the expected log likelihood of datapoint i should be maximized (equivalent to minimizing the expected reconstruction error).

2.4 Multi-task Learning

Our work leverages the concept of multi-task learning to learn fine-grained category labels of misogynistic memes. According to Ruder (2017), as long as a model is optimized by more than one loss functions, it is doing multi-task learning. When the tasks are relevant and the knowledge learned from one task could benefit the learning of other tasks, applying multi-task learning will have promising performances (Caruana, 1997). Multi-task learning has been successfully applied in many NLP tasks such as text classification (Cheng et al., 2020; Khattar et al., 2019), sentiment analysis (Majumder et al., 2019), neural machine translation (Niehues and Cho, 2017), etc. However, the most common issue of multi-task learning is the negative transfer when the performance on single task is undermined. Lee et al. (2016) avoids negative transfer by allowing asymmetric transfer between tasks. Wu et al. (2020) observes that misalignment between tasks can cause negative transfer. Wu et al. (2019) proposed a method to filter and select shared feature to prevent adverse features being integrated into certain tasks.

3 Problem Statement

The paper strives to build a classifier that can distinguish misogynous *vs.* non-misogynous memes. We break this down into two sub-tasks:

- Sub-task A: Given a meme's image I and its corresponding text transcription T, we must predict its binary (0/1) label on *misogyny* (Fersini et al., 2022).
- Sub-task B: Given a meme's image I and its corresponding text transcription T, we must

predict its binary (0/1) label on the following classes: *shaming*, *stereotype*, *objectification* and *violence* (Fersini et al., 2022), which are types of misogyny.

Note, the meme's image I has the embedded text on it, and T is transcribed from the meme's embedded text.

4 Our Approach

As illustrated in Figure 3, our MMVAE model consists of 3 components: (*i*) the Image/Text embedding Module, (*ii*) the Variational AutoEncoder Module and (*iii*) the Multi-Task Learning Module. The embedding module turns the inputs into unimodal vector representations. After that, the VAE module fuses multi-modal representations and generates a co-representation. Finally, the multi-task learning module gives the label prediction. In this section, we first introduce each part of our proposed model, and then demonstrate how to put them all together and jointly train the model.

4.1 Image/Text Embedding Module

In our pipeline, we first adopt two pre-trained models to embed the meme's text and image (illustrated in Figure 3 left part). We directly input the provided text transcription and meme's image to the pre-trained models to get embeddings as module output. However, when using ResNet-50 and BERT as pre-trained models, we apply data preprocessing beforehand.

Image Embeddings. To obtain the meme's image embedding, we have experimented with 2 different pre-trained models: ResNet-50 (He et al., 2016) pre-trained on ImageNet (Deng et al., 2009) and the multi-lingual version of OpenAI CLIP-ViT-B32 (Radford et al., 2021). When using ResNet-50 to embed images, we transform the input images by resizing it to 224×224, applying random rotation, random horizontal flip, random crop and normalization for data augmentation. We use the last fully connected layer's output as our image embedding. When using CLIP to embed images, although we have experimented with data transformation techniques, our optimal performance is achieved by directly embedding the raw image.

Text Embedding. To obtain the meme's text embeddings, we experiment with 4 different pre-trained models: BERT for sentence classification (Devlin et al., 2019), LASER (Artetxe and Schwenk, 2019), LaBSE (Feng et al., 2020) and the multi-lingual version of OpenAI CLIP-ViT-B32. We set the maximum input sentence length to 512 tokens when using BERT while we directly input the meme's text to other pre-trained models.

4.2 Variational AutoEncoder (VAE) Module

The next module in our pipeline takes the embeddings as an input and finds a multi-modal co-representation. We assume that there is an effective multi-modal co-representation in the latent space which can better capture the inter-relationship between text and image data.

In our pipeline, we leverage VAE to learn the multi-modal co-representation (illustrated in Figure 3 middle part). The input to this module are the embeddings generated from the pre-trained models, and the output is the reconstructed embeddings. Yet what we need for later meme detection classifiers is the latent variable generated from the VAE encoders.

Encoders. We build a text encoder and an image encoder to first learn the latent variables of the text embedding and image embedding separately. In our case, since the input embeddings are already semantically meaningful, there is less need to further extract semantic information using complex and deep layers. Therefore, we decide to use 1 fully connected layer for each modality as the encoder structure. And then we concatenate the learned latent variables to form a multi-modal co-representation z in the latent space.

Decoders. Accordingly, we build a text decoder and an image decoder to reconstruct the text embedding and image embedding from the learned multi-modal co-representation z. Our decoders still consists of 1 fully connected layer, with the number of output channels equal to the number of input channels in the encoder network.

Losses. We calculate the reconstructed image embedding loss $\mathcal{L}_{img}$, the reconstructed text embedding loss $\mathcal{L}_{txt}$ (corresponding to the 2nd part of eq. 2) and the KL loss KLD (corresponding to the 1st part of eq. 2) from the sampled latent variable z for gradient descent. The reconstruction loss is calculated by L_2 loss function (squared error). The KL loss is calculated using the formula in Appendix B of Kingma and Welling (2014).

4.3 Multi-task Learning

We leverage multi-tasking learning because we expect that learning the fine-grained hateful class labels will benefit the misogyny meme detection and

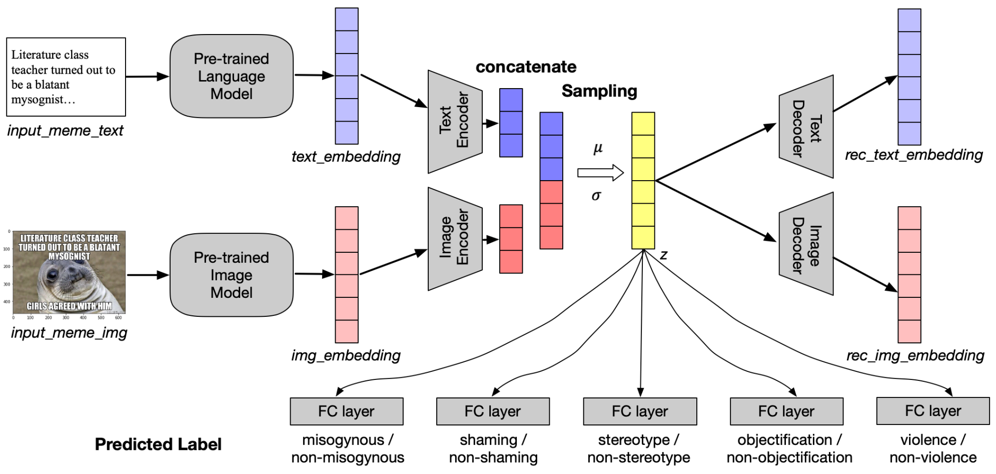

Figure 3: The architecture of our proposed Multi-modal Multi-task VAE (MMVAE) model. The upper part illustrates the image/text embedding module and the VAE module from left to right. The lower part shows the multi-task learning module.

vice versa. The input to this module is the latent variable z (colored yellow in Figure 3) learned in Section 4.2 and the output is label predictions on each class.

Our model learns 5 tasks at the same time: misogyny detection, shaming detection, stereotype detection, objectification detection and violence detection. The latter 4 classes are more specific types of misogyny. Note, if a meme is misogynous, it could fall into more than one specific misogyny classes.

The architectures are the same across all the sub-networks in our model as shown in Figure 3: 1 fully connected layer followed by the softmax binary classifier. Yet the sub-networks are independent - the parameters are not shared.

Here the cross entropy loss function is used to calculate the loss for each task:

$$\mathcal{L}_t = -\mathbf{E}_{y \sim Y_t}\left[y \log y_t + (1-y)\log(1-y_t)\right] \tag{3}$$

where y is the ground-truth label of data point x in t detection (e.g. misogyny detection) and y_t is the predicted probability of x belonging to class t (e.g. misogyny).

4.4 Putting It All Together

We have introduced each module in our MMVAE and how to calculate their standalone losses. Next, we introduce how to jointly train the model by putting three modules together.

The total loss used to compute gradient descent is composed of the reconstructed image error L_{img}, reconstructed text error L_{txt}, KL divergence KLD, and multi-task cross entropy losses L_t, where $t \in \{$*misogyny*, *shaming*, *stereotype*, *objectification*, *violence*$\}$. This can be expressed as:

$$\mathcal{L}_{total} = \lambda_i \mathcal{L}_{img} + \lambda_t \mathcal{L}_{txt} + \lambda_{kl} KLD + \sum_t \lambda_t \mathcal{L}_t \tag{4}$$

where λs are used to adjust the learning focus, so that we can direct the focus of learning to the task we care more about. We calculate gradient descent on $\mathcal{L}_{total}$ and back propagate it to update model's parameters.

5 Experimental Setup

In this section, we first introduce the Multimedia Automatic Misogyny Identification (MAMI) dataset released by the task organizer (Fersini et al., 2022) and then discuss our experimental settings.

5.1 Dataset

The MAMI dataset contains 10,000 memes in the training set and 1,000 memes in the test set. Each meme has an associated text transcription in English and labels on 5 classes. The label distributions of given classes are not balanced and are summarized in Table 1. Only in the misogyny class, the labels are totally balanced. Detailed task descriptions can be found in Section 3.

5.2 Experimental Settings

We have experimented with different latent variable (z) sizes of 256, 512, and 1024. 512 has the best

Class	# Positive	# Negative
Misogyny	5,000	5,000
Shaming	1,274	8,726
Stereotype	2,810	7,190
Objectification	2,202	7,798
Violence	953	9,047

Table 1: Number of positive labels and negative labels in each class.

performance on the validation set. Hence, we set the latent variable size to 512 during the evaluation phase.

Different pre-trained models generate embeddings with different dimensions, D. In both encoders, we map the input embeddings' dimension from D to half of z's dimension.

For the optimizer, we use the Adam optimizer with weight decay set to 1e-5. The batch size is set to 64. In addition, the initial learning rate is 1e-4 and divided by 4 every 8 training epochs. The model is trained for 30 epochs in total with early stopping.

We split the training set into the training and validation set with a ratio of 9:1. We train our model on 9,000 memes from the original training set and test it on the rest of 1,000 memes to evaluate our model's performance.

5.3 Baselines

BERT (Devlin et al., 2019). As the text-only baseline, we use BERT for sequence classification. Here, only the text transcription is used for misogyny detection. BERT has achieved SOTA performances on most NLP benchmark tasks. Therefore, we consider it as a robust textual baseline model for this task.

ResNet-50 (He et al., 2016). As the image-only baseline, we use ResNet-50. Here, only the image is used for misogyny detection. ResNet-50 has achieved SOTA performances on ImageNet, a benchmark task in CV. Therefore, we consider it as a robust image baseline model for this task.

CNN-Based VAE. We build an image-only VAE model whose encoder and decoder are both composed of 5 CNN layers. Here, only the meme image is used for misogyny detection. This image-only input model is used to compare with our MMVAE: both of them are constructed based on VAE.

Note, we only experiment with BERT and ResNet-50 with sub-task A because we directly use the pre-trained model's architecture without incorporating multi-task learning into them.

6 Results and Analysis

In this section, we present our model's performances on both tasks, and give further analysis on its strengths and weaknesses.

6.1 Evaluation Metrics

The main evaluation metric for both tasks is F_1 score (macro-F_1 for sub-task B), which calculates the average of F_1 for both labels:

$$F_1 = \frac{pos\_F_1 + neg\_F_1}{2} \tag{5}$$

We also extend it to include *precision* and *recall* by calculating the average score similarly.

6.2 Results

Table 2 summarizes the performances of our model and the baselines. The first group of models are unimodal. The second group of models share the same architecture, MMVAE, but with different embedding methods. Furthermore, MMVAEs used in the third group come from the best performed model of the second group, *i.e.* MMVAE$_{\text{LASER+CLIP}}$. In the third group, we have tried a number of techniques to mitigate the overfitting problem: adding different dropout rates, concatenating the word embeddings generated by LASER and LaBSE, adding one more liner layer to the text VAE encoder, and introducing image transforms.

For sub-task A, the optimal F_1 performance is 0.723, which is achieved by applying batch normalization layers and set dropout = 0.2 after each linear layer in the encoders and decoders of the VAE. Among all the tweaks we apply to reduce overfitting, introducing dropout is the most effective by which we get our top two F_1 scores (0.723 and 0.714). Instead of dropping more parameters, keeping 80% of them produces a better result (0.723).This might because the number of parameters in our model is not large, so excluding more will harm the learning capability. We also see a performance improvement to 0.712 by concatenating text embeddings from LASER and LaBSE, which introduces more information, thereby reducing overfitting. The other two attempts fail to improve the performance, the reason might be that adding more layers doesn't make the model more generalizable and image transforms is not effective when applying pre-trained models to embed.

Model	Sub-task A			Sub-task B		
	Precision	Recall	F1	Precision	Recall	macro-F1
BERT	0.608	0.632	0.589	-	-	-
ResNet-50	0.635	0.656	0.622	-	-	-
CNN-VAE	0.526	0.550	0.462	0.514	0.545	0.469

Table 2: Performance of our MMVAE model and variants on the test set.

For sub-task B, the optimal performance in F_1 is 0.634, which is achieved by applying batch normalization layers after each linear layer in the encoders and decoders, and adding one more linear layer to the text encoder in the VAE.

Our MMVAE's best performance on sub-task A is significantly higher than that of the uni-modal baselines: 22.8% higher than the text-only BERT baseline, and 16.2% higher than the image-only ResNet-50 baseline. This confirms that our proposed model has effectively learned from both textual and visual features.

Our constructed image-only CNN-based VAE produces the least F_1 score, probably because CNN layers are less effective in capturing complex semantic information contained in meme images.

6.3 Text-Based Error Analysis

We observe that on our randomly selected validation set (10% of memes from the training set), MMVAE obtains nearly 0.87 as F_1 score on subtask A. But on the test set, we see a 16.7% performance drop. Thus, there is a large gap between our model's performance on the validation set and the test set. We speculate that multiple factors could cause the misclassifications, for instance, similarities between images that are associated with different text. For simplicity, here we only investigate the impact of hateful text on the classification results. We delay further investigations to future work.

To start, we compute the confusion matrix of our best model: MMVAE$_{\text{+dropout=0.2}}$, which is displayed in Figure 4. There are 500 misogynous memes and 500 non-misogynous memes in the test set. As a result, the number of false negative (56) is much lower compared to the false positives (214). Our model correctly classifies 88.8% of misogynous memes yet only 57.2% of non-misogynous memes.

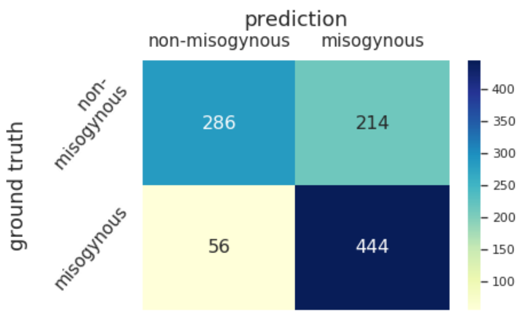

Figure 4: Confusion matrix of MMVAE$_{\text{+dropout=0.2}}$'s prediction.

We conjecture that issues with performance may be driven by the nature of hateful text. To analyze this, we calculate the hateful scores on the memes' text using the sentiment analysis toolkit in (Pérez et al., 2021). Figure 5 presents boxplots showing the scores. We observe that for true positives (TP) and false negatives (FN), the hateful score distributions are similar, although the former's 2nd quartile is much higher. In contrast, we find that true negatives (TN) contain less hateful text in memes compared to false positives (FP), and the mean score value is significantly different. Apparently, non-misogynous memes tend to have lower hateful scores for their text. Based on our analysis, we infer that our model is more confident in assigning the correct non-misogynous label to a meme with less hateful text content. Yet, when assigning misogynous labels (although FNs have comparably lower hateful scores), our model is less accurate. As such, we cannot tell the decision boundary between FN and TP by simply looking at the hateful messages contained in meme's text.

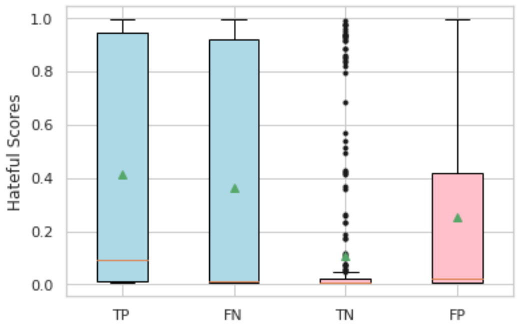

Figure 5: Boxplots of hateful scores on true positives (TP), false negatives (FN), true negatives (TN) and false positives (FP). Green triangle indicates the mean value of the given class. Blue and pink respectively refer to misogynous and non-misogynous memes in ground-truth.

Manual inspection on FPs suggests that the misclassification is potentially driven by several different types of meme. The misogynous text is crossed out in the left meme of Figure 6, but it's still included in the text transcription, which can be confusing for the classifier. Similarly, although the other meme in Figure 6 is not misogynous, it is related to women. We suspect that the presence of certain words associated with femininity e.g. woman, girl, is a another determinate in the prediction. We will test this hypothesis in our future work.

WHEN A NEW WOMAN JOINS THE GROUP

(a) Hateful score: 0.017 (b) Hateful score: 0.086

Figure 6: Two examples of FPs, *i.e.* the ground-truth labels are non-misogynous while the predicted labels are misogynous.

7 Related Work

The misogynous meme detection task is novel, but has similarities to other more general hateful meme detection tasks. Related datasets has been released on a number of shared hateful meme detection/classification tasks (Kiela et al., 2020; Mostafazadeh Davani et al., 2021). Most of the prize-winning models adopted visual-and-linguistic pre-trained models. Velioglu and Rose (2020) utilized pre-trained VisualBERT (Li et al., 2019b) to encode the meme image regions and caption all together. Sharif et al. (2021) and Zia et al. (2021) leveraged visual and textual pre-trained models to encode the meme image and the embedded text respectively, and then learned multi-modal co-representation through vector concatenation. Instead of concatenating the vectors, Pramanick et al. (2021) applied self-attention to learn intra-modality semantic alignments. Lippe et al. (2021) used an ensemble of existing multi-modal pre-trained models based on UNITER (Chen et al., 2020). Zhu (2020) showed that directly applying state-of-the-art multi-modal models on hateful meme classification won't get the optimal performance. They used various data pre-processing approaches to get sufficient features, *e.g.* entity tags, as additional inputs to the pre-trained models. Note, there have also been studies of misogyny in uni-modal platforms (Guest et al., 2021; Zeinert et al., 2021; Jiang et al., 2022).

Our work differs from the above. Many of these previous works directly leverage uni-modal embeddings produced by pre-trained models. They then build a relatively simple model afterwards, of which the learnt multi-modal features are not integrated. In contrast, we strive to overcome this limitation via the co-representation of both textual and image modalities. Moreover, we differ in that we are focusing on misogynous meme detection, rather than the broader topic of hateful meme detection.

8 Conclusion

The spread of hateful memes targeting certain groups has become an important problem on social media platforms. To mitigate the negative consequences brought by misogynous memes, we propose a Multi-modal Multi-task Variational AutoEncoder (VAE) to identify them and assign them more fine-grained labels. Our model consists of three main components: the Image/Text Embedding Module, the Variational AutoEncoder Module, and the Multi-Task Learning Module. Our model's performance outperforms the state-of-the-art unimodal baselines by 22.8% and 16.2%. It effectively learns the co-representation of visual and textual features, and is jointly trained on multiple downstream classification tasks. In our future work, we plan to integrate attention mechanism into our model and carry out more comprehensive statistical analysis on model's results.

Abstract

Women are influential online, especially in image-based social media such as Twitter and Instagram. However, many in the network environment contain gender discrimination and aggressive information, which magnify gender stereotypes and gender inequality. Therefore, the filtering of illegal content such as gender discrimination is essential to maintain a healthy social network environment. In this paper, we describe the system developed by our team for SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification. More specifically, we introduce two novel systems to analyze these posts: a multimodal multi-task learning architecture that combines Bertweet for text encoding with ResNet-18 (He et al., 2016) for image representation, and a single-flow transformer structure which combines text embeddings from BERT-Embeddings and image embeddings from several different modules such as EfficientNet (Tan and Le, 2019) and ResNet (He et al., 2016). In this manner, we show that the information behind them can be properly revealed. Our approach achieves good performance on each of the two subtasks of the current competition, ranking 12th for Subtask A (0.746 macro F1-score), 10th for Subtask B (0.706 macro F1-score) while exceeding the official baseline results by high margins.

1 Introduction

Women are influential online, especially in image-based social media such as Twitter and Instagram : 78 percent of women use social media multiple times a day, compared with 65 percent of men.(Elisabetta Fersini) However, although the Internet has opened new opportunities for women, systematic offline inequality and discrimination are replicated in cyberspace in the form of offensive content against them. The popular communication tool in social media platforms is MEME. Memetics is essentially an image, which is characterized by the content of the image and the poster cover text introduced by human beings. Its main goal is fun or irony. Although most of them were created for a joke, in a very short period of time, people began to use them as a form of hatred against women, and then magnified gender stereotypes and gender inequality. Women are exposed to gender discrimination and aggressive information in the network environment. Therefore, the filtering of illegal content such as gender discrimination is essential to maintain a healthy social network environment.

In this paper, we describe the system developed by our team for SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification. More specifically, we introduce two novel systems to analyze these posts: a multimodal multi-task learning architecture that combines Bertweet (Nguyen et al., 2020) for text encoding with ResNet-18 (He et al., 2016) for image representation, and a single-flow transformer structure which combines text embeddings from BERT-Embeddings and image embeddings from several different modules such as EfficientNet (Tan and Le, 2019) and ResNet (He et al., 2016).

2 Related Work

Language Model Pre-training. The MLM-based pre-training method used in BERT (Devlin et al., 2019) opens up the pre-training paradigm of language model based on Transformer structure. RoBERTa (Liu et al., 2020) carefully measured the influence of key hyperparameters and training data size, and further enhanced the effect. SpanBERT (Joshi et al., 2020) extends BERT by masking continuous random spans rather than random markers, and trains the span boundary representation to predict the whole content of the shielded span without relying on a single marker representation. MacBERT (Cui et al., 2020) improved RoBERTa in several aspects, especially using MLM as the correction masking strategy (Mac). BERTweet (Nguyen et al., 2020) is the first large-scale language model for English Tweets and produced better performance results than the previous state-of-the-art models on three Tweet NLP tasks: Part-of-speech tagging, Named-entity recognition and text classification.

Visual and Language Multimodal Learning. Some studies explored cross-modal transmission between images and text. Some ideas are related to cross-model representation learning (Aytar et al., 2017; Ngiam et al., 2011), aiming to generate representations that effectively correlate different sensor modes. Recently, several ideas have been proposed to focus on the transformer backbone by improving the pre-training strategy rather than optimizing the backbone structure. VideoBERT (Sun et al., 2019) learns the bidirectional joint distribution of visual and linguistic tag sequences, which are respectively from the vector quantization of frame data and the ready-made speech recognition output. VisualBERT (Li et al., 2019) uses MLM to pre-train specific tasks, which uses the same type ID for language & visual input. VL-BERT (Su et al., 2020) uses a simple Transformer model as the backbone, and uses a mixture of region of interest (ROI) and words in the image as input.

In addition, some ideas have become focused on improving the transformer backbone network. Unicoder-VL (Li et al., 2020) uses three pre-training tasks, including mask language modeling (MLM), mask object classification (MOC) and visual language matching (VLM), to learn the joint representation of vision and language. ViLBERT (Lu et al., 2019) extends the BERT architecture to a multi-modal dual-flow model and processes it in separate flows interacting through the common attention converter layer

3 Task Description

The proposed task, i.e. Multimedia Automatic Misogyny Identification (MAMI) consists in the identification of misogynous memes, taking advantage of both text and images available as source of information. The task will be organized around two main sub-tasks:

- Sub-task A: a basic task about misogynous meme identification, where a meme should be categorized either as misogynous or not misogynous;
- Sub-task B: an advanced task, where the type of misogyny should be recognized among potential overlapping categories such as stereotype, shaming, objectification and violence.

4 Methodology

For this task, we have tried a variety of modeling and optimization methods, which are described in detail as follows.

4.1 Model design

We designed two kinds of multimodal model schemes with different architectures : transformer single-flow structure and double-tower structure.

Transformer Single-flow Structure. The model of this structure only contains a set of longitudinal stacks of transformer modules. For image and text features, after their respective processing and stitching, together as the input of the model, so called single-stream transformer model. The advantage of this model is that it can express image and text cross-modal features in the same vector space, which is equivalent to mapping multi-modal features to single-modal vector representation space. The prediction effect of single-flow model is very dependent on pre-training. This work uses VisualBERT (Li et al., 2019) pretraining weights on COCO-VQA tasks. The text features directly use BERT-base-uncased (Devlin et al., 2019) tokenizer for word segmentation and post-vectorization. The image features are vectorized by ResNet-152 (He et al., 2016), EfficientNet-b2, EfficientNet-b4 and EfficientNet-b7 models (Tan and Le, 2019) to improve the richness of image feature expression. Finally, the image and the text vector are spliced together as the input of the model.

Double-tower Structure. Different from single-flow models, the double-tower model is actually two parallel models. For images and text, each builds a model structure and adds MLP to the output side to parallel them for joint training. Although the twin-tower structure cannot retain a large amount of prior knowledge through pre-training as the single-flow model does, nor can it fully excavate the cross-modal interaction characteristics as the twin-flow model does, the twin-tower structure is less dependent on the amount of training sample data, and is more flexible. Compared with the single-flow and double-flow transformer structures, it is more suitable for this task. Due to less training data, in order to avoid overfitting, we choose a relatively simple network structure, image side feature representation model using

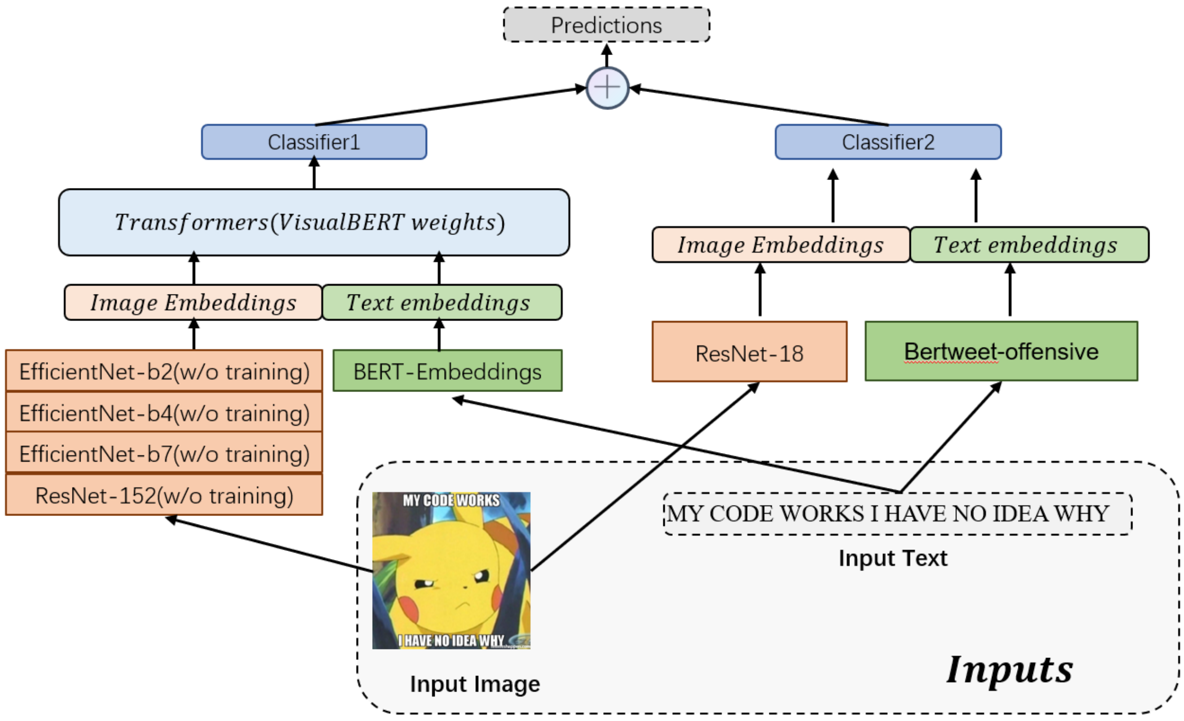

Figure 1: An overview of the two model structures. Transformer single-flow structure on the left and double-tower structure on the right.

ResNet-18 (He et al., 2016), text side feature representation model using Bertweet.

Model Ensemble. In order to make full use of the differences between models to achieve the best prediction effect, we use the weighted average method to obtain the final prediction results. The method is as follows:

$$Y_{pred} = \alpha \cdot Y_1 + (1 - \alpha) \cdot Y_2 \tag{1}$$

Where Y_{pred} is the final prediction probability, Y_1 is the single flow model prediction, Y_2 is the double tower model prediction, $\alpha = 0.1$.

4.2 Training Framework

As shown in Fig 2, we use a three-stage training framework consists of multi-task binary classification for sub-task B, single-task binary classification for sub-task A and post-processing.

Stage1: Multi-task binary classification. Sub-task A is a single-task binary classification problem, and sub-Task B is a multi-task binary classification problem. We tried to define sub-Task B as a single-task binary classification, so that the amount of data becomes five times that of multi-task binary classification to expand the training samples. However, the experimental results show that the effect is basically the same as that of multi-task binary classification. Therefore, we first define a multi-task binary task and obtain the respective prediction probabilities of the model for misogynous, stereotype, shaming, objectification and violence.

Stage2: Single-task binary classification. For sub-task A, we use external data from the memotion task (Sharma et al., 2020; Mem) for the misogynous binary classification. Although these data predict different targets, they are homologous to the task data. Through the analysis, it is found that there is almost no gender discrimination in the samples of 'Not Offensive' and 'Slight Offensive'. Therefore, this part of the external data is used to expand the training set, which greatly improves the prediction results of sub-task A. The reason why external data is not used in multi-task stage is that the proportion of positive samples in 'shaming', 'stereotype', 'objectification' and 'violence' tasks is very low, and increasing the number of negative samples will increase the prediction difficulty of these fields, so only external data is used in this stage.

Stage3: Post-processing. Through analysis, it is found that when 'shaming', 'stereotype', 'objectification' and 'violence' are positive samples, 'misogynous' must be positive samples. Due to the higher F1 value predicted by 'misogynous' in the

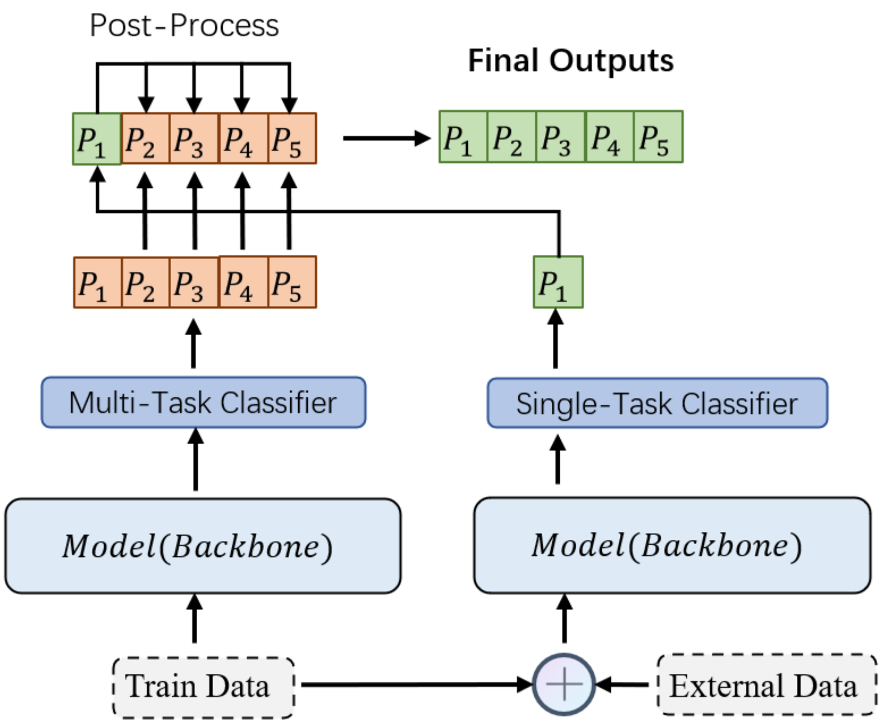

Figure 2: An overview of the proposed three-stage training framework. Firstly, we only use the training data to train the multi-task model and obtain the prediction probability of each task. Then, we use the external data to expand the training data to train the single task model and obtain the probability of 'misogynous'. Finally, we use the probability of 'misogynous' to post-process other tasks and obtain the final prediction results.

second stage, the prediction results of 'shaming', 'stereotype', 'objectification' and 'violence' are corrected by the prediction results of 'misogynous' in the second stage. We modify the prediction results of samples 'shaming', 'stereotype', 'objectification' and 'violence' with 'misogynous' prediction 0 to 0, which will improve the prediction results.

5 Experiments

This section is organized as follows. First we introduce the MAMI dataset (Elisabetta Fersini), then we introduce the experimental setup in detail. Finally, we show the effectiveness of our proposed method on MAMI datasets.

5.1 Datasets Analysis

The number of samples in the dataset is shown in table 1. Sub-task A uses external data, so the training data contains 10000 original samples and 14820 external data samples, and the predicted data contains 1000 samples; sub-task B does not use external data, so the training samples contain only 10000 original items and the predicted data also contains 1000 samples.

In the original 10000 training samples, there are five prediction labels, 'misogynous', 'shaming', 'stereotype', 'objectification' and 'violence'. Their respective number and proportion of positive samples are shown in table 2.

Dataset	Sub-task A	Sub-task B
train	10000	10000
external-train	14820	0
test	1000	1000

Table 1: Datasets statistics.

Category	Samples	Percentage
misogynous	5000	50.0%
shaming	1274	12.7%
stereotype	2810	28.1%
objectification	2202	22.0%
violence	953	9.5%

Table 2: Datasets analysis.

5.2 Experiment Settings

We implement our model using Pytorch. Using a workstation with an Intel Xeon processor, 64GB of RAM and a Nvidia P40 GPU for training. We apply AdamW as an optimization algorithm with

10% steps of warmup. For the hyperparameters, we set epochs=10, batch size=64. We also set the earlystop patience epoch as 3. We resize all images to 256 $\times$ 256 RGB pixels, and set the maximum cut length of text to 64. For the single-flow model, learning rate is set to 5×10^{-5}. For the double-tower model, we use the sub-regional learning rate strategy. The learning rate of text module is 5×10^{-5}, the learning rate of image module is 1×10^{-4}, and the learning rate of combined multi-layer percetron (MLP) module is 1×10^{-3}. We used multi-label stratified k-fold method to split training data into 5 folds.

Augmentation method used in image preprocessing. In the field of computer vision, because the image data have high dimensional characteristics, it is necessary to expand the training data, and usually do so. We use the following procedures to expand. In the training phase, we use (i) random resizing and cropping, (ii) random horizontal flipping, and (iii) random vertical flipping. In the inference phase, we use “five-crop inference” for robust prediction. This is essentially an average ensemble of the predictions on augmented images.

5.3 Experimental Results

Table 3 contains the results obtained from running the experiments. It can be seen that the prediction effect of single-flow model is worse than that of double-tower model, because the prediction effect of single-flow model is very dependent on pre-training. For the pre-training of single-stream model, most of the current mainstream models such as VisualBERT, UNITER (Chen et al., 2019) and so on are based on ImageNet (Deng et al., 2009), COCO (Lin et al., 2014) and other data sets for graph-text matching pre-training. There are some differences between these data sets and the scene of this task : (i) Twitter images contain text, and it is essential for emotional tendency expression, while ImageNet, COCO and other data sets contain almost no text ; (ii) The text of ImageNet, COCO and other data sets is the semantic expression of the image, and the text does not appear directly in the image, but the text information in the twitter sample is the text extracted from the image by OCR, which can be said to be a subset of image features from the feature information. The pre-training method of image-text matching is not very suitable. These reasons limit the prediction effect of the single-flow transformer structure model to a certain extent. Although compared with baseline, the potential of the model is still quite large. Sufficient training data and appropriate pre-training task design can further significantly improve the prediction results.In the single model, the twin-tower model has the best prediction results. Precisely because a particular module of the model contains only prior knowledge of a particular modality, it is more adaptable to different scenes. The cross-modal features are only learned through the current task, and do not depend on the prior knowledge. When the training data are not sufficient for pre-training, this modeling method can achieve the best results.

Method	**Sub-task A**	**Sub-task B**
organizers baseline	0.650	0.621
transformer single-flow	0.658	0.685
double-tower	0.684	0.706
model ensemble	0.682	0.707
post-processing	**0.746**	**0.708**

Table 3: Results on MAMI dataset.

Benefit from the huge difference in the feature representation of the two models, the difference of prediction results between single-flow model and double-tower model is very large, and better prediction results can be obtained by simple weighted average method. Finally, the model obtained by subtask A is used to post-process other prediction results, and the final best result is obtained.

5.4 Error Analysis

As shown in Table 4 and Fig 3, we select some typical samples that can reflect the performance of the methods for analysis. In Table 4, the first two columns are the file name and the text recognized in the image. SF, DT, ME and PP represent the prediction results of transformer single-flow, double-tower, model ensemble and post-processing methods in Table 2 on the misogyny task, respectively.

We can see that the transformer single-flow method is more dependent on text information than image. For some non-misogyny images, due to some gender-biased words like "she", "cute girl" and "sex", the transformer single-stream method mispredicts misogyny images, and the double-tower method can correctly distinguish them. For some misogyny images, the single-flow method fails to predict correctly because there is no misogyny tendency in the text.

15795.jpg
15460.jpg
16146.jpg

Figure 3: Error analysis of typical samples.

Many samples of misogyny are very obscure and do not tend to discriminate either from text or from images alone, but there is a combination of discriminatory hints that post-processing method is more capable of detecting such samples. At the same time, the post-processing method also calibrated some samples that were mistakenly identified as misogyny due to humor expression.

6 Conclusions and Future Works

In this paper, we describe the system developed by our team for SemEval-2022 Task 5: Multimedia Automatic Misogyny Identification. More specifically, we introduce two novel systems to analyze these posts: a multimodal multi-task learning architecture that combines Bertweet for text encoding with ResNet-18 (He et al., 2016) for image representation, and a single-flow transformer structure which combines text embeddings from BERT-Embeddings and image embeddings from several different modules such as EfficientNet (Tan and Le, 2019) and ResNet (He et al., 2016).In addition, we also use the model fusion and the post-processing method of prediction results, and improve the prediction results.

In the future, we will try to get more unlabeled sample data to pre-train the transformer single-flow method more fully and look forward to getting better multimodal methods in Twitter scenarios.

Abstract

This paper describes the participation of the University of Hildesheim at the SemEval task 5. The task deals with Multimedia Automatic Misogyny Identification (MAMI). Hateful memes need to be detected within a data collection. For this task, we implemented six models for text and image analysis and tested the effectiveness of their combinations. A fusion system implements a multi-modal transformer to integrate the embeddings of these models. The best performing models included BERT for the text of the meme, manually derived associations for words in the memes and a Faster R-CNN network for the image. We evaluated the performance of our approach also with the data of the Facebook Hateful Memes challenge in order to analyze the generalisation capabilities of the approach.

1 Introduction

Hate in Social Media continues to be a societal problem. The identification of problematic content based on text has made progress, but the performance is still not satisfying (MacAvaney et al., 2019; Modha et al., 2020b). Visual content and multi-modal construction on semantics is a reality in social media today (Dancygier and Vandelanotte, 2017). Systems for realistic scenarios in social media platforms (e.g. (Modha et al., 2020a) require image processing (Sai et al., 2022).

The Multimedia Automatic Misogyny Identification (MAMI) Challenge (SemEval-2022 task 5) is addressing this problem (Fersini et al., 2022). MAMI provides a testbed for algorithms which are capable of processing text and image of memes in one system. The experiments described in this paper measure the effectiveness of different models and their combination into a fusion system. We implemented a basic text classifier based on BERT and an image processing system based on the Faster R-CNN network. In addition, the generalization capabilities between collections are tested. We conducted the experiments with the MAMI dataset as well as with the dataset provided by the Facebook Memes Challenge (Kiela et al., 2021).

2 Previous Work

The detection of Hate Speech can be considered part of Natural Language Processing. Current research is driven by benchmark data and deep learning algorithms have shown to provide best performance.

Data sets such as Offensive Language Detection in Spanish Variants (MeOffendEs@IberLEF 2021) (Plaza-del Arco et al., 2021) and DEtection of TOXicity in comments In Spanish (DETOXIS) (Gonzalo et al., 2021) focus on general concepts of offensive content while other data sets are dedicated to more specific topics than general offensive content. The SemEval 2019 Task-5 (Basile et al., 2019) focused on the detection of hate speech against immigrants and women in Spanish and English messages extracted from Twitter. Besides the main binary task to detect hate speech, there was a fine grained task to further classify into aggressive attitude and the target harassed, to distinguish whether a message contains incitement against an individual rather than a group. The best performing system (Indurthi et al., 2019) trained a SVM model with a RBF kernel using Google's Universal Sentence Encoder (Cer et al., 2018) as features.

The shared task HASOC (Modha et al., 2019) created a large multilingual dataset for hate Speech identification. The first HASOC track focused on the identification of Hate Speech in Indo-European languages (Hindi, English and German). HASOC introduced a binary classification into problematic content and other content.

While most data sets include English data, several recent shared tasks have created new collections for other languages such as Greek (Pitenis et al., 2020) and Turkish (Çöltekin, 2020). Specific forms of Hate Speech based on the targeted groups have also been analyzed automatically. For this work, the detection of misogyny is especially relevant. In the Automatic Misogyny Identification (AMI) task at Evalita, a Twitter collection of misogynous messages was assembled. Overall, 10.000 tweets were available and classified into misogynous and non-misogynous tweets. They were also further analyzed into more fine-grained classes(Fersini et al., 2018). The second edition of the Automatic Misogyny Identification (AMI) task in 2020 followed up on binary classification. It also included the prediction of aggressiveness as a binary concept for the misogynous tweets and provided a subtask for the analysis of bias in the models (Fersini et al., 2020). Multi-modal processing of text and image simultaneously has made great progress recently. There are approaches for late fusion which first analyze image and text and combine the representations. Early fusion systems process both text and image in parallel in order to benefit from the dependencies. Systems like ImageBERT (Qi et al., 2020) and Uniter (Chen et al., 2020) have achieved promising results. Uniter relates text and image parts to one another and tries to capture their interaction.

3 Multimedia Datasets

The data for the SemEval-2022 task 5 (Multimedia Automatic Misogyny Identification, MAMI) is described in the overview paper (Fersini et al., 2022). The system presented here is aiming at a binary classification. It did not use the fine-grained classification on kinds of misogyny. In addition and in order to observe how well the multimodal system generalizes over similar datasets from similar tasks, we also processed the Facebook Hateful Meme Challenge (HM) dataset (Kiela et al., 2021). This dataset provides examples for hateful memes in general and includes also other kinds of problematic content than misogyny. However, because the tasks are related a system might also work across these two datasets. Table 1 gives an overview over the two sets. Another multimodal dataset is available for English. Some 700 memes related to the presidential election in the USA in 2016 were collected and annotated (Suryawanshi et al., 2020).

4 System Description

Our system includes six single models. They were all tested as classifiers and we explored several

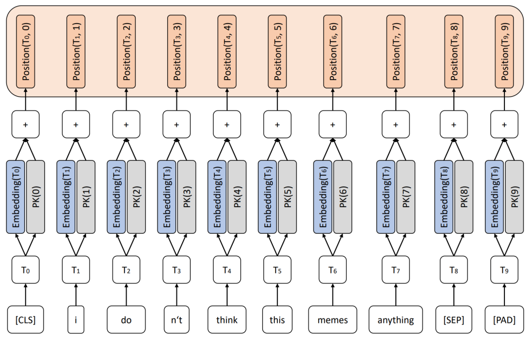

Figure 1: Transformer encoding of meme texts

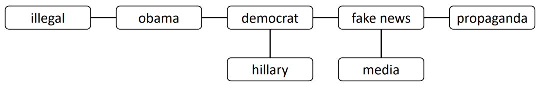

Figure 2: Examples for associations from the knowledge graph

combinations in the experiments.

4.1 Text classification with BERT

The first system is processing the text sequence associated with the meme (Devlin et al., 2019). We used the the model *bert-base-uncased* [1]. It creates a transformer based presentation of the text. The principle of BERT is illustrated in Figure 1.

4.2 Associations from Text

The association system includes semantic knowledge to enrich the representation. The assumption is that memes might often use words in another meaning than the obvious one. Looking for associations could help to enrich the representation. The associations might also be misleading. The associations were manually assembled into a knowledge graph. They were extracted after looking at many of the examples from the dataset and observing the intended meaning of many tweets.

For all words in the text sequence, the system looks for associated words in the knowledge graph. For example, the token *Obama* is related to *democrat* and to *illegal* (see figure 2). These relations represent world knowledge and prejudice which can be helpful for understanding the memes. A similar approach to incorporate knowledge graphs in classification systems has been taken by Liu et. al. (Liu et al., 2020). The approach is illustrated in Figure 3.

[1]https://huggingface.co/bert-base-uncased

Feature	HM	MAMI
Number of memes	9.000	10.000
Number of hateful memes	3.300	5.000
Characters per text meme	62	101
Recognized objects per meme	2	2
Memes with recognized objects	7856	7777
Recognized associations per meme	2	2
Memes with recognized associations	3968	5419

I'M A GREAT GUY, WHY AM I A VIRGIN?
imgflip.com

Figure 4: Object Detection for one meme

The tokens for the associations are extracted from the BERT model and given the position encoding of the word from the original text. All associations found are used. If more associations are found than the sequence length, then the last ones are cut off.

4.3 Sentiment Analysis in Text

In the approach presented here, sentiment analysis is used on the text of the meme. The rationale is that highly emotional texts could indicate a tendency toward hatefulness. Overall, six values are collected. The system VADER suggested by Hutto [2] is used to obtain the first two values for the overall sentiment and intensity (Hutto and Gilbert, 2014). The third and fourth value record the maximum and minimum values for sentiment for all tokens. The method of Loria [3] was used to obtain a measure of subjectivity and of sentiment.

[2]https://github.com/cjhutto/vaderSentiment

[3]https://textblob.readthedocs.io/

4.4 Faster R-CNN-Network

The first visual feature classifier is built with an object recognition system. It uses a Faster R-CNN-Network (Ren et al., 2017) as available online [4]. This system identifies interesting regions which contain much information. The visual features of these regions and their location embedding are fed into a ResNet system. Only the N most likely objects are used. Layer normalization is applied to obtain a final embedding. An example for a result of the object recognition for the dataset is given in figure 4.

4.5 Tile Approach for Image Analysis

A tile approach is splitting the image into 196 rectangular tiles of equal size. These are tiles are analyzed by CNNs and processed as suggested by (Dosovitskiy et al., 2021) and (Lin et al., 2021). The resulting feature vector is associated with a

[4]https://pytorch.org/vision/stable/models.html,

number indicating the position of the tile.

The ResNet architecture is used to obtain an embedding of the entire image. The output embedding is split in two parts of the same size which are used for further processing (Huang et al., 2020).

5 Experiments

For combining the single classifiers, they are fed into a fusion system. For that processing step, a transformer is used. After a layer normalization (Ba et al., 2016), all embedding values are concatenated and fed into a transformer. A sigmoid function is used for the final prediction. First, the models were tested individually. Then, combinations were tested. For finding the optimal fusion of the classifiers above, we applied Sequential Forward Selection (SFS) and Sequential Backward Elimination (SBE). For all experiments, the models were fully trained. Learning rates were adapted for each underlying model so that models converging faster did not overfit. Models with larger embeddings were assigned a higher dropout in the fusion system.

For SFS, all systems were tested individually first and the best system is used as the first component of the combined system. Afterwards, SFS iteratively adds further components. In each iteration, the current version of the combined system is extended by each individual system that is not part of the combined system yet. The combination that leads to the best improvement is taken as the new best combination. SFS converges, when no further improvement can be accomplished. SBE works similar to SFS but starts with a combination of all systems and iteratively detaches individual systems from the combined system. The submitted result was assigned the team name milan_kalkenings.

6 Results and Discussion

The main results refer to the training on the two datasets. Furthermore, we used the two datasets for training and testing respectively. These cross-dataset experiments are reported in the subsequent section.

6.1 Experiments within Datasets

First, the classification by each system individually was tested. As Table 2 shows, the best performance was given by the text classification system. It was followed by the associations system which is another system based on text analysis.

System	AUC-ROC
Text	0.6617
Sentiment	0.5706
Associations	0.6588
Image	0.5958
Tiles	0.5633
Object detection	0.5607

Table 2: Results for each system

The SFS selection method for the SemEval task 5 (MAMI) led to the following optimal combination: text, objects and associations (0.8509 AUC-ROC score). The SFS selection method for HM led to the following optimal combination: text, sentiment, associations and tiles (0.7136 AUC-ROC score). SBE led to the best performance for MAMI with the following combination: text, sentiment, associations and tiles (0.7136 AUC-ROC score). For HM, SBE gave best performance for this set of featues: text, associations and objects (0.8556 AUC-ROC score). The fusion led to improved scores as compared to processing one single modality. It is obvious, that text based metrics are more often in the optimal set.

Selection method	Systems	AUC-ROC
SFS	text, object detection and associations	0.8509
SBE	text, sentiment, associations and tiles	0.7136

Table 3: Results for fusion systems on the MAMI dataset

After the optimal fusion of single systems was determined, we obtained the performance on the test data. Table 4 reports the experiments for the optimal combination as well as for late fusion.

The HM dataset includes many benign confounders which either modify the text of a meme to

Experiment	AUC-ROC	Recall	Precision
HM	0.7146	0.6134	0.5334
HMlate	0.7069	0.3131	0.6712
MAMI	0.8421	0.8217	0.7261
MAMIlate	0.846	0.8529	0.7321

Table 4: Results of experiments with the two datasets

change its class or use the text of a hateful meme in another image. These were introduced to make the task more challenging (Kiela et al., 2021). Leaving out these duplicates changes the performance drastically. Leaving out the memes with identical text increases the performance by some 10%. On the contrary, leaving out the memes with identical images decreases the performance by some 20%. This shows again the impact of the text for this task.

6.2 Experiments Across Datasets

Across datasets, we first trained a classifier for distinguishing between the two datasets. That turned out to be fairly easy for the system (0.94 AUC-ROC). It seems that there are inherent features inserted during data creation which make that distinction easy for systems. Pretraining with the other dataset does not lead to a better performance overall. Only for the MAMI dataset, a performance close to the best overall performance was achieved.

7 Conclusion

The experiments have shown that the identification of hateful memes is still a challenging problem. In our experiments, text features are the most beneficial ones for the system. The influence of associations in particular needs to be further analyzed. First analysis seems to suggest that the number of found associations has a correlation with the performance for the problematic class. The performance across the two datasets is not optimal. Further datasets are needed to analyze the generalization across different collections. In future work, we intend to analyze the impact of each system for the fusion in more detail. We also plan to experiment whether training with a misogyny text dataset can be beneficial for a multimodal system.

Abstract

Everyday more users are using memes on social media platforms to convey a message with text and image combined. Although there are many fun and harmless memes being created and posted, there are also ones that are hateful and offensive to particular groups of people. In this article present a novel approach based on the CLIP (Radford et al., 2021) network to detect misogynous memes and find out the types of misogyny in that meme. We participated in Task A and Task B of the Multimedia Automatic Misogyny Identification (MaMi) challenge (Fersini et al., 2022) and our best scores are 0.694 and 0.681 respectively.

1 Introduction

In the past few years more and more people have been using memes on social media platforms to express their thoughts and sometimes their beliefs. Although there are countless memes that are humorous and fun without expressing hate towards any certain group of people, there are also memes that aim to attack people.

Misogynistic memes use a combination visual and textual content to put down women and some of them are so violent that can be triggering to previous sexual abuse victims. That is why it would be so useful if these instances could be identified automatically.

One of the main challenges of this problem is that the images of these memes come in various forms. Also, the text on the memes adds occlusion to the objects in the images which makes the image understanding part of the problem even more challenging.

To address these challenges, we present a novel multi-modal classification approach based on CLIP (Radford et al., 2021) to identify misogynistic memes and also determine which 4 subcategories of shaming, stereotype, objectification or violence they belong to. CLIP is a multi-modal network trained for object detection. We use a multi-label classification method and detect misogynistic memes and all the subcategories using one single pipeline.

2 Related Work

There have been numerous researches conducted to solve hateful speech detection online in the past decade. Many of these approaches such as (Samghabadi et al., 2020) and (Cao et al., 2020) focus on only one modality which is text. More recently, researchers such as (Gomez et al., 2020) gathered multi-modal data-sets to be able to detect those instances of hate that go undetected by using only textual context.

Memes are also a form of multi-modal data that are widely used to indirectly communicate some meaning online. For the past few years, researchers have tried to solve the problem of hateful meme detection in various ways. In (Suryawanshi et al., 2020) a small data-set was gathered and an approach based on VGG16 (Simonyan and Zisserman, 2014) neural network was proposed. In 2020 Facebook gathered a the Hateful Meme data-set with 10,000 instances which was part of a Hateful Meme Detection challenge (Kiela et al., 2020). The winner of that challenge (Zhu, 2020) used an ensemble of visual-linguistic models such as Visual-Bert (Li et al., 2019) and Ernie-Vil (Yu et al., 2020) and fine-tuned them to solve the problem.

3 Proposed Method

3.1 Data Description

The Multimedia Automatic Misogyny Identification (MaMi) data-set which was gathered for SemEval Task5 challenge (Fersini et al., 2022), consists of 10,000 instances for training phase and 1000 instances for test. An example meme from this dataset is shown in Figure 1. Each instance has 5 binary labels depicting if it is misogyny, shaming, stereotype, objectification and violence.

It is important to note that these subcategories are not mutually exclusive, that is more than one label can be 1 for each instance. So we are dealing with a multi-label classification problem.

Label	Training Data	Test Data
Non-Misogynous	5000	500
Misogynous	5000	500
Shaming	1274	146
Stereotype	2810	350
Objectification	2202	348
Violence	958	153

Table 1: Training and Test Data-set Distributions

The challenge (Fersini et al., 2022) has two parts, in Task A the goal in to detect the misogynous memes. In the second part, Task B, the goal is to determine the type of misogyny that was present. We participated in both parts of the challenge using a multi-label classification scheme.

3.2 Classification Pipeline

In our proposed model, the pre-trained multi-modal object detection network CLIP has an important role. CLIP was initially introduced as multi-modal way of object detection. It was trained on 400,000 million pairs of images and text. It has proven to be much more efficient than many other state-of-the-art object detection techniques.(Radford et al., 2021)

We use CLIP to encode the image and text separately and concatenate the features as can be see in Figure 2 .The main idea is that there is a non-linear function $f(X_I, X_T)$ between the image feature space X_I and text feature space X_T that will help determine if an instance belongs to each one of the 5 categories or not. To find out the parameters of this non-linear function we create a feed-forward neural network and feed the concatenated features to that. The network has 5 output nodes, each for one of the labels.

Before feeding the image input to the CLIP image encoder we had to resize the image to 224x244 with 3 channels to match the input shape requirements. The text was also truncated to a sequence of length 77 to be seamlessly used with the CLIP tokenizer.

Additionally, we use Sigmoid layer as the activation function because in contrast to softmax, the probabilities of each instance belonging to a class do not have to sum up to 1 and so they can be independent of each other. Therefore, it is more suitable for multi-label classification. After getting the output of the pipeline, we determine the binary value for the predictions based on a threshold of 0.5.

3.3 Training Process

As no validation data-set was provided, we randomly split the 10,000 instances into 9000 for training and 1000 for validation purposes. We used binary cross-entropy loss function and used Adam optimizer for the process. The optimal hyper-parameters were found empirically with learning rate of 0.001, batch size of 128 and the training was done for 10 epochs.

At the end of each training epoch, the evaluation metrics including precision, recall and F1-score with macro averaging was calculated on the validation data-set. If a higher F1-score was found then the state of the model was saved as the best state.

As CLIP comes with different options for image feature extractions, we made sure to try two different ones, Visual Transformer (ViT) (Dosovitskiy et al., 2020) with 32x32 patches and Residual Network(He et al., 2016) with 101 layers to see if they have an impact on the classification results.

4 Evaluation and Results

4.1 Evaluation Metrics

All the submissions to the challenge were automatically evaluated by a script that was programmed by the organizers. After the challenge was over, the script was released and we investigated how the F1-scores for each task was calculated.

First the confusion matrix was calculated resulting in $M = \left(\begin{smallmatrix} tp & fp \\ fn & tn \end{smallmatrix}\right)$. Then, as shown in Equations 1 - 7, positive precision P^+, positive recall R^+, negative precision P^- and negative recall R^- was calculated separately and the final F1-score is the average of positive F1-score and negative F1-score.

$$P^+ = \frac{tp}{tp + fp} \tag{1}$$

$$R^+ = \frac{tp}{tp + fn} \tag{2}$$

$$F1Score^+ = \frac{2 \times (P^+ \times R^+)}{P^+ + R^+} \tag{3}$$

$$P^- = \frac{tn}{tn + fn} \tag{4}$$

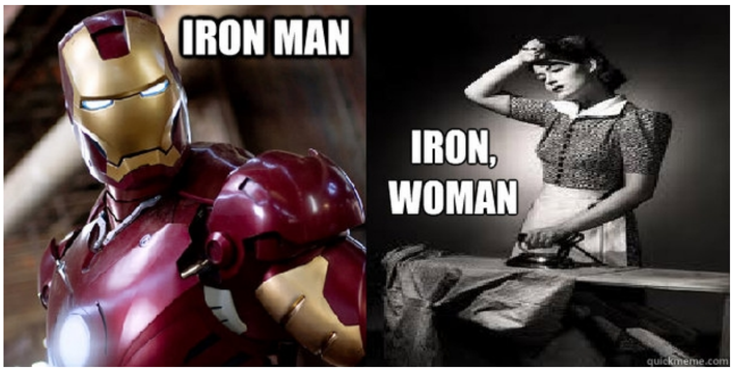

Figure 1: Sample number 152 of Training data which is Misogynous and Stereotype

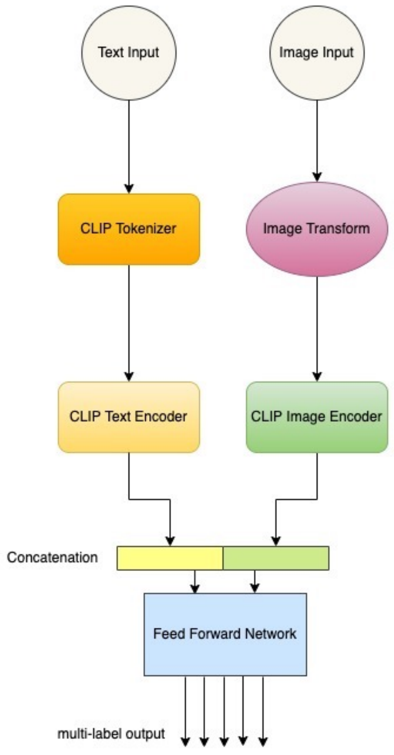

Figure 2: Proposed Classification Pipeline

$$R^- = \frac{tn}{tn + fp} \tag{5}$$

$$F1Score^- = \frac{2 \times (P^- \times R^-)}{P^- + R^-} \tag{6}$$

$$F1Score = \frac{F1Score^+ + F1Score^-}{2} \tag{7}$$

4.2 Experiments and Results

We conducted multiple experiments in the evaluation phase of the challenge. We tried different architectures for the feed forward network of our pipeline to get the best results.

In our initial experiments we had more layers in the feed forward network and did not include dropout layer and batch normalization. As the challenge progressed we realized that those models lacked in generalization, so we started using a simpler architecture and added dropout and batch normalization to get better results. Additionally, we tried switching the image encoder and discovered that using Resnet-101 based encoder results in much better scores, especially in Task B.

4.3 Error Analysis

As can be seen in the Table 2 our best result significantly outperforms all the baseline provided by the organizers. As informed by the organizers, the baseline models are grounded upon VGG-16 model for image feature extraction and USE model for textual feature extraction. Our best model achieves 0.694 score in Task A and 0.681 in Task B. It uses the pre-trained Resnet101 as the image encoder and also has 200 nodes in the hidden layer of our feed forward network.

5 Conclusion

In this paper we demonstrated how a successful model such as CLIP can be used to detect misogynous memes. We presented a novel architecture based on that multi-modal model and used multi-label training. We were able to achieve good results using this approach.

Abstract

This paper presents our submission to task 5 (Multimedia Automatic Misogyny Identification) of the SemEval 2022 competition. The purpose of the task is to identify given memes as misogynistic or not and further label the type of misogyny involved. In this paper, we present our approach based on language processing tools. We embed meme texts using GloVe embeddings and classify misogyny using BERT model. Our model obtains an F1-score of 66.24% and 63.5% in misogyny classification and misogyny labels, respectively.

1 Introduction

SemEval 2022 task 5 (Fersini et al., 2022) is a sentiment analysis task aimed at memes[1], divided into two subtasks of increasing complexity. Subtask A is misogynous meme identification, *i.e.*, whether a meme should be categorized either as misogynous or not misogynous; subtask B, on the other hand, is a multi-label classification problem, *i.e.*, classifying what kind of misogyny is involved in the meme. A meme is usually intended to convey a sarcastic message, but in a short time, people have started to use them to deliver sexist messages in an online environment. The anonymity of the internet tends to make them more aggressive. Such an environment amplifies the offline world's sexual stereotyping and gender inequality.

Meme sentiment analysis is a challenging task as often it relies on implicit themes or knowledge and trending news at the time of the creation of the meme. Meme analysis has been of growing interest for the NLP community. Our approach also relies on various NLP-based tools and the code to implement the paper is available at https://github.com/gagansh7171/IITR-CodeBusters .

*These two authors contributed equally.

[1]The term meme used in this task refers to an idea or a message conveyed via an image and embedded text.

The rest of the paper is organized as follows. In Section 2 we briefly describe the details regarding the datasets used. In Section 3 we describe some recent related work conducted in the field of meme classification. In Section 4 we describe and define the models and baselines for the task. In section 5 we describe the low-level details including scoring parameters, pre-processing, libraries and hyper-parameters used for the experimental setup. In Section 6 we describe the results obtained and some insight of why the models are performing the way they performed. In section 7 we conclude the paper.

2 Background

The dataset used for this task consists of a set of 10000 memes images whose text has already been extracted. Each meme has already been labeled as *misogynous* for subtask A and as *shaming*, *stereotype*, *objectification* ,and *violence* for subtask B. The dataset is perfectly balanced in terms of classification of misogyny, *i.e.*, precisely 50% of the memes are misogynous and the rest 50% are not. Of these 5000 misogynous memes -

- 1274 or 25.48% are labelled as shaming category.
- 2810 or 56.2% are labelled as stereotype category.
- 2202 or 44.04% are labelled as objectification category.
- 953 or 19.06% are labelled as violence category.

The data is provided as zip file of memes in image format and a .csv file where the memes are labelled according to the following structure (Fersini et al., 2022).

- **file_name:** name of the file denoting the meme

- **misogynous:** a binary value (1/0) indicating if the meme is misogynous or not. A meme is misogynous if it conveys an offensive message having as target a woman or a group of women.
- **shaming:** a binary value (1/0) indicating if the meme is denoting shaming. A shaming meme aims at belittling women because of some body characteristics.
- **stereotype:** a binary value (1/0) indicating if the meme is denoting stereotype. A stereotyping meme aims at representing a fixed idea or preconceived notion regarding women.
- **objectification:** a binary value (1/0) indicating if the meme is denoting objectification. A meme that describes objectification represents a woman like an object through over-analysis of physical or sexual appeal or comparing women to inanimate objects.
- **violence:** a binary value (1/0) indicating if the meme is denoting violence. A violent meme describes physical or verbal violence or harassment represented by textual or visual content.
- **Text Transcription:** transcription of the text reported in the meme.

3 Related Work

Memes are essentially language of the internet but such widespread use of memes had also made them a target for spreading hateful and offensive messages by fringe web communities (Zannettou et al., 2018). Many online communities accept sexism and harassment in the name of humour in the form of memes and has resulted in increased attraction of attention from academics (Drakett et al., 2018). Thus, memes had emerged as a multi-modal expression of online hate.

Research in the field of multi-modal sentiment analysis has been mostly focused on video and text or speech and text (Rao et al., 2021; Zadeh et al., 2016). Sentiment analysis of memes was conducted by French (2017) but it was based on correlation of the meme and online discussion in the comments.

Recent study for meme classification was done by Zia et al. (2021) where hateful memes were classified based on the protected category they attacked which were *race*, *sex*, *religion*, *nationality*, *disability*. The study included usage of state-of-the-art visual and textual representations to produce respective embedding of the memes which were then concatenated to train a logistic regression classifier model. Facebook recently launched The Hateful Memes Challenge to accelerate development in this field (Facebook, 2020).

We follow a more humble approach of using GloVe to embed text in the memes but tried models more sophisticated than Logistic Regression Classifier for the classification. The study conducted by Zia et al. (2021) reflects that better results emerge when both text and image are considered. But we do not consider the images for the challenge and consider this challenge an opportunity to learn about NLP first-hand.

4 System Overview

BERT[2] model is a state-of-the-art model developed by the AI team at Google (Vaswani et al., 2017). Traditional NLP models are unidirectional, *i.e.*, they read the text from left-to-right or right-to-left. On the other hand, BERT is bidirectional, understanding the correlation of a word with words on both sides by reading the entire sequence of the words at once. Google showed that this scheme helps better understand the statement's sentiment, making this model the best fit for the task.

RoBERTa[2] model is built on top of the BERT model. It has the same architecture but differs in terms of tokenizer and pre-training scheme, *i.e.*, much larger mini-batches and learning rates are used. The architecture similarity with the BERT model makes this model suitable for this task.

Baseline scores are made available by the organizers and are mentioned in Table 1. We provide additional baseline scores obtained by traditional classification models as well for comparison with the BERT and RoBERTa model. The different baseline models used are Logistic Regression (LR)[3], K Nearest Neighbours (KNN)[3], Random Forest (RF)[3] and Multilayer Perceptron (MP)[3].

5 Experimental Setup

The scoring parameters, pre-processing, language, libraries and hyper-parameters used are mentioned in this section for ease in reproduction.

[2]We use transformers 4.16.2 implementation of the model.
[3]We use Scikit-learn 1.0.2 implementation of the model.

Model	A	B
Baseline_Image_Text	54.3%	0%
Baseline_Text	64%	0%
Baseline_Image	63.9%	0%
Baseline_Flat_Multilabel	43.7%	42.1%
Baseline_Hierarchical_M	65%	62%

Table 1: Baseline Scores obtained by SemEval Organizers.

5.1 Scoring parameters

Macro F1 score is used as a measure of performance for the models for subtask A and weighted average of F1 scores for each prediction category for subtask B.

5.2 Pre-processing

The text is converted to lowercase before being used for training. Each meme is vectorised using GloVe embedding (Pennington et al., 2014).

Glove consists of word to vectors mapping and these vectors come in various dimensions. We are using 200-d vectors. For embedding one meme we find out word-vectors for every word and calculate an average of these vectors to finally calculate a vector representation of a meme. Glove vectors map words to a point in n-dimensional space where words with similar meaning are closer to each other. So taking average of these vectors should give us a vector in this space which represent an average gist of the message.

5.3 Language and libraries used

The experiment is conducted at Google Colab platform using Python 3.7.2 as the programming language. The packages are listed in Table 2

Package	Version
Pandas	1.3.5
Jupyter	1.0.0
Keras	2.7.0
Tensorflow	2.7.0
Tensorflow-hub	0.12.0
Numpy	1.19.5
Transformers	4.16.2
Scikit-learn	1.0.2

Table 2: List of Python Packages used for the Experiment.

5.4 Hyper-parameters of the models

This section details hyper-parameters for each model.

K Nearest Neighbours 5 CPU jobs, other values are default from Scikit-learn (refer KNN).

Logistic Regression random seed of 42, solver is liblinear, maximum iterations of 1000, 5 CPU jobs, f1_macro scoring is used, refit is set to True, other values are default from Scikit-learn (refer LogisticRegressionCV).

Multilayer Perceptron maximum iteration is set to 200, other values are default from Scikit-learn (refer MLPClassifier).

Random Forest 5 CPU jobs, bootstrap samples are used while building trees, out-of-bag samples are used to estimate the generalization score, 10 trees are used in the forest, all features are considered while looking for best split, other values are default from Scikit-learn (refer RandomForestClassifier).

BERT transformers based implementation of BERT is used. Pretrained bert-base-uncased model and tokenizer are used. Adam optimizer with 3e-6 learning rate, 1e-08 epsilon and 1.0 clipnorm as parameters is used as the optimizer. Sparse Categorical Crossentropy with from_logits set to True is used as loss function. Early stopping is done with a patience value of 4 and minimum increment of validation accuracy as 0.005. The model which gave best result for validation set is restored before training is complete. Other values are default from Hugging-Face implementation (refer BERT).

RoBERTa transformers based implementation of RoBERTa is used. Pretrained roberta-base model and tokenizer are used. Rest of the parameters are same as used in BERT model. Other values are default from Hugging-Face implementation (refer RoBERTa).

6 Results

Models are trained with 80% of data as training data and 20% of data as validation data. The results obtained for subtask A and B are mentioned in Table 3 and 4 respectively. The models' hyper-parameters were tuned for subtask A and were reused for subtask B, hence training and validation scores are omitted in Table 4, instead score for each classification category[4] and final scores are listed. Baseline results obtained by the SemEval

[4]These scores are obtained in post-evaluation phase after the labels for test data were released by the organizers.

Model	Training Score	Validation Score	Subtask A
KNN	78.05%	64.27%	57.54%
LR	73.95%	71.03%	58.69%
MP	89.97%	71.32%	58.05%
RF	98.56%	61.97%	58.81%
BERT	**87.26%**	**82.10%**	**66.24%**
RoBERTa	88.63%	80.60%	60.80%

Table 3: Scores obtained for subtask A.

Model	Misogynous	Shaming	Stereotype	Objectification	Violence	Subtask B
KNN	57.54%	53.62%	58.24%	54.51%	56.38%	56.50%
LR	58.69%	53.35%	55.63%	51.52%	52.65%	55.17%
MP	58.06%	52.30%	54.50%	60.66%	62.66%	57.74%
RF	58.88%	48.01%	54.19%	45.04%	47.16%	52.30%
BERT	**66.24%**	**64.06%**	**61.75%**	**65.20%**	**66.51%**	**64.76%**
RoBERTa	60.80%	46.06%	62.10%	66.11%	53.36%	60.14%

Table 4: Scores obtained for subtask B.

Organizers are listed in Table 1 for comparison.

From the results we can see that Random Forest model has high level of over-fitting as the score difference of training and validation is highest in this model.

The least difference in training and validation score appears in Logistic Regression model but this is mostly due to high level of under-fitting as the least training score is obtained in this model. BERT model provides the best results. The model obtains a high training score and score difference in training and validation is the least for this model. The trend maintains in subtask B as well with the model obtaining highest score.

Ranking phase - We submit our scores obtained from BERT model for the leader board. The scores obtained are 66.24% and 63.5%[5] for subtask A and B respectively. The ranks obtained for subtask A and B are **47** and **34** respectively.

7 Conclusion

The results show that BERT model is the best among those we tried for the given problem statement. However, these results are obtained using purely NLP based tools and techniques, the image component of the memes is not considered. As discussed in the Background section, there is a scope of improvement if we consider the images of the memes as well for the classification.

[5]The score of 64.76% mentioned in the table is obtained using the same model used in making the submission for evaluation phase. This score is obtained post-evaluation with test-labels being made public by the organizers.

Abstract

With the growth of the internet, the use of social media based on images has drastically increased like Twitter, Instagram, etc. In these social media, women have a very high contribution as of 75% women use social media multiple times compared to men which is only 65% of men uses social media multiple times a day. However, with this much contribution, it also increases systematic inequality and discrimination offline is replicated in online spaces in the form of MEMEs. A meme is essentially an image characterized by pictorial content with an overlaying text a posteriori introduced by humans, with the main goal of being funny and/or ironic. Although most of them are created with the intent of making funny jokes, in a short time people started to use them as a form of hate and prejudice against women, landing to sexist and aggressive messages in online environments that subsequently amplify the sexual stereotyping and gender inequality of the offline world. This leads to the need for automatic detection of Misogyny MEMEs. Specifically, I described the model submitted for the shared task on Multimedia Automatic Misogyny Identification (MAMI (Fersini et al., 2022)) and my team name is IIT DHANBAD CODECHAMPS.

1 Introduction

With the growth of the internet, social media becomes a crucial part of everyone's life. As every coin has two side positive and negative, social media also comes with a number of problems. The challenge of identifying misogyny (Srivastava et al., 2017) in different social media specially in forms of meme which contains both image and text is very complicated. Misogyny meme highly affected the life of women's as its spread hate and prejudice behaviour against women's. Social media like twitter, Instagram, etc have handled by their own ways. However, detecting such memes is highly challenging. Due to this challenge, it attracts the researcher's attention. According to one social media Instagram, more than 1 million users shared memes daily. So, with this huge amount of data in social medias and internet it is impossible to detect every misogyny meme by man power. So, we need machine learning, deep learning and artificial intelligence techniques to detect automatically misogyny memes in social media. In this paper, we have explored various Machine Learning (ML) and Deep Learning (DL) algorithms for misogyny identification in shared task MAMI (Fersini et al., 2022) challenge and my team's name is IIT DHANBAD CODECHAMPS. As per requirement of MAMI, I have submitted 4 runs for Subtask-A. My best run in Subtask-A has achieved Macro-F1 score of 0.656.

2 Related Works

Many works related to automatic detection of misogyny, hate, sexism on social media and web have been proposed.
Abir Rahali (Rahali et al., 2021) proposed a approach for automatic misogyny detection in social media using attention based bidirectional LSTM.
Endang Wahyu Pamungkas (Pamungkas et al., 2020) proposed a method for Automatic Identification of Misogyny in English and Italian Tweets at EVALITA 2018 with a Multilingual Hate Lexicon.
Mario Anzovino, Elisabetta Fersini (Anzovino et al., 2018) proposed a method for Automatic Identification and Classification of Misogynistic Language on Twitter. The main contribution of this paper is two-fold: (1) a corpus of misogynous tweets, labelled from different perspective and (2) an exploratory investigation on NLP features and ML models for detecting and classifying misogynistic language.
Rachael Fulper (Fulper et al., 2014) proposed a relation between misogynistic language in twitter and sexual Violence. In their paper they consider all 50 states in Washington DC.

Lakes Goenaga, Aitziber (Goenaga et al., 2018) Atutxa proposed a Automatic misogyny identification using neural networks. In this paper they focus on recurrent neural network (RNN) approach using a Bidirectional Long Short Term Memory (Bi-LSTM).

3 Task and Dataset Description

Here we have described the dataset and task provided by Multimedia Automatic Misogyny Identification (MAMI (Fersini et al., 2022)) challenge.
Multimedia Automatic Misogyny Identification (MAMI) task is divided into two sub task. Sub-task A: a basic task about misogynous meme identification, where a meme should be categorized either as misogynous or not misogynous (shown in Table 1).

Sub-task B: an advanced task, where the type of misogyny should be recognized among potential overlapping categories such as stereotype, shaming, objectification and violence. *e.g.*

1026.jpg 10101 POV: You’re my wife made with mematic

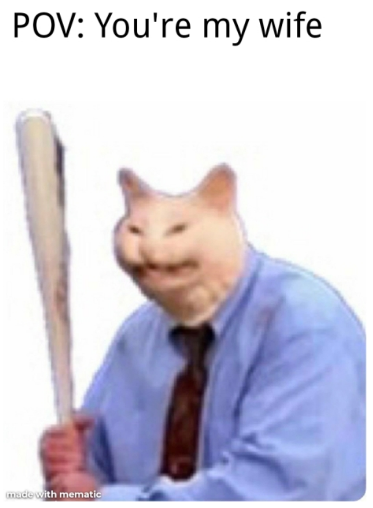

Figure 1: 1026.jpg

Here, 1026.jpg represent meme file name . Next column contains 5 numbers of zeros and ones . First numbers represent wheather meme is misogynous . Second numbers represent wheather meme is shaming . Third numbers represent wheather meme is stereotype .Fourth numbers represent wheather meme is objectification .Fifth numbers represent wheather meme is violence . Next column represent Text Transcription of the meme.

4 Methodology

4.1 Text Preprocessing

First, we removed all the punctuations, numbers, links and stop words. We have used lemmatization for grouping together the different forms of a word into a single word. NLTK wordnet (Loper and Bird, 2002) is used for lemmatization.

4.2 Feature Extraction

TfidfVectorizer (Kumar and Subba, 2020) is used for converting the text into numerical features. Pipeline [1] is used for doing TfidfVectorizer and classification in pipelined manner. Tokenizer by keras library is used for LSTM and Bert. For Logistic regression and SVM we have used TfidfVectorizer from scikit-learn library.

Models Proposed

For Subtask-A, we have submitted 4 runs based on four different algorithms, namely- Logistic Regression (Sammut and Webb, 2010), SVM (Noble, 2006), LSTM (Hochreiter and Schmidhuber, 1997), Bert (Devlin et al., 2018) with different parameters like batch size, epochs, number of perceptron etc. We have used the scikit-learn library for logistic regression based models and SVM (support vector machines) models. Keras is used for LSTM and BERT. We scored maximum F1 score 0.656 using BERT. We have used the following value of parameters :-
1.For TfidfVectorizer, we have used mindf=20, maxfeatures=2000 and maxdf=0.6 .
2. For LSTM and BERT, we have used batch size = 2, epochs = 3 and number of layers = 2 .

5 Result and Discussions

The results of Subtask-A are represented in terms of Macro-F1 (shown in Table 2). The best score as Macro-F1 for Subtask-A we get is 0.656. Table 2 shows the score of our submissions based on different algorithms on MAMI challenge official ranking.
For Subtask-A BERT performs better than all other models with the parameters batch size = 2 , epochs = 3 , number of hidden layers = 2 and number of perceptron’s is 128 in first layer and 64 in second layer.

SVM	0.584
LSTM	0.651

Table 2: Result of Subtask-A based on different Models

6 Conclusions and Future Work

We have completed the task using various classification algorithms and evaluated the performance of different classification algorithms for Multimedia Automatic Misogyny Identification (MAMI) shared task. Our overall score is 0.656 for subtask-A which were average as compared to other submissions obtained in the Multimedia Automatic Misogyny Identification (MAMI) shared task. We look forward to experimenting with different advance algorithm or neural network models. Also, till now our algorithms works only with text classification. We are looking forward to work in text and image simultaneously for better accuracy and classification. Also, fine tuning the parameters of the algorithm can help in improvement of the overall performance. We shall be exploring these tasks in the coming days.

QiNiAn at SemEval-2022 Task 5: Multi-Modal Misogyny Detection and Classification

Qin Gu, Nino Meisinger, Anna-Katharina Dick
University of Tuebingen
{firstName.lastName}@student.uni-tuebingen.de

Abstract

In this paper, we describe our submission to the misogyny classification challenge at SemEval-2022. We propose two models for the two subtasks of the challenge: The first uses joint image and text classification to classify memes as either misogynistic or not. This model uses a majority voting ensemble structure built on traditional classifiers and additional image information such as age, gender and nudity estimations. The second model uses a RoBERTa classifier on the text transcriptions to additionally identify the type of problematic ideas the memes perpetuate. Our submissions perform above all organizer submitted baselines. For binary misogyny classification, our system achieved the fifth place on the leaderboard, with a macro F1-score of 0.665. For multi-label classification identifying the type of misogyny, our model achieved place 19 on the leaderboard, with a weighted F1-score of 0.637.

1 Introduction

Even though women are as much present online as men, some online spaces, such as microblogging websites, are still male dominated. Misogynistic jokes and memes are inevitably somewhat common in certain parts of the Internet and have the potential to perpetuate harmful ideas about gender or instill false ideas and expectations. Notably, the way they are spread is often through various modalities, most commonly visual and textual. Therefore, it would be useful to have a system that could automatically detect if certain combinations of texts and images are misogynistic or not. This is not a trivial task however, since misogyny can manifest in many different forms such as stereotyping, objectifying or threatening violence against women. A crucial difficulty in this multi-modal classification task is also the interplay between text and image. Some memes may appear harmless if only either the image or text are viewed separately. The Multimedia Automatic Misogyny Identification (MAMI) challenge at SemEval-2022 (Fersini et al., 2022) seeks to find solutions to solve this task.

We propose two models that automatically detect English misogynistic memes and classify the type of problematic ideas they perpetuate.[1] For simple binary misogyny detection, we created an ensemble model that makes predictions based on majority voting on two text-based and two image-based classifiers using partly hand-crafted features such as age, gender and nudity classification. For task B we relied only on text information and used a transformer based approach, creating a RoBERTa model (Liu et al., 2019) that classifies the type of misogyny that is perpetuated in the memes.

2 Background

Automatically identifying misogynistic texts has been explored in the past. In 2020, this task was proposed as an EVALITA shared task, using Italian tweets (Fersini et al., 2022). So far, the research in the area of misogyny detection has mostly focused on pure text data from social media, specifically Twitter (Anzovino et al., 2018; Frenda et al., 2019). In the current multi-modal task however, competitors were given the opportunity to explore classification using both visual and textual data given. Singh et al. (2020) used a multi-modal multi-task learning system with BERT (Devlin et al., 2018) features to extract textual information and ResNet features to handle image classification. A similar approach proved to be useful in another related shared task, in which Tamil memes should be identified as trolling or not (Suryawanshi and Chakravarthi, 2021).

[1]The code is made available at https://github.com/cicl-iscl/SemEval-2022_Multimedia_Automatic_Misogyny_Identification.

shaming	THE FACE YOU MAKE WHEN TRUMP HAS THE CLASSY FOREIGN CHICK AND YOU'RE MARRIED TO KERCHAK imgrip.com
stereotype	creator made native women beautiful, to hide all that crazy
objectification	When my girlfriend is trying to have a serious conversation with me TITTY

shaming + stereotype	CAN'T TELL IF THIS IS AN UGLY HIPPY CHICK OR REALLY PRETTY HIPPY BOY quickmeme.com
stereotype + objectification	Keeping your dishwasher clean will make it last longer Take care of your appliances
objectification + violence	inglip.com IS RAPING A PROSTITUTE A THEFT?

Table 1: Examples of text transcriptions that fit the four categories of misogyny and combinations of multiple labels.

The provided data set includes both images and text transcriptions of memes. The two subtasks we participated in were structured as follows: In subtask A, the memes should simply be identified as misogynous or not misogynous. Subtask B posed a more advanced challenge, as memes should additionally be classified as being part of four overlapping categories. These categories specify the type of misogyny expressed in the meme: stereotypes, shaming, objectification and violence. Shaming memes will insult women's appearance, stereotypes perpetuate harmful ideas about (groups of) women, objectification reduces women to their sexuality or body and violence downplays or advocates for violence against women. Examples of text transcriptions of these categories can be found in Table 1. The dataset for training includes 10000 memes with all of these labels, with exactly half of the memes being classified as misogynous and half as harmless. 2810 memes in the training set perpetuate stereotypes, 2202 objectification, 1274 shaming, and 953 violence. Many of the misogynistic memes have therefore overlapping categories, being classified as two or even three or all types of misogynous.

3 Subtask A: Binary misogyny classification

3.1 System Overview

For the binary classification of memes we experimented with a number of classification algorithms for both the image and the text transcriptions, as well as with a variety of different features. We decided to examine the benefits of an ensemble model that uses more traditional forms of text classification, as optimized ensemble models have been shown to perform well on similar tasks such as hate speech detection (Van Thin et al., 2019). The resulting model consists of four estimators, as illustrated in Figure 1.

The first set of classifiers are a multinomial naive Bayes classifier and a separate Gradient boosting classifier with tf-idf transformed vectors of the text transcriptions found in the data set. Originally we considered training the models on n-gram features, as previous research has shown that they can be useful to classify short texts (Buda and Bolonyai, 2020), but tf-idf vectors consistently performed better. Similarly, we experimented with adding more classifiers trained on tf-idf vectors, however, performance stayed consistent or decreased, thus we stayed with two.

Secondly, we introduce a Random forest classifier trained on a variety of features pertaining to the images themselves, rather than the text. The features used are Hu moment invariants (Hu, 1962), Haralick textures (Haralick et al., 1973) and image histograms. All three features are expected to help in gaining general insights into the image structure of the meme: Hu moment invariants are used to characterize the shape of an object in an image, Haralick textures should provide information about regions of interest, and the image histogram are employed to gain information about the color distribution, as the former two features require images to be converted into grayscale. To make all images equivalent, they were re-scaled to 500x500 pixels.

Lastly, with this being a multi-modal classifica-

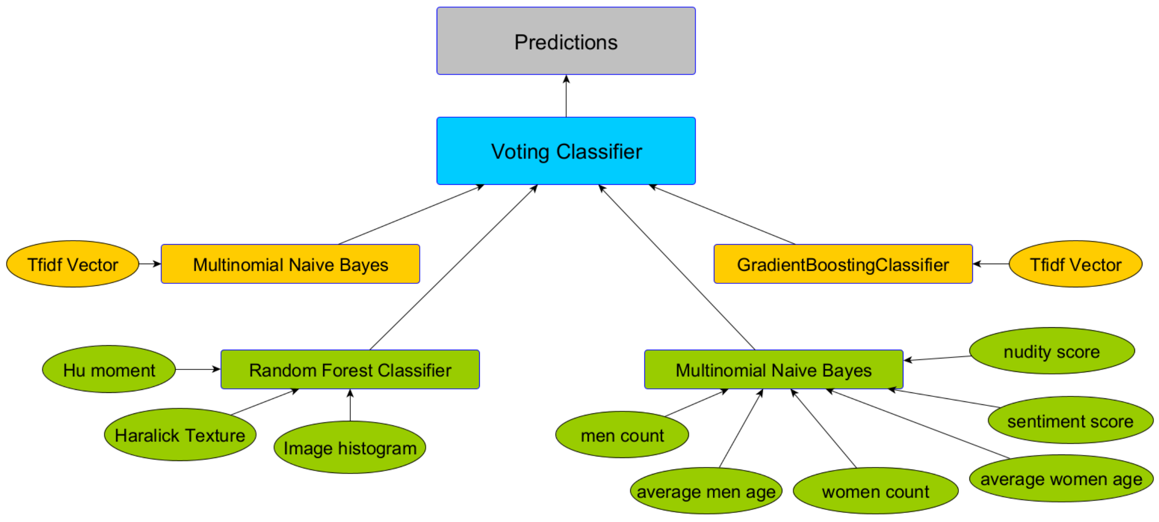

Figure 1: Ensemble Model used for Subtask A.

tion task, we were interested in whether we can extract additional information from the images/text transcriptions that might be relevant to decide if a meme is misogynistic or not. Thus, we enhanced the data set with the following features:

- The number of men/women depicted in the meme, as there might be a gender imbalance relevant for the classification process in combination with other features. Examining the text transcriptions, 'women' and 'woman' were the first and third most used word in misogynistic memes. It is not unreasonable to assume that women are also more likely to be featured in the corresponding images.
- For the same reason as above, we included the average estimated age of all men/women depicted in the meme.
- A binary nudity score, indicating whether an image is sexually explicit or not. In the training data, 15.75% of the misogynistic and only 2.86% of the non-misogynistic memes were sexually explicit.
- A sentiment score ranging from [-1, 1], indicating the polarity of any given text. A score of 1 indicates a positive statement, a score of -1 a negative sentiment. Misogynistic memes are usually hateful, so it can be assumed that the are more likel to use negative language in their texts.

All numerical scores retrieved from these features were transformed into a vector representation and used to train another multinomial naive Bayes classifier.

Finally, we built an ensemble model, using a majority voting rule, with all estimators created so far. Said model was hyperparameter tuned using a grid search, as well as cross-validated using five folds.

3.2 Experimental Setup

To extract information about the number of men/women and their estimated age, we made use of the Facial Recognition API provided by Face++.[2] The nudity score was obtained from the images using the NudeClassifier from NudeNet.[3] The classifier returns probabilities whether an image is sexually explicit or not. These probabilities were then transformed into a binary label. The sentiment was obtained using the TextBlob[4] library and the polarity scores added to the data set. The image features for the Random forest classifier were calculated through the opencv-python library,[5] whereas the tf-idf vectors, as well as the model itself, was built with the scikit-sklearn library (Pedregosa et al., 2011).[6]

The model was hypertuned using a grid search and a 5-fold cross-validation. The parameters for the grid search can be found in Table 2. The tf-idf vectors were tuned separately for the Multinomi-

nalNB classifier and the GradientBoostingClassifier. Similarly, the two MultinominalNB classifier were tuned separately, one in combination with the tf-idf vectors, and on in combination with the gender, age, nudity, and sentiment features.

3.3 Results

Model	**Macro F1**
(1) MultinominalNB (tf-idf)	0.626
(2) GradientBoosting + (1)	0.645 *(+0.019)*
(3) MultinomialNB (gender) + (2)	0.649 *(+0.004)*
(4) RandomForest + (3)	**0.665** *(+0.016)*

Table 3: Gradual built-up of the ensemble model.

Our system for Subtask A achieved place 5 on the leaderboard, with a macro F1 score of 0.665. To make sure that each estimator of our ensemble model actually improves the classification of misogynistic memes, we gradually built it up and run it against the test data. As can be seen from the results in Table 3, both the GradientBoostingClassifier as well as the RandomForestClassifier provide substantial performance gains compared to the handcrafted gender, age, nudity, and sentiment features.

While the nudity score seems to offer strong support on whether a meme is misogynistic or not, the same cannot be said for the other handcrafted features. Given the sentiment score, for example, 1119 out of 5000 misogynistic memes received a negative sentiment score. Compared to 1103 non-misogynistic memes that also received a negative sentiment score, it seems likely that the score provides very little information for the classification process. Similarly, a direct correlation cannot be derived from the number of men/women or their estimated average age. Because of that, it is likely that they provide little information gain as well. The ensemble model from Subtask A was able to correctly classify instances of more explicit forms of misogyny. Memes that include the word "rape", mention "cooking" or "cleaning", show (exposed) female body parts in the image or explicitly mention them in the text are correctly identified as sexist. When only one of these features is present, the model produces false positives, for example harmless memes that feature women doing housework. The memes the model was not able to identify as misogynistic often do not feature human faces or only represent them by minimalistic drawings, are low quality, or have more subtle references to sexuality that the nudity detection cannot identify (such as handprints on breasts).

4 Subtask B: Multi-label classification of misogyny types

Although the ensemble model performed reasonably well for Subtask A, performance was significantly worse when using it for the extended misogynistic labels introduced in Subtask B. Because of this, we built and trained a different model infrastructure using a deep learning approach (which performed worse than our ensemble model, when applied to Subtask A).

4.1 System Overview

Subtask B is a multi-label classification task, so each meme can be assigned to one or more categories. To capture the features which differentiate those memes among different subtypes, we made use of a multi-label model from the Simple Transformers library,[7] using text data only.

In this task, we have five distinct binary labels for each data entry in the training set: misogyny, shaming, stereotype, objectification, and violence. The transformer-based model consists of a transformer model plus a classification layer on top of it. The main difference between this model and the binary classification model is that, in this model, the classification layer has five output neurons, corresponding to each out of the five labels in the training set. For the transformer model, we chose a pretrained RoBERTa model, which is imported by the Simple

[7] https://simpletransformers.ai/

	Misogyny (model A)		Shaming		Stereotype		Objectification		Violence	
	1 pred	0 pred	1 pred	0 pred	1 pred	0 pred	1 pred	0 pred	1 pred	0 pred
1 true	**333**	167	54	92	160	**190**	148	**200**	58	**95**
0 true	168	**332**	**98**	**756**	137	**513**	122	**530**	32	**815**

Table 4: Confusion matrices for all classification categories. Analysis was performed on the test set.

Transformer library from the Transformer library (Wolf et al., 2020) that was developed by HuggingFace. It is based on the RoBERTa model proposed by Liu et al. (2019).

RoBERTa removed the next sentence prediction task from BERT (Liu et al., 2019) which is one of the reasons why we chose RoBERTa over BERT, as the majority of the text transcriptions of memes in this task are consisting of either one or two sentences. The other reason being, that RoBERTa was trained on a larger dataset than BERT, thus more likely to result in better predictions.

4.2 Experimental Setup

The SimpleTransformers library is designed with the purpose of easily setting up a transformer model. Transforming text into a suitable vector representation is done automatically, and various hyperparameters can be tuned to improve performance. we set the threshold in our implementation to 0.8. The model was trained for 20 epochs using a GPU provided by the Kaggle notebook environment.[8]

4.3 Results

Our system achieved place 19 on the leaderboard, with a macro F1 score of 0.637 using the above-mentioned transformer-based model. We have also experimented with other approaches like the FastText library[9] which did not show better performance on this multi-label classification task than the transformer approach.

Compared to the true and false negatives in the ensemble model's prediction from Subtask A, which are very balanced, the model for Subtask B produces a lot more false negatives for the test set(see Table 4). True and false positives and negatives are very balanced in the ensemble model's predictions from Subtask A, as shown in Table 4. The model for Subtask B on the other hand produces more false negatives than positives for all categories except shaming. For this task, it would be favorable if the model was stricter and produced more false positives instead. The classifier performed reasonably well, even without information about the images. Still, some memes, especially in the stereotype and objectification category, cannot be understood to belong in that category without this information. Only about a third of the pictures (379 of 1000) are completely correctly identified when it comes to the four categorization labels, but 731 have at least 3 labels matching. Only 9 samples in the test set were classified in a way that no label matched the gold standard and 67 matched less than 2.

5 Conclusion

In our experiments, we explored and compared different models for multi-modal analysis of misogynistic memes. Surprisingly, ngram-models on both word and character levels did not perform as well as expected for this task. We discovered that ensemble models using text and image information can work well even if the text classifier uses simple features such as tf-idf vectors. BERT based text analysis performs better than the baselines, even if image features are not included. We found that an ensemble model can be improved through gradient boosting and adding information about nudity, age, gender of depicted humans, and text sentiment. In the future, it would be worth exploring how well a similar ensemble model with an (additional) BERT-classifier or other more powerful text classifier performs. For Subtask B, a RoBERTa-based multi-label classification model showed its power with purely text information. It would be interesting to train it with a class of weights and different threshold values. However, we were not able to create a well-performing multi-modal model that uses image information, which might be another interesting direction for further studies.

Abstract

In this manuscript we describe the participation of the UMUTeam on the MAMI shared task proposed at SemEval 2022. This task is concerning the identification of misogynous content from a multi-modal perspective. Our participation is grounded on the combination of different feature sets within the same neural network. Specifically, we combine linguistic features with contextual transformers based on text (BERT) and images (BEiT). Besides, we also evaluate other ensemble learning strategies and the usage of non-contextual pretrained embeddings. Although our results are limited, we outperform all the baselines proposed, achieving position 36 in the binary classification task with a macro F1-score of 0.687, and position 28 in the multi-label task of misogynous categorisation, with an macro F1-score of 0.663.

1 Introduction

This manuscript describes the participation of the UMUTeam in the Multimedia Automatic Misogyny Identification (MAMI) shared task (Fersini et al., 2022), proposed at SemEval 2022. This shared-task consists in the identification and categorisation of misogynous content from a dataset composed of memes (Dawkins and Davis, 2017). A meme is essentially a pictorial content with an overlaying text that pretends to be funny. However, some of these memes are being used as a form of hate against women, with sexist messages in online social networks that amplify misogynous traits such as sexual stereotyping or gender inequality.

MAMI shared task proposes two challenges. A binary classification task, in which each meme should be labelled as misogynous or not misogynous, and a multi-label classification task, to categorise different misogynous traits, namely shaming, stereotype, objectification, and violence.

2 Background information

From the last years, the number of shared tasks in workshops regarding hate-speech and misogyny detection are increasing. To name just but a few, in Italian there is the EVALITA 2018 dataset (Bosco et al., 2018); in Spanish, the AMI 2018 dataset (Fersini et al., 2018) and the EXIST dataset (Rodríguez-Sánchez et al., 2021). In German, the GermEval 2021 (Risch et al., 2021) dataset.

The common approaches for misogyny detection and categorisation consists in the training of an automatic machine learning classifier. For example, the authors of (Anzovino et al., 2018) compiled and labelled a corpus from Twitter focused on misogynous content, and evaluate several feature sets and machine-learning models. In Spanish, a similar approach was conducted in (García-Díaz et al., 2021), in which the authors released the Spanish MisoCorpus 2020. This dataset is organised into three splits: (1) VARW (Violence Against Relevant Women), focused on aggressive messages on Twitter to women who have gained social relevance; (2) SELA (European Spanish vs that of Latin America), focused on distinguish between misogynistic messages from Spain and Latin America; and (3) DDSS (Discredit, Dominance, Sexual harassment and Stereotype), focused on general traits related to misogyny. The Spanish MisoCorpus 2020 is balanced and contains 3841 misogynous documents, annotated by three human annotators.

It is worth noting that our research group evaluated of a set of hand-crafted linguistic and negation features along with Spanish pre-trained contextual and non-contextual embeddings for detecting hate-speech (García-Díaz et al., 2022b). These work included two datasets concerning misogyny and sexist behaviour.

3 Dataset

Table 1 depicts the dataset proposed by MAMI. For the training and validation split, the labels were balanced, with 5000 misogynist memes and 5000 safe memes that were manually annotated using crowd sourcing platforms. Our first experiments consider a balance between both labels. However, during the final evaluation phase we suspect that there was a strong imbalance among the labels. As our first results were limited, we sub sampled the dataset removing some misogynous documents with less than 8 words. We are aware that there are better techniques for handling class imbalance but, due to time constraints, we could not evaluate them.

Split	**Original dataset**	**Subsampled**
training	8000	6709
val	2000	1677
test	1000	1000
total	11000	9386

Table 1: Dataset statistics of the MAMI dataset. We show the original distribution (left) and our sub sampled distribution (right)

Table 2 depicts the label distribution per misogynous trait for the second challenge. It should be noticed that shaming and violence traits are the traits with less instances, hinder their detection.

Split	**(OBJ)**	**(SHA)**	**(STE)**	**(VIO)**
training	1762	1020	2248	763
val	440	254	562	190
total	2202	1274	2810	953

Table 2: Misogynous trait distribution: Objectification (OBJ), Shaming (SHA), Stereotype (STE), and Violence (VIO)

4 Methodology

For solving the challenges proposed in MAMI, we build a system which architecture is depicted in Figure 1. It a nutshell, our system works as follows. First, we select some of the documents of the training MAMI dataset to create a custom validation dataset. Next, we extract a subset of language-independent linguistic features (LF), non-contextual sentence (SE) and word embeddings (WE) from fastText, the contextual word embeddings from BERT (BF), and the image embeddings from BEiT (BI). Second, we train several neural network models by performing an hyperparameter tuning process. The models evaluated included one model per feature set, and models based on several feature sets together. Besides, we evaluate two ensembles based on soft voting (mode) and averaging all the probabilities (mean) of the neural networks trained with each feature set. To handle the multi-label challenge, we repeat this process per trait. That is, we evaluate the problem as a binary classification problem per trait.

Next, some insights of the feature sets involved are given. As the memes are images with overlaying text, this shared-task has a multi-modal perspective. Our proposal uses several feature sets based on texts, and one for the images. First, we use the UMUTextStats tool to obtain a set of relevant psycho-linguistic features (LF). This tool has already been used in studies related to misogyny, such as (García-Díaz et al., 2021, 2022a). The LF included low-level linguistic categories concerning phonetics and syntax's, and high-level features related to semantics and pragmatics, including features proper from figurative language (del Pilar Salas-Zárate et al., 2020). Moreover, these kinds of features have proven to be effective for performing other automatic classification tasks such as irony and satire identification (García-Díaz and Valencia-García, 2022). As some of the dictionaries of UMUTextStats are not translated to English, we select a subset of language-independent linguistic features, based on linguistic metrics, Part-of-Speech features and the usage of social media jargon. Second, we extract sentence and word embeddings using the pre-trained fastText model (Joulin et al., 2016). Third, we use contextual sentence embeddings from BERT (Devlin et al., 2018), which sentence embeddings are obtained in a similar manner as described at S-BERT (Reimers and Gurevych, 2019). Forth, we use visual embeddings from BEiT (Bao et al., 2021), which is a self-supervised model trained with ImageNet-21k with more than 21000 labels. BEiT learns the embeddings images as a sequence of fixed-size elements using relative position. This allows us to perform the classification using a mean-pooling strategy from the final hidden states of the patches instead of placing a linear layer on top of the final classification token. However, the suggested way to fine-tune the model for performing downstream tasks is to attach a new linear layer that uses the last hidden state of the

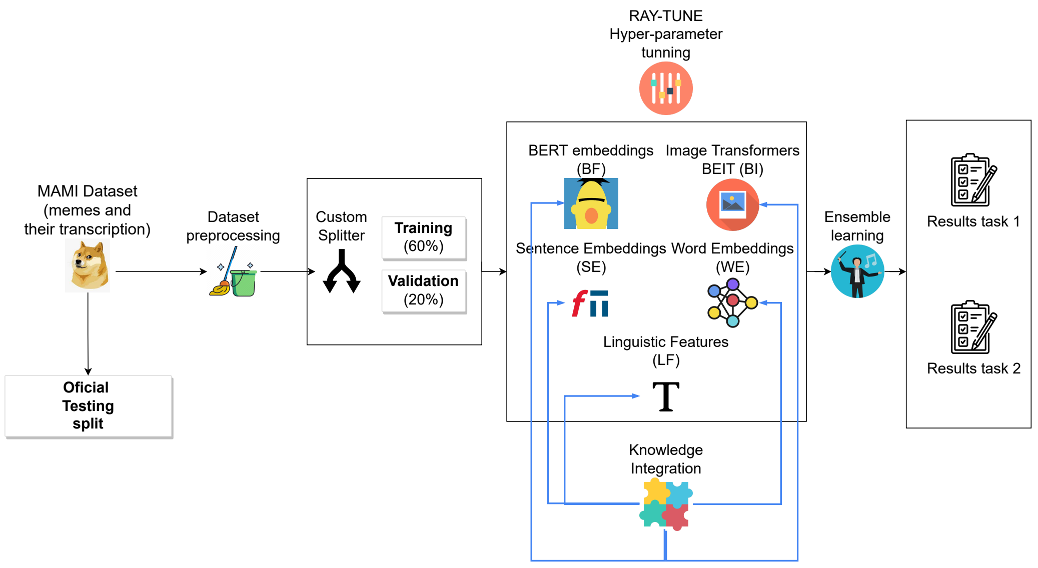

Figure 1: System architecture proposed by the UMUTeam for solving the MAMI shared task

classification token as a representation of the whole image.

To obtain the embeddings from BERT (for text) and BeIT (for images) we conduct an hyperparameter optimisation stage using RayTune (Bergstra et al., 2013) with a Tree of Parzen Estimators (TPE) to select the best combination of the hyperparameters over 10 trials. The hyperparameters evaluated and their interval range are: (1) weight decay (between 0 and .3), (2) training batch size ([8, 16]), (3) warm-up steps ([0, 250, 500, 1000]), (4) number of training epochs ([1-5]), and (5) learning rate (between 1e–5 and 5e–5).

Once all features are obtained, we train a neural network per feature set. The training of each neural network is performed with hyperparameter optimisation. Each training involved: (1) 20 shallow neural networks, that are multi-layer perceptrons (MLP) composed by one or two hidden layers with the same number of neurons per layer connected with one activation function (`linear`, `ReLU`, `sigmoid`, and `tanh`); (2) 5 deep-learning networks, that are MLP between 3 and 8 hidden layers, in which the neurons per layer are disposed for each layer in different shapes, namely brick, triangle, diamond, rhombus, and funnel, and connected with an activation function (`sigmoid`, `tanh`, `SELU` and `ELU`). The learning rate of the deep-learning models is `10e-03` or `10e-04`. Besides, on the neural networks with the pre-trained word embeddings from fastText (WE) we also evaluate 10 convolutional neural networks (CNN) and 10 bidirectional recurrent neural network layers (BiLSTM). In all experiments, we evaluate two batch sizes: `16` and `32`. These small values were selected because the training split was balanced, and a dropout mechanism (`[False, .1, .2, .3]`) for regularisation.

Apart of the neural networks trained with the feature sets separately, we evaluate different forms for combining the strengths of each feature set in the same system. The combination of the feature sets is performed using two strategies: (1) knowledge integration, in which each feature set is used as input of the same neural network. For this, we train another neural network repeating the hyperparameter optimisation stage; and (2) ensemble learning, in which the output of each neural network model trained with a feature set is combined by averaging the predictions or calculating the mode of the predictions.

5 Results and discussion

Each system was evaluated using the custom validation split (see Section 3).

The results for the first challenge are depicted in Table 3. Note that we remove some of the documents with fewer words to sub sample the dataset. For that reason, our validation split contains 677 misogynous and 1000 non-misogynous documents.

As it can be observed in Table 3, the performance of LF in isolation is limited. This fact is not surprising because not all of the features from UMUTextStats are available in English. For the rest of the textual embeddings (SE, WE, and BF), BF obtains the best results, with a macro F1-score of

Feature set	MIS	N-MIS	F1
LF	58.956	75.771	67.363
SE	73.286	80.860	77.073
WE	76.614	83.367	79.991
BF	79.690	87.306	83.498
BI	65.744	81.984	73.864
LF,BF,BI	**80.277**	**87.549**	**83.913**
LF,BF,BI (mode)	75.874	86.524	81.199
LF,BF,BI (mean)	76.853	85.183	81.018

Table 3: Results for the Task A with the custom validation split, reporting the F1-score of the misogynous (MIS) and non-documents (N-MIS) and the macro F1-score (F1).

83.498, outperforming the non-contextual sentence and word embeddings from fastText (SE and WE). Due of this, we decided to discard non-contextual embeddings and use BERT for the knowledge integration strategy. The combination of LF, BF, and BI in the same neural network outperformed the results achieved by BF, increasing slightly the F1-score of both labels and the macro f1-score. However, the ensemble learning strategy achieved lower results for the F1-score of the misogynous label, regardless of the strategy employed for combining the predictions.

For the second challenge, the results with the custom validation split are depicted in Table 4. We report the F1-score of each binary model that we train for each misogynous trait. Similar to the first challenge, the results achieved by LF are limited, achieving results below 60% in all the traits. Concerning non-contextual embeddings, the results with WE are superior to SE for all traits, but inferior compared to BF. In case of BI, it draws our attention the high macro F1-score achieved in objectification and shaming, outperforming BF. However, their results are inferior to BF for stereotype and violence. When LF is combined with BF and BI embeddings within the same neural network, the results are superior to the ones achieved separately, except in shaming. However, the results achieved with the ensemble learning strategy are quite limited, specially with the mean strategy. The result obtained with the violence trait is especially striking. We observe that the resulting model achieved a perfect recall over the violence class, which suggests that this model is always predicting all tweets as violence.

Table 5 depicts the official results for the first challenge. We achieve position 36/83 with a macro F1-score of 68.7. As it can be observed, our submission outperforms all the proposed baselines that consisted in: (1) sentence embeddings from the USE pre-trained model; (2) image features from VGG-16; (3) a combination of deep image and text representations based a shallow neural network with a single layer. In addition, two baselines focused on the second challenge were also evaluated: (4) a multi-label model, based on the concatenation of deep image and text representations, for predicting simultaneously if a meme is misogynous and the corresponding type; and (5) a hierarchical multi-label model, based on text representations, for predicting if a meme is misogynous or not and, if misogynous, the corresponding type.

The best result for the first challenge is achieved by the *SRCB_roc* team, with an F1-score of 83.4. It is worth mentioning that, although there was a restriction of the number of accounts available in Codalab per team and user, the organisers of the task are not able to control it. Nevertheless, in the official leader board the second best result was also achieved by the team *SRCB_roc*, with an F1-score of 81.1. However, as the team name is the same, we have removed this result from the table. Therefore, for the official results we ask to the reader to check the official results published in the overview of the task.

For this first challenge we send different runs and modify our strategy according to the results. We also send some basic results to obtain some baselines. For example, we achieved an macro F1-score of 52.85 with LF. This result is more limited than the ones achieved in the validation split. With non contextual embeddings, SE and WE, the results are, respectively, 61.30 and 61.96 (vs 77.073 and 79.99 with the validation split), and 64.75 for BF. Because of these results, we suspect that there are relevant different between the training and testing splits. Then, we examined carefully the testing split but we could not find relevant differences so we suspect to imbalanced as an possible explanation of this problem. To confirm this, we send a toy submission with a baseline consisting in all the predictions as non-misogyny and we observed a ratio similar to 1:3 between misogynous and non-misogynous instances. Then, we reduced the training dataset and retrained all models in order to make them stronger against class imbalance (see Section 3). It is worth noting that our methods

Feature set	Objectification	Shaming	Stereotype	Violence
LF	59.449	57.858	57.733	59.052
SE	66.983	66.479	70.923	66.730

Table 6: Official results for the Task B

already consider some good practises concerning class imbalance, such as setting the initial bias, adding class weights to the model, heavily weight the few examples that are available

Finally, the official results for the second challange are depicted in Table 6. It can be observed that our best result achieved a 66.3 of F1-score, outperforming the two baselines proposed: (1) a hierarchical multi-label model (baseline 1), based on text representations, and (2) a multi-label model (baseline 2), based on the concatenation of deep image and text representations, for predicting the corresponding misogynous type.

The best result was a F1-score of 73.1, with a triple tier between teams *SRCB_roc*, *TIBVA*, and *PAFC*. Our best proposal, however, achieved position 28 in the official leader board, outperforming all baselines.

6 Conclusions

In this paper the participation of the UMUTeam in the MAMI shared task, concerning the identification and categorisation of misogynous content in memes, is described. Our approach for solving the binary and multi-label classification tasks consisted in the combination of a set of language-independent linguistic features with contextual images and textual features obtained from the documents. Our best result was achieved in the misogynous categorisation task, with an macro F1-score of 66.3, reaching position 28 in the ranking.

We consider that the weakest point of our proposal is that we have not handle class imbalance in the testing dataset. However, we have evaluated some strategies that have improve our results, as reducing the number of instances and the application of class weight. As further work, we will evaluate data augmentation techniques, both for images and for text in order to deal class imbalance.

Abstract

This paper describes our system used in the SemEval-2022 Task5 Multimedia Automatic Misogyny Identification (MAMI). This task is to use the provided text-image pairs to classify emotions. In this paper, We propose a multi-label emotion classification model based on pre-trained LXMERT. We use Faster-RCNN to extract visual representation and utilize LXMERT's cross-attention for multi-modal alignment. Then we use the Bilinear-interaction layer to fuse these features. Our experimental results surpass the F_1 score of baseline. For Sub-task A, our F_1 score is 0.662 and Sub-task B's F_1 score is 0.633. The code of this study is available on GitHub[1].

1 Introduction

In social networks, meme is mainly used to express the emotion of netizen. It usually consists of text and images. But at the same time, memes also convey some negative emotions, such as negative comments about women. SemEval-2022 Task5: Multimedia Automatic Misogyny Identification (MAMI) (Fersini et al., 2022) focuses on identifying whether meme conveys negative emotions towards women.

- Sub-task A: a basic task about misogynous meme identification, where a meme should be categorized either as misogynous or not misogynous;
- Sub-task B: an advanced task, where the type of misogyny should be recognized among potential overlapping categories such as stereotype, shaming, objectification, and violence.

Since the Transformer (Vaswani et al., 2017) and BERT (Devlin et al., 2019) models were proposed, researchers have begun to work on image and text multi-modality work in recent years, in addition to using one modality such as only image or text. Nowadays, for multimodal models, they can be divided into two categories, single-stream model and dual-stream model. In the single-stream model, language information and vision information are fused at the beginning and directly input into the encoder. Some representative single-stream models include ImageBERT (Qi et al., 2020), Unicoder VL (Li et al., 2020), VL-BERT (Su et al., 2020), VisualBERT (Li et al., 2019), etc. In the dual-stream model, in addition to the LXMERT, we will introduce below, there were ViLBert (Lu et al., 2019) and UNIMO (Li et al., 2021), etc.

As for emotion recognition, in previous tasks, there are also emotion classification tasks based on multi-modal graphics and text, such as Zhu et al. (2021) used text-CNN and ALBERT to Identify the persuasion skills of Meme. Peng et al. (2020) used the adversarial learning of sentiment word representations for sentiment analysis. A tree-structured regional CNN-LSTM (Wang et al., 2020) and dynamic routing in a tree-structured LSTM (Wang et al., 2019) were used for dimensional sentiment analysis. In previous SemEval competitions, Tian et al. (2021) extracted heterogeneous visual representations (i.e., face features, OCR features, and multimodal representations) and explored various multimodal fusion strategies to combine the textual and visual representations. In addition, in multimodal analysis combining images and text, Yuan et al. (2020) proposed a parallel channel ensemble model combining BERT embedding, BiLSTM, attention and CNN, and ResNet for sentiment analysis of memes.

The main difficulty of multi-modality is how to extract the two modalities' features and express the semantics more accurately, which involves the representation of multi-modality, the alignment between multi-modality, and the fusion of multi-

[1] `https://github.com/HC-super/SemEval-2022-Task-5`

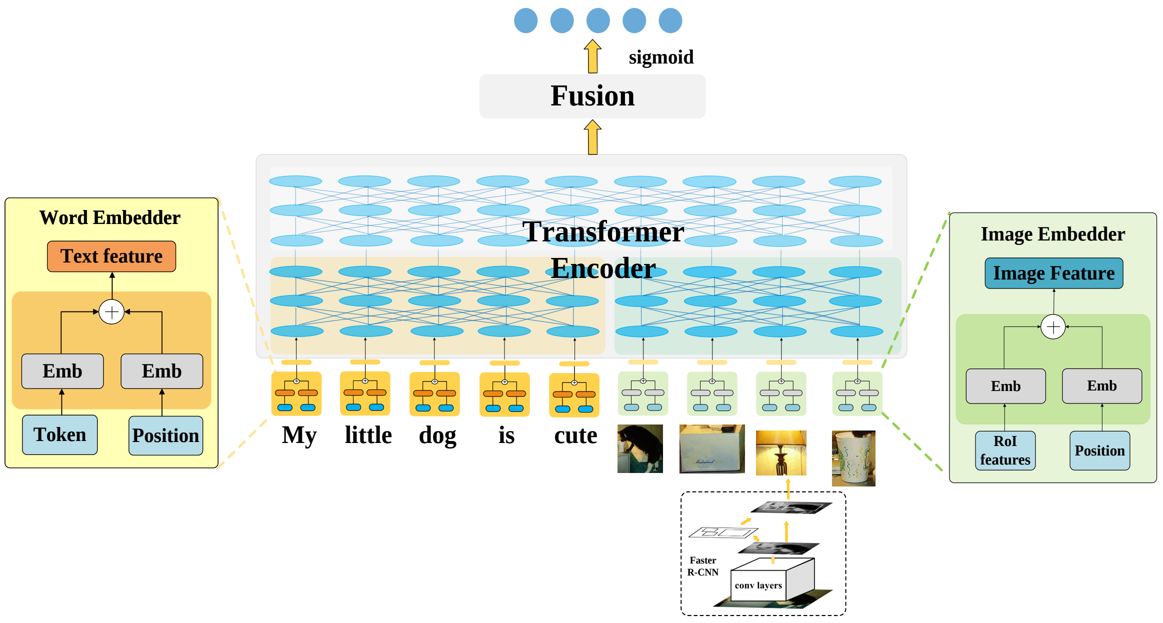

Figure 1: Overview of the proposed model specifically shows the general structure of Faster R-CNN and the details of the embedders.

modality. For the multi-modal task of text and image, the previous practice is to input the text and image into two different pre-training models for processing the text and image modalities respectively, and then concatenate the output features and predict the emotion. However, this method lacks the processing of the alignment relationship between modalities. The proposed model considers the above three problems in the multi-modality field. Inspired by LXMERT, we use it as the main framework of our model. We use Faster R-CNN (Ren et al., 2017) to extract image RoI features and their position. For texts, we use BERT to extract text embedding. Then our system uses LXMERT (Tan and Bansal, 2019) to deal with the multi-modal alignment of text and image. After when two modalities are processed by LXMERT, we use the learnable integration mechanism Bilinear-interaction layer to fuse these features.

The remainder of this paper is organized as follows. In section 2, we described LXMERT and our fusion method in detail. The experimental results are presented in section 3. Finally, a conclusion is drawn in section 4.

2 System Overview

Task A and Task B are very similar in model structure except for the output layer. Therefore, we introduce the model we proposed as a whole. This model can be divided into four parts. They are the embedding layer for image and text preprocessing, the encoder for multi-modal presentation and alignment, the feature fusion layer, and the final output layer. The proposed model is as shown in Figure 2.

2.1 Embedding

For images, LXMERT does not simply use a convolutional neural network to output feature map but uses (Anderson et al., 2018) to extract objects from images. The image processing of LXMERT is similar to text processing inspired by BERT. The specific idea is to use Faster R-CNN to select 36 RoI (region of interest) boxes with high confidence for each image and use these boxes as the features of the image. Similar to the text processing of BERT, the model also considers the position of each box and embeds the corresponding position. 36 objects are extracted by Faster R-CNN as $\{o_1, \ldots, o_{36}\}$. f_j is the 2048 dimension RoI features of o_j, and p_j is its position. As is shown in figure 2, the processing of these variables is as follows:

$$\begin{aligned} \hat{f}_j &= \text{LayerNorm}\left(W_{\text{F}} f_j + b_{\text{F}}\right) \\ \hat{p}_j &= \text{LayerNorm}\left(W_{\text{P}} p_j + b_{\text{P}}\right) \\ v_j &= \left(\hat{f}_j + \hat{p}_j\right)/2 \end{aligned} \tag{1}$$

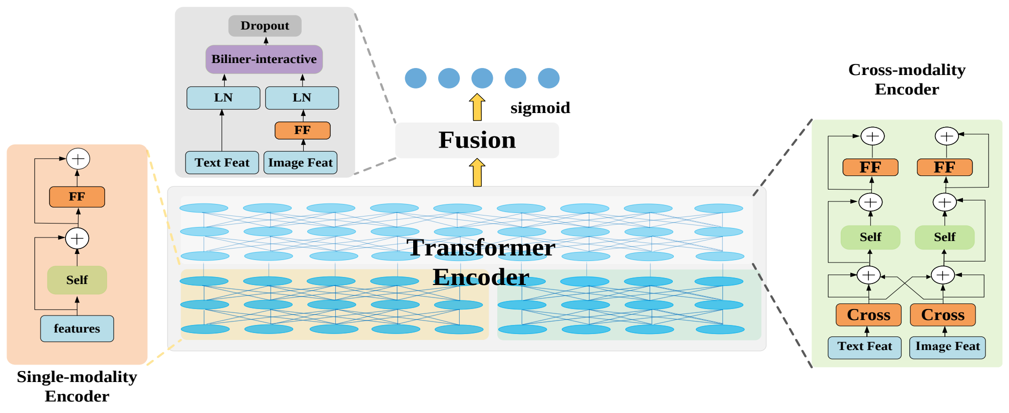

Figure 2: Overview of the proposed model, which specifically shows the details of the encoders and fusion layer. 'Self' and 'Cross' represent self-attention sub-layers and cross-attention sub-layers, respectively. 'FF' denotes a feed-forward sub-layer.

where W_F and W_P are the trainable weights of fully connected layer in matrix format. Moreover, b_F and b_P are the bias of the layer. $\hat{f}_j$ and $\hat{p}_j$ are the output of the layer-normalization.

For the text, sentences are converted into tokens whose length is equal to the length of scent according to the practice of WordPiece tokenizer (Wu et al., 2016). For instance, when the length of the sentence is n, the word tokens are $\{w_1, ..., w_n\}$. Then word w_i and its index i (the absolute position of w_i) are projected to vectors by embedding sub-layers.The specific structure of embedder is shown in Figure 1. Then added to the index-aware word embedding:

$$\begin{aligned} \hat{w}_i &= \text{WordEmbed } (w_i) \\ \hat{u}_i &= \text{IdxEmbed } (i) \\ h_i &= \text{LayerNorm } (\hat{w}_i + \hat{u}_i) \end{aligned} \tag{2}$$

The specific structure of embedder is shown in Figure 1.

2.2 Attention layer

In this subsection, we will give a brief description of the attention mechanism. The principle of the attention mechanism is to give a request vector x and its context vector y_j, then, calculate the correlation between x and each y_j, and get a correlation score. The correlation score used in LXMERT is the dot product of vector x and vector y_j. After calculating the scores of all relevant context vectors y_j for x, LXMERT uses softmax to convert each score into a probability α_j to obtain the attention distribution.

$$\begin{aligned} a_j &= \text{score}\,(x, y_j) \\ \alpha_j &= \exp\,(a_j) \,/ \sum_k \exp\,(a_k) \end{aligned} \tag{3}$$

$$\text{Att}_{\text{X}\rightarrow\text{Y}}\,(x, \{y_j\}) = \sum_j \alpha_j y_j \tag{4}$$

The output of the layer is the weighted sum of all probabilities with y_i.

The self-attention layer in LXMERT is implemented in a similar way to the attention layer, except that the query vector x in self-attention comes from the context-dependent vector y_i.

2.3 Encoder

The processing of image modality and text modality is shown in Figure 2. After embedding two modalities, LXMERT uses the two transformer single-modality encoders. One is a text encoder and another is an image encoder. Each layer in a single-modality encoder contains a self-attention ('Self') sub-layer and a feed-forward ('FF') sub-layer, where the feed-forward sub-layer is further composed of two fully-connected sub-layers. We take N_L and N_R layers in the language encoder and the object-relationship encoder, respectively. We add a residual connection and layer normalization (annotated by the '+' sign in Figure 2) after each sub-layer as in Transformer (Vaswani et al., 2017). The features processed by a single-modality encoder will be first sent to another encoder called the cross-modality layer. Its main function is to align the features of the two modalities. The bi-directional cross-attention sublayer

Emotion category	Number of label '1'	Overall proportion
misogynous	5000	50.00%
shaming	1274	12.74%
stereotype	2810	28.10%
objectification	2202	22.02%
violence	953	9.53%

Table 1: Training dataset label analysis.

contains two unidirectional cross-attention sub-layers, one from image to text and the other from text to the image. LXMERT stacks them N_x times, the input of k-th layer is the output of the previous$(k-1)$-th layer. Similarly, the query and context vectors are the outputs of the $(k-1)$-th layer. The method of processing the text features h_i^{k-1} and the image features v_j^{k-1} in unidirectional cross-attention sub-layers is as follows:

$$\begin{aligned}\hat{h}_i^k &= \text{Cross } Att_{\text{L}\rightarrow\text{R}}\left(h_i^{k-1}, \left\{v_1^{k-1}, \ldots, v_m^{k-1}\right\}\right)\\ \hat{v}_j^k &= \text{Cross } Att_{\text{R}\rightarrow\text{L}}\left(v_j^{k-1}, \left\{h_1^{k-1}, \ldots, h_n^{k-1}\right\}\right)\end{aligned} \quad (5)$$

where $\hat{h}_i^k$ and $\hat{v}_j^k$ are the output of the cross-attenton layer.

Then LXMERT further inputs the features processed by the cross-modality sublayer to the self-attention sublayer. This method aimed to further construct the internal connection of each modality after alignment. The specific treatment is:

$$\begin{aligned}\tilde{h}_i^k &= \text{Self } Att_{\text{L}\rightarrow\text{L}}\left(\hat{h}_i^k, \left\{\hat{h}_1^k, \ldots, \hat{h}_n^k\right\}\right)\\ \tilde{v}_j^k &= \text{Self } Att_{\text{R}\rightarrow\text{R}}\left(\hat{v}_j^k, \left\{\hat{v}_1^k, \ldots, \hat{v}_m^k\right\}\right)\end{aligned} \quad (6)$$

$\hat{h}_i^k$, $\hat{v}_j^k$ then processed by self-attention to $\tilde{h}_i^k$ and $\tilde{v}_j^k$, which will be further input to an 'FF' sublayer, connected through a residual, and input to the normalization to obtain the final output h_i^k, v_j^k. For each text in the data, the model will generate a Pooler output. We use the Pooler of each sentence as the output of the text modality.

2.4 Fusion

The method of this layer is inspired by Sina's paper FiBiNET by Huang et al. (2019). After LXMERT outputs two modality features, we need to further process its output. The dimension of image features is 36×768, while the dimension of text features is 768. To better integrate the two modalities, we flatten the image features and change its dimension to 768 through a feed-forward layer. Then, each modality will be normalized through layer normalization. Then, the features of each modality are sent to the Bilinear-interactive layer.

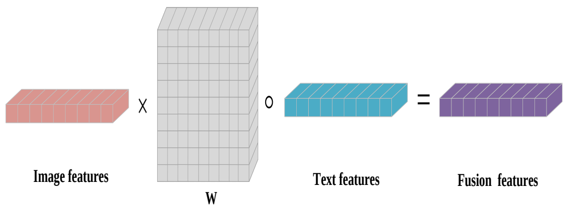

Figure 3: Bilinear-interactive layer.

The idea of the Bilinear-interactive layer is as shown in Figure 3. We establish a k-order square matrix W, which is trainable. To fuse the information of various modalities, 768-dimensional image features will first inner product with W. Then, for text features, we use Hadamard product to multiply the previous matrix. We finally use the dropout layer to improve the generalization ability of the model.

2.5 Output layer

- Sub-task A: this task is a binary classification task, so in the output layer, we use a shape of 768×1 full connection layer and use sigmoid as the activation function to process the results.

- Sub-task B: this task is a multi-label classification task. Therefore, in the output layer, we use a full connection layer whose shape is 768×5. Since each label classification is equivalent to binary classification, we use sigmoid as the activation function to process the results during output.

3 Experiments and Evaluation

3.1 Dataset

The task organizer provided 10000 pieces of data for training, including meme images with image serial numbers and text descriptions corresponding to the image. In the training dataset, there are 10000 images and an excel table to record the text corresponding to the images and supervise the learning of the corresponding labels.

When analyzing the data, we found that different labels account for different proportions in the number of their respective classifications. For the misogynous tag, both 0 and 1 categories account for 50%, so the data sample tag is more balanced for a supervision task. However, for the other four labels such as sharing, the proportion of label 1 is only 12.74%. Among 10000 samples, the label of violence accounts for only 9.53%. Table 1 shows the proportion of each label in the training dataset. As shown in Table 1, we find that the proportion of labels of different categories is very different, and there is data imbalance. This will make the model have a strong learning effect on a large classification label and easy to classify. However, for the low proportion of classification tags, it is difficult to learn and classify.

Based on this, we use Focal loss by (He et al., 2016) as the loss function of our model.

3.2 Experimental configuration

Our model is based on TensorFlow platform version 2.5.0. The main model adopts LXMERT from the Hugging Face transformers toolkit. We first use*UNC-NLP/LXMERT-base-uncased* tokenizer-Fast to process our text to embeddings, and we also use *UNC-NLP/LXMERT-base-uncased* pre-trained model as our base model LXMERT's pre-trained model. The Adam optimizer (Kingma and Ba, 2015) was used to update all trainable parameters. The Hyper-parameters configuration used in the model is shown in Table 2: We use Faster R-CNN to extract features of images, which is based on the paper by (Anderson et al., 2018). In this task, we use an open-source docker image *airsplay / bottom-up attention* and use a Faster R-CNN pre-training model based on ResNet101 to extract 36 RoI feature boxes and their corresponding position.

3.3 Evaluation Metrics

Sub-task A Systems will be evaluated using macro-average F1-score. In particular, for each class label (i.e. misogynous and not misogynous) the corresponding F1-score will be computed, and the final score will be estimated as the arithmetic mean of the two F1-score. Sub-task B Systems will be evaluated using weighted-average F1-score. In particular, the F1-score will be computed for each label and then their average will be weighted by support, i.e, the number of true instances for each label.

Adam Optimizer config	**Value**
Learning rate	5e-5
epsilon	1e-8
Focal loss config	**Value**
alpha	0.25
gamma	3
batch size	16
epoch	20

Table 2: Hyper-parameters config.

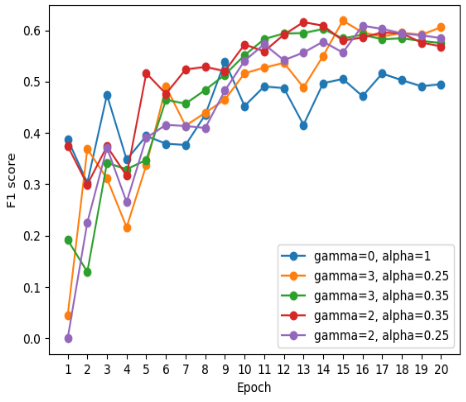

Figure 4: The ablation experiment of the Focal loss for different hyperparameter

$$\begin{aligned} \text{precision} &= \frac{TP}{TP+FP} \\ \text{recall} &= \frac{TP}{TP+FN} \end{aligned} \tag{7}$$

TP is the number of true positives classified by the model. FN is the number of false negatives classified by the model. FP is the number of false positives classified by the model.

$$\text{F}_1\text{-score} = \frac{2 \times \text{ precision } \times \text{ recall}}{\text{precision } + \text{ recall}} \tag{8}$$

F_1-score is the harmonic average of recall and precision.

3.4 Hyperparametric selection

In this section, we mainly introduce the hyperparametric selection of focal loss of the model. We adjust the two hyperparameters γ and α of Focal loss and train the model. In the training dataset, we randomly take 90 % data for the training model and the remaining 10 % as the test dataset to test

Model	Task A F1-score	Task B F1-score
Only image(Base line)	0.639	N/A
Only text(Base line)	0.640	N/A
Only ELECTRA	N/A	0.5454
Only ResNet	N/A	0.4581
ELECRTA and ResNet with concatenate	N/A	0.4816
ELECRTA and and ResNet with Fusion	N/A	0.5041
Image and Text(Base line)	0.650	0.621
LXMERT without Fusion	0.655	0.629
LXMERT with Fusion	**0.662**	**0.633**

Table 3: Performance comparison of different models. As shown in the table, our proposed model achieves the best results.

the performance of the model. The loss function focal loss is modified based on the standard cross-entropy loss.

This function can reduce the easy-to-classify samples so that the model can more focus on the samples that are difficult to classify in training. p_t in cross-entropy loss function reflects the recognition ability of the model to this sample (i.e. how well the knowledge is mastered). We define p_t is:

$$p_{\mathrm{t}} = \begin{cases} p & \text{if } y = 1 \\ 1 - p & \text{otherwise} \end{cases} \tag{9}$$

The smaller the p_t is, the more difficult it is to classify, so contribution should be improved to the loss function when calculating the loss. Therefore, the specific method of Focal loss is to multiply a weight with p_t before the entropy loss function. α is balancing factor,$\alpha \in [0,1]$, γ is modulating factor, $\gamma \in [0,5]$. The Focal loss is as:

$$Focal\_loss(p_t) = -\alpha(1-p_t)^{\gamma} log(pt) \tag{10}$$

Thus, when $\alpha = 1$, $gamma = 0$, focal loss is similar to the cross-entropy loss function. By changing the values of γ and α, we found that when $\alpha = 0.25$ and $\gamma = 3$, for sub-task B, the weighted F_1 score of our model reached 0.662 and 0.633. See Figure 4.

3.5 Model comparison

We compare our model to a baseline and a model that combines two pre-trained models based on ELECTRA (Clark et al., 2020) and ResNet-101 (Ren et al., 2017) in this section. ELECTRA deals with text modality and ResNet is used to deal with image modality. The methods of feature fusion are compared with the Bilinear-interactive layer and concatenate layer using direct concatenate. The specific task is based on sub-task B. See Table 3 for details.

4 Conclusion

In this task, we design an image and text multi-modality model based on LXMERT for multi-modality representation and alignment, and modality fusion based on the Bilinear-interaction layer. Compared with the traditional method of stitching two pre-training models for each modality then concatenating two features to predict emotion, this model considers the representation, alignment, and fusion of multi-modality, and achieves better results than the baseline method.

At the same time, we found that after adding the Bilinear-interaction layer, the performance of the model is better than using only feature concatenate. See Table 3. Meanwhile, when analyzing the data, we found that the background of the meme graph and some characters in the graph were not used as the target input model by Faster R-CNN, which may affect the accuracy of the model. Meanwhile, the size of the meme image is too small to include multiple targets, and the target is relatively single, which may affect the performance of the model.

Abstract

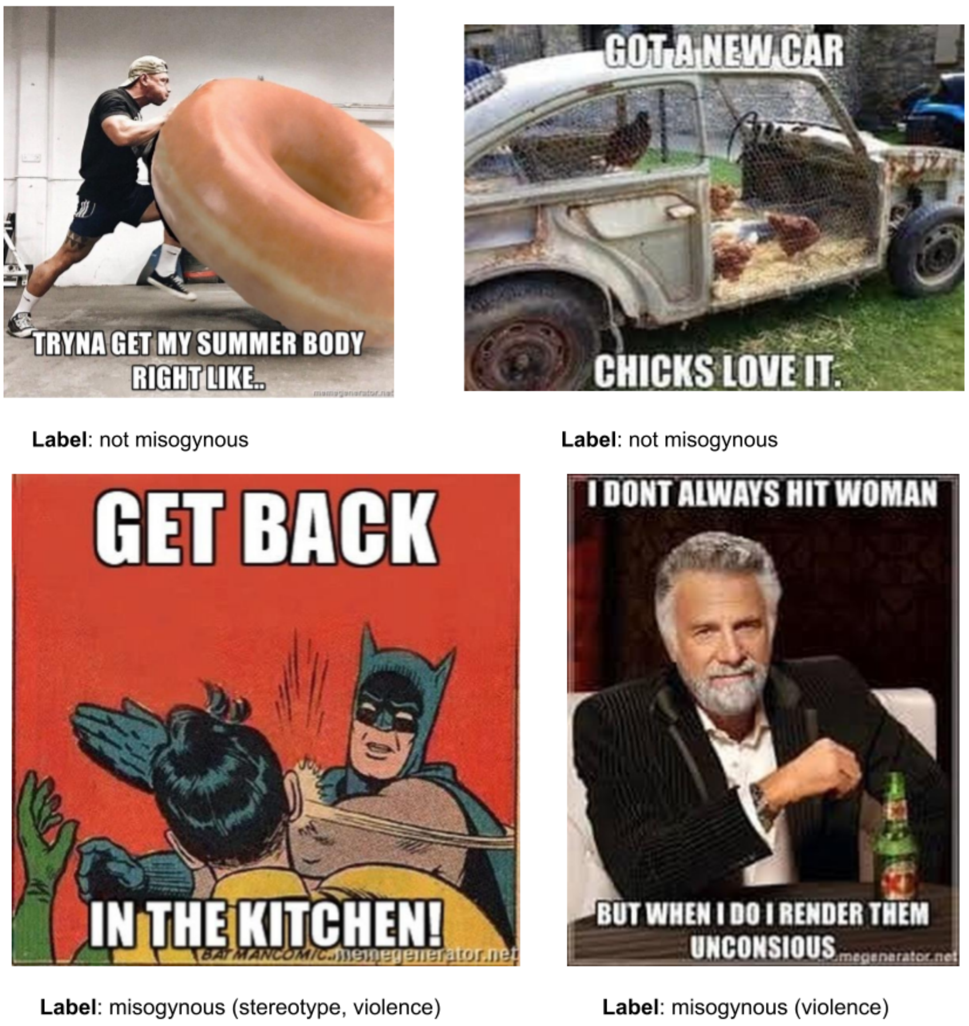
The detection of offensive, hateful content on social media is a challenging problem that affects many online users on a daily basis. Hateful content is often used to target a group of people based on ethnicity, gender, religion and other factors. The hate or contempt toward women has been increasing on social platforms. Misogynous content detection is especially challenging when textual and visual modalities are combined to form a single context, e.g., an overlay text embedded on top of an image, also known as *meme*. In this paper, we present a multimodal architecture that combines textual and visual features to detect misogynous memes. The proposed architecture is evaluated in the *SemEval-2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification* challenge under the team name *TIB-VA*. We obtained the best result in the *Task-B* where the challenge is to classify whether a given document is misogynous and further identify the following sub-classes: *shaming*, *stereotype*, *objectification*, and *violence*.

1 Introduction

Detection of hate speech has become a fundamental problem for many social media platforms such as Twitter, Facebook, and Instagram. There have been many efforts by the research community and companies to identify the applicability of advanced solutions. In general, hate speech is defined as *a hateful language targeted at a group or individuals based on specific characteristics such as religion, ethnicity, origin, sexual orientation, gender, physical appearance, disability or disease*. The hatred or contempt expressed towards women has been drastically increasing, as reported by Plan International (2020) and Vogels (2021). Detection of such misogynous content requires large-scale automatic solutions (Gasparini et al., 2018; Suryawanshi et al., 2020; Menini et al., 2020) and comprehensive annotation processes (Zeinert et al., 2021).

The detection of hateful content has been mainly studied from the textual perspective based on the Computational Linguistics and Natural Language Processing (NLP) fields. However, hateful content on social media can be found in other forms, such as videos, a combination of text and images, or emoticons. Misogynous content detection is especially challenging when textual and visual modalities are combined in a single context, e.g., an overlay text embedded on top of an image, also known as *meme*. Recent efforts in multimodal representation learning (Lu et al., 2019; Radford et al., 2021) pushed the boundaries of solving such problems by combining visual and textual representations of the given content. Several datasets have been proposed using multimodal data (Gomez et al., 2020; Kiela et al., 2020b; Sharma et al., 2020; Pramanick et al., 2021; Suryawanshi et al., 2020; Menini et al., 2020) for various tasks related to hate speech. Each dataset includes an image and corresponding text, which is either an overlay text embedded on an image or a separate accompanying text such as tweet text. In contrast to existing datasets based on memes (Kiela et al., 2020b; Sharma et al., 2020; Pramanick et al., 2021; Suryawanshi et al., 2020), the addressed task in this paper aims to identify misogyny in memes specifically. Among the previously mentioned work, only the dataset from Menini et al. (2020) is intended for misogyny detection, in which the text is in the Italian language. In terms of dataset size, the dataset by Gomez et al. (2020) contains approximately 150,000 image-text pairs, while other datasets have moderate sizes that range between two and ten thousand image-text pairs. Moreover, existing model architectures that are evaluated on such benchmark datasets use a combination of various textual and visual features extracted from pre-trained visual and textual models (Kiela et al., 2020a).

The *SemEval-2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification* (Fersini et al.,



TRYNA GET MY SUMMER BODY RIGHT LIKE..
GOT A NEW CAR
CHICKS LOVE IT.
Label: not misogynous
Label: not misogynous
GET BACK
IN THE KITCHEN!
I DONT ALWAYS HIT WOMAN
BUT WHEN I DO I RENDER THEM UNCONSIOUS
Label: misogynous (stereotype, violence)
Label: misogynous (violence)

Figure 1: Four data samples from *MAMI - Multimedia Automatic Misogyny Identification* with their corresponding class labels. Misogynous samples have additional sub-classes from *stereotype*, *shaming*, *objectification*, and *violence*.

2022)[1] is a new challenge dataset that focuses on identifying misogynous memes. The memes in this dataset are composed of an image with an overlay text. Some samples with their corresponding class labels are shown in Figure 1. The dataset includes two sub-tasks as described below.

- Task-A: a basic task about misogynous meme identification, where a meme should be categorized either as misogynous or not misogynous
- Task-B: an advanced task, where the type of misogyny should be recognized among potential overlapping categories such as stereotype, shaming, objectification and violence.

[1]https://competitions.codalab.org/competitions/34175

In this paper, we present our model architecture for which we submitted results under the team name *TIB-VA*. The model architecture is based on a neural model that uses pre-trained multimodal features to encode visual and textual content and combines them with an LSTM (Long-short Term Memory) layer. Our proposed solution obtained the best result (together with two other teams) on the *Task-B*.

The remainder of the paper is structured as follows. In Section 2, we describe the proposed model architecture. In Section 3, the experimental setup, dataset details, as well as evaluations of the model architecture are described in detail. Finally, Section 4 concludes the paper and outlines areas for future work.

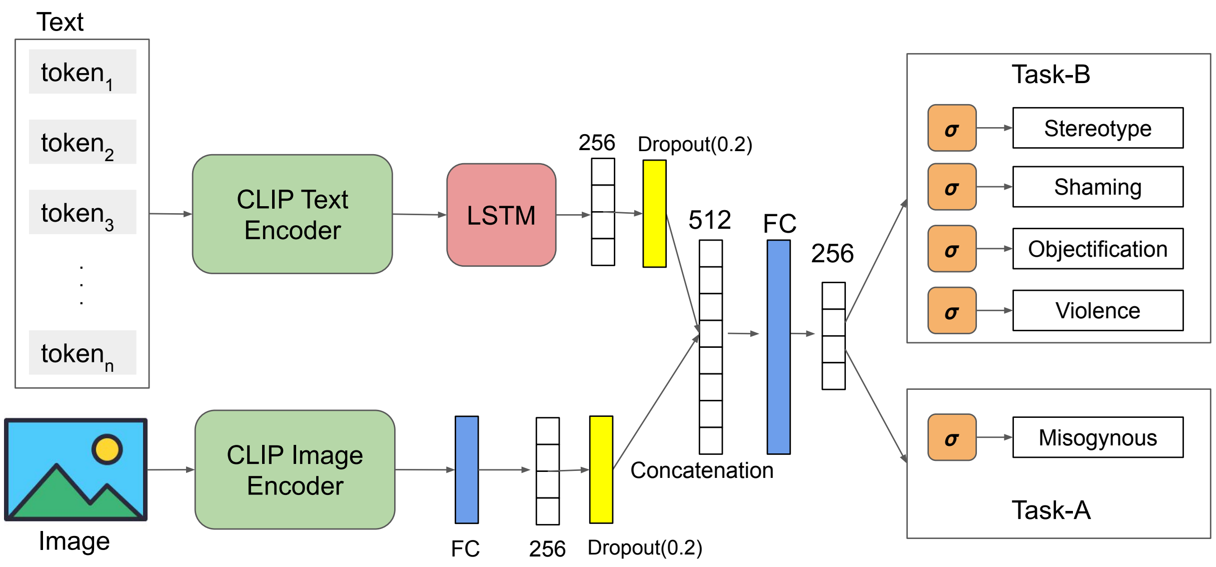


Figure 2: The model architecture that combines textual and visual features to output probabilities for Task-A (misogynous) and Task-B (stereotype, shaming, objectification, violence). FC: Fully connected layer, σ: sigmoid function.

2 Multimodal Architecture

Our model architecture is a neural model that uses a CLIP (Radford et al., 2021) model to extract textual and visual feature representations, which is pre-trained on over 400 million image-text pairs. The goal is to investigate whether this model is applicable to identify misogynous content in memes where both visual and textual content are considered. We used recently available *ViT-L/14* variant of CLIP. The tokens in the overlay text and the image are fed into *CLIP Text Encoder* and *CLIP Image Encoder* respectively. The text encoder outputs a sequence of 768-dimensional vectors for each input token. These token vectors are then fed into an LSTM layer with a size of 256. This layer is another essential part of the proposed architecture. It learns the contextual relatedness among tokens in the text by combining all token representations extracted from the CLIP text encoder branch. The output from the image encoder is fed into a fully-connected layer with a size of 256. The output from an LSTM layer for text and output from the fully-connected layer for the image are fed into separate dropout layers (dropout rate of 0.2), the outputs are concatenated, and then fed into another fully connected layer with a size of 256. The final vector representation is then fed into separate sigmoid functions for each task. For Task-A, the sigmoid outputs a single value that indicates the probability of misogyny. For Task-B, each sub-class of misogyny (stereotype, shaming, violence, objectification) has a separate sigmoid function that outputs a probability value for the corresponding class. The model architecture is shown in Figure 2. The source code of the described model is shared publicly with the community[2].

3 Experimental Setup and Results

3.1 Dataset

The *SemEval-2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification* (Fersini et al., 2022) aims at identifying misogynous memes by taking into account both textual and visual content. Samples from the dataset are given in Figure 1. The dataset includes the overlay text extracted from an image. The challenge is composed of two sub-tasks. Task-A is about predicting whether a given meme is misogynous or not. Task-B requires models to identify sub-classes of misogyny (stereotype, shaming, violence, objectification) in cases where a given meme is misogynous. The samples in Task-B can have multiple labels where a meme can have a single or all of the above sub-classes of misogyny. The train and test splits have 10 000 and 1000 samples, respectively. The distribution of samples for the corresponding two sub-tasks is given in Table 1.

[2]`https://github.com/TIBHannover/multimodal-misogyny-detection-mami-2022`

Splits	Task-A		Task-B				Total
	Misogynous	NOT	Shaming	Objectification	Violence	Stereotype	
Train	5000	5000	1274	2202	953	2810	10 000
Test	500	500	146	348	153	350	1000

Table 1: Distribution of samples in Task-A and Task-B for train and test splits in the *MAMI - Multimedia Automatic Misogyny Identification* dataset.

3.2 Experimental Setup

Training Process: The model architecture is trained using Adam optimizer (Kingma and Ba, 2015) with a learning rate of *1e-4*, a batch size of *64* for maximum of *20* epochs. We decrease the learning by half after every five epochs. We use 10% of the training split for validation to find the optimal hyper-parameters.

Implementation: The model architecture is implemented in Python using the PyTorch library.

Team	Task-A	Task-B
Ours (TIB-VA)	0.734	**0.731**
SRC-B	**0.834**	**0.731**
PAFC	0.755	**0.731**
DD-TIG	0.794	0.728
NLPros	0.771	0.720
R2D2	0.757	0.690

Table 2: Experimental results for the selected top-performing teams on the *MAMI* dataset. The results on Task-A and Task-B are Macro-F1 and Weighted F1 measures, respectively.

3.3 Results

The official evaluation results[3] for the top-performing teams are presented in Table 2. The results on Task-A and Task-B are macro-averaged F1 and weighted-average F1 measures, respectively. Our model architecture (team *TIB-VA*) achieves the best result (0.731) on Task-B along with other two teams: *SRC-B* and *PAFC*. The *SRC-B* team has the highest performance on Task-A. Our results on Task-A are ten points below the best result from the team *SRC-B*. Despite this gap in Task-A, our result is still among the top 20 percentile of all submitted results.

4 Conclusion

In this paper, we have presented a multimodal model architecture that uses image and text features to detect misogynous memes. The proposed solution is built on the pre-trained CLIP model to extract features for encoding textual and visual content. While the presented solution does not yield top results on Task-A, it achieves the best performance in Task-B for identifying sub-classes of misogyny such as stereotype, shaming, objectification, and violence. In future work, we will explore the combination of multiple multimodal features that measure different aspects of visual content such as violence, nudity or specific objects and scene-specific content.

Abstract

This paper describes the multimodal deep learning system proposed for SemEval 2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification. We participated in both Subtasks, i.e. Subtask A: Misogynous meme identification, and Subtask B: Identifying type of misogyny among potential overlapping categories (stereotype, shaming, objectification, violence). The proposed architecture uses pre-trained models as feature extractors for text and images. We use these features to learn multimodal representation using methods like concatenation and scaled dot product attention. Classification layers are used on fused features as per the subtask definition. We also performed experiments using unimodal models for setting up comparative baselines. Our best performing system achieved an F1 score of 0.757 and was ranked 3rd in Subtask A. On Subtask B, our system performed well with an F1 score of 0.690 and was ranked 10th on the leaderboard. We further show extensive experiments using combinations of different pre-trained models which will be helpful as baselines for future work.

1 Introduction

Internet and social media sites have played an integral role in bringing people together by providing a simple yet effective way of communication. Over recent times, internet memes have become a popular choice for sharing sentiment on the internet. A meme is an approach, concept, idea, or style that spreads through social media within a society, often to express a trend, topic, or significance represented by it (Peirson and Tolunay, 2018). Memes shared on the internet are often harmless and used to express humour; however, recent trends have increased their usage to spread hate or cause social unrest (Lippe et al., 2020). Hate speech and, in particular, hate against women has seen an exponential rise in social media platforms (Pamungkas et al., 2020). Misogyny, a subset of hate-speech (Safi Samghabadi et al., 2020), is defined as hate or prejudice against women, which can be manifested in numerous ways, including social exclusion, sex discrimination, hostility, patriarchy, male privilege, belittling of women, disenfranchisement of women, violence against women, and sexual objectification(Anzovino et al., 2018). Women have a strong presence online, particularly on Instagram and Twitter. Women use social media multiple times a day compared to men(Fersini et al., 2020). This makes it extremely important to identify and remove such content to make the internet safer for women.

Efforts have been made to identify misogynous textual content on social media (Anzovino et al., 2018) (Fersini et al., 2018b) (Pamungkas et al., 2020) (Hewitt et al., 2016), however, no efforts have been made to identify the misogynous content spanning multiple modalities like memes. Memes are uniquely multimodal and convey information using images and text. The multimodal nature of memes allows them to combine harmless texts/images into misogynist memes when used together. This poses an exciting challenge as memes require joint language and visual understanding to infer their true meaning. SemEval 2022 Task 5: MAMI (Fersini et al., 2022) draws attention to the problem of identifying misogynous memes and further identifying the type of misogyny. The task provides a dataset of misogynist memes and its type. Both images and the corresponding text was available as a source of information; the text content of the provided dataset was in English.

Our proposed system for both subtasks uses the late fusion of visual and textual features obtained from pre-trained models. We use separate pre-trained models for each modality, i.e. text and image, and fuse the features to learn multimodal representation for memes. We experimented with simple concatenation of image and text features; and scaled dot product attention (Vaswani et al., 2017), followed by a convolution layer to learn multimodal features. Once multimodal features are learnt, we stack classification layers on them as per the subtask requirements. We also performed extensive experiments using a single modality (text/image) to set up comparative baselines. We used ViT (Vision Transformer) for image feature extraction. We experimented with various PLMs for textual feature extraction like Bidirectional Encoder Representations from Transformers(BERT), Robustly Optimized BERT Pretraining Approach(RoBERTa), MPNet, and Decoding-enhanced BERT with disentangled attention(DeBERTa).

The results of unimodal experiments showed that text-only models had a superior performance than image-only models. We experimented with feature concatenation and scaler dot product attention for multimodal models. Feature concatenation led to only minor performance gains. In case of scaler dot product attention, choice of query(Q) (Vaswani et al., 2017) turned out to be an essential factor. Our experiments showed that image features as query performed significantly well for all models and outperformed all unimodal and concatenation baselines. Our best performing model was a voting ensemble of attention based multimodal models and achieved an F1 score of 0.757 with a 3rd rank on the official leaderboard for Subtask A. For Subtask B we used BERT and ViT based attention model, which performed well, attaining an F1 score of 0.690 and 10th rank on the leaderboard. Our code available at GitHub[1] for method replicability.

2 Background

Identifying misogynous content is critical to making the internet accessible and safe for women. In recent times there has been an exponential rise in hateful content and, in particular, the phenomenon of hate against women on social media (Pamungkas et al., 2020) (Hewitt et al., 2016). There have been previous attempts to identify hate/toxic content on social media platforms ((Zampieri et al., 2020) (Zampieri et al., 2019) (Sharma et al., 2021a) (Pavlopoulos et al., 2021) but none deal specifically with identifying the hate against women. The first benchmark dataset to identify misogynous content was proposed in (Anzovino et al., 2018). The task and the papers of AMI@Evalita 2018 (Fersini et al., 2018a) and AMI@IberEval2018 (Fersini et al., 2018b) highlight the difficulties and barriers involved in automatically identifying misogynist content on social media. Workshop on Trolling, Aggression and Cyberbullying (TRAC) shared task (Kumar et al., 2020) contained a subtask to identify gender-based identification of hateful content.

Type	Misogynous	Not misogynous	Total
Train	4742	4758	9500
Validation	258	242	500
Test	500	500	1000

Table 1: Dataset Statistics for Subtask A

There has been a rise in multimodal content over the internet in the form of memes. Most efforts to identify toxic and misogynous content consider only the textual content. Due to the rapid increase of multimodal content, efforts have been made to analyse it. Memotion analysis (Sharma et al., 2020a) aimed to perform sentiment analysis on internet memes. It involved identifying offensive sentiment as part of its Subtasks. (Sharma et al., 2020b) used a feature fusion model using LSTMs, GRUs with attention and attained the best results in identifying offensive memes. Hateful memes challenge (Kiela et al., 2020) aimed to study and identify the hateful nature of internet memes. Analysing memes is an intrinsically difficult task as it requires multimodal reasoning capable of understanding textual and visual features. The common strategy used in analysing memes involved learning features for each modality and then fusing the features to represent joint features. Work done in (Pranesh and Shekhar, 2020) uses the simple concatenation of text and visual features for meme sentiment analysis. (Lippe et al., 2020) used early fusion models like LXMERT (Tan and Bansal, 2019), UNITER (Chen et al., 2020) uses Transformer (Vaswani et al., 2017) architecture and neural attention to learn joint representation.

Social media provides a platform for numerous people to express and share their thoughts. Misogyny which can be simplified as hate or prejudice against women, is on the rise in social media platforms. Hence, it is crucial to identify and remove such content from the internet. Attempts have been made to identify hateful/toxic and misogynist content on the internet, but none focuses on multimodal

Table 2: Dataset Statistics for Subtask B

content like memes. SemEval 2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification (Fersini et al., 2022) aims to study the misogynist nature of memes and is divided into two subtasks which we define as:

Subtask A: Given a labelled dataset D of internet memes and their text, the objective of the task is to learn a classification function that can predict if a meme is misogynous or not.

Subtask B: Given a labelled dataset D of internet memes and their text, the objective of the task is to learn a multilabel classification function that can predict the type of misogyny M for a given misogynous meme, where $M \in \{$stereotype, shaming, objectification and violence$\}$.

Dataset Statistics: The dataset for the task consisted of internet memes and their textual content. For Subtask A, the memes were labelled as misogynous/non-misogynous. Misogynous memes from Subtask A were further labelled into the type of misogyny. Subtask B involved recognising the type of misogyny from overlapping categories like stereotype, shaming, objectification, and violence. We also split the provided dataset into train and validation sets for training and evaluating the models before using them to make predictions on the test set. Table 1 and Table 2 show the dataset statistics for Subtask A and Subtask B.

3 System Overview

3.1 *Pre-trained Models:*

Finetuning (Qiu et al., 2020) pre-trained language models has become a popular approach in the deep learning community (Sharma et al., 2021b). It is a form of transfer learning that utilizes models trained on enormous amounts of unannotated text data to learn general-purpose representations. These models are then finetuned on downstream tasks. In recent times there has been a rapid rise in pre-trained models in Natural Language Processing (NLP). The knowledge from these models can be easily transferred to tasks where small amounts of data are present, making them extremely useful. The maximum of these PLMs like BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), MPNet (Song et al., 2020), DeBERTa (He et al., 2021) are based on transformers. Pre-trained models used in computer vision mostly rely on convolutional networks. Architectures like classic ResNet (He et al., 2016) have attained state of the art performance in large scale image recognition tasks (Kolesnikov et al., 2020) (Xie et al., 2020). Recently the transformer architecture has also been used in computer vision and performs at par with convolutional networks (Touvron et al., 2021) (Dosovitskiy et al., 2021) (Bao et al., 2022). The use of transformers in computer vision has also led to multimodal pre-trained models (Kim et al., 2021) (Li et al., 2019) (Tan and Bansal, 2019). Pre-trained models provide an efficient and scalable way to use large-scale learning to simple downstream tasks efficiently. Next, we describe the pre-trained models used in our multimodal system.

3.2 *Brief overview of Pre-trained models:*

Vision Transformer (ViT): ViT (Dosovitskiy et al., 2021) was proposed by Google and aimed to use the transformer architecture with minimal changes to computer vision tasks. Transformers use sequences to process data and cannot process grid-structured data. The images in the transformer were converted into smaller image patches and used as sequences. Trainable positional encodings were used to retain positional information of smaller image patches. These positional encodings help to learn the relationship between smaller image patches. Finally, the whole model is pre-trained as a classification task on the ImageNet dataset (Russakovsky et al., 2015).

BERT: It stands for Bidirectional Encoder Representations from Transformers (Devlin et al., 2019) is a PLM based on the transformer architecture. It is pre-trained on text corpus using Masked Language Modelling (MLM) and Next Sentence Prediction (NSP) objective.

RoBERTa: A Robustly Optimized BERT Pretraining Approach (Liu et al., 2019) was developed by Facebook. They used the BERT architecture with few modifications and obtained better performance. They used dynamic masking in their pre-training and removed the NSP objective. They also trained the model using a larger batch size with more data for longer durations.

MPNet: MPNet (Song et al., 2020) was proposed by Microsoft. Most language models are pre-trained using either MLM or permuted language modelling objectives. MPNet makes the best of both permuted language modelling and MLM. It proposed a unified view of MLM and permuted language modelling by splitting and rearranging the tokens into predicted and non-predicted parts. It uses MLM to see the positional information of complete sentences and permuted language modelling to model dependency among predicted tokens.

DeBERTa: DeBERTa stands for decoding-enhanced BERT with disentangled attention (He et al., 2021), was proposed by Microsoft and outperformed human performance on the SuperGlue benchmark (Wang et al., 2019). It used disentangled attention where two vectors are used, one to represent the content and the other to store the positional information. Attention weights are calculated using disentangled matrices on their content and relative positions. It also uses an enhanced mask decoder during pre-training to incorporate absolute positions while predicting masked tokens.

3.3 *Unimodal models (baselines):*

Meme classification is an intrinsically complex problem due to textual and visual cues. Memes can convey a message using image, text, or both, thus requiring textual, visual, and multimodal understanding. We first modelled misogyny detection using purely unimodal approaches to form comparative baselines as part of our experiments. BERT, RoBERTa, MPNet, DeBERTa were used for meme text classification, and ViT was used for meme image classification. The unimodal baselines were also helpful in understanding the predictive power of text vs image features. We experimented with unimodal models only for Subtask A.

3.4 *Multimodal models:*

The multimodal nature of memes makes it extremely difficult to understand their true meaning. They may contain a combination of completely different visual and textual content, which, when joined, turn out to be misogynist in nature. To understand this multimodal nature of memes, we used two different techniques to join visual and textual representations to learn multimodal features, which we will discuss next.

Feature concatenation: To learn jointly from image and text features, we used late fusion to concatenate the features learnt by image and text pre-trained models. Concatenated features are then fed to the final classification layer to label the meme as misogynistic (Subtask A) or identify the type of misogyny (Subtask B). The image and text pre-trained models are jointly finetuned with the classification layer using the classification objective.

Attention-based feature fusion: Attention has been widely used in various NLP tasks. It forms the critical component of transformer architecture. The main idea behind attention is to learn representation for a given feature based on its relative relevance with respect to other features. We use the same idea to learn joint image-text features using attention mechanism. We use scaler dot product attention (Vaswani et al., 2017) which uses concept of queries(Q), keys(K), and values(V) and is defined as:

$$Attention(Q, K, V) = softmax(QK^T/\sqrt{d_k})V$$

where dimension of Q and K is (N, d_k), dimension of V is (N, d_v), and N is sequence length. The output of the attention step has the dimension of (N, d_v), which represent the context vectors. The language and vision models we used both utilised transformer architecture. As we know, transformers work with data sequences, which helped us get highly localised feature representations, allowing us to use attention to fuse visual and text features. The features from pre-trained text models represent the information corresponding to input tokens. The visual features from ViT represent information corresponding to $N \times N$ patches from the input image. We use the dot product attention defined above on these set of features to learn the multimodal representation.

Another essential aspect of scaler dot product attention is the choice of query and key during attention. In transformers, self-attention is calculated, which makes this choice trivial. However, while using attention on visual and text features, it is essential to note that attention is not commutative. Therefore, we performed experiments using both visual and textual features as the query parameter in attention. The context vectors obtained from the attention layer were then passed through a one-dimensional convolution layer to learn final

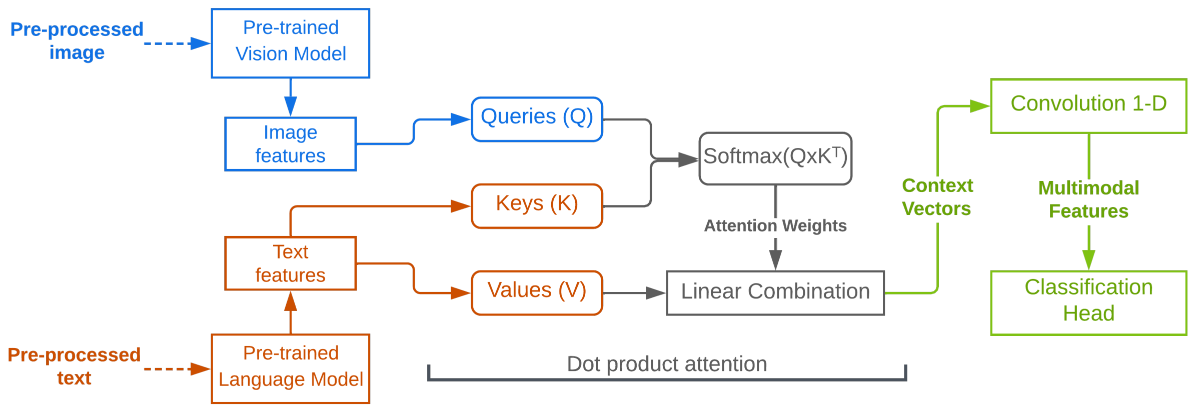

Figure 1: Architecture of our model using attention with image features as query.

multimodal features. These features were finally flattened and fed to the final classification layers. Figure 1 shows the architecture diagram of our attention based multimodal model using image features as query.

3.5 *Classification layers and finetuning:*

We finetuned the unimodal text models by stacking a simple dense and batch normalisation layer followed by a one-neuron classifier on top of features learnt by pre-trained models. We used the features from [CLS] token in the case of BERT and RoBERTa and start the token(<s>) in the case of MPNet and DeBERTa. For ViT we used the [class] token, which is taken as image representation. We pass the joint visual and text features through a batch normalisation and simple dense layer followed by a one-neuron classifier for multimodal models. Visual and text models along with concatenation/attention layer were wrapped into a single model for finetuning multimodal models.

4 Experimental setup

4.1 *Pre-processing images and texts*

Text: We used the ekphrasis (Baziotis et al., 2017) library for text pre-processing. It normalises time, date, numbers to a standard format and corrects misspelt words. Chatwords are commonly used in memes, so we converted them into their full forms. PLMs need text to be tokenised before it can be fed to them. We used Hugging Face's (Wolf et al., 2020) implementation of Fast tokenisers[2] for each pre-trained model.

Image: Images need to be pre-processed before being fed to ViT. We first resized the image to 224×224. We also divided the pixel values by 255 to bring them within a range of 0-1. Finally, the images were normalised using the mean and standard deviation of 0.5 across all channels.

4.2 *Task-wise model definition:*

Subtask A: We experimented with unimodal and multimodal techniques. Our unimodal baselines used BERT, RoBERTa, MPNet, DeBERTa for text and ViT for images. We extracted the features from these models and passed them through a dense layer with 32 neurons, followed by a batch normalisation layer. Finally, we used a classification layer with a single neuron and sigmoid activation to label the input as misogynous/not misogynous. For multimodal models, we experimented with concatenation as well as attention using BERT and ViT initially. We passed the fused features through a batch normalisation and dense layer consisting of 64 neurons, followed by a single neuron classification and sigmoid activation. Further, we experimented using a combination of RoBERTa, MPNet, and DeBERTa with ViT using attention mechanism (image features as query). The one-dimensional convolution layer in multimodal models used 32 filters with a kernel size of 30 and stride 15.

Subtask B: We used only the multimodal models using concatenation and attention to learn multimodal features. Subtask B was a multilabel task where a misogynous meme could belong to more than one category: stereotype, shaming, objectification, and violence. We trained a single model to classify the memes into the given categories. We created a multi-branch model where each branch tries to predict if meme belongs to one of the given categories. The branch takes the independent text

[2]Hugging Face's Fast Tokenizers

and visual features fused using simple concatenation or a combination of attention and 1-D Convolution. The fused multimodal features for each branch are then passed through a 32-neuron dense layer, batch normalisation layer and finally through a single neuron classification layer with sigmoid activation.

4.3 *Hyperparameters and training:*

We developed our models using TensorFlow[3], Keras [4] (Chollet et al., 2015) and Hugging Face's [5] implementation of transformer[6] (Wolf et al., 2020) models. The models were trained using GPU/TPU on Google Colab. We fixed the sequence length to 80 tokens across both subtasks for text modality. Sequences greater or shorter than 80 tokens were accordingly truncated or padded. We used their base versions for all PLMs; for ViT we used the base model with the patch size of 16×16 and input image size of $224\times$ 224. Finetuning was performed using Adam (Kingma and Ba, 2015) optimiser against a binary cross-entropy loss. We experimented with learning rates ranging from 2e-5 to 5e-5 with a batch size of 128 for TPU and 16 for GPU. Finetuning was done for ten epochs, and weights corresponding to the best results on the validation set were used to make predictions on the test set. For Subtask A, we finetuned the entire dataset containing misogynous as well as non-misogynous memes. For Subtask B, we trained the model only on misogynous memes to identify the type of misogyny. For evaluation on the test set, we used a hierarchical approach where we made predictions only on samples predicted as misogynous from the best performing model on Subtask A.

4.4 *Evaluation metric:*

Subtask A used the macro-averaged F1 score to evaluate the model's performance. F1 scores were calculated individually for each class and then averaged to give the Macro F1 score. For Subtask B, the weighted-average F1 measure is used as the evaluation metric. F1 scores are computed for each label, and then the weighted average is computed based on true instances belonging to each label category.

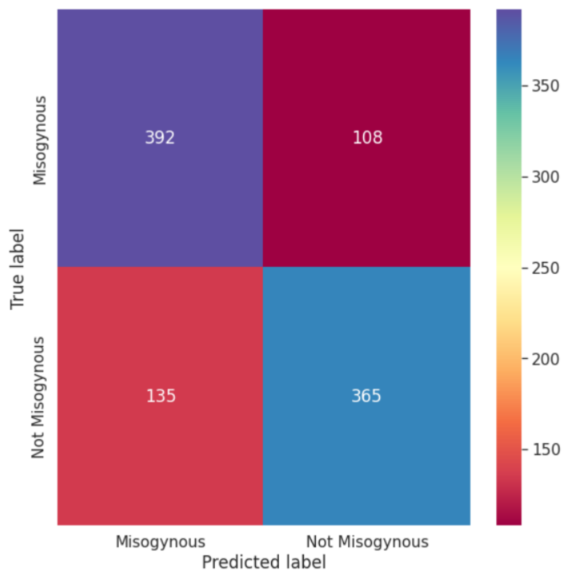

Figure 2: Confusion Matrix for Subtask A (ensemble model)

5 Results and Analysis

Table 3 and Table 4 contain the results of our models for Subtask A and Subtask B. In Subtask A our best performing model was a voting ensemble of attention (image as a query) models trained with different seed values attaining an F1 score of 0.757 and was ranked 3rd on the leaderboard. Figure 2 shows the confusion matrix for our ensemble model. In Subtask B we used a hierarchical model. We made predictions only for samples classified as misogynous by our best performing ensemble model on Subtask A. Our BERT + ViT model using attention (image as a query) performed best with an F1 score of 0.690 and was ranked 10th on the leaderboard.

Table 3 contains a comparative analysis of unimodal vs multimodal techniques we used as part of our experiments for Subtask A. If we compare unimodal models, we can see that text-based models have better performance than the image-based models on both development and test sets. It points to the possibility that text present in memes is a prominent factor in identifying misogynous content. DeBERTa outperforms other models by a considerable margin among text models, performing almost equivalent to the multimodal concatenation model. For multimodal models, we performed initial sets of experiments using BERT and ViT over different methods of fusing the modalities. The simple concatenation worked well and provided a slight improvement when compared to unimodal

Model	Type	Development					Test

techniques.

Our next set of experiments used scaler dot product attention using BERT and ViT. As we can see from the results, the choice of query(Q) played a crucial role in calculating the multimodal features using attention. BERT + ViT model using text features as query performed poorly when compared to concatenation and best performing textual models. However, when we use the same architecture and change the query(Q) term to image features, there is a significant gain that outperforms all other models. The attention mechanism uses queries(Q), keys(K) and values(V) to calculate the context vectors. We can observe from the formula defined in section 3 that while the query(Q) and key(K) is used to calculate attention weights, the final features are a linear combination of attention weights over the values(V). Our experiments using unimodal models showed that textual features perform better than visual features, almost as good as concatenation based multimodal models. Using image features as a query allows us to preserve the textual features which are used as values(V) while modelling the correlation between images and text using query-key matching. This might be one of the possible reasons for the better performance of attention-based models with image features as query. We performed further experiments using only attention-based fusion with image features as queries(Q). We used MPNet, RoBERTa, and DeBERTa with ViT, which outperformed all unimodal and multimodal baselines. For Subtask B, we experimented with only concatenation and attention methods and found that attention (image as a query) performed better than concatenation.

6 Conclusion

This paper describes our approach for SemEval 2022 Task 5: MAMI - Multimedia Automatic Misogyny Identification. We propose a dot product attention-based mechanism for learning multimodal representation from independent text/image features. Our work also describes a comprehensive set of experiments using unimodal/multimodal models using different pre-trained models. Our system performed well, attaining 3rd rank on Subtask A and 10th in Subtask B. Our experiments highlight the non-commutative nature of dot product attention, with the choice of the query being a critical design decision. Our results showed that textual features dominate over image features in multimodal understanding. In the future, we would like to explore more on how attentions learn multimodal features and further compare the role of individual modalities in multimodal tasks.

Abstract

This paper describes the multimodal late fusion model proposed in the SemEval-2022 Multimedia Automatic Misogyny Identification (MAMI) task. The main contribution of this paper is the exploration of different late fusion methods to boost the performance of the combination based on the Transformer-based model and Convolutional Neural Networks (CNNs) for text and image, respectively. Additionally, our findings contribute to a better understanding of the effects of different image preprocessing methods for meme classification. We achieve 0.636 F1-macro average score for the binary sub-task A, and 0.632 F1-macro average score for the multi-label sub-task B. The present findings might help solve the inequality and discrimination women suffer on social media platforms.

1 Introduction

The proposed task, SemEval-2022 Task 5 Multimedia Automatic Misogyny Identification (MAMI) (Fersini et al., 2022) consists in the identification of misogynous memes in English language, taking advantage of both text and images available as a source of information.

Overall, our proposed method consists of a multimodal approach combining different features (e.g., logits, probabilities, embeddings) of a text Transformer-based model and an image CNN model in a late fusion approach. This late fusion step implies that both models are trained and fine-tuned separately to the task. Then, the features from each model are concatenated and jointly used as input for a final classifier that combines their knowledge to obtain a final prediction (see Figure 1). Different preprocessing steps, text and image models, concatenated feature combinations, and classifiers are explored to obtain the final multimodal architecture.

Our presented method has been developed for sub-task A and B from the MAMI competition independently. sub-task A consists of misogynous meme binary classification, where a meme should be categorized either as misogynous or not misogynous. On the other hand, sub-task B requires a more detailed multi-label classification where misogynous content should be recognized among potential overlapping categories such as stereotype, shaming, objectification, and violence.

It is noteworthy that our multimodal late fusion method outperforms single models in both sub-tasks, being more remarkable in complex sub-task B. Similarly, considering that both sub-tasks share the same data, the results of model evaluation on both tasks show how the model trained on complex sub-task B can achieve the same results as a model trained only on binary sub-task A. Therefore, future studies should investigate the complexity and pruning of the required models.

This paper provides new insights into information fusion for tackling multimodal tasks, presenting an in-depth exploration of different late fusion approaches and image processing steps. The presented work might help identify malicious be-

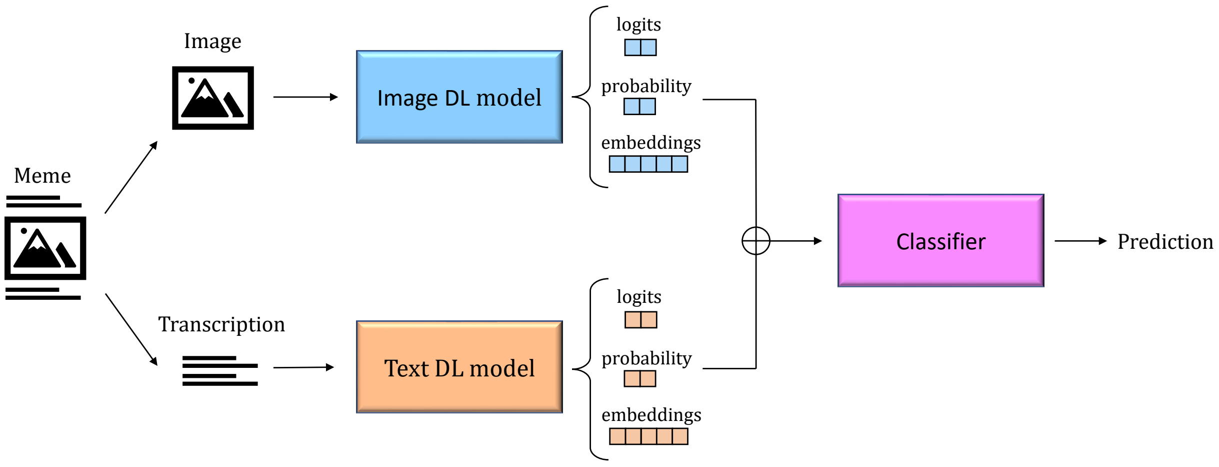

Figure 1: Summarized diagram of the late fusion multimodal system proposed for misogyny detection

haviours towards women on social media.

2 Background

Misogyny comprises every hateful and prejudicial action against women, ranging from discrimination, objectification, violence and disdain affecting women to all the types of manifested male superiority like patriarchy, androcentrism and privilege (Pamungkas et al., 2020). Misogynist posts represent one type of hate speech on Online Social Networks, but it is complex to distinguish them from other sorts of offensive discourses in an automated way (Shushkevich and Cardiff, 2019).

Whereas research shows a survey of methods for misogyny recognition in text including traditional methods and their ensembles and neural networks (Shushkevich and Cardiff, 2019), studies reviewing mysogyny in images are more scarce, and more work can may be found under the generalization of sexist content (Campisi et al., 2018; Fersini et al., 2019) than under the particular topic of misogyny.

These sexist images can be in the form of memes, multimedia content with a humorist goal composed of photos and/or illustrations with some text on it (Sabat et al., 2019). Furthermore, this initially shows that sexist and also misogynist content on social networks do not need just the isolated use of image and text processing but the combination of both. In fact, having images or texts on their own may not lead to hateful speech and only their mix is offensive (Sabat et al., 2019), underlining the major necessity of architectures that encode the global meaning of memes.

On the one hand, the latest advances in NLP for text classification include the use of Transformers, which has demonstrated to be successful in the detection of misogyny (Samghabadi et al., 2020; Aldana-Bobadilla et al., 2021). These distributional models encode the meaning of texts in vectors that also capture the context (Devlin et al., 2018). However, they may not be so optimal for the detection of subclasses, for instance between the absence and the implicit or sarcastic presence of aggressiveness (Samghabadi et al., 2020), or when the female subject that is attacked is not present in the text (Aldana-Bobadilla et al., 2021).

On the other hand, when images are also taken into account, the use of Convolutional Neural Networks (CNNs) for images is still present (Gomez et al., 2020) through image-based state-of-the-art models such as `VGG16`, `ResNet`, `DenseNet` and `Inception`. Specifically, `VGG16` works by itself for the prediction of offensive memes and succeeds when combined with different models for the text inside them (LSTMs, BiLSTMs and CNNs), which were later compared (Aman et al., 2021), but when the comparison is among vision models, depending on the dataset and the multimodal approach followed, `ResNet50` can surpass `VGG16` and `ResNet152` for VGCN-BERT combined pipelines for hateful images detection (Vlad et al., 2020), but `Inception` outperforms the F1-scores from `ResNet50` for multimodal approaches with BiLSTMs for 'troll' (sarcastic or offensive) meme detection (Hossain et al., 2021), and just using `DenseNet` alone for meme emotion recognition can be even better than `ResNet` alone and than either `DenseNet` or `ResNet` in image joining forces with BERT for the textual features (Guo et al., 2020). Alternative implementations for vision are Transformers such as VisualBERT, which represents an architecture with image and text models (Lippe et al., 2020) or CLIP, which predicts the text that better describes the images (Zia et al., 2021).

Recent research has shown that joining the probabilities from the CNN classification and the output statistical variables obtained after training a successive classifier (Huertas-Tato et al., 2022) improves the task. These results invite to use this advance in information fusion for practical applications such as hateful images and, specifically, misogynist memes. In line with this theoretical framework, our work will concatenate the different outputs (e.g, logits, probabilities, last hidden embeddings) from CNN-based image classification and from Transformers-based text classification towards a better performance in MAMI.

3 System overview

As previously mentioned, our proposed approach is depicted in Figure 1. This section details the preprocessing steps, the text and image models employed, and the methodology followed to train the final multimodal late fusion classifier that combines different features.

3.1 Image Preprocessing

To rule out the possibility of text misleading the image CNN model and to enhance its focus on the image, three different preprocessing steps are separately explored. Consequently, three different image models are trained: (1) no preprocessing, (2) blacking out, and (3) inpainting the text from the image. These preprocessing methods make use of EasyOCR[1] and OpenCV (Bradski, 2000). Figure 2 illustrate some examples of the results of these preprocessing steps. Additionally, an application for applying the inpainting preprocessing to images has been publicly published with the aim of contributing to the scientific community[2].

3.2 Text Preprocessing

Ftfy package (Speer, 2019) was used as a preprocessing step for fixing text and ensuring it is uniformly UTF-8 encoded. URLs, emojis, or other native features present in the text are not modified as we consider these characteristics crucial for this task.

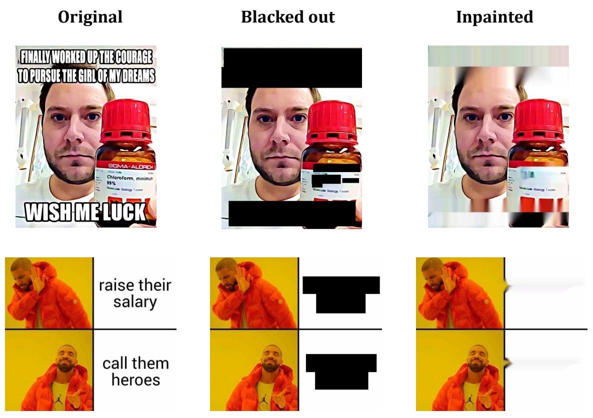

Figure 2: Example of different image preprocessing steps

3.3 Explored Models

According to the models employed, it is worth mentioning that different Transformer-based models publicly available at Hugging Face (Wolf et al., 2020) are evaluated as the textual model:

- `bertweet-base` (Nguyen et al., 2020): large-scale language model pre-trained for English Tweets based on RoBERTa (Liu et al., 2019) pre-training procedure and BERT architecture (Devlin et al., 2019).
- `all-distilroberta-v1`[3]: pre-trained `distilroberta-base` (Sanh et al., 2019) model fine-tuned on a 1B sentence pairs dataset using a contrastive learning objective.
- `all-miniLM-L6-v2`[4]: pre-trained Microsoft `MiniLM` (Wang et al., 2020) model fine-tuned on a 1B sentence pairs dataset using a contrastive learning objective.
- `twitter-roberta-base-offensive` (Barbieri et al., 2020): `roberta-base` model trained on 58M tweets and finetuned for offensive language identification with the TweetEval benchmark.
- `twitter-xlm-roberta-base` (Barbieri et al., 2021): `xlm-roberta-base` model trained on 198M multilingual tweets.

For image processing we have used CNNs, which extract features with convolutional layers and deduce knowledge with dense layer. We use

Table 1: Hyperparameters optimized during the development of the proposed approaches. *Only for multi-label subtask B.

different architectures pretrained from state of the art:

- `VGG16` (Simonyan and Zisserman, 2014): it is composed by a feed-forward set of units and is the most straightforward without additional forward connections or auxiliary outputs. However this architecture has to adjust lots of parameters.

- `ResNet50` (He et al., 2016): The main advantage of this architecture is the shortcut connections, these links skip one or more layers, aggregating their output to the outputs of the stacked layers.

- `DenseNet201` (Huang et al., 2017): Instead of adding more layers to the architecture, it increases the number of connections between units, connecting every units with later ones.

- `Inception_v3` (Szegedy et al., 2016): it factorises the convolution into smaller ones (that can be asymmetric) to reduce the cost. Moreover, this architecture has an auxiliary classifier between layers, that acts as regularizer.

- `EfficientNetB0` (Tan and Le, 2019): This architecture uses a compound coefficient to scale all dimensions of depth, width and resolution.

Finally, the Auto-sklearn package (Feurer et al., 2015, 2020) is used to automatically explore a wide range of models and preprocessing approaches available in scikit-learn and identify the best ensemble configuration for the multimodal late fusion step. We opted for this method because it implements Bayesian Optimization for searching the optimal pipeline configuration and Ensemble Selection to choose the suitable model.

3.4 Multimodal late fusion approaches

From the text and image models, three features are used for the late fusion step; the output of the activation function from the last classification layer (i.e., probabilities) and its input (i.e., logits), and the vectorize output representation of the last hidden layer (i.e., embeddings). In order to develop the final multimodal classification predictions, different late fusion approaches for combining these features are considered.

Naive baseline approaches consist of averaging or taking the maximum logit or probability values from both models for each class or label depending on the sub-task. An advanced baseline approach consists of finding the weights for each model that will give the lowest mean square error (MSE) score between multimodal predictions and real values using logits or probabilities. For this purpose, Sequential Least Squares Programming (SQLSP) from Scipy package (Virtanen et al., 2020) is the optimization method used. Finally, logits, probabilities or embeddings from both models are used as input in Bayesian Optimization for searching the optimal pipeline configuration and Ensemble Selection using Auto-sklearn.

4 Experimental Setup

As previously mentioned, both sub-tasks share the same data and the official metric for system evaluation, F1-macro averaged. The dataset consists of 10.000 memes and its corresponding text transcriptions. To develop the proposed approach, balanced data for sub-task A is split into 64% train, 16% validation and 20% test in a stratified way using scikit-learn package (Pedregosa et al., 2011) with 42 as random state. Regarding multi-label sub-task B where the data is unbalanced, the data is split into 64% train, 16% validation and 20% test using the "iterative_train_test_split" method from scikit-multilearn package (Szymański and Kajdanowicz, 2018) to equally represent the different combination of overlapping labels in the splits.

To obtain the best results and avoid overfitting, we optimized several hyperparameters. Table 1 summarizes the hyperparameters tuned for both sub-tasks using their respective development sets. The experiment tracking and the selected hyperparameter values are published in Weight and Biases[5][6]. The resulting model are openly available in HuggingFace[7].

5 Results

5.1 Sub-task A - Binary misogyny classification

5.1.1 Image

Firstly, we analysed which of the three preprocessing techniques performed best for this task, where we observed that the images without preprocessing showed the best results. Therefore, all models were trained on this dataset. Table 2 shows performance from the five models, where the best model is `EfficientNetB0` which achieves the highest F1 score.

Image Model	F1 macro Avg
VGG16	0.5224
ResNet	0.6143
DenseNet	0.6608
EfficientNet	**0.6825**
Inception	0.6792

Table 2: Evaluation results of image models in the validation split of subtask A.

5.1.2 Text

The Trasnforme-based models results for validation split are shown in Table 3. As can be derived from these results, `bertweet-base` model has the best score and it is the one selected for the next multimodal late fusion step.

5.1.3 Multimodal Late Fusion

As explained in 3.4 different late fusion methods are explored. The best score is obtained using Auto-sklearn and probabilities from both text and image models as input data (see Table 4). The best Auto-sklearn ensemble configuration is composed

of three SGD classifiers [8].

These scores presented are remarkable, as logits contain more information about the model's decisions, but the concatenation of probabilities as late fusion input proves to be more useful for sub-task A. This might be explained by the fact that logits from different models have different distributions, not being as useful as normalized inputs.

5.2 Sub-task B - Multi-label misogyny classification

5.2.1 Image

In multilabel task the preprocessing is interesting. The third technique, inpainting the text from the images has better performance than the no preprocessing, however, the difference between them is low (as f1 score is 0.02) so it was decided to continue with the non-preprocessed images in order to maintain the methodology of the sub-task A. In this sub-task the best model is `EfficientNetB0`, as in the first one, which reached the highest performance.

all-distilroberta-v1	0.5570
twitter-roberta-base-offensive	0.4666
twitter-xlm-roberta-base	0.4218
all-miniLM-L6-v2	0.2057

Table 6: Evaluation results of Transformer-based models in the validation split of subtask B.

5.2.3 Multimodal Late Fusion

As in sub-task A, Auto-sklearn and probabilities from both text and image models as input data (see Table 7) shows the best results. The Auto-sklearn ensemble configuration is composed of Random Forest MLP, and Naive Bayes classifiers.

It is interesting to note that in a more in-depth analysis of the classification results performed by the different fusion methods, the simplest (e.g., average, max) only learned to correctly separate the majority label (misogynous or non-misogynous). However, the models using Auto-sklearn did manage to also classify the less frequent labels.

Finally, we report our test competition results along with the baseline results from the organizers of the competition. For sub-task A, the baselines are grounded a fine-tuned sentence embedding using the USE pre-trained model; fine-tuned image classification model grounded on `VGG-16`; and a concatenation of deep image and text representations using a single layer neural network. For sub-task B, the baselines are grounded on a multi-label model, based on the concatenation of deep image and text representations; a hierarchical multi-label model, based on text representations, for predicting if a meme is misogynous or not and, if misogynous, the corresponding type.

6 Conclusion

As a conclusion of the results obtained in the exploration and evaluation of models for the development of the multimodal late information fusion architecture, it is evident that the contribution between image and text is different, being the text much more informative in both sub-tasks.

In the case of the image model, it is interesting to note that the different proposed pre-processing techniques do not seem to have a beneficial effect on model training. Although further future analysis is needed, one possible justification could be that the information supplied by the text present in the images provides valuable information rather than noise in the CNN models.

Finally, it is also important to point out that in sub-task A, the multimodal strategy is not as relevant as expected as the baseline strategy that combines image and text information and our approach has the lowest scores in Table 8. A possible explanation for the results obtained could be the difference distribution between train and test sets of the competition, which would have facilitated overfitting in the development of the models in sub-task A. On the contrary, our method proves to be beneficial in sub-task B. Therefore, this could reinforce the idea of overfitting in sub-task A since sub-task B is more complex and better results are obtained. Following the same line, obtaining text models in sub-task B that maintain sub-task A performance supports future research exploring pruning techniques to avoid this situation. Additionally, this study provides a springboard for exploring the late fusion methods applied in this work in different modal problems and other domain scenarios, and comparing them to an end-to-end deep classifier.

In general, our results from the presented multimodal late fusion approach are encouraging to counteract malicious misogynistic behavior against women on social media.

Abstract

This paper presents a deep learning system that contends at SemEval-2022 Task 5. The goal is to detect the existence of misogynous memes in sub-task A. At the same time, the advanced multi-label sub-task B categorizes the misogyny of misogynous memes into one of four types: stereotype, shaming, objectification, and violence. The Ensemble technique has been used for three multi-modal deep learning models: two MMBT models and VisualBERT. Our proposed system ranked 17th place out of 83 participant teams with an F1-score of 0.722 in sub-task A, which shows a significant performance improvement over the baseline model's F1-score of 0.65.

1 Introduction

Participating in online social networks (OSN) has become more common nowadays, especially for women, as 78 percent of them use social media several times per day compared to 65 percent of the men. Anyhow, hateful speech against women did not stop until offline methods but also found its way on the web using popular communication tools such as memes. A meme is an online spread of captioned pictures or GIFs meant to be funny or critical to people or society. It has the most humor characteristics on social network platforms. However, in a short period, some minorities started to develop memes aiming at gender discrimination, inequality, and spreading hate against women.

Due to the growth of Artificial Intelligence (AI), Natural Language Processing (NLP), and Computer Vision (CV), the machine started to recognize and understand languages and images more than ever. Therefore, preventing hate speech and misogyny became more achievable by applying these methodologies. This paperwork presents our participation in SemEval-2022 Task 5 (Elisabetta Fersini, 2022) which aims to detect misogyny in memes. In this study, MultiModal BiTransformers (MMBT) (Kiela et al., 2019) and VisualBERT (Li et al., 2019) have been used to build the proposed model by employing the ensemble technique. The proposed model reaches an F1-score of 0.722 in sub-task A depending on the provided 10K memes dataset and without external datasets.

This paperwork is constructed as follows: Section 2 presents the related work, followed by Section 3, which clarifies the task description. Section 4 shows dataset details and preprocessing procedures. Section 5 shows off the architecture of the solution system. Finally, sections 6, 7, and 8 provide the experiments, results, and conclusion.

2 Related Work

Several researchers are attracted to detecting hate, harm, sarcasm, and satire on Social media (Faraj and Abdullah, 2021; Isaksen and Gambäck, 2020; Watanabe et al., 2018). Internet Memes are considered one of the most popular ways to communicate on all topics on social media. Since it is a global issue and a world trend, many researchers have started to compete in preventing harmful memes from pervasion. This paperwork (Shang et al., 2021) aimed to detect offensive analogy memes to prevent this from spreading out. The focus was here on images as it attracts more people and has richer information than the text alone.

One competition from Facebook (Kiela et al., 2021) aimed to detect hate speech in memes as it is hard to be tackled by having humans checking out every meme. From their vision, hate speech was understood as "any communication that disparages a target group of people based on some characteristic such as race, color, ethnicity, gender, sexual orientation, nationality, religion, or other characteristics" (Levy et al., 2000). The dataset consisted of

12540 memes, split between 7834 for non-hate and 4706 for harmful.

On the other hand, deep learning models have been successfully applied to learning features for single modalities: text (Abdullah and Shaikh, 2018; Abedalla et al., 2019) and images (Abedalla et al., 2021, 2020). Moreover, learning-based models that combine elements from multiple modalities are more robust in visual-linguistic tasks such as detecting hateful memes (Sandulescu, 2020).

3 Task Description

The main objective of this task (Elisabetta Fersini, 2022) is the identification of misogynous memes. Memes can be identified using text, images, or both. Using both images and text surely produces better results. The task is divided into two sub-tasks:

- Sub-task: This task aims to classify the meme as either misogynous or not misogynous.
- Sub-task B: this is a multi-label task, and the goal is to identify the type(s) of misogyny in misogynous memes. Types of misogyny are stereotypes, shaming, objectification, and violence.

Although we did not use any external datasets, it is allowed for participants to do so.

4 Dataset

4.1 Dataset Description

The training dataset provided by (Elisabetta Fersini, 2022) consists of 10,000 memes along with a file containing the extracted text, image file names, and five columns representing labels. The evaluation dataset consists of 1,000 memes, provides the extracted text and does not contain the labels. Competitors are supposed to use the evaluation dataset to produce and submit evaluation results. Memes were gathered by searching on social media platforms, such as Twitter and Reddit, and other meme creation and sharing websites, such as 9GAG, Knowyourmeme, and Imgur.

4.2 Data Preprocessing

Regarding the extracted text of memes, it is considered clean, and there is not much pre-processing required, but a lot of memes contain a web address in the bottom-right corner, which might better be removed. Also, Twitter hashtags and usernames are removed. Furthermore, any unwanted non-English or non-understandable characters are removed. The previously mentioned pre-processing steps provide a slight performance improvement. Regarding the images, no pre-processing is applied.

Statistical Property	Value
Maximum sentence length	325
Minimum. sentence length	2
Average sentence length	21.46
Standard deviation of sentence length	16.97

Table 1: Statistical properties of memes text

4.3 Data Analysis

The dataset contains 5,000 misogynous memes and 5,000 non-misogynous memes. Thus, the dataset is perfectly balanced for sub-task (A). As shown in Table 1, the longest sequence of memes text is 325 words long, and the shortest sequence is only two words long. The average sentence length is 21.46, and the standard deviation of sentence lengths is 16.97. The previous statistics indicate that most sequences are nearly 2-38 words long, and fewer sentences contain more than 38 words. Therefore, the chosen threshold for sequence length (maximum sequence length) is 64.

5 Systems Description

5.1 Text-based Model

The first approach uses pre-trained language models to identify misogynous memes based on text. We ended up choosing RoBERTa (Liu et al., 2019) as it is one of the state-of-the-art language models. Unfortunately, relying on text-only is not good enough to classify memes robustly.

5.2 Image-based Model

The second approach uses pre-trained computer vision models to identify misogynous memes based on images. The chosen model is VGG (Simonyan and Zisserman, 2014), it is one of the most popular Convolutional Neural Network (CNN) models, and the chosen variant is VGG-16 which consists of 16 layers. Unfortunately, similar to text, using images only does not classify memes robustly.

5.3 Multimodal Models

As memes contain both text and images, it is reasonable to use deep learning models that use both text and images to produce more accurate and robust predictions.

The first model used in our solution is Multimodal Bi-Transformers (MMBT) (Kiela et al., 2019). MMBT was developed based on the transformer architecture. It uses the attention modules of the transformer to combine embeddings of different modalities (text and image in our case). The key approach used in MMBT is to take the image as an input, extract its features using a CNN model, concatenate the generated features with the text input tokens used in BERT (Devlin et al., 2018), and feed the model with the text and image tokens. We used ResNet-152 (He et al., 2016) as the CNN model for feature extraction (image encoding) in MMBT.

The second model in our solution is VisualBERT (Li et al., 2019) which is built to fulfill a wide range of vision and language tasks. It consists of a stack of transformer layers similar to BERT architecture to prepare embeddings for image-text pairs. BERT tokenizer is used as a text encoder. For images, a custom pre-trained object detector must be used to extract regions and bounding boxes fed to the model as visual embeddings. We used Detectron2 (Wu et al., 2019) to generate the visual embeddings using MaskRCNN+ResNet-101+FPN model checkpoint.

As shown in Figure 1, The final model is constructed using the voting technique between two MMBT models and the VisualBERT model. Both MMBT models use ResNet-152 for image encoding, but they differ slightly as one uses BERT-base-uncased for the text while the other uses BERT-large-uncased. It is worth mentioning that the two MMBT models were trained using different random seeds.

6 Experiments

Regarding sub-task A, we have experimented with RoBERTa as it is one of the state-of-the-art language models. We have used Huggingface (Wolf et al., 2019) and Pytorch (Paszke et al., 2019) to implement roberta-base. We chose a maximum sequence length of 64. Following this, we have experimented with VGG-16, which is one of the most popular pre-trained CNN models, and implemented it using Keras (Chollet, 2015). We set the model to expect images of size 300x300 and added a dropout layer with a drop rate of 0.3, followed by a dense layer. For RoBERTa and VGG-16, we split the provided dataset into training and validation datasets with a validation split value of 0.1. Both RoBERTa and VGG-16 performed poorly, as memes classification tasks require models that understand images and text.

Model	RoBERTa	VGG-16	MMBT	VisualBERT
Epochs	2 5	50	5 10	5 10
Batch Size	32 64	32 64	16 32 64	32 64
Learning Rate	2e-5 5e-5	0.001	1e-5 2e-5 5e-5	3e-5 5e-5
Weight Decay	0	0	0.0001 0.001	0.001
Gradient Acc. Steps	1	1	1 2	1
Random Seed	17	17	1337 17	42

Table 2: Hyper-parameters of all models for sub-task A.

Subsequently, we have experimented with two vision+language models: MMBT and VisualBERT. Both of them were implemented using Huggingface and Pytorch. MMBT was experimented with using ResNet-152 as image encoder and BERT as text encoder. Two BERT variants were used: BERT-base-uncased and BERT-base-large. Visual embeddings for visualBERT were generated using MaskRCNN+ResNet-101+FPN model checkpoint from Detectron2. For MMBT and VisualBERT, we used k-fold cross-validation with a k value of 5. In other words, the training and validation datasets consist of 8000 and 2000 memes, respectively, and after each epoch, the validation dataset switches to a completely different 2000 memes. This allows the models to train on the entire dataset eventually. In our experiments, MMBT outperformed VisualBERT. AdamW optimizer was used for all models. Table 2 shows different sets of hyper-parameters used for all previously mentioned models.

ResNet-152 + BERT-base-uncased

Figure 1: The architecture of the final system for sub-task A. ŷ represents the final prediction after applying voting technique between models. The pipeline also illustrates some pre-processing steps before modelling.

7 Results

The final results for sub-task A are produced using the ensemble technique between two MMBT models trained using different random seeds and VisualBERT. RoBERTa and VGG-16 were not included in the final system as they performed poorly compared to MMBT and VisualBERT. As shown in Table 3, both MMBT models slightly outperformed VisualBERT, but the latter still has a positive effect on the final result after the ensemble.

Looking at Figure 2, which shows the confusion matrix for the final results in Sub-task A, We can see that the final system succeeded in predicting 359 non-misogynous memes and 363 misogynous memes. The system also failed to identify 137 misogynous memes and mistakenly identified 141 non-misogynous memes as misogynous.

Model	MMBT (ResNet + Bert-base)	MMBT (ResNet + Bert-large)	VisualBERT	Ensemble
Epochs	5	5	5	*
Batch Size	32	32	32	*
Learning Rate	1e-5	1e-5	5e-5	*

Gradient Acc. Steps	1	1	1	*
Random Seed	1337	17	42	*
F1-Score	0.695	0.697	0.679	0.722

Table 3: Final experiments used in sub-task A. The final F1-score of 0.722 is obtained by using ensemble technique between the three models.

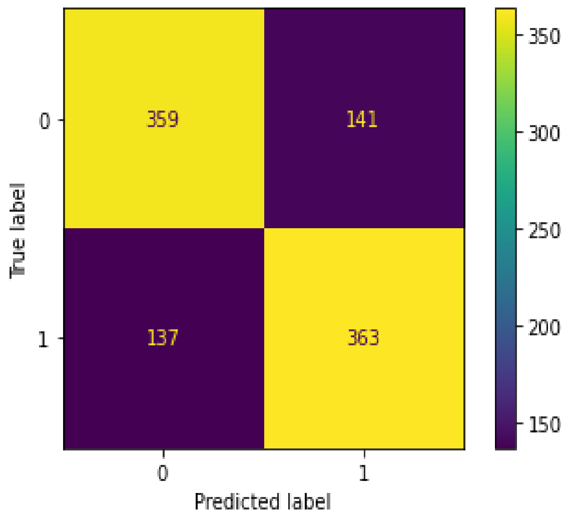

Figure 2: Confusion matrix for the final results in sub-task A

8 Conclusion

This paper presented our deep learning system that contended at SemEval-2022 Task 5. We experimented with different deep learning models, starting with the RoBERTa language model and the VGG-16 CNN model. Subsequently, we experimented with vision and language models, such as MMBT and VisualBERT, which significantly outperformed VGG-16 and RoBERTa. Using ensemble technique between two MMBT models and VisualBERT produced an F1-score of 0.7222 which led to ranking 17th place in sub-task A.

UIC-NLP at SemEval-2022 Task 5: Exploring Contrastive Learning for Multimodal Detection of Misogynistic Memes

Charic Farinango Cuervo and **Natalie Parde**
Natural Language Processing Laboratory
Department of Computer Science
University of Illinois at Chicago
{cfarin2, parde}@uic.edu

Abstract

Misogynistic memes are rampant on social media, and often convey their messages using multimodal signals (e.g., images paired with derogatory text or captions). However, to date very few multimodal systems have been leveraged for the detection of misogynistic memes. Recently, researchers have turned to contrastive learning solutions for a variety of problems. Most notably, OpenAI's CLIP model has served as an innovative solution for a variety of multimodal tasks. In this work, we experiment with contrastive learning to address the detection of misogynistic memes within the context of SemEval-2022 Task 5. Although our model does not achieve top results, these experiments provide important exploratory findings for this task. We conduct a detailed error analysis, revealing promising clues and offering a foundation for follow-up work.

1 Introduction

Hateful expressions on the Internet are widespread and mostly based on religion, gender, race, or physical attributes (Lippe et al., 2020). Such language exacerbates damaging societal problems such as racism, sexism, and other types of discrimination. In particular, misogynistic abuse has become very prevalent and poses a serious problem in cyberspace (Citron, 2014). Although extensive research on hate speech and misogyny has been conducted (Kumar et al., 2020), it has thus far centered on the analysis of text or images alone.

Memes, or social media images that communicate messages through the creative use of imagery understood to carry specific rhetorical value among members of a community, are a common platform for misogyny and hateful expressions. Approximately 78% of women use image-based social media multiple times per day (compared to 65% of men) (Fersini et al., 2022), making exposure to this harmful content alarmingly common. Classifying memes is challenging because of their multimodal interplay between image and text, as well as their region-specific interpretation, and existing multimodal approaches do not perform very well in the classification of hateful memes (Kiela et al., 2020). The underlying goal of SemEval-2022 Task 5 was to address this research gap, tackling the challenge of identifying misogynistic memes using multimodal data by inviting researchers to experiment with a variety of approaches.

Our team, *UIC-NLP*, investigated an adapted version of the Contrastive Language-Image Pre-training (CLIP) technique recently established and applied with success to numerous other tasks (Radford et al., 2021; Conde and Turgutlu, 2021; Galatolo et al., 2021). Our model, recorded on the leaderboard in the 6th leaderboard cluster under the OpenReview username "Charicfc," ranked 71st out of 83 participants and obtained an average F_1 score of 0.62. We analyze our model's predictions and offer insights and recommendations for improving upon it in the future.

2 Background

2.1 SemEval-2022 Task 5 (MAMI)

SemEval-2022 Task 5 was created to address the rise in the use of memes as a form of hate against women, which contributes to sexual stereotyping and gender inequality. The data used for this challenge is comprised of English-language memes collected from the web and manually annotated via crowdsourcing platforms. Each data sample has an image, its raw text in English (*transcript*), a binary annotation indicating the presence of misogyny, and (if applicable) the type of misogyny (shaming, objectification, stereotype, or violence). Our model addresses *Subtask 1*, which focuses on binary classification of memes as misogynist or not misogynist. The output for a given sample is a confidence score for the predicted class. Although no approaches have sought to perform multimodal detection of misogynistic memes to date, we review work on classifying misogynistic expressions in text and multimodal classification of hateful memes in the following sections.

2.2 Identifying Misogyny in Text

Previous approaches in the related IberEval 2018 Automatic Misogyny Identification (AMI) task for misogyny detection in tweets (Fersini et al., 2018) leveraged statistical classification models, including variations of Support Vector Machines (SVM) (Nina-Alcocer, 2018; Pamungkas et al., 2018). Other recent work towards identifying misogyny in text has leveraged CNNs, LSTMs, and combined representations from models like BERT (Basile et al., 2019; Parikh et al., 2021). Recently, the Evalita 2020 AMI challenge best results were obtained by ensembles of fine-tuned BERT models (Lees et al., 2020).

2.3 Multimodal Classification of Hateful Memes

Multimodal learning has recently gained attention due to the poor performance of existing (unimodal) models on multimodal tasks (Lippe et al., 2020), with most recent solutions (context aware) employing neural architectures such as CNNs, RNNs, and Transformer-based attention models like BERT (Afridi et al., 2020; Modi and Parde, 2019; Parde, 2020). Although existing work on hate speech detection has largely relied on text-based features, this has gradually started to shift with the introduction of multimodal datasets (Lippe et al., 2020). In general, the focus has been shifted to BERT-based models (Afridi et al., 2020). In Facebook AI's Hateful Memes Challenge (Kiela et al., 2021) the top two models involved an ensemble of four Transformer-based models (Zhu, 2020; Muennighoff. 2020). The third and fourth place used fine-tuned VisualBERT (Velioglu and Rose, 2020) and UNITERT (Hossain et al., 2021) models. Aggarwal et al. (2021) extracted image features with a pretrained ResNet-152 model while passing the text data through Facebook's FastText encoder (Bojanowski et al., 2017), concatenating both feature vectors and passing them to a fully connected layer for classification. Due to its novelty, few solutions to date have explored the use of CLIP in challenging scenarios such as misogynistic memes classification. For this work, we trained a version of CLIP resembling Shariatnia's (2021).

3 System Overview

Our system architecture is a variation of OpenAI's CLIP model (Radford et al., 2021). We refer readers to the original paper for a detailed overview and illustrations of the architecture, and summarize it here. Inspired by the idea of usability and generality, CLIP uses a contrastive learning objective to build a joint visual-linguistic space for learning visual concepts from natural language supervision. We describe the various components of our architecture below.

3.1 Encoders

ResNet-50: OpenAI's best CLIP performance was achieved using a pretrained encoder which the authors called ViT-L/14@336px. In our case, we experimented with several pretrained image encoders. Although Shariatnia (2021) used ResNet-50 by default, we also considered ViT-B/16@224px, ViT-L/16@224px, and ViT-L/16@384px (Dosovitskiy et al, 2020). Nonetheless, we empirically determined that ResNet-50 (He, 2016), a deep CNN trained on more than a million images from the ImageNet database with an objective of classifying images into 1000 categories, yielded the best performance.

DistilBERT: OpenAI's CLIP used a modified Transformer to encode text. We instead used a lighter version of BERT (Devlin et al., 2018) called DistilBERT (Sanh et al, 2019) which Shariatnia (2021) also uses. BERT is a large Transformer-based language model that has achieved strong performance in many NLP tasks, and DistilBERT uses a process known as knowledge distillation to reproduce its behavior by training a smaller model to replicate its probability distributions across class predictions.

3.2 Learning Objective

Radford et al. (2021) introduced contrastive objectives as a mechanism for learning multimodal representations from raw images and paired descriptions. In essence, the contrastive objective seeks to learn a multimodal embedding space where image embeddings and text embeddings are

I_1 I_2 ... I_N
$I_1 \cdot T_1$ $I_1 \cdot T_2$ ... $I_1 \cdot T_N$
$I_2 \cdot T_1$ $I_2 \cdot T_2$ ... $I_2 \cdot T_N$
$I_N \cdot T_1$ $I_N \cdot T_2$ ... $I_N \cdot T_N$

Figure 1. Learning stage. Adapted from Radford et al., 2021.

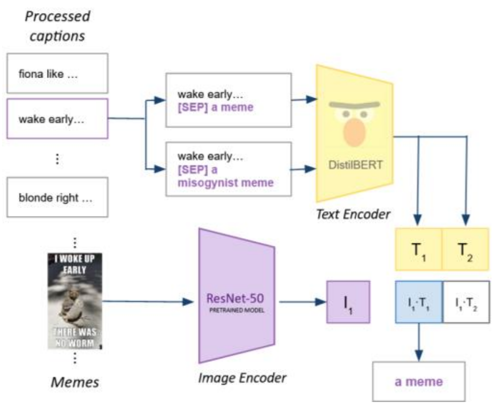

Figure 2. Evaluation stage. Adapted from Radford et al., 2021.

mapped to the same point if they describe the same thing, and different points otherwise. Cosine similarity is used to measure the distance between embeddings. Figure 1 shows the "logits" matrix obtained after applying the dot product between images and text embeddings. Each cell in the matrix (*logits*) is a measure of similarity between an image and a text caption in the dataset (N^2 pairs). It is expected that cells along the diagonal (N pairs), which contain the similarity between an image and its actual text, are maximized. Simultaneously, the $N^2 - N$ incorrect pairs should be minimized.

The *targets* for the images and texts where the similarities are maximum are obtained by computing dot products between embedding matrices. These are averaged and passed through a SoftMax, with the result being a *target* matrix where the diagonal is close to 1.0 and the other pairs are close to 0.0. The loss for images and texts is obtained by calculating the cross-entropy between the target and the logits matrix.

3.3 Training Procedures

The target output for the original CLIP model was the correct caption for an image. For example, one could input an image of a cat along with the captions: {"Image depicting a cat," "Image depicting a dog"} with the expectation that it would return the correct caption. We refer readers to the original paper for further implementation details.

We slightly modified this approach in our own model, such that the training text instead was the language content from the meme followed by the correct label. We separated the text and label using the [SEP] token as defined for BERT's next-sentence prediction objective. Therefore, we concatenated each instance with the following sentences depending on the example's class:

1. For class MISOGYNY: <text_1> + "[SEP] a misogynist meme"
2. For class NOT MISOGYNY: <text_1> + "[SEP] a meme"

When evaluating new samples using this architecture, each instance must be a paired image and text caption. Thus, we created two versions of each text caption: one for class MISOGYNY, and one for class NOT MISOGYNY. Figure 2 shows the procedure. The predicted label for the test instance was the one for which the model made its prediction with higher confidence.

4 Experimental Setup

4.1 Exploratory Analysis

Prior to conducting our experiments, we performed preliminary descriptive analyses on the training data, comprising 10,000 memes (image + paired text content) with a total vocabulary of 12,611 tokens. From these, 6,649 tokens only appear once. Figure 3 shows a word cloud for the 100 most frequent words in the corpus. Interestingly, we determined that the vocabulary for non-misogynist memes is much richer, including 9,285 compared to 7,348 unique words. We also observed that while the word "woman" is repeated 1,416 times in the misogyny class, it is repeated only 528 times in the not misogyny class.

Aiming to find greater insights we computed the Pointwise Mutual Information (PMI) score for all words given each class. PMI is a feature scoring metric that can be used to estimate the association between a feature and a class (it has also traditionally been used to identify collocations in text). A close association indicates which features

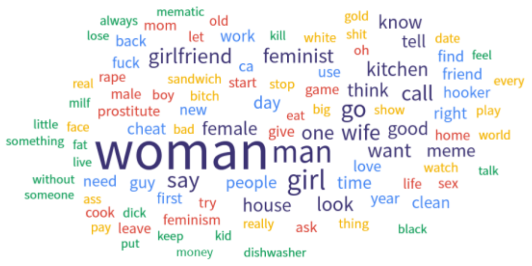

Figure 3: Word cloud of the 100 most frequent words in the corpus. *Warning: This image includes language that may be offensive or upsetting.*

(words) are more important for a class. PMI is computed using the following formula:

$$PMI(w,c) = \log\frac{p(w,c)}{p(w).p(c)} = \log\frac{p(w|c)}{p(w)} = \log\frac{p(c|w)}{p(c)} \qquad (1)$$

Table 1 shows the 15 words with the highest PMI for each class. As shown, despite its frequency, the word "woman" carries less value when measured via PMI. Some swear words are classified as important for the MISOGYNY class, but not the NOT MISOGYNY class.

4.2 Preprocessing

A large challenge in this task was that since the text content from memes was extracted with an OCR tool, it contained substantial noise. Therefore, we created the following preprocessing pipeline that we applied to all texts before training and evaluating:

1. **Case Normalization:** All text was normalized by converting it to lowercase.
2. **Part of Speech (POS) Tagging:** POS tags were assigned to each word.
3. **Proper Name Removal:** Regular expressions were applied to convert some wordforms (e.g., urls) to generic tokens.
4. **Special Token Categorization:** Words belonging to several word sets of interest, including *celebrity names* and *profanity terms*, were kept.
5. **Lemmatization:** Words were converted to their base forms.
6. **Stopword Removal:** Highly frequent words (e.g., "the") were removed.
7. **Special Character Removal:** Non-alphabetical characters (e.g., digits or punctuation) were removed.

Aspects of this preprocessing pipeline were similar to those reported by Cardoza (2022) and

Misogynist			Non-Misogynist	
Token	**PMI**		**Token**	**PMI**
dishwasher	0.660357		gold	0.591098
sandwich	0.599215		house	0.587787
rape	0.567609		cheat	0.470893
feminist	0.560566		clean	0.457903
fat	0.479573		call	0.456758
feminism	0.478848		people	0.430466
girl	0.453501		cook	0.407265
bitch	0.425832		game	0.40027
woman	0.403349		kid	0.394994
always	0.291434		girlfriend	0.391106

Table 1: Top 15 PMI scores. *Warning: This table includes language that may be offensive or upsetting.*

Kovács et al. (2020). POS tagging allowed us to target the "proper noun" and "other" tags. By excluding these tags, we resolved many lingering issues following application of regular expressions, such as remaining usernames and gibberish words. Removing specific instances of these terms aided the model in avoiding overfitting to superfluous names or unknown tokens that were irrelevant to the overarching task of recognizing misogyny. Since certain terms removed by our POS filtering may carry importance to the task (e.g., certain celebrity names or swear terms), we also searched for these terms in several predetermined word sets and kept them if and when they were found.

4.3 Experimental Settings

The training set provided by the task organizers was divided into training (80%) and validation (20%) sets of 8000 and 2000 examples respectively. We primarily adapted our hyperparameter settings from Shariatnia (2021), using AdamW (Loshchilov and Hutter, 2017) as our optimizer with an initial learning rate (LR) of 1e-3 and a scheduler to reduce the LR on plateau. The batch size is left at 32 and the maximum number of epochs was set to 4. The model converges quickly, so this early stop helps to control overfitting. The learning rates for the image and text encoders were left at 1e-4 and 1e-5 respectively. All of the texts were tokenized using the DistilBERT base model with a max number of tokens set to 200. We experimented with CLIP's temperature hyperparameter, finding that the best results were achieved with a value of 1e-0.2.

We selected the best epoch and the best hyper-parameters as measured by F_1 score and accuracy. In the test set evaluation, Subtask 1 systems were evaluated using macro-averaged F_1; thus, the final score is the mean of the F_1 for the two classes.

Development			
	Precision	Recall	F1
Non-Misogynist	0.66	0.71	0.68
Misogynist	0.69	0.64	0.66
Accuracy			0.67
Evaluation			
	Precision	Recall	F1
Non-Misogynist	0.73	0.43	0.54
Misogynist	0.60	0.84	0.70
Accuracy			0.64

Table 2: Results on the development (from training data) and evaluation (from test data).

5 Results

During development we used the training data provided by the MAMI task. We divided it into training (90%) and test (10%) sets, and measured performance using F1, accuracy, precision, and recall on the 10% test set. We provide our results on the development data in Table 2. Once the official test set was released (*Evaluation* in Table 2), we computed the same metrics on that set. The macro-averaged F1 as returned by the task organizers was 0.62, with the system ranking 71st in performance.

5.1 Quantitative Analysis

We briefly analyze our best models' results on the test set for Subtask 1. In particular, we observe a fairly low recall for the NOT MISOGYNY class (0.43), indicating that the system may be struggling to capture all members of this likely more diverse class. As further highlighted in the confusion matrix in Figure 4, the model classifies 28.6% of the NOT MISOGYNIST memes as MISOGYNIST. Thus, most errors were false positives.

5.2 Error Analysis

When manually analyzing the misclassified instances, we observed that they were diverse, containing cartoons, animals, people, drawings, and more. Some images contained text that was unrelated to the caption, creating additional noise. Examples of these images are shown in Figure 5. Several recurring themes occurred among false positives and false negatives, which we summarize below:

False Positives: Most images that were incorrectly classified as misogynistic were primarily dominated by one or more people. For images where humans were not present, the text

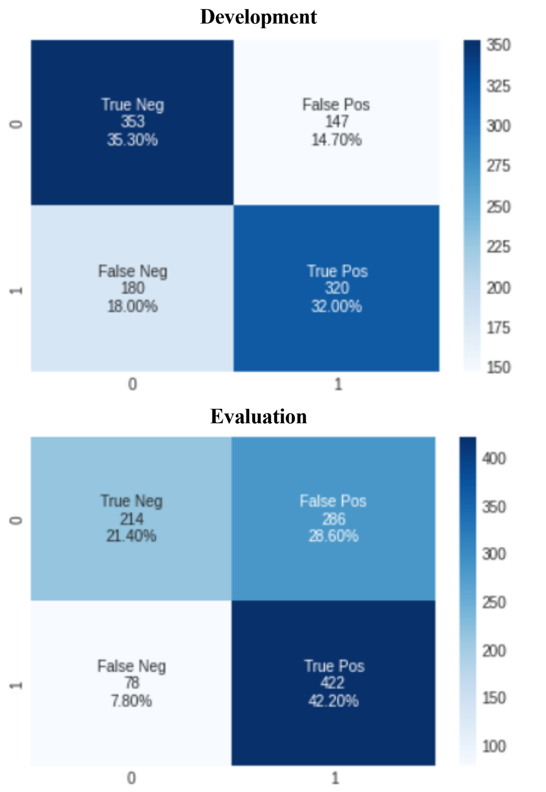

Figure 4: Confusion matrices for the development and evaluation data.

often contained swear words or synonyms for "woman," some of which were offensive although not employed with purposeful misogyny.

False Negatives: Most images that were incorrectly classified as not misogynistic contained cartoons, animals, storyboards or non-explicitly sexist images, although women were occasionally present.

To address these errors, we recommend actions leveraged in prior work for other tasks to improve the performance of future systems. For instance, Lippe et al. (2020) upsampled their dataset as a solution for poor performance on text confounders. Although the dataset they used (Facebook's Hateful Memes) was specially designed to introduce benign confounders, it might also work in this problem. Nozza et al., (2019) discuss biases introduced in the model by a set of identity terms that are frequently associated with the misogynistic class (e.g., "woman"). The authors propose to upsample the dataset with examples that have the identity terms for the alternate class.

6 Conclusion and Future Work

In this paper, we describe our system implementation for SemEval-2022 Task 5. Our

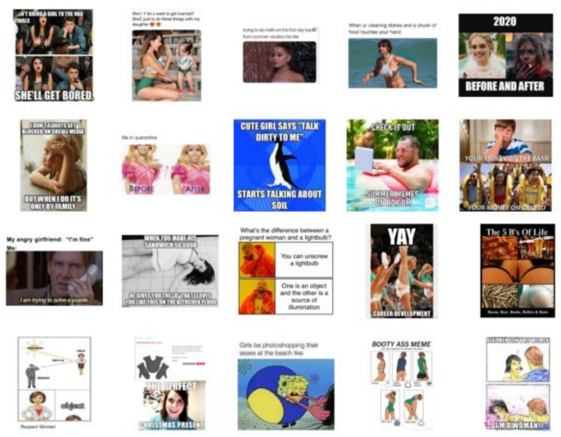

Figure 5: False positives (top 10) and false negatives (bottom 10). *Warning: This image includes content that may be offensive or upsetting.*

model ranked 71st out of 83 participants' teams on Subtask 1. We comprehensively investigate the use of a state-of-the-art multimodal contrastive learning approach for the classification of misogynistic memes. More experiments and tests should be done to improve the model's performance on this task. In particular, upsampling the dataset and addressing the possible biases caused by identity terms should be investigated. Finally, at an architectural level, our current system encodes images as one form of input and encodes paired text content and labels as another form of input, similarly to text encoding strategies used for unimodal sequence prediction tasks. Exploring joint encodings of image and paired text content as a single form of input, with only labels as the other form of input, may be an additional design avenue worth pursuing. Overall, it is our hope that this work motivates additional interest in contrastive learning solutions for multimodal misogynistic meme detection. We make our source code[1] available to other researchers to facilitate follow-up work by others.

Poirot at SemEval-2022 Task 5: Leveraging Graph Network for Misogynistic Meme Detection

Harshvardhan Srivastava
Oracle India
Indian Institute of Technology, Kharagpur
harshvardhan.srivastava@oracle.com

Abstract

In recent years, there has been an upsurge in a new form of entertainment medium called memes. These memes although seemingly innocuous have transcended the boundary of online harassment against women and created an unwanted bias against them. To help alleviate this problem, we propose an early fusion model for the prediction and identification of misogynistic memes and their type in this paper for which we participated in SemEval-2022 Task 5. The model receives as input meme image with its text transcription with a target vector. Given that a key challenge with this task is the combination of different modalities to predict misogyny, our model relies on pre-trained contextual representations from different state-of-the-art transformer-based language models and pre-trained image pre-trained models to get an effective image representation. Our model achieved competitive results on both SubTask-A and SubTask-B with the other competing teams and significantly outperforms the baselines.

1 Introduction

Meme culture in today's virtual climate gives us a variety of insight into the pop culture, general ideology and linguistic conversational manner of the generation. To understand the internet culture, it becomes essential to study memes (Shifman, 2013) and the impact it has on people on the internet. Some of the most popular communication tools on social media platforms are memes. Memes are essentially images characterized by the content of a picture overlaid with text that was introduced by people with the main purpose of being interesting and ironic. Women have a strong presence online, especially on image-based social media like Twitter, Snapchat, and Instagram. 78% of women use social media several times a day, compared to 65% of men (Fersini et al., 2022). While new opportunities are being opened up for women online, systematic inequality and discrimination are being replicated offline from these online spaces in the form of offensive content for women. Most of them were created to make funny jokes, but soon people began to use them as a form of hatred for women, leading to sexist and offensive messages in the online environment, and as a consequence, the sexual stereotyping and gender inequality of the offline world where sexuality stereotypes and gender inequality have been strengthened. This insensitive and obscene type of meme has a profound effect on a person's mental health and can exhibit harmful effects on cognitive and emotional processes leading to mental illnesses as shown in Paciello et al. (2021).

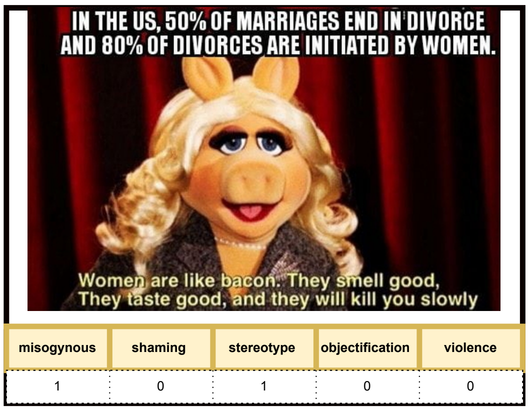
In this work, we present team Poirot's solution to SemEval - 2022 Task 5 competition as described in detail in Fersini et al. (2022). We focused our efforts on our primary approach of building a Multi-Modal module that uses features from both images and text. Furthermore, in this paper, we provide ablation studies on different modalities, relative importance of the different modalities and some training parameters, and show how by changing the module parameters, the predictions on the misogynistic identification of memes aggravates or allays.

2 Background

2.1 Task Description

The organisers have provided us with data tasked with the identification of misogynous memes, taking advantage of both text and images available as source of information. The task is comprised around two main sub-tasks:

- Sub-Task A: first task about misogynous meme identification, where a meme is categorized in a binary format; either as misogynous or not misogynous;
- Sub-Task B: second task, where the type of misogyny is recognized among potential over-



IN THE US, 50% OF MARRIAGES END IN DIVORCE AND 80% OF DIVORCES ARE INITIATED BY WOMEN.
Women are like bacon. They smell good, They taste good, and they will kill you slowly
misogynous

Figure 1: Misogyny in meme

lapping categories such as stereotype, shaming, objectification and violence as described in (Fersini et al., 2022).

The sub-tasks are arranged in an increasing range of difficulty. The competition is challenging, as identifying the misogynous nature of a meme is more complex in a multi-modal setting than performing the same task only on textual data. For memes, comprised of image and text information, a multi-modal approach for understanding both visual and textual cues is needed. Also, in sub-task B, the nature of problem difficulty is increased as the type of misogyny has to be identified, which can belong to multiple categories due to the nature of the dataset.

2.2 Dataset

The datasets for the competition provided by the task organisers are memes collected from the web and manually annotated via crowdsourcing platforms (Fersini et al., 2022). Each sample is supported by an image and the corresponding text transcription (if it exists) on the image. An example of the sample is given in Figure 1. The statistical information about the datasets can be found in Table 1.

Additionally, we provide a quick look into the training dataset which has a significant data imbalance for *4* of labels in a number of samples belonging to each of the *4* given labels except the label "misogynous". This imbalance affects the performance of the models on the test set specially in the case of multilabel prediction as not equal training instances are available for each of the classes. The information about the number of samples belonging to each of the 5 classes for the training set is given in Table 1. This dataset imbalance is dealt with in section 3.3.

2.3 Evaluation Criteria

The teams' performance is evaluated by the macro F1 score for task A. For tasks B, the weighted F1 score is computed for each subtask (misogynous, shaming, stereotype, objectification, violence)(Fersini et al., 2022), and the average F1 score of these subtasks is used to rank the systems.

2.4 Related Work

Earlier, some other meme datasets have been created like the dataset created in Oriol et al. (2019) with the intention of automatically detecting hate speech, and the hateful memes dataset by Facebook (Kiela et al., 2020), which created a challenge set for multimodal classification of hatred in memes. Previous work encompassing categories like hate speech, sexism, and toxicity detection in memes has primarily been explored from a textual perspective using Natural Language Processing(NLP). However, recent methods are aiming to use multimodal approaches to solve the issue at hand. VL-BERT(Su et al., 2020) used the single-stream architecture, where a single Transformer is applied to both images and text. ViLBERT(Lu et al., 2019) and LXMERT(Tan and Bansal, 2019) introduced a two-stream architecture where two transformers are applied to images and text independently and later merged by a third transformer. ERNIE-ViL(Yu et al., 2021) incorporates structured knowledge obtained from scene graphs to learn joint representations of vision-language. Zia et al. (2021) presents the multimodal pipeline based on pre-trained visual and textual representations for the shared task involving the detection of hateful memes.

Set	Number of Samples
`Trial`	100
`Train`	10000
`Test`	1000

Label	Positive Samples
misogynous	5000
shaming	1274
stereotype	2810
objectification	2202
violence	953

Table 1: Dataset and Labels Information

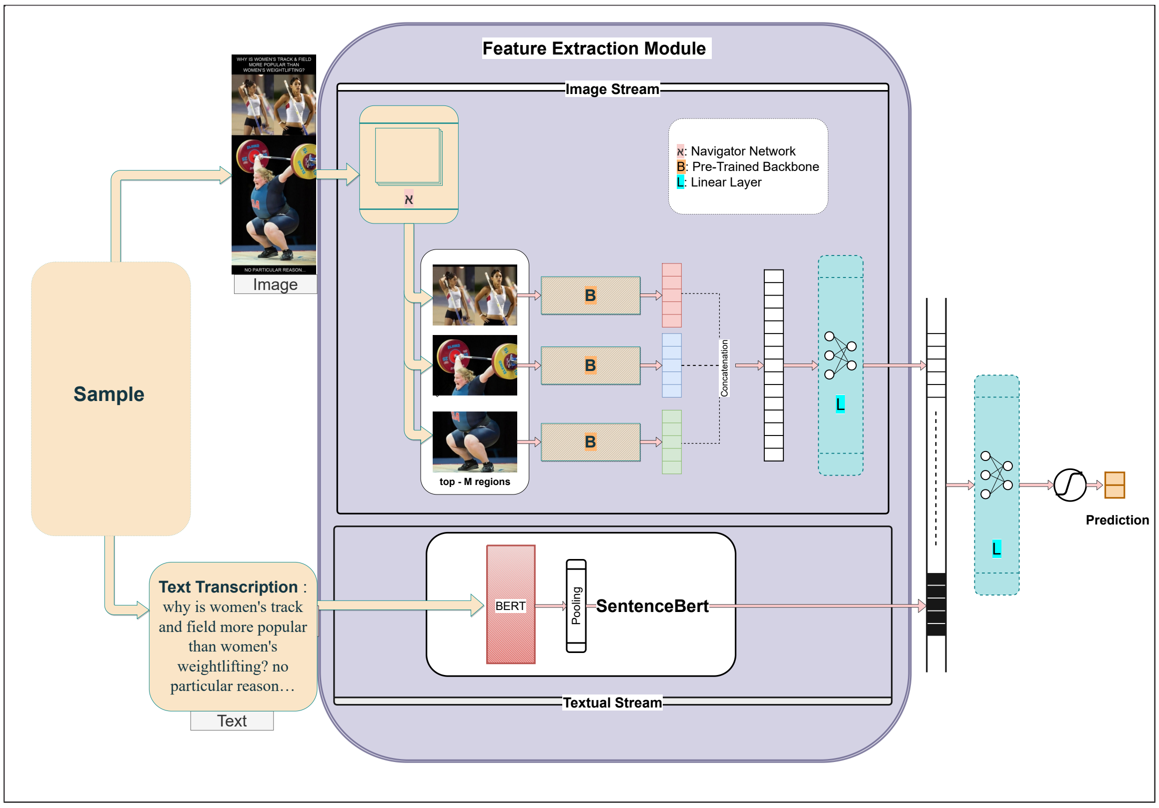

Figure 2: Overview of the binary model used for misogyny detection. The two modalities are passed simultaneously through the Feature Extraction Module in two separate paths and trained together and finally fused together and passed through a linear layer to get binary logits.

3 System Overview

The solution system comprises of 2 separate systems for both the sub-tasks. The approach can be broadly divided into binary approach and multi-label approach.

3.1 Binary Model

Broadly, the model consists of two modal information streams, text and image. The proposed approach leverages on multi-modal information to provide the classification of a sample. We exploit text transcriptions written in natural language jointly with visual information coming from the meme image. In the initial stage the pipeline is divided into two streams running in parallel which on later stage is joint together. The outline of the proposed architecture is shown in Figure 2. The sub-modules are described below:

1. **Image Features Extraction** : This stream is also separated into two sub-modules :
   - *pre-trained Representation Module* : We can use any backbone CNN base models to learn the features of an image. For our experimentation, we use ResNet-101 and ResNet-50 (He et al., 2016) as the backbone *B* model. The rationale behind choosing two separate backbone models is to compare generalised image representation as compared to domain-specific image representation in this case where outright misogyny in images can be detected quickly by looking at nsfw content in the image part of the meme. Thus if the input image $I \in \mathbb{R}^{d \times d}$, where d = 224, the output of the feature extractor would give us intermediate level features $\kappa \in \mathbb{R}^{D}$, where D = 2048,

$$\kappa = B(I)$$

   - *Navigator Module* : We use Navigator Module from the NTS-net as described in (Yang et al., 2018) model to decouple the image into several parts. For an input image, the image is fed into the Navigator network to compute the informativeness of all regions. It is fed to the navigator network, which extracts meaningful parts to separate *top-M* regions. The feature extractor extracts its deep feature map for each of those parts. These features are then concatenated C together:

$$\kappa_i = \aleph(I), i \in [0, M-1]$$

$$f_v = C(\kappa_0, \kappa_1, \kappa_2, ..., \kappa_{M-1}) \in \mathbb{R}^{M \times D}$$

2. **Text Features Extraction:** : The second modality being the textual Stream, uses the SentenceBERT model (Reimers and Gurevych, 2019). SBert modifies the BERT network using a combination of siamese and triplet networks to derive semantically meaningful embedding of sentences. As a state of the art language model, BERT has greatly influenced results in the text classification task as shown in Minaee et al. (2021), we use SentenceBert S model trained on Siamese BERT networks. Thus we convert the given text T transcription into features vector f_t. Formally :

$$f_t = S(T) \in \mathbb{R}^E$$

where E = 768.

The image extraction part and text extraction part is clubbed together to form the **Feature Extraction Module**. If C_{mc} is multimodal feature concatenation logic, then,

$$F = C_{mc}(f_v, f_t)$$

This module outputs a feature vector of size $N = E + D$ features. These features are then passed through a f(linear layer) to output logits which are then passed on to σ function to generate predictions.

$$y_{pred} = \sigma(f(F))$$

3.2 Multi-Label Model

The multi-label model, keeps the feature extracting pipeline of the network in the binary model intact while changing the final output method by using Graph Neural Networks. The model consists of two essential parts : (i) Feature Extraction Module and (ii) Graph classification module. The overall architecture of our model is explained in the Fig. 3.

1. **Feature Extraction Module** : Same as in binary model 3.1

2. **Graph Classification Module** : A graph has an effective message passing system, which can be modelled to find the inter-dependency of the labels amongst each other, and hence, efficiently capture the semantic importance of a label u_1 depending on co-occurring label u_2. We represent each node of the graph input to be a label, having the node features as GloVe embedding having *e* features. Formally, we use Graph Network to learn the multi-label classification model to learn label representation:

$$L_{n+1} = \phi(L_n, A)$$

where $L_n \in \mathbb{R}^{u \times e}$ represents class label representation at *nth* graph layer, ϕ represents the message passing network and $A \in \mathbb{R}^{u \times u}$ represents the adjacency matrix. Through stacking multiple Graph Network Layers, we model the complex inter-relationships among classes.

Creation of Adjacency Matrix : We calculate the label adjacency matrix $\mathbb{A}$ by mining label co-occurrence patterns in the training and trial dataset. Let the label matrix $L_m \in \mathbb{R}^{n_s \times u}$, where n_s are the number of training and trial samples. Then the co-occurrence matrix

$$A_{coo} = L_m^T \times L_m \in \mathbb{R}^{u \times u}$$

To create the adjacency matrix from the co-occurrence matrix and to remove the self node loop from the graph, we create a vector $N_u \in \mathbb{R}^u$, having

$$N_u[i] = A_{coo}[i][i]$$

Finally, the adjacency matrix $\mathbb{A}$ can be constructed as:

$$A_{ij} = \begin{cases} 0 & \text{if } i = j, \\ \frac{A_{coo}[i][j]}{N_u[i]} & \text{otherwise} \end{cases}$$

3.3 Multi-Label Classification Loss

We notice the imbalance present in data for different classes which we can see in Table 1, but the extent of imbalance is different for different labels.

Multi-Label Loss

Figure 3: : The general architecture of our Multi-Modal-Multi-Label model. We use image features and text features from the *Feature Extraction* (FE) which has a pre-trained ResNet, pre-trained sentence transformer SBert. The features are passed through a 5-layer classifier stack generated from the Graph Classification Module which takes input the label's semantic information to generate the output multi-label prediction.

This knowledge can be passed to the neural network in terms of class weights in order to penalize adequately. Let n_s be the number of samples in the dataset. We calculate the weighted importance of a class using the below equations:

$$W_p[i] = \frac{N_p[i]}{n_s}, W_n[i] = \frac{N_n[i]}{n_s}$$

where $N_p[i]$, is the number of positive samples for class *i* and $N_n[i]$, is the number of negative samples for class *i*.

$$-dl = W_p * y * \log(p) + W_n * (1 - y) * \log(1 - p)$$

where y is the ground truth and p is the predicted output. The calculated weights are shown in table 2.

	Weights	
Label	**Positive** (W_p)	**Negative** (W_n)
misogynous	1.000	1.000
shaming	3.924	0.573
stereotype	1.779	0.695
objectification	2.270	0.641
violence	5.246	0.552

Table 2: Calculated weights for regularizing cross-entropy loss in the custom loss function

4 Experimental Setup

4.1 Baselines

We use the baseline provided by the task organisers [1] which depend on the Sub-Task and use a different set of features for different tasks:

1. Sub-Task A: Misogynous Meme Identification
   - ***Baseline-Text***: deep representation of text, i.e. a fine-tuned sentence embedding using the USE(Cer et al., 2018) pre-trained model
   - ***Baseline-Image***: deep representation of image content, i.e. based on a fine-tuned image classification model grounded on VGG-16(Liu and Deng, 2015).
   - ***Baseline-IT***: concatenation of deep image and text representations, i.e. based a single layer neural network.
2. Sub-Task B : Type of Misogynous Meme Identification

[1] https://github.com/MIND-Lab/MAMI

- ***Baseline-Flat***: a multi-label model, based on the concatenation of deep image and text representations, for predicting simultaneously if a meme is misogynous and the corresponding type
- ***Baseline-Hierarchical***: a hierarchical multi-label model, based on text representations, for predicting if a meme is misogynous or not and, if misogynous, the corresponding type.

4.2 Hyperparameters and Implementation Details

Before passing the text transcription to the text stream, we apply some basic text preprocessing to all our sentences. First, we normalize all the sentences by converting all white-space characters to spaces. Also, in the image stream, before passing the image to the navigator network, we resize the image to size [224,224] for uniformity and perform random crops and flips before feeding it to the network. When concatenating the image features with textual features, we use a parameter λ to combine the two together. The final feature vector is formulated as following,

$$F = [(1 - \lambda) \times f_v; \lambda \times f_t]$$

We adopt a 2-layer graph network for our best performing system. For node features, we use the 300-Dimensional GloVe embeddings (Pennington et al., 2014) trained on the Wikipedia Dataset. Table 3 contains the list of general hyperparameters we used. We implement the network based on PyTorch.

Parameter Name	Value
Optimizer	AdamW
Pre-Trained BERT LR	2e-4
Navigator Network LR	1e-3
Graph Learning Rate	1e-2
Graph Layer 1 Dim	512
Graph Layer 2 Dim	2048
λ (Concatenation Parameter)	0.7

Table 3: Major hyperparameters used

5 Results

Table 5 and 6 compares the macro and weighted f_1 scores of our best performing models on the binary classification task and the multi-label task respectively alongside the score achieved by the baseline models. We also present several ablations for the best performing models on λ parameter and its effect on the final score achieved by the model. The λ ablations can be found in Table 4.

		Binary	**Multi-Label**
Backbone Model	λ	f_1^{macro}	$f_1^{weighted}$

	3-layer	**0.643**
	4-layer	0.629
	5-layer	0.621

Table 7: Graph Network Depth effect on model performance

For Subtask-A, the models that used multi-model training and an additional navigator network on the image end outperformed the single modality models and the simple multimodal concatenation model. One of the major reasons for our model outperforming the image-only baseline model could be that the navigator network learns to recognise relevant parts of the image as compared to passing the complete image as one. Amongst the model using *ResNet* backbone, the model fine-tuned on *nsfw* had an edge over the model which had been pre-trained on *imagenet* dataset. This can indicate that there is an indicator of women's image representation with the meme being a misogynistic one.

Subtask-B: The results of the experiments for the multi-label classification task can be seen in Table 6. For Subtask-B, the models that used graph network to create independent classifiers and an additional navigator network on the image end outperformed the models using the simple multi-modal concatenation model with classification head and the hierarchical multi-label model using text representations. Amongst the model using *ResNet* backbone, the model fine-tuned on *nsfw* dataset performed poorer to the model which had been pre-trained on *imagenet* dataset. This can be an indicator that general feature representations are perhaps more important for the identification of the specificity of misogyny as compared to that of the fine-tuned feature representations.

5.2 Ablation Studies

In this section, we perform ablation studies from two different aspects, particularly including the sensitivity of the classification models to effects of λ when concatenating the two different types of modalities, visual and textual together, to determine the relative importance of the two with respect to each other, and the other being the depths of Graph Classification Module which we use for the multi-label classification model.

Effects of different threshold values λ : We vary the values of the threshold concatenation parameter λ from 0.1 to 0.9 in steps of 0.1. $\lambda = 0$ corresponds to building the entire feature vector from the visual stream while $\lambda = 1$ corresponds to the entire information coming from the textual stream. The results are shown in table 4, where the performance of the two models based on ResNet-101 backbone are compared pre-trained on two different datasets. It can be observed that the textual stream information is of higher importance in both the classification problem as the performance boost is skewed for roughly $\lambda = [0.6, 0.7]$. It may be due to the fact that in the images as well, a good amount of information that is used to recognise the misogyny of the meme is cognitively of the textual nature, while the image content of the meme is lesser in comparison to its textual counterpart. It may also be that the image content is not of high quality.

Effects of different depth of Graph Classification Network: We vary the values of the number of layers of the graph network from 2 to 5 and observe its effect on the model performance. For the two-layer model, the output dimensions of the layers are 512, 2048, for the three-layer model, the output dimensionalities are 512, 1024 and 2048 for the sequential layers, for the four-layer model, the dimensionalities are 512, 1024, 1024 and 2048, and for the five-layer model, the output dimensions are 512, 1024, 1024, 1024, 2048. As shown in table 7, when the number of graph convolution layers increases, multi-label recognition performance drops on both datasets. The possible reason for the performance drop may be that when using more GCN layers, the propagation between nodes will be accumulated, which can result in over-smoothing.

Effects of using Custom Loss Function: We compare the results for multi-label classification with two types of losses : (i) MultiLabel Soft Margin Loss (`SM Loss`); (ii) Custom Loss as described in 3.3. From table 6, we can see that the `Custom Loss` out performs the `SM Loss` in the experimental runs.

The result can be explained by the fact that weighted classes affect the loss value for positive as well as negative labels.

(i) If the model predicts a positivity for the label which has a higher positive weightage the loss value would increase, thereby forcing the model to not favour one particular label. Similarly, when the model predicts a negative value for a particular label that has a higher negative weightage, the loss value would increase, forcing the model to not favour negativity of a particular label.

(ii) If the model predicts a positivity for the label which has a lower positive weightage, the loss value would decrease, thereby forcing the model to predict favourably for that particular label. Similarly, when the model predicts a negative value for a particular label that has a lower negative weightage, the loss value would decrease, forcing the model to favour the negativity of that particular label.

6 Conclusion

We have described the systems developed by as to solve the Multimedia Automatic Misogyny Identification challenge at Semeval 2022. In our best performing submission for SubTask-A, we framed the problem as a binary classification task and used two separate streams of information simultaneously to identify misogyny, while for our model for SubTask-B, we tried to find the semantic relation between the type of misogyny and their relative importance to solve the problem for Multi-Label classification. By making use of powerful, state-of-the-art, pre-trained models for text and images, our models were able to achieve a high F1 score for both the tasks. Our best performing model ranked 3rd out of the 10 teams submissions on SubTask-A and 22nd out of 30 team submissions on SubTask-B.

As part of future work, we aim to explore alternate approaches to model the multi-label dependencies using Knowledge-Graph and GAT Networks. Also, there seems to be a problem of oversmoothing when increasing the depth of the Graph Classification Module, which we aim to resolve using effective Normalization layers between the graph layers.

Abstract

iSarcasmEval is the first shared task to target intended sarcasm detection: the data for this task was provided and labelled by the authors of the texts themselves. Such an approach minimises the downfalls of other methods to collect sarcasm data, which rely on distant supervision or third-party annotations. The shared task contains two languages, English and Arabic, and three subtasks: sarcasm detection, sarcasm category classification, and pairwise sarcasm identification given a sarcastic sentence and its non-sarcastic rephrase. The task received submissions from 60 different teams, with the sarcasm detection task being the most popular. Most of the participating teams utilised pre-trained language models. In this paper, we provide an overview of the task, data, and participating teams.

1 Introduction

Sarcasm is a form of verbal irony that occurs when there is a discrepancy between the literal and intended meanings of an utterance. Through this discrepancy, the speaker expresses their position towards a prior proposition, often in the form of surface contempt or derogation (Wilson, 2006).

Sarcasm is present on the social web and, due to its nature, it can be disruptive of computational systems that harness this data to perform tasks such as sentiment analysis, opinion mining, author profiling, and harassment detection (Liu, 2012; Rosenthal et al., 2014; Maynard and Greenwood, 2014; Van Hee et al., 2018). In the context of SemEval, in particular, Rosenthal et al. (2014) show a significant drop in sentiment polarity classification performance when processing sarcastic tweets, compared to non-sarcastic ones. Such computational systems are widely deployed in industry, driving marketing, administration, and investment decisions (Medhat et al., 2014). In the context of Arabic, Abu Farha and Magdy (2021) show the effect of sarcasm on Arabic sentiment analysis systems, where the performance dropped significantly for the sarcastic tweets. As such, it is imperative to devise models for sarcasm detection.

Such models are usually built in a supervised learning paradigm, relying on a dataset of texts labelled as either sarcastic or non-sarcastic. Two methods have typically been used to label texts for sarcasm: distant supervision (Ptáček et al., 2014; Khodak et al., 2018; Barbieri et al., 2014), where texts are considered sarcastic if they meet predefined criteria, such as including the tag #sarcasm; or manual labelling (Filatova, 2012; Riloff et al., 2013a; Abercrombie and Hovy, 2016), where texts are presented to human annotators. However, as argued by Oprea and Magdy (2020a), both methods could produce noisy labels, in terms of both false positives, and false negatives. For instance, when human annotators label texts, they are limited by their subjective perception of sarcasm, which might differ from the intention of the authors of those texts.

In response, we suggest the current shared task, iSarcasmEval[1]. We rely on a novel method of labelling texts for sarcasm, where the sarcastic nature of texts is self-reported by the authors of those texts. Our shared task is also novel in that it includes two languages, English and Arabic, and includes three subtasks. The first subtask, covering both languages, is sarcasm detection as commonly understood: given a text, determine whether or not it is sarcastic. Next, as the sarcastic texts in our English dataset are also further labelled for the ironic speech category that they represent out of the categories specified by Leggitt and Gibbs (2000), the second subtask is: given an English text, determine which ironic speech category it represents, or whether it is non-sarcastic. Finally, for both languages, we also ask authors to provide

[1]iSarcasmEval datasets are available at: https://github.com/iabufarha/iSarcasmEval

non-sarcastic rephrases of their sarcastic texts. As such, the third subtask, covering both languages, is: given a sarcastic text and its non-sarcastic rephrase, identify the sarcastic text.

We discuss related work in dataset creation, and related SemEval tasks, in Section 2. We introduce the data labelling method, and present statistics on the resulted datasets, in Section 3. We provide details on the shared task in Section 4, and on the submissions in Section 5.

2 Related Work

Most previous textual sarcasm detection datasets have been annotated using a **distant supervision** method. In this approach, texts are considered sarcastic if they meet predefined criteria, such as including specific tags (e.g. #sarcasm, #irony) (Ptáček et al., 2014; Khodak et al., 2018), or being generated by specific accounts (Barbieri et al., 2014). However, this can lead to noisy labels for several reasons. First, the tags may not mark sarcasm, but may constitute the subject or object of conversation, e.g. *"there is so much #sarcasm around!"*. Second, the assumption that certain tags always appear in conjunction with sarcasm, or that certain accounts always generate sarcasm (Barbieri et al., 2014), could lead to further false positives. Third, considering those texts that do not meet the criteria as non-sarcastic is a strong assumption that can lead to false negatives.

Due to the issues outlined above, other work has relied on **manual labelling**, where sarcasm labels are provided by human annotators (Filatova, 2012; Riloff et al., 2013a; Abercrombie and Hovy, 2016). As such, the labels represent *annotator perception*, which may actually differ from *author intention*. Annotators might lack awareness of the contextual devices that, as linguistic studies suggest (Grice, 1975; Sperber and Wilson, 1981; Utsumi, 2000), could be essential for clarifying the sarcastic intention of the authors.

Previous shared tasks in sarcasm detection (Van Hee et al., 2018; Ghanem et al., 2019; Ghosh and Muresan, 2020; Abu Farha et al., 2021) present datasets annotated via the two methods discussed above. The potential noisy labels that these methods can produce gives us reason to be concerned about the effectiveness of models that were trained on such datasets. Recently, (Shmueli et al., 2020) proposed a third method, **reactive supervision**, which aims to collect sarcastic examples based on the conversation dynamics, addressing some of these issues by using statements such as "I was being sarcastic" to automatically label texts. However, this method relies on specific cues of sarcasm which may lead to a sample that is biased toward more confusing examples that required clarification.

Further, the vast majority of sarcasm detection work (Campbell and Katz, 2012; Riloff et al., 2013b; Joshi et al., 2016; Wallace et al., 2015; Rajadesingan et al., 2015; Bamman and Smith, 2015; Amir et al., 2016; Hazarika et al., 2018; Oprea and Magdy, 2019) has focused exclusively on the English language and, due to the sociocultural aspects of sarcastic communication (Oprea and Magdy, 2020b), it is unclear if models trained on English could generalise to other languages. To our knowledge, the small amount of work on other languages such as Arabic (Karoui et al., 2017; Ghanem et al., 2019; Abbes et al., 2020; Abu-Farha and Magdy, 2020) relies on either manual labelling or distant supervision. Representative of distant supervision is the work of Karoui et al. (2017), who consider Arabic equivalents of #sarcasm, such as #سخرية, #مسخرة, and #استهزاء, to collect sarcastic tweets. Other work, (Abbes et al., 2020; Ghanem et al., 2019; Abu-Farha and Magdy, 2020; Abu Farha et al., 2021), used either manual labelling, or a mix between manual labelling and distant supervision. When working with Arabic data, these two labelling methods are even more problematic considering the large number of dialects of the language that vary both across and within countries. Relying on predefined tags in modern standard Arabic (MSA), such as those specified above, can thus lead to a plethora of false negatives. Similarly, the third-party annotators might be unfamiliar with the dialect of the texts they are annotating, resulting in erroneous manual labels.

3 Dataset

3.1 Overview

In light of the issues raised in Section 2, we propose the current shared task for sarcasm detection. We introduce a new data collection method where the sarcasm labels for texts are *provided by the authors themselves*, thus eliminating labelling proxies (in the form of predefined tags, or third-party annotators). We use this method to collect two datasets, one in English and one in Arabic.

Within each dataset, for each sarcastic text, we also ask its author to rephrase the text to convey the same intended message without using sarcasm. Finally, for the English texts, we ask trained annotators to further label each text into one of the categories of ironic speech defined by Leggitt and Gibbs (2000): sarcasm, irony, satire, understatement, overstatement, and rhetorical question. For the Arabic dataset, we also include the dialect label of the text. As such, in both datasets, each text has at least the following information attached to it: (a) a label specifying its sarcastic nature (sarcastic or non-sarcastic), provided by its author; and (b) a rephrase provided by its author that conveys the same message non-sarcastically.

3.2 Data Collection

For both English and Arabic, the sarcasm labels of texts, as well as their non-sarcastic rephrases, are provided by the authors those texts. However, the methods in which we reach authors, and how their texts are sourced, differ slightly across the two languages.

For **English texts**, we used the Prolific Academic platform[2] to recruit native English speakers who were Twitter users. We asked these participants to provide links to one sarcastic and three non-sarcastic tweets that they had posted in the past. The tweet labels were, thus, implicitly specified by the authors themselves in the process.

To collect **Arabic texts**, we were unable to find a suitable number of native Arabic speakers through Prolific Academic. Further, through our pilot study, we found that asking for tweets directly resulted in low quality data. Therefore, we used the Appen crowdsourcing platform[3] to recruit native Arabic speakers, and instead of asking for previous tweets, we asked the participants to write a short sarcastic text on the spot. Through our pilot study, we found this on-the-spot generation approach to result in high quality data. However, this methodology only provided us with sarcastic examples. As non-sarcastic examples, we used a subset of the ArSarcasm-v2 dataset (Abu Farha et al., 2021), mainly those tweets that were annotated as non-sarcastic with 100% confidence, i.e. labelled non-sarcastic by all annotators.

For each sarcastic text in **both** the English and the Arabic datasets, we also asked participants to provide an *explanation* of why the text was sarcastic, and a *rephrase* that would convey the same message non-sarcastically. For Arabic, we also collected the dialect label. We included five main dialects: Modern Standard Arabic (MSA), Gulf, Nile Basin, Levant, and North Africa.

While we asked participants to provide examples of *sarcastic* texts, we found that the provided English texts that reflected a range of different ironic speech categories, not just sarcasm. Therefore, in a second annotation stage, we paid a trained annotator to further label each English-language text with the ironic speech categories that it reflected. We adopted the categorisation presented by Leggitt and Gibbs (2000): (1) *sarcasm*: contradicts the state of affairs, is directed towards an addressee, and expresses a critical attitude; (2) *irony*: contradicts the state of affairs, may or may not be directed towards an addressee, but if it is, is not obviously critical towards that addressee; (3) *satire*: is directed towards and addressee whom it appears to support, but underneath it express disagreement, mocking, contempt, or derogation; (4) *understatement*: does not contradict the state of affairs, but undermines its weight; (5) *overstatement*: does not contradict the state of affairs, but assigns unrealistically high weight to it; (6) *rhetorical question*: a question with an implicated answer that contradicts the state of affairs. Note that these categories are not mutually exclusive. A text could belong to more than one category, e.g. it could be both sarcastic, and an understatement. Regarding Arabic, we did not go the next step to include the sarcasm categories. This is because Arabic linguists had similar disagreements regarding the differences between sarcasm and irony (Andalib and Far Shirazi, 2019). Also, it would have been a challenging task to recruit linguists who are familiar with available dialects.

3.3 Test Sets

To construct our test sets, we employed, for both languages, an approach similar to that used to collect training data in Arabic. We chose this method for collecting English test data due to restrictions that were imposed on us by the Prolific Academic crowdsourcing platform on the collection of tweets that belonged directly to survey participants.

3.4 Quality Control

For English, we made sure all tweets were posted at least 48 hours before the survey submission, and came from the same account. Further, a trained an-

Language	**Sarcastic text**	**Unsarcastic rephrased**
EN	Gotta love people who follow you and unfollow because you don't follow them within in an hour or 2. Sorry I don't stay on Twitter 24/7.	I dislike people who follow me, only to unfollow me when I don't follow back right away. I'm not on Twitter that much to follow right away.
AR	محمد صلاح ينقذ سمكة من الغرق، الله على اخلاقك يا فخر العرب (Mo Salah saves a fish from drowning. Amazing manners, you Arabs' pride)	محمد صلاح يحمل سمكة (Mohammad Salah holds a fish)

Table 1: Examples of sarcastic tweets (tweet text) from our English and Arabic dataset along with the rephrase that authors gave that convey the same meaning non-sarcastically (rephrased).

notator consulted all survey responses provided and filtered out spurious sarcastic examples that were either unlikely to reflect sarcasm, or had uninformative explanations as to why they were sarcastic.

For Arabic, the data collection was run multiple times during a period of 8 months. In this stage, we managed to collect around 2,000 sarcastic sentences. After manual inspection, we noticed that a large portion of the texts were not truly sarcastic, or that the non-sarcastic phrasing was not informative. Thus, we hired native speakers for each of the dialects to check texts for sarcasm, and to provide or improve the non-sarcastic phrasing, if needed.

4 iSarcasmEval Details

4.1 Task Description

We formulate three subtasks:

- **Subtask A - Sarcasm Detection**: Given a text, determine whether it is sarcastic or non-sarcastic;
- **Subtask B - Sarcasm Category Classification**: Given a text, determine which ironic speech categories it belongs to, if any;
- **Subtask C - Pairwise Sarcasm Identification**: Given a sarcastic text and its non-sarcastic rephrase, i.e. two texts that convey the same meaning, determine which is the sarcastic one.

Subtasks A and C are suggested for both languages. Subtask B is only suggested for English, as we only have ironic speech category labels for English texts.

4.2 iSarcasmEval dataset

The datasets for both languages are provided as a list of texts. Each text is accompanied by a sarcasm label, indicating whether or not it is sarcastic. For sarcastic texts, there is a rephrase that conveys the same message non-sarcastically. For English sarcastic texts, there is a label specifying the category of ironic speech that it reflects. For Arabic texts, there is a label specifying the dialect. Table 1 shows a sample from our datasets, one in English, and one in Arabic. For English, the training set

split	**total**	**sarcastic**	**non-sarcastic**
train	3,103	745	2,358
test (subtask A)	1,400	200	1,200
test (subtask C)	400	200	200

Table 2: Statistics for the Arabic training set, and test sets for subtasks A and C, as discussed in Section 4.2.

split	**total**	**sarcastic**	**non-sarcastic**
train	4,335	867	3,468
test (subtask A)	1,400	200	1,200
test (subtask C)	400	200	200

Table 3: Statistics for the English training set, and test sets for subtasks A and C, as discussed in Section 4.2.

contains 867 and 2,601 sarcastic and non-sarcastic texts, respectively. Recall that each sarcastic text has an associated non-sarcastic rephrase. These 867 rephrases can be used as additional non-sarcastic examples. The division of sarcastic texts into ironic speech categories in the training set is shown in Table 4. There is a separate test set for each subtask. As such, the test set for subtask A contains 200 sarcastic texts, and a total of 1,200 non-sarcastic texts. The same texts, in the same arrangement, constitute the test set for subtask B. The test set for subtask C contains 200 sarcastic texts, along with their 200 non-sarcastic rephrases. These are presented as pairs, the task being to distinguish the sarcastic text from its rephrase. This information is summarised in Table 3 (training set, and test sets for subtasks A and C); and in Table 4 (training set, and test set for subtask B).

For Arabic, the training set contains 3,103 texts, 745 of which are sarcastic. Similar to English, the sarcastic text have their non-sarcastic phrasing too. The test sets are the same size as the English test sets for both subtasks A and C. Table 2 provides a summary of the Arabic dataset splits. Table 5 provides the distribution of the whole dataset over the available dialects. It is noticeable that the majority of the sarcastic examples are in the Egyptian dialect (Nile Basin). In the future, we hope to have a higher coverage of the other dialects.

split	sarcasm	irony	satire	underst.	overst.	rhet. quest.
train	713	155	25	10	40	101
test (subtask B)	180	20	49	1	10	11

Table 4: Statistics for the English training set, and test set for subtask B, as discussed in Section 4.2.

dialect	total	sarcastic	non-sarcastic
MSA	2,035	82	1,953
Nile Basin	2,072	827	1,245
Levant	322	76	246
Gulf	278	36	242
North Africa	195	124	71

Table 5: Distribution of the Arabic dataset over the dialects.

4.3 Evaluation Metrics

The main evaluation metric for subtask A is the F1-score of the sarcastic class, referred to as $F_1^{\text{sarcastic}}$. It is computed as follows:

$$F_1^{sarcastic} = 2 \cdot \frac{P^{sarcastic} \cdot R^{sarcastic}}{P^{sarcastic} + R^{sarcastic}}, \qquad (1)$$

Where $P^{sarcastic}$, $R^{sarcastic}$ are the precision and recall with respect to the sarcastic class, respectively.

For subtask B, the main evaluation metric is the macro-F1 score over all the categories of ironic speech:

$$F_1 = \frac{1}{n}\sum_{c=1}^{n}(F_1^c) \qquad (2)$$

Where F_1^c represents the F_1 score for the cth category and n is the number of categories.

For subtask C, the main evaluation metric is accuracy. This is appropriate since we have an equal number of sarcastic and non-sarcastic examples.

$$Accuracy = \frac{C}{N} \qquad (3)$$

Where C is the total number of correct predictions and N is the total number of pairs of text.

5 Participating Teams

5.1 Overview

The shared task saw the participation of 60 unique teams. The most popular task was subtask A (sarcasm detection) with 43 participants for English and 32 for Arabic. Subtask B received 22 submissions and subtask C received 16 submissions for English and 13 for Arabic. The following sections provide an overview of the top teams' approaches.

5.2 Subtask A (Sarcasm Detection) - English

Table 6 shows the results for English. We created two baseline models for subtask A. The first one uses the BERT language model (Devlin et al., 2019) to produce contextual representations of the input text, and considers the embedding corresponding to the [CLS] token as the aggregated representation of the input. Finally, this is provided to a classification head whose output we interpret as the probability that the input is sarcastic. We use the implementation provided as part of the transformers library Wolf et al. (2020), and initialise the encoder with the `bert-base-uncased` checkpoint published on the Huggingface model hub [4]. We fine-tune it for a maximum of 100 epochs, but use early stopping regularisation with a patience of 3. We use a learning rate of $5e-5$, and clip the norm of the gradients to 1. This results in a baseline $F_1^{\text{sarcastic}}$ of 0.348, listed as baseline-bert in Table 6. The second baseline uses a support vector machine (SVM), with a polynomial kernel of degree 3, to classify tf-idf representations of input texts. This results in a baseline $F_1^{\text{sarcastic}}$ of 0.275, listed as baseline-svm in Table 6. For both baselines, we consider the rephrases as additional non-sarcastic examples. In a preprocessing step, we remove all hashtags and urls, and replace user handles with the token `@user`.

As shown in Table 6, the team ranking first, `stce` (Yuan et al., 2022), achieved an $F_1^{\text{sarcastic}}$ of 0.605. They use an ensemble learning approach with a combination of hard and soft voting between three models, all based on the transformer architecture: RoBERTa (Liu et al., 2019), initialised with the `roberta-large` checkpoint; DeBERTa (He et al., 2021), initialised with the `deberta-v3-large` checkpoint; and XLM-RoBERTa (Conneau et al., 2020), initialised with the `xlm-roberta-large` checkpoint. XLM-RoBERTa is employed to make use of the Arabic training data for informing the classification of English texts. They experiment with several strategies to achieve their results. First, in addition to the task dataset, they also consider public datasets, including iSarcasm (Oprea and Magdy, 2020a), the dataset published by Van Hee et al. (2018), and a sample of texts from the multimodal sarcasm dataset [5]. Second, they extract statistical

[4] https://huggingface.co

[5] https://github.com/headacheboy/data-of-multimodal-sarcasm-detection

and text features that they concatenate to the text itself before providing it to the models above, such as emoji and part-of-speech information. They also use multi-sample dropout, contrastive loss functions, and adversarial training.

The team ranking second, `X-PuDu` (Han et al., 2022), achieved an $F_1^{\text{sarcastic}}$ of 0.569. They ensemble two transformer-based models: ERNIE-M (Ouyang et al., 2021), and DeBERTa, mentioned above. After providing the input text to the models, they consider the embedding corresponding to the [CLS] token as the representation of the input, which they provide to a classification head. The final ensemble considers not just the individual architectures above, but also the same architecture under different hyperparameter configurations. Using ERNIE-M, they train on both English and Arabic at the same time.

The team ranking third, `TUG-CIC` (Aroyehun et al., 2022), achieved an $F_1^{\text{sarcastic}}$ of 0.530. They use the BERT model mentioned above, but initialised with different `BERTweet` checkpoints, which they fine-tune on the SPIRS sarcasm dataset (Shmueli et al., 2020), before fine-tuning it on the data provided here. They also apply label smoothing.

5.3 Subtask A (Sarcasm Detection) - Arabic

As mentioned previously, the main metric for subtask A is the F-score of the sarcastic class. Table 7 shows the results for Arabic. The participating teams made extensive use of Arabic pre-trained language models such as MARBERT (Abdul-Mageed et al., 2021). We created two baselines for this task, the first is a Bert-based model and the other is an SVM model. We fine-tuned MARBERT for 6 epochs with a learning rate of 5e-5. For the SVM model, we used uni-gram features. Both models were trained without the non-sarcastic phrasing.

As shown in the Table 7, the top team `CS-UM6P` (El Mahdaouy et al., 2022a) achieved an $F_1^{\text{sarcastic}}$ of 0.563. This team utilised a transformer encoder (MARBERT), attention layer, and a classifier. They applied the attention to the contextualised embeddings. The classifier, which is composed of one hidden layer, is fed the concatenation of the pooled output of the encoder and the attention's output. The official submission was an ensemble of two variants of this model that are trained with and without the non-sarcastic rephrasing. `AlexU-AL` (Lotfy et al., 2022) achieved the second place with an $F_1^{\text{sarcastic}}$ of 0.508. Their model is similar to our baseline where the fine-tuned MARBERT for text classification. The results are quite close to our baseline with a small difference that can be attributed to the choice of hyperparameters. The third team, `remarchka` (Abdel-Salam, 2022), also used MARBERT in a similar way to the baseline and `AlexU-AL` team. Their results are quite close to the other two models with $F_1^{\text{sarcastic}}$ of 0.477. The other teams followed a similar approach where they utilise one of the many flavours of Arabic-specific models or the multilingual ones. A few of the participants relied on hand-engineered features along with conventional classifiers such as SVM and Decision Trees.

5.4 Subtask B (Sarcasm Category Classification)

Table 8 shows the results. We created two baseline models for subtask B. The first baseline, listed as baseline-majority in the table, always predicts that the input reflects the ironic speech category of sarcasm, and no other category. This was chosen as it is dominant in the training set, as seen in Table 4. As a second baseline, we use the BERT language model to produce contextual representa-

Table 8: Subtask B results in descending order according to the main metric (macro F-score). The table shows the teams' names, rank, affiliation, and score.

tions of the input text, and consider the [CLS] embedding. We provide this to a classification head with a 6-dimensional output, one corresponding to each category of ironic speech. We apply the sigmoid function to each unit in the classification head, interpreting the output as the probability that the input text reflects the ironic speech category corresponding to that unit. We fine-tune the model in a similar setting as we did for subtask A. This results in a baseline macro F-score of 0.0431, listed as baseline-bert in Table 8[6].

As shown in Table 8, the team ranking first, `PALI-NLP` (Du et al., 2022), achieved a macro F-score of 0.1630. They use an ensemble learning approach, where the weight assigned to a model corresponds to its performance on a validation set. The models they consider are BERT, initialised with the `BERT-base` checkpoint; RoBERTa, initialised with the `RoBERTa-base` checkpoint; and BERTweet, initialised with the `BERTweet-base` checkpoint. Models have a classification head attached that inputs the embedding corresponding to the [CLS] token. They also use adversarial training and multi-sample dropout to improve generalisation.

The team ranking second, `CS-UM6P` (El Mahdaouy et al., 2022b), achieved a macro F-score of 0.0875. They use a model similar to GAN-BERT (Croce et al., 2020). It uses a generator that, conditioned on an ironic speech category, produces fake embeddings from a random noise that would resemble representations of examples from that ironic speech category. A discriminator is trained to recognise real examples from fake ones, while the generator is trained to cause the discriminator to classify fake examples as real. The discriminator is also trained to classify the real examples as either sarcastic, or non-sarcastic.

The team ranking third, `MaChAmp`, achieved a macro F-score of 0.0851. They first we pretrain a RemBERT (Chung et al., 2020) multi-task model across all the tasks. Then, they re-train a model for each task individually. They use the hyperparameters of `MaChAmp v0.3`(van der Goot et al., 2021), which were finetuned on the xTREME benchmark (Hu et al., 2020).

5.5 Subtask C (Pairwise Sarcasm Identification) - English

Table 9 shows the results for English. We used baselines similar to those from subtask A, but modified the input. Specifically, given a sarcastic text and its rephrase, we produced two training examples. The first was the concatenation of the sarcastic text and the rephrase, in this order, separated by a [SEP] token. This example had label 0, indicating the position of the sarcastic text. The second example was the concatenation of the rephrase and the sarcastic text, in this order, and had label 1. The first baseline, shown as baseline-bert in Table 9, achieves an accuracy of 0.765, while the second

[6]The complete results are available in Table 11 in Appendix A. Those include the scores over each sarcasm category.

Table 10: Subtask C (Arabic) results in descending order according to the main metric (accuracy). The table shows the teams' names, rank, affiliation, and score.

one, baseline-svm, achieves 0.495.

As shown in Table 9, the team ranking first, X-PuDu (Han et al., 2022), achieved an accuracy of 0.870. The same team ranked second for task A, and the approach here is rather similar, except for representing the input as we do above. The team ranking second, Naive, achieved an accuracy of 0.855. They used a RoBERTa model, initialised with the RoBERTa-large checkpoint, with a classification head appended. The team ranking third, YNU-HPCC (Zheng et al., 2022), achieved an accuracy of 0.805. They also used a RoBERTa model. They did not use any external datasets during training. We suspect the difference in performance between the second and third teams to be, at least in part, the result of data preprocessing and hyperparameter optimisation.

5.6 Subtask C (Pairwise Sarcasm Identification) - Arabic

Table 10 shows the results of this task. To prepare the baselines, we utilised the models from subtask A. Since the task is to decide which text is sarcastic out of the given pair, we ran the models from subtask A on each sentence and chose the one that had a higher probability of being sarcastic. The top team, Naive (Zefeng et al., 2022), achieved an accuracy of 0.930. They utilised the model created for subtask A, where they would compare the probabilities for each sentence and choose the one with a higher probability. Their model in subtask A relied on the voting of a 5 folds cross-validation of a Bert model. High-Tech team (Hamza et al., 2022) achieved the second place with an accuracy of 0.885. They fine-tuned AraBERT (Antoun et al., 2020) on the concatenation of the sarcastic sentence and its non-sarcastic phrasing. The third team, MarSan_AI (Najafi and Tavan, 2022), achieved an accuracy of 0.875. Their model consisted of a T5 encoder (Raffel et al., 2020) followed by a transformer and Bi-LSTM, the output of the Bi-LSTM is fed to an attention layer followed by a fully connected layer. The final prediction is the softmax of the output from the fully connected layer. The other teams followed the same trend where they utilised the models from subtask A for this task. Most of these models are transformer-based models such as MARBERT and AraBERT.

In general, it is noticeable that the results on Arabic are slightly higher than the ones on English. This can be due to the slight difference in the nature of the data. As mentioned in Section 3.2, the English data are original tweets that the authors wrote before our data collection process. The Arabic data was collected on the fly, and therefore more likely to contain clear signs of sarcasm as the authors were specifically asked to provide new sarcastic and non-sarcastic phrasings.

6 Conclusion

This paper provides an overview of SemEval-2022 task 6, iSarcasmEval, which targets intended sarcasm detection. We provide an overview of the current state of research on sarcasm detection focusing on data collection methods. We introduce two new datasets for sarcasm detection in English and Arabic. The data was collected by asking people to provide and label their own words as sarcastic or not, hence intended sarcasm. iSarcasmEval contains three subtasks: sarcasm detection, sarcasm category classification, and sarcasm identification given a pair of sentences. The task was quite popular with the participation of around 62 teams. In this paper, we provide a high-level overview of the approaches of top teams in each of the subtasks. Transformer models were dominant in all subtasks.

Detecting sarcasm in texts remains challenging; detecting the ironic speech category even more so. We hope our shared task will draw the attention of the community towards these important tasks. We suggest two main directions that future work could consider.

First, in this shared task, sarcasm detection was performed by solely mining lexical and pragmatic cues from the texts being classified. However, the sarcastic intention of the authors might be unclear without reference to their previous utterances, and their sociocultural background (Oprea and Magdy, 2020b). We suggest future datasets are needed to provide access to such information, and future models that account for it effectively.

Second, the low performance achieved by the models on subtask B requires further investigation. First, alternative categorisations could be considered. Second, the ironic speech category labels should either be provided by the authors themselves, to avoid any bias introduced by trained annotators, or more emphasis should be placed on annotator training and annotation guideline clarity, to mitigate labelling noise that might indeed account, at least in part, for the low performance presented here. Finally, more effort is needed to develop more effective models, likely making use of information outside of the texts being classified, including prior assumptions about the nature of ironic speech, sociocultural information about the authors, if available, as well as commonsense facts.

Abstract

This paper describes the method we utilized in the SemEval-2022 Task 6 iSarcasmEval: Intended Sarcasm Detection In English and Arabic. Our system has achieved 1st in SubtaskB, which is to identify the categories of intended sarcasm. The proposed system integrates multiple BERT-based, RoBERTa-based and BERTweet-based models with finetuning. In this task, our contribution is listed as follow: 1) we reveal several large pre-trained models' performance on tasks coping with the tweet-like text. 2) Our methods prove that we can still achieve excellent results in this particular task without a complex classifier adopting some proper training method. 3) we found there is a hierarchical relationship of sarcasm types in this task.

1 Introduction

Generally speaking, when we communicate through natural language, the literal meaning of the words is consistent with the meaning we want to express. Sarcasm is a form of linguistic expression when this "congruence" is broken (Wilson, 2006).

Due to the inherent metaphorical nature and subtle sentimental expression of this particular form of language expression. The detection task related to this kind of text, which is a negative expression of a positive emotion or the positive expression of negative emotion, is extremely difficult for machines (Yaghoobian et al., 2021). This sarcasm data also weakens the detection modules that are widespread in our society (Maynard and Greenwood, 2014).

Previous work shows that sarcasm often comes with incongruity between expectation and reality (Gibbs Jr et al., 1994). Many works attempt to model this incongruity within the text (Tay et al., 2018; Xiong et al., 2019). For multi-model data, some works use the features from different modalities (Schifanella et al., 2016; Cai et al., 2019), and some works shows that inter-modality incongruity is also an important feature for multi-modal sarcasm detection (Pan et al., 2020).

The SemEval-2022 Task6 (Abu Farha et al., 2022) is designed to detect sarcasm and sarcasm types in twitter texts. In Subtask B, if a tweet is not sarcastic, it should not be annotated with any sarcasm label; if it is sarcastic, we need to detect which sarcasm it is, and it could have different sarcasm type at the same time. The main metric of this task is the Macro-F1 score of all sarcasm types.

We design a simple and effective system for this task. The system is based on a large-scale pre-trained model based on bi-directional transformers (Vaswani et al., 2017) and fine-tuned to obtain the final output. First, we augmented the iSarcasm dataset with additional datasets, and then we set an appropriate learning rate for each layer and set the model with an appropriate initialization state. Next, we strengthen the model's generalization ability through adversarial training, multi-sample dropout and other approaches. Finally, we use the [CLS] token of the last layer of the encoder to perform fine-tuning on the final training dataset and ensemble them using the hierarchical way.

2 System Overview

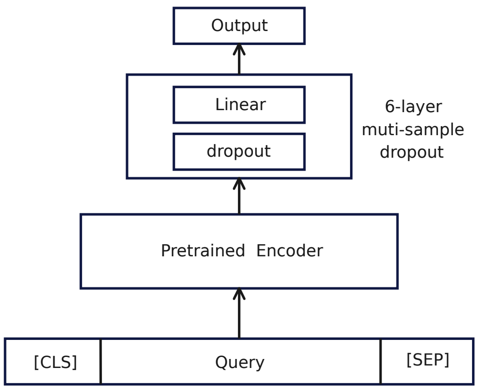

Figure 1: The overall architecture

Figure 1 shows our model architecture. This task is a multi-label text classification task, so we follow the common input format of BERT, that is, using [CLS] and [SEP] as the starting and ending token of the text. In addition to this, we applied data cleaning to the text, replacing "@xxx" with <user>, "#xxx" with <tag>, and "http:xxx" with <url>. It is worth mentioning that we did not do any processing on emojis because we think emojis may be an important feature representing the gap between text semantics and underlying sentiment. These actions are done automatically by the tokenizer. The obtained final token embedding, segment embedding and position embedding constitute the input of the pre-trained model encoder.

In the last layer of the pre-trained encoder, we can acquire the representation of all tokens. In this task, we only select the representation of the first [CLS] token. After that, a layer-norm operation and multi-sample dropout will be utilized on the representation from the encoder. Finally, we use BEC loss as our loss function.

2.1 Pretrained Model

Our submitted architecture integrates three pre-trained language models of different architectures.

BERT-base(BERT) (Devlin et al., 2018): BERT adopts the multi-layer bidirectional transformer encoder to obtain the representation of a query. In the pre-training procedure, BERT conducts two different pre-training objectives. 1. Masked language modelling (MLM) objective. This task predicts a masked token based on a randomly masked input. 2. Next sentence prediction (NSP) objective. The goal of this task is to predict whether the second sentence is the following sentence of the first one.

RoBERTa-base(RoBERTa) (Liu et al., 2019): RoBERTa adopts the same model architecture as BERT and improves the pre-training. It believes that the pre-training of BERT is insufficient, so RoBERTa executes pre-training using longer sentences, more data, and a larger batch size than BERT uses. The author also believes that the NSP task of BERT is redundant and removed NSP from pre-training. Meanwhile, the MLM task is improved at the same time, and the token is dynamically masked during the training process.

BERTweet-base(BERTweet) (Nguyen et al., 2020): BERTweet follows the RoBERTa training procedure, and it is the first large-scale pre-trained language model that uses Twitter texts as a pre-training corpus. Therefore, BERTweet has better performance on tasks related to the tweet-like text.

2.2 Adversiral Training

We also incorporate adversarial training into the training process. The objective of adversarial training is to improve the generalization of the model by perturbing the embedding. For the calculation of this perturbation, we mainly implement two different methods. The Fast Gradient Method (FGM) calculates the disturbance at the moment through the gradient (Miyato et al., 2016), while the Projected Gradient Descent (PGD) executes this process through more steps and additionally adds spherical mapping to prevent the perturbation from being too large (Madry et al., 2017). During the training process, we adopt adversarial training on both the embedding layer and the first layer of the encoder.

2.3 Multi-sample Dropout

Dropout is a common and effective way to increase the generalization of deep neural networks. It can effectively reduce the overfitting of the model by ignoring some neurons in training according to a certain probability. The multi-sample dropout (Inoue, 2019) we use in this paper is an enhanced dropout method. It goes through multiple dropout operations and averages the output obtained by each dropout operation as the final output. In multi-sample dropout, the weights of each dropout layer and classifier layer will be shared, so multi-sample dropout can achieve better results than the original dropout and not bring a significant increase in computational cost.

2.4 Contrastive Loss

Contrastive learning has drawn attention for its' excellent performance. The main idea is to shorten the distance between similar samples(in this task, similar means having the same label) and separate the samples that are not similar. In the SubtaskB, we mainly implement supervised contrastive loss (SupConLoss)(Khosla et al., 2020).

2.5 Ensemble method

For this task, we adopt a hierarchical model ensemble approach. First, we give the models corresponding voting weights based on the performance of each model on the validation set. The weights are calculated as the square root of the inverse of the model's rank among all models. Then we conduct two votes, one for the first two labels (Sarcasm, Irony) and one for the last four labels (Satire, understatement, overstatement, rhetorical question). In this way, we get the final output.

3 Experimental Setup

3.1 Dataset

iSarcasm-2022. Dataset of SemEval-Task6, consisting of tweets text and correspoding sacarsm types. For tweets that are sarcasm, the sarcasm type is given as annotated by language experts, and a single tweet may contain one or more sarcasm types. Along with the sarcastic tweets is the "Rephrase" written by the same poster of the tweet. "Rephrase" contains the same expressive meaning as sarcastic tweets but without sarcasm.

iSarcasm (Oprea and Magdy, 2019). iSarcasm dataset, consisting of tweets texts and correspoding sacarsm types just like iSarcasm-2022. We only leverage the sarcastic tweet which is identityfied as sarcasm. The publisher of sarcastic tweets provides the sarcasm type of iSacarsm. No "Rephrase" is provided.

3.2 Training Details

We fine-tune the pre-train models with batch size 128, sequence length 64,multi-sample dropout of 0.4, threshold 0.2. We set peak learning rate 1e5 for ten epochs and apply layer-wise learning rate Decay for each layer. We set AdamW and Lookahead as our optimizer and set cosine warm-up during the first 0.1 of the updates followed by a linear decay. We conduct validation three times per epoch and perform early stopping. We set the multi-sample layer to six layers and adopt PGD on the embedding and first encoder layers. The training is done on NVidia V100 GPUs. All the F1 result is performance on the test set.

4 Results

Our model performence is shown in Table 1

4.1 Pretrained Model Selection and Data Analysis

We try three transformer-based pre-trained language models in this task, BERT, RoBERTa and BERTweet. From the Table 1 we can see that although RoBERTa achieves better results than BERT, they both perform far worse than BERTweet. The possible reason is due to the difference in the pre-training corpus. The dataset texts of this competition are all tweeted texts of users, and these texts have linguistic features like hashtags and emoji, making them significantly different from standard texts. BERTweet conducts pre-training on tweet texts while BERT and RoBERTa do not have such settings, which leads to BERTweet being better able to handle this particular type of data.

For the fine-tune dataset selection, we extend the dataset provided by the organiser with an additional 777 samples based on the competition requirements that additional data could be used. By analysing the dataset, we found that: 1) The competition dataset reflects a long tail that Understatement, Overstatement, and Rhetorical question are pretty rare. 2) There is an apparent hierarchical relationship between each label. We analysed the combination of labels and found that six labels can be categorised into primary labels (sarcasm, irony) and secondary labels(satire, understatement, Overstatement, rhetorical question). The hierarchical relationship is presented in the Fig 2 . The standard BEC loss and re-weighted BEC loss are tested in this task. The result is shown in the Table 2. Models gain a significantly 10.37% increase in the test set from 0.1417 to 0.1564 of macro-f1 score in the latter setting. We used this system as our baseline.

4.2 Multi-sample Dropout

We experiment with four different multi-sample dropout layer settings, ranging from 2 to 8 layers and the result is shown in Tabel 3. We finally implement 6-layer multi-sample dropout in this task, which achieved 0.1578 in macro-f1 compared to the 0.1564 of baseline.

4.3 Adversiral Training

Tabel 4 display the performance of different adversarial training strategies. We conduct experiments on two common used adversarial training methods and test the effect of the adversarial rate. In the end, we find that PGD is slightly better than FGM as a whole. When the ratio is 0.5, PGD is optimal as adversarial rate 0.5, which increases 1.98% compared to the baseline. If combined with the optimal multi-sample dropout method, the model can obtain 7.10% improvement, reaching a macro-f1 score of 0.1675.

4.4 Contrastive Loss

We experiment with SupCon loss. We can see the result on Tabel 5. There is an indeed decrease when

Model	Macro-F1	F1-SCM	F1-IRN	F1-ST	F1-UST	F1-OST	F1-RQ

`Base`	True	0.1578
`Base+SupCon`	True	0.1670

Table 5: Performance of models applying SupCon loss

performing SupCon loss. However, when multi-sample dropout is adopted along with SupCon loss, it shows excellent results, an increase of 6.77% compared to baseline. See Table 5 for performance of contrastive loss applied.

5 Conclusion

We employ the large pre-trained models and fine-tune them for sarcasm category discrimination. We compare the performance of different pre-trained models on Subtask B of SemEval-2022 Task 6. The results show that the difference between the pre-training corpus and the downstream task corpus will significantly affect the performance of the model. We find that the pre-trained model using the default training settings performed poorly on this task, and good model initialization and training strategies can help improve this situation. We also find that there is a hierarchical relationship between the types of sarcasm which we believe is an important feature worth exploiting.

Abstract

This paper describes the systematic approach applied in "SemEval-2022 Task 6 (iSarcasmEval) : Intended Sarcasm Detection in English and Arabic". In particular, we illustrate the proposed system in detail for SubTask-A about determining a given text as sarcastic or non-sarcastic in English. We start with the training data from the officially released data and then experiment with different combinations of public datasets to improve the model generalization. Additional experiments conducted on the task demonstrate our strategies are effective in completing the task. Different transformer-based language models, as well as some popular plug-and-play proirs, are mixed into our system to enhance the model's robustness. Furthermore, statistical and lexical-based text features are mined to improve the accuracy of the sarcasm detection. Our final submission achieves an F1-score for the sarcastic class of 0.6052 on the official test set (the top 1 of the 43 teams in "SubTask-A-English" on the leaderboard).

1 Introduction

Sarcasm is a sophisticated communication technique to express emotions, attitudes, feelings, and evaluations. Sarcastic and ironic texts typically do not contain words with negative polarity, hostile attitudes, or offensive in their literal sense, but rather express the contradiction or opposite of the literal meanings (Filik et al., 2016; Van Hee et al., 2018; Reyes and Rosso, 2014; Verma et al., 2021). Sarcasm detection can be considered a particular sentiment analysis task, applied to detect texts that are intended to use some exaggeration, understatement, or rhetoric content to express criticism or praise for people or events. Many researchers have conducted different deep learning methods (Poria et al., 2016; Kumar et al., 2020; Zhang et al., 2019), traditional machine learning method (Buschmeier et al., 2014; Hernández-Farías et al., 2015; Yaghoobian et al., 2021), and big data approaches (Bharti et al., 2016; Sarsam et al., 2020; Ortega-Bueno et al., 2019) to improve the accuracy of irony or sarcasm auto-detection.

SemEval-2022 Task 6 (iSarcasmEval) is a sarcasm detection task (Abu Farha et al., 2022). The standard training dataset includes 3468 English tweets and 3102 Arabic tweets. The English training dataset provides 862 sarcastic tweets along with their non-sarcastic rephrases, while the Arabic datasets provides 745 sarcastic samples. For the English dataset, each sarcastic tweet is also labeled as a fine-grained multi-class and multi-label ironic tag such as satire, understatement, overstatement, and rhetorical questions.

SubTask-A is a binary classification task to predict whether a given tweet is sarcastic or not. Table 1 shows one sarcastic tweet and its non-sarcastic version, and one non-sarcastic tweet from the released dataset. We could notice that the raw tweets are pretty noisy and contain user information, URLs, hashtags, etc. Some of the sarcastic tweets also contain sarcastic-related words such as "irony" or "sarcastic" in their hashtags. Many non-sarcastic tweets include confused, unfriendly words or denial attitudes.

In this paper, we demonstrate the following contributions: 1) The discrepancy in prediction performance using different transformer-based language models; 2) The improvement of adding the public dataset and mining effective text features; 3) The enhancement obtained by incorporating various constrative learning loss functions; 4) Model generalization is improved by incorporating the multi-sample dropout layer into the output of pretrained language models. On Subtask-A, our system achieves an F1 score for the sarcasm category of 0.6052 and a Macro F1 score of 0.7675.

2 System Overview

The final submitted result is a contribution from various classification models using the voting mech-

Sarcastic tweet	@PFTompkins Her family should definitely not seek mental health guidance.
Sarcastic tweet rephrase	They should seek guidance.
Non-sarcastic example	I wonder if it's too late for me to re-enroll in University and relive it all just one last time.

Table 1: Sarcastic and non-sarcastic tweet examples

anism. The outcome is a fusion of 15 predictions trained using different transformer-based language models, external datasets, text features, and deep learning-based techniques such as constrastive loss, adversarial training, multi-sample dropout, etc.

The proposed model is trained with a 5-fold cross-validation with a randomly distributed seed. The basic classification model is structured with a multi-sample dropout layer after the pooling layer of the pretrained model. RoBERTa-large, XLM-RoBERTa-large and DeBERTa-v3-large are alternatively adopted in these 15 models. Models are trained using the AdamW optimizer with a learning rate of 1e-05 in the fast gradient method. Four dropout layers with a rate of 0.4 are picked in our multi-sample dropout module. When we make models based on DeBERTa-v3-large, we change the dropout rate to 0.2, which has been suggested by previous studies (He et al., 2020b, 2021).

The cross-entropy loss (L_{Xent}) is used as the classification loss, and the additional XNET loss (L_{NTXent}) with a temperature of 0.2 is selected as the metric learning loss in our system. Equation 1 shows the combination of two types of loss. The weight parameter (w) used to balance the combination of multiple losses is set as 0.1.

$$Loss = (1 - w)L_{Xent} + wL_{NTXent} \quad (1)$$

Additionally, three external datasets are added to the official SemEval-2022 data in the proposed models for further training. Text features are directly concatenated to the training texts in some proposed models as well. The featuring mining, text preprocessing, and the voting method are described below. The scheme of data preparation, training, and prediction processes is demonstrated in Figure 1.

2.1 Pre-processor

The raw English tweets in the official training data contain many noises such as misleading hashtags, usernames, website links, and emojis in different formats. We detected and replaced usernames and links with special tokens. Additionally, we extended some common English abbreviations, such as U, idk, omg, sry, etc. to full-spelled words to keep the whole dataset in the same phase. However, we intend to keep words with unusual capitalization, wrong spelling, and repeated punctuation in raw tweets since people sometimes prefer to express exaggeration and emphasis in this way.

2.2 External Data

Besides the officially released data, we trained the model with three public datasets. The description and the source for additional data are illustrated as below.

(1) The iSarcasm [1] is a public dataset of English tweets. Each tweet is labeled as either sarcastic or non-sarcastic. Each sarcastic tweet is labeled with a fine-grained ironic label as well. We obtained 2279 non-sarcastic and 563 sarcastic tweets using the tweet API (Oprea and Magdy, 2020).

(2) The Multi-modal Sarcasm data [2] contains 33,859 images with descriptions where the sarcastic and non-sarcastic text are uniformly distributed. We used the text information only to train our classification model. In reality, we randomly took 10,000 texts out of the full dataset as the additional dataset. This strategy can speed up the training process and avoid the bias from a large number of additional datasets as well.

(3) The dataset released by SemEval-2018 task3 [3] is also considered in our training dataset (Van Hee et al., 2018). The data format and the task description are pretty similar to our task. This dataset contains 3800 tweets with uniform sarcastic/non-sarcastic labels.

[3] https://competitions.codalab.org/competitions/17468

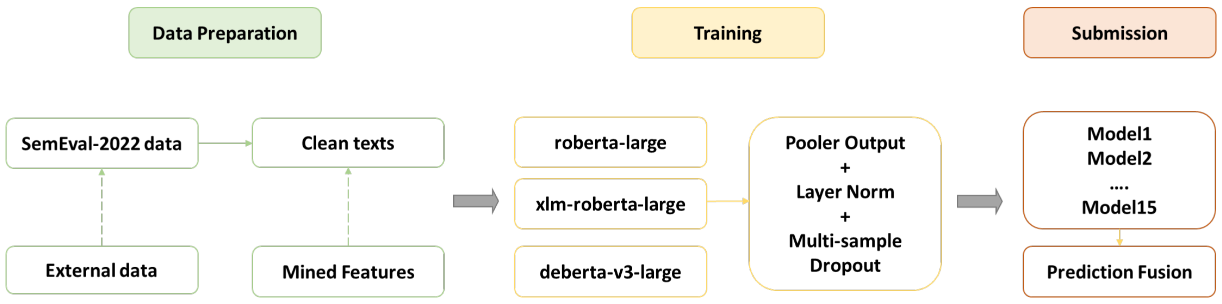

Figure 1: Task experimental progress

2.3 Language Models

We have adopted the RoBERTa-large (Liu et al., 2019) and DeBERTa-v3-large (He et al., 2020b, 2021) as the pretrained models from Hugging Face. We also applied the XLM-RoBERTa-large (Conneau et al., 2019) as a pretrained model for the dataset which includes the Arabic tweets during training.

2.4 Feature Mining

Moreover, we mined different types of statistical and lexical-based features that were previously applied in irony detection. Additional text features can improve the detection of sarcasm in many related tasks (Hernández-Farías et al., 2015; Yaghoobian et al., 2021). All the text features are simply added to the preprocessed tweets using the splitting token "$</s></s>$". Figure 2 demonstrates how we concatenate different features into the original text.

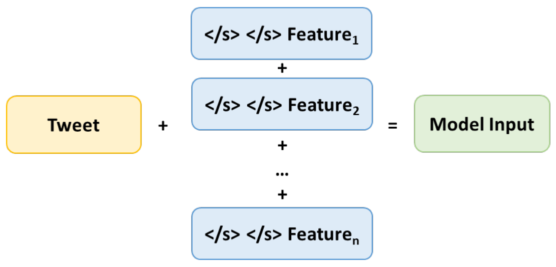

Figure 2: Text and features concatenation

(1) Emoji is a prominent multi-model feature that indicates human emotions after analyzing large amounts of tweet data [4]. On social media, emojis with few characters can easily turn common text into humorous, sarcastic, or ironic expressions.

(2) Parts-of-speech (POS) information is applied as an important feature as well. It is worth mentioning that we mined the POS-based features from the sarcastic tweets and their own rephrases in the official SemEval-2022 dataset. A list of adjectives and adverb words is generated by comparing the differences between the sarcastic tweets and their rephrased versions. For example, some words like "really", "never", "actually", etc. can be considered a symbol of sarcasm and express some contradictory and criticized attitudes.

(3) We also notice that some misspelled words (e.g., "so"->"soooo", "love"->"looove", "sure"->"sureeee") and capitalized words (not located at the beginning of a sentence) can sometimes exaggerate the emotional expression. Those words are detected and added to the tweets as additional text features.

(4) Transitional words and words with negative polarity are also considered as two potential sarcastic features (Tayal et al., 2014). Transitional words can express opposition or contradiction or indicate different meanings in a same sentence, such as "on the other hand" and "neverthelsess" [5]. The polarity of words or lexicon sometimes helps to identify the level of praise or criticism of a text. For the polarity-based feature, we adopted the AFINN dataset [6] (a list of words labelled with a polarity valence) as a reference.

2.5 Ensemble

The final submitted result is fused, utilizing the voting-based mechanism, with the predictions of 15 pretrained models. Voting from different models can usually hinder obvious mis-classifications from a single model (Ruta and Gabrys, 2005; Zhang et al., 2014). Hard voting and soft voting are two classical voting methods in classification tasks.

[4]https://github.com/MathieuCliche/Sarcasm_detector

[5]http://www.csun.edu/~hcpas003/transwords.html;https://wordcounter.net/blog/2016/07/19/101889_transition-words.html

[6]http://github.com/abromberg/sentiment_analysis/blob/master/AFINN/AFINN-111.txt

Hard voting directly fuses different ensembles by picking the highest number of votes. The amount of sarcasm and non-sarcasm votes from different models directly determines the label of a test sample. Soft voting combines all ensembles by adding the probabilities of each prediction and picking the prediction with the highest probability summation. The predicted label would be sarcasm when the mean probability of the sarcasm category is greater than our selected threshold of 0.5. We mixed the hard and soft voting methods for the final submitted prediction. The hard voting method is adopted when the difference between the amount of sarcasm and non-sarcasm is greater than 2. Otherwise, the soft voting method is adopted.

3 Experimental Setup

Four major improvements in F1 score are given by adding the public dataset, multi-sample dropout layer, text features, and tuning the parameters in the contrastive loss function. In this paper, we evaluate different modules and tricks that are adopted in our proposed model to show their effect on the Semeval-2022 official dataset. Table 2 shows the F1 scores for the competition blind test set based on different pretrained models, strategies and datasets.

The DeBERTa-v3-large model outperforms about 5% the other two pretrained models we used in this task. Many other tasks show the outperformance of the DeBERTa model as well. DeBERTa modes proposed two novel tricks to improve the ability to solve many natural language tasks. Compared with the BERT and RoBERTa models, the disentangled attention mechanism is applied to show each word in two vectors, which represent its content and relative position. The disentangled matrices are used to calculate the attention weights between the word content and position. An enhanced mask decoder is adopted to help with model pre-training by using the absolute position to predict the masked tokens. The DeBERTa model also shows a big improvement in how well the model generalizes when the virtual adversarial training method is used.

Multi-sample dropout is a regularization technique which can accelerate training convergence and improve the model generalization compared to the network structure with a traditional dropout layer (Inoue, 2019). Four dropout layers were applied to the pooling layer output from the pretrained model. Table 2 shows that additional multi-sample dropout layer provides a remarkable effect (4% improvement on F1 score) on this classification task.

Moreover, many effective adversarial training and vitual adversarial training methods can improve the model robustness and the regularization on classification tasks (Madry et al., 2017; Miyato et al., 2016; Goodfellow et al., 2014; Zhu et al., 2019; Jiang et al., 2019; Qin et al., 2019; Shafahi et al., 2019). In this task, we adopted Projected Gradient Descent (PGD) and the Fast Gradient Method (FGM) to implement the perturbation on sequence embedding in this task (Madry et al., 2017; Miyato et al., 2016). Table 2 shows a pretty similar F1 score for both methods. The FGM adds small perturbations to the embedding layers to enhance the quality of word embedding. The submitted models are fused by models trained in the fast gradient method, credited with its fast training converges and fewer computation resources.

Additionally, the constrastive loss is considered in our training progress. It maximizes the amount of agreement between different augmented views of the same dataset through adding a contrastive loss in the latent space. (Hadsell et al., 2006; Chen et al., 2020; He et al., 2020a). Many tasks are competitively performed by adding contrastive loss functions, such as triple margin loss, NPair loss, InfoNCE loss, and SupCon loss (Sohn, 2016; Chen et al., 2020; Van den Oord et al., 2018; He et al., 2020a; Khosla et al., 2020). In this task, we considered the NTXent and SupCon losses as the additional contrastive loss. We added the selected contrastive loss to the cross-entropy loss to improve the classification accuracy.

The effect of the contrastive temperature reflects the attention of difficult samples. The smaller temperature pays more attention to the separation of the sample from the most similar one to it (Wang and Liu, 2021). We tuned the contrastive temperature in both NTXent and SupCon loss to train different classification models. NTXent with a contrastive temperature of 0.2 creates the best performance on the competition blind test set according to Table 2.

Furthermore, the weighted voting on multiple models with different pretrained models and random seeds improves final performance on the competition's blind test set. Figure 3 shows the minimum, mean, and maximum F1, precision and recall scores for predictions from 15 single models. The mixed voting method we applied for the final sub-

4 Conclusion

According to the performance on the blind test set, the proposed model with the highest F1 score in the sarcastic category applied four layers of multi-sample dropout with a rate of 0.4 following the pooling layer outputting from the XLM-RoBERTa-large model. The model is trained in the fast gradient method using the AdamW optimizer at a learning rate of 1e-05. The combination of the cross-entropy and the NTX contrastive loss is applied during the training process. Additionally, incorporating text features and data from other sources can help improve the prediction's accuracy.

Abstract

Sarcasm refers to the use of words that have different literal and intended meanings. It represents the usage of words that are opposite of what is literally said, especially in order to insult, mock, criticise or irritate someone. These types of statements may be funny or amusing to others but may hurt or annoy the person towards whom it is intended. Identification of sarcastic phrases from social media posts finds its application in different domains like sentiment analysis, opinion mining, author profiling and harassment detection. We have proposed a model for the shared task iSarcasmEval - Intended Sarcasm Detection in English and Arabic by SemEval-2022 considering the language English. The Subtask A and Subtask C were implemented using a Convolutional Neural Network based classifier which makes use of ELMo embeddings. The Subtask B was implemented using Gaussian Naive Bayes classifier by extracting TF-IDF vectors. The proposed models resulted in macro-F1 scores of 0.2012, 0.0387 and 0.2794 for sarcastic texts in Subtasks A, B and C respectively.

1 Introduction

In the Internet era, specifying user comments, views and opinions through social media has become very common and these may not be specified directly and can include indirect phrases with implicit meanings (Abu Farha and Magdy, 2020). The posts may also represent undesirable characteristics using positive words and they may not be formal in nature. It is common to use abbreviations, uncommon, ambiguous and multilingual words in social media posts and no predefined structures are explicitly defined for sarcastic messages (Sarsam et al., 2020). So the identification of sarcastic posts cannot be considered as a direct process. Exhaustive understanding of the contextual meaning of the posts is considered as an important factor in identifying sarcastic posts. Sarcasm detection is considered as a challenging task associated with sentiment analysis. Sarcasm detection also plays an important role in analysing the voice of the customer based on which major decisions will be taken.

Sarcasm requires some shared knowledge between speaker and audience and it is considered as a profoundly contextual phenomenon. Using sarcastic phrases in sentences is a common way of ironic or satirical speech for the common man. That being said, social media platforms, such as Twitter, Facebook and YouTube contain millions of tweets and comments that include sarcastic phrases, thus making it a field of study under the domain of NLP. For example, a user can change a supposedly negative comment using positive words as in the sentence, *"It is awesome to go to bed at 3 am #not"*. In such cases it becomes important to ensure that the right sentiment is drawn out of the sentence through proper analysis (Vu et al., 2018).

The shared task iSarcasmEval was part of SemEval 2022 (Abu Farha et al., 2022) and there were three subtasks associated with it. Two of the subtasks - Subtask A and Subtask B, were conducted for both English and Arabic languages, while Subtask C only pertains to English. We as a team participated in all the three subtasks associated with the language English.

Subtask A: Sarcastic vs. Non-Sarcastic

The first subtask was a straightforward Binary Classification problem, in which the model had to predict whether a given phrase is sarcastic or not. For example, *"I work 40 hours a week for me to be this poor." is sarcastic, whereas "Her husband is serving a three-year sentence for fraud."* is non-sarcastic.

Subtask B: Different types of irony

The second subtask was a Multi-Label Classification problem, where the aim was to identify which type of irony a given sentence falls under from six specific labels: sarcasm, irony, satire, understatement, overstatement and rhetorical question.

Subtask C: Differentiation between sarcastic

phrase and its rephrase

The final subtask is another Binary Classification problem, wherein, given a sarcastic phrase and its rephrase, the model needs to identify which of the two is sarcastic. For example, the phrase *"Taxes are just the best and I cannot wait to pay more"* is sarcastic, whereas its rephrase - *"I dislike paying taxes.*" is non-sarcastic (Goutte et al., 2014).

Considering all the three subtasks the training of the proposed model was done using the training data set provided for the corresponding task and language. This model was then tested with a testing data set provided by the shared task, based on which the task was evaluated.

2 Related Works

Sarcasm detection can be posed as a text classification task in which the given text needs to be identified as sarcastic or not. In simple systems it could be considered as a binary classification task where the presence of sarcasm is only detected. But if the irony associated with the sarcastic message needs to be identified then it is considered as a multi label classification task. Different machine learning and deep learning models could be used for identifying sarcasm in text and it is not evident that a particular algorithm provides the best result for any data. The features of the data set like the number of instances in the data set, distribution of data in the training data set are important factors on which the performance of the algorithm relies. So it becomes necessary to analyse the data set, to choose the model for implementing the classification task.

It had been shown that Support Vector Machine provided the best performance for sarcasm detection considering posts from twitter (Sarsam et al., 2020). A combination of Convolutional Neural Network (CNN) and SVM had also offered high prediction accuracy. Even though feature rich SVM model perform well, Avinash Kumar and et al. (Kumar et al., 2020) had shown better performance by combining multi-head attention mechanism with bidirectional long-short memory (BiLSTM) to detect sarcastic messages.

Use of deep learning models with BiLSTM to detect sarcasm from Arabic texts had been illustrated by (Abu Farha and Magdy, 2020). A sarcasm detector had been implemented by fine tuning BERT and considering both affective and contextual features (Babanejad et al., 2020). The features of sarcastic text had been captured using a multi-level memory network to take care of sentiment semantics and the contrast between it and the situation in each sentence (Ren et al., 2020). Different transformer-based language models were used for sarcasm detection in Arabic language text and had found that MARBERT and AraELECTRA performed well and AraGPT2 had shown poor performance (Abu Farha and Magdy, 2021).

Pre-trained transformer models when ensembled with Recurrent Convolutional Neural Network to form hybrid neural architecture to detect sarcastic messages had resulted in better performance when compared to other relevant state-of-the-art methodologies (Potamias et al., 2020). A hybrid model implemented using bidirectional long short-term memory with a softmax attention layer and convolution neural network when used for sarcasm detection had resulted in better performance (Jain et al., 2020). Sarcasm detection had been implemented by taking into account the contextual information using a dual channel Convolutional Neural Network and the user's expression habit had been identified using attention mechanisms (Du et al., 2022).

In addition to the above approaches, various novel approaches like statistical approaches, graph based approaches, fuzzy logic based approaches and pseudo labelling approaches had been used for identifying sarcastic messages. A complex-valued fuzzy network had been used to identify the text with sarcasm by leveraging the mathematical formalisms of quantum theory and fuzzy logic (Zhang et al., 2021). Sarcasm detection had been implemented by taking the contextual information of a sentence into account in a sequential manner using the concept of pseudo-labeling (Kumar Jena et al., 2020), (Kalaivani and Thenmozhi, 2020). Long-range literal sentiment inconsistencies had been taken into account in sarcasm detection by constructing an affective graph and a dependency graph for each sentence and had then used an Affective Dependency Graph Convolutional Network (ADGCN) framework for the classification process (Lou et al., 2021). Statistical approach had been proposed for sarcasm detection by combining TF-IDF features with the important features related to sentiments and punctuations that are identified using chi-square test (Gupta et al., 2020).

Social media posts may have both text and images associated with it and identifying sarcasm in

Task	Category	Instances
Subtask A	Sarcastic	867
	Non Sarcastic	2601
Subtask B	Sarcasm	713
	Irony	155
	Satire	25
	Under Statement	10
	Over Statement	40
	Rhetorical question	101
Subtask C	Rephrase	867

Table 1: Data Distribution

such case had been implemented using a multimodal framework using Coupled-Attention Networks (CANs) which captures and integrates information from both text and image for the classification task (Zhao et al., 2021). As the imbalanced nature of the data set affects the performance of the model oversampling had been done to convert the data set into a balanced one and had shown that SMOTE and BorderlineSMOTE–1 techniques when used for oversampling had resulted in the improvement of performance (Banerjee et al., 2020). It could be summarized from the related works that identifying sarcasm from social media posts is an emerging research area that requires more insights. Different techniques like traditional machine learning models such as SVM and Random Forest, Convolutional Neural Network based models, Transformer models and Ensemble models could be used for this purpose. It could be found that the performance of the approach depends on the dataset on which the model is being trained (Abdulraheem et al., 2015). It is hard to identify a particular approach that can detect sarcastic messages under any circumstances which provides the best performance.

3 Data set

The data set that we used to implement sarcasm detection was the training and the test dataset that was provided by the organisers of the shared task. Each instance of the training dataset had the following informations attached to it:

1. Label specifying the sarcastic nature of the text

2. Rephrase text that convey the same message of the text non-sarcastically

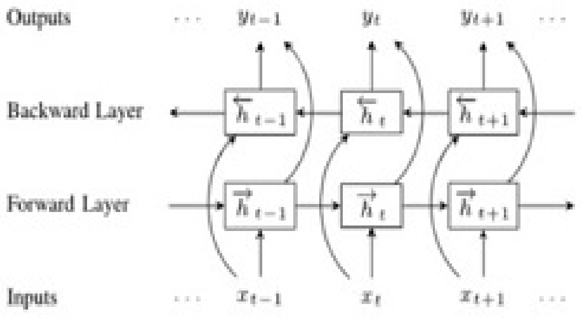
3. Label specifying the category of ironic speech which includes sarcasm, irony, satire, understatement, overstatement and rhetorical question

There were 3468 instances in the training data set of which 867 instances were under the sarcastic category and remaining 2601 instances were under the non sarcastic category. This shows the unbalanced nature of the data set. The test data had 1400 instances for which the predictions had to be done using the proposed model. The distribution of the data in the training dataset is shown in Table 1. As separate data set was not provided for the evaluation purpose, under both category 80% of the training data instances were used for training purpose and 20% of the instances from the training data set was used for the evaluation purpose.

4 System Description

The proposed methodology uses ELMo embedding based Convolutional Neural Network model for implementing the Subtasks A and C with an embedding layer followed by two dense layers. The Subtask B has been implemented using TF-IDF based Gaussian Naive Bayes classifier.

4.1 ELMo Model



Outputs
$\cdots$ y_{t-1} y_t y_{t+1} $\cdots$
Backward Layer
$\overleftarrow{h}_{t-1}$ $\overleftarrow{h}_t$ $\overleftarrow{h}_{t+1}$
Forward Layer
$\overrightarrow{h}_{t-1}$ $\overrightarrow{h}_t$ $\overrightarrow{h}_{t+1}$
Inputs
$\cdots$ x_{t-1} x_t x_{t+1} $\cdots$

Figure 1: Architecture of ELMo Model

It stands for Embeddings from Language Models and is a novel way to represent words in vectors or embeddings (Peters et al., 2018). In ELMo the syntax and semantics of the word and the linguistic context associated with it are modelled as a deep contextualised word representation. Huge text corpus had been used to pretrain the model and is constructed using deep bidirectional models[1]. It is implemented with 4096 units and the input embedding transform using 2048 convolutional filters.

[1]https://allenai.org/allennlp/software/elmo

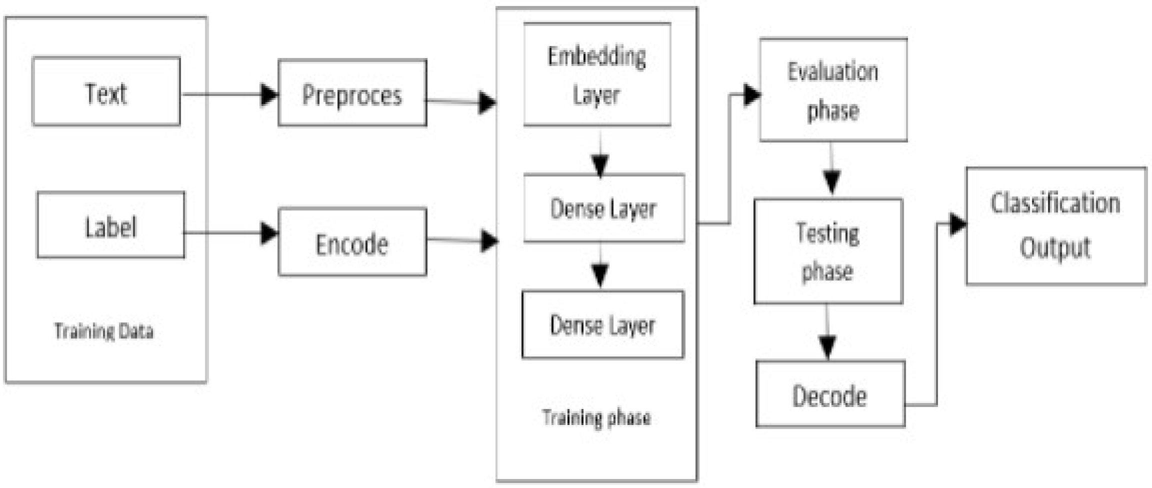


Figure 2: Proposed Architecture

The context of the word usage forms the base for the word representation. ELMo word representations take the entire input sentence into equation for calculating the word embeddings. The architecture of ELMo model[2] is shown in Figure 1.

ELMo is a bidirectional language model. The forward LM is a deep LSTM that goes over the sequence from start to end to predict the token and the backward LM is a deep LSTM that goes over the sequence from end to start to predict the token.

$$P(x_i \mid y) = \frac{1}{\sqrt{2\pi\sigma_y^2}} \exp\left(-\frac{(x_i - \mu_y)^2}{2\sigma_y^2}\right)$$

Figure 3: Likelihood of Gaussian Naive Bayes

4.2 Gaussian Naive Bayes Classifier

It follows Gaussian Normal Distribution and is a variant of Naive Bayes which are a group of supervised machine learning classification algorithms based on the Bayes theorem. The concept of conditional probability is used while using this for the classification problem[3]. The likelihood of the features in Gaussian Naive Bayes Classifier is represented by Figure 3. Predictions using this classifier is done by providing new input values for the parameters which will result in an estimated probability by the Gaussian function.

The task of determining whether the given text is sarcastic or non-sarcastic represents a binary classification problem, which is Subtask A. The task of determining the sarcastic one from two texts that convey the same meaning also represents a text classification problem which is the problem statement associated with Subtask C. The proposed model uses an ELMo model to implement the above two tasks. Subtask B is a binary multi-label classification task in which the correct ironic speech category has to be identified from the given set of labels. Figure 2 shows the architecture of the proposed model.

The first step associated with all the subtasks is to prepare the data set, which involves preprocessing of the text within. This is carried out by removing any escape sequences and stop words associated with the text, generating the associated tokens and lemmatizing the same. The idea behind preprocessing is to remove the parts from the text which do not contribute to the actual intent of the text.

For implementing Subtask A and C which were binary classification problem, the labels were normalized by using a one hot encoding scheme, which transformed the labels into a categorical value for which embedding is done and the encoded labels are returned[4]. The encoded data is used to train the model which is a Convolutional Neural Network with an embedding layer followed by two dense layers. The embedding layer gener-

Metric	Score
F1-Sarcastic	0.2012
F-Score	0.5101
Precision	0.5137
Recall	0.5196
Accuracy	0.705

Table 2: Subtask A Scores

ates the ELMo embeddings which is implemented with the help of tensorflow hub. The first dense layer has 256 units and makes use of relu activation function. The output is generated from the second dense layer with two units as it performs Binary Classification. The activation function used by the last layer is softmax. As Subtask B involved multi label classification, TF-IDF vectors were generated for the input text and the classification was carried out using a Gaussian Naive Bayes classifier[5], which uses the concept of Bayes theorem.

The training data set provided as a part of the shared task was used for training the model. As a separate data set was not provided for validation, 20% of the training instances were selected and used for the evaluation process. Finally the testing phase was implemented using the testing data set provided for the shared task.

5 Results

The metrics that were considered for the evaluation of all the three subtasks were precision, recall, accuracy and macro-F1 score. Precision represents the ratio of the number of correct positive results to the number of positive results predicted by the classifier. The recall measures the model's ability to detect positive samples. The higher the recall, the more positive samples are detected. Classification accuracy is the ratio of number of correct predictions to the total number of input samples. F1 score is an overall measure of a model's accuracy that combines precision and recall. A high F1 score means that the classification has resulted with low number of false positives and low false negatives. The proposed model resulted in an F1 score for sarcastic texts as 0.2012 based on which Subtask A was evaluated and we were ranked 36 on the leaderboard. Table 2 shows the values that were obtained for various metrics like precision, accuracy and recall considering Subtask A.

Subtask B was evaluated based on the macro-F1 score of the model and the proposed model had resulted in a macro-F1 score of 0.0387. We ranked 19 on the leaderboard under this category. Table 3 shows the F1 scores that were obtained for different type of sarcastic texts like Irony, Satire, Understatement, Overstatement and Rhetorical Question.

Metric	Score
Macro F	0.0387
F1-Sarcasm	0.2321
F1-Irony	0.0000
F1-Satire	0.0000
F1-Understatement	0.0000
F1-Overstatement	0.0000
F1-Rhetorical Question	0.0000

Table 3: Subtask B Scores

Metric	Score
Accuracy	0.3400
F-Score	0.2794

Table 4: Subtask C Scores

Accuracy was the metric that was used for the evaluation of Subtask C, and our model achieved an accuracy of 0.34 with rank 15 on the leaderboard. The F1 score that we obtained for this subtask was 0.2794 and these are tabulated in Table 4.

6 Conclusions

Sarcasm detection has become an important area of research as it is interlinked with different areas of application that includes sentiment analysis, opinion mining, offensive and hate speech detection. Having this in mind SemEval-2022 had come up with the task of Sarcasm detection which was represented by three subtasks namely sarcasm detection, identifying the type of irony associated with the sarcastic text and identifying whether the text or its rephrase is sarcastic. We have applied ELMo embedding based Convolutional Neural Network model for implementing the binary Subtasks A and C. Gaussian Naive Bayes classifier based on TF-IDF vectors was used to implement Subtask B. All the three subtasks were implemented considering the language English. The performance of the models used, were not up to the mark and it is found from the task overview that the transformer models when applied over this tasks provides better results.

Dataset for sarcasm detection could be created with contextual information which can help in ef-

[5]https://scikit-learn.org/stable/modules/naive$_{b}ayes.html$

fectively detecting sarcasm. Usage of hybrid approaches where different machine learning and deep learning models are combined can also facilitate efficient detection of sarcasm from text. Often it could be observed that sarcasm is not in the text, but could be detected from the intonation or facial expression, which has made mulitmodal sarcasm detection also as a promising research area.

Abstract

This paper describes the submission of the team Amrita_CEN to the shared task on iSarcasm Eval: Intended Sarcasm Detection in English and Arabic at SemEval 2022. The sarcasm detection task was formulated as a classification problem and modelled using machine learning classifiers. We used K-Nearest Neighbor (KNN), Support Vector Machine (SVM), Naïve Bayes, Logistic Regression, Decision Tree, and the Random Forest ensemble method. In addition, the class imbalance problem in the dataset was addressed using a feature engineering technique. We submitted the predictions by SVM, Logistic Regression and Random Forest ensemble based on the performance during training.

1 Introduction

Sarcasm is an ironic form showing a disparity between the actual and intended meaning of the text affecting the decision-making process. These are reflected in our day-to-day communication with each other happening in social media forums. Twitter exhibits rich sarcasm phenomena, thereby encouraging automatic sarcasm detection methods and removing such tweet data. Due to the sociocultural aspects of sarcastic communication, the majority of the sarcasm detection work has been focused only on the English language (Oprea and Magdy, 2020b), and only a limited amount of work was done in other languages such as Arabic (El Mahdaouy et al., 2021).

Identification of sarcastic comments from social media contexts is essential since the author and the receiver are at various places. Therefore, exchanging conversations may sometimes lead to a negative meaning of the text that even the author has not meant to convey. Moreover, the data stream for sarcasm does not exhibit any static structure like specific tags in the form of #sarcasm, and #irony (Ptáček et al., 2014) (Khodak et al., 2018). This event can lead to noisy labels due to several reasons, as outlined by (Oprea and Magdy, 2020b). Other works reported on the topic mainly depend on manual labelling, provided with manually annotated sarcasm labels. In (Oprea and Magdy, 2020b) the authors pointed out that manual labelling represents the author annotation in contrast with the intention of the authors.

The sarcasm prediction on Twitter that influences Machine Intelligence is a challenging task (Khare et al., 2022). It can be achieved with the help of the Natural Language Processing (NLP) approach, and many recent works on automatic sarcasm detection have focused on Twitter data as it primarily requires an understanding of the human expressions, language, and emotions expressed via textual or non-textual content (Kumar et al., 2021). Therefore, the goal of the SemEval shared task is to facilitate the development of machine learning models that can detect sarcasm from tweets. The shared task consists of two subtasks:

- Subtask A: For a given text, determine whether it is sarcastic or non-sarcastic.
- Subtask B (English only): A binary multi-label classification task for a given a text, determine which ironic speech category it belongs.

In this paper, we describe the machine learning models designed for solving the problems given in iSarcasm shared tasks (Abu Farha et al., 2022). The performance of the models was evaluated using the F1-score. The models submitted achieved the following scores: 0.4966 in English, 0.6127 in Arabic and 0.0567 F1-score in subtasks A and B, respectively.

2 Literature Review

The majority of the published works developed for the text sarcasm detection used datasets that were annotated using a weak supervision method, where the texts were regarded as sarcastic only if they met

preset criteria, including specific tags like sarcasm and irony (Oprea and Magdy, 2020a) (Ptáček et al., 2014) (Khodak et al., 2018). In (Oprea and Magdy, 2020b), S.V Opera and W Magdy reported that labelling using a weak supervision method could lead to noisy labels. Other works on this topic were based on manual labelling, where the human annotators are given the role of labelling the texts (Filatova, 2012) (Riloff et al., 2013) (Abercrombie and Hovy, 2016). The disadvantage of such a labelling procedure is that it represents the perception of the annotator, which may differ from the author's intention (Oprea and Magdy, 2020b).
In addition to the above-mentioned method, a significant majority of works on sarcasm detection were centered exclusively on the English language (Oprea and Magdy, 2019) (Campbell and Katz, 2012) (Riloff et al., 2013) (Joshi et al., 2016) (Amir et al., 2016) (Rajadesingan et al., 2015) (Bamman and Smith, 2015). It is because of its sociocultural aspects on sarcastic communication (Oprea and Magdy, 2020b), leading to the uncertainty that, the models trained on English could generalize to other languages. All the reported works on sarcasm detection in other languages such as Arabic (Karoui et al., 2017) (Ghanem et al., 2019) (Abbes et al., 2020) (Farha and Magdy, 2020) were relied on the afore-mentioned labelling techniques.

3 Dataset and Task Description

The dataset comprises tweets in English and Arabic. There are two subtasks in English and one in Arabic. Tweets in the English dataset were categorized into two: Sarcastic and Non-sarcastic. It contains 3,467 instances of tweets and ten columns containing the attributes (id, tweet, sarcastic, rephrase, sarcasm, irony, satire, understatement, overstatement, rhetorical question). The objective of task-1 is to determine whether a given text is sarcastic or not. Task-2 is a multi-label classification that aims to classify a tweet into different ironic speech categories, such as Sarcasm, Irony, Satire, Understatement, Overstatement, and Rhetorical questions. The shared task-1 in Arabic focused on categorizing a tweet into sarcastic or non-sarcastic, similar to task-1 in English. The Arabic dataset contains 2,601 instances of tweets and five attributes (id, tweet, sarcastic, rephrase, dialect). Table 1 describes the datasets used for task-1 and task-2 in English and task-1 in Arabic.

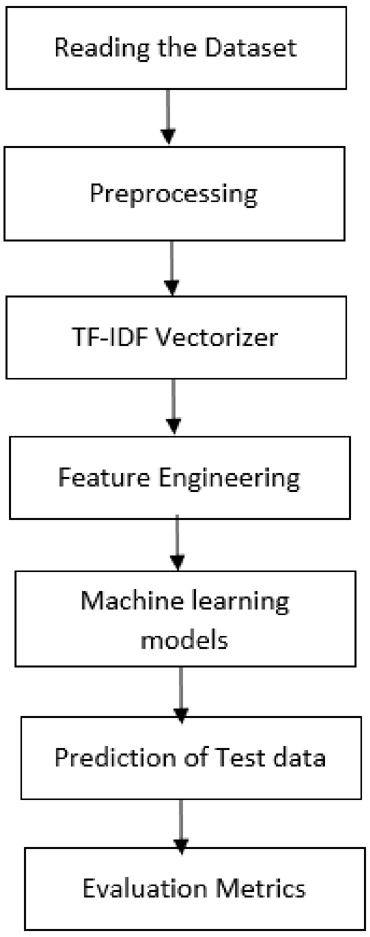

Figure 1: Workflow of the Model

4 System Overview

This section discusses the overview of the models submitted to the shared tasks. The flow of the model building is illustrated in Figure 1.

4.1 Data preprocessing

The shared task was provided with two kinds of input

(a) *Task-1*: text file contain tweets provided with its label, rephrased form and also the irony of the same for both English and Arabic language.

(b) *Task-2*: English text file considered for task 1 is used for irony identification in csv format.

The "Tweet" column from the datasets (Tasks 1 and 2) contains tweets, which must be preprocessed before extracting features for model creation. The preprocessing steps include tokenization, lemmatization, stop word removal and represented tweets

Dataset properties	Task-1 English	Task-2 English	Task-1 Arabic
No. of rows	3,467	3,467	2,601
No. of classes	2	6	2
No. of words	22,623	22,623	38,885
Vocabulary size	5,509	5,509	16,226
Maximum tweet length	72	72	31

Table 1: Description of the dataset used for Task-1 and Taks-2 in English and Task-1 in Arabic

as vectors using the Term Frequency-Inverse Document Frequency (TF-IDF) algorithm (HB et al., 2016).The preprocessing of the tweets was carried out by using the functions available in the NLTK][1] library, whereas the sklearn TfidfVectorizer() [2] helps to vectorize the tweets.

4.1.1 Tokenization

Tokenization is the first step that we executed in preprocessing. Here, the tweet from the user is split into tokens for the ease of feature extraction.

4.1.2 Lemmatization

Lemmatization refers to correctly identifying the base form of a word and converting it into the meaningful base form considering the context.

4.1.3 Stopword removal

Stop word removal is performed to remove the most commonly occurring words in the tweet, such as pronouns and articles. A similar operation was performed on Arabic data by collecting a publicly available stopword list.

4.2 Term Frequency-Inverse Document Frequency (TF-IDF)

TF-IDF is a feature extraction method for vectorizing a sentence or tweet. The TF-IDF vector can be obtained for a sentence by computing Equation 1 for each word in that sentence.

$$TF-IDF(t,D) = TF(t,D) \times IDF(t) \quad (1)$$

Where the Term Frequency

$$TF(t) = \frac{N(t)}{T} \quad (2)$$

and Inverse Document Frequency

$$IDF(t) = log\frac{n}{df(t)} \quad (3)$$

where,
t is the word in a tweet, $N(t)$ is the number of times word t occurs in a document, T is the number of words in a document, n is the total number of sentences/tweets in the dataset, and $df(t)$ is the number of documents in which the term t appears.

4.3 SMOTE

SMOTE (Synthetic Minority Oversampling Technique) (Chawla et al., 2002) is an oversampling method for solving the class imbalance problem in the dataset. It resolves the problem by increasing the number of data points in the minority class with synthetically generated random data points. It is achieved by randomly selecting one or more k nearest neighbours of each minority class. The process can be initiated using the following steps:

1. Given the minority class S, for each $y \in S$, the nearest k-neighbours of y are obtained using Euclidean distance of y and every other elements in S.

2. Sampling rate T is given according to the proportion of imbalance. For each $y \in S$, T elements are selected randomly from nearest k-neighbours. And the set S_1 is made.

3. For every $y_k \in S_1$, $k = 1, 2, 3..., T$, the formula for generating new example (y')is,

$$y' = y + rand(0,1) * |y - y_k| \quad (4)$$

The SMOTE algorithm was implemented using the SMOTE function available in the imblearn Python package[3].

4.4 Model development

We utilized K-Nearest neighbour (KNN) (Guo et al., 2003), Support Vector Machine (SVM) (Soman et al., 2009), Naïve Bayes (Huang and Li,

[1]https://www.nltk.org/
[2]https://scikit-learn.org/stable/modules/generated/sklear.feature_extraction.text.TfidfVectorizer.html

[3]https://imbalanced-learn.org/stable/references/generated/imblearn.over_sampling.SMOTE.html

2011), Decision Tree (Priyam et al., 2013) and Random Forest (Premjith et al., 2019) ensemble method for developing the models for various subtasks in iSarcasm. The procedures for model development for different tasks are given in the following subsections.

4.4.1 Sub task1: Sarcasm Identification

We built a binary classifier to determine whether the given tweet is sarcastic or not. Therefore, for the same purpose, we applied machine learning classifiers to the processed train data. For English tweet data, encouraging results were obtained by Decision tree and logistic regression. The decision tree is a particular type of probability tree that makes the decision about the process (Rahaman et al., 2021), and Logistic Regression is used for predicting the categorical dependent variable using a given set of independent variables (Sarsam et al., 2020). SVM and Random forest classifiers obtained the best performance for Arabic data. The Random Forest classifier reduces the bias due to overfitting and class imbalance between tweets. Bouazizi and Ohtsuki (Bouazizi and Ohtsuki, 2016) used logistic regression to label the data as sarcastic or non-sarcastic.

4.4.2 Sub task2: ironic speech category Identification

A multi-label classifier was developed for this task to determine the ironic speech category of the tweets. We applied a multi labelled classifier strategy with fitting one classifier per target, allowing multiple target variable classifications. The primary purpose behind this class is to extend estimators enabling estimation of a series of target functions mentioned in the dataset, which are trained using a single predictor matrix to predict a series of responses. We implemented a classification model using Logistic Regression, and a decision tree for the same as mentioned above (Sarsam et al., 2020)-(Rahaman et al., 2021).

4.5 Evaluation Metrics

The trained models were evaluated using macro F1-score, Precision, Recall and Accuracy. Accuracy is given by the ratio of the total number of correct predictions to the measure of total predictions done by the model, regardless of correct or incorrect predictions. Precision defines the actual positive among the predicted positive. The recall is a measure of the correctly classified total number of positives. Moreover, F1-score is the harmonic mean of precision and recall. Macro-average is defined as the average of precision, recall, and F1-score in different classes.

5 Experimental Setup

We implemented the models using Python version 3. The training data is split into train and validation sets for confirming the best performing model. In the Arabic sarcasm identification model using the SVM classifier (subtask 1), we used a range of gamma values $(0.1, 1, 10, 100)$ and c regularization parameter values $(0.1, 1, 10, 100)$ and changed the kernel type to RBF, linear and polynomial to see how the accuracy and F1-score vary. In random forest classifier different, n_estimators value $(10, 100, 1000)$ and the maximum features are given to $sqrt$, $log2$ to see the changes (Premjith and Kp, 2020). The English tweet irony detection model (subtask 2) is a multi-class classification problem and implemented using a multioutput classifier set to multilabel.

The model performance was analyzed using macro F1-score obtained using the sklearn metrics along with the accuracy, precision and recall (Pedregosa et al., 2011) of the trained model.

6 Result

All the subtasks were evaluated on the macro-average F1-scores of each information unit. We fixed the best performing models by using cross-validation. The Random Forest classifier and SVM obtained the best F1-scores for English task 1 and Arabic, respectively. In subtask 2, Logistic Regression gave the higher F1-score. We were officially ranked 23rd in task1 English with an F1-score of 0.4966 and accuracy of 56.71% using the Random Forest classifier and ranked 20th in Arabic with 0.6127 of F1-score and 79.21% accuracy using SVM binary classifier. In subtask 2, we were ranked 14th with a macro F1-score of 0.0567 using the Logistic Regression model. The obtained result from our model among all participating teams are shown in table 2, 3 below.

7 Conclusion

This paper presents the submission of Amrita_CEN towards the SemEval 2022 Task 6 competition named " iSarcasmEval - Intended Sarcasm Detection in English and Arabic ". A total of six machine learning algorithms were used, including five

Metrics	Task-1 English	Task-1 Arabic
F1-Sarcastic	0.3052	0.3490
F1-score	0.4966	0.6127
Precision	0.5550	0.6050
Recall	0.6121	0.6246
Accuracy	0.5671	0.7921

Table 2: Result for Subtask 1 English and Arabic

Metrics	Task-2 English
Macro-average F-score	0.0567
F1-score Sarcasm	0.2180
F1-score irony	0.0293
F1-score satire	0.0461
F1-score understatement	0.0074
F1-score overstatement	0.0245
F1-score rhetorical question	0.0150

Table 3: Result for Subtask 2 English

classical ML models and one ensemble technique. The class imbalance problems were dealt with by oversampling technique called SMOTE, and for evaluation, macro F1-score were considered for both the subtasks. The model trained using Random forest, SVM and logistic regression performed well among the subtasks given, and the results were submitted using the same.

8 Acknowledgements

We wish to express our sincere gratitude to our facualty Dr Sowmya V for her help throughout this work and the research underlying it. Your guidance, willingness to share the vast knowledge and expertise made us to understand this work and its manifestations in great depth and helped us to complete the assigned task on time.

Abstract

This paper presents our proposed methods for iSarcasmEval shared task. The shared task consists of three different subtasks. We participate in both subtask A and subtask C. The purpose of the subtask A was to predict if a text is sarcastic while the aim of subtask C is to determine which text is sarcastic given a sarcastic text and its non-sarcastic rephrase. Both of the developed solutions used BERT pre-trained models. The proposed models are optimized on simple objectives and easy to grasp. However, despite their simplicity our methods ranked 4 and 2 in iSarcasmEval subtask A and subtask C for Arabic texts.

1 Introduction

Nowadays, social media users provide a huge amount of text, images and videos. This large amount of data contains useful information (users ideas, opinions, events, etc) for various domains such as stock predictions, marketing, or politics. In order to benefit from these data, new fields of study have been introduced including sentiment analysis, opinion mining, author profiling, and harassment detection (Liu, 2012; Rosenthal et al., 2014; Maynard and Greenwood, 2014; Van Hee et al., 2018). Natural Language Processing (NLP) algorithms are used extensively in these fields to extract useful information. For instance, to determine whether a given product has a positive or negative sentiment in the market, we can apply NLP techniques to analyse a list of twitter posts to infer a sentiment about the product.

According to Oxford dictionary, sarcasm is "*The use of irony to mock or convey centempt*". Sarcastic text convey negative implied sentiment, however it can have positive, negative, or no surface sentiment. Sarcasm is commonly used in social media, thus it introduces errors in various tasks such as sentiment analysis and opinion mining. This is explained in the work of Rosenthal et al. (2014), it shows a significant drop in sentiment polarity classification performance when processing sarcastic tweets, compared to non-sarcastic ones. In this context, the task *iSarcasmEval: Intended Sarcasm Detection In English and Arabic* (Abu Farha et al., 2022) is organized by SemEval 2022. The main tasks consists of three subtask:

- Subtask A: Given a text, determine whether it is sarcastic or non-sarcastic.
- SubTask B (English only): A binary multi-label classification task. Given a text, determine which ironic speech category it belongs to, if any.
- SubTask C: Given a sarcastic text and its non-sarcastic rephrase, i.e. two texts that convey the same meaning, determine which is the sarcastic one.

In this paper, we describe our contribution to iSarcasmEval shared task, Arabic language only. For subtask A, we built a BERT-based neural network (Devlin et al., 2019; Antoun et al., 2020) classifier to determine whether a tweet is sarcastic or not.

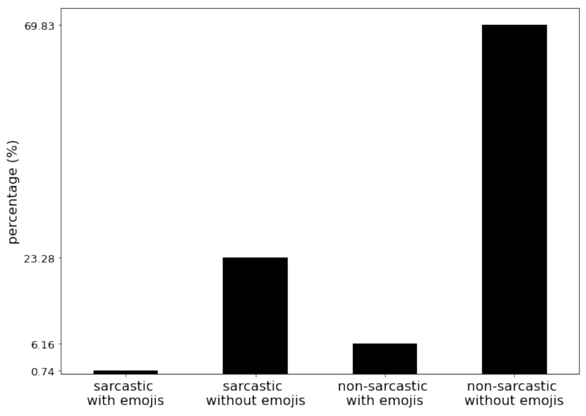

Figure 1: The train dataset distribution according to 4 classes including sarcastic texts that contains emojis, sarcastic texts without emojis, non-sarcastic texts with emojis, and non-sarcastic texts without emoji.

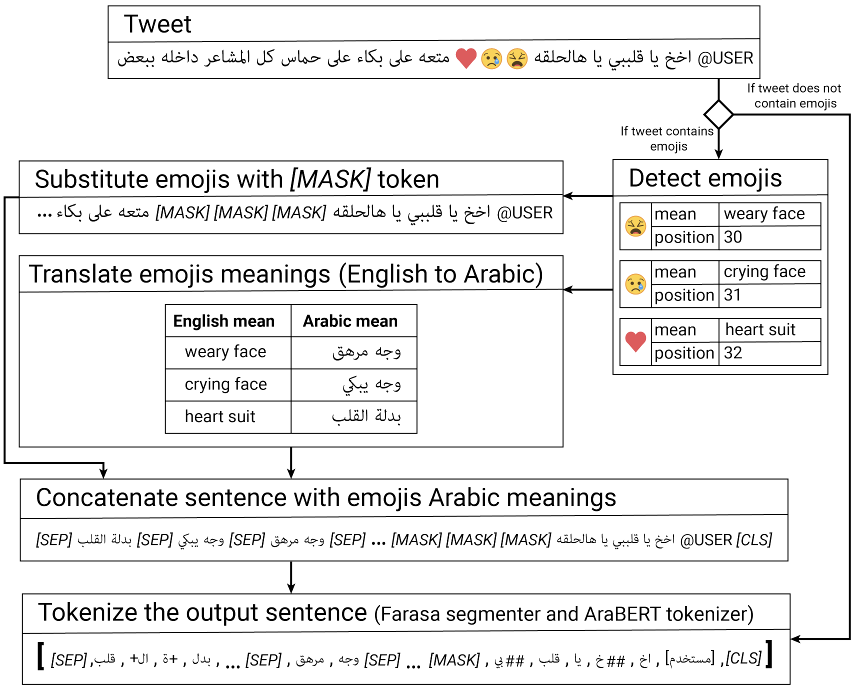

Tweet
If tweet does not contain emojis
If tweet contains emojis
Detect emojis
mean weary face
position 30
mean crying face
position 31
mean heart suit
position 32
Substitute emojis with *[MASK]* token
Translate emojis meanings (English to Arabic)
English mean
Arabic mean
weary face
وجه مرهق
crying face
وجه يبكي
heart suit
بدلة القلب
Concatenate sentence with emojis Arabic meanings
Tokenize the output sentence (Farasa segmenter and AraBERT tokenizer)

Figure 2: Text preprocessing proposed by Alami et al. (2020).

Our model obtained the fourth best performance in the subtask A. For subtask C, we built also a BERT-based classifier to detect the sarcastic text from two text that convey the same meaning. We scored the second best performance in the subtask C. The results are promising and there is much room for improvement.

The rest of the paper is organized as follows: Section 2 presents our method overview; Section 3 provides performance evaluation; Section 4 concludes the paper and provides future work.

2 Method Overview

In this section, we first describe how we split data to evaluate our models. Next, we explain preprocessing steps. Next, we discuss our models for each subtask, and the experimental setup we used. We also provide illustrations and examples, when necessary.

2.1 Dataset split

The organizers of iSarcasmEval provided Arabic texts annotated with their sarcasm labels. The train set contains 3102 samples where 75.98% (2357 samples) are non-sarcastic and 24.02% (745 samples) are sarcastic. The test set consists of 1400 samples. All the samples are annotated also with their dialect. We build a validation set from train set based on emojis. We first split the train data into 4 classes including sarcastic texts that contains emojis, sarcastic texts without emojis, non-sarcastic texts with emojis, and non-sarcastic texts without emojis. Fig. 1 illustrates the distribution of this 4 classes in the train dataset. We notice that only 6.9% of train samples contain emojis while 20.86% test samples include emojis. Considering this we use 4 splits to validate our models:

- Split A: The validation set contains all the sarcastic samples with emojis, 10% sarcastic samples without emojis, 10% non-sarcastic samples with emojis, and 10% non-sarcastic samples without emojis.
- Split B: The validation set contains 50% sarcastic samples with emojis, 10% sarcastic samples without emojis, 10% non-sarcastic samples with emojis, and 10% non-sarcastic samples without emojis.
- Split C: The validation set does not contain any sarcastic samples with emojis and contains 10% sarcastic samples without emojis, 10% non-sarcastic samples with emojis, and 10% non-sarcastic samples without emojis.
- Split D: The validation set contains 20% of train samples. We applied stratified split to have the same distribution of classes as the train set.

Table 1: Performance evaluation of different models for sarcasm prediction

	Split A			**Split B**			**Split C**			**Split D**			**Score**
	Precision	Recall	F1	Precision	Recall	F1	Precision	Recall	F1	Precision	Recall	F1	
AraBERTv02-twitter	84.76	64.10	72.99	76.92	73.53	75.19	75.00	82.76	78.69	78.66	86.58	82.43	**77.32**
CAMEL-MIX	86.67	66.67	75.36	78.95	66.18	72.00	74.24	84.48	79.03	77.07	81.21	79.08	76.36
AraBERTv02-twitter / Emojis	90.74	62.82	74.24	55.93	48.53	51.97	75.41	79.31	77.31	77.22	81.88	79.48	70.75

2.2 Preprocessing

Our preprocessing step consists of tokenization. We apply the pre-trained BERT tokenizer which is based on wordpiece model (Schuster and Nakajima, 2012). For comparison purposes, we applied the same preprocessing process applied by Alami et al. (2020). The main idea is to integrate the meaning of emojis whitin the initial text. Fig. 2 presents the preprocessing step used in (Alami et al., 2020).

2.3 SubTask A

The objective of this task is to predict whether a text is sarcastic or not. We fin tune various BERT-based models pre-trained with Arabic large corpora. These models are used to extract valuable features from raw text. These features are then used with a softmax classifier to predict the label of the input text. All models are optimized to minimize the cross entropy loss.

2.4 SubTask C

The aim of this task is to predict the sarcastic text given two texts with the same meaning. Like the model used in subtask A, we fine tune BERT-based models for this specific task. The input of these models is the concatenation of the two texts separated by the special token *[SEP]*. Features are extracted with BERT-based models, then a softmax layer is applied to compute the probabilities of the events: first text is sarcastic and second text is sarcastic. All models are optimized to minimize the cross entropy loss.

2.5 Experimental Setup

We implemented our models using HuggingFace (Wolf et al., 2020). We used AraBERTv02-twitter (Antoun et al., 2020) and CAMEL-Mix (Inoue et al., 2021) as the pre-trained language models. To train our models, we used a batch size of 8, a learning rate 10^{-5}. We used the AdamW optimizer (Loshchilov and Hutter, 2017). We ran the experiments on a Google colaboratory environment [1].

[1]https://colab.research.google.com/

3 Performance Evaluation

In this section, we present the performance of various models trained on both subtasks A and C.

3.1 Subtask A

First, we compared the performances of two models: a model fine tuned with AraBERTv02-twitter and a model fine tuned with CAMEL-MIX. Table 1 shows the obtained results according to the 4 splits we previously discussed in subsection 2.1. We compute the overall score of a model by averaging all the f1 scores of the sarcastic class obtained from different splits. The model fine tuned with AraBERTv02-twitter scored the best results.

To investigate the impact of the substitution of emojis with their meanings. We evaluated the performances of a model based on AraBERTv02-twitter and take as input text preprocessed as proposed in Alami et al. (2020). Table 1 shows that emojis processing didn't improve the overall score.

Therefore, we submit the predictions obtained using AraBERTv02-twitter with the test set. We scored the fourth best score in the leaderboard (46.84% f1 score for sarcastic class).

3.2 Subtask C

Since the AraBERTv02-twitter model obtained the best result in subtask A, we trained the same base model to predict the sarcastic text given two text that convey the same meaning. We augmented the dataset by applying a simple rule which consist of switching the positions of the sarcastic text with the non-sarcastic text and replace the label with 0. We ranked 2 in the leaderboard with (88.5% accuracy).

4 Conclusion

We developed two methods for sarcasm prediction. The first one aim to predict if a text is sarcastic or not. This method is based on AraBERTv02-twitter pretrained model which extract valuable features from raw text. We achieved the fourth top performance in the iSarcasmEval subtask A for Arabic with a 46.84% f1 score for the sarcastic class. The second model has the objective to detect the sarcastic text given two texts that convey the same meaning. We trained a BERT-based model that take as input two text and predict the sarcastic one. We ranked 2 in the leaderboard with 88.5% accuracy. In future work, we plan to improve the performance of our models by using linguistic rules and some external datasets.

Abstract

Sarcasm is a form of figurative language where the intended meaning of a sentence differs from its literal meaning. This poses a serious challenge to several Natural Language Processing (NLP) applications such as Sentiment Analysis, Opinion Mining, and Author Profiling. In this paper, we present our participating system to the intended sarcasm detection task in English and Arabic languages. Our system[1] consists of three deep learning-based models leveraging two existing pre-trained language models for Arabic and English. We have participated in all sub-tasks. Our official submissions achieve the best performance on sub-task A for Arabic language and rank second in sub-task B. For sub-task C, our system is ranked 7th and 11th on Arabic and English datasets, respectively.

1 Introduction

Sarcasm is an important aspect of human natural language. It is characterized by the occurrence of a discrepancy between the intended and the literal meaning of utterance (Wilson, 2006). The prevalence of this phenomenon may jeopardize the performance of many NLP applications, such as Sentiment Analysis, Opinion Mining, and Emotion Detection, among others (Maynard and Greenwood, 2014; Rosenthal et al., 2014; Van Hee et al., 2018). Indeed, sarcasm detection has been the subject of many systematic investigation, where several shared tasks have been organized and a number of datasets have been introduced (Van Hee et al., 2018; Ghanem et al., 2019; Ghosh et al., 2020; Abu Farha et al., 2021). The existing datasets are either labeled by a human annotator or using distant supervision signals such as the presence of a set of predefined hashtags (Oprea and Magdy, 2020). However, these labeling methods might be sub-optimal for intended sarcasm detection as the author's sarcastic intent may differ from an annotator's perceived meaning (Oprea and Magdy, 2019, 2020). Besides, most existing research works have focused on English language (Van Hee et al., 2018; Ghosh et al., 2020), while few studies have been introduced for other languages such as Arabic (Ghanem et al., 2019; Abu Farha et al., 2021).

To overcome the aforementioned limitations, Abu Farha et al. (2022) have organized the iSarcasmEval shared task for intended sarcasm detection in English and Arabic languages. In contrast to previous research work, the introduced dataset, for intended sarcasm detection, is labeled by the authors themselves. The authors are then asked to provide non-sarcastic rephrases that covey the same intended meaning of their sarcastic texts. Further, the iSarcasmEval's organizers have relied on linguistic experts to categorize sarcastic texts into sarcasm, irony, satire, understatement, overstatement, and rhetorical questions (Leggitt and Gibbs, 2000).

In this paper, we present our participating system to iSarcasmEval shared task (Abu Farha et al., 2022). Our system rely on three transformer-based deep learning models. In all our models, we use existing Pre-trained Language Model (PLM) to encode the input text and apply a single attention layer to the contextualized word embedding of PLM (Barbieri et al., 2021; Abdul-Mageed et al., 2021). For all our models, we use the same classifier architecture composed of one hidden layer and one classification layer. The classifier is fed with the concatenation of the pooled output of the PLM as well as the attention layer output. We model the sub-task A as a binary classification (first model) and as a multi-class classification (second model). Motivated by the small size of the datasets and similarly to GAN-BERT architecture (Croce et al., 2020), the third model uses a conditional generator that tries to generate fake samples that are similar to the PLM's embedding of the real input data. The

[1]The source code of our system is available at https://github.com/AbdelkaderMH/iSarcasmEval

discriminator of the third model is trained to discriminate between fake and real samples as well as classify the real ones correctly. For sub-task B, we only employ the GAN based model (third model), while for sub-task C, we utilize all models trained on Task A and we compare the probabilities of the sarcastic class of the left and the right text. We train our models using several loss functions, including the focal loss (Lin et al., 2017). Besides, for sub-task A, we train our models with and without the non-sarcastic rephrase texts.

For the official submissions, we employ hard voting ensemble of our trained models. Our system achieve promising results as we rank 1st, 15th, 2nd, 7th, and 11th on sub-task A AR, sub-task A EN, sub-task B, sub-task C AR, and sub-task C EN, respectively.

2 Background

2.1 Task description

The organizers of iSarcasmEval shared task have provided training data and testing data for intended sarcasm detection in English and Arabic languages (Abu Farha et al., 2022). The datasets are collected from Twitter and labeled for intended sarcasm detection by the authors of the tweets. For English, the training data consists of 3,468 samples out of which 867 samples are sarcastic. For Arabic, the training data contains 3,102 samples, where 745 samples are sarcastic. The organizers also provide the non-sarcastic rephrase of sarcastic texts for both languages and the dialect of the given Arabic tweets. The shared task consists of the flowing sub-tasks:

- **Sub-task A** is a binary classification task, where the aim is to determine if a tweet is sarcastic or not. This sub-task consists of two sub-tasks A EN and A AR. The test data contains 1,400 for each language.

- **Sub-task B** is a multi-label classification task, where the aim is to assign a given tweet into the sarcasm, irony, satire, understatement, overstatement, and rhetorical question categories of ironic speech (Leggitt and Gibbs, 2000). This task is provided for English language only and the test data contains 1,400 samples.

- **Sub-task C** aims to identify the sarcastic tweet and the non-sarcastic rephrase given two texts that convey the same meaning. This sub-task consists of two sub-tasks C EN and C AR. The test sets of both languages consist of 200 samples.

2.2 Related work

In recent years, there has been a growing number of research works focusing on fine-tuning the existing PLMs on NLP tasks. These PLMs are based on the transformer architecture and are trained using self-supervised learning objectives such as Masked Language Modeling (MLM) amongst others (Devlin et al., 2019). Several multilingual and monolingual PLM variants are introduced (Devlin et al., 2019; Conneau et al., 2020; Antoun et al., 2020). For domain-specific data, domain adaptive fine-tuning of existing PLMs using MLM or domain adaptation have been shown to improve the performance of NLP applications (Rietzler et al., 2020; Barbieri et al., 2021; El Mekki et al., 2021a). Nevertheless, when the domain-specific data is sufficiently large, these transformers can be trained from scratch (Abdul-Mageed et al., 2021; Inoue et al., 2021).

For sarcasm detection, several research studies have been introduced based on fine-tuning the existing PLMs for English and Arabic languages (Ghanem et al., 2019; Ghosh et al., 2020; Abu Farha et al., 2021). El Mahdaouy et al. (2021) have shown that incorporating attention layers on top of the contextualized word embedding of the PLM improves the performance of multi-task and single-task learning models for both sarcasm detection and sentiment analysis in Arabic. The main idea consists of classifying the input text based on the concatenation of the PLM's pooled output and the output of the attention layer. This Architecture has yielded promising results on other tasks such as detecting and rating humor, lexical complexity prediction, and fine-grained Arabic dialect identification (Essefar et al., 2021; El Mamoun et al., 2021; El Mekki et al., 2021b).

Although transformer-based architectures have shown state-of-the-art performance on many NLP tasks, their task-specific fine-tuning requires a reasonable amount of labeled data. Nevertheless, in real-world applications, one may not always have enough labeled training data. Motivated by the performance of Semi-Supervised Generative Adversarial Networks (SS-GAN) in computer vision (Odena, 2016), Croce et al. (2020) have introduced GAN-BERT. The latter extends BERT fine-tuning procedure by training a generator and a discriminator. The generator is trained to generate fake samples embeddings that are similar to the real input text embeddings, whereas, the discriminator is trained to detect fake examples and categorize the real text inputs.

3 System overview

The submitted system to the iSarcasmEval shared task relies on three transformer-based models for intended sarcasm detection. In order to encode the input text, we utilize the Twitter-XLM-Roberta-base (Barbieri et al., 2021) and MARBERT (Abdul-Mageed et al., 2021) for English and Arabic texts, respectively. The former is a variant of XLM-RoBERTa PLM that is adapted to Twitter data using MLM objective, while the latter is a variant of BERT PLM that is pre-trained from scratch on Arabic tweet corpora. In the following subsection, we describe the components of our system.

3.1 Preprocessing

The tweet preprocessing component spaces out emojis and substitutes user's mention and URL with their special tokens of the PLM's tokenizer. For Twitter-XLM-Roberta-base, URLs and user's mentions are replaced by 'http' and '@user'. For MARBERT, they are replaced by 'user' and 'url' special tokens. To leverage the dialect information for Arabic data, we replace the dialect string with its full Arabic name and pass the input text to MARBERT's tokenizer as follows:

- [SEP] dialect [SEP] preprocessed text [SEP]

3.2 Deep Learning Models

Our three deep learning models are described as follows:

- **Model 1** consists of a transformer encoder, one attention layer, and a classifier. Following the work of (El Mahdaouy et al., 2021), we apply attention to the contextualized word embedding of the encoder. The classifier is composed of one hidden layer and one classification layer for binary classification. The classifier is fed with the concatenation of the PLM's pooled output and the attention layer's output.

- **Model 2** is similar is to **Model 1** and the task is modeled as multi-class classification problem. In other words, the classification layer of this model consists of two hidden units. Figure 1 illustrates the overall architecture of Model 1 and Model 2.

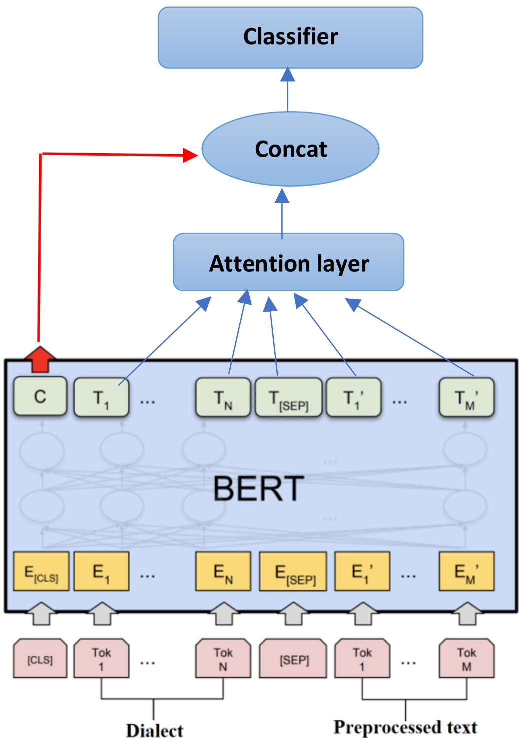

Figure 1: The overall architecture of Model 1 and Model 2.

- **Model 3** is similar to GAN-BERT model (Croce et al., 2020), whereas, we employ a conditional generator that generates fake embeddings from a random noise and the class category. The model 3 consits of three components, a BERT-based encoder with an extra attention layer on top of the contextualized word embedding, a generator, and a discriminator. The encoder represents the input sentences using the CLS token embedding and the output of the attention layer. The generator is trained to fool the discriminator by generating fake embedding representations that are similar to the input text embedding. It consists of two hidden layers and one output layer. Each hidden layer is flowed by a dropout layer and the relu activation layer. The discriminator is trained to discriminate between fake examples and real ones and to classify real input texts into sarcastic and non-sarcastic labels. The discriminator is also composed of two hidden layers and one classification layer. Similarly to the generator, the hidden layers are followed by one dropout layer and the relu activation layer.

3.3 Training objectives

For training our models, we utilizes several loss functions, including the Focal Loss (Lin et al., 2017). The aim is to assess the performance of the following training objectives under class imbalance:

- For **Model 1**, we investigate the Binary Cross-Entropy loss (BCE), the Weighted Binary Cross-Entropy loss (W. BCE), and the Binary Focal Loss (BFL). For the W. BCE loss, the positive class weight is set to:

$$\frac{batch\_size - positive\_count}{positive\_count + \epsilon}$$

- For **Model 2 and 3**, we investigate the Cross-Entropy loss, the Weighted Cross-Entropy loss (W. CE), and the Focal Loss (FL). For the W. CE, the positive and the negative class weights are computed as follows:

$$\begin{cases} pos\_weight = \frac{batch\_size - positive\_count}{positive\_count + \epsilon} \\ neg\_weight = \frac{batch\_size - negative\_count}{negative\_count + \epsilon} \end{cases}$$

4 Experimental setup

All our models are implemented using the PyTorch[2] framework and the open-source Transformers[3] libraries. Experiments are conducted on a PowerEdge R740 Server having 44 cores Intel Xeon Gold 6152 2.1GHz, a RAM of 384 GB, and a single Nvidia Tesla V100 with 16GB of RAM. 20% of the training set is used for the model validation. All our models are trained using Adam optimizer with a linear learning rate scheduler. Based on our preliminary results, obtained on the validation set, the learning rate, the number of epochs, and the batch size are fixed to 1×10^{-5}, 10, and 16 respectively. For the focal loss, the hyper-parameters γ and α (the weight of the negative class) are set to 2 and 0.8 respectively. All models are evaluated using the Accuracy as well as the macro averaged Precision, Recall, and F1 measures. Besides, we train our models with and without rephrase texts for sub-task A. For sub-task B, our models are trained on sarcastic tweets.

[3] https://huggingface.co/transformers/

5 Results

In this section, we present the obtained results of our models as well as our official submissions. It is worth mentioning that for sub-task C, we employ the trained models on sub-task A and we use their output probabilities to discriminate between the sarcastic text and the non-sarcastic rephrase. Besides, for our official submissions, we use the hard vote ensemble of our trained models. For each loss function, the best performance obtained is highlighted in **bold** font, while the overall best performance for each task is highlighted in ***bold-italic*** font.

5.1 Sub-task A

Table 1 summarizes the obtained results. The results show that training the models on tweets as well as the non-sarcastic rephrases improve the performance for both languages, especially Arabic where an important performance increment is yielded. Moreover, the performance of the evaluated models depends on the employed loss function. Although Model 1 and Model 2 are simple, they achieve better results than the GAN-based model (Model 3). The best performances on sub-task A are obtained using Model 2 in conjunction with the FL loss (0.6217) and Model 1 in conjunction with BCE loss (0.3833) for Arabic and English respectively. In our official submission, ensembling the models that are trained with and without the rephrase data harms the results. Our submitted system achieves the best performance on Arabic and ranked 15th on the English.

5.2 Sub-task B

Table 2 presents our obtained results for sub-task B. Since we use the sarcastic tweets only for training, we only train the Model 3. The results show that the best performance is obtained using the BCE loss. The FL and W. BCE loss functions have not improved the results. This might be explained by the fact that we did not tune the hyper-parameters α and $gamma$ of FL loss. Besides, in the W. BCE, the positive classes are assigned larger importance weights in comparison to the negative ones (see Section 3.3). Our official submission yields the second-best results on this sub-task.

5.3 Sub-task C

Table 3 summarizes the obtained results on sub-task C test sets of Arabic and English languages. In accordance with the results of sub-task A, the

Table 1: The obtained results on the test set of sub-task A for both Arabic and English. For our non official submissions, we report the macro F-1 score of the sarcastic class only.

models that are trained on the tweets and the non-sarcastic rephrases yield better performances. The best-obtained accuracy scores are 0.85 and 0.71 in comparison to 0.78 and 0.69 obtained by our official submission for Arabic and English respectively. Hence, ensembling the models that are trained with and without the rephrase data harms the performance of our official submission. Our official submission is ranked 7th and 11th on Arabic and English respectively.

6 Conclusion

In this paper, we present our participating system in the iSarcasmEval shared task for intended sarcasm detection in English and Arabic. Our system relies on three deep learning-based models that leverage two existing pre-trained language models for Arabic and English. We participate in all sub-tasks, investigate several training objectives, and we study the impact of including non-sarcastic rephrase in the training data. The results show that ensembling models that are trained with and without rephrases have a negative impact on the official results. Our official submissions achieve the best performance on sub-task A for the Arabic language and rank in the second position on sub-task B.

Acknowledgments

Experiments presented in this paper were carried out using the supercomputer Toubkal, supported by Mohammed VI Polytechnic University (`https://www.um6p.ma`), and facilities of simlab-cluster HPC & IA platform.

Abstract

Irony detection in the social media is an upcoming research which places a main role in sentiment analysis and offensive languague identification. Sarcasm is one form of irony that is used to provide intended comments against realism. This paper describes a method to detect intended sarcasm in text (SemEval-2022 Task 6). The TECHSSN team used Bidirectional Encoder Representations from Transformers (BERT) models and its variants to classify the text as sarcastic or non-sarcastic in English and Arabic languages. The data is preprocessed and fed to the model for training. The transformer models learn the weights during the training phase from the given dataset and predicts the output class labels for the unseen test data.

1 Introduction

Sarcasm is a form of verbal irony that occurs when there is a discrepancy between the literal and intended meanings of an utterance. This is often used to express the opposite meaning of the words spoken. This is used frequently while making fun of someone or something, and is used in a variety of contexts, like casual conversation, memes, or even public speaking, to convey a variety of meanings, providing a certain level of depth and sophistication to the communication of the language.

Sarcasm is present in all overcontemporary social media networks and may reduce the efficiency of systems that perform operations on these sarcastic data such as sentiment analysis, opinion mining, author profiling, and harassment detection (Liu, 2012; Rosenthal et al., 2014; Maynard and Greenwood, 2014; Van Hee et al., 2018). It generates misleading conclusions, due to its nature to imply different meaning than what is intended on the surface. Even in SemEval, (Rosenthal et al., 2014) shows that there is a significant drop in system performance when processing sarcastic text data, in comparison to non-sarcastic data. These systems are used in industry, driving marketing, administration, and investment decisions (Medhat et al., 2014). This clearly shows that developing models to find and detect sarcasm is becoming more important by the day.

The iSarcasmEval Task 6 for SemEval 2022 (Abu Farha et al., 2022) is comprised of three SubTasks: To classify the input text as sarcastic or not, in English (SubTaskA English) and Arabic (SubTask A Arabic), and further classify sarcastic text into categories (SubTask B), and given two phrases with same meaning, identify the sarcastic one (SubTask C English, SubTask C Arabic). Of these, the TechSSN team has attempted to solve SubTaskA English, SubTask A Arabic, and SubTask B.

2 Related Work

A lot of the previous sarcasm detection datasets have been annotated using a weak supervision method. In weak supervision, text data is classified as sarcastic only if it meets a certain set of conditions that are decided upon prior to the collection and analysis of the data. This includes using tags (e.g. #sarcasm, #irony) (Ptacek et al., 2014; Khodak et al., 2018) to perform the above mentioned classification. However, this can result in noisy labels for many reasons, as demonstrated by (Oprea and Magdy, 2020).

Other work makes use of manual labelling, where sarcasm labels are provided by human annotators (Filatova, 2012; Riloff et al., 2013a; Abercrombie and Hovy, 2016). But, this can mean that labels are subjective in nature, i.e. labels may reflect annotator perception, which may differ from the meaning intended by the author, as pointed out by (Oprea and Magdy, 2020).

Moreover, a lot of sarcasm detection work applies only to the English language and, because of the socio-cultural aspects of sarcastic communication (Oprea and Magdy, 2020), it is doubtful that the models trained to detect sarcasm in the English language could do the same task with the same effectiveness on other languages such as Arabic (where most of the sarcasm detection is carried out using the above-mentioned weak supervision).

We have participated for irony and sarcasm detection SemEval task in (Sivanaiah et al., 2018) and used MultiLayer Perceptron model to find the ironic and sarcastic tweets. We have used CNN, RNN, LSTM, BERT and COLBERT models for offensive language detection in earlier SemEval workshop tasks (Sivanaiah et al., 2021), (Sivanaiah et al., 2020), (Sivanaiah et al., 2019) in which BERT models provides better results than other machine learning and deep learning models.

3 Methodology

3.1 Dataset

We used the dataset provided by the organizers of the Task to train and build the model. The dataset has fields for sarcasm, irony, satire, understatement, overstatement, rhetorical questioning, all of which are binary, and other categories of sarcastic text, along with a field for a non-sarcastic rephrase. It contains about 3467 entries of which about 866 are sarcastic and the rest are not sarcastic. The Arabic dataset has fields for sarcasm, rephrased text, and the regional dialect. It has about 3102 entries of which about 746 entries are sarcastic and the rest are not sarcastic. The test dataset entries for Task A English is 1400, Task A Arabic is 1400, Task B is 1616. In addition, the Task B dataset has fields for sarcastic rating and regional dialect.

3.2 Data Pre-processing

First, the raw data is tokenized. This means that each sentence is tokenized or split into sub-words for the BERT model. This is done using thecompute_input_arrays method that is available under the BertTokenizer class. This method makes use of a pre-trained 'BERT-base-uncased' model to tokenize the input sentences. The maximum sequence length is set as 200 as BERT requires inputs to be in a fixed size and shape. After trimming the input, the pre-trained model combines segments and creates appropriate masks for the given data. The input representation for the model is shown in Figure 1. The token embeddings, segmentation embeddings and position embeddings are summarized together to form the input embeddings.

3.3 Models and training

We have used pre-trained models for each Subtask. We have used BERT and its modifications such as Contextualized Late Interaction over BERT (CoLBERT) (Khattab and Zaharia, 2020) and A Robustly Optimized BERT Pretraining Approach (RoBERTa) (Liu et al., 2019). BERT, simply put, is a stack of encoders part of the transformer architecture. It uses attention on the decoder side, and self-attention on the encoder side. Base BERT has 768 hidden units, 12 attention heads, and 110M parameters. Similarly, Large BERT has 1024 hidden units, 16 attention heads, and 340M parameters. The BERT model takes a classification token, followed by a sequence of words as input. The input is then passed through several layers of encoder stack (12 in Base BERT, 24 in Large BERT). Each of the many layers applies self-attention, sends the output through a feedforward network of hidden layers, and then sends the output to the next encoder layer.

The procedures for pretraining and finetuning the model is shown in Figure 2. Same architecture structure is used in pre-training anf fine-tuning, differs only in the output layers. Both the encoder and decoder stream tasks are initialized with the same pre-trained model parameters. All parameters are fine-tuned in tuning phase. [CLS] is a special symbol added in front of every input example, and [SEP] is a special separator token (e.g. separating questions/answers).

RoBERTa is a modification to the original BERT, and needs about the same amount of parameters that Base BERT requires (110M). It takes more training time than BERT, about 4-5 times more than BERT, but can provide more accurate results and predictions compared to BERT. CoLBERT is faster than many other BERT-based models and uses a pre-trained BERT model to handle late interactions. The model is trained with the training data provided by the organizers.

4 Results and Discussions

The test dataset was provided by the SemEval-2022 organizers and was given to different models for each Subtask and the results are listed in Tables 1 to 3.

ColBERT model gives better accuracy for the English language than Arabic. For subtask B we have used multilabel classifier to predict the output.

5 Conclusion

It is obvious that the detection of sarcasm and its various categories is important as it is pivotal in computations like sentiment analysis, opinion mining, author profiling, or harassment checking. This can become increasingly difficult and tedious to compute, as sarcasm is extremely subjective as its nature itself is implying and contradictory, and the amount of data to be analyzed is getting larger and complex by the day. It is also a big step for Natural Language Processing (NLP) as it can tremendously help in the creation of more sophisticated virtual assistants and chatbots, which can emulate conversations that are closer to human interactions and life-like.

SemEval-2022 Task 6 is comprised of three SubTasks of which the TechSSN team has participated in Subtask A English, Subtask A Arabic and Subtask B. Deep learning models like BERT, RoBERT, and CoLBERT were used to carry out the tasks successfully. The team was able to obtain the 27th rank in Task A – English, 29th rank in Task A – Arabic, and 17th rank in Task B. Results show that BERT based models perform better on average than other conventional models like Logistic Regression Decision Tree, Support Vector Machines etc. Because of BERT's multilingual nature, sarcasm detection can be carried out in other languages across the globe. We would like to investigate further and apply these models to other languages. The accuracy could potentially be improved by using more advanced and efficient pre-processing techniques.

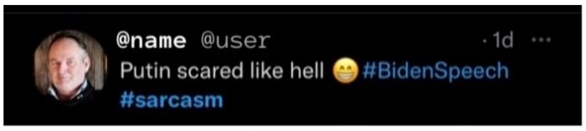
Abstract

Sarcasm is often expressed through several verbal and non-verbal cues, e.g., a change of tone, overemphasis in a word, a drawn-out syllable, or a straight looking face. Most of the recent work in sarcasm detection has been carried out on textual data. This paper describes how the problem proposed in *Task 6: Intended Sarcasm Detection in English* (Abu Arfa et al. 2022) has been solved. Specifically, we participated in *Subtask B: a binary multi-label classification task*, where it is necessary to determine whether a tweet belongs to an ironic speech category, if any. Several approaches (classic machine learning and deep learning algorithms) were developed. The final submission consisted of a BERT based model and a macro-F1 score of 0.0699 was obtained.

1 Introduction

Existing social media analysis systems are limited by their inability to accurately detect and interpret figurative language. Sarcasm is often used by individuals to express opinions on complex matters and regarding specific targets (Carvalho et al. 2009).

Early computational models for verbal and irony and sarcasm detection have relied on shallow methods exploiting conditional token count regularities. But lexical clues alone are insufficient to discern sarcasm intent. Appreciating the context of expression is critical for this; even for humans (Wallace et al. 2014). Indeed, the exact same sentence can be interpreted as literal or sarcastic, depending on the speaker. Consider the sarcastic tweet in Figure 1 (ignoring for the moment the attached *#sarcasm* hashtag). Without knowing the author's political inclination, it would be difficult to conclude with certainty whether the tweet was intended as sarcastic or not.



@name @user · 1d ···
Putin scared like hell 😁 #BidenSpeech #sarcasm

Figure 1: An illustrative tweet.

This task is about the binary classification of tweets in English based on the category of ironic speech. As a Multilabel-Classification, a tweet can belong to multiple categories or none. This research is important because social networking sites have changed our lives in recent years. For companies, this social reality has turned into an obligation to set up communication and marketing channels through social networks. Besides, companies require feedback from consumers, through comments or messages that mark the acceptance or rejection of each of the proposals, products or services.

For this competition 2 models/strategies were used:

- The first model is a binary multilabel classifier using Bayesian networks.
- The second model and final submit on the competition consisted of six different binary classifiers using BERT. In other words, one for each evaluable label: sarcasm, irony, satire,

understatement, overstatement and rhetorical question.

In this task we have analysed the sarcastic behaviour of people on social networks, in this case twitter, and the ways in which people express it. The dataset proposed by the organization was very unbalanced, so we had to apply several data balancing techniques in order to achieve good results.

The rest of this paper is organized as follows: in section 2 we explain the dataset, the meaning of the labels and data distribution. Therefore, we refer to other research that has helped us in our approach to this one. In section 3, several techniques and methods applied to our models to improve their performance and metrics are described. In section 4 we explain the libraries used and their usefulness. Finally, in section 5, the scores obtained with our proposed approaches are presented.

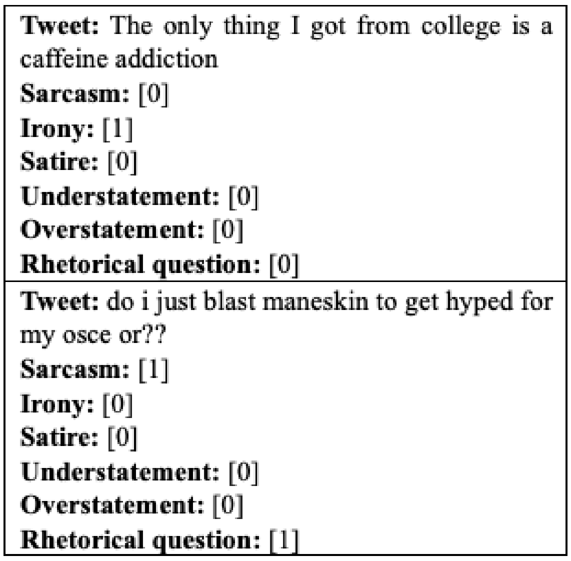
2 Background

As mentioned above, this paper is focused on Subtask B: binary multilabel classification. The original dataset has 3467 tweets in English with a maximum size of 280 characters (tweet limit). As a matter of fact, only the first 867 tweets will be useful for our task because the rest of the tweets do not have the labels that we are going to work with. Furthermore, the columns “Unnamed:0”, “rephrase” and “sarcastic” have been removed because they are useless for our task perfomance.

For a better analysis and understanding of the multiple labels that we have in our dataset it is important to mention the *ironic speech* exposed in (Leggitt and Gibbs 2000):

1. *Sarcasm*: tweets that contradict the state of affairs and are critical towards an addressee
2. *Irony*: tweets that contradict the state of affairs. but are not obviously critical towards an addressee.
3. *Satire*: tweets that appear to support an addressee but contain underlying disagreement and mocking.
4. *Understatement*: tweets that undermine the importance of the state of affairs they refer to
5. *Overstatement*: tweets that describe the state of affairs in terms that are obviously exaggerated.
6. *Rhetorical question*: tweets that include a question whose invited inference (implication) is obviously contradicting the state of affairs.

In Figure 2, two samples of the dataset with the information used in our approaches can be seen.



Tweet: The only thing I got from college is a caffeine addiction
Sarcasm: [0]
Irony: [1]
Satire: [0]
Understatement: [0]
Overstatement: [0]
Rhetorical question: [0]

Tweet: do i just blast maneskin to get hyped for my osce or??
Sarcasm: [1]
Irony: [0]
Satire: [0]
Understatement: [0]
Overstatement: [0]
Rhetorical question: [1]

Figure 2: Example of two rows

When it comes to the multiple labels (categories) of sarcasm, Table 1 shows the distribution of the tweets into these categories. As can be seen, the dataset is imbalanced so, in the next section, we explain how the dataset was balanced for a better performance.

Category	Number of tweets
Sarcasm	713
Irony	155
Satire	25
Understatement	10
Overstatement	40
Rhetorical question	101

Table 1: Distribution of tweets in each category

This challenge has been approached by different researchers. In (Davidov et al., 2010), experiments with semi-supervised sarcasm identification on a Twitter dataset (5.9 million tweets) were carried out using 50 Twitter tags and 15 emojis as sentiment labels. They used a 5-fold cross validation on their classifier getting a F1-score of 0.55.

In addition, in (Tsur et al.,2010), they propose a semi supervised system for sarcasm recognition over 66,000 products reviews from Amazon. They used the same strategy as in the previous mention and obtained and F-score of 0.83 on the product reviews dataset.

More recently, other approaches have been developed to solve the task of sarcasm detection. In (Ashwita et al. 2021), the authors experimented by varying the amount of context used along with the response (text to be classified) and found that including the last utterance in the dialogue along with the response improved the performance of their system.

In (Khatri, P, Pranav, y M, Dr. Anand Kumar 2020), a model using machine learning techniques with BERT and GloVe embeddings to detect sarcasm in tweets was proposed.

3 System Overview

This section describes the two types of models that were submitted and the techniques and methods applied to each model to improve their performance and metrics.

3.1 Data augmentation

One of the main problems with the dataset is the small number of tweets to train our models (only 867 tweets). To solve this, a data augmentation technique was applied. In particular, a synonym augmenter (Wordnet, English) (McCrae et al. 2019) was used to create a new tweet but only swapping one random word by its synonym and keeping their labels. An example of this technique can be seen in Table 2.

Original tweet	The quick brown fox jumps over the lazy dog
New tweet	The quick gray fox jumps over the lazy dog

Table 2: Example of data augmentation

We suggest applying this technique only once because our model could overfitting the data and could yield overrated results of the metrics.

3.2 External databases

Another technique applied in the proposed models for the data augmentation was the manual insertion of tweets and labels (Oprea and Magdy 2019). Most of the tweets inserted belong to minority labels (we can see the minority classes on Table 1) such as satire, overstatement or understatement. Finally, once the new tweets were manually added, the dataset consisted of 904 tweets.

3.3 Text Processing

We have applied three versions of text processing to clean and simplify the text based on the work described in (Alzahrani and Jolonian 2021).

Text processing v1.0: this is the most basic pre-process. For this version, the following guidelines were applied:

- Conversion of all characters to lowercase.
- Extent of all possible contractions in English (e.g., what's → what is).
- Removal of emojis.
- Removal of special characters.
- Removal of multiple spaces between characters.

Text processing v2.0: this is the intermediate version. In addition to the features described at v1.0, the following features were added:

- Removal of emojis made from keyboard characters
- Removal of mentions
- Removal of links

Text processing v3.0: this is the full version. In addition to the features presented in v2.0, a removal of stopwords in English was added.

3.4 First model: Bayesian networks

The first model that was developed involves the classic algorithm of Bayesian networks (Heckerman and Wellman 1995) to study the pattern of behavior that the categories of sarcasm may present in our dataset.

We used a naive Bayes classifier (NBC) which assumes that the attributes are independent of each other. That is to say, the probability can be obtained by calculating the product of the individual conditional probabilities of each attribute given the class node as it can be seen on Figure 3.

In this model, an input (a single tweet) is provided, and it returns a vector of size six (one for each tag) with the predicted label.

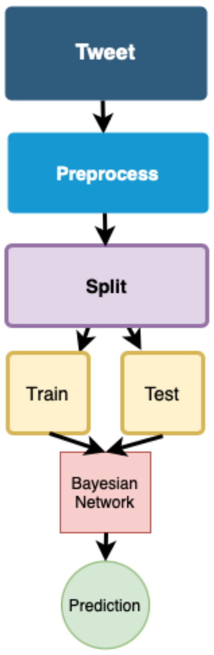


Figure 3: Steps followed on the first model

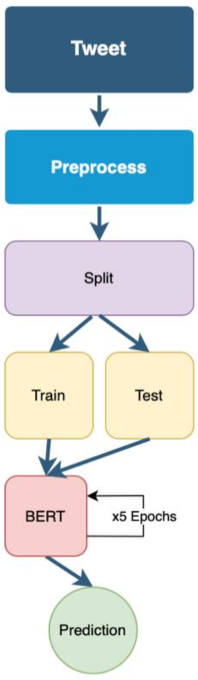

Figure 4: Steps followed on the second model

3.5 Second model: BERT

Bidirectional Encoder Representations from Transformers (BERT) is a transformer-based machine learning technique for natural language processing (NLP) pretraining developed by (Devlin et al. 2018). *BERT-base-uncased* model is pretrained from unlabeled data extracted from BooksCorpus (Bandy and Vincent 2021) which have 800M of words and from English Wikipedia with 2,500M of words.

BERT uses Transformers (Wolf et al. 2019) as an attention mechanism that learns contextual relations between words (or sub-words) within a text. Transformers includes two separate mechanisms: an encoder that reads the text input and a decoder that produces a prediction of the label.

For this model, the binary relevance (BR) strategy (Luaces et al. 2012) was used, which splits the learning process of the dataset into a sets of binary classification tasks, in other words, one per label. The main disadvantage of this strategy is that BR ignores any label dependency and could fail in predicting some combination of labels that presents any dependency.

We have trained our second model with a batch of 32 instances and 5 epochs. Figure 4 represents the strategy of this model.

4 Experimental Setup

To obtain the above models, some libraries were used:

- For the data augmentation, the *nltk* library (Wang and Hu 2021, 1041-1049).
- For padding the sequences of the inputs id's, the *keras* library.
- *Sklearn* library for the metrics and splitting the dataset (Hao and Ho 2019).
- *Pandas* library for working with dataframes (Stepanek 2020).
- *Transformers* library for everything related with BERT.

For all the experiments, tweets were preprocessed and then they were randomly split using a stratified method (80% training and 20% testing). That means that the proportion of values in the samples produced is the same as the proportion of values provided for the parameter to stratify.

During the training phase of the competition, we have only focused on the macro-F1 score as the key metric of the Subtask B.

5 Results

Two submissions were sent using Bayesian Networks: the first one with the text processing v1.0 and the second one with the text processing v3.0. Table 3 shows the results obtained during the training phase.

Metrics	v1.0. Text processing	v3.0. Text processing
F1 Sarcasm	0.89	0.84
F1 Irony	0.26	0.20
F1 Satire	0.38	0.51
F1 Overstatement	0.17	0.48
F1 Understatement	0.47	0.47
F1 Rhetorical Question	0.12	0.20
Macro F1-Score	0.38	0.45

Table 3: Results obtained using Bayesian Networks

Metrics	v1.0	v2.0	v3.0	v4.0	v5.0
F1 Sarcasm	0.45	0.78	0.81	0.80	0.70
F1 Irony	0.45	0.72	0.77	0.77	0.64
F1 Satire	0.49	0.63	0.66	0.64	0.57
F1 Understatement	0.50	0.60	0.63	0.62	0.52
F1 Overstatement	0.49	0.65	0.69	0.71	0.60
F1 Rhetorical Question	0.84	0.90	0.91	0.89	0.87
Macro F1-Score	0.54	0.71	**0.75**	0.74	0.65

Table 4: Results obtained using BERT

Regarding the final submission using BERT-base-uncased, different approaches were used. Table 4 shows the results obtained during the training phase. The approaches were:

- **v1.0.** Nothing extra applied
- **v2.0.** Previous versions + Data Augmentation in minority class only.
- **v3.0.** Previous versions + insert data of an external database.
- **v4.0.** Previous versions + v2.0 of text processing.
- **v5.0.** Previous version + v3.0 of text processing.

Taking a look at Table 3 and Table 4, can be seen that in v3.0 of Table 4, the best macro F1-score is obtained. So that was our final submission.

According to the official metrics, as was mentioned before, we achieved a macro F1-score of 0.0699 and we were ranked 10th among 22 teams that participated on this subtask.

Analyzing our systems, we can state that the main problem found in the subtask was the lack of data towards unbalanced data at the dataset, which is why we have been constantly applying data augmentation on the minority classes and even inserting data from an external database. Applying these two techniques, a big improvement in the performance of our systems can be seen.

Furthermore, our research shows that any kind of preprocessing technique is mostly useless because any character, capital letter, overextended word or symbol, could be the determining factor in recognizing ironic speech.

6 Conclusion

In this paper our approach to solve *Task 6 (iSarcasmEval) – Subtask B: Given a text, determine which ironic speech category it belongs to, if any; in English*, has been described.

Our best result was reached with a deep learning algorithm (BERT) model, with which we achieved a macro F1-score of 0.0699. We obtained the 10th position in the ranking.

For future works, an improved version of our BERT model could be developed by training with a bigger dataset. It is also possible to look for new preprocessing techniques that enable the removal of information that is useless to the meaning of the tweet but still maintain the ironic speech patterns (if any).

Abstract

The intended sarcasm cannot be understood until the listener observes that the text's literal meaning violates truthfulness. Consequently, words and meanings play an essential role in specifying sarcasm. Enriched feature extraction techniques were proposed to capture both words and meanings in the contexts. Due to the overlapping features in sarcastic and non-sarcastic texts, a CNN model extracts local features from the combined class-dependent statistical embedding of sarcastic texts with contextualized embedding. Another component BiLSTM extracts long dependencies from combined non-sarcastic statistical and contextualized embeddings. This work combines a classifier that uses the combined high-level features of CNN and BiLSTM for sarcasm detection to produce the final predictions. The experimental analysis presented in this paper shows the effectiveness of the proposed method.

1 Introduction

Sarcasm detection is a specific case of sentiment analysis where the focus is on detecting sarcasm in text. Therefore, the task is to detect if a given text is sarcastic or not. According to (Hacker, 2011), sarcasm refers to the use of words that mean the opposite of what you want to say, especially to insult someone, show irritation, or provide humor. However, (Oprea and Magdy, 2020; Wilson, 2006) define sarcasm as a form of irony marked by a discrepancy between the literal and intended meanings of an utterance, through which the speaker usually manifests a hostile, derogatory, or contemptuous attitude. Generally, sarcasm tweets/texts are the utterances of a positive statement with harmful intent, and since the intent is hard to detect not only for computers but also for humans, it has attracted a considerable body of research in the natural language processing field to study opinions given by the users of online social media platforms such as Twitter, Facebook, Reddit, and Instagram. In the SemEval 2022 at Task 6: iSarcasmEval (Abu Farha et al., 2022), the goal is to identify intended sarcasm in both English and Arabic languages. This task consists of 3 subtasks, and we will focus on SubTask A defined as: *SubTask A: Given a text, determine whether it is sarcastic or non-sarcastic*.

Since sarcasm is an utterance of a statement with negative intent (e.g., *He has the best taste in music.*") and an admiring tone (e.g., "*She always makes dry jokes.*"). We hypothesized that contextualized representation might not be enough to represent intent when considering the sentiment analysis challenge. Therefore, we combined the representation of stylistically statistical and contextualized word embeddings using deep neural networks (DNNs) as a high-level feature extractor and classifier for the task. In this work, we studied the effect of the combination of stylistic and contextualized representation. The rest of the article is organized as follows. We first describe sarcasm studies in Section 2. Section 3 presents the proposed methodology. Sections 4 and 5 describe experimental setups and results. Moreover, in section 6 we made the discussion. Finally, in section 7 we conclude the article.

2 Related Works

Sarcasm detection research has seen a significant surge in interest in the past few years (Potamias et al., 2020; González et al., 2020; Babanejad et al., 2020; Gregory et al., 2020; Kumar et al., 2021; Ahuja and Sharma, 2021). At early stages, most works considered content as the only source for identifying sarcasm (Yaghoobian et al., 2021). To differentiate between sarcasm and non-sarcasm handcrafted rules and features have been applied (Veale and Hao, 2010; Bharti et al., 2015; Riloff et al., 2013). For instance, (Barbieri et al., 2014) used seven sets of lexical features to detect sarcasm by its inner structure. Frequency and Structure (i.e., length, punctuation, emoticons) are two examples of sarcasm features. However, the model based on these stylistic features shows promising results but lacks external knowledge (i.e., common sense). Our proposed method incorporates stylistic features with XLM-RoBERTa model to cope with the limitations of prior methods. Most recently, dominant approaches are Context-based, utilizing background knowledge and contextual dependencies as prior knowledge about the event mentioned in a sarcastic context (Li et al., 2020; Agrawal et al., 2020; Potamias et al., 2020). (Wallace et al., 2014) provided empirical evidence that to make judgments concerning ironic intent annotators require additional contextual information. Hazarika et al. is one of a few works that tried to capture the stylometric and personality features of the users and used user embeddings to encode stylometric and personality features of users combined by a content-based feature extractor (i.e., CNN)(Hazarika et al., 2018). This sarcasm detection model shows promising results on a large Reddit corpus. The improvement in results by this work inspired us to investigate the effectiveness of incorporating content-based features for SemEval-2022 Task 6: iSarcasmEval, but the problem we faced was the lack of data assigned to each user. As a result, instead of a users' unique features, we investigate the stylometric features of each class. In other words, we tried to find general styles of users who tried to write sarcastic texts by finding the distribution of their frequent words and other features provided in section 3. Results provided in section 5 empirically demonstrate the effectiveness of this incorporation. The effectiveness of transfer learning has given rise to a diversity of approaches, methodology, and practice, and they are also gaining attention in Sarcasm detection. BERT, RoBERTa, and XLNet are examples that deliver significant improvements. For example, (Potamias et al., 2020) proposed Recurrent CNN RoBERTa (RCNN-RoBERTa), which obtained %79 on the SARC dataset. Based on its effectiveness and multilingualism, we utilized the RoBERTa model for this research.

3 Model Description

In this section, we describe the details of our proposed deep learning model. The goal is to predict whether the given text is sarcastic or non-sarcastic. Figure 1 depicts an overview of our proposed method.

First, preprocessing (Appendix A.1) is applied to the raw texts. Next, character-based lower dimensionality statistical embedding (Char-LDSE) (Rangel et al., 2017; Giglou et al., 2021) captures the stylistic information about sarcastic and non-sarcastic data in form of class-dependent features based on the term frequency of tokens in sarcastic and non-sarcastic classes. The calculated LDSE features for sarcastic class in combination with contextualized representation are fed into Convolutional Neural Networks (CNNs) (LeCun et al., 1999) to extract local information of the texts. In another setting, the LDSE for non-sarcastic class in combination with contextualized representation is fed into Bidirectional Long Short-Term Memory (BiLSTM) (Schuster and Paliwal, 1997) to learn the long-dependent information in the texts. The features from CNN and BiLSTM layers combined for enhancing the feature extraction ability of the model. Extracted high-level features are fed into the classifier. In the following, we describe each component elaborately.

3.1 Representation

Preprocessed texts are fed into Char-LDSE and contextualized representations. Where it outputs an embedding for models.

Char-LDSE: First, a character n-gram matrix with TFIDF weight is created. Using TFIDF matrix the LDSE weighted probability of terms per class was obtained. As a result, $P(sarcastic)$ and $P(non-sarcastic)$ embeddings are calculated for sarcastic and non-sarcastic, respectively. The union of n-grams with TFIDF weighing on the training set is applied to achieve the input matrix of LDSE. We utilized character-level n-grams features with an n-gram range of $(2, 3)$, and word-level unigrams features for building input matrix to LDSE. For English character-level and word-level settings, and for Arabic, the only character-level setting is applied. As a result, we obtain the following matrix:

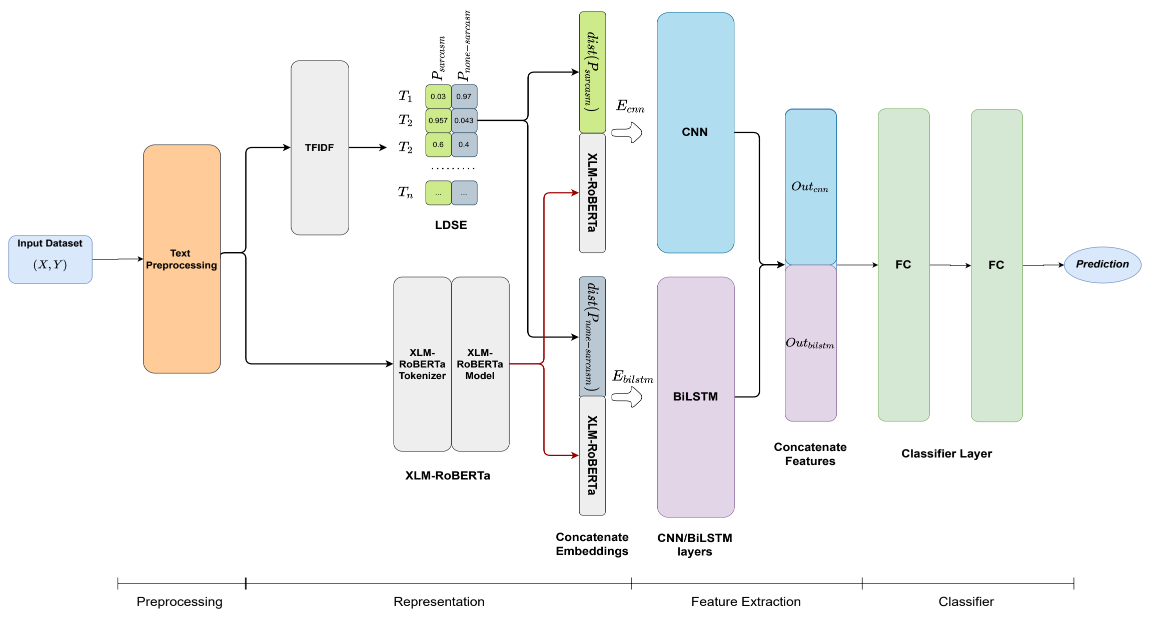

Figure 1: Architecture of Proposed Model

$$M = \left[\begin{array}{ccc|c} W_{11} & ... & W_{1n} & \beta(iS_{C_0}) \\ W_{21} & ... & W_{2n} & \beta(iS_{C_0}) \\ ... & ... & ... & ... \\ W_{(m-2)1} & ... & W_{(m-2)n} & \beta(iS_{C_1}) \\ W_{(m-1)1} & ... & W_{(m-1)n} & \beta(iS_{C_1}) \\ W_{m1} & .... & W_{mn} & \beta(iS_{C_1}) \end{array}\right]$$

Where each row in the matrix M represents a intended Sarcasm (iS) iS_i, each column represents vocabulary term T and W_{ij} represents its TFIDF weight and β represents the assigned class (C_1 - sarcastic, C_0 - non-sarcastic) of the iS text. Also, m and n represent the number of the training set and vocabulary size, respectively. To obtain the class-dependent term T weight embedding LDSE the following $LDSE(T, c)$ formula has been calculated:

$$LDSE(T, c) = \frac{\sum_{is \in \beta(iS_c)/c=\beta(iS_c)} W_{is,T}}{\sum_{is \in \beta(iS_c)} W_{is,T}}$$

$$\forall is \in iS, \; c \in \{C_0, C_1\}$$

Next, we calculated LDSE for each class for term T:

$$P_{sarcastic} = LDSE(T, c)$$

$$P_{non-sarcastic} = LDSE(T, c)$$

At the end, using $P_{sarcastic}$ and $P_{non-sarcastic}$ we extract the following representations:

$$feat(P_{sarcastic}) \; , \; feat(P_{non-sarcastic})$$

Where $feat(P)$ contains the set of features presented as followings:

$$feat(P) = \{max, min, std, avg, Q_1, ..., Q_{100}\}$$

Where $feat(P) \in \mathbb{R}^{104}$ is the class-dependent LDSE features. Accordingly, max, min, std, and avg are maximum, minimum, standard deviation, and average of weights P, respectively. Moreover, the $\{Q_1, ..., Q_{100}\}$ is the Q-th quantile of P's.

Contextualized Embedding: The XLM-RoBERTa (Conneau et al., 2020) is a pre-trained language model with the Masked Language Modeling (MLM) objective. The XLM-RoBERTa is a multilingual version of RoBERTa (Liu et al., 2019), which is pre-trained on 2.5TB of CommonCrawl data containing 100 languages. The model learns an inner representation of 100 languages that can then be used to extract features useful for downstream tasks. The function $CE \in \mathbb{R}^{768}$ is a base version of contextualized XLM-RoBERTa word embeddings. CE takes iS texts, uses XLM-RoBERTa tokenizer and XLM-RoBERTa model for word embedding generations.

$$CE(iS) := XLMRoBERTa(iS)$$

Concatenate Embeddings: In representations combination, we took the following approach. For CNN layer we combined $feat(P_{sarcastic})$ with $CE(iS)$, and for BiLSTM layer we combined $feat(P_{non-sarcastic})$ with $CE(iS)$. We obtained the following equations.

$$f\colon feat(P_{sarcastic}) \oplus CE(iS) \rightarrow E_{cnn}$$

$$f\colon feat(P_{non-sarcastic}) \oplus CE(iS) \rightarrow E_{bilstm}$$

Where $E_{cnn}, E_{bilstm} \in \mathbb{R}^{872}$, which will be the inputs of CNN and BiLSTM models in feature extraction module.

3.2 Feature Extraction

The CNN is applied on E_{cnn} and BiLSTM is applied on E_{bilstm} to extraction high-level features. Next, outputs of CNN and BiLSTM models are concatenated as an input to the classifier.

CNN Feature Extractor: CNN is a feature extraction technique with strong adaptability and is good at mining data local characteristics. Our CNN's has architecture as follows:

1. Two CNN layer with $Conv2D : conv2d \rightarrow maxpooling1d \rightarrow activation$ scheme.
2. Concatenate output of the two CNN layers: $Out_{cnn} = Conv2D_1 \oplus Conv2D_2$.
3. Dropout layer.

Where $Out_{cnn} \in \mathbb{R}^{200}$ with output channel number of 100 in both CNN layers. The first layer in CNN uses a kernel size of $(4, 872)$, padding of $(2, 0)$, and stride of 3. However, the second layer employs a kernel size of $(3, 872)$, padding of $(1, 0)$, and stride of 2. Next, for an activation function, the Gaussian Error Linear Unit (GELU) (Hendrycks and Gimpel, 2020) that nonlinearity weights inputs by their percentile, rather than gates inputs by their sign as in ReLUs (Agarap, 2019) is applied. It has been used in most of the transformers.

BiLSTM Sequence Learner: For a better representation of contextual information, single BiLSTM layer was employed. The BiLSTM is composed of two LSTM network that is capable of reading input texts in both directions, forward and backward. The forward LSTM processes information from left to right, and backward LSTM processes information vice versa and hidden state can be shown as:

$$\overrightarrow{h}_t = LSTM(E_{bilstm}, \overrightarrow{h}_{t-1})$$

$$\overleftarrow{h}_t = LSTM(E_{bilstm}, \overleftarrow{h}_{t+1})$$

Next, output of BiLSTM can be summarized as following where the max-pooling is applied to output h_t to retrieves a maximum value of each feature in the BiLSTM layer.

$$h_t = \overrightarrow{h}_t \oplus \overleftarrow{h}_t$$

$$Out_{bilstm} = MaxPool1d(h_t)$$

Where $Out_{bilstm} \in \mathbb{R}^{200}$.

Concatenate Features: As a final high-level feature, the Out_{cnn} and Out_{bilstm} outputs are concatenated as follows, Where $Out_{cnn \oplus bilstm} \in \mathbb{R}^{400}$.

$$Out_{cnn \oplus bilstm} = Out_{cnn} \oplus Out_{bilstm}$$

3.3 Classifier

The two fully connected layers use $Out_{cnnbilstm}$ for classification objectives. The first layer takes 400 neurons as input and outputs 200 neurons. Next, GELU activation is applied. Finally, the second layer takes 200 neurons and outputs 2 neurons (the prediction module).

4 Experimental Setup

Dataset: For sarcastic or non-sarcastic detection tasks, the collected dataset where the sarcasm labels for texts are provided by authors themselves, thus eliminating labeling proxies. For hyperparameter tuning and model selection we split the training set into train and dev sets with a 10% split rate for both English and Arabic languages. More information about the datasets (train, dev, and test sets) has been presented in Appendix A.2. The dataset is highly imbalanced.

Training Setup: The preprocessing (Appendix A.1) is applied to text, first. Next, using train and dev sets we made hyperparameters tuning (Appendix A.3). Due to the imbalanced setting of the data we made a data argumentation (Appendix A.4) as one of our experiments. The experimental design shows the positive effect of data augmentation. More information about preprocessing, hyperparameter setting, and data augmentation are described in the appendix section. As an evaluation metric to this task (SubTask A of iSarcasmEval), the main metrics for SubTask A is F1-score for the sarcastic class.

5 Results

Main Quantitative Findings: The table 1 presents the final results on the test set for English and Arabic languages. The main quantitative findings are:

Language	Accuracy	Precision	Recall	F1-Score	F1-Sarcastic	FP	FN	Rank
English	0.6136	0.5290	0.5558	0.4992	**0.2599**	436	105	28
Arabic	0.6671	0.5835	0.6600	0.5667	**0.3581**	396	70	18

Table 1: Evaluation results on test set for SubTask A.

- For English, the proposed model achieved 28th place among 43 teams, and 18th place among 32 teams for the Arabic.
- According to type I error (FP), the model for both languages wrongly predicts the high rate of non-sarcastic samples as sarcastic data. Regarding this phenomenon, the task suffers from type I error mostly.
- For the English language, among 200 sarcastic samples model captures 95 samples correctly, however, for the Arabic language, 130 samples were predicted correctly as sarcastic. About 65% TPR (True Positive Rate) of sarcastic samples in Arabic, but 47.5% of sarcastic samples in English were detected. It shows the task is more sensitive in English rather than Arabic.

Quantitative Analysis: We have used experimentations on the dev set to conclude the CNN-BiLSTM model as a final system for intended sarcasm detection at iSarcasmEval. The experiments are presented in Appendix A.5, and the table 6 shows experimental results. The quantitive analysis is presented as follows:

- The character-based n-gram with an n-gram range of $(2, 3)$ was implemented as a baseline representation with logistic regression, linear SVM, and multi-layer perceptron (MLP) as baseline models. The experimental results on both English and Arabic languages show neural networks (MLP) are performing well on this task.
- The experimentation of *LDSE + MLP* shows that stylistic representations are promising, but they are not enough.
- To find a candidate representation in combination with LDSE, as a performance booster, the XLM-RoBERTa masked language model is been considered. The *XLM-RoBERTa + MLP* shows that contextualized representation is very capable.
- The *Combination + MLP* model is combined LDSE and XLM-RoBERTa representation. The achieved result is promising for Arabic but it is 2% higher for English, this shows stylistic features in combination with contextualized representation perform well. The more complex model may boost the performance.
- The *Proposed Model (1)* uses preprocessing followed by the enriched representation with CNN-BiLSTM model. It is more capable than *Combination + MLP* model.
- Due to the unequal class distribution in the dataset, we employed weights in the cross-entropy loss function. The *Proposed Model (2)* results show its positive effects.
- We experimented with data augmentation techniques (Appendix A.4) and discovered that due to the word importance in achieving high-quality features for LDSE, data augmentation works more considerably well for this task (*Proposed Model (2) + Aug* model).
- The data augmentation probability shifts show the effects of LDSE representations (table 4). And considering *Proposed Model (2)* and *Proposed Model (2) + Aug*, We can observe that data augmentation affects mostly the stylistic features and results in boosting the performance. It represents that high-level feature extraction from a multi-space domain such as LDSE and XLM-RoBERTa play an important role in sarcasm detection.

6 Discussion

Type-1 Error: In either language, non-sarcastic samples are predicted wrongly as sarcastic. Type-1 error is the major source of error. Analysis of English FP samples indicated that most of the samples were in response to a post or reply to another person and indeed, with no information about the text context nor the writer profile, this indicates a lack of primordial clues for sarcasm detection. To make an improvement in reducing the error two approaches can be taken. First, consider more information about the text context such as the tread or post. Second, using a finer feature representation, since the lack of primordial clues leads to low-quality features. Moreover, the analysis revealed the following findings in the data which can be taken into account to improve the results by reducing the error (all of the findings come from the analysis of 436 FP samples for the English test set).

- We have found that samples in the dataset may be labeled wrongly as sarcasm so correcting them may boost the performance (e.g *"10 dec 2021, 4:46 am, All in on $PYR (28,07$)"* or *"pointing-downmedium-skin-tone-emoji this"*)

- A few samples were in single words (e.g *"Rubbish"*) which in a few cases such as *"pointing-downmedium-skin-tone-emoji this"* and *"Followed"* they didn't convey any meaning, tackling them in modelin could be more challenging since they don't have enought information for models.

- In a few cases preprocessing causes a low quality text generation (e.g *"10 dec 2021, 4:46 am, All in on $PYR (28,07$)"* will be converted into *'dec am all in on"* which is less valuable for modeling).

- Sometimes, emojis make the text sarcasm, so using them as features could be useful for this task since most of the comments in FP samples had emojis (almost 60% of them). In the whole preprocessing we converted emojis into texts, but in this way we thread the emojis similar to text, however, threading them in a different way may boost the performance.

Weighted Loss and TFIDF Data Augmentation Improvements: According to table 6, and model *Proposed Model (2)*, adding weighted loss cross-entropy increased results on the dev set by 1% in English, and 2% in Arabic. Similar to weighted loss cross-entropy, the model *Proposed Model (2) +Aug* in table 6 shows TFIDF data augmentation improved results on the dev set by 1% in English, and 4% in Arabic. Overall, weighted loss cross-entropy and TFIDF data augmentation together improved results by 2% in English, and 6% in Arabic. So using these techniques is promising in boosting the sarcasm detection models.

Task Sensitiveness in Languages: We proposed a class-dependent LDSE that considers character n-grams in stylistic information calculations. Character n-gram contains information on the more important tokens and the less important ones as well. So it captures the differences using token counts. However, The stress patterns of most Arabic dialects are broadly similar and appear regularly. Changes happen frequently in English, as word stress can change the lexical variety and meaning of the word (Watson et al., 2011). This affects both LDSE and contextualized representation.

Because LDSE is doing a probability-based calculation for tokens using a character n-gram matrix, the similarity in dialects will lead to a high-quality n-gram matrix in Arabic rather than English. Table 6 experimentation on the TFIDF matrix reveals this fact precisely. Accordingly, as a result of changes in the meaning, neural network feature extractors may have found some variant features which leads to misclassification (Type 1 error). The experimentations with *XLM-RoBERTa + MLP* (table 6) show that neural network models are performing better on Arabic contextualized representation rather than English. Experiments clearly show why this task is more sensitive in the English language than in Arabic.

7 Conclusion

This paper presented our approach for SemEval-2022 Task 6: iSarcasmEval: Intended Sarcasm Detection In English and Arabic. We investigated this problem by employing statistical and contextualized representations with deep learning techniques. We conducted the experimental and statistical analysis and presented the CNN-BiLSTM framework. The proposed studies in this paper show that considering stylistic features with deep learning frameworks is promising for intended sarcasm detection in both English and Arabic languages.

A Appendices

A.1 Preprocessing

Text preprocessing is often the first step in the pipeline of an NLP system. We consider the following preprocessing techniques to be applied to an input text:

- Lowercasing
- Punctuation removal
- Special character removal
- Demojify[1](converting emoji into texts)
- URL, #, @ removal
- Number removal

These preprocessing techniques were applied for both English and Arabic languages.

A.2 Train, Dev, and Test Sets

Each text in the datasets has a label specifying its sarcastic nature (sarcastic or non-sarcastic), provided by its author. The stats of the datasets are presented in table 2.

A.3 Hyperparameter Setting

For training DNNs there are multiple hyperparameters to be fine tuned. Batch size, learning rate, epoch, loss function, weight decay, dropout, wighted loss, and optimizer. The hyperparameters are described in the table 3 for both English and Arabic languages.

A.4 Data Augmentation

Data augmentation is a way to generate synthetic data for improving model performance without manual effort. Since we are dealing with an imbalanced binary classification problem and due to the importance of terms likelihood in LDSE we made a TFIDF data augmenter that learns the word preferences for samples in sarcastic class only, then generates new synthetic samples. For generating new samples we have followed the following steps:

1. Getting sarcastic samples from training data for data augmentation.
2. Preprocessing selected samples.
3. Training TFIDF data augmenter using *nlpaug* (Ma, 2019) a python library.
4. Augment sarcastic samples using data augmenter.
5. Generate new samples for sarcastic samples only.

The overall stats of the data augmentation are presented in the table 4. According to the mean average probability of terms in sarcastic and non-sarcastic, the data augmentation shifts the average probabilities in both classes. Since we were using the same set of data for argumentation so we observe the proper number of changes in tokens. Samples from data augmenter for both languages are presented in the table 5.

A.5 Experiments

The table 6 presents the experimental results for hyperparameter tunings. According to the table

Abstract

Sarcasm has gained notoriety for being difficult to detect by machine learning systems due to its figurative nature. In this paper, Bidirectional Encoder Representations from Transformers (BERT) model has been used with ensemble loss made of cross-entropy loss and negative log-likelihood loss to classify whether a given sentence is in English and Arabic tweets are sarcastic or not. From the results obtained in the experiments, our proposed BERT with ensemble loss achieved superior performance when applied to English and Arabic test datasets. For the validation dataset, our model performed better on the Arabic dataset but failed to outperform the baseline method (made of BERT with only a single loss function) when applied on the English validation set.

1 Introduction

In recent times, Social media platforms such as Twitter have turned out to be one of the most influential media for the expression of views, emotions, and information. To characterize sarcasm on Twitter; (Parmar et al., 2018) proposed the following: (a) strife between negative situation and positive sentiment, (b) strife between positive situation and negative sentiment, (c) Tweet starts with an interjection word, (d) likes and dislikes contradiction, (e) tweet conflicting ubiquitous facts, (f) tweets with positive sentiment and antonym pair, and (g) tweet contrasting facts that are time-sensitive.

With a huge amount of content being churned on social media and the need to analyze and detect sarcasm closely, text classification methods have been widely introduced to deal with these sophisticated tasks. Sarcasm has been shown to pose a major difficulty for sentiment analysis models (Liu, 2010), mainly because sarcasm acts as a form of verbal irony which enables the concealment of the true intention of denigration and negativity under a pretence of open a respectful representation such as; “The only thing I got from college is a caffeine addiction". As a result, the ability to detect sarcasm is crucial for understanding the real intents and beliefs of people (Maynard and Greenwood, 2014).

To address these issues and limitations, (Abu Farha et al., 2022) have organized the iSarcasmEval shared task for intended Sarcasm Detection In English and Arabic where different tweets in English and Arabic languages have to be classified as either sarcastic or not.

Several models for detection of sarcasm have been proposed in literature which incorporate statistical, machine learning, and rule-based approaches but predominantly (Mandal and Mahto, 2019). However, these techniques are not able to effectively perceive the figurative and ironic meaning of words (Joshi et al., 2016). Also, these methods require manually engineered features and are unable to understand the patterns in passive voice sentences (Bajwa and Choudhary, 2006). However, instead of utilizing manually engineered features, the incorporation of transformer models has the ability to automatically learn the important features.

In this paper, we present our participating system to the iSarcasmEval shared task (Abu Farha et al., 2022). In this work, we seek to apply a novel transformer-based approach to detect sarcastic statements in both English and Arabic languages and propose a novel approach to fine-tune the BERT model for sarcasm detection of both Arabic and English tweets using ensemble loss. BERT is a model that is gaining increasing popularity due to its outstanding performance for multiple NLP tasks.

Recently, the language model called BERT has been widely used in several tasks. The pre-trained model can generate word/token or sentence representations that are enriched with prior knowledge. Then, they can be fine-tuned specifically for many downstream tasks such as sarcasm detection. The traditional BERT model only uses one loss function whilst our proposed model which combines a cross-entropy loss with a negative log-likelihood function leads to a better penalization of incorrect predictions that the model is confident about more than incorrect predictions the model is less confident about. This leads to better detection of sarcasm due to an improved F-1 sarcastic.

One of the main contributions of this work is the use of ensemble loss with BERT (Devlin et al., 2019) to address the task of sarcasm detection of tweets in both English and Arabic languages with improved sarcasm detection ability.

The rest of the paper is organized as follows: The Related Work in section 2 discusses the research works which are closely related to the current study. Section 3 contains the system description part and highlights the description of the proposed approach and its working methodology. The dataset used for experiment setup is provided in the Experiments section in section 4, whilst the results and Discussion segment can be found under section 4.1 and contains the experimental results and the performance metrics. The conclusion and future work for this research work are all captured in section 5.

2 Related Work

The conversation aspect in sarcasm detection was investigated by (Ghosh et al., 2017), and sarcastic and non-sarcastic tweets were collected to create a dataset for their experiments. BERT, which is a transformer-based machine learning model has been exploited to provide a deep contextual representation of words and used for sarcasm detection. They are pre-trained language models and have been also been widely utilized in many NLP domains. These models have been proven to be effective since they are enriched with knowledge from the pre-training resources (Avvaru et al., 2020). (Moores and Mago, 2022) recently surveyed automated sarcastic detection on Twitter and found out that there was a shift towards the use of deep learning methods due to the benefit of using a model with induced instead of discrete features combined with the innovation of transformers. BERT and GloVe embeddings were combined with machine learning classifiers to detect sarcasm in tweets in the work of (Khatri and P, 2020). Semi-supervised techniques were used by (Tsur et al., 2010) to detect sarcasm Sentences in Online Product Reviews whilst (Amir et al., 2016) also deployed the use of automatic learning and exploiting word embeddings to recognize sarcasm. Other approaches such as Bi-Directional Gated Recurrent Neural Network (Bi-Directional GRNU) have also been used to detect sarcasm (Zhang et al., 2016). Bert has been used with a crowd layer on tweets with noisy labels to achieve improved results (Osei-Brefo et al., 2021).

3 System description

For each sample in the English and Arabic dataset, a tweeted text and a given token were first concatenated in the following format:

[CLS] + Tweeted text + [SEP] sarcastic sentence [SEP]

where '[CLS]' token was added for classification and two '[SEP]' tokens were used to identify the sarcastic nature of the tweet. Each sentence was initially organized, after which the '[CLS]' and '[SEP]' tokens were added to their start and end. The tokenized sentence was then truncated or padded to a maximum length of 64. Each generated token was then mapped to its individual IDs to create an attention mask for each sentence. A hidden size of 768 was utilized for the BERT, whilst 120 and 2 were respectively used as the hidden size of the classifier and the number of labels. A one-layer feed-forward classifier was then instantiated after which the last hidden state of the token '[CLS]', was extracted for classifying whether a statement was sarcastic or not.

Binary Classification for detecting sarcasm To fine-tune the models for sub-task A, a fully-connected layer was added on top of the pooled output (the sequence embedding from the pre-trained model). This layer had an output size of 2 with a softmax activation function which outputs the probability of each class as either 1 or 0. For sub-task A, the baseline model used was a Bert model with the same parameters as our proposed model except that it was made up of a single cross-entropy loss function. A cross-entropy loss and Negative log-likelihood loss functions were combined in different weights proportion to form the ensemble loss used as a loss function for fine-tuning. These proportional weight functions were 0.8/0.2 and 0.2/0.8 for the cross-entropy loss and Negative log-likelihood loss functions respectively as can be seen in Tables 1 and 2 as **BERT Ensemble loss A** and **BERT Ensemble loss B** respectively. The final prediction of each sentence was made by selecting the class with the maximum probability. Due to the difficulties inherent nature of detecting sarcasm by machines, a higher threshold of about 70 % was used as the minimum probability beyond which a tweet can be classified as being sarcastic for both the English and Arabic datasets.

Ensemble loss function Two loss functions were combined together in such a way that the benefits derived from each loss function were embedded in the model. These loss functions were cross-entropy loss and negative log-likelihood loss. The weights of these combinations were 0.8 to 0.2 and 0.2 to 0.8 for BERT Ensemble loss A and BERT Ensemble loss B respectively. On the other hand, the Baseline model loss was made up of only the cross-entropy loss.

4 Experiments

Experiments were conducted on the respective English and Arabic training and test sets provided by the task organizers. The training set of the English language had 3467 samples whilst that of the Arabic language had 3120 data samples. During the development stage, the training datasets were divided into 90% and 10% splits sets respectively for the training and validation datasets. The test sets for both languages on the other hand had a total of 1,400 data samples used in the evaluation phase.

All the models were fine-tuned by using the Adam optimizer for 12 epochs with the batch size 32 and the learning rate of 0.000005 and 0.000000001 as the default epsilon value. For sub-task A, the models were evaluated by Accuracy, Recall, false positives, F-1 sarcastic, Accuracy, and F1-macro.

4.1 Results and Discussion

Table 1 shows the results of the baselines and our approaches in both sub-task A using the Validation dataset. Table 2 also shows the results obtained using the test data sets

Our proposed model with the ensemble loss had different performance strengths on the validation dataset and the test datasets. Their relative performance also varied depending on the particular Language they were applied to. Among the 5 metrics used, the most effective metric that can be used to determine how accurate a model is able to detect sarcastic statements is the F-1 sarcastic metric. For the validation dataset, the baseline model outperformed our proposed model in all the 5 metrics used when applied to the English Language dataset. For the Arabic dataset, our model outperformed the baseline in all the other 3 metrics used with the exception of the false positive and f1-macro metrics where our model could not outperform the baseline. It is worth noting that our model had an F-1 sarcastic metric of 83.53% when it was applied to the Arabic language test dataset. For the test dataset, our proposed model outperformed the baseline model for both the English languages with an

English	Baseline	**37.04**	**58.54**	**71.84**	**63.76**	**74.06**
	BERT Ensemble loss A	37.15	55.03	67.51	57 .00	72.33
	BERT Ensemble loss B	42.43	54.87	58.82	41.48	70.89
Arabic	Baseline	**23.60**	64.92	83.35	**77.75**	83.28
	BERT+ Ensemble loss A	25.61	**65.75**	**83.53**	77.41	**83.92**
	BERT Ensemble loss B	26.82	61.62	64.61	42.94	75.24

Table 1: Results of validation dataset for sub-task A, where BERT+ Ensemble loss A and BERT+ Ensemble loss B represents 80% /20% and 20% /80% combination of the cross entropy loss and negative log likelihood loss respectively. Where FP represents False positives

Test set	Model	Sub-task A				
		FP	Recall	F-1 sarcastic	F1-macro	Acc
English	Baseline	46.59	**52.66**	79.37	54.88	81.00
	BERT Ensemble loss A	**38.86**	52.25	**79.75**	**58.00**	80.07
	BERT Ensemble loss B	46.65	51.51	79.12	46.15	**85.71**
Arabic	Baseline	38.86	**52.25**	79.74	**57.99**	80.07
	BERT+ Ensemble loss A	**37.22**	51.28	76.10	56.60	73.79
	BERT+Ensemble loss B	40.13	52.61	**79.12**	46.15	**85.71**

Table 2: Results of Test dataset for sub-task A, where BERT+ Ensemble loss A and BERT+ Ensemble loss B represents 80% /20% and 20% /80% combination of the cross entropy loss and negative log likelihood loss respectively. Where FP represents False positives

F-1 sarcastic metric of 79.75% Its application on the Arabic language test set yielded an F-1 sarcastic metric of 79.12%, which was just below the value obtained from the baseline model which was 79.74%

Figures 1 and 2 show the Receiver Operating Characteristic (ROC) Curve of the different models applied to the test and validation data sets, which is a plot of the true positive rates against false-positive rates. It graphically shows and compares the performance of the baseline model and our ensemble loss model at all classification thresholds. It pictorially shows the evaluation of the strength of a model; with the bigger area under the curve indicating superior model performance and the smaller area under the curve signalling poorer model classification performance respectively.

5 Conclusion

This work has proposed the use of ensemble loss on the BERT model to detect whether a given sentence in English or Arabic language is sarcastic or not. The results indicate that the use of our ensemble loss on the Bert Model exhibits superior performance over the baseline models when applied to the English and Arabic test datasets. Future work will involve the undertaking of further investigation to find the optimal proportion of each combination that yields the optimal results. It will also involve the use of ensemble loss on Arabic-based Bert models such as Ara-Bert and other Bert-Based models to find their performance. Different types of losses will also be investigated and added to the ensemble loss portfolio in order to explore the different types with superior performance. Since the two language datasets used were unbalanced in nature, future work will also explore other data balancing techniques to help improve the results of our model.

Abstract

In this paper we present our approach and system description on iSarcasmEval: a SemEval task for intended sarcasm detection on social networks. This derives from our participation in *SubTask A: Given a text, determine whether it is sarcastic or non-sarcastic*. In our approach to complete the task, a comparison of several machine learning and deep learning algorithms using two datasets was conducted. The model which obtained the highest values of F1-score was a BERT-base-cased model. With this one, an F1-score of 0.2451 for the sarcastic class in the evaluation process was achieved. Finally, our team reached the 30th position.

1 Introduction

Sarcasm is a form of mockery intended to imply the opposite or to express displeasure. It can be classified as irony, satire, understatement, overstatement, rhetorical question and sarcasm itself. Social media platforms allow people to express themselves and speak about several different topics via text, emojis and multimedia. Many companies collect information about people's opinions to aid in marketing decision-making about their products.

Sarcasm detection is relevant in data analysis because it can be wrongly interpreted due to its nature, becoming potentially harmful to different computational systems. For example, if a computer system understands the sentence "*The only thing I got from college is a caffeine addiction*", its literal meaning would not be understood, as it refers to how stressful college can be.

Defining a phrase as sarcastic is a really challenging task to solve for the text mining community because there are many details that need to be considered such as the writer's personality and the sentence context. For instance, depending on the ideology of the person, "*Trump, that respectful man*" could be sarcastic or not.

In iSarcasmEval: Task 6, SubTask A (Abu Farha et al. 2022) participants had to decide if a particular tweet includes a sarcastic connotation or not.

2 Background

Two sample datasets were used to train the model.

The first one was the original dataset without any preprocessing. This dataset is composed of 3467 rows, with 2600 0-value rows (non-sarcastic) and 867 1-value rows (sarcastic).

The second sample dataset (Tweet – Rephrase) consists of a phrase and rephrase contrast in which the aim was to adequately learn the differences between a phrase with a sarcastic connotation and that same sentence expressing the same thing but in a literal way. This dataset is composed of 1734 rows: 867 1-value rows and 867 0-value rows, where these last ones are rephrases related to each tweet taken as a 1-value row.

So, these two datasets follow the same structure:

- tweet: *"See Brexit is going well"*
- sarcastic: "1"

In the second dataset, the column "rephrase" was added to the list of tweets. The rephrase example for the tweet below would be:

- tweet: "*Brexit really isn't going to plan.*"
- sarcastic: "0"

Table 1 shows some examples followed by both datasets.

The issue of sarcasm detection has been addressed by various authors in recent years. In the last several years, researchers have been working on a technique to analyze social media data in order to identify possible undisclosed information so it can be useful to assess new patterns and make important decisions through it (Shah and Shah 2021, 247-259). Sentiment analysis is also used for sarcasm detection (Suzuki et al. 2017), dividing a sentence into phrases and judging the situation and the sentiment separately.

In (Verma, Shukla, and Shukla 2021), the authors present a review of methodologies and techniques of sarcasm detection. They concluded that deep learning is the most common technique to identify sarcasm.

3 System overview

In this section, the models used to solve the sarcasm detection issue will be described.

Due to the nature of the problem, a decision was made not to carry out any preprocessing. The reason is that we think that sarcasm interpretation requires the original phrase to be considered in its entirety, so letter cases, emojis and punctuation were kept.

3.1 Models

A total of 30 models were used to train both datasets. In the first experiments, machine learning techniques such as LinearSVC, DecissionTrees and RandomForests using CountVectorizer and TFIDF (Pedregosa, Fabian and others 2011) were used. We also trained some deep learning techniques as LSTM Neural Networks (Hochreiter and Schmidhuber 1997) and Transformers (Vaswani et al. 2017).

For LSTM Neural Network we implemented the LSTM Simple Neural Network and we used the BERT model (Devlin et al. 2018) for Transformers.

In Table 2, the results of machine learning techniques mentioned before can be seen.

3.1.1 BERT: Bidirectional Encoder Representations from Transformers

BERT is designed to pretrain deep bidirectional representations from unlabeled text by jointly conditioning both the left and right contexts in all layers. As a result, the pretrained BERT model can be finetuned with just one additional output layer to create state-of-the-art models for a wide range of tasks, such as question-answering and language inference, without substantial task-specific architecture modifications.

It uses Transformer, which is a simple network architecture based on attention mechanisms, dispensing with recurrence and convolutions entirely.

There are two ways to read a sentence for BERT. On one hand we have BERT-base-cased, in which BERT differences between capital letters and uppercase letters and, on the other hand, BERT-base-uncased, which will take the sentence and make all single letters uncased. As mentioned above, we did not miniscule the text of the tweets

Tweet	**sarcastic**
"Nice to be compared to a brick wall"	1
"Not happy i have been compared to a brick wall"	0
"Social Care for the young is basically a bath board and bed rest and your done"	1
"Social care for the young is non existent"	0
"I've been doing physics for 40 minutes I think I deserve a break"	1
"I'm never going to get it all done at this rate"	0

Table 1: Tweet examples

Dataset	Model		Metrics	
			Accuracy	F1-Score (class 1)
Original dataset	CountVectorizer	LinearSVC	0.68	0.28
		DecissionTree	0.74	0.10
		RandomForest	0.74	-
	TFIDF	LinearSVC	0.71	0.22
		DecissionTree	0.74	0.10
		RandomForest	0.74	-
Tweet – Rephrase	CountVectorizer	LinearSVC	0.60	0.61
		DecissionTree	0.56	0.37
		RandomForest	0.65	0.61
	TFIDF	LinearSVC	0.58	0.60
		DecissionTree	0.57	0.37
		RandomForest	0.61	0.61

Table 2: Results obtained in training phase using machine learning techniques

to preserve the sarcastic meaning of the sentence. Therefore, the BERT-base-cased was used.

The BERT model was trained with a batch size of 32 instances and 5 epochs by using a training/validation split.

3.1.2 LSTM Simple Neural Network

Long Short-Term Memory (LSTM) is a well-known recurrent neural network architecture. The most important feature of recurrent networks is their ability to persist introduction loops information in its diagram, so it can remember previous states and use this information in subsequent stages.

In order to find better results, a pretrained word vector with a size of 200d was added to our model. GloVe (Pennington, Socher, and Manning 2014) is a global log-bilinear regression model for the unsupervised learning of word representations that outperforms other models on word analogy, word similarity and named entity recognition tasks.

For this approach, a batch size of 32 instances, and 10 epochs was used. Besides, we implemented an early stopping to improve the performance.

4 Experimental setup

Many libraries were imported to develop the experiments. Some of them are: “NumPy” (Harris et al. 2020)”, a fundamental package for scientific computing; “spaCy” (Honnibal and Montani 2017), a library for advanced natural language processing; “NLTK” (Loper and Bird 2002), a tool-kit to work with human language information; “Keras” (Chollet 2015), a neural-network library; “scikit-learn”, which contains simple and efficient tools for predictive data analysis and “Pandas” (McKinney 2010), used for manipulating data.

For all the experiments, the datasets were split using 80% to train and 20% to test. We use a stratify approach.

Finally, when the test dataset was released, the whole train dataset was used to train the final model through BERT-base-cased, which was the best algorithm to complete the task.

The metrics obtained to evaluate our model are accuracy and F1-score.

5 Results

Table 3 shows the results obtained in our experiments during the training phase. The algorithm that reached the best results was BERT-base-cased with the use of the Tweet - Rephrase dataset, obtaining a score of 0.86 accuracy and F1-score.

Results shown in the leaderboard with the test dataset yielded a 0.2451 F1-score. Finally, our team reached the 30th position.

6 Conclusions

In this paper our approach to solve Task 6 (iSarcasmEval) - SubTask A: Given a text,

Dataset	**Model**	**Metrics**	
		Accuracy	**F1-Score (class 1)**
Original dataset	LSTM Simple Neural Network	0.65	0.38
	BERT-base-cased	0.72	0.43
	BERT-base-uncased	0.69	0.39
Tweet – Rephrase	LSTM Simple Neural Network	0.65	0.62
	BERT-base-cased	**0.86**	**0.86**
	BERT-base-uncased	0.84	0.84

Table 3: Results obtained in training phase using deep learning techniques

determine whether it is sarcastic or non-sarcastic, in English, has been described.

The main idea was to check models of deep learning algorithms such as BERT or LSTM Neural Network trained with the dataset Tweet – Rephrase. After training and analyzing each model and comparing deep learning with machine learning techniques, BERT-base-cased model obtained higher results F1-Score and accuracy.

In the future, a BERT model will be trained using a larger corpus and more innovative techniques such as the application of sentiment analysis in broken-down sentences.

Abstract

This paper describes the systems submitted to iSarcasm shared task. The aim of iSarcasm is to identify the sarcastic contents in Arabic and English text. Our team participated in iSarcasm for the Arabic language. A multi-Layer machine learning based model has been submitted for Arabic sarcasm detection. In this model, a vector space TF-IDF has been used as for feature representation. The submitted system is simple and does not need any external resources. The test results show encouraging results.

1 Introduction

Analyzing social media becomes a crucial task, due to the frequently usage of social media platforms. Sarcasm detection, the conflict of using the verbal meaning of a sentence and its intended meaning (CLIFT, 1999; Lee and Katz, 1998), is an important task. Sarcasm detection is a challenge, since sarcastic contents are used to express the opposing of what is being said. Recently sarcasm detection has been studied from a computational perspective as one of classification problems that separates sarcastic from non-sarcastic contents(Reyes et al., 2013; Nayel et al., 2021).

Arabic is an important natural language having an extensive number of speakers. The research in Natural Language Processing (NLP) for Arabic is continually increasing. However, there is still a need to handle the complexity of NLP tasks in Arabic. This complexity arises from various aspects, such as orthography, morphology, dialects, short vowels, and word order. Sarcasm detection in Arabic is a particularly challenging task (Alayba et al., 2018).

In this paper, we describe the system submitted to the iSarcasm detection shared task(Abu Farha et al., 2022). The shared task aims at detecting the sarcasm contents in Arabic tweets. In this work, a machine learning framework has been developed and various machine learning algorithms have been implemented. Term Frequency-Inverse Document Frequency (TF-IDF) has been used as vector space model for tweet representation. The rest of this paper is organized as follows: in section 2, a background about sarcasm detection is given. Section 3 and section 4 overview the dataset and the system respectively. Experimental setup and results are given in section 5 and section 6 respectively. Finally, section 7 concludes the proposed work and suggests future work to be continued.

2 Background

The research work have been done on Arabic sarcasm detection were mainly focused on creating datasets and establish a baseline for each created dataset (Ghanem et al., 2020). Karoui et al. (2017) created a corpus of sarcastic Arabic tweets that are related to politics. Distant supervision has been used for the creation of corpus. The authors used keywords that are like sarcastic contents in Arabic to label the tweets as sarcastic tweets. They implemented different machine learning algorithms such as SVM, logistic regression, Naïve Bayes, and other classifiers on the developed corpus.

An ensemble classifier of XGBoost, random forest and fully connected neural networks has been designed by Khalifa and Hussein (2019). They extracted a set of features that consists of sentiment and statistical features, in addition to word n-grams, topic modelling features and word embeddings. Nayel et al. (2019) developed an ensemble-based system for irony detection in Arabic Tweets. A set of classification algorithms namely Random forests, multinomial Naïve Bayes, linear, and SVM classifiers have been used as base-classifiers. In (Nayel et al., 2021), sarcasm detection has been formulated as a binary classification problem and SVM has been implemented.

3 Dataset

A new data collection method has been introduced, where the sarcasm labels for texts are provided by the authors themselves. The author of each sarcastic text rephrased the text to convey the same intended message without using sarcasm. Leggitt and Gibbs (2000) defined a set categories of ironic speech namely; sarcasm, irony, satire, understatement, overstatement, and rhetorical question. Linguistic experts have been asked to further label each text into one of these categories. Each text in the Arabic dataset has the following information attached to it:

- a label specifying the text dialect;
- a label specifying the nature of sarcasm (sarcastic or non-sarcastic), provided by its author;
- a rephrase provided by its author that conveys the same message non-sarcastically.

4 System Overview

In this section, we review the main structure of the proposed model. The proposed system, as shown in figure 1, consists of three phases namely; preprocessing, feature extraction and training the classification algorithms. Then, the resulted model used to predict the unseen test data.

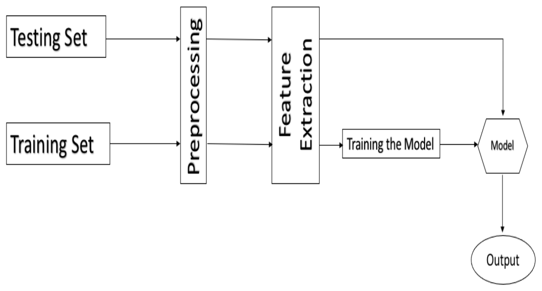

Figure 1: The structure of the proposed model

4.1 Preprocessing

The first stage of developing systems is preprocessing, where unwanted and uninformative piece of text has to be removed, it is also called text cleaning. We performed text cleaning by removing:

- special symbols, such as $\{+, -, =, \$, ...\}$;
- repeated characters such as ("*hhhhhhhh*" will be normalized to "*hh*");
- non-Arabic words, such as English characters or any other language;
- punctuations and Arabic diacritics.

4.2 Features Extraction

To prepare features to build classification model and before feeding the text into the classifier and after performing text cleaning, Term Frequency-Inverse Document Frequency (TF-IDF) technique was used to change over content to vectors and all the algorithms to investigate the best performing algorithm.

TF-IDF has been used to represent comments as vectors. If $< w_1, w_2, \dots, w_k >$ are the tokenized words of a comment $\mathcal{T}_j$, the vector associated to the comment $\mathcal{T}_j$ will be represented as $<v_{j1}, v_{j2}, \dots, v_{jk}>$ where v_{ji} is the weight of the token w_i in tweet $\mathcal{T}_j$ which is calculated as:-

$$v_{ji} = tf_{ji} * \log\left(\frac{N+1}{df_i + 1}\right)$$

where tf_{ji} is the total number of occurrences of token w_i in the comment $\mathcal{T}_j$, df_i is the number of comments in which the token w_i occurs and N is the total number of comment.

4.3 Methodology

We explored various classification algorithms as well as ensemble approach by combining the output of these classifiers (also known as base classifiers) using hard voting. The base classifiers used in this work are listed below:

- Support Vector Machines (SVMs)
- Random Forest (RF)
- K-Nearest Neighbours (KNN)
- Multinomial Naïve Bayes (M-NB)
- Multi-Layer Perceptron (MLP)
- Stochastic Gradient Descent (SGD)
- AdaBoost Classifier
- Voting Classifier

Table 1: 5-fold Cross-Validation accuracy for all classifiers in the training set

Classifier	Accuracy	STD
SVM-Linear	81.0%	0.055
SVM-RBF	76.6%	0.003
MNB	76.6%	0.005
SGD	80.0%	0.045
MLP	83.6%	0.045
RF	75.8%	0.056
KNN	79.7%	0.058
AdaBoost	75.2%	0.052
Voting	80.4%	0.043

5 Experimental Setup

For feature extraction phase we used unigram model. For the purpose of training the model, we have used 5-fold cross-validation technique to adjust the parameters.

The Scikit-Learn library implementation of classification algorithms were used in the training phase. For SVM, two kernels have been tested: linear kernel and RBF with two parameters $\gamma = 2$ and $C = 1$. While, for SGD classifier the loss function used was Hinge and the maximum iteration was set at 10000 iterations.

The number of nodes in the hidden layer of MLP was set at 20, logistic function was used as activation function and Adam solver was used. The maximum number of decision trees in random forests is set at 300.

5.1 Evaluation Metrics

F1-score has been used to evaluate the performance of all submissions. F1-score is a harmonic mean of Precision (P) and Recall (R) and calculated as follow:

$$F\text{–}score = \frac{2 * P * R}{P + R}$$

F1-score for the sarcastic class (F1-sarcastic) has been used for final evaluation.

6 Results

The cross validation accuracy of all training classifiers for the training set is given in Table 1. It is clear that MLP gives the best accuracy with moderate Standard Deviation (STD) for the five folds while development phase, so we decided to submit the output of this classifier.

Table 2: Results of MLP classifier for the test set

Measure	Value	Rank
F-1 sarcastic	0.3746	14
F-score	0.6024	11
Precision (P)	0.5968	15
Recall (R)	0.6608	17
Accuracy	0.7329	8

Results for test set is given in Table 2. The reported results show that, while training MLP gives better accuracy among implemented machine learning classifiers. Also, it gives better rank in accuracy for the unlabelled test set. While in other metrics, the performance was not satisfied. This may resulted because of using accuracy metric while comparing different classifiers in development phase.

A good suggestion is to use different evaluation metrics while developing the system. In addition, using different word representation models such as word embeddings, which encompasses the semantic meaning of words could improve the performance. Complex models such as deep learning models is promising, but the challenge in such models is the availability of suitable resources.

7 Conclusion

In this work, a classical machine learning framework has been designed for sarcasm detection in Arabic tweets. The proposed framework reported reasonable results. The future work may include applying complex framework such as deep learning structure. In addition, word representation is very important factor that can be used in different manner such as word embeddings and transformers.

Abstract

Due to the widespread usage of social media sites and the enormous number of users who utilize irony implicit words in most of their tweets and posts, it has become necessary to detect sarcasm, which strongly influences understanding and analyzing the crowd's opinions. Detecting sarcasm is difficult due to the nature of sarcastic tweets, which vary based on the topic, region, the user's attitude, culture, terminologies, and other criteria. In addition to these difficulties, detecting sarcasm in Arabic has its challenges due to its complexities, such as being morphologically rich, having many different dialects, and having low resources. In this research, we present our submission of (iSarcasmEval) sub-task A of the shared task on SemEval 2022. In Sub-task A; we determine whether the tweets are sarcastic or non-sarcastic. We implemented different approaches based on Transformers. First, we fine-tuned the AraBERT, MARABERT, and AraELECTRA. One of the challenges that faced us was that the data was not balanced. Non-sarcastic data is much more than sarcastic. We used data augmentation techniques to balance the two classes, significantly affecting the performance. The performance F1 score of the three models was 87%, 90%, and 91%, respectively. Then we boosted the three models by developing an ensemble model based on hard voting. The final performance F1 Score was 93%.

1 Introduction

According to the Cambridge dictionary definition of Sarcasm, it is the use of remarks that mean the opposite of what they say, made to hurt someone's feelings or humorously criticize something, Like when you say Love this weather. (When the weather is horrible).

Sarcasm detection is determining whether or not a piece of text is sarcastic. Sarcasm is a significant challenge for sentiment analysis systems. This is because a sarcastic sentence usually contains an implicit negative sentiment that is expressed with positive expressions. This discrepancy between the surface and intended sentiments creates a difficult challenge for sentiment analysis systems.

Sarcasm detection is a difficult task for a variety of reasons. First of all, there aren't many labeled data resources for sarcasm detection. Moreover, any available texts that can be collected (for example, Tweets) contain many issues, such as an evolving dictionary of slang words and abbreviations, so it usually takes many hours for human annotators to prepare the data for any potential use. Furthermore, the nature of sarcasm detection adds to the task's difficulty, as Sarcasm can be considered relative and varies significantly between people, and it depends on many factors such as the topic, region, time, the events surrounding the sentence, and the readers/writers mentality and the; in other words, a sentence that one person finds sarcastic may sound normal to another. (Farha and Magdy, 2021)

In addition to these previous challenges, discovering irony in the Arabic language has its own set of challenges due to the complexities of the language, such as being formally rich, different dialects, lack of resources, and rapid development due to the inclination of the Arabic language. The Arab citizen makes fun of all his affairs, especially politics, which uses many words and terms that are implicit in it.

Transformers greatly assisted in significant advancements in NLP tasks. They are a new neural network that does not employ convolution or recursion. They instead use their attention to find correlations between words in the text. Transformers can process text in parallel, allowing them to learn much faster than sequential methods. They also outperform previous methods in terms of results.

Transformer-based language models have recently proven to be highly efficient at language understanding, giving promising results across various NLP tasks and benchmark datasets. The language modeling capability of these models aids in capturing the literal meaning of context-heavy texts. For Arabic NLP in particular, the best results for sentiment analysis are currently achieved by AraBERT, a language model proposed by (Antoun et al., 2020).

Despite recent advances, detecting sarcasm remains a difficult task because of implicit, indirect phrasing and the symbolic nature of language. When working with Twitter data, the task becomes even more difficult because the social media posts are often short and contain noise sources, code-switching, and the use of nontraditional dialectal variations. Furthermore, BERT-based models have struggled with rare words, which are more common in social media texts due to their informal nature and the prevalence of slang words. It is difficult for language models like AraBERT, which have been trained on structured corpora from Wikipedia.(Hengle et al., 2021)

In this study, we tackle (iSarcasmEval) sub-task A of the shared task on SemEval 2022.In SubTask A; we determine whether the tweets are sarcastic or non-sarcastic. We have proposed models based on transformers to discover the sarcasm that transformers have proven to excel in other NLP tasks such as sentiment analysis. We summarize what has been accomplished in this research in the following:

- Fine-tuning the state-of-the-art transformers-based models such as AraBERT, AraELECTRA, and MARBERT.

- One of the challenging problems in this task is that the dataset is unbalanced, with 2357 non-sarcastic tweets and 745 sarcastic. We solved this problem by using augmentation and balancing the two classes.

- We proposed an ensemble model based on hard voting between the three fine-tuned transformers, and it outperforms each of them.

The following sections are organized as follows; Section 2 presents the background, section 3 describes the task and dataset description, section 4 gives an overview of the proposed system, section 5 explores the results and discussion, and section 6 concludes and gives possible directions for the future.

2 Background

There are few attempts to work on Arabic sarcasm. The workshops in the field of Natural language processing for the Arabic language revived the interest in detecting sarcasm, as this workshop provided annotated datasets, which was considered a challenging obstacle in front of researchers. Such as the previous shared tasks on irony detection(Ghanem et al., 2019) along with the participants' submissions and dialectal sarcasm datasets by (Abbes et al., 2020); (Farha and Magdy, 2021);(Abu Farha et al., 2021).

This survey mainly focuses on the WANLP 2021 workshop and its shared task on sarcasm in Arabic. This shared task seeks to promote and draw attention to Arabic sarcasm detection, which is critical for improving performance in other tasks such as sentiment analysis. The dataset used in this collaborative task, ArSarcasm-v2, comprises 15,548 tweets that have been labeled for sarcasm, sentiment, and dialect. Subtask 1 on sarcasm detection received 27 submissions. The majority of approaches relied on using and fine-tuning pre-trained language models like AraBERT and MARBERT (Abdel-Salam, 2021); (Abuzayed and Al-Khalifa, 2021); (Alharbi and Lee, 2021);(Bashmal and AlZeer, 2021);(Faraj et al., 2021);(Gaanoun and Benelallam, 2021);(Hengle et al., 2021);(Husain and Uzuner, 2021);(Israeli et al., 2021);(Naski et al., 2021);(Wadhawan, 2021). Deep learning and traditional machine learning approaches were used by a few of the participants(Nayel et al., 2021).

The BhamNLP(Alharbi and Lee, 2021) team was ranked best in the sarcasm detection task, with an F1-Score 0.6225. They deployed a multi-task learning architecture trained for sarcasm and sentiment classification in their approach. The model is based on both a MARBERT and a CNN-LSTM model, with each model's output being concatenated and supplied to the final output layer. The CNN-LSTM utilized both word and character embeddings.

3 Task And Dataset Description

In SemEval 2022 Task 6: iSarcasmEval (Intended Sarcasm Detection In English and Arabic)(Abu Farha et al., 2022). The organizer offered two datasets, Arabic and English. There are three subtasks. SubTask A its aim is to determine whether the given text is sarcastic or non-sarcastic; SubTask B is applied in (English only): it aims to determine which ironic speech category the given

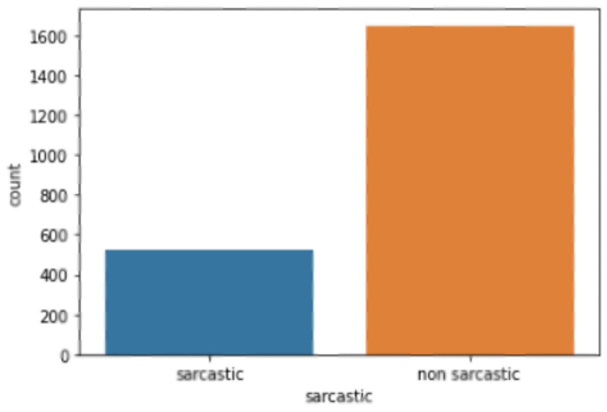

Figure 1: The distribution of the original dataset.

text belongs to, if an. It's a binary multi-label classification task. SubTask C: it aims to determine which text is the sarcastic one; if it is given two texts that convey the same meaning,
we have to clarify that our proposed system is a solution to Subtask A on the offered Arabic dataset. The Arabic dataset consists of 3,102 tweets with 2357 non-sarcastic tweets and 745 sarcastic ones. The test set contains 1400 tweets. It was released without labels for evaluation purposes. The dataset is provided with dialects and sarcasm labels. Table 1 shows some statistics of the released training set. Figure 1 shows the distribution of sarcastic and non-sarcastic tweets. Table 2 shows a sample of sarcastic and non-sarcastic tweets.

4 System Overview

The proposed model comprises two main phases: Data augmentation and the Ensemble module, consisting of three pre-trained transformers(AraBERT, MARABERT, AraELCTRA) and the Voting module, as shown in this Figure 2.

4.1 Data Augmentation

One of the challenging problems in this dataset is its small size, and it's unbalanced. The number of non-sarcastic tweets is 2357, while sarcastic is 745. We used data augmentation to balance the minority classes, Sarcastic. We used the NLPAug tool for augmentation. It is a python library based on non-contextual embeddings like Glove, Word2Vec, etc. And also for contextual embeddings like BERT and RoBERTa. By inserting or replacing words using word embedding, we used AraBERT for that purpose. Tables 3 shows a sample of tweets before and after augmentation.

4.2 Ensemble Module

This module consists of two phases. Firstly, apply three of the state of art pre-trained transformers, then use an ensemble hard voting technique.

(I) **Transformer Based Models:**

Deep learning methods have shown promising results in many machine learning domains, including natural language processing, computer vision and speech recognition. Due to architectures inspired by the human brain, deep learning techniques have recently outperformed traditional machine learning methods in terms of performance. Most deep learning techniques in the context of NLP use word vector representations to represent textual inputs (Mikolov et al., 2013a),(Mikolov et al., 2013b). These traditional techniques are being replaced by transformer-based techniques and significantly improve most NLP tasks, such as classification. As a result of the pre-training process, transformer-based techniques can generate efficient word embedding, making them powerful language models.

- **AraBERT** (Antoun et al., 2020) Pre-trained to handle Arabic text, AraBERT is a language model that is inspired by Google's BERT architecture. Six variants of the same model are available for experimentation: AraBERTv0.2-base, AraBERTv1- base, AraBERTv0.1-base, AraBERTv2-large, AraBERTv0.2-large, and AraBERTv2-base.
- **AraELECTRA**
(Antoun et al., 2020) With reduced computations for pre-training the transformers, ELECTRA is a method aimed toward the task of self-supervised language representation learning. ELECTRA models are inspired by the two primary components of Generative Adversarial Networks: generator and discriminator. They aim at distinguishing between real input tokens and fake ones. These models have shown convincing state-of-the-art results on Arabic QA data.

- **MARBERT**
provided by (Abdul-mageed et al., 2020). These models are based on the BERT-

Table 1: Distribution of tweets among different dialects

SARCASTIC/DIALECT	EGYPT	GULF	LEVANT	MAGHREB	MSA	NILE	TOTAL
NON-SARCASTIC	472	67	81	12	1470	255	2357
SARCASTIC	0	17	35	77	49	567	567

Table 2: Sample of tweets with Dialect and classified to sarcastic and non-sarcastic.

DIALECT	SARCASTIC	NON-SARCASTIC
Egypt	- -	احمد الشيخ احسن لاعب في الدورى و المصرى احسن كوره لحد دلوقتى Ahmed Al-Sheikh is the best player in the league and Al-Masry team is the best football so far.
Gulf	الف مبروك الانتصار لفريقنا، مدرب الفريق الثاني ماخذ وضعية سوي نفسك ميت ! Congratulations to our team for wining , the coach of the another team didn't take anyting expect the week breath	اغنية رامي عياش اللي بحكي فيها على عيني و راسي والله عنك لحظة ما أتخلى كتير حلوة Ramy Ayash song's which is about on my eyes and my head I swear I will not let you it's awesome
Levant	مافي حدا مثله يضحك عليك There is no one like him laughs of you	اللهم انتقم منه انتقم من كل من فرح بدماء المسلمين حسرك على ابناءك Oh God, take revenge on him, take revenge on everyone who rejoiced in the blood of Muslims
Magreb	واحد قال لمو بغيت نتزوج بوحدة بيضاء وطويلة وخدامة قالت له خد الثلاجة Someone said to her mom: I wanted to marry a white woman and tall and serve me, she told him to take the refrigerator instade	طاح القدر يا ليبيا عارفين OH MY GOD, Libya, you know
MSA	رياض محرز ينقذ سمكة من الغرق، الله على اخلاقك يا فخر العرب Riyad Mahrez saves a fish from drowning, may God bless your morals, the best arabian player	بعد غيبة و طول انتظار ها قد عاد الاستقرار من جديد :)) النور قطع الهرم After an absence and a long wait, stability has returned again :)) The light cut agine
Nile	ضبط شخص بدبلوم انتحل صفة طبيب The arrest of a person with a diploma who pretended to be a doctor without getting in faculty of medicine	دراكولا لو كان عايش معانا لغاية دلوقت كان زمانه بيمص قصب If Dracula had been living with us until now, his time would have been sucking a cane

Table 3: Sample of the original and augmented tweets.

Original Text	Augmented Text
الليله دي دموع تماسيح	دي دموع تماسيح
ياعم مبارك دا جلده و مش بيطلع منه جنيه	ياعم دا جلده و مش بيطلع جنيه
الشحات مين له نص دستور البلد يا بلد	الشحات له نص البلد يا بلد

base and trained on a set of books and news articles. AraBERT was trained on 66GB of text-only news articles. MARBERT was trained on a larger dataset (128 GB), 50% of which is tweets. The variation in MARBERT's training data gives it the ability to handle better the variations in colloquial Arabic, which is very useful for sarcasm detection

(II) **Voting Module:** The three classifier outputs are fed into the voting module based on hard voting. It selects the majority prediction, whether sarcastic or non-sarcastic. For example, the ensemble module predicts sarcastic if two models predicted sarcastic, as shown in Figure 3.

5 Results and Discussion

5.1 Performance Evaluation Metrics

We used a variety of metrics to evaluate the proposed model quality. To evaluate the model's performance, we have to compute its Accuracy, Recall, Precision, and F1-Score. The equations for these evolution metrics are as follows:

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \tag{1}$$

$$Precision = \frac{TP}{TP + FP} \tag{2}$$

$$Recall = \frac{TP}{TP + FN} \tag{3}$$

$$F1 - Score = \frac{2 * Precision * Recall}{Precision + Recall} \tag{4}$$

5.2 Experimental Results

We applied two experiments, one without augmentation and the other with augmentation. We split the data into 60% for training, 20% for validation, and 20% for testing.

- **First experiment,** After splitting, we fine-tuned the three pre-trained transformers AraBRT, MARBERT, AraELECTRA on the original data and the ensemble model. The results show that F1-Score for AraBERT, AraELECTRA, MARABERT, and the Ensemble model were 74%, 69%, 77%, 77% respectively. As shown in Table 4.

- **Second experiment,** after data augmentation, and the number of tweets in sarcastic and non-sarcastic are equal. Experiment 2 shows that F1-Score for AraBERT, AraELECTRA, MARABERT, and the Ensemble model were 87%, 90%, 91%, 93% respectively. As we see in Table 5, there is an improvement in the performance of ARAELECTRA, MARABERT, and the Ensemble model.

  The results show that our proposed model ranked sixth on the official competition. F1-score for sarcastic tweets is 0.4438, while F1-score for non-sarcastic tweets is 0.6222.

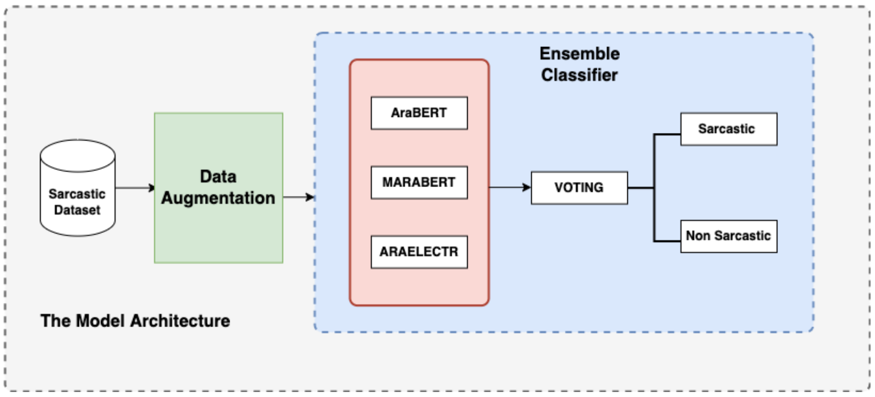

Figure 2: The proposed model architecture

Table 4: AraBert, MARBERT, ARAELECTRA, and Ensemble models on the original data.

Models	Precision	Recall	Accuracy	Macro-F1 score	F1 sarcastic
ARABERT	83%	84%	88%	83%	74%
ARAELECTRA	84%	79%	87%	81%	69%
MARABERT	89%	83%	90%	86%	77%
ENSEMBLE	88%	84%	90%	85%	77%

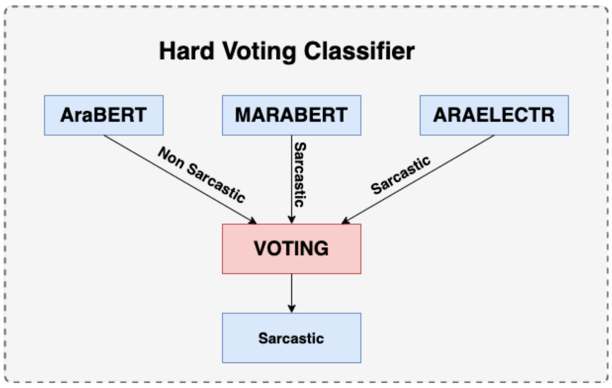

Figure 3: Hard voting Module.

6 Conclusion

We presented our submission on the shared Subtask A on Arabic sarcasm detection iSarcasmEval 2022 to tackle the problem of detecting sarcasm in Arabic. We explored different pre-trained models based on BERT. We noticed that the performance of AraELECTRA, MARABERT, and the Ensemble model is greatly improved after data augmentation and balancing the sarcastic and non-sarcastic tweets. The best submission model was the ensemble model; it applies hard voting on the AraBERT, MARABERT, and AraELCTRA. In the future, we plan to improve the performance of the proposed model by understanding and identifying which features are essential that contribute to enhancing the model prediction and troubleshooting unexpected model outputs.

Abstract

Sarcasm detection is an important task in Natural Language Understanding. Sarcasm is a form of verbal irony that occurs when there is a discrepancy between the literal and intended meanings of an expression. In this paper, we use the tweets of the Arabic dataset provided by SemEval-2022 task 6 to train deep learning classifiers to solve the sub-tasks A and C associated with the dataset. Sub-task A is to determine if the tweet is sarcastic or not. For sub-task C, given a sarcastic text and its non-sarcastic rephrase, i.e. two texts that convey the same meaning, determine which is the sarcastic one. In our solution, we utilize fine-tuned MARBERT (Abdul-Mageed et al., 2021) model with an added single linear layer on top for classification. The proposed solution achieved 0.5076 F1-sarcastic in Arabic sub-task A, accuracy of 0.7450 and F-score of 0.7442 in Arabic sub-task C. We achieved the 2^{nd} and the 9^{th} places for Arabic sub-tasks A and C respectively.

1 Introduction

Sarcasm is ubiquitous phenomenon on the social web, and is difficult to be analysed automatically and manually by humans because of its nature. Sarcasm data can be very confusing to computer systems which use it to perform tasks such as sentiment analysis, opinion mining, author profiling, and harassment detection (Liu, 2012; Rosenthal et al., 2014; Maynard and Greenwood, 2014; Van Hee et al., 2018).

(Rosenthal et al., 2014) show that the sentiment polarity classification performance on non-sarcastic tweets is much better than on sarcastic ones, in the context of SemEval. Sentiment polarity classification is used widely in industry, driving marketing, administration, and investment decisions (Hassan Yousef et al., 2014). So it is important to create models for sarcasm detection.

A comparatively small dataset is a challenge we faced when working on the Arabic dataset that makes it difficult to train complex models. We used transfer learning to treat this issue. By using a transfer learning, a pre-trained model for some task on a large dataset can be used as a starting point in another task which improves the performance. It is used in a wide range of natural language processing (NLP) tasks.

Word embeddings such as word2vec (Mikolov et al., 2013), FastText (Joulin et al., 2016) and Glove (Pennington et al., 2014) can be used to initialize vectors learnt form large dataset. Recently, Bidirectional Encoder Representations from Transformers (BERT) (Devlin et al., 2018) became the most popular NLP approach to transfer learning. Google AI Language team pretrained BERT model and fine-tuned it for a large range of tasks, such as question answering and language inference where it achieved state-of-the-art performance. MARBERT is built using the same network architecture as $BERT_{Base}$ (Devlin et al., 2019), without the next sentence prediction (NSP). MARBERT is trained on a large Twitter dataset. Therefore, we utilize fine-tuned MARBERT to solve this challenge.

This paper is organized as follows. In Section 2, we discuss relevant related works in sarcasm detection. We describe our proposed system in Section 3. The models implementation details are explained in Section 4. Section 5 describes the dataset for the shared task. Then we report and analyze the evaluation results in Section 6. Finally, we provide our conclusions in Section 7.

2 Related Work

A weak supervision and manual labelling methods can be used for the annotation process. A weak supervision method is to consider the texts sarcastic, if they meet predefined criteria, like including specific tags (e.g. #sarcasm, #irony) (Ptáček et al., 2014; Khodak et al., 2018). As pointed out by (Oprea and Magdy, 2020), noisy labels can be induced by this labelling method. Manual labelling is collecting texts and presenting them to human annotators for labelling (Filatova, 2012; Riloff et al., 2013; Abercrombie and Hovy, 2016). This can lead to a problem when annotator perception differs from author intention, as further outlined by (Oprea and Magdy, 2020).

Compared to English, only a few studies have been made on Arabic sarcasm detection. Among the studies completed in this area are research by (Riloff et al., 2013; Oprea and Magdy, 2019; Joshi et al., 2016; Bamman and Smith 2015; Campbell and Katz, 2012; Amir et al., 2016; Hazarika et al., 2018). (Oprea and Magdy, 2020) show the effect of sociocultural variables on sarcasm communication online, which makes the performance of models trained on English unpredictable, if they are trained on other languages. (Benamara et al., 2017; Abbes et al., 2020; Abu Farha and Magdy, 2020) relay on the two labelling methods mentioned above. Recently, efforts have been made by (Abu Farha and Magdy, 2020; Abu Farha et al., 2021 and Abbes et al., 2020) to create standard datasets to support sarcasm detection. In the SemEval-2022 Workshop, a shared task ('iSarcasmEval: Intended Sarcasm Detection In English and Arabic') (Abu Farha et al., 2022) was organised to contribute to the development of this area using a new labelling method that avoids the limitations of previous labelling methods.

3 Proposed System

SemEval 2022 task 6 focuses on detecting sarcastic tweets. The task supports Arabic and English languages and we tackle the problem on Arabic language. This task has three sub-tasks.

1. Sub-task A: Given a text, determine whether it is sarcastic or non-sarcastic.
2. Sub-task B (English only): A binary multi-label classification task. Given a text, determine which ironic speech category it belongs to, if any.
3. Sub-task C: Given a sarcastic text and its non-sarcastic rephrase, i.e. two texts that convey the same meaning, determine which is the sarcastic one.

We convert the input tweet to a fixed length sequence of words by padding shorter tweets and truncating longer ones. Then each word is replaced by its representation vector obtained from the pre-trained word embeddings model.

A MARBERT model is fine-tuned for sub-task A and then used for sub-tasks A and C. For sub-tasks C, the input tweets are passed to the model simultaneously and we consider the class of the tweet with the higher predicted score. We perform hyper parameters tuning to find the best parameters configuration.

Dialect	Non-Sarcastic	Sarcastic	Total
MSA	1470	49	1519
Egypt/Nile	727	567	1294
Gulf	67	17	84
Levant	81	35	116
Magreb	12	77	89
Total	2357	745	3102

Table 1: Arabic dataset statistics for sarcasm detection over the dialects.

4 Data Description

As mentioned above, annotator perception may differ from author intention. To overcome this problem, the authors annotated the data themselves, which is a new method to collect data introduced by the task's organisers.

Arabic and English datasets are collected using this method. For each sarcastic text, they provide a non-sarcastic rephrase to convey the same intended message, for English and Arabic datasets. Eventually, for English dataset, linguistic experts label each tweet to one of the ironic speech categories outlined by (Leggitt and Gibbs, 2000): sarcasm, irony, satire, understatement, overstatement, and rhetorical question. The dialect label of the text is included for the Arabic dataset.

Table 1 shows statistics of the Arabic training set, where we can find that 24% of the data is sarcastic (745 tweets). Most of the data is either in Modern Standard Arabic (MSA) or the Egyptian/Nile dialects, while there are few examples of the Magreb and Gulf dialects.

5 Implementation

We trained the proposed solution model using the given Arabic dataset. We divided its training data into 80% for training, 10% for validation and 10% for testing. In this section, we discuss the details of the different deep learning models we built or fine-tuned[1].

For our solution, we fix the tweets length to 64 by truncating longer tweets and padding shorter ones. This length is selected as the max value of the Arabic training tweets lengths after tokenization. After that each token in the input tweet is replaced with its vector representation obtained from a pretrained word embeddings model. We used pretrained MARBERT to initialize the words embeddings but these representations are then updated during the training of the deep learning models. The huggingface[2] pytorch implementation includes a set of interfaces designed for a variety of NLP tasks. Though these interfaces are all built on top of a trained BERT models, each has different top layers and output types designed to accomodate their specific NLP task. We used BertForSequenceClassification which is the normal MARBERT model with an added single linear layer on top for classification that we used as a sentence classifier.

5.1 MARBERT Model

Language models (LMs) exploiting self-supervised learning such as BERT (Devlin et al., 2019) which became a popular NLP approach to transfer learning. Transfer learning is used to reduce the time of the training and provide a better performance. This uses a pre-trained model as a starting point for training. Monolingual LMs pre-trained with larger vocabulary and bigger language-specific datasets usually perform better than multilingual models such as mBERT (Devlin et al., 2019; Virtanen et al., 2019).

Arabic has a large number of diverse dialects. Multilingual and Monolingual models such as mBERT and AraBERT (Antoun et al., 2020), respectively, are trained on mostly MSA datasets. The Arabic dataset used in this task has multiple dialects. This motivated us to use MARBERT which is trained on a large Twitter dataset (1B Arabic tweets), which involves both MSA and diverse dialects. The authors used the same network architecture as $BERT_{Base}$ (Devlin et al., 2019) to build the model, without the NSP objective which was found not crucial for model performance (Liu et al., 2019).

[1]The source code for the developed models can be found through: https://github.com/AyaLotfy/iSarcasmEval.

[2]https://huggingface.co/UBC-NLP/MARBERT.

Metric	Non-Sarcastic	Sarcastic
Precision	$\frac{TN}{TN+FP}$	$\frac{TP}{TP+FP}$
Recall	$\frac{TN}{TN+FN}$	$\frac{TP}{TP+FN}$

Table 2: Precision and recall with respect to the sarcastic and non-sarcastic classes.

6 Experiment Results

In this section we report and discuss the results of the proposed solution when evaluated on our testing data. Moreover, we show the results of our submission to SemEval 2022 task 6 on Arabic data.

Our model ranked the second out of 32 participants for sub-task A and the 9^{th} out of 13 participants for sub-task C, SemEval 2022 task 6 (iSarcasmEval: Intended Sarcasm Detection In English and Arabic).

6.1 Results and Evaluation

We divided the training data into 80% for training, 10% for validation and 10% for testing. The official evaluation metric for sub-task A was the F-score of the sarcastic class (F1-sarcastic), the macro average of the F-score for sub-task B and the accuracy for sub-task C. F1-sarcastic is calculated using the following equation:

$$F1^{sarcastic} = 2 \times \frac{P^{sarcastic} \times R^{sarcastic}}{P^{sarcastic} + R^{sarcastic}}$$

Where $P^{sarcastic}$, $R^{sarcastic}$ are the precision and recall with respect to the sarcastic class. Table 2 presents the equations to calculate the precision and recall with respect to the sarcastic and non-sarcastic classes.

Table 3 presents the models' performance for sub-task A, the best result (0.9) was obtained by BertForSequenceClassification, which is the normal MARBERT model with an added single linear layer on top for classification that we used as a sentence classifier. The proposed system has also been submitted for the sub-task C, and was ranked the 9^{th} out of 13 participants. For sub-task C, the input tweets are passed to the model simultaneously and we consider the class of the tweet with the higher predicted score. We believe this result should be studied as a future work by investigating different

Model	**F1-sarcastic**
MARBERT	**0.90**

Table 3: Performance of the model using our testing set for sub-task A on Arabic dataset.

Task	**Main Metric**	**Result**	**Rank**
A	F1-sarcastic	0.5076	2^{nd}
C	Accuracy	0.7450	9^{th}

Table 4: Main metric results obtained by the proposed model on the official test set for both sub-tasks A and C on Arabic dataset.

setup settings and, more importantly, to analyse errors on the test dataset. The model was fine-tuned for 4 epochs using the initial learning rate $2e^{-06}$, a batch size of 32, Adam weight decay optimizer and cross-entropy loss function. As well, we built other models but MARBERT outperforms them. The submitted model achieved an F1-sarcastic of 0.5076 on the official testing set for sub-task A.

6.2 Submission Results

For both aforementioned sub-tasks, we (AlexU-AL team) submitted the predicted classes based on the MARBERT model. For sub-task A, the proposed model achieved the second rank compared with the other systems proposed by other 31 participants. The submitted model achieved an F1-sarcastic of 0.5076 on the official testing set for sub-task A. For sub-task C, the model achieved an F-Score of 0.7442 and an accuracy of 0.7450 on the official testing set. Table 4 presents the official results achieved by our proposed model on the official testing set for sub-tasks A and C.

7 Conclusion

We used the fine-tuned MARBERT model in our submissions to SemEval 2022 task 6. We participated in the A and C sub-tasks for sarcasm detection in Arabic tweets. Our proposed approach is ranked the 2^{nd} and the 9^{th} in sub-tasks A and C, respectively. For future work, we explore the impact of building deeper neural networks with multiple convolutions or recurrent layers applied sequentially on the input text.

reamtchka at SemEval-2022 Task 6: Investigating the effect of different loss functions for Sarcasm detection for unbalanced datasets

Reem Abdel-Salam
Computer Engineering Department
Cairo University
reem.abdelsalam13@gmail.com

Abstract

This paper describes the system used in SemEval-2022 Task 6: Intended Sarcasm Detection in English and Arabic. Achieving 20th, 3rd places with 34& 47 F1-Sarcastic score for task A, 16th place for task B with 0.0560 F1-macro score, and 10, 6th places for task C with 72% and 80% accuracy on the leaderboard. A voting classifier between either multiple different BERT-based models or machine learning models is proposed, as our final model. Multiple key points have been extensively examined to overcome the problem of the unbalance of the dataset as: type of models, suitable architecture, augmentation, loss function, etc. In addition to that, we present an analysis of our results in this work, highlighting its strengths and shortcomings.

1 Introduction

Sarcasm detection in any language text is hard for many reasons. First Sarcasm is much more than just written words. It is the tone, emphasis, experience, personal knowledge, and even facial expressions and body language that convey the meaning. When written into text such information is lost completely. Another reason is cultural references which make it hard for non-natives to get. In addition, all that is needed to show sarcasm is to be clear and articulate and not be as sketchy and without formatting, punctuation, proper use of language as texting might be for some people in their usual use of such media. Sarcasm is widespread on the social web and, by definition, may be extremely disruptive to machine learning/ deep learning models that use this data to perform tasks such as sentiment analysis, opinion mining, author profiling, and harassment identification. Thus, sarcasm detection might be the first crucial step in these systems. Several methods have been proposed to detect sarcasm in text as the recent shared-task for sarcasm detection in Arabic language (Abu Farha et al., 2021), where several teams used pretrained language models such as AraBERT and MarBert (Wadhawan, 2021; Song et al., 2021; Naski et al., 2021; Faraj et al., 2021; Abdel-Salam, 2021; Abuzayed and Al-Khalifa, 2021). In some of the work proposed in English language sarcasm detection involved rule-based and statistical approaches using: (a) Unigrams and pragmatic features (for example emoticons, etc.) (b) Sentiment and polarity estimation (c) Extraction of common patterns (Nagwanshi and Madhavan, 2014; Kumar et al., 2020; Bouazizi and Ohtsuki, 2016). A Recent shared-task for English language (Ghosh et al., 2020), where several methods has been proposed were based on pretrained model (i.e. BERT and RoBERTa) (Baruah et al., 2020; A. and D., 2020; Amir et al., 2016; Shangipour ataei et al., 2020).

In SemEval-2022 Task 6 (Abu Farha et al., 2022), the goal is to determine if sarcasm is presented in text or not, based on the text that is manually labeled by the task organizers. The shared task consists of three subtasks:

- Subtask A: this subtask is a binary classification task, where the goal is to determine whether is tweet is sarcastic or not, for the English language and Arabic languages. The official metric for this subtask is F1-Sarcastic.
- Subtask B: this subtask is a multi-label classification task where the goal is to determine which ironic speech category the tweet belongs to (English only). There are 6 ironic speech categories which are: irony, sarcasm, satire, understatement, overstatement, and rhetorical question. The official metric for this subtask F1- Macro score
- Subtask C: the goal of this task is to determine which text is more sarcastic given a pair of texts. The official metric for this subtask is accuracy.

This paper describes the system developed by the rematchka team for SemEval-2022 Task 6. Given that a key challenge in this task is the limited size of annotated data and the unbalanced distribution, we follow best practices from recent work on enhancing model generalization and robustness and propose a voting classifier model that leverages pre-trained representations(i.e. BERT and RoBERTa).

The main contributions of our work are as follows:

1. Identifying appropriate loss functions to help train Bert-Base models and Deep learning models in presence of extremely unbalanced datasets.
2. Investigating the importance of different layers in Bert-Base models. In addition, we present an analysis of our results in this work, highlighting its strengths and shortcomings.

Our code is made public and can be found here[1]. The rest of the papers goes as follow: section 2 discusses the proposed methods, section 4 shows experimental results, and section 5 concludes the paper.

2 System Overview

In this section, we discuss our prepossessing techniques, different hand-crafted features. We further explore different training techniques using Bert (Devlin et al., 2018), RoBERTa (Liu et al., 2019), BertTweet (Nguyen et al., 2020), Deberta (He et al., 2020), XLNet (Yang et al., 2019), and CANINE (Clark et al., 2022) models for English Language, and AraBert (Antoun et al., 2020), MarBert (Abdul-Mageed et al., 2021) and QARiB (Abdelali et al., 2021) models for Arabic Language. Moreover we investigate machine learning based models.

2.1 Dataset

In subtasks A, B, and C of the English language the dataset provided consisted of a total of 3468 manually annotated tweets. As shown in table 2, for subtask A English language, 867 of the total tweets are labeled sarcastic while 2601 are labeled not sarcastic. While in subtask A, C Arabic language the dataset provided consisted of 3102 manually annotated tweets. 745 of the total tweets are labeled sarcastic while 2357 are labeled not sarcastic. Table 1 shows distribution of labels for subtask B. For subtask B irony types: 713 out of the 867 sarcastic tweets are labeled sarcasm, 155 out of 867 are labeled irony, 25 out of 867 are labeled satire, 10 out of 867 are labeled understatement, 40 are labeled overstatement and 101 are labeled rhetorical-question.

2.2 Machine learning Based Approaches

The machine learning pipeline for subtask A and subtask B goes as follows: given a tweet a set of features are computed: lexical, syntactic, semantic, pragmatic, and polarity feature representations. These features are then fed to multiple models such as SVM, Logistic Regression (LR), random forest, boosting classifiers, and Xgboost for classification.

The Sarcastic tweets in the provided dataset are categorized as sarcasm, irony, satire, overstatement, rhetorical question, and understatement. It is crucial to extract features that cover those classes. For example, overstatement contains exaggerated terms, one way to extract it is to calculate the number of elongated punctuation or the number of characters in the word. Therefore a large set of hand-crafted features including lexical, syntactic, semantic, pragmatic, and polarity features are used.

Lexical features our lexical features contains word and character level n-grams. For word-level we use 1-gram, and for character level we use 4-gram, top 5000 n-grams are utilized based only on the term frequency-inverse document frequency (TF-IDF) values.

Syntactic features for syntactic features we use Spacy to calculate the number of adjectives, adverbs, nouns, pronouns, and verbs. In addition to that, we calculated the count of NER words in the tweet.

Sentiment & Polarity features sarcasm is used to express annoyance or outrage about a bad circumstance. As a result, people employ exaggerated and extremely positive terms to describe their negative condition (Yadollahi et al., 2017). Therefore it is important to extract them. For polarity & sentiment estimation, each tweet is divided into two parts. Then, for each part, its polarity and sentiment are calculated using NLTK Senti-WordNet (Baccianella et al., 2010). In addition to that, the overall polarity and sentiment for the whole tweet are calculated. Furthermore, the number of positive and negative sentiment words in a document, the number, and the count of the longest run of positives/negatives are computed as described in (Joshi

[1] https://github.com/rematchka/Intended-Sarcasm-Detection-In-English-and-Arabic-for-extremly-unbalanced-datasets

Task	Tweets Distribution					
	sarcastic	irony	satire	understatement	overstatement	rhetorical-question
B	713	155	25	10	40	101
Total	867					

Table 1: Dataset distribution for subtask B for English language

Language	Number of Tweets	Task	
		A	C
EN	Total Number	3468	1734
	Number of Sarcastic Tweets	867	867
	Number of Non-Sarcastic Tweets	2601	867
AR	Total Number	3102	1490
	Number of Sarcastic Tweets	745	745
	Number of Non-Sarcastic Tweets	3102	745

Table 2: Dataset distribution for subtask A and C for English and Arabic language

et al., 2015).

Pragmatic features it is hard to detect sarcasm in speech, as the word may have several meanings, and also the text contains behavioral aspects such as low tones, facial gestures, or exaggeration. These forms can be translated into elongation, repetition, and punctuation. To recognize such characteristics, we extract a set of features known as punctuation-related features. For each tweet, the following is computed:

- Presence of emoji's (González-Ibánez et al., 2011)
- Count of number of question marks
- Count of number of colons
- Count of number of a dollar sign
- Count of the number of quotes.
- Count of the number of exclamation marks.
- Count of number of special characters
- Count of number of hashtags
- Count of number of mentions
- Rate of capitalization
- Mixed cases count
- Rate of punctuation

Although punctuation is not relevant in itself and may not indicate whether the user is expressing sarcasm or any other emotion, when paired with other features, these attributes are anticipated to provide value to the classification.

Semantic& other features semantic features usually capture the conceptual relationship between words. For this we extracted multiple semantic features such as the presence of contradiction, interjections, the number of laughing expressions (Bouazizi and Ohtsuki, 2016) and the number of specific hashtags such as: "irony", "sarcasm", "hypocrisy" and "seriously". In addition to these features, other features are extracted as profanity count, topic modeling, and the presence of a numeric mismatch.

2.3 BERT-based Models

Figure 1 and 2 show overall architecture for BERT-based models used for most of the subtask A, subtask B and subtask C. The pipeline for training for most of the models in subtasks A and B as shown in figure 1 goes as follows, the input text is fed to BERT-base models, and the output of arbitrary 4 layers is taken and fed to KimCNN. The output is fed finally to the Fully connected layer (FC) layer. 4 losses can be used to assess the model performance F1-Cross-Entropy, Recall-Cross-Entropy, Balanced loss, and Asymmetric loss.

2.4 Subtask A& B English language

One of the biggest challenges in this task was the presence of an extremely unbalanced dataset. Using the provided dataset without any external dataset or modification of the widely used loss function as cross-entropy, hinge loss, etc leads to bad model performance, where the model focuses only on the majority class which was the Non-Sarcastic class. Even data augmentation couldn't boost performance that much. In one of our early experiments using RoBERTa model on the provided dataset, the model could achieve 77% accuracy and an F1-sarcastic score of zero. Therefore, increasing the length of the dataset seemed crucial at that point to allow better fine-tuning. NLPAug (Ma, 2019) was used for augmentation. Spelling augmentation and ContextualWordEmbsAug for insertion and substitution using Bert and RoBERTa were used. Furthermore, SynonymAug and ContextualWordEmbsForSentenceAug were used to make the dataset balanced, resulting in a balanced dataset where the number of non-sarcastic examples was 1560 and the number of sarcastic examples was 1040. Using this setting with RoBERTa model the model performance improved having F1-sarcastic 27 and accuracy 73% on the dev set. However augmentation didn't work all the time, some augmentation may lead to performance degrading or no improvements as RandomWordAug and WordEmbsAug using google news. Another interesting key point is that loss function does matter. Early experiments using cross-entropy with any BERT-based models achieved high accuracy however, achieved a 0 F1-sarcastic score on the dev set. When using loss functions that incorporate class imbalance the model performance improved. In one of the experiments conducted using Bert-Base uncased with sigmoid focal cross-entropy without any augmentation, the model performance improved reaching a 32 F1-Sarcastic score on the dev set. Therefore, we believe that there are 5 key points needed to be adjusted in order to improve model performance and recognition for the Sarcastic class:

- BERT-based models: which BERT-based model to use and achieve high performance.
- Model architecture: it is crucial to adjust the model architecture whether to use only the last layers and feed it to the Fully connected layer (FC), or whether to use the last n-layers from the model and apply average pooling which is then fed to FC layer, or feed output to Convolution or LSTM layer then FC layer. Also if important to choose which layer/s output will be used.
- Augmentation: it is important to decide whether to use augmentation to balance the dataset (however it is debatable whether it's okay to use them or not since the original dataset is manually labeled. Therefore augmentation might produce new examples we are not sure if it's truly sarcastic or not), or just down-sample the provided dataset by removing some examples.
- Loss function: loss function plays a key role in improving model performance. Therefore choosing the appropriate one will hugely impact the model performance to focus on both classes. A good choices may be sigmoid focal cross-entropy, recall-cross entropy loss (Tian et al., 2020), Dice Loss (Li et al., 2019), Asymmetric loss for multi-label classification and multi-class classification (Ben-Baruch et al., 2020), Distribution Balanced Loss (Wu et al., 2020) and F1-cross-entropy loss (which we believe is effective in our problem and propose).
- Data-Sampler: whether to use data-sampler instead of using augmentation. However, in this case, there are no examples removed from the dataset. The sampler (Yang et al., 2021) just makes sure that each batch fed to the model is balanced.

4 out of the 5 key points were heavily investigated: 1) BERT-based models, 2) Loss functions 3) Different architectures 4) Data-Sampler. For BERT-based models. It turns out that BertTweet, Bert-Base Uncased, RoBERTa, were the best performing models. Furthermore using multiple layers from the BERT-based model improves model performance drastically by 5-15%. Moreover, sigmoid focal cross-entropy, F1-cross-entropy, and also data-sampler improve model performance by 4-10%. F1-cross-entropy loss is denoted by this equation 1

$$\sum_{c=1}^{c=C} -(1 - F1_c) * N_c * log(P_c) \tag{1}$$

, where c is the class number, $F1_c$ is the F1-Score corresponding to specific class, P_c output of sigmoid/softmax for specific class c. Similarly, the recall-cross-entropy loss is denoted by this equation 2.

$$\sum_{c=1}^{c=C} -(1 - Recall_c) * N_c * log(P_c) \tag{2}$$

2.5 Subtask A Arabic Language

For the Arabic language, multiple Bert-Base models were fine-tuned on the provided dataset as AraBert, MarBert, and QARiB. Although the Arabic dataset was also imbalanced the model fine-tuning was easier. Without any modification to the dataset or the loss function, these models could achieve high performance on the dev set, unlike the English language. This might indicate that it is easier to detect sarcasm or find the sarcastic pattern in the Arabic language than the English.

2.6 Subtask C English and Arabic Languages

Based on Analysis and Experiments conducted in subtasks A & B, the following were investigated:

A) several architectures were investigated including the usage of the output of the last layer from Bert-Base models only of the usage of multiple layers from Bert-Base models. In addition to that, all architecture was similar to the siamese network where, the input to the model is both sarcastic and non-sarcastic, and the loss function is calculated based on the model prediction for both texts.

2.7 Final Recipe

In this subsection, we discuss the final models that were used during the evaluation phase for all subtasks.

2.7.1 subtask A English

A voter classifier is used based on different approaches since the voter classifier is model-agnostic, and can be tested on a variety of models and tasks to ensure that our findings are generalizable. 7 different approaches were used for the final classification. The first Model was Berttweet, where we used the output of the last four layers and fed it into KimCNN (Chen, 2015) while using recall-cross-entropy loss and data-sampler. The second model was Berttweet, where the input to the model was the original dataset. The input is fed to the model then the output of the last four layers is extracted and fed to four LSTM layers. The output of the four LSTM layers is fed into the FC layer. F1-cross-entropy loss is used with a data sampler. The third model is Bert-Base Uncased, where the input to the model was the original dataset and all hand-crafted features described in the previous subsection. The input is fed to the model then the output of the last four layers is extracted and fed to four LSTM layers. The output of the four LSTM layers is fed into the FC layer, the hand-crafted features are fed into another FC layer then the output of both is concatenated and fed to the last FC layer with sigmoid activation. F1-cross-entropy loss is used with a data sampler. For the fourth model, the architecture is similar to the first model except that Deberta model is used, and for the fifth model RoBERTa model is used with the same architecture and data-sampler as the first model but F1-cross-entropy loss is used instead of recall-cross-entropy loss. For the 6th and 7th models, linear SVM and linear SVM bagging classifiers were used with all of the set of hand-crafted features.

2.7.2 Subtask A Arabic

For this subtask, MarBert was used only. The input was fed to the model then the output was fed into FC layers. Cross-entropy loss was used.

2.7.3 Subtask B

The final model was a voting classifier between 5 models. The first and the second models were based on BertTweet model with KimCNN. However, the first model was trained using Asymmetric loss and the other model was trained using Distribution Balanced Loss with data sampler. RoBERTa model was used as the third model where the output of the 6th, up t 9th layers, were fed to KimCNN, and the model was trained using Asymmetric loss. For the 4th and 5th models multi-output linear SVM and multi-output linear SVM bagging classifiers were used with all of the set of the hand-crafted features.

2.7.4 subtask C English and Arabic

In the English subtask, the final model was voting classifiers between three models. The first model was based on XLM-RoBERTa (Conneau et al., 2019), where the output of the 6th, up t 9th layers, were fed to KimCNN and the model was trained using Margin ranking loss. For the second and third models, RoBERTa model was used with Margin ranking loss. However, for the second model architecture, the output of the last layer of RoBERTa was fed into FC layer, while for the third model the output of the 6th, up to 9th layer was fed to KimCNN. Similarly for the Arabic language subtask, a voting classifier between three models where used. The first and the second models were based on Arabert and MarBert where the output of the last layer was fed into FC layer, and the models were trained using Margin ranking loss. For the third layer, MarBert with KimCNN was utilized with Margin ranking loss for training. The whole training pipeline is demonstrated in figure 2. Since, the target of the subtask is to determine, which tweet is more sarcastic. During inference, both tweets are fed into the final model and whoever has a larger value is determined as a sarcastic tweet.

3 Experimental setup

Experiments were conducted via Python and PyTorch framework, running on Google Colab resources, which are Nvidia Tesla P100-PCIE-16GB GPU, Intel ® Xeon ® CPU @ 2.20 GHz, and 12GB RAM. We used 70%-10%-20% strategy for train-validation-test splits respectively for the training phase and 5-fold cross-validation during training. All of the presented models (submitted to the leaderboard) were trained on the provided dataset for the shared task only with no augmentation and the same splitting criteria. If augmentation is used in the dev-phase/test-phase, the following types of augmentation were used: 1) Spelling augmentation and contextual Word embedding augmentation for insertion and substitution using BERT and RoBERTa. 2) Synonym augmentation and contextual word embedding for sentence augmentation. Precision, recall, f-score (f1-sarcastic for subtask A, and macro average f1-score for subtask B), and accuracy (for subtask C) were used as evaluation metrics. All BERT-based models were trained using an AdamW optimizer with an initial learning rate of 0.001, weight decay rate of 0.0000001, and cosine annealing learning rate scheduler with minimum learning rate values of 0.0000001 and maximum temperature of 500. All the models were fine-tuned for 3-5 epochs. Pre-processing wasn't conducted on the dataset. During inferences, an ensemble of the 5 models is used (due to 5-fold validation)and is referred to as 1 model during our discussion.

4 Results

In this section, we discuss our main results during the development and evaluation phases. In addition to that failed cases analysis is discussed.

4.1 Results on Trial and Simulated Data

The evaluation was based on the train-test split criteria on the provided dataset. Table 3 shows different models' performance on the dev-set, for subtask A in the English language based on F1-sarcastic and accuracy. Early experiments were based on augmentation and Dice/cross-entropy loss. The performance of the models started to increase when using suitable architecture, multiple outputs from BERT-based models, and a suitable loss function that is sensitive for low classes. The difference between RoBERTa with dice loss and augmentation and RoBERTa with KimCNN and F1-cross-entropy is around 20 in F1-score. Surprisingly machine learning models could achieve a good F1-Sarcastic score. Table 7 shows different models performance on the dev-set, for subtask B based on F1-macro. The model performance is not high due to the small size of the dataset. It can be seen that Distribution Balanced Loss and Asymmetric loss is a good choice for unbalanced multi-label classification. For subtask, A Arabic language MarBert could achieve 89 F1-sarcastic while AraBert and QARiB achieve 54 and 79 F1-sarcastic on dev-set. For subtask C English language XLM-RoBERTa KimCNN could achieve 89% accuracy, while RoBERTa KimCNn and RoBERTa could achieve 90% and 85% on dev-set. For subtask C Arabic language, AraBert could achieve 82%, while MarBert and MarBert KimCNN could achieve 83% and 76% on dev-set.

4.2 Test Results

Tables 5, 4, 6, and 8 show the results of the proposed models and the official model (Voting classifier) that was used in the leaderboard. The voting classifier model is our official submitted model. Table 4 shows the results of our submitted model and the performance of each individual model that is used in the voting classifier. Table 8 shows the results of our submitted model (the voting classifier) in both languages. In addition, the performance of each model contributed to the voting classifier. For subtask C, In the English language, the voting classifier is composed of XLM-RoBERTa and RoBERTa with KimCNN and RoBERTa. For the Arabic language, the voting classifier is composed of MarBert, MarBert, and MarBert with KimCNN. Table 5 shows the results of our submitted model (the voting classifier). In addition to other models that were described in the dev-phase. The final voting classifier for subtask A English is composed of Bagging SVM with feature engineering, SVM with feature engineering, RoBERTa with KimCNN and F1-Cross-Entropy, Deberta with KimCNN and Recall-Cross-Entropy, BertTweet with KimCNN and Recall-Cross-Entropy, BertTweet with LSTM and F1-Cross-Entropy, Bert-Base-Uncased with LSTM and feature engineering and Recall-Cross-Entropy.

Our voting based classifier achieved 20th, while MarBert achieved 3rd place for subtask A, voting based classifier achieved 16th place for subtask B and 10, 6th places for subtask C. For subtask C the performance of the voting classifier and the other models are similar to the dev-set. For subtask B the voting classifier model performance was bad compared to a single model. All the models failed to detect over-statement in the test set. For subtask A English languages the voting classifier model performance was bad compared to a single model, this happened as the performance of machine learning models was bad on the test set. For subtask A, Arabic language the model performance falls below the performance observed on the dev-set. Based on tables 3 and 5 it can be seen that suitable architecture and loss aware function are the key to better performance. In addition to that, it seems that Augmentation has promising performance, and might boost results significantly if integrated with suitable architecture and loss function.

4.3 Error Analysis

In subtask A, the test-set contains 1400 examples, 200 of which are sarcastic, and 1200 of which are non-sarcastic. For subtask1 English language, the submitted model (Voting classifier) miss-classified 224 tweets as sarcastic and 113 as not-sarcastic. In the misclassifications, there were numerous prominent trends. Among the false negatives and false positives in the samples (Most of the time), the sarcasm and non-sarcasm communicated in many cases could only be extrapolated via world knowledge (for example:"Max Verstappen is such a clean driver, he never makes dirty moves when racing." and "This does not surprise me! Kat is a PR queen "). Some of the false positives (detected as sarcasm which is not) depend on the personality and the situation, which is in reality hard to detect is it a touch of sarcasm or not (for example: "Brrrr it's cold outside...I love it!" and "What people?"). For the Arabic language subtask A, Marbert miss-classified 324 tweet as sarcastic and 36 as not-sarcastic. Similarly most the wrongly tweets miss-classified as no-sarcastic was due to world knowledge (for example: trasnalted as "fifi abdo the ideal mother"). الام المثالية فيفي عبده

Some of the miss-classified tweets as sarcastic was related to personal life and personality (for example: trasnslated as "The class who shouldn't be called/named"). الدفعة التي لا يجب ذكر اسمها
In subtask B, the test-set contains 1400 examples, 180 are labeled sarcastic, 20 labeled irony, 49 labeled satire, 1 labeled under-statement, 10 labelled over-statement, and 11 labelled rhetorical-question. One the biggest problems that the dataset contained alot of non-sarcastic tweets, which affected the model prediction performance. A modification that should have done was to enter the tweet to subtask A models and then for the predicted sarcastic tweet subtask B model should be used to determine the type. In subtask C, the test-set contains 200 examples, 107 of them text 0 is more sarcastic than text 1. The voting model miss-classified 52 as text 0 being sarcastic and 4 examples as text 1 being more sarcastic. Some of the errors were a result of unclear sarcasm as an example these two text"Brr! It's really cold outside today" and "I'm loving how warm it is outside today". The more sarcastic text is the second one, however, it's hard to determine whether the weather is hot or cold, to come to this conclusion. Another common type of error is world knowledge as an example: "Benioff and Weiss will definitely go down in history for how terrible the script they wrote for GOT S8 was." and "Benioff and Weiss will definitely go down in history for their amazing work on the script of GOT S8.". If the model doesn't have a knowledge about the TV series and rating it's hard to tell that the second on is the sarcastic. In conclusion common error can be classified to:

- World knowledge
- Personality
- Personal experiences.

5 Conclusion

In this paper, we have discussed our system submitted to the SemEval-2022 Task 6. our model ranked 20th out of 43 participating teams in subtask A English language, 3rd out of 32 participating teams in subtask A Arabic language, 16th out of 22 participating teams in subtask B, 10th out of 16 teams in subtask C English language, and 6th out of 12 participating teams in subtask C Arabic language. We proposed a voting classifier that leverages fine-tuned, per-trained models. We proposed the usage of the different loss functions in each task to accommodate dataset imbalance and improve model training. Overall we showed the power of the loss function to improve model performance without the need to access any external dataset or to use any kind of augmentation. We also investigated the main common error, which disturbs model performance. In future efforts, we plan to further improve our model to better handle data-imbalance constraints and world knowledge needed to improve model performance.

niksss at SemEval-2022 Task 6: Are Traditionally Pre-Trained Contextual Embeddings Enough for Detecting Intended Sarcasm ?

Nikhil Singh
Manipal University Jaipur
nikhil3198@gmail.com

Abstract

This paper presents the 10th and 11th place system for Subtask A - English and Subtask A - Arabic respectively of the SemEval 2022 - Task 6. The purpose of the Subtask A was to classify a given text sequence into sarcastic and non-sarcastic. We also breifly cover our method for Subtask B which performed subpar when compared with most of the submissions on the official leaderboard . All of the developed solutions used a transformers based language model for encoding the text sequences with necessary changes of the pretrained weights and classifier according to the language and subtask at hand .

1 Introduction

According to (Yaghoobian et al., 2021), "Sarcasm detection is the task of identifying irony containing utterances in sentiment-bearing texts". Even though sarcastic humor is present throughout social media, it is hard for even humans to comprehend it certainly as the reader doesn't always perceive it the same way the speaker intended with intricate socio-psychological and cultural references. With the way, current models for text representation are trained like Word2Vec (Mikolov et al., 2013) and Glove (Pennington et al., 2014), which have the same representation for a particular word irrespective of the context they fail to incorporate the meaning of sarcastic texts. Even though the recent state-of-the-art language models provide contextual embeddings for words, it still fails to tell the sarcastic humor from normal as we explain later in the paper.

There have been a lot of attempts at computationally automating sarcasm detection in the literature. Discernibly, the task of sarcasm detection can be classified into content and context-based methods. With features like Structural, morphosyntactic and semantic ambiguity features (Reyes et al., 2012),User mentions (replies), emoticons, N-grams, dictionary- and, sentiment-lexicon-based features(González-Ibáñez et al., 2011)) and features based on word embedding similarity (Joshi et al., 2016) coming inside content based method. With the surge of seq2seq based model such as BERT (Bidirectional Encoder Representations from Transformers (Devlin et al., 2018), RoBERTa (Liu et al., 2019), and XLNet (Yang et al., 2019), etc. have been heavily employed for sarcasm detection in the literature. (Potamias et al., 2020) proposed an R-CNN-RoBERTa which is a hybrid model leveraging RoBERTa's contextual embedding into a recurrent convolutional neural network. (Dadu and Pant, 2020) created an ensemble of RoBERTa and ALBERT (Lan et al., 2019). Seeing the success of pre-trained language model, we decided to leverage the pre-trained contextual embeddings and transformers toward sarcasm detection.

While some of the previous textual sarcasm detection datasets involved annotation via finding some predefined criteria, such as including specific tags (e.g. sarcasm, irony) (Ptácek et al., 2014) associated with the text. Other datasets involved manual labeling (Filatova, 2012) (Yang et al., 2016). However, the mentioned labeling techniques produced noisy or uncertain labels which would further compromise the effectiveness of the models trained on them. Further, most of the sarcasm detection work has been done in the English language and it is highly unlikely that the models trained on one language would generalize well on other languages.

The purpose of SemEval-2022 Task 6 - Intended Sarcasm Detection in English and Arabic (Abu Farha et al., 2022) is to advance the development of automatic textual sarcasm detection by providing a dataset which overcomes the problem of noisy and uncertain labels by having the authors provide the labels themselves. The shared task is divided into three subtasks:

- SubTask A(English Arabic): Given a text, determine whether it is sarcastic or non-sarcastic;

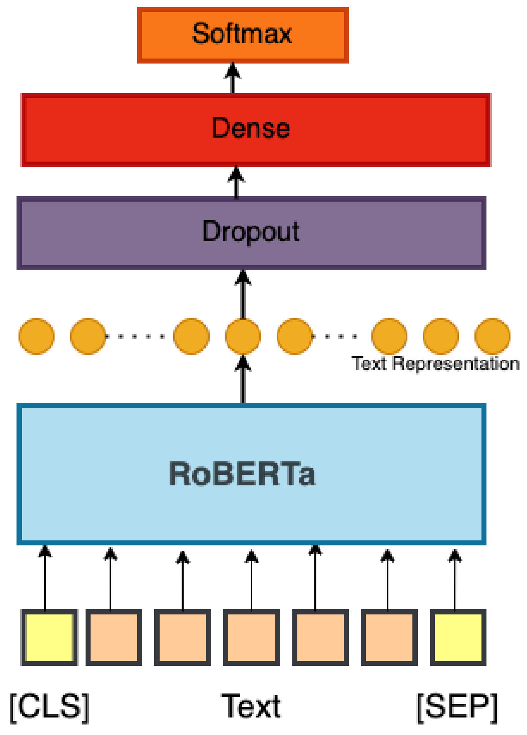

Figure 1: Model Architecture for Subtask A

- SubTask B (English only): A binary multi-label classification task. Given a text, determine which ironic speech category it belongs to, if any;

- SubTask C(English Arabic): Given a sarcastic text and its non-sarcastic rephrase, i.e. two texts that convey the same meaning, determine which is the sarcastic one.

2 System Overview

Here, we describe the data pre-processing steps along with the models for each subtask, and the experimental setup for the system. We provide an overview of the system in Figure 1.

2.1 Data

Manually examining the provided dataset, it was found that the datapoints were mostly from social media. Hence, basic text denoising steps such as user-handle removal, number removal, de-emojifying and repeating punctuation were handled for all three subtasks.

2.2 SubTask A

For this task the participating teams had to develop a system which, given a text, determines whether it is sarcastic or non-sarcastic. We develop a binary sequence classifier as shown in Figure 1. It comprises of a roberta base model as the text encoder with weights taken from cardiffnlp/twitter-roberta-base-sentiment(Barbieri et al., 2020) for English and AraBERT (Antoun et al., 2020) for Arabic. Both of these models are hosted on the HuggingFace library [1] .

The detailed steps involved in this experiment is present below.

- The pre-processed data comprising of cleaned text sequences is tokenized using a BertTokenizer from Huggingface and is passed through the model mentioned above to embed it into a 768 dimensional feature vector containing the syntactical information of the input string.

- The feature vector is then passed through a dropout layer to increase the regularization which in-turn increases the generalizability of the model.

- The model was trained in a supervised manner in a binary classification regime for 5 Epochs with a batch size of 32. Rest of the Hyper-parameters are shown in Table 1. A seed value of 42 to keep the model deterministic.

- The model took approximately 45 minutes to train on Nvidia's P100 GPU with a memory of 16Gb.

- The complete experiment was done on Google Colab Pro.

2.3 SubTask B

For this subtask the participants were required to determine which ironic speech category the given input text belongs to. We treated this problem as a multilabel classification with the same encoder as subtask A but with a multilabel classifier instead of a binary classifier to capture the dependency of one sarcasm type on other. We trained this model using a Label Ranking average precision loss for 3 Epochs, with a batch size of 4 and rest of the parameters same as Subtask A for English. Simple Transformers[3] was used to do the development. The model was trained on Google colab and it took

3 Results

3.1 Subtask A

All the submitted systems for Subtask A were evaluated using the five metrics that are, Accuracy, Precision, Recall, F1 score, and F1 score of the sarcastic class. However, the ranking of the systems was determined using the F1 score of the sarcastic class. We were officially ranked 10th in Subtask A - English and 11th in Subtask A - Arabic. With an F1 score of 40.16% for English and 40% for Arabic. The rest of the metrics are shown in Table 3.

3.2 Subtask B

The submitted systems for Subtask B were evaluated using the F1 scores of the respective classes in the dataset. The ranking was determined by the Macro F1 score. We ranked at position 22 with a Macro F1 score of 0.0380. The rest of the scores are present in Table 3.

4 Error Analysis

After examining the predictions from the submitted model, we saw that the model struggled significantly in classifying the text sequences to sarcastic type. We inferred that, even though we put less weight on the non-sarcastic class during the loss computation, the model overfitted to the abundant class of non-sarcastic text sequences with a ratio of roughly around 3:1 between the two classes for both Engligh and Arabic tasks. We also noted that individual hyper-parameters had significant roles in the performance of the model. Training different models with different hyper-parameters and ensembling them together showed a significant increase in performance in the post evaluation period. For Subtask B, the main reason for the poor performance of our model and most submitted models on the leaderboard, is the inter-class difference between individual sarcasm types is very low.Which in-turn confuses the model and the output probability is roughly close to each other.

5 Conclusion

We developed a system to classify sarcastic text from non-sarcastic text using contextualized embeddings from a language model which didn't have any prior information about what the fundamental concepts of sarcasm. It inculcates language understanding through self-supervised training techniques namely, masked words prediction and next sentence prediction. However, sarcasm doesn't work in the same way as declarative, exclamatory, imperative, and interrogatory sentences. These were the major type of sentences used for pre-training the language models.

In future work, we plan to use a seq2seq based encoder-decoder model for instilling knowledge of sarcasm in the already available seq2seq models like T5 (Raffel et al., 2019). Wherein we'll use data similar to what was provided in SubTask C and train a seq2seq model with input as the sarcastic text and the model will learn to paraphrase that input sentence into a non-sarcastic sentence as output.

Language	F-1 score	Precision	Recall	Accuracy
English	0.6353	0.6215	0.6683	0.7850
Arabic	0.5800	0.6083	0.7167	0.6571

Abstract

This paper introduces the result of Team Dartmouth's experiments on each of the five subtasks for the detection of sarcasm in English and Arabic tweets. This detection was framed as a classification problem, and our contributions are threefold: we developed an English binary classifier system with RoBERTa$_{\text{BASE}}$, an Arabic binary classifier with XLM-RoBERTa$_{\text{BASE}}$, and an English multilabel classifier with BERT$_{\text{BASE}}$. Preprocessing steps are taken with labeled input data prior to tokenization, such as extracting and appending verbs/adjectives or representative/significant keywords to the end of an input tweet to help the models better understand and generalize sarcasm detection. We also discuss the results of simple data augmentation techniques to improve the quality of the given training dataset as well as an alternative approach to the question of multilabel sequence classification. Ultimately, our systems place us in the top 14 participants for each of the five subtasks.

1 Introduction

Sarcasm is a form of irony that occurs when there is a discrepancy between the literal and intended meanings of a text or utterance. This discrepancy typically manifests itself in the form of dislike, contempt, or derogation. Furthermore, sarcasm can be divided into multiple types: general sarcasm, irony, satire, understatement, overstatement, and rhetorical question.

This task concerns itself with the detection of sarcasm in online tweets (Abu Farha et al., 2022). This is an important issue to solve because the nature of sarcasm can interfere with the effectiveness of natural language processing models, particularly when conducting sentiment analysis, opinion mining, or other emotion-based tasks. Machine learning models deployed for such business use cases can be negatively impacted when processing sarcastic texts and provide inaccurate results, thereby harming an organization's bottom line. Therefore, it is critical that machine learning models be developed that can understand how to detect, ingest, and truly understand sarcasm.

This paper discusses how to identify sarcastic tweets in binary and multi-label classification contexts for both English and Arabic, as directed by SemEval-2022 Task 6 (Abu Farha et al., 2022). There are five subtasks: general sarcasm detection in standalone English and Arabic tweets (Task A), identification of sarcastic category in an English tweet (Task B), and identification of the sarcastic tweet in an English/Arabic pair of tweets (Task C).

Our experiments show that pre-trained transformer models demonstrate a strong ability of solving most of the subtasks of this challenge. Specifically, we fine-tune a RoBERTa$_{\text{BASE}}$ model to detect the presence of sarcasm in tweets for the English components of Tasks A and C. For the Arabic version of Tasks A and C, we apply an XLM-RoBERTa$_{\text{BASE}}$ model. For Task B, which is framed as a multilabel sequence classification problem, after experimenting with several RoBERTa and BERT models, we report the performance of a BERT$_{\text{BASE}}$ model which is fine-tuned to detect the categories of sarcasm in English tweets, if any.

While these models perform reasonably well in the evaluations, the imbalanced distributions of labels and poor annotation quality for some instances introduce unexpected noise to the fine-tuning process of these models and harm their performance in the evaluations. Despite our effort to augment unrepresented classes in the training data, simple data augmentation approaches do not show clear positive effects on the models' performance. More advanced data augmentation methods could be tried to trigger notable performance improvements on the challenge test dataset.

2 Approaches

As mentioned above, there are three systems designed for the five subtasks. We discuss the model architecture, input processing, and other key elements for each of the systems below.

2.1 RoBERTa for Binary Classification

The English component for Tasks A and C require us to distinguish whether a tweet is sarcastic, either as a standalone text (Task A) or in comparison to another tweet (Task C). Both of these tasks were framed as binary classification problems and our solution leveraged the RoBERTa model (Figure 1) from Facebook AI to achieve this by producing rich feature representations from the inputs.

In particular, RoBERTa builds upon the Bidirectional Encoder Representations from Transformers (BERT) by modifying some key hyperparameters, training with much larger learning rates and batches, and removing BERT's next-sentence pretraining objective (Liu et al., 2019). Critically, this allows RoBERTa to improve on the masked language modeling objective and allows for better task performance down the road. The RoBERTa base is composed of 12-layers, 768-hidden, 12 self-attention heads, and 125M parameters.

Processing each input tweet first began with changing sarcasm labels from 1 (sarcastic) to 0.8 and 0 (non-sarcastic) to 0.2, although the 0.2 was eventually changed back to 0. This was to account for random noise in the dataset and for training examples that were of lesser quality than others.

The next step was tweet normalization: among other things, this included replacing hyperlinks, user tags, and emojis with a standardized token (`"@URL"` for hyperlinks and `"@USER"` for user tags, for example). Furthermore, contracted words were separated out to extract the key token. This was to ensure the model did not learn from random, irrelevant noise found in hyperlinks or user tags.

Before passing each normalized tweet into the tokenizer, however, we first extracted all verbs and adjectives from the original tweet (Sequence A) and strung them together with whitespace to create a new string (Sequence B). In turn, those verbs and adjectives were replaced with the `<mask>` token in the original tweet. This was executed in an attempt to help the model better learn the relationship between a tweet's sarcastic presence and any available verbs or adjectives in it. These two sequences were then joined together with separator tag `</s>` and fed into the tokenizer as a single sequence.

Padding tokens were added to make each input the same length for the RoBERTa model. The maximum length used for this system was 256. Although the longest string of tokens from the available training dataset was 111, we set it to 256 for the sake of safety. This ensured that all tensor inputs were set to equal the maximum sequence length used for batched parallelized training. This meant the ultimate input passed into the tokenizer looked like Table 1, where `<s>` is the classifier token, `</s>` is the separator token, `<pad>` is the padding token, `Seq-A` contains `<mask>` tokens where its adjectives and verbs originally were, and `Seq-B` is a string of all verbs and adjectives from the original tweet.

Input	`<s>Seq-A</s>Seq-B<pad><pad>`

Table 1: A sample input for encoding.

A sequence classification head containing a linear layer was applied on top of the final hidden-states output, with a label prediction of 1 denoting a sarcastic tweet and 0 denoting a non-sarcastic tweet. For standalone tweets (Task A), the threshold to pass a tweet as sarcastic was set to 0.40, where tweets with a score higher than that were marked as sarcastic while those underneath this threshold were not. For determining which of two tweets is sarcastic (Task C), the tweet with the highest absolute score, regardless of its relation to a threshold, was marked as sarcastic.

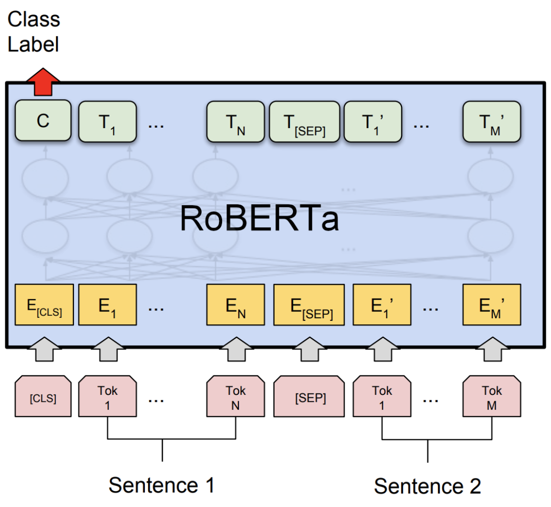

Figure 1: The RoBERTa model architecture.

2.2 XLM-RoBERTa for Binary Classification

The Arabic subtask for Tasks A and C require us to distinguish whether a tweet is sarcastic, either as a standalone text (Task A) or in comparison to another tweet (Task C). We framed these as binary classification problems and leveraged the XLM-RoBERTa$_{\text{BASE}}$ model, which is a multi-lingual version of the RoBERTa model and is pre-trained on 2.5TB of filtered CommonCrawl data containing 100 languages (Conneau et al., 2019). It is composed of 12-layers, 768 hidden, 8 self-attention heads, and 125M parameters.

In preprocessing each input Arabic tweet, we began by changing the sarcasm confidence labels from 1 to 0.8. This was again executed to account for random noise as well as subpar training data examples that did not encapsulate sarcastic qualities nearly as well as others.

Regular tweet normalization does not apply to Arabic. Certain qualities in the written form of Arabic, such as diacritization, further complicate this matter. The same word in two different diacritizations can have meanings that are seemingly completely unrelated (Alkhatib, 2017). This introduces difficulty in extracting the true semantic meaning of a text in Arabic.

We therefore relied on CAMeL Tools, a Python library designed for the Arabic language to execute dediacritization and remove any non-essential components from the input texts (Obeid et al., 2020). Further normalization was also conducted with functions from this specialized library, such as removing orthographic ambiguity.

After processing input tweets, the technique of extracting verbs and adjectives to form a secondary sequence was utilized. As in the first approach, the extracted verbs and adjectives were replaced with `<mask>` tokens in the original input tweet, and this was prepended to the secondary sequence of verbs and adjectives using a `</s>` separator token. This combined sequence was then fed into the XLM-RoBERTa's tokenizer to be encoded. In this particular case, a specialized part-of-speech tagger was used from CAMeL Tools to identify and extract each input tweet's set of verbs and adjectives.

During tokenization, padding tokens were added to the right to make all the tensor inputs of uniform length. Although the longest examined length of any tweet was 143, we utilized 256 to account for any unexpected inputs.

The final element of this system was a sequence classification head containing a linear layer that was applied on top of the final hidden-states output with a label of 1 predicting sarcasm and a label of 0 predicting otherwise. For detection of sarcasm in standalone Arabic tweets (Task A), those with a score that exceeded our threshold of 0.40 were marked as sarcastic while others were not. For determining the sarcastic tweet in a pair of tweets (Task C), the tweet with the highest absolute score, regardless of whether it exceeded Task A's threshold of 0.40, was marked as sarcastic, while the other tweet was not.

2.3 BERT Base for Multilabel Classification

Task B required us to distinguish which category of sarcasm an English tweet belonged to, of which there are six: general sarcasm, irony, satire, understatement, overstatement, and rhetorical question. A tweet can belong to none, one, or multiple categories. We framed this task as a multilabel sequence classification problem and we leveraged the BERT$_{\text{BASE}}$ model (see Figure 2 for a high-level architecture visual). It is composed of 12-layers, 768-hidden, 12 self-attention heads, and 110M parameters (Devlin et al., 2018).

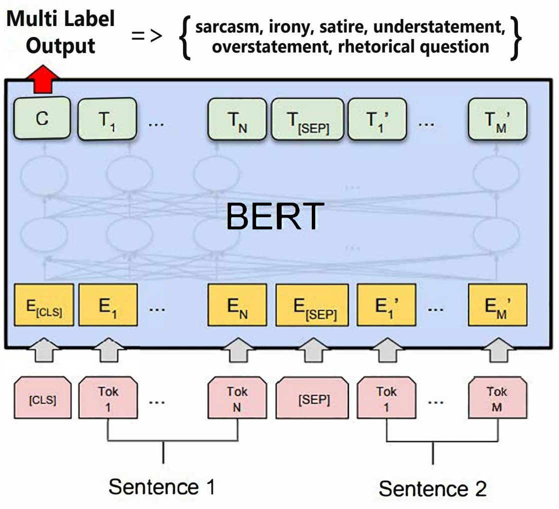

Figure 2: The BERT model architecture modified to reflect multilabel output.

Each tweet was first normalized following the steps outlined in the first approach. This included ”demojifying” any present emojis and standardizing any present hyperlinks and user tags with `"@URL"` and `"@USER"`. Before feeding the tweet into the tokenizer, however, we utilized an approach to improve the model's understanding of the keywords that might point towards a particular

Data Augmented Results	**Scores**		
	Weighted Recall	Weighted Precision	Macro-F1 Score
Baseline (No Augmentation)	0.549	0.091	0.156
Category Duplication	**0.642**	0.089	0.156
Manual Sentence Generation	0.561	**0.093**	**0.159**
GPT-3 Sentence Generation	0.552	0.082	0.151

Table 2: A summary of the performance of data-augmented systems for multilabel classification. The highest performing technique is bolded for weighted recall, weighted precision, and macro F1 score.

category of sarcasm. A TF-IDF vectorizer was used to extract the 15 most significant and representative keywords across sentences of each category. Then, for each input training tweet, all the keywords associated with the categories of sarcasm the tweet belonged to were strung together to create a secondary sequence (Sequence B) that was appended to the original input tweet (Sequence A) and separated with a separator token (`</s>`). This combined sequence was then fed into the BERT$_{\text{BASE}}$ tokenizer as a whole. This was done in an attempt to help the model be able to better seek out key phrases and words that might indicate a tweet's categorization as sarcastic, ironic, satirical, etc.

After training the multilabel classifier and generating six predictions for a tweet's likelihood of categorization in each of the six sarcastic categories, the tweet would be marked as valid for a category if its score was greater than 0.30. This was a relatively low threshold that we felt was necessary to account for the similarities across tweets belonging to different categories of satire. Furthermore, we needed to compensate for the lack of training data in categories like satire, understatement, and overstatement, which had 25, 10, and 40 training examples, respectively. By setting a lower threshold, we are able to ensure that we are not prohibitively preventing classifying any tweets as satire, understatement, overstatement, or any other category.

2.3.1 Data Augmentation

To support our efforts for multilabel classification, we explored three data augmentation techniques.

Our first technique was simply duplicating the satire, understatement, and overstatement categories to double the quantity of sentences in each of those categories. This involved copying and pasting each sentence back into the category to hopefully strengthen the model's understanding of sarcastic keywords, phrases, and qualities. We observed no meaningful improvement in results.

The second technique involved the manual generation of sentences to expand the dataset. As mentioned before, a TF-IDF vectorizer was used to extract the 15 most relevant and representative keywords for sentences across each category. See Figure 2 for some example keywords extracted through this technique. Using basic sentence templates, new training data examples were created with keywords for each satirical category being substituted into various parts of each new training datapoint. 30-40 new training examples were created for each of the satire, understatement, and overstatement categories. However, this effort did not yield meaningful or significant improvement in results.

Sarcasm	”just”, ”like”, ”really”
Understatement	”good”, ”like”, ”sorta”
Overstatement	”hate”, ”love”, ”worst”

Table 3: A subset of keywords observed as the most representative for sarcasm and under/over-statements through a TF-IDF vectorizer.

A final technique involved utilizing GPT-3 for generating new sentences. A prompt like ”Generate 10 sarcastic sentences” or ”Create 15 rhetorical questions” was provided to the model, however it was observed that the produced sentences were particularly repetitive with little variance in structure or style. The difference between most sentences produced by the model was a simple substitution in topic, object, or subject, especially as we asked the model to produce an increasing number of new sentences. A lack of training data to properly finetune the GPT-3 model was likely an issue here, and this technique was eventually dropped.

Results for each of these techniques are provided in Table 2, with the highest performing technique bolded for each metric. As observed, while most techniques seemed to perform better than the baseline, the improvements are marginal and unreliable.

2.3.2 Additional Techniques

It is worth noting that another system was explored to conduct multilabel classification. Specifically, we attempted to create 6 binary classifiers (one for each category of sarcasm) with the intent of aggregating results across all binary classifiers to mimic a multilabel classifier's output. This, however, was complicated by the severe lack of training examples for some categories as well as issues with computational capacity and consumption on Google Colab Pro. This system was eventually dropped in favor of a single multilabel classifier built with $\text{BERT}_{\text{BASE}}$, as described earlier.

3 Experimental Setup

3.1 Dataset

The task provided two training data files, one for English and another for Arabic. In each case, the task organizers provided the sarcasm labels for each tweet themselves. This avoided the need to rely on existing proxies like predefined tags or third-party labelers (Abu Farha et al., 2022).

Within the English training file, there are nine pieces of information: the tweet, a `0/1` value for the presence of sarcasm, a non-sarcastic rephrase of that tweet, and a `0/1` value for each of the various sarcasm subtypes (general sarcasm, irony, satire, understatement, overstatement, and rhetorical question). This dataset contained 3466 training examples, of which 866 were sarcastic and the remaining 2600 were not. These 866 examples are further split into multiple labels as follows: 713 for sarcasm, 155 for irony, 25 for satire, 10 for understatement, 40 for overstatement, and 101 for rhetorical question. The underresourced nature of categories like satire, understatement, and overstatement introduced challenges for our multilabel classifier system in extracting and understanding the key characteristics belonging to those categories. It is worth noting that data quality is, at times, questionable, with training examples such as *"whoop diddy scoop poop"* adding random noise into an already scarce dataset.

Within the Arabic training file, there are four pieces of information: the tweet, a `0/1` value for the presence of sarcasm, a non-sarcastic rephrase of the tweet, and a dialect label for that particular tweet (e.g. Nile, Maghreb). This training file contained 3102 training examples, of which 745 were sarcastic and the remaining 2357 were not.

3.2 Evaluation Metric

For both the English and Arabic binary classification approaches, a confusion matrix was produced to determine accuracy, precision, recall, and F-1 scores. For the multilabel classification task, weighted precision/recall for each category as well as macro F-1 scores were utilized.

3.3 Implementation Details

All three systems were developed with the PyTorch framework, HuggingFace's transformers library for the BERT, RoBERTa, and XLM-RoBERTa models, and Google Colab Pro using a single Tesla P100-PCIE-16GB GPU. For Tasks A and C, the English and Arabic binary classifiers trained for those problems shared the same hyperparameters: training and validation batch sizes of 16, a maximum sequence length of 256, 6 training epochs, and an AdamW optimizer with a learning rate of 3e-5 and epsilon value of 1e-8. For Task B, the English multilabel classifier's training policy utilized the following hyperparameter values: training and validation batch sizes of 16, a maximum sequence length of 256, 4 training epochs, and an AdamW optimizer with a learning rate of 1e-05 and epsilon value of 1e-12. All other hyperparameter values were set to their defaults according to the HuggingFace implementation. It should also be noted that for all systems, a random seed was set for the sake of reproducibility.

4 Experimental Results

Team Dartmouth received the following ranks:

- Task A (English): 13th place
- Task A (Arabic): 9th place
- Task B: 14th place
- Task C (English): 12th place
- Task C (Arabic): 10th place

Table 4 on the following page displays a tabular summary of all official scores received on each of the five subtasks, which vary from accuracy and precision to recall and macro F1 scores. As observed, our best performing system for binary classification was the English classifier developed for Task A, whereas our worst performing for binary

Binary Classification Tasks	Scores				
	F-1 Sarcastic	F1-Score	Precision	Recall	Accuracy
Task A (English)	0.386	0.635	0.625	0.648	**0.804**
Task A (Arabic)	0.350	0.529	0.581	0.665	0.597
Task C (English)	-	0.659	-	-	0.660
Task C (Arabic)	-	0.679	-	-	0.680

	Macro F1	F1-Sarcasm	F1-Irony	F1-Satire	F1-Under	F1-Over	F1-Rhet-Q
Task B	0.0590	0.2293	0.0202	0.0824	0.0000	0.0077	0.0143

Table 4: A tabular summarization of the performance of all three systems across all five subtasks, reporting various metrics including accuracy, precision, recall, and regular/macro F-1 scores. Experiments revealed that further data augmentation did not improve the scores of any system.

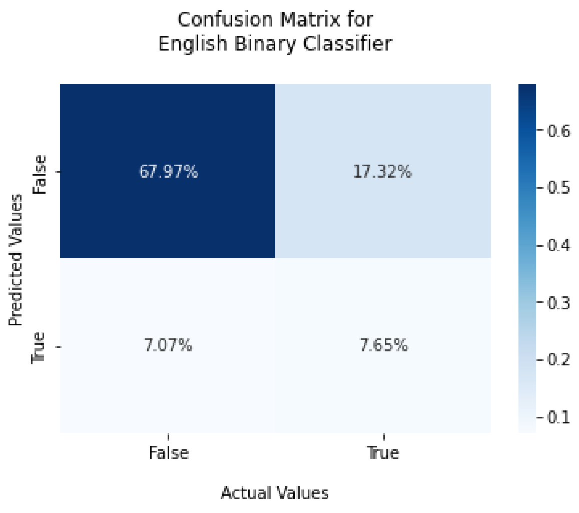

Figure 3: A confusion matrix of the English binary classifier developed for Tasks A and C.

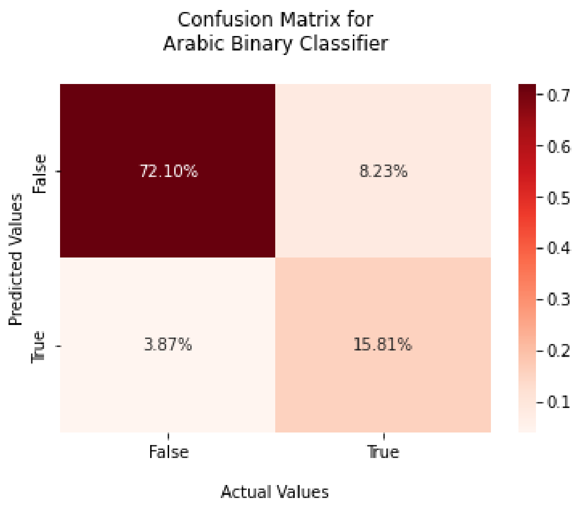

Figure 4: A confusion matrix of the Arabic binary classifier developed for Tasks A and C.

classification was the Arabic classifier also developed for Task A. For the multilabel classification task, macro F-1 as well as weighted categorical scores are provided.

Confusion matrices displaying our best development metrics are provided in Figures 3 and 4. This reveals insights into the relatively imbalanced split of the training dataset, creating issues which were further compounded by the overall small number of training examples.

4.1 Case Study: Task A (English)

It's worth exploring Task A (English) in greater detail to understand the elements that factored into our model's scores. To begin, it should be noted that certain inputs in the test dataset for this subtask were sometimes single tweets like ”Followed” or ”Pinball!”, while other tweets were random noise, such as the following:

> ”20:00 GMT:
> Temp: 13.7°C,
> Wind: SSW, 3 mph (ave), 8 mph (gust),
> Humidity: 92
> Rain (hourly) 0.0 mm,
> Pressure: 1017 hPa, rising slowly.”

The prevalence of random noise such as the above in the test set can make it somewhat challenging for the model at hand to be able to relate the test input to what it has learned. There's very little context to learn from in one-word tweets like the ones mentioned, and this may bias the model towards marking such tweets as non-sarcastic, when in reality they may be sarcastic (e.g. perhaps the one-word tweet was a sarcastic remark towards another tweet). Granted, this is the nature of text in short-form online social forums like Twitter, but it does contribute to a concrete decrease in model performance.

Furthermore, our technique of masking verbs and adjectives in the original tweet while simultaneously stringing those verbs and adjectives together into a second sequence to be fed into the tokenizer alongside the tweet input may have overfit the model towards certain words and phrases from the training dataset. While this may have been helpful in identifying sarcastic tweets which did include those words, it may also have caused the model to overlook other sarcastic sentences that did not include them in the test dataset.

As such, random noise, poor quality, and certain learning techniques may have been factors in contributing to the scores received by our binary and multilabel classification systems. The same observations apply to Tasks A and C in Arabic as well as Task B. In particular, our technique of extracting and appending the top 15 words for each category a tweet belongs to may have inadvertently overfit the model to overlook other textual signals that indicate a tweet's sarcastic categorization in preference for certain words and phrases.

5 Conclusion and Future Work

In this paper, we have described three binary and multilabel sequence classification systems using the BERT, RoBERTa, and XLM-RoBERTa architectures from HuggingFace for the detection of sarcasm in English and Arabic tweets. We found that additional work to augment the training data with duplication of sentences and manually/automatically synthesizing new sarcastic sentences did not improve the results of the model. Furthermore, challenges were observed with the multilabel classifier in learning to extract the key characteristics that categorize a tweet as a distinct example of satire, understatement, or overstatement – categories which were generally underresourced in the training dataset.

Further investigation could include implementing six binary classifiers instead of a single multilabel sequence classifier for Task B. Given enough training time, data, and resources, it could certainly be the case that aggregating results across specialized binary classifiers provide more concrete results than what has been produced. In particular, this may allow each of the binary classifiers to more deeply learn the unique characteristics, keywords, and structure of the sarcastic sentences it ingests.

It would also be interesting to see how the results across all three systems change with sufficient training data, with perhaps tens of thousands of more valid examples that can allow the models to truly capture the essence of sarcasm across a wide and varied set of training examples.

Abstract

Robust sarcasm detection is critical for creating artificial systems that can effectively perform sentiment analysis in written text. In this work, we investigate AI approaches to identifying whether a text is sarcastic or not as part of SemEval-2022 Task 6. We focus on creating systems for Task A, where we experiment with lightweight statistical classification approaches trained on both GloVe features and manually-selected features. Additionally, we investigate fine-tuning the transformer model BERT. Our final system for Task A is an Extreme Gradient Boosting Classifier (XGB Classifier) trained on manually-engineered features. Our final system achieved an F1-score of 0.2403 on Subtask A and was ranked 32 of 43.

1 Introduction

Sarcasm is the use of irony–which communicates the opposite of what is said–to humorous and derisive effect (Bouazizi and Ohtsuki, 2016). On the web, sarcasm is ubiquitous–not least because social media users often apply sarcasm to incorporate a sardonic sense into their statements (Hancock, 2004). This poses a substantial challenge to artificial systems evaluating tasks including sentiment analysis (Liu and Zhang, 2012). It is already a challenge enough for human annotators to determine what is intended to be taken at face-value or not in context-lacking text; it is even more difficult for NLP systems to distinguish between what should be taken literally and what is sarcastic.

Task 6 of SemEval-2022 (Abu Farha et al., 2022) provides an environment to build systems to approach these challenges. In particular, Subtask A in Task 6 (Table 1) of SemEval-2022 tests the ability of automated systems to determine whether a text is sarcastic or non-sarcastic. We investigate whether lightweight models (which use few computational resources) are able to effectively identify sarcastic speech; we also experiment with fine-tuned Transformer-based models to identify whether larger models perform better.

2 Dataset

In Subtask A, we train our models on the official SemEval-2022 Task 6 English training set, which was curated from a set of tweets. Each sentence (examples in Table 6) has been annotated for sarcasm status by the text authors themselves, with 1 denoting a sarcastic text and 0, a non-sarcastic text.

Task	Description	Metric
A	Determine whether a given text is sarcastic or non-sarcastic.	F1, sarcastic-class

Table 1: Subtask A overview.

2.1 Train-test Split

The dataset has a total of 4868 examples, with 3468 being part of the training set, and 1400 being part of the test set. In total, there are 867 sarcastic and 2601 non-sarcastic texts in the training set. As the testing set labels were not provided until after the competition, we created our own validation set with a 75 : 25 train : test split. Thus, our train set has 2774 examples and our test set has 693 examples.

Feature	Description	LR Coefficient
POL	Words referring to political leaders (e.g. "Boris," "Trump").	0.127
GAY	The word "gay."	0.008
BANG	The character "!".	-0.067
AT	The character "@".	0.005
DEFINITELY	The word "definitely."	0.035
PLEADING FACE	The pleading face emoji.	0.136
EMOJI	The grinning face emoji.	0.095
HASH	The character "#".	-0.095
THANK	The word "thank."	0.008
HAHA	The word "haha."	0.095

Table 2: Manual features for sarcasm detection.

Model	F1 Sarcastic	F-score	Precision	Recall	Accuracy
XGBClassifier	0.2403	0.1332	0.3651	0.4792	0.1464

Table 3: Official test set performance of our best-performing lightweight model (XGBClassifier trained with manual features) on Subtask A (binary classification). LR coefficient represents the linear regression coefficient value for the given feature.

3 Methods

3.1 Subtask A: Sarcasm Detection

This subtask examines whether a given text is sarcastic, and we investigate using the following models. Our lightweight machine learning models were implemented using the Scikit-learn library (Pedregosa et al., 2011):

- **Logistic Regression** is a supervised learning algorithm that predicts a binary outcome using a logistic function.
- **GaussianNB** is a type of Naive Bayes algorithm used for continuous data that follows a normal distribution (Qiu et al., 2020).
- **SVM** is a non-probabilistic binary linear supervised learning algorithm that can be used for classification and regression (Yu and Kim, 2012).
- **AdaBoostClassifier** is a meta-algorithm that assigns higher weights to incorrectly classified samples to improve the following classifiers (Solomatine and Shrestha, 2004).
- **XGBClassifier** stands for e**X**treme **G**radient **B**oosting **Classifier** and is a decision tree based algorithm that uses gradient boosting methods to avoid overfitting (Kumar et al., 2021).
- **BERT** is a transformer based algorithm that uses masked language modeling. We fine-tune BERT–an approach commonly used in tasks such as sentiment prediction–which was pretrained on language modelling and next-sentence prediction tasks. In particular, we use BERT base cased, BERT large cased, BERT base uncased, and BERT large uncased (Devlin et al., 2018).

3.2 Results

On the unofficial evaluation set, XGBClassifier performed the best compared to other models. On the official evaluation set, we achieve a F1-score of 0.2403. We were ranked 32 out of 43. Our official and unofficial results are listed in Table 3 and Table 4 respectively. The hyperparameters that we used for all models trained on manual features is included in Table 5.

4 Conclusion

Our models were trained to determine whether texts were sarcastic or not. For the most part, our models struggled to detect sarcasm in text—-as was expected, given that the task was quite challenging even for humans. We find that the models that achieve the highest degree of success in detecting sarcasm were GaussianNB and XGBClassifier models.

Model	Features	positive-class F1	Accuracy	Normalize
LogisticRegression	Manual	0.44	0.34	True
LogisticRegression	GloVe	0.09	0.71	False
GaussianNB	Manual	0.43	0.34	True
GaussianNB	GloVe	0.42	0.47	False
SVM	Manual	0.30	0.63	True
SVM	GloVe	0.08	0.72	False
AdaBoostClassifier	Manual	0.06	0.72	False
AdaBoostClassifier	GloVe	0.23	0.68	False
XGBClassifer	**Manual**	**0.45**	**0.32**	**False**
XGBClassifier	Glove	0.38	0.59	False
BERT base cased	–	0.32	0.63	False
BERT large cased	–	0.14	0.50	False
BERT base uncased	–	**0.40**	**0.75**	**False**
BERT large uncased	–	0.26	0.63	False

Table 4: Unofficial validation set performances of candidate models. For this task, the highest-performing lightweight model is XGBClassifier and the highest-performing transformer model is BERT base uncased.

We also find that using manual features, as listed in Table 2, is a fruitful approach to determining the sarcasm status of a sentence. In particular, we preprocess the data by identifying the number of instances of characters or words described in each feature category, then train our models on these summed feature values. Our top-scoring classifiers yielded substantially greater postive-class F1 scores with manual features than with automatic GloVe features. That being said, it should be noted that using these manual features also lowered the accuracy greatly, which indicates a tradeoff between F1 score and accuracy due to the extreme class imbalance of the dataset.

Finally, fine-tuning BERT achieves reasonable results while detecting sarcasm. However, this method is still inferior to a lightweight approach.

Overall, our best model, the XGBClassifier with manually engineered features, did not perform significantly better than the Logistic Regression model. Our results demonstrate that boosting algorithms can predict sarcasm in text to a moderate degree of success.

Abstract

The paper describes our submission to SemEval-2022 Task 6 on sarcasm detection and its five subtasks for English and Arabic. Sarcasm conveys a meaning which contradicts the literal meaning, and it is mainly found on social networks. It has a significant role in understanding the intention of the user. For detecting sarcasm, we used deep learning techniques based on transformers due to its success in the field of Natural Language Processing (NLP) without the need for feature engineering. The datasets were taken from tweets. We created new datasets by augmenting with external data or by using word embeddings and repetition of instances. Experiments were done on the datasets with different types of preprocessing because it is crucial in this task. The rank of our team was consistent across four subtasks (fourth rank in three subtasks and sixth rank in one subtask); whereas other teams might be in the top ranks for some subtasks but rank drastically less in other subtasks. This implies the robustness and stability of the models and the techniques we used.

1 Introduction

Sarcasm is a figurative language where speakers or writers usually mean the contrary of what they say. Recognizing whether a speaker or writer is sarcastic is essential to downstream applications to understand the sentiments, opinions, and beliefs correctly (Ghosh et al., 2020). Sarcasm is ubiquitous on the social media text and, due to its nature, can be highly divisive of computational systems that perform tasks on that kind of data such as sentiment analysis, opinion mining, and harassment detection (Van Hee et al., 2018; Bing, 2012; Rosenthal et al., 2014; Maynard and Greenwood, 2014).

Our team Plumeria participated in SemEval 2022 task 6 (Abu Farha et al., 2022) in all its subtasks on English and Arabic. Previous shared tasks on sarcasm detection (Hee et al., 2018; Ghanem et al., 2019; Ghosh et al., 2020; Abu Farha et al., 2021) have only two subtasks; one is sarcasm detection and another is predicting the type of sarcasm. However, in SemEval 2022 task 6 (Abu Farha et al., 2022) organizers formulate three subtasks for both languages following the methods described in (Oprea and Magdy, 2020).

Using the two datasets for English and Arabic, organizers formulate three subtasks as follows:

- **Subtask A (English and Arabic):** It is a binary classification subtask where submitted systems have to predict whether a tweet is sarcastic or not.
- **Subtask B (for English only):** It is a multi-label classification subtask where submitted systems have to predict one or more labels out of six ironic-speech labels: sarcasm, irony, satire, understatement, overstatement, and rhetorical question.
- **Subtask C (English and Arabic):** It is a binary classification subtask. Given two texts, a sarcastic tweet and its non-sarcastic rephrase which conveys the same meaning, submitted systems have to predict which text is the sarcastic one.

In this shared task, our submitted systems primarily focused on the transformer based approaches because of their success in the field of NLP. The multi-head attention mechanism in transformers captures the relations between the words in a sentence which helps in identifying sarcasm. Moreover, to capture long-term dependencies between words, especially the contradicting ones, we used a hierarchical network by stacking a BiLSTM layer on top of a transformer. In order to emphasize the important tokens afterwards, we tried adding a dot-product attention layer to give different weights to the tokens. For prediction, the final information

[*]These authors contributed equally to this work

are passed to a fully connected layer followed by a linear layer with a softmax activation function for classification (i.e. subtask A and C) or a sigmoid activation function for multi-label classification (i.e. subtask B).

The major constraint of a neural network is that they need lots of data for training to give satisfactory results. In addition, if the dataset is imbalanced with few instances of a class, this can result in poor results for detecting instances that belong to the class. This motivates us to create biased datasets, towards the concerned class/label, from existing datasets by increasing the number of instances of such a class/label. A detailed explanation of dataset creation is in section 3. We also illustrate the composition of created datasets in each subtask and the performance of the models on them.

The rank of our team was consistent across most subtasks (fourth rank in three subtasks, sixth rank in one subtask, and tenth rank in one subtask); unlike many teams which scored high in one or two subtasks but scored considerably less in other subtasks. This shows that the robustness and the consistency of our methods. The biased datasets were crucial for subtask A and subtask B, while augmenting a dataset plays a key role in subtask C. We released the codes and datasets for all subtasks via GitHub[1].

The paper is organized as follows. Section 2 lists some abbreviations used across the paper. Section 3 shows the datasets we used for fine-tuning the models. In Section 4 we list the preprocessing types applied on the datasets. The experiments and results are presented in section 5, and the analysis of the results is presented in section 6. This is followed by a conclusion in section 7.

2 Abbreviations

The following abbreviations were used frequently, and are shown in Table 1.

Full Form	Abbreviation
Language	Lang
Sarcastic	S
Non-Sarcastic	NS
English	En
Arabic	Ar
External	Ext
True Positive	TP
False Positive	FP
True Negative	TN
False Negative	FN

Table 1: Abbreviations used in the paper.

3 Datasets

The organizers provided datasets for English and Arabic. Regardless of the dataset, these are the fields in each row of a dataset:

- **Tweet**: a text specifying a tweet. This field is for all subtasks.
- **Sarcastic**: a binary field specifying whether a tweet is sarcastic or not. This field is for subtask A.
- **Rephrase**: a text specifying a non-sarcastic rephrase of a sarcastic tweet. This field is for subtask C.
- **Sarcasm, Irony, Satire, Understatement, Overstatement, and Rhetorical question** (English only): These binary fields are the labels of a sarcastic tweet. These fields are for subtask B.
- **Dialect** (Arabic only): a text specifying the dialect of a tweet from one of five dialects: Modern Standard Arabic (MSA), Egyptian, Levantine, Maghrebi, and Gulf. This field is for subtask A and C.

In the following sections we will describe the datasets given by the organizers, other available datasets, and augmented datasets.

3.1 Datasets Given by Organisers (Original)

The organizers released two training datasets for Arabic and English to train the systems on them for all subtasks. Later on, they released a test dataset for each subtask. We called these datasets "original" datasets as they are the official datasets for the subtasks. Information about the distribution of sarcastic and non-sarcastic tweets is presented in Appendix A.7 in Table 27 and Figure 6. Furthermore, information about sarcastic labels for subtask B is presented in Appendix A.7 in Table 28 and Figure 7.

3.2 Other Available Datasets (External)

The datasets in this section are not the official datasets and thus we called them "external" datasets. However, we used these datasets for subtask A and subtask B as they are created for similar subtasks.

[1]https://github.com/mosab-shaheen/iSarcasm-SemEval-2022-Task-6

Datasets Downloaded Using Twitter API: Initially the organizers provided the participants with train and test datasets which covered subtask A and subtask B for English only (later on the original datasets explained in subsection 3.1 were released instead). However, they provided the tweet ID instead of the tweet text and they asked the participants to download the tweet text using the Twitter API[2] and the tweet ID. Therefore, we downloaded the tweet texts we found for these two datasets. We were able to download 2841 tweets for training and 713 tweets for testing as shown in Table 27. The distribution of the tweets over the sarcastic labels is presented in Table 28.

Datasets of SemEval-2018 Task 3: These datasets are on same subtasks of subtask A and subtask B but for SemEval 2018 (Hee et al., 2018). We used the dataset for subtask A which has emojis and sarcasm hashtags. The datasets are available for download in this link[3]. More information about the distribution of sarcastic and non-sarcastic tweets is presented in Table 27.

ArSarcasm-v2 Dataset: It contains train and test datasets for sarcasm detection in Arabic (Abu Farha et al., 2021). Each row contains a tweet, sarcastic class, sentiment, and dialect. The datasets are available for download in this link[4]. More information about the distribution of sarcastic and non-sarcastic tweets is presented in Table 27.

3.3 Augmented Datasets

In addition to the original and external datasets, we created more datasets with more number of instances using the following methods:

1. **Augmenting an original dataset with external datasets:** We added instances to an original dataset from the matching external datasets either to balance it or just to augment it, and we filtered out the NAN entries .

2. **Augmenting a dataset using word embeddings:** For word embeddings we used Gensim library[5] together with GloVe word vectors[6] trained on two billion tweets with 100 dimension word vectors (glove-twitter-100). To create new instances in a dataset, we took a copy of one instance in the dataset and replaced up to four keywords in a tweet (or its rephrase) by replacing each keyword with one of the top three similar words according to the similarity between the corresponding word vectors, then we added the copied modified instance to the dataset and we repeated the process for other instances till we reached the required number of instances.

3. **Augmenting a dataset by repeating instances:** We repeated instances from a dataset mostly to balance the classes/labels in a dataset.

The final datasets used for each subtask is explained in the dedicated section for it.

4 Preprocessing

- **Type I:** no preprocessing

- **Type II:** Emotion icons were converted to their string text using the "emoji" Python library. Then, URLs were converted to "HTTPURL" token, also every mention in a tweet was converted to "@USER" token using regular expressions. These conversions was done because the BERTweet model (we will talk about it later) was pre-trained on tweets after these conversions.

- **Type III:** same as in Type II besides converting the smiley face codes e.g. ":-)" and ":)" to one of three values (smiley, sad, and playful). More than two successive occurrences of any punctuation like in "why?!!!!" were removed, then we removed more than two successive occurrences of same character like in "Superrrr" which can be found frequently in tweets. Moreover, a contraction (e.g. "isn't and "'cause") was replaced with its full form (e.g. "is not" and "because").

- **Type IV:** same as in Type III besides stemming and stop-word removal. For English we used WordNet lemmatizer and for Arabic we used ISRI stemmer. The NLTK Python library[7] was used for this purpose.

5 Approaches and Results for Subtasks

5.1 Conventions

In the following tables, if a table cell is highlighted with a light brown color, it means the score is

[2]developer.twitter.com/en/docs/api-reference-index
[3]SemEval2018-Task3 Dataset
[4]ArSarcasm-v2
[5]Gensim Library
[6]GloVe Word Vectors
[7]NLTK Python Library

among the best results, in the corresponding section of the table, on the validation dataset; whereas the one with brown color is the highest score. Furthermore, if a cell is highlighted with a green color, it means that the score is our final submission score (released by the organizers) in the subtask on the test dataset; whereas the one with blue color is the score of a submitted model but not the final one (a team can have multiple submissions).

5.2 Subtask A (English)

5.2.1 Datasets

- **Original**: The train split of the original dataset for English in Table 27 is splitted into train and validation datasets as shown in Table 2.
- **External**: As the measure for this task is F1-score for the sarcastic class, thus we created datasets which are biased towards the sarcastic class as shown in Table 29 in Appendix A.7.

Dataset	Total	S%	NS%
Original Train	2080	25	75
Original Val	1388	25	75

Table 2: Original datasets for subtask A (English) with the total number of tweets and the percentage of sarcastic (S%) and non-sarcastic (NS%) tweets.

5.2.2 Approaches

We primarily focused on the transformer based models. Since the task is a binary classification on tweets, the excellent choice to start with is BERTweet-base[8] and BERTweet-large[9] (Nguyen et al., 2020), a pre-trained language model on 845M English Tweets. Likewise, we tried the ELECTRA[10] (Clark et al., 2020) replaced token detection model (a pre-training task in which the model learns to distinguish real input tokens). In ELECTRA model, some tokens in the input are replaced with sample tokens instead of masking the tokens as in BERT. Moreover, we used a hierarchical network by passing the input tokens to the BERT model, then each token embedding is passed to a Bi-LSTM layer either with or without attention. The architecture of the BERT model, ELECTRA model, and hierarchical network is shown in Appendix A.3, A.4, and A.1 respectively. The final layer of each model was a linear layer with softmax activation function and we used the cross entropy loss function.

[8]HuggingFace Bertweet-Base
[9]HuggingFace Bertweet-Large
[10]HuggingFace Electra Large Discriminator

Note: We ran several experiments on all the approaches of this subtask with different datasets and preprocessing types. We also experimented with different learning rates, epochs, and loss functions to verify which one is performing best.

5.2.3 Results

Metric: The main metric is F1-score for the sarcastic class.

BERT: We used BERTweet-large in the following experiments, as it gave better performance than BERTweet-base, on the original train dataset shown in Table 2. We experimented with different learning rates and preprocessing types, and ran for 5 epochs. The results are shown in Table 3.

Learning Rate	Type	Val	Test
2 e - 6	I	0.0057	0.0293
	II	0.5017	0.457
	III	0	0
	IV	0	0

Table 3: F1-score of the BERT model for subtask A (English) on original datasets.

From these experiments we found that Type II preprocessing is performing better than other types and same applies for the learning rate 4e-6. We conducted similar experiments on the external datasets in Table 29 in Appendix A.7 and we found similar results. We tried using the cross entropy loss function with and without weights on the external datasets using the same learning rate, preprocessing type, and number of epochs. We got our best result on the B4 dataset with weighted loss function which was our final submission score for this subtask. The results are shown in Table 4.

Biased	Loss1: Without Weights		Loss2: W1=1/#NS, W2=1/#S

B9	0.4002	0.25

Table 6: F1-score of the ELECTRA model for subtask A (English) on external datasets.

BERT+BiLSTM with and without attention: The results we got using this architecture were not deterministic (i.e. they change when re-running the experiment and they may become better or worse than the results of BERT alone) and thus we did not use this model for the official submission. More details about the results of the model can be found in Appendix A.6.

5.3 Subtask A (Arabic)

5.3.1 Datasets

Original: The train split of the original dataset for Arabic in Table 27 is splitted into train and validation datasets as shown in Table 7.

Dataset	Total	S%	NS%
Original Train	1861	24	76
Original Val	1241	24	76

Table 7: Original datasets for subtask A (Arabic).

External: Same as in subtask A (English), we created datasets which are biased towards the sarcastic class as shown in Table 30 in Appendix A.7.

5.3.2 Approaches

The approaches used here are similar to subtask A (English) except for the used transformers. Since the data is in the Arabic language, we tried some models from The **C**omputational **A**pproaches to **M**odeling **L**anguage (CAMeL) research lab [11]. They majorly focused on Arabic and Arabic dialect processing, machine translation, text analysis, and dialogue systems.

The models are available on the Hugging Face library. CAMeLBERT is a collection of BERT models pre-trained on Arabic texts with different sizes and variants (Inoue et al., 2021). They released pre-trained language models for Modern Standard Arabic (MSA), dialectal Arabic (DA), and classical Arabic (CA). We tried CAMeLBERT-DA and CAMeLBERT-Mix for sarcasm detection. Likewise, we tried the AraBERT v2 which is a pre-trained BERT based on Google's BERT architecture for Arabic Language Understanding[12] (Antoun et al.).

5.3.3 Results

Metric: The main metric is F1-score for the sarcastic class.

BERT: We used CAMeLBERT-Mix in the following experiments as it performed the best among other BERT models. We applied it on the external datasets with non-weighted cross entropy loss function, 5 epochs, and 2e-5 learning rate because they

[11] HuggingFace CAMeL-Lab
[12] HuggingFace Bert-Base-Arabert-v02

gave the best results, which included our final submission score for this subtask, as shown in Table 8.

Biased	Val	Test

Original Val	261	70% 1%	14.20% 4.50%	1.90% 8.40%

Table 11: Original datasets for subtask B (English).

the validation dataset) were added together to form a new dataset (Ext-NB). Then the resulting dataset was balanced either by using word embeddings (Ext-UW) or by repeating instances (Ext-UR). We created a dataset (Ext-EB) to give more importance to the labels of low number of instances by repeating the instances of these labels up to the limits specified by these heuristic formulas:

#irony=#sarcasm*(1+1/sqrt(#irony)) (1)

#satire=#sarcasm*(1+2/sqrt(#satire)) (2)

#understatement=#sarcasm*(1+3/sqrt(understatement)) (3)

#overstatement=#sarcasm*(1+1.5/sqrt(overstatement)) (4)

#rhetorical=#sarcasm*(1+1.2/sqrt(#rhetorical)) (5)

The datasets are shown in Table 31 in Appendix A.7.

5.4.2 Approaches

This subtask primarily focused on BERTweet-large. As it is a multi labeling subtask, we used sigmoid as the activation function in the last layer and binary cross entropy as the loss function.

5.4.3 Results

Metric: The main metric is Macro-F1 score.

BERT: We used BERTweet-large in the following experiments on the external datasets using 5 epochs, 6e-6 learning rate, and Type II preprocessing. The results are shown in Table 12 which included our final submission score for this subtask.

Dataset	Val	Test
Ext-NB	0.1513	0.038
Ext-UW	0.318	0.0716
Ext-UR	0.3412	0.076
Ext-EB	0.4152	0.0778

Table 12: Macro-F1 score of the BERT model for subtask B (English) on external datasets.

Rank	User	macro F1-score
1	Duxy	0.163
2	Abdelkader	0.0875
3	robvanderg	0.0851
6	**ShubhamKumarNigam**	**0.0778**

Table 13: Scores and leader-board ranks for subtask B (English).

5.5 Subtask C (English)

5.5.1 Datasets

Original: The train split of the original dataset for English in Table 27 in Appendix A.7 is splitted into train and validation datasets. As we do not have external datasets here, so we augmented the train split once with word embeddings (Original-Embedding) and once with repetition (Original-Repetition). We swapped between the tweet and its rephrase for half of the instances together with flipping the value of the sarcastic field, so that the model will be able to learn. Otherwise, it may always predict the first text as the sarcastic tweet and the second one as its non-sarcastic rephrase. The datasets are shown in Table 14.

Dataset	Total
Original-Train	606
Original-Validation	261
Original-Embedding	1606
Original-Repetition	1606

Table 14: Original datasets for subtask C (English).

5.5.2 Approaches

Organizers provide a sarcastic text, and its non-sarcastic rephrase, i.e., two texts convey the same meaning. Since the input format changed in this subtask, we input both texts together to the BERT model as one text separating them by the separating token. We focused on transformers which are trained on question-answering tasks. We tried BERT models trained on the **S**tanford **Q**uestion **A**nswering **D**ataset (SQuAD) dataset (Rajpurkar et al., 2018). SQuAD is a reading comprehension dataset consisting of questions posed by crowdworkers on a set of Wikipedia articles.

We took models from the Hugging Face library; one is BERT large model (cased)[13], trained on whole word masking, and fine-tuned on the SQuAD dataset. Another is BERT base model (uncased)[14], trained on Masked language modeling (MLM), and fine-tuned on the SQuAD dataset.

[13]HuggingFace Bert-Large-Cased-Whole-Word-Masking-Finetuned-Squad

[14]HuggingFace Bert-Base-Uncased-Squad2

5.5.3 Results

Metric: The main metric is the accuracy.

BERT: We used BERT large model (cased) on the original datasets, because it gave better results compared to the other models, using 15 epochs, 8e-6 learning rate, and the cross entropy as the loss function. The results are shown in Table 15. We did our submission using Type I preprocessing as it gave the best result on the validation dataset.

Dataset	Type	Val	Test
Original-Training	I	0.951	0.79
	II	0.9395	0.8
	III	0.9193	0.83
	IV	0.9135	0.79
Original-Embedding	I	0.9454	0.83
	II	0.9385	0.8
	III	0.9366	0.82
	IV	0.8588	0.72
Original-Repetition	I	0.9395	0.8
	II	0.9222	0.815
	III	0.9078	0.8
	IV	0.9078	0.68

multilingual model mBERT base (cased), trained on the Question Answering (QA) dataset in seven languages and fine-tuned on the combination of XQuAD (Artetxe et al., 2020) and MLQA (Lewis et al., 2020) datasets. We compared their performance to the CAMeLBERT-Mix model.

5.6.3 Results

Metric: The main metric is the accuracy.

BERT: We used CAMeLBERT-Mix model, because it gave better results among the other models, on the original datasets using 5 epochs, 3e-5 learning rate, and the cross entropy as the loss function. The results are shown in Table 18. We used Type II preprocessing for submitting the results as it is the best performing.

Dataset	Type	Val	Test
Original-Train	I	0.6242	0.5
	II	0.6242	0.5
	III	0.6711	0.72
	IV	0.3758	0.5

6 Analysis

6.1 Subtask A

English: There are 1400 instances in the test set out of which our model correctly classified 1060 instances (TP=155 and TN=905). There are bigger number of misclassified negative (NS) instances (FP=295) than the number of misclassified positive (S) instances (FN=45) and these are reflected in the precision (34.44) and the recall (77.5). This can be due to the fact that our model was trained on B4 dataset (59% S and 41% NS) taking F1-score for the sarcastic class as the metric for evaluation. This made the model focus more on identifying the positive instances sacrificing the considerable number of misclassified negative instances.

We dived into the details to see when the model predicted well and when it could not predict properly. We found that the majority of tweets which have specific punctuation marks like the exclamation mark were classified correctly. Short tweets were not classified properly which can be due to the insufficient information present in the tweets for classification. Interestingly, the existence of emojis highly increased the recall but not the F1 score and this is because sarcastic tweets can be easily recognized from their emojis but this does not apply on non-sarcastic ones. Also, tweets which include opposite emotions tend to be more sarcastic and to give better F1-score. Moreover, we found that tweets which contain misspellings or that need human knowledge to interpret can cause misclassification. Examples of all previous cases are presented in Table 20.

Arabic: There are 1400 instances in the test set out of which our model correctly classified 903 instances (TP=170 and TN=733). There are bigger number of misclassified negative (NS) instances (FP=467) than the number of misclassified positive (S) instances (FN=30) and these are reflected in the precision (26.69) and the recall (85). The number of instances which contain exclamation marks are less compared to English, and short tweets also were not classified properly for the same reason. Tweets that contain emojis were classified poorly and this is because we used Type II preprocessing which converted the emojis to text similar to the preprocessing of the model we used for English "BERTweet-large" and unlike the preprocessing of the model we used for Arabic "CAMeLBERT-Mix".

Example	Prediction
Exclamation Mark	
So you think the vaccine is a bad idea then. Glad you have that PHD in immunology!	TP
So many error codes in R today!	TN
Short Tweets	
Probably Jude mate	FP
Having the worst time on holiday	FN
Opposite Emotions	
Don't you just love Monday mornings, they are even better when its freezing cold and you have an uncooperative child too!	TP
Emojis	
Wow, can't wait to go into ANOTHER lockdown 🙄	TP
it doesn't need a consultation. Just ban it 🙃	FP
Human Knowledge	
Max Verstappen is such a clean driver, he never makes dirty moves when racing.	FN
Misspelling	
Boris has to bring in these restrictions he is dammed if he does and dammed if he doesn't. I live Boris.❤️❤️❤️❤️	FP

Table 20: Examples of the cases where tweets were classified correctly and incorrectly in subtask A (English).

6.2 Subtask B

Since the train and test datasets contain a very small number of instances of the understatement and overstatement tweets; therefore, the model could not identify any of them and the scores of them were zeros as shown in Table 21. For other labels, the model has far higher recall scores than precision scores which means the model performed well at identifying instances that belong to particular labels at the cost of mislabeling many instances.

	Precision	Recall	F1-score	Support
sarcasm	0.1335	0.8333	0.2301	180
irony	0.0708	0.75	0.1293	20
satire	0.0345	0.0204	0.0256	49
under-statement	0	0	0	1
over-statement	0	0	0	10
rhetorical_question	0.061	0.4545	0.1075	11

Table 21: Performance analysis for subtask B.

6.3 Subtask C

The model performed well in this subtask for both English and Arabic as shown in Table 22. This can be attributed to the nature of the task where the sarcastic tweet and its non-sarcastic rephrase of same meaning are given, besides the ability of the model to extract the relevant information for classification.

	Precision	Recall	F1-score	Support
English				
non_sarcastic	0.7576	0.8065	0.7812	93
sarcastic	0.8218	0.7757	0.7981	107
Arabic				
non_sarcastic	0.8936	0.84	0.866	100
sarcastic	0.8491	0.9	0.8738	100

Table 22: Performance analysis for subtask C.

7 Conclusion

The paper describes our participation in SemEval-2022 Task 6. The models used for sarcasm detection were mainly stand-alone transformers. In addition to this, we ran other experiments by stacking a BiLSTM layer with or without attention mechanism on top of the transformers. We created new datasets for each subtask by augmenting with external datasets, word embedding, or repetition. Our results shows that the augmented datasets enhanced the results for most subtasks. Moreover, we found that the fine-tuned stand-alone transformers gave the best results especially with Type II preprocessing. We also showed the enhancement when using a weighted loss function and the effect of using different learning-rates, epochs, and preprocessing types. We gave analysis of the performance of the models for each subtask, and revealed the possible cases that might have enhanced or deteriorated the performance. Finally, the rank of our team is consistent across most of the subtasks (the fourth rank) which shows the robustness of the used techniques.

A Appendix

A.1 Hierarchical Architecture

Figure 1 shows a hierarchical network based on a transformer. The input tokens are passed to the transformer, then the output token embeddings are passed to a Bi-LSTM layer which can be with or without attention mechanism.

A.2 Sarcasm Types Description

1. **Sarcasm:** tweets that contradict the state of affairs and are critical towards an addressee.

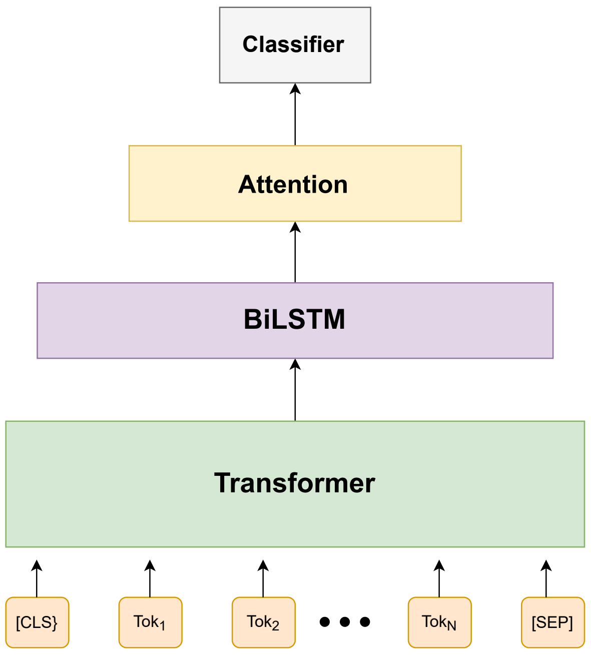

Figure 1: Hierarchical architecture.

2. **Irony:** tweets that contradict the state of affairs but are not obviously critical towards an addressee.

3. **Satire:** tweets that appear to support an addressee, but contain underlying disagreement and mocking.

4. **Understatement:** tweets that undermine the importance of the state of affairs they refer to.

5. **Overstatement:** tweets that describe the state of affairs in obviously exaggerated terms.

6. **Rhetorical question:** tweets that include a question whose invited inference (implicature) is obviously contradicting the state of affairs.

A.3 BERT Classification Architecture

Figure 2 shows the BERT-base classification architecture[15]. From the output of the final (12th) transformer, only the first embedding (corresponding to the [CLS] token) is used by a classifier.

A.4 ELECTRA:- Replaced Token Detection

ELECTRA (**E**fficiently **Le**arning an **E**ncoder that **C**lassifies **T**oken **R**eplacement **A**ccurately) (Clark et al., 2020) replaces the MLM of BERT with Replaced Token Detection (RTD), which looks to be more efficient and produces better results. In BERT, the input is replaced by some tokens with [MASK] and then a model is trained to reconstruct the original tokens.

[15]BERT Fine-Tuning Tutorial with PyTorch by Chris McCormick and Nick Ryan

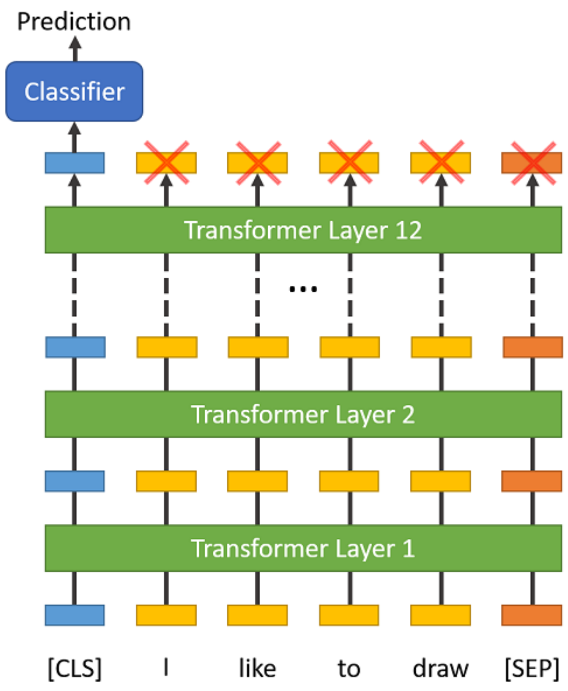

Figure 2: BERT classification architecture.

In ELECTRA, instead of masking the input, the adopted approach corrupts it by replacing some input tokens with plausible alternatives sampled from a small generator network. Then, instead of training a model that predicts the original tokens, a discriminative model is trained that predicts whether each token in the corrupted input was replaced by a generator sample or not.

This approach trains two neural networks, a generator and a discriminator. Each one primarily consists of an encoder (e.g., a transformer network) that maps a sequence of input tokens into a sequence of contextualized vector representations. The discriminator then predicts whether it's fake by analyzing its data distribution.

A.5 Effect of Learning Rates and Epochs in Subtask A (English)

In Subtask A (English), we fine-tuned the BERT model on the B4 dataset with different learning rates and epochs as shown in Table 23 and Table 24 respectively. As shown in tables the best learning rate was 4e-6 and the best number of epochs was 5.

A.6 Performance of BERT+BiLSTM with and without Attention in Subtask A (English)

BERT+BiLSTM: The best results we got using this architecture were on the B4 dataset with 4e-

Val	Test	Learning Rate

A.7 More Information about the Datasets:

Total number of tweets and percentage of sarcastic and non-sarcastic tweets in each dataset for subtask A is shown in Table 27, and the total number of tweets and percentage of sarcastic labels in each dataset for subtask B is shown in Table 28.

External datasets for subtask A (English) is shown in Table 29, for subtask A (Arabic) is shown in Table 30, and for subtask B (English) is shown in Table 31.

Density of the number of words in tweets and their rephrases in the original datasets is shown in Figure 3 for English and in Figure 4 for Arabic.

In addition to this, information about dialects for Arabic subtasks is presented in Figure 5 and Table 32.

Information about the distribution of sarcastic and non-sarcastic tweets in the original datasets is presented in Figure 6.

Information about sarcastic labels, for subTask B, in the original datasets is shown in Figure 7.

Hidden State Size	Val	Test

Abstract

This paper describes the system and the resulted models submitted by our team "IISERB Brains" to SemEval-2022 Task 6 competition. We participated in the three sub-tasks for English language datasets. Our submitted models use BERT-based classifiers along with data augmentation. We ranked **19th** out of **43 teams** for sub-task A, **8th rank** out of **22 teams** for sub-task B, and **13th rank** out of 16 teams for sub-task C. In this paper, we describe details of our submissions, related evaluation and additional experiments conducted post the termination of the shared task. Our code and used additional resources are present in GitHub[1] for reproducibility. *Authors with equal contributions are marked by *.*

1 Introduction

Sarcasm in spoken or written form is a type of verbal irony that indicates the difference between the literal and intended meanings of an utterance (Joshi et al., 2017). While many people use it as a bitter remark to mock or ridicule a target(Patro et al., 2019), some also use it as a joke to amuse others(Joshi et al., 2015a). Sarcasm often used together or interchangeably with other ironic categories, is considered an essential component of human communication. A large portion of the web and social media text is sarcastic, which creates a challenge for traditional natural language processing (NLP) tasks like sentiment classification, opinion mining, harassment detection, author profiling etc. Since these systems are deployed widely across various industries, administration, data analysts etc, designing a robust sarcasm detecting component would help the downstream tasks substantially. The SemEval-2022 task 6(Abu Farha et al., 2022) identifies some of the challenges persisting till now, particularly in English and Arabic texts. Our team participated in the tasks floated for the English language under the name "IISERB Brains". The organizers have floated three sub-tasks: (i)Sub-task A to detect whether a given text is sarcastic, (ii)Sub-task B to identify which ironic category the sarcastic tweet belongs to, and (iii) Sub-task C to given two pieces of text, identify the sarcastic one.

In this paper, we report the details of our participating systems and their performance on the evaluation data. The paper also contains details of additional experiments that were a part of our participation in the shared task. The paper is organised as follows. Section 2 describes past work related to the sub-tasks, while section 3 presents the dataset and task details. Following that, Section 4 reports the details of our systems followed by experiments and results in Section 5. Finally, in section 6, we conclude the paper with a summary of the overall results.

With our submitted systems, we obtained the **19th rank** out of **43 teams** for sub-task A, **8th rank** out of **22 teams** for sub-task B, and **13th rank** out of 16 teams for sub-task C. Our code is made public to ensure the reproducibility of our results.

2 Related Work

Sarcasm has been an interesting research topic for computational linguists for a long time(Joshi et al., 2017; Pilling et al., 2017). Researchers have studied the topic from depth(sarcasm sub-categories, linguistic nuances etc.) and breadth (multi-modal sarcasm(Castro et al., 2019a), multi-lingual sarcasm (Liu et al., 2021; Bansal et al.), sarcasm targets (Patro et al., 2019), etc). A considerable amount of work has been reported on the task 'sarcasm detection' itself. This task particularly deals with identifying whether a given text is sarcastic. The sub-task A proposed by the organizers also belongs to this task.

[1]https://github.com/manojmahan/iSarcasmEval-Intended-Sarcasm-Detection-In-English-main

While the traditional approaches have used feature-based machine learning models, recent approaches mostly relied on deep-neural models to report state of art performance. Lexical features like emoticons, special characters, word-patterns have always been preferred features along with semantic features like parts-of-speech tags, contrasting sentiments etc(Davidov et al., 2010)(Veale and Hao, 2010) (Riloff et al., 2013)(Joshi et al., 2015b)(Ghosh et al., 2018) in traditional approaches. Deep-neural methods, on the other hand, learn latent features for the same task. They rely on architectures like RNNs, CNNs, transformers etc. In their models (Joshi et al., 2017; Pilling et al., 2017; Tay et al., 2018; Tarunesh et al., 2021; Jaiswal, 2020). Pre-trained language models like BERT, RoBERTa, XLNet etc, have been extensively used as token-encoders in these models.

Identifying sarcastic intention has always been a challenging task, even humans sometimes have difficulties. Recently, researchers have started focusing on contextual information such as author context (Ghosh et al., 2020), multi-modal context (Ghosh et al., 2020), eye-tracking information (Govindan et al., 2018), or conversation context (Ghosh et al., 2020; Srivastava et al., 2020) to capture it. The sub-task A is related to shared tasks in the domain of figurative analysis such as a SemEval task on irony detection in Twitter that focuses on the utterances in isolation.

3 Background

3.1 Dataset details

We used the English dataset provided by the task organizers(Abu Farha et al., 2022). It has 3468 English tweets. It has 867 sarcastic and 2601 non-sarcastic tweets, which indicates that the dataset is highly unbalanced. For each sarcastic tweet, the organizers have also provided the ironic sub-classes to which the tweet belongs. The sub-classes are sarcasm, irony, satire, understatement, overstatement, and rhetorical question. Also, there are many tweets with multiple labels assigned to them. The distribution of tweets over their labels are shown in Table 1.

Several sarcasm detection datasets are often annotated by a person who is not the author of a piece of text. However, in this dataset, the sarcastic label of each tweet is marked by its author. This makes the dataset unique in terms of capturing the sarcastic intention of the tweet-author(s). Additionally, for each sarcastic tweet, the organizers have asked the authors to rephrase the tweet-text to convey the same message without using sarcasm. However, the organizers have relied on linguistic experts to annotate the sub-categories. Experts referred Leggitt and Gibbs (2000) for the definitions of sub-categories.

Labels	**|N|**
Non-sarcastic	2601

Sarcasm, understatement and rhetorical question	1
Total	***3468***

Table 1: Label-wise distribution of tweets. |N| refers to the sample size

3.2 Task details:

Based on the dataset they have released, the task organizers have formulated three challenges as sub-tasks. The details of the sub-tasks are,

- **Sub-task A:** Given a text, determine whether it is sarcastic or non-sarcastic;
- **Sub-task B:** This sub-task is designed for particularly English dataset. It is a binary multi-label classification task. Here, given a text, we have to determine which ironic speech category it belongs to, if any;
- **Sub-task C:** Given a sarcastic text and its non-sarcastic rephrase, i.e. two texts that convey the same meaning, determine which of the two is the sarcastic.

For all of the three sub-tasks, the organizers have informed us that precision, recall, accuracy, and macro-F1 of the participating models will be reported. According to them the main metrics of evaluation for the sub-task A is the F1-score for the sarcastic class. Similarly, for sub-task B and sub-task C, it is the macro-F1 score and the accuracy, respectively.

4 System overview

4.1 Additional resources

As shown in Table 1, the dataset is highly unbalanced, and the sample size is small. To mitigate this issue, we considered additional publicly available datasets published earlier for a similar task with some synthetically generated text. The details of such datasets are following,

- **SemEval-2018 task 3:** We used the training and test data provided by SemEval-2018 task on irony detection (Van Hee et al., 2018) as an additional resource for training of our models.
- **MUStARD:** We used the textual part of the multi-modal sarcasm detection dataset provided by Castro et al. (2019b) as an additional resource for training of our models.
- **FigLang 2020 Sarcasm:** We used the sarcasm dataset[2] released as a part of shared task of FigLang2020 [3] workshop as additional data for training of our models.

  Augmentation: For increasing the instances labeled with sub-categories in the train data provided by the task organizers, we performed data augmentation using the python NLPAUG library[4]. NLPAUG applies a set of transformations to textual datasets in order to create augmented data for deep learning models that rely on high volumes of data. We took sarcastic tweets given by organizers used the word-replacement procedure provided by NLPAUG to synthesize three additional tweets from each input tweet. We used 'distilbert-base-uncased'[5] contextual embedding as the input embedding for this process.

Table 2: Basic statistics of additional sources. |N| refers to the sample size.

The statistical distribution of additional resources is shown in Table 2. After elimination of the duplicates, the final dataset had 19986 tweets.

4.2 Data preprocessing

We followed the following preprocesing steps for every instance in our dataset.

- **Case conversion:** We converted the dataset into lowercase except for those words in which the whole word is in uppercase.
- **Stop-word removal:** We removed all stop-words as they contain low information. We did this using python NLTK library [6].
- **Data cleaning:** We did basic data cleaning which include removal of links, punctuation marks, floating point(.) characters and user-name. However, we did not apply stemming and lemmatization techniques because we believe they will distort the meaning of instances.
- **Special Tokens:** We added special tokens at the starting and ending of the instances as required by different tokenizers for respective transformer based models.

4.3 Model description

We relied on Transformer-based architectures to design our models for all sub-tasks since Transformers are regarded as state-of-the-art in NLP. We built our models using Hugging Face's Transformer library. They support generic transformer based architectures with the ability to seamlessly initialize the tokens with different pre-trained embeddings.

- **Sub-task A:** For this sub-task, we deployed the binary classifier versions of different transformer based architectures provided by the

[6]https://www.nltk.org/

Hugging Face transformer library. We particularly experimented with BERT(Devlin et al., 2019), RoBERTa(Liu et al., 2019), XLNet(Yang et al., 2019) and DistilBERT(Sanh et al., 2019) architectures. Apart from initializing the tokens with respective pre-trained embeddings, we fine-tuned the last layers of the models according to our training data. Further, we added the non-sarcastic versions of 867 sarcastic tweets given by the organizers to the training set.

- **Sub-task B:** Here, instead of using a multi-label classifier, we used six binary classifier versions of the transformer based architectures provided by the same Hugging Face library. As in the previous sub-task, here we have also experimented with BERT, RoBERTa, XLNet, and DistilBERT architectures. We constructed training data(refer Table 6) for label-wise models to fine-tune it. We merged the predictions of all six models to get the final prediction labels.
- **Sub-task C:** We formulated this sub-task as a parallel combination of two sub-task A models. We considered the same architecture for both parallel sub-components in all of our experiments.

5 Experiments and results

5.1 Sub-task A

For this sub-task, in addition to the data given by the organizers, we considered the other datasets as mentioned in Table 2. We applied the pre-processing(details in section 4.2) steps before sending them to the respective tokenizers of the considered architectures. The tokens are initialized by respective pre-trained embeddings. The dataset is divided into three parts i.e. training, validation and test set with a ratio of 0.7:0.2:0.1 for the parameter and hyper-parameter tuning. We generated the predictions for the unlabeled data provided by the organizers and submitted them in the codalab submission site[7] for evaluation. As the organizers have later released the labels for their evaluation data, we can compare all our models by ourselves too. The performance of our models for the evaluation data is reported in Table 3. The number of epochs for which the models are trained are different for different models. We trained until our models started over-fitting. Note that the best performing result reported in the table is different from that we have submitted in the codalab site. We experimented with our models even after the evaluation period and the results in Table 3 show the best performance we have achieved till date. The models submitted as a part of competition is reported in Table 5. The hyper-parameters for all models are reported in Table 4.

[7]https://codalab.lisn.upsaclay.fr/competitions/1340

5.2 Sub-task B

As stated in the previous section, for this sub-task we considered separate binary classifiers for each label. The sample size of the datasets created for individual classifiers are shown in Table 6. Note that we did not include the non-sarcastic tweets provided by the organizers in our new datasets. Rather, we added the synthetic tweets generated by the nlpaug library (see section 4.1) to amplify the label for which it is created. We didn't generate any additional synthetic text for the dataset corresponds to 'sarcasm' label as it is the dominant class in the provided 'sarcastic' data. Thus, the dataset created for the binary classification of 'sarcasm' class has the original 867 sarcasic tweets. In other label-specific datasets we increased the corresponding label tweets with the help of nlpaug library. As stated in section 4.1, we did this by generating three similar texts for each tweet tagged with the considered label. Thus, the newly created label-specific datasets have different sample size as shown in Table 6. We fine-tuned BERT model for each category of ironic speech. The organizers have evaluated sub-task B based on macro-F1 score. The results are reported in Table 7.

5.3 Sub-task C

As reported in Section 4.3, we formulated the task as two parallel combination of sub-task A models. The considered same model across the parallel sub-components. The accuracy(evaluating measure considered by the organizers) of different models are reported in Table 8. As we can infer, BERT based fine tuned model performed best on the evaluation data among all with an accuracy of **0.62**.

6 Conclusion

In this paper, we discussed our models for different sub-tasks proposed by SemEval 2022 task 6 organizers for the English dataset. We experimented

Model	Precision	Recall	F-1 score	F-1 sarcastic	accuracy
DistilBERT	0.57	0.64	0.53	0.34	0.62
XlNet	0.63	0.61	0.62	0.34	0.82
BERT	0.60	0.69	0.60	0.39	0.70
RoBERTa	***0.70***	0.68	***0.69***	***0.47***	***0.86***

Table 3: Performance measures of our models submitted for sub-task A

Model	Learning-rate	MAX_SEQ_LEN	BATCH_SIZE	EPOCHS
RoBERTa	2e-6	256	16	10
BERT	2e-5	128	32	3
Xlnet	2e-5	128	32	4
DistilBERT	5e-5	1213	16	5

Table 4: Hyper-parameters of our models.

SubTask A	
Model	*F1*
BERT	0.34
SubTask B

connotation_clashers at SemEval-2022 Task 6: The effect of sentiment analysis on sarcasm detection

Patrick Hantsch and **Nadav Chkroun**
University of Tübingen
{patrick.hantsch, nadav.chkroun}@student.uni-tuebingen.de

Abstract

We investigated the influence of contradictory connotations of words or phrases occurring in sarcastic statements, causing those statements to convey the opposite of their literal meaning. Our approach was to perform a sentiment analysis in order to capture potential opposite sentiments within one sentence and use its results as additional information for a further classifier extracting general text features, testing this for a Convolutional Neural Network, as well as for a Support Vector Machine classifier, respectively.

We found that a more complex and sophisticated implementation of the sentiment analysis than just classifying the sentences as positive or negative is necessary, since our implementation showed a worse performance in both approaches than the respective classifier without using any sentiment analysis.

1 Introduction

According to Cambridge dictionary, sarcasm is defined as the use of remarks that mean the opposite of what they say, in order to hurt someone's feelings or to criticize something in a humorous way. While detecting sarcasm can be very difficult even beyond the text level, it is a real challenge to detect sarcasm in textual data. When having conversations in person, it is easier for people to detect sarcasm because they have additional information in form of the speaker's emphasis of words, his facial expressions and body gestures. All of this information is not available in written language. Yet, detecting sarcasm from text becomes more and more important, since everyday life nowadays takes place on social media platforms to a large extent, unfortunately including things like hate speech in order to offend people. Sarcasm is often used as a tool for that (Frenda, 2018), so operators need ways to detect and remove offensive material expressed in a sarcastic way in large amounts of messages and posts released by millions of people every day.

The shared task (described in Abu Farha et al., 2022) consisted of three sub tasks:

- Sub task A: Determining if a given input text is sarcastic or not
- Sub task B: Determining if a given input text belongs to a ironic speech category and if so, to which one exactly
- Sub task C: Given two input texts, one being sarcastic and the other one being its non-sarcastic rephrase, determining which is the sarcastic one

We only participated in sub task A of the shared task. Our strategy was to additionally perform a sentiment analysis on the given text data, using the contradictory nature of a sarcastic statement, between the actual utterance and its true meaning/intent. For example in the sentence "I love how ill i became last night…", a sentiment analysis might recognize the clash of connotations between the positive connotated word "love" and the negative connotated fact of "being ill". Van Hee et al. (2018) also mentioned the inversing effect of using irony (a form of sarcasm) in a sentence on the overall sentiment of that sentence and even included this notion in form of a class called "Verbal irony by means of a polarity contrast" in one of their sub tasks of the task they provided for the SemEval competition in 2018.

In an earlier work described in Poria et al. (2017) a similar approach to our strategy was used, combining several Convolutional Neural Networks (CNNs), pre-trained on recognizing and classifying sentiment, emotion and personality features respectively, with a Support Vector Machine classifier for classification only. However, for the best of our knowledge there was no earlier work investigating the impact of sentiment analysis on sarcasm detection for linear models. Inspired by the previously mentioned work, we combined the result of our sentiment analysis with all other features subtracted from the given text and investigated the influence of sentiment analysis on the final sarcasm detection for both a linear model, as well as for a Deep Learning model, also comparing the performance of both approaches.

2 Training Data

According to sub task A, our system should classify an input text as either sarcastic, or non-sarcastic. If, for example, the string "I love how it rains for the seventh day in a row" was fed as input to our system, the output would be either "1" (sarcastic), or “0” (non-sarcastic). As training data, two collections of tweets were given, one in English and one in Arabic. In table 1 you can see the amount of sarcastic and non-sarcastic tweets in both datasets.

	English	**Arabic**
total amount of tweets	**3468**	**3102**
`sarcastic`	867	745
`non-sarcastic`	2601	2357

Table 1: Amount of sarcastic and non-sarcastic tweets in training data

3 System Overview and Experimental Setup

Both approaches we decided to test for solving the task were implemented in Python 3.8. In terms of sentiment analysis we decided to focus on English, for which we tested each of those approaches both combined with a sentiment analysis and without it. The predictions contained in our official submission were created by our Deep Learning model not being combined with sentiment analysis, for both English and Arabic.

3.1 Official Submission

We chose to build a CNN as a Deep Learning Model for sarcasm detection. CNNs are several layers of convolutions with non-linear activation functions like ReLU (Brownlee, 2019) or tanh applied to the results.

3.1.1 Preprocessing

All tweets were split into a sarcastic and a non-sarcastic tweet collection. We used the tokenizer class from Keras library (Chollet et al., 2015), which allows vectorization of a text corpus, by turning each text into a sequence of integers, while calculating the maximum number of words to keep based on their frequency. In addition, we split the training data into training set (80%) and validation set (20%) for hyperparameter optimization. We were setting each tweet a length, and padding or truncating it, based on the length of 100 words, respectively.

3.1.2 Training

In our model, we converted words to vocabulary indices. We did not use pre-trained embeddings. Instead, the embedding was done by the embedding layer of our model. In total, 6 layers were used, which are described in table 2.

name of layer	**parameters**
embedding	vocab_size=8879, embedding_dim=32, input_length=100
convolution 1D	filters=128, kernel_size=3, activation= “relu”
pooling 1D	-
Dense	units=100 activation=“relu”
Dense	units=32 activation=“relu”
Dense	units=1 activation=“sigmoid”

Table 2: Description of the model’s architecture

We compiled the model using the Adam optimizer (Kingma and Ba, 2014) with a learning rate of 0.01. The loss function for the optimizer was Binary Cross Entropy, which compares each of the predicted probabilities to the actual class labels which can be either 0 or 1. For the tuning, random search was used to find the optimal hyperparameters. This method sets up a grid of hyperparameter values and selects random combinations. We tuned the parameters with the respective values as shown in table 3.

In total, 5 different hyperparameter settings were tried by our random search.

3.1.3 Evaluation

According to the official metrics, which was F1-score for the sarcastic class, our CNN trained on the English data scored 0.2024, unweighted mean precision being 0.5016 and unweighted mean recall being 0.5029. All in all, our CNN achieved a

Description	Name	Values
learning rate of the optimization algorithm	learning_rate	0.01, 0.001, 0.0001
length of the convolution window	kernel_size	3, 5
size of the dense layer	units	32-128 (interval: 16)
number of convolution units	filters	32-256 (interval: 32)

Table 3: Hyperparameters and values to which the random search was applied

bad rank (37/43). The CNN trained on the Arabic training data achieved a F1-score of 0.3013, a unweighted mean precision score of 0.5647 and the unweighted mean recall was 0.5954. It ranked 23rd of 32 total submissions.

3.2 CNN Influenced by Sentiment Analysis

The preprocessing used for the CNN we combined with the sentiment analysis is the same as for the CNN which created our official submission.

3.2.1 Sentiment Analysis & Transfer Learning

We implemented sentiment analysis for sarcasm detection, used as a "transfer learning" method. The sentiment analysis assigns each tweet a label of either being "positive" or "negative". The sentiment analysis dataset we used was the IMDB movie review sentiment classification dataset of Keras. It consists of 25000 movie reviews, labeled as 1 ("positive") or 0 ("negative"). We split it into a training set consisting of 20000 of the reviews and a test set containing 5000 reviews.

First, we trained our CNN model on the training set for sentiment analysis. We saved the weights and then trained the model on the sarcasm detection training set that we created previously. It is important to note that the sentiment analysis scores were used in a way that although the model labeled each sentence as a float number between 0 to 1. The final labels (0 or 1) were given to each sentence according to its proximity to 0.5.

3.2.2 Training

In order to get a more fine-tuned model for the combination with the sentiment analysis, we changed the model's architecture. The reason for this change is a result that another random search, which we conducted after we applied the transfer learning, picked for our combined model. The same hyperparameters and values were tested as in our first random search described in section 3.1.2. We changed the hyperparameters accordingly, leading to the architecture depicted in table 4.

name of layer	parameters
embedding	vocab_size=88584, embedding_dim=32, input_length=100
convolution 1D	filters=128, kernel_size=3, activation="relu" kernel_regularizer=l2(0.001)
dropout	rate=0.1
convolution 1D	filters=128, kernel_size=3, activation="relu" kernel_regularizer=l2(0.001)
dropout	rate=0.1
pooling 1D	-
dropout	rate=0.1
Dense	units=32 activation="relu" kernel_regularizer=l2(0.001)
dropout	rate=0.1
Dense	units=1 activation="sigmoid" kernel_regularizer=l2(0.001)

Table 4: Description of the model's architecture for the transfer learning

3.2.3 Evaluation

Our CNN which was influenced by the sentiment analysis performed worse than the CNN on its own. The F1 score on the sarcastic class was 0.1679. Unweighted mean precision was 0.5109, unweighted mean recall 0.5117.

3.3 Comparing Results of both CNN's

Comparing the scores of both the CNNs shows that the CNN augmented by the sentiment analysis performed worse than the CNN on its own, as shown in table 5.

3.4 Linear Model Approach

In the following subsections we discuss our linear model based approach. The preprocessing steps, as

model	f1-score	precision (unweighted mean)	recall (unweighted mean)
CNN without transfer learning of sentiment analysis	0.2024	0.5016	0.5029
CNN including transfer learning of sentiment analysis	0.1679	0.5109	0.5117

Table 5: Both CNN model's scores on the English test set

well as the implementation of sentiment analysis differ from what we did in our Deep Learning based approach.

3.4.1 Preprocessing

One challenge we were confronted with was a huge amount of data imbalance. The English data consisted of only 25% sarcastic tweets, the Arabic data also of around 24%, while the rest of the data was non-sarcastic, respectively. To account for this in our linear model approach, in each language respectively, first, all tweets were split into a sarcastic and a non-sarcastic tweet collection. After shuffling both collections, we chose 867 tweets each, i.e all sarcastic tweets were used, for the further training process. We put 694 tweets each (80%) into the training set, while keeping the other 173 tweets (20%) of each category as held-out data for testing. This way, we had a guaranteed sarcastic/ non-sarcastic ratio of 50% each to avoid bias due to the previously mentioned imbalance. After shuffling both the training set and the test set again, we obtained our final datasets.

3.4.2 Feature Extraction

We extracted the features from our training data by using a simple count vectorizer, while applying tf-idf weighting, both as implemented in scikit-learn (Pedregosa et al., 2011). The vectorizer considered word n-grams from unigrams up to 4-grams. This feature extraction process was used in the grid search we performed for choosing a linear classifier as described in section 3.4.3, as well as for training both with and without sentiment analysis, described in section 3.4.5.

3.4.3 Model Choice

For the linear model approach we chose three different linear models and performed a grid search on them, trying to optimize F1-score for the sarcastic class on a held-out dataset (20% of all training data, see Section 3.4.1), to find the best hyperparameter settings for fitting on our training data. The three models chosen were a Naive Bayes Classifier, a Support Vector Machine model and a Random Forest classifier. The following hyperparameters of the respective models were included in the grid search:

- For Naive Bayes Classifier:

Description	Name	Values
Parameter for add-k smoothing	alpha	0.1, 1.0, 2.0, 5.0, 10.0, 20.0, 50.0, 100.0

- For Support Vector Machine

Description	Name	Values
Probability estimates for classification	probability	True, False
Kernel type	kernel	linear, poly, rbf, sigmoid
Kernel coefficient	gamma	scale, auto
Degree of the polynomial kernel function	degree	0-6 (interval: 1)

- For Random Forest Classifier:

Description	Name	Values
Number of decision trees in the forest	n_estimators	10, 20, 50, 100, 200, 300, 400, 500
Minimum number of samples needed to split a node (make a decision)	min_samples_split	3, 5, 10, 20, 30, 50
Maximum depth of a tree	max_depth	None, 3, 5, 15, 25, 50, 100
Maximum number of features considered when looking for each split	max_features	3, 5, 10, 20

The F1-score of the sarcastic class was calculated using cross-validation. Features of the used training data during the grid search were extracted as described in section 3.4.2. Both the grid search and the classifiers were implemented via scikit-learn. We chose the classifier which achieved the highest F1-score for the sarcastic class with its best hyperparameter settings respectively, obtained from the previously mentioned grid search. This classifier was the Naive Bayes Classifier. However, after making predictions on the organizer‘s test data, we decided to finally use the Support Vector Machine model, since almost all test instances were classified sarcastic by the Naive Bayes Classifier, while the predictions made by the Support Vector Machine model were mixed and seemed more reasonable. The best hyperparameter setting found for the Support Vector Machine classifier were its default values for all possible hyperparameters, as defined in scikit-learn.

3.4.4 Sentiment Analysis

To implement the sentiment analysis for English we used a pre-trained model from the Flair NLP library (Akbik et al., 2019). Flair is a NLP framework providing a lot of different models for several common NLP tasks, including sentiment analysis. We can feed an input text to the pre-trained Flair model to get a classification for the text being positive or negative, as well as a score indicating how confident the model was about the classification between 0.5 and 1.0.

Our idea for how to use this result to help us solve the task at hand was to feed each input sentence into the Flair model and obtain a sentiment prediction, "positive" or "negative", together with the model's confidence score. We then assign one of six categories to the respective sentence. We created three categories, each resembling a certain range of the model's confidence score for both the positive and negative class. Thus, we obtained the following six categories:

confidence score	**classified "positive"**	**classified "negative"**
> 0.95	very positive	very negative
0.75 - 0.95	quite positive	quite negative
< 0.75	rather positive	rather negative

Depending on the sentence's category we then created a one-hot encoded vector. For example, if a sentence would be categorized as very positive, the respective vector would be "[1 0 0 0 0 0]", with each integer resembling one of the categories and its value showing if it is the sentence's category (1) or not (0).

Applying this to each input sentence results in a matrix, which we attached in the training process (see section 3.4.5) to the feature matrix that was created by our feature extraction described in section 3.4.2.

3.4.5 Training

For training in both cases (with and without sentiment analysis), we preprocessed our training data as described in section 3.4.1 and obtained our feature matrix as described in section 3.4.2.

For training with sentiment analysis, we attached the sentiment matrix, obtained in the process described in section 3.4.4, horizontally. That means the first row of the sentiment matrix was appended to the first row of the feature matrix etc. such that the final matrix resembles all input sentences of the training set (rows) with all extracted features, including the result of our sentiment analysis (columns).

To get our final predictions we fit our Support Vector Machine classifier on our respective feature matrix, depending on training with or without sentiment analysis.

3.4.6 Results

The linear model trained without the input of our sentiment analysis scored 0.2738 according to the official metrics, which was F1-score for the sarcastic class. The model trained with the input of the sentiment analysis scored only 0.2721, so the model influenced by the sentiment analysis performed slightly worse.

model	**f1-score**	**precision (unweighted mean)**	**recall (unweighted mean)**
SVM with sentiment analysis	0.2721	0.5318	0.564
SVM without sentiment analysis	0.2738	0.5336	0.5673

Table 6: Scores of the linear model with and without sentiment analysis for the English test set

4 Conclusions

The Support Vector Machine model (SVM) performed better than the CNN both when sentiment analysis was included, as well as on its own. The SVM without sentiment analysis also showed the highest F1 score of all four tested models. However, in general our results show that our ways of implementing sentiment analysis even had a negative impact on the classification for sarcasm on both systems.

One reason for the bad performance of the sentiment analysis could have been that we performed the sentiment analysis on the input sentences as a whole for both training and classifying. In order to recognize a contradiction within one sentence, as explained in Section 1, improvements might be achieved if the sentence is split in several sub parts and sentiment analysis is performed on those parts. This way, positive and negative classifications with high confidence scores might be observed, clearly indicating the aforementioned clash of connotations. Potential challenges that could come up in that case are to determine where to split the sentences exactly, or deciding which parts of even the sub parts the sentiment analysis should be performed on, since not all word types convey sentiment (e.g. stop words could be considered neutral). To account for this, alternatively to our approaches, a sentiment lexicon could be used to calculate scores on sub parts of sentences.

Even without splitting the input sentences, we could have implemented our idea better for both approaches. For example, for the Deep Learning approach, sentiment analysis datasets might be more useful, if their genre is the same or closer to our training data. An additional way to adjust our implementation for this approach would be to shift our decision boundary, classifying sentences contradictory, if output values of the sigmoid function between for example 0.35 and 0.65 can be observed, since clearly positive and negative sub parts might lead to a rather neutral sentiment in total.

Similarly, for the linear model approach we could have weighted the "rather positive" and the "rather negative" category as more important, compared to the more extreme categories.

Acknowledgements

We would like to thank Çağrı Çöltekin for his advice and support while creating this work. We would also like to thank everyone who reviewed an earlier version of this paper and provided helpful comments and suggestions for improvement.

Abstract

We present our systems and findings for the iSarcasmEval: Intended Sarcasm Detection In English and Arabic at SEMEVAL 2022. Specifically we take part in the Subtask A for the English language. The task aims to determine whether a text from social media (a tweet) is sarcastic or not. We model the problem using knowledge sources, a pre-trained language model on sentiment/emotion data and a dataset focused on intended sarcasm. Our submission ranked third place among 43 teams. In addition, we show a brief error analysis of our best model to investigate challenging examples for detecting sarcasm.

1 Introduction

According to the Freedictionary[1], sarcasm is a cutting statement to express contempt or ridicule, often using words to convey a meaning that is the opposite of their literal or actual meaning.

Due to its ambiguous nature, sarcasm plays an important role for resolution of several NLP tasks, such as Sentiment Analysis (Liu et al., 2010; Joshi et al., 2017; Maynard and Greenwood, 2014), Hate speech (Frenda et al., 2022), disagreement classification (Ghosh et al., 2021), Opinion Mining (Kannangara, 2018) among others. One example of benefits of modeling sarcasm is presented by Bouazizi and Ohtsuki (2015) about the use of sarcastic tweets to improve Sentiment Analysis.

In this work we present our submission to iSarcasmEval at Semeval-2022 for subtask A (Given a text, determine whether it is sarcastic or non-sarcastic). Our solution system is at the top three teams among 43 teams. The proposed approach uses the pre-trained language model well informed of this task, because it uses sentiment/emotion data and we enhanced it with a dataset about intended sarcasm texts.

The rest of the document goes as follows: Section 2 overviews some related works about sarcasm detection tasks. In Section 3, we give a detailed description of our conducted experiments, including the dataset used. Section 4 summarizes our results and offers an interpretation to our findings. Finally, Section 5 presents our conclusion, contributions and future work.

2 Related works

Beside the importance of detecting sarcasm for industry applications related to understanding comments on social networks or commercial products reviews (Yavanoglu et al., 2018), sarcasm detection has received great attention from the NLP community, influencing the creation of diverse approaches, benchmark datasets and evaluation methods.

The methods for modeling sarcasm range from rule-based system and statistical approaches by exploiting handcrafted features using traditional machine learning (Joshi et al., 2015; Wicana et al., 2017) to modern techniques using deep learning architectures together with word embeddings and pretrained language models (Mehndiratta and Soni, 2019; Srivastava et al., 2020; Wang et al., 2021).

Previous attempts for benchmarking sarcasm detection were proposed by "SemEval-2018 Task 3: Irony Detection"[2], ALTA Shared Task 2019[3], FigLang 2020[4] and WANLP 2021[5]. They crafted their datasets either using weak supervision tech-

niques like scraping tweets having the #irony, #sarcasm hashtags, or by manual labeling from third party annotators, which leads to several shortcomings as exposed in Oprea and Magdy (2020), instead the dataset used in this work (iSarcasm) was crafted by asking the authors themselves to provide the sarcastic/non-sarcastic labeling for their tweets.

	Training	validation
Sarcastic	867	86
Non-Sarcastic	2601	259
Total examples	3468	345

Table 1: Number of classes in train and validation splits

3 Experiments

Our experiments aim to determine whether a given text is intended to be sarcastic or non-sarcastic. The metric for ranking systems on the competition is the F1-score for the sarcastic class (positive label) only.

Datasets. As part of the iSarcasm shared task (Abu Farha et al., 2022), the organizers provide training and test datasets for English and Arabic, however, we only participated in the English track. Table 1 displays the number of samples and the distribution over sarcastic and non-sarcastic texts for train and validation splits. As observed sarcastic texts roughly account for the 25% of data in each split.

In addition to the iSarcasmEval dataset, we also employed the SPIRS dataset[6] which is a collection of sarcastic and non-sarcastic tweet ids (15,000 for each category) gathered using "reactive supervision", a new data capturing method (Shmueli et al., 2020). From SPIRS only intended and negative examples were considered which amount to 15,950 and 1,773 examples in the training and development splits, respectively. Therefore, tweets perceived as sarcastic were discarded, since perceived sarcasm accounts for a related but different task.

Pre-processing steps. We perform minimal preprocessing which includes conversion of user mentions and links to @USER and URL, respectively. Also, consecutive whitespaces are normalized to a single occurrence and punctuation marks are surrounded with a single space character.

Our approach. Our approach is informed by insights from the literature on the effectiveness of sentiment/emotion information for sarcasm detection. Additionally, the creators of the SPIRS dataset also provided perspectives (intended vs. perceived) for their heuristically-labeled sarcasm dataset. Building on these, we examine the effect of these two knowledge sources on the sarcasm detection task. Specifically, we combine pre-training on sentiment/emotion with a second pre-training step on the intended sarcasm subset of the SPIRS dataset. In the final step, we fine-tune the pretrained model on the dataset provided for the shared task.

Pre-trained models. We employed four publicly available pre-trained models from the Huggingface model hub. The models namely: BERTweet-base[7], BERTweet-sentiment[8], BERTweet-emotion[9], and BERTweet-large[10] are trained on twitter data using masked language modeling as well as sentiment and emotion detection where applicable.

Training details/hyperparameters. We use the adapter-transformers library for the experiments. We add a classification layer (consisting of two dense layers) on top of the pooled output of the last transformer layer and optimize this layer jointly with the pre-trained layers. We optimize the model using Adamw with a batch size of 64 on a single Nvidia V100 GPU (32GB) and a maximum learning rate of 1e-5. We use a warmup ratio of 0.1 and set the maximum number of epochs to 15 with earlystopping on the validation performance metric (F1) using a patience of 5 evaluation runs. We evaluate the performance of the model every 20 steps on the validation set. Furthermore, we employ three regularization techniques: weight decay with a factor of 0.01, dropout applied to the pooled output of the last transformer layer with a probability of 0.2, and label smoothing with a factor of 0.1.

Table 2: Performance scores on the validation and test sets (All metrics are for the sarcastic class).
*Suggested by one of the reviewers for completeness and better comparison.

Case	Example	Explanation
Not enough context to determine the intention of the phrase(s)	- JUSTICE HAS BEEN DONE . - i ' ve never had protected sex - i'm dying	Chances are that the required context are on other parts of the post, e.g. in the comments
Common sense or Knowledge of real world is required	Mad how many cars they make now without indicators [happy-emoji]	It is not that new cars had a design without indicators, it is just that for many reasons, some people refuse to use them, and that make other drivers angry because of the difficulties while driving.
Common sense or Knowledge of real world is required	Vaccinated this morning . Not sure it ' s worked - still committed to Apple and no extra autism detected . Bloody science .	Those 'secondary effects' are not even related with vaccines; it seems that the user is just joking with that concept.
Common sense or Knowledge of real world is required	hello to all three of my followers, this is my big return to twitter	People who are familiar with Twitter knows that having three followers is not actually impressive. Instead this author is making fun of it.
Sentiment contradiction between key words and emojis	- I hate it here [happy emoji] - Headaches that last all day nonstop [happy emoji] - @ user thanks for shutting down the only Disney Store in northeastern Ohio . The other two stores went out of business yrs ago . It ' s not the same with shipping costs online not to mention LE doll sales are an absolute nightmare online . So unbelievably disappointing . [sad emoji]	Not all examples use positive emoji to end sarcastic messages. Here, the contradiction lies in the pair thanks-[sad emoji]

Table 3: Error analysis of model predictions on the validation set

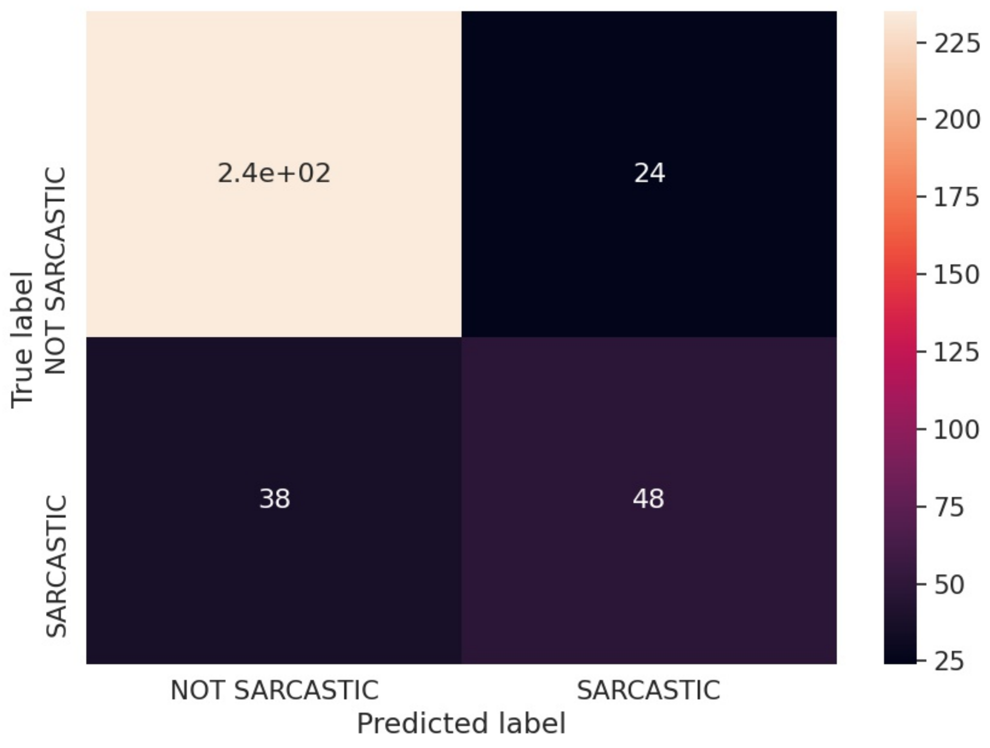

Figure 1: Confusion matrix for the best model predictions on the validation set

4 Results and error analysis

Our system ranks third on the leaderboard for the competition with an F1-score for the sarcastic class (positive label) of 0.530. The performance scores for our submissions on the validation and test sets are in Table 2. The BERTweet-large model achieved the best score out of our four submissions. It seems that pre-training on sentiment or emotion detection is not beneficial in our experimental settings. This observation can be confirmed in our post-evaluation runs where the BERTweet-base model shows superior performance (up to 5 F1 points on the test set) when compared to the same model that has been further pre-trained on sentiment or emotion detection task. Further investigation of this observation is required to identify alternative approaches to incorporate these sources of information for transformer-based models. Figure 1 shows the confusion matrix of the predictions made by our best model on the validation set.

As for error analysis, we use the validation set to identify possible explanations for why the model fails at predicting correctly positive labels (sarcastic tweets). Table 3 shows three cases as challenges for detecting sarcasm, which are usually hard to overcome in many NLP tasks as well.

These results show that still modern language model techniques struggle to grasp the pragmatics of messages expressed in social media, which are particularly difficult.

5 Conclusion

We present our systems for the task of sarcasm detection using a variety of knowledge sources that explore the capabilities of pre-trained language models to understand pragmatic phenomena such as sarcasm. We found that although these knowledge sources help to shed light over the sarcasm detection task, still more external knowledge would be required to correctly classify difficult cases that require a deeper understanding of real world context.

Based on our analysis, we plan to further examine the impact of including say emoji modelling to measure its influence, especially over cases that show a contradiction on expressed sentiments.

Abstract

In this paper, we (a YNU-HPCC team) describe the system we built in the SemEval-2022 competition. As participants in Task 6 (titled "iSarcasmEval: Intended Sarcasm Detection In English and Arabic"), we implement the sentiment system for all three subtasks in English and Arabic. All subtasks involve the detection of sarcasm (binary and multilabel classification) and the determination of the sarcastic text location (sentence pair classification). Our system primarily applies the sequence classification model of a bidirectional encoder representation from a transformer (BERT). The BERT is used to extract sentence information from both directions for downstream classification tasks. A single basic model is used for single-sentence and sentence-pair binary classification tasks. For the multilabel task, the Label-Powerset method and binary cross-entropy loss function with weights are used. Our system exhibits competitive performance, obtaining 12/43 (21/32), 11/22, and 3/16 (8/13) rankings in the three official rankings for English (Arabic).

1 Introduction

Satirical text is a rhetorical device for implicitly expressing emotions by using words that are contrary to the actual intention to achieve a satirical or humorous linguistic effect. The true semantics of satirical texts cannot be directly inferred from the text vocabulary, and contradictions exist between their literal meaning and the true intention. Therefore, the detection of sarcasm and its sentiment discrimination are more challenging in natural language processing (NLP) problems.

Task 6 in the SemEval-2022 competition is a sarcasm detection task that consists of three subtasks (Abu Farha et al., 2022).

- Subtask A: Detect sarcastic meaning from a given tweet.
- Subtask B: Identify the tweet as "no sarcasm" or one or more of the six given sarcastic speech categories.
- Subtask C: Determine the position of the satirical text from the given tweets and their non-satirical restatements (0 means the first sentence is satirical, and 1 means the second sentence is satirical).

In previous sarcasm detection tasks, researchers used supervised learning methods based on the support vector machines and logistic regression (González-Ibáñez et al., 2011) to study ironic and non-ironic tweets that directly express positive and negative views. However, these traditional machine learning methods cannot mine the deep semantic information hidden in the text. Relying only on the surface semantic information can easily result in an incorrect judgment regarding irony. In contrast, deep learning methods show excellent results in deep semantic mining. By using the context information of the text to be detected (Bamman and Smith, 2015), we can further mine the behavior information of social users. We can achieve better performance by using a bidirectional recurrent neural network to capture the syntactic and semantic information of the target tweet text and the automatic learning features of historical tweets related to the target tweet for sarcasm detection (Zhang et al., 2016). The convolutional long-term and short-term memory network (CNN-LSTM-DNN) (Ghosh and Veale, 2016) achieved remarkable results.

In this paper, we propose a deep learning system for Task 6 in SemEval-2022, titled "iSarcasmEval: Intended Sarcasm Detection In English and Arabic." We use a pre-trained bidirectional encoder representation from a transformer (BERT) (Devlin et al., 2019) sequence classification model as the base model. For single-sentence and sentence-pair binary classification tasks, we use fine-tuning methods on a basic model. We employ the Label-

Powerset (Nazmi et al., 2020) approach and train the basic model by applying a binary cross-entropy loss function with weights for the multi-label task. The contributions of this study are as follows.

- For the sentiment analysis problem, we propose a basic model using a pre-trained BERT sequence classification model.
- The use of a binary cross-entropy loss function with weights is more advantageous for performing multi-label classification with uneven label distribution task.
- Fine-tuning on multilingual datasets (Pires et al., 2019) leads to a significant improvement in the scores of prediction results.

The remainder of this paper is organized as follows. In Section 2, we describe the proposed system and model in detail. The experiments and results are discussed in Section 3. Finally, conclusions are presented in Section 4.

2 System Description

The general structure of our system consists of four modules, described as follows.

Input layer. In this layer, we build text-processing tools to perform pre-processing of text and embedding of words. A large amount of useless information in the given text, such as user (@user), URL (http://ie.com), and escape symbols (\s, \j, etc.), increases the computational effort and complexity of a model. We remove the useless information in advance by using regular expressions and convert all words to lowercase, without breaking the structure of hashtags (#hashtag). We believe that the search and tagging of these tweets depends mainly on their hashtags (Peng et al., 2018). The preservation of the hashtag structure improves the accuracy of sarcasm detection. Tokenizers provided by HuggingFace[1] are used to process information such as punctuation, emoticons, non-English (or non-Arabic) letters, numbers, and hashtags (#hashtag) that are still present in the text and to rapidly perform word separation. Tokenizers can also perform word embedding using continuous low-dimensional vectors to represent word features (Mikolov et al., 2013). In this layer, we obtain the sequence of representations to be used as inputs to the subsequent modules.

[1]https://huggingface.co/.

Context encoder. Devlin et al. proposed a new natural language representation model named BERT in 2018, which successfully achieved state-of-the-art results in 11 NLP tasks, winning a plethora of accolades from the NLP community. The model is based on a bidirectional transformer for large-scale pre-training and can be fine-tuned by users to handle different text-processing tasks. One variant of the BERT is RoBERTa (Liu et al., 2019), which enhances the effect of the BERT by improving its pre-training method without affecting the structure of the BERT. Unlike the BERT static mask approach, RoBERTa uses dynamic masks, where the tokens masked for each sequence are changed in different epochs of training. RoBERTa removes the NSP task and uses the FULL-SENTENCES training approach. RoBERTa also uses a larger minibatch, more data, and larger number of sentences. Therefore, the RoBERTa-pretrained model yields better results. In this module, we mainly use the pre-trained BERT model and its variant RoBERTa model to complete the contextual encoder.

Fully connected layer. Fully connected networks are used for downstream classification tasks.

Output layer. The output of the fully connected layer is processed to complete the label prediction. Different tasks require different processing methods.

The details of each subtask in each module are discussed in the following.

2.1 Subtask A: Sentence Classification

The first part of this task was to extract semantic information from a given tweet text. We termed this sentence classification (Dao et al., 2020), where we predict whether a sentence is sarcastic. For this purpose, our approach generated 768-dimensional word embeddings for each word in a sentence by using a pre-trained BERT model. We selected the first token (i.e., "[CLS]") of the sentence into the sequence classification because it integrated the semantic information of the entire sentence. The word embeddings obtained from the previous step were then connected to a fully connected layer, which transformed the 768-dimensional input into two-dimensional values. These values were then fed into Softmax to calculate the probability that the sentence is sarcastic. Finally, the probability results were fed into argmax to form labels; in our experimental setup, 1 indicated sarcasm and 0 indicated non-sarcasm. The model architecture is

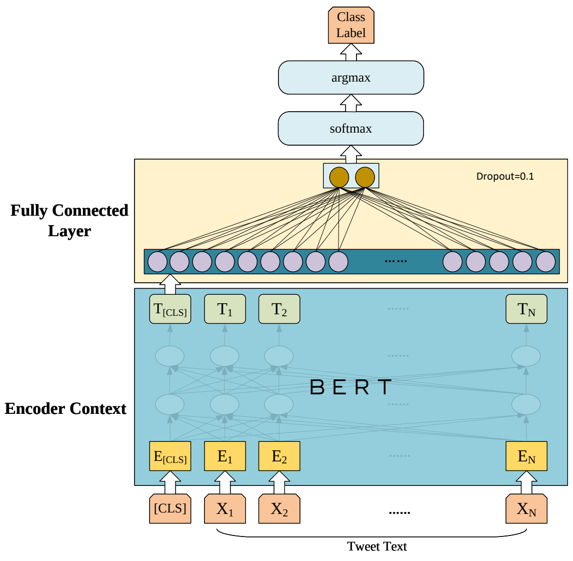

Figure 1: System of binary classification for sentence

Table 1: Quantity of labels by category in English dataset.

Category	Quantity
sarcasm	713
irony	155
satire	25
understatement	10
overstatement	40
rhetorical_question	101

illustrated in Figure 1.

2.2 Subtask B: Multi-Label Classification

This task was also a sentence classification task, with the difference being that it involved the prediction of multiple binary targets simultaneously based on a given input. For the upstream task of sentence information extraction, we used the pre-trained BERT model. For the downstream classification task, we used the Label-Powerset method (Tsoumakas et al., 2011), which sets the number of labels to the number of output neurons in the network. We can directly apply an arbitrary binary classification loss function to the neural network model, and the model can simultaneously output all targets. At this point, we only need to train one model; the training time is shorter, and the network can also learn the relevance of different labels through the output neurons. We counted the number of various types of labels in the English dataset (Table 1) and discovered that the number of labels is dozens of times different. To solve the problem of label imbalance, we appropriately added a network layer to improve the classification effect. We employed the RELU activation function for fast computation between two linear layers to boost the sparsity of the simultaneous network and reduce the interdependence of parameters to alleviate the overfitting problem. In addition, we utilized a binary cross-loss function with weights to focus the model on the sparse labels, as stated in Section 2.4.

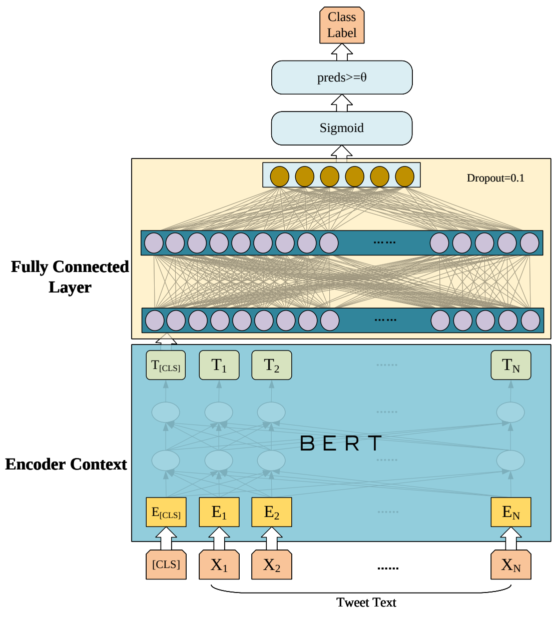

Figure 2: Multi-label classification system for sentence

We selected the values generated by the aforementioned work into sigmoid and mapped their range to (0, 1) to reply to the confidence level of each label. We set a threshold of $\theta = 0.5$, and when the predicted value was greater than or equal to θ, we considered that the prediction contained this label; otherwise, it did not. The model architecture is shown in Figure 2.

2.3 Subtask C: Sentence-Pair Classification

This task is a sentence pair classification task, similar to subtask A, but with two sentences as the input. In the input layer, in addition to the work done in Subtask A, we must split the two sentence representations using the "[SEP]" token. The inputs are then passed to the pre-trained BERT model to obtain the "[CLS]" token, which integrates the semantic information of the entire sentence. The subsequent model structure was the same as that for Subtask A. The "[CLS]" token is passed to the subsequent module to obtain the location label of

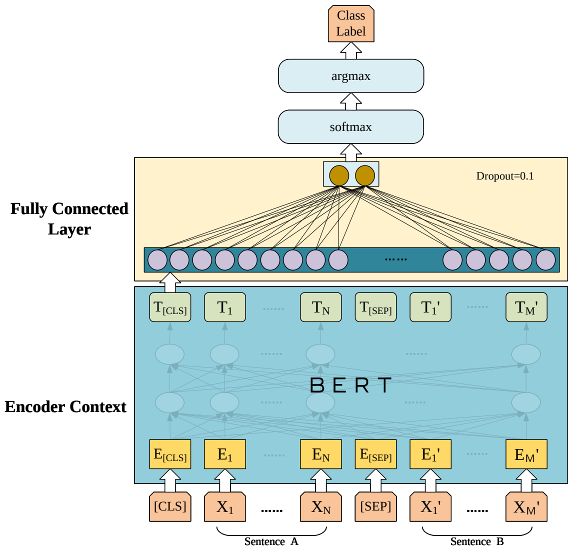

Figure 3: System of binary classification for sentence pair

the sarcastic text, with 0 indicating sentence A and 1 indicating sentence B. The model architecture is illustrated in Figure 3.

2.4 Training and Hyper-parameters

We used a binary cross-entropy loss function for subtasks A and C and a binary cross-entropy loss function with weights for subtask B to train the model. For the sample imbalance between labels in the multilabel classification task of subtask B, we introduced parameter w_i. We increased the attention of the system to scarce labels by assigning higher weights to labels that appear less frequently. For batch data D(x, y) containing N samples with M labels per sample, the loss function is calculated as follows:

$$loss = \frac{1}{\text{N}} \sum_{n=1}^{\text{N}} l_n, \tag{1}$$

$$l_n = \frac{1}{\text{M}} \sum_{i=1}^{\text{M}} l_n^i, \tag{2}$$

where l_n^i is the loss corresponding to the i-th label of the n-th sample.

$$l_n{}^i = -w_i[y_n^i \cdot \log \sigma(x_n^i) + (1 - y_n^i) \cdot \log(1 - \sigma(x_n^i))] \tag{3}$$

where σ is the sigmoid function. w_i is the weight parameter of the i-th label, which is calculated from the i-th label number, $Label_i$, by applying the following equation.

$$w_i = \frac{\sum Label}{Label_i} \tag{4}$$

For all the subtasks, we used the AdamW (Loshchilov and Hutter, 2019) optimizer to train the model with a batch size of 16.

Hyperparameters. The dimensionality (d) of the word embedding was 100, learning rate was 2e-5, weight decay was 0.01, and dropout ratio was 0.1 for all layers in all models.

3 Experimental

Datasets. The datasets used were the English dataset (3467 data) and Arabic dataset (2602 data) provided by the competition, with no other external corpus. Only one dataset in English was used for subtask B, except for subtasks A and C, in which two sub-datasets were used. We thank the organizers for their contributions to the data.

Evaluation Metrics. The main evaluation metrics are as follows:

- SubTask A: F1-score for the sarcastic class.
- SubTask B: Macro-F1 score.
- SubTask C: Accuracy.

Implementation Details. To solve the data imbalance problem, we sampled the data selected for training such that the number of 0/1 tags was as similar as possible. For the sentence pair classification task, we take the tweet text in the dataset as sentence A and the rephrase text as sentence B, and assign label 0. After switching the positions of tweet text and rephrase text, we assign label 1. We divided the training data into a training set and a development set at a ratio of 8:2. We trained our models on the training set, evaluated the predictions on the development set using evaluation measures, and saved the models with the highest evaluation scores during the process. We used the Pytorch framework provided by the Huggingface library for the pre-trained BERT model and bert-base-multilingual-uncased and roberta-base for the binary classification, multi-label classification, and sentence pair classification included in this task.

Results and Analysis. Tables 2, 3, and 4 present comparative results for each task. The bolded scores are those assessed by participating in the competition leaderboard. On the competition leaderboard, our system ranked 12/43 (21/32) in

Table 2: Comparable results of experiments for subtask A.

Model	Fine-tune	Test	F1
bert-base-multilingual-uncased	English	English	0.306

	English+Arabic		**0.805**
	Arabic	Arabic	0.5
	English+Arabic		**0.755**
roberta-base	English	English	0.860
	Arabic	Arabic	0.5

English (Arabic) in Task A, 11/22 in Task B, and 3/16 (8/13) in Task C.

As shown in the tables, our approach achieves significant results. This is mainly because the BERT model is a multilayer bidirectional transformer encoder that can be integrated into various NLP downstream tasks and obtains the best results. In addition, the training results using the roberta-base model are significantly better, indicating that the pre-training approach of the BERT can be improved. Moreover, fine-tuning with multiple languages significantly improved the training results, particularly for Arabic. As revealed in Table 4, fine-tuning the model on the Arabic dataset individually shows worse results, which may be due to the fact that very little information is extracted from the Arabic dataset only. In the future, we can improve the method of fine-tuning in multiple-language datasets by balancing the vectors of different languages to improve the model effect. For multi-label classification, the Label-Powerset method is not as effective as stand-alone dichotomous classifier training; however, combined with a dichotomous cross-entropy loss function with weights, the results can be slightly improved while saving a lot of training time.

4 Conclusion

In this paper, we describe a deep learning model for the sentiment analysis task in the SemEval-2022 competition (Task 6: iSarcasmEval: Intended Sarcasm Detection In English and Arabic). A BERT sequence classification model was used as the base model. The final submitted system performed admirably and ranked third in one of the rankings. However, there is still considerable potential for improvement. Therefore, in future investigations, we will attempt to extend this model with improved capabilities to achieve better outcomes.

Abstract

Sarcasm is a term that refers to the use of words to mock, irritate, or amuse someone. It is commonly used on social media. The metaphorical and creative nature of sarcasm presents a significant difficulty for sentiment analysis systems based on affective computing. The methodology and results of our team, UTNLP, in the SemEval-2022 shared task 6 on sarcasm detection are presented in this paper. We put different models, and data augmentation approaches to the test and report on which one works best. The tests begin with traditional machine learning models and progress to transformer-based and attention-based models. We employed data augmentation based on data mutation and data generation. Using RoBERTa and mutation-based data augmentation, our best approach achieved an F1-sarcastic of 0.38 in the competition's evaluation phase. After the competition, we fixed our model's flaws and achieved an F1-sarcastic of 0.414.

1 Introduction

Billions of internet users use social networks not only to stay in touch with friends, meet new people, and share user-generated content but also to express their opinions on a wide range of topics using a variety of methods such as posting comments, videos, photos, etc. with specific groups of people (Tungthamthiti et al., 2016). In these platforms, users could submit information on whatever topic they wanted, with no restrictions on the sort of content they may share. The lack of constraints and individuals' anonymity on these networks led to humorous sarcastic texts.

Because sarcasm indicates sentiment, detecting sarcasm in a text is critical for anticipating the text's accurate sentiment, making sarcasm detection a valuable tool with multiple applications in domains such as security, health, services, product evaluations, and sales. Sarcasm detection is an essential aspect of creative language comprehension (Veale et al., 2019) and online opinion mining (Kannangara, 2018). Even for humans, identifying sarcasm is difficult due to heavily contextualized expressions (Walker et al., 2012). There are few labeled data resources for sarcasm detection. Any available texts that can be collected (for example, Tweets) contain many issues, such as an evolving dictionary of slang words and abbreviations, requiring many hours of human annotation to prepare the data for any potential use. Furthermore, the nature of sarcasm identification adds to the task's difficulty, as sarcasm may be considered relative and varies significantly across people, depending on a variety of criteria such as the context, area, time, and events surrounding the statement.

In an attempt to solve this issue, we participated in SemEval-2022 shared task 6 (Abu Farha et al., 2022), which aims to recognize whether a tweet is sarcastic or not. Our contributions are as follows:

1. We experiment with simple machine learning models like Support Vector Machine (SVM) and various word encodings.
2. To discover the optimum data preprocessing method, we tested the effect of various data preprocessing.
3. We put several data augmentation techniques to the test.
4. On our best dataset, we evaluated Long Short Term Memory (LSTM) based models, Bidirectional Encoder Representations from Transformers (BERT) based models, and attention-based models. Different neural network topologies are compared, and the model with the highest performance is reported.

With RoBERTa (A Robustly Optimized BERT Pretraining Approach), no preprocessing, and mutation-based data augmentation, our top result gets an F1-sarcastic of 0.38. However, we obtain

*equal contribution

better outcomes, with a 0.414 F1-sarcastic after fixing the problems of our proposed method.

The rest of this paper is organized as follows. In Section 2, we discuss the related work, Section 3 introduces the dataset. In Sections 4 and 5, we present our methodology and results, respectively. Finally Section 6 concludes the paper.

2 Related Work

We give a quick review of previous works on sarcasm detection in this part, followed by works on data augmentation.

2.1 Sarcasm Detection on Twitter

Sarcasm detection has been represented as a binary classification issue, with most tweets labeled with specific hashtags (e.g., #sarcasm, #sarcastic) being considered sarcastic. Many techniques in various languages have been proposed using this framework.

In (Davidov et al., 2010), Semi-supervised sarcasm detection experiments were done using a Twitter dataset (5.9 million tweets) and 66,000 Amazon product evaluations. On the product review dataset, they acquired an F-measure of 0.83. On the Twitter dataset, they obtained an F-measure of 0.55 using 5-fold cross-validation on their k-Nearest Neighbor (kNN) like classifier.

(González-Ibánez et al., 2011) used 900 messages from Twitter sorted into three groups (sarcastic, positive sentiment, and negative sentiment). To find sarcastic tweets, they utilized the hashtags #sarcasm and #sarcastic. SVM with Sequential Minimum Optimization (SMO) and logistic regression were employed as classifiers. The best accuracy for the sarcastic class was 0.65.

(Reyes et al., 2012) presented elements to capture ambiguity, polarity, unexpectedness, and emotive situations in figurative language. F1-sarcastic of 0.65 was the best result in categorizing irony and general tweets.

The representativeness and significance of conceptual elements have been investigated in (Reyes et al., 2013). Punctuation marks, emoticons, quotations, capitalized words, lexicon-based features, character n-grams, skip-grams, and polarity skip-grams are all examples of these characteristics. Each of the four categories (irony, comedy, education, and politics) in their corpus has 10,000 tweets. Using the Naive Bayes and decision trees algorithms, they evaluated two distributional scenarios: balanced distribution and unbalanced distribution (25% ironic tweets and 75% tweets from the three non-ironic categories). The decision trees classified the balanced distribution with an F1-sarcastic of 0.72 and the unbalanced distribution with an F1-sarcastic of 0.53.

One sort of sarcasm identified by (Riloff et al., 2013) is the difference between a good mood and a bad scenario. Using a bootstrapping approach, the authors gathered collections of positive sentiment phrases and negative circumstance words from sarcastic tweets. They suggested a method for classifying tweets as sarcastic if they contain a positive predictive close to a negative context phrase. They used a SVM classifier using unigrams and bigrams as features to evaluate a human-annotated dataset of 3000 tweets (23% sarcastic), getting an F1-sarcastic of 0.48. The F1-sarcastic of the hybrid strategy, which combined the findings of the SVM classifier with their baseline method, was 0.51.

(Lukin and Walker, 2017) used bootstrapping, syntactic patterns, and a high precision classifier to classify sarcasm and nastiness in online chats. On their snark dataset, they got an F1-sarcastic of 0.57.

In (Oprea and Magdy, 2019), LSTM, Att-LSTM, CNN, SIARN, MIARN, 3CNN, and Dense-LSTM models were used to assess the task dataset that was introduced in (Oprea and Magdy, 2019), which is an unbalanced dataset and labeled by the tweets' writers. Using Multi-Dimension Intra-Attention (MIARN) (Tay et al., 2018) Network, they could get an F-score of 0.364.

In (Guo et al., 2021), the Latent Optimized Adversarial Neural Transfer (LOANT) model was suggested as a novel latent-optimized adversarial neural transfer model for cross-domain sarcasm detection. LOANT surpasses classical adversarial neural transfer, multitask learning, and meta-learning baselines using stochastic gradient descent (SGD) with a one-step look-ahead and sets a new state-of-the-art F-score of 0.4101 on the iSarcasm dataset.

2.2 Data Augmentation

Natural Language Processing(NLP) encompasses a wide range of tasks, from text categorization to question answering, but no matter what you do, the quantity of data you have to train your model has a significant influence on the model's performance. Using the data you already have, data augmentation techniques are used to produce extra, synthetic data. Augmentation techniques are widely used in computer vision applications, but they may also be used in natural language processing.

In the instance of Twitter, (Van Hee et al., 2018) and (Ilić et al., 2018) found that adding more data from the same domain did not improve the performance for recognizing sarcasm and irony. Although their result is not general for all sarcasm detection tasks and the result of data augmentation depends on the data and augmentation method.

(Lee et al., 2020)'s idea is to make a new datapoint out of the context sequence [c1, c2,, cn] and label it "NOT SARCASM." The sequence could not be identified as "SARCASM" without the answer [r1]. They believe that the newly created negative samples will aid the model in focusing on the link between the response [r1] and its contexts [c1, c2, cn]. They also create positive samples using back-translation procedures(Berard et al., 2019; Zheng et al., 2019) in French, Spanish, and Dutch to balance out the quantity of negative examples.

In (Feng et al., 2020) different data augmentation methods were tested on Yelp Reviews dataset(Yel, 2014) for GPT-2 generative model(Radford et al., 2019). They used "Random Insertion, Deletion, & Swap", "Semantic Text Exchange (STE)", "Synthetic Noise", and "Keyword Replacement". They showed in some case data augmentation could help them to reach better performance.

This paper is the first to look at generative-based and mutation-based data augmentation strategies in sarcasm detection.

3 Dataset

We mostly used the iSarcasm (Oprea and Magdy, 2019) dataset in this study. In specific experiments, we integrated the primary dataset with various secondary datasets, including the Sarcasm Headlines Dataset (Misra and Arora, 2019) and Sentiment140 dataset (Go et al., 2009) to increase the quantity of data and compensate for the lack of sarcastic data. For each dataset, the details are further discussed. It is worthy to mention that all of the supplementary datasets we included had a negative impact on our model's performance. We believe this was the result of a different data gathering method. Because to the differing labeling process and domain, the distribution diverged from that of iSarcasm. As a result, the following sections are solely dependent on the iSarcasm dataset, with no other datasets being used.

3.1 Main Task Dataset: iSarcasm

According to (Oprea and Magdy, 2019), the sarcasm labeling using hashtags to build datasets captures just the sarcasm that the annotators were able to detect, leaving out the intended sarcasm. When the author intends for the content to be sarcastic, it is called intended sarcasm. The iSarcasm dataset includes 4484 tweets: 3707 non-sarcastic and 777 sarcastic. Because some tweets had been erased, we only had access to 3469 tweets for the job. The unbalanced dataset and the scarcity of sarcastic data were two of the most significant issues we encountered. Table 1 displays some of the dataset's annotated remarks.

3.2 Sarcasm Headlines Dataset

Sarcasm Headlines Dataset (Misra and Arora, 2019; Misra and Grover, 2021) was gathered from two news websites. It is beneficial since it overcomes the constraints of Twitter datasets due to noise. As the second edition of this dataset includes more data and a greater variety of data than the first version, we chose the second version.

3.3 Sentiment140 Dataset

We needed to compensate for the limited data to train our model successfully. As a result, we chose the sentiment140 dataset (Go et al., 2009) because it has a large quantity of data and is based on Twitter. The sentiment tweet message is labeled using an automated classification approach in this dataset. The accuracy is more than 80% when using a machine learning algorithm.

4 Methodology

In this study we examined and analyzed various models and data augmentation strategies for sarcasm detection. First, we go through data augmentation methods; then, we discuss the structure and hyperparameters of these models in this section. The codes of all models are available on GitHub[1].

4.1 Data Augmentation

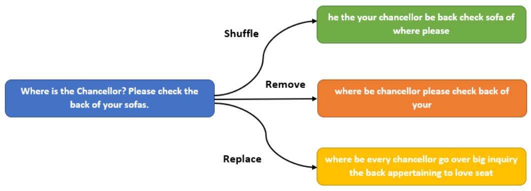
4.1.1 Generator-based

For this augmentation method, we used GPT-2 (Radford et al., 2019) generative model to generate 4000 tweets for both sarcastic and non-sarcastic classes. Then we selected 2000 tweets of each

[1]https://github.com/AmirAbaskohi/SemEval2022-Task6-Sarcasm-Detection

Table 1: Example of Sarcastic and Non-Sarcastic tweets.

Tweet	Sarcastic	Sarcasm Type
Oh my goodness. It's the first week of the summer holidays and @name has found his recorder Give.Me.Strength.	Sarcastic	['Sarcasm']
90% of adulthood is just refilling your @name pitcher.	Sarcastic	['Irony', 'overstatement']
True bliss is laying in an ice cold bath during the hottest part of the year	Non-Sarcastic	[]



Where is the Chancellor? Please check the back of your sofas.
Shuffle
he the your chancellor be back check sofa of where please

where be chancellor please check back of your
Replace
where be every chancellor go over big inquiry the back appertaining to love seat

Figure 1: Effect of shuffling, word elimination, and replacing with synonyms on a tweet sample.

class randomly to increase dataset quantity and have more sarcastic samples.

4.1.2 Mutation-based

We used three distinct ways to change the data in this method: eliminating, replacing with synonyms, and shuffling. These processes were used in the following order: shuffling, deleting, and replacing. The removal and replacement were carried out systematically. We used the words' roots to create a synonym dictionary. Synonym dictionary is created by scarping the Thesaurus website[2]. When a term was chosen to be swapped with its synonyms, we chose one of the synonyms randomly (Figure 1). We tried each combination of these processes to find the best data augmentation combination (a total of seven).

4.2 Models

4.2.1 Support Vector Machine (SVM)

We utilized SVM to discover the optimal approaches for dataset preprocessing and word embeddings. For data augmentation, we employed both generator-based and mutation-based methods. We also put other data preprocessing approaches to the test, such as link removal, emoji removal, stop word removal, stemming, and lemmatizing. We utilized TF-IDF, Word2Vec (Mikolov et al., 2013), and BERT (Devlin et al., 2018) for word embedding. We found that using a regularization value of 10 and a Radial Basis Function (RBF) kernel, BERT word embedding, and no data preprocessing will give us the best results.

4.2.2 LSTM-based Methods

We begin with the intuition that a memory model can help us reach a better result. So we started with Long Short Term Memory (LSTM) model (Hochreiter and Schmidhuber, 1997). We used one LSTM layer followed by time distributed dense layer. We repeated these two layers one more time, and then we used another LSTM layer followed by two dense layers. This model and all of the following models in this section were trained in 10 epochs.

In addition, we used Bidirectional Long Short Term Memory (BLSTM). Using bidirectional will run the inputs in two directions, one from past to future and the other from future to past. We used one BLSTM layer for this network, followed by a time-distributed dense layer. We repeated these two layers one more time, and then we used another BLSTM layer followed by two dense layers.

Furthermore, we combined LSTM and BLSTM with Convolutional Neural Networks (CNNs). CNN layers for feature extraction on input data are paired with LSTM to facilitate sequence prediction in the CNN-LSTM architecture. Although this model is often employed for video datasets, (Rehman et al., 2019) demonstrated that it could perform better in sentiment analysis tasks. We used three 1D convolutional layers followed by a 1D global max-pooling layer for the convolutional part. We used these layers at the end of LSTM-based networks.

[2]https://www.thesaurus.com

4.2.3 BERT-based Methods

The use of bidirectional training of transformer and a prominent attention mode for language modeling is BERT's fundamental technological breakthrough (Devlin et al., 2018). The researchers describe a new Masked Language Model (MLM) approach that permits bidirectional training in previously tricky models. They found that bidirectionally trained language models can have a better understanding of language context and flow than unidirectional ones.

Robustly Optimized BERT or RoBERTa has a nearly identical architecture to BERT, however, the researchers made some minor adjustments to its architecture and training technique to enhance the results on BERT architecture (Liu et al., 2019).

We used both RoBERTa with twitter-roberta-base, which has been trained on near 58 million tweets and finetuned for sentiment analysis with the TweetEval benchmark and BERT with bert-base from Huggingface (Wolf et al., 2019). For both models, we employed five epochs, batch size of 32, 500 warmup steps, and a weight decay of 0.01.

4.2.4 Attention-based Methods

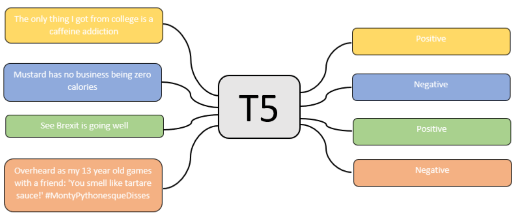
One of the most important achievements in deep learning research in the recent decade is the attention mechanism (Vaswani et al., 2017). The Encoder-Decoder model's restriction of encoding the input sequence to one fixed-length vector to decode each output time step is addressed via an attention mechanism. This difficulty is thought to be more prevalent when decoding extended sequences.

We start with the assumption that if a model with an attention layer is trained to identify sarcasm at the sentence level, the sarcastic words will be the ones the attention layer learns to value. As a result, we added an attention layer to our LSTM-based and BERT-based models. The results will be discussed further.

4.2.5 Google's T5

Google's T5 (Raffel et al., 2019) text-to-text model outperformed the human baseline on the GLUE, SQuAD, and CNN/Daily Mail datasets and earned a remarkable 88.9 on the SuperGLUE language benchmark.

We fine-tuned T5 for our problem and dataset by giving the sarcastic label the target and the tweets as the source. We used two epochs, batch size of 4, 512 tokenization max length, Adam epsilon of 1e-8, word decay of 0, no warmup steps, and learning rate of 3e-4 (Figure 2)[3].



The only thing I got from college is a caffeine addiction
Mustard has no business being zero calories
See Brexit is going well
Overheard as my 13 year old games with a friend: 'You smell like tartare sauce!' #MontyPythonesqueDisses

Figure 2: Fine-tuning T5 model for sarcasm detection problem.

Table 2: F1-sarcastic and accuracy for different data augmentation methods on SVM model with BERT word embedding and no preprocessing.

Data Augmentation	F1-sarcastic	Accuracy
Shuffling	0.305	0.7471
Shuffling + Replacing	0.301	0.741
Shuffling + Removing	0.306	0.747
Removing	0.301	0.747
GPT-2	0.292	0.675

5 Results

In this section we report the results of our models introduced in Section 4.

It's important to note that after the competition, we discovered that none of our preprocessing strategies improved the performance of our model. So we were able to get an F1-sarcastic of 0.414 without using any preprocessing methods, which was 0.034 higher than our performance in the competition, which was based on the best combination of preprocessing methods.

5.1 Support Vector Machine (SVM)

The optimum augmentation technique, preprocessing method, and word embedding were all determined using the SVM model. Without any augmentation, BERT obtained the greatest F1-sarcastic of 0.2862, compared to 0.2541 and 0.0924 for Word2Vec and TF-IDF, respectively.

We have also looked at several ways of data augmentation. The F1-sarcastics for shuffling with replacing words, only word elimination, just shuffling, and shuffling with word elimination were the highest in the mutation-based augmentation (Table 2). We also tried these data augmentation and

[3]We were not able to test a larger version of the model with better hyperparameters due to resource constraints

Table 3: Best results for each model using iSarcasm dataset and mutation-based data augmentation.

Model	F1-sarcastic	Accuracy
SVM	0.3064	0.7478
LSTM-based	0.2751	0.7251
BERT-based	0.414	0.8634
Attention-based	0.2959	0.7793
Google's T5	0.4038	0.8124

GPT-2 data augmentation on RoBERTa because the results were close, and we found that merely word removal was the best data augmentation. The following results are based on no data preprocessing, BERT word embedding, and mutation-based data augmentation utilizing only word removal.

5.2 LSTM-based Methods

LSTM obtained an F1-sarcastic of 0.2176 using BERT word embeddings, mutation-based data augmentation, and no preprocessing, whereas BLSTM's F1-sarcastic was 0.2439 using BERT word embeddings, mutation-based data augmentation, and no preprocessing. By adding CNN layers, the F1-sarcastic of the LSTM was increased to 0.2453, and the BLSTM was increased to 0.2751. The CNN model's F1-sarcastic was 0.2263.

5.3 BERT-based Methods

We employed a mutation-based data augmentation approach with no preprocessing for BERT-based procedures. We got an F1-sarcastic of 0.323 using BERT. We achieved our best result with RoBERTa with an F1-sarcastic of 0.414, which was better than LOANT (Guo et al., 2021) model on the same dataset.

5.4 Attention-based Methods

Adding attention layers to this job was not helpful, and it decreased our models' performance. RoBERTa's F1-sarcastic dropped to 0.2959 using the attention layer. LSTM model with the attention layer earned an F1-sarcastic of 0.2145. The F1-sarcastic of BLSTM with attention layer was 0.2336.

5.5 Google's T5

Based on the hyperparameters listed in the Section 4, our F1-sarcastic for this model is 0.4038. However, we believe that we may get better results by increasing the tokenization max length, increasing the batch size, and utilizing the t5-large pre-trained model.

6 Conclusion

In this study, we reviewed and contrasted a number of sarcasm detection methods. To improve the performance of our model, we experimented with two different types of augmentation. In the job of sarcasm detection, we observed that mutation-based data augmentation can assist us in achieving better results than generative-based data augmentation. Additionally, we tested with other deep-learning techniques, including RNN and BERT-based models. Our best system, an ensemble model, has an F1-sarcastic of 0.414.

Acknowledgements

We want to convey our heartfelt gratitude to Prof. Yadollah Yaghoobzadeh, who provided us with invaluable advice during our research.

Abstract

The "iSarcasmEval - Intended Sarcasm Detection in English and Arabic" task at the SemEval 2022 competition focuses on detecting and rating the distinction between intended and perceived sarcasm in the context of textual sarcasm detection, as well as the level of irony contained in these texts. In the context of SemEval, we present a binary classification method which classifies the text as sarcastic or non-sarcastic (task A, for English) based on five classical machine learning approaches by trying to train the models based on this dataset solely (i.e., no other datasets have been used). This process indicates low performance compared to previously studied datasets, which indicates that the previous ones might be biased.

1 Introduction

One of the most challenging tasks facing natural language processing (NLP) is the automatic figurative language detection (Gifu Daniela, Samson Mihai, 2021), (C. Van Hee, E. Lefever, and V. Hoste, 2018), such as humor, sarcasm or irony. In general, this way of expressing takes advantage of linguistic elements in order to project complex and explainable meanings. In this paper, we investigate the binary classification models for figurative language, as is sarcasm (Dan Alexandru and Daniela Gîfu, 2020). In general, it is omnipresent on the public space, being disruptive of computational systems that harness this data to perform tasks such as opinion mining and sentiment analysis in elections (Gîfu, Daniela, 2010). The political actors themselves introduce a specific language based on sarcasm or irony, making their message analysis very challenging (Reyes, Antonio and Rosso, Paolo and Buscaldi, Davide, 2012). In order to identify the figurative meaning of a specific message, it is required to encode each sentence separately. The research question guiding this paper is what are the most efficient sarcasm detection algorithms? We propose an approach based on three classical machine learning (ML) approaches by trying to train the models based on this dataset solely (i.e., no other datasets have been used). Furthermore, we experimented with architectures ranging from Naïve Bayes (multinomial, complement and bernoulli variants), Support Vector Machines (SVMs with linear, polynomial and RBF kernels) to Logistic Regression which we tried to train using only the dataset provided by the SemEval-2022 Task 6 competition (Ibrahim Abu Farha, Silviu Oprea, Steven Wilson, and Walid Magdy, 2022). The rest of the paper is organized as follows: section 2 briefly presents studies related to sarcasm detection, section 3 presents the dataset, the required pre-processing and plausible methods for it, section 4 resumes the results of the conducted experiments, with their interpretations, followed by section 5 with the conclusions.

2 Related work

This topic is a widely researched subject in recent years, evidenced in this competition at several workshops (e.g., SemEval-2017 Task 4: Using Sarcasm Detection for Enhancing Sentiment Classification and Quantification or SemEval-2018 Task 3: Irony Detection in English Tweets). Such a competition is challenging, especially since the problem of labeled data is time consuming and not cheap. Moreover, the automatic sarcasm detection depends on the annotation process, which always introduce some biases to the data. For the binary task, as in this case, there are many computational models to solve it or to capture the (actual) sarcasm or subcategories of it (John S. Leggitt and Raymond W. Gibbs Jr. , 2000) (Silviu Oprea and Walid Magdy, 2020). Thus, work on this topic was never followed by high results, as this problem is still debatable and text classification even for humans is very controversial and biased. It is a task that can be considered as sentiment analysis for which most of the authors used LSTM (Dzmitry Bahdanau, Kyunghyun Cho, and Yoshua Bengio, 2014), (Zichao Yang, Diyi Yang, Chris Dyer, Xiaodong He, Alex Smola, and Eduard Hovy, 2016) or CNN (Yi Tay, Anh Tuan Luu, Siu Cheung Hui, and Jian Su, 2018) and (Tao Shen, Tianyi Zhou, Guodong Long, Jing Jiang, Shirui Pan, and Chengqi Zhang, 2018). New approaches concentrate on using attention-based methods (Joshi et al., 2017), in particular transformer architectures such as BERT (Devlin, Jacob and Chang, Ming-Wei and Lee, Kenton and Toutanova, Kristina, 2018), RoBERTa, spanBERT (Amardeep Kumar, Vivek Anand, 2020) etc. These transformers are pre-trained on unlabeled data to be later fine-tuned for a variety of tasks like single sentence classification, sentence pair classification, etc. to understand role of context for sarcasm detection. Here, we used five machine learning approaches by trying to train the models based on this dataset solely (i.e., no other datasets have been used).

3 Dataset and Methods

This section is focused on two issues: Twitter dataset in English and two types of methods for classification task, both binary and multi-class. For the first type, we mostly tried classical machine learning approaches that resulted in satisfactory outcomes when evaluated on the training set. On the second one, a RNN with a few GRU layers was the architectural choice. At this moment, the results were modest, probably due to the lack of to much data (it is empirically known that neural networks require a high volume of data to work properly)

3.1 Dataset

The dataset that this competition provided consists of 3468 samples. Each sample is made of a short tweet and 8 binary columns which specify whether or not the text belongs to a certain class. The target column in the binary classification case is ”sarcastic” while the other 7 (sarcasm, irony, satire, understatement, overstatement, rhetorical_question, ambiguity) compose the outputs for the multi-class scenario. At a first glance, we can clearly see that the data is heavily unbalanced. However, this is pretty standard and conforms to the reality where, for example, only a few people are sarcastic, ironic or satirical and so on. Sure, data imputation methods could have been useful (for example, replacing the words of each text with the corresponding synonyms and adding the new texts to the dataset or doing some sort of oversampling on the positive label texts that are heavily lacking in examples) to make the set a little bit bigger but we chose to just stick to what was given! In the following picture (Figure 1), you can see a bar-chart of how the output column labels are distributed across the dataset.

One big inconvenience that we observed is the presence of many 0s in the target columns. This is difficult to solve since replacing nans with certain labels is not tractable. In the end, we went forward with the missing values. Before getting into the proper implementation details, we want to present an image of the overall architecture (Figure 2) so that every step is clear right from the start. The right arrows in the image define transitions from one step to another. A step title is written inside a cloud and the boxes under it are nothing but its definitory operations.

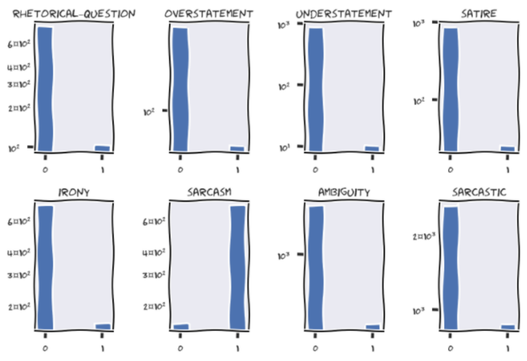

Figure 1: Bar charts of the labels distribution. The Y axis represents the counts for each value that the labels take.

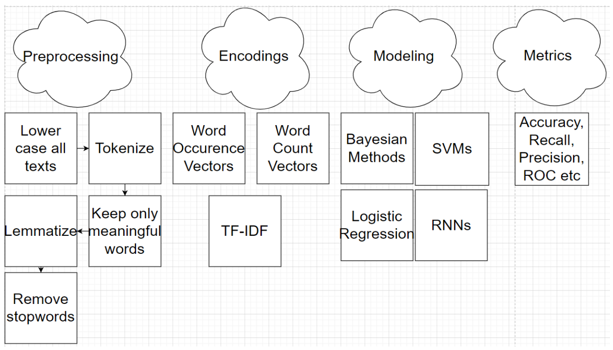

Figure 2: The architecture is made out of 4 parts. The separation between them is made through arrows.

3.2 Methods

3.2.1 Pre-processing

Before talking about the machine learning models, we will explain the pre-processing step that had to be done in order to ”clear” the data. First, we lowered all the training texts and tokenized them into words. Since many compound words could exist (e.g. ”state-of-the-art” or ”equality”; note that these are not actual words from the set) the natural thing to do is to split them by space. After that, for each sample, we are left with lists of words only, hence getting rid of the non alphanumeric words is advisable (the punctuation marks do not add any real value to our task). Another requirement is the lemmatization of the words. We want the root forms of our words in order not to consider multiple derivations of the same word as different (e.g. ”goes” should be the same with ”go”, ”going” or ”gone” and so on). Now, as a final touch, we eliminate the stopwords (the stopwords list is taken from the corpus class of the nltk library) since they don’t add any value to our models. We also built a vocabulary which contains all the unique words of the corpus and this will help us when constructing the numerical representations. Given the processed texts, we can start the well known one hot, doc-term and tf-idf encodings. For each one of them, we define a matrix where the rows represent the indexes of the texts and the columns are nothing but the words from our vocabulary. In the case of one-hot representation, one cell is either 1 or 0, noting the apppearance of a word (column) in the text (row). Alternatively, doc-term counts the number of appearances of a word in a text while tf-idf is built on top of doc-term and gives some scores according to the frequencies of the terms. All of these encodings were used with different machine learning methods.

3.2.2 Classical Machine Learning Approaches

As a first approach to classification we tried bayesian methods. We chose them because they are fast to build and have low variance. As another plus, the performance is very good with both small training sets, as well as big ones. Having a reputation as a bad estimator, but a decent classifier, we decided that it’s a good starting point (please note that the previous statements can be deducted from the books (Tom M. Mitchell, 1997), the Bayesian Learning Chapter and (Christopher Bishop, 2006), the Graphical Models chapter). Throughout time, NB has been the most used one when it comes to NLP tasks and we thought that our numerical representations could work very well on it. Bernoulli Naïve Bayes (BNB), Multinomial Naïve Bayes (MNB) and Complement Naïve Bayes (CNB) are the options we have through the scikit-learn library. BNB deals with binary features, hence one-hot encoding is the only choice here. Multinomial Naïve Bayes works with word counts or word scores, therefore doc-term and tf-idf representations are the way to go in this direction. As a last resort, we also tried a CNB because, according to the scikit documentation (Complement Naive Bayes documentation of scikit), CNB is an adaptation of the standard MNB algorithm that is particularly suited for imbalanced data sets, just like ours. The inventors of CNB show empirically that the parameter estimates for CNB are more stable than those for MNB. Further, CNB regularly outperforms MNB (often by a considerable margin) on text classification tasks (Jason D. M. Rennie, Lawrence Shih, Jaime Teevan, David R. Karger). It is well known that logistic regression is the discriminative correspondent of Naïve Bayes. Moreover, if the conditional independence supposition of NB is true and the amount of training data tends to infinite, the 2 models should give similar results. Therefore, we tried to fit a logistic regression on our data to check the previous statement (these statements are based on the Generative and discriminative classifiers (Tom M. Mitchell) book chapter). Moving onto the next level, support vector machines (SVMs) come into play. Considering that each numerical representation has lots of features (words) and only a few lines (samples), the dual form is preferred, since the complexity is O(rows) (rows are the number of samples). Besides this, we work with the soft-margin SVM because it allows us to avoid overfitting through the slack variable. When it comes to kernels, we had 3 options. The first one we chose is the linear kernel (a.k.a the ”no kernel”) because in a very high dimensional space as ours, it's plausible to find a good separating hyperplane. After that, we decided to try a polynomial kernel as well. This one maps our data into a higher dimension, hoping to find a better suited hyperplane. The degrees used were 2 and 3 and we compared the results with the previous model. In the end, the RBF kernel seemed to be the natural step forward because it's the only one that is guaranteed to find a separating hyperplane by mapping the features into an infinite dimensional space. The hyper-parameters gamma and C (the weight of the slack variables) were chosen with a randomized grid search (no specific random seed, we just used the scikit default option) with cross validation. In other words, different values from 2 exponential distributions have been generated to each hyper-parameter and then, a SVM was applied. The one that gave the best results at cross validation was kept.

3.2.3 Deep Learning Approaches

Even though it was not the main target of the project, we chose to take a closer look at the other classes of the dataset and fit a neural network that could be the starting point of some future work. On the multi-class classification, as we've said, we fitted a RNN. However, this was not a classic RNN, since those lose to much early information. To mediate this problem, we thought that GRU hidden layers (HL) are a good option. Moreover, due to the lack of data, we had to stick to a number of 3 hidden layers only. Each one of them has 10 neurons. The output layer is, of course, a 7 neurons dense layer with softmax activation. To avoid overfitting, we also added a dropout of 10% on each HL. When it comes to the input layer, the situation is a bit different. Given that each text sample has a different number of words, some padding had to be done. Therefore, we calculated the length of the longest words sequence sample and padded the rest of the samples with 0 until we would obtain that maximum length for each training observation. The last requirement was a word2vec matrix where the indexes represent a word and the columns are the dimensions of our numerical mappings. This number of dimensions was chosen by us to be 5 because we don't have that many words. To speed up the training process, a batch normalization layer was used immediately after the input layer. The results were not the best, as we will see in the next section. We definitely needed more training data.

4 Results and Interpretations

We would like to make it clear that the results have been obtained on the training set here, since we didn't have a test set available at the time we were working on the project. Moreover, the results should be viewed with caution since the models have been trained on a small sized data set that has not to many samples, hence not to many words. A big problem arises: what do we do when the future testing samples don't contain words we've seen before? To answer this, one could simply drop the unseen words and focus on those seen only. Moving on, the main metrics we have used throughout the project are: recall, precision, F-score, balanced accuracy, accuracy and the ROC graph. It's worth noticing that the metrics have been evaluated on all the numerical representations we have mentioned before. We will start with the Naïve Bayes algorithms since these were the ones that surprisingly produced the best results (Table 1).

Bear in mind that the results have obtained on a multinomial variant with doc-term numerical representation. We can clearly see that there is a difference between the accuracy and the balanced accuracy of 8%. This is quite a big percentage, but not as big as other models resulted. Of course, the standard accuracy is not very relevant since the data is imbalanced, hence one should pay attention to the balanced accuracy more. When it comes to precision and recall on the negative labels (i.e., the not sarcastic texts), the system is very precised. Both a high sensitivity and high precision are what you would normally want from a system. In other words, the non-sarcastic texts are very well classified. On the positive labels, although not as big, the rate on recall and precision maintains at a strong above 80% percentage. Judging by the F-scores, we are pleased with the result, however, as we've said in the previous chapter, Naïve Bayes is a good classifier, but a bad estimator, so even though the results are great, the independence supposition in this case is very general and wide and tricks the statistical principles. The results for the rest of the other NB variants are given in Table 2 and Table 3.

Moving on to logistic regression, we can see that the results are really far away from NB. Therefore, we can definitely say that the Naïve Bayes independence supposition here is strongly untrue. We can see that the recall on the positive labels is very small, but the precision is almost close to 100%. In other words, among all the texts that are positive in reality, only a small percentage of them are classified as positive, but those that are predicted positive, are done so with very high certainty. So, we could say that someone who is interested in getting a very precised sarcastic prediction should choose this model. Also, an interesting observation that we can draw from all the analysed algorithm results is that a high recall on the positive class leads to a high precision on the negative class and alternatively a high precision on the positive class leads to a high recall on the negative class (Table 4).

The support vector machines are the ones that behaved the most poorly among the tried models. This is somehow weird since most of the articles out there indicate SVMs as the best option for binary classification in NLP when having little data. As mentioned before, we tried different kernel variants, but nothing good came up, unfortunately.

The polynomial kernel seems to have given the best results, but these are weak. Table 5 and Table 6 are associated to the linear and polynomial variants. Judging by the F-scores and balanced accuracy, we can easily conclude that the bayesian methods are behaving way better. What we found to be very curious is the fact that the randomized grid search didn't give any good SVM, even after 200 iterations and generous exponential distributions for "C" and "gamma" hyper-parameters. For this reason, we chose to skip showing the results for the RBF kernel. In the end, we will look at the ROC curve (Figure 9) that sums up all the models that we fitted in our project. Again, the curve with the highest area under it is the Multinomial Naïve Bayes one. The other curves just seem to overlap, firmly bellow the best one!

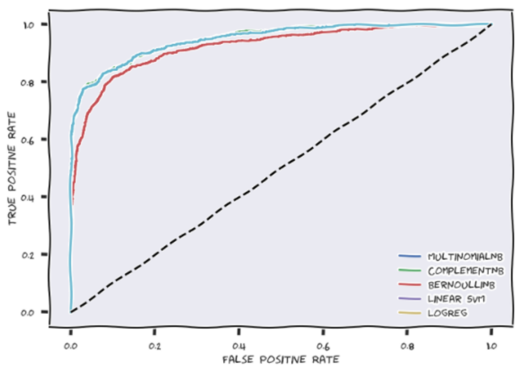

Figure 3: ROC curve

5 Conclusion

For sarcasm classification task (binary or multiclass), a small dataset is a really challenging. The classical machine learning approaches we have presented so far cannot answer convenient to it. This lack of data is a big downside because it means that not many words are numerically encoded, hence having the same vocabulary on a testing set is absolutely mandatory. In practice, it is very rarely. We may conclude that the best model is the Multinomial Naïve Bayes one, but again, it is not guaranteed that it has not overfitted the training data. In the future, some more attention could be payed to the neural network if data imputation is done and the dataset reaches a reasonable number of samples.

`{maryam.najafi, ehsan.tavan}@partdp.ai`

Abstract

The paper describes SemEval-2022's shared task "Intended Sarcasm Detection in English and Arabic." This task includes English and Arabic tweets with sarcasm and non-sarcasm samples and irony speech labels. The first two subtasks predict whether a text is sarcastic and the ironic category the sarcasm sample belongs to. The third one is to find the sarcastic sample from a sarcastic sample and its non-sarcastic paraphrase. Deep neural networks have recently achieved highly competitive performance in many tasks. Combining deep learning with language models has also resulted in acceptable accuracy. Inspired by this, we propose a novel deep learning model on top of language models. On top of T5, the architecture uses an encoder module of the transformer, followed by LSTM and attention to utilizing past and future information, concentrating on informative tokens. Due to the success of the proposed model, we used the same architecture with a few modifications to the output layer in all three subtasks.

1 Introduction

Sarcasm is a sophisticated form of expression that implicitly conveys the content of a sentence. Automated sarcasm detection focuses mainly on the lexical, syntactic, and semantic levels of text analysis Hazarika et al. (2018).

Natural language understanding(NLU), dialogue systems, and text mining can benefit from sarcasm detection. Arguably, the most challenging part of sarcasm is its rarity, infrequency, difficulty in detecting, and ambiguity in meaning. Sarcasm, for instance, can imply a negative meaning with the use of positive words. For example, "Taxes are just the best, and I cannot wait to pay more 🥰 🥺 😇" a sarcastic sentence that uses positive words but carries a negative meaning of "I dislike paying taxes." As a result, detecting sarcasm poses a challenging task due to the nature of sarcastic texts, which are influenced by several factors, such as context, region, and mentality.

A sarcasm detection algorithm goes beyond sentiment analysis, and instead of looking at sentiment in a sample, it focuses on sarcasm. The purpose of this field is to identify whether a given text is sarcastic or not.

Recently, it has been shown that neural language models trained on unstructured text can implicitly store and retrieve knowledge. Studies have revealed that the Text-To-Text Transfer Transformer (T5) architecture Raffel et al. (2019) can achieve high performance for various NLP applications. An essential step in creating NLP models is choosing an appropriate embedding vector. In this research, the T5 and Multilingual T5 (MT5) (Xue et al., 2020) Encoder module for English and Arabic was implemented, respectively. Our task is comprised of three Subtasks:

- Subtask A: Predict the sarcastic nature (sarcastic or non-sarcastic) of a sample.
- Subtask B: Determine which one of the irony speech categories the sample belongs to.
- Subtask C: Given two samples, determine which one is sarcastic.

There are insufficient instances in the dataset for this task, particularly the low number of sarcastic instances which make deep learning models unsuitable for extracting text features. Fine-tunning the language model on two large open-source datasets in English and Arabic is the key to solving this challenge. A fine-tuning step may provide the model with valuable awareness of task context. For the English task, the dataset of 4,484 tweets named iSarcasm (Oprea and Magdy, 2019) was selected, while for the Arabic task, the dataset of 10,547 tweets Farha and Magdy (2020) was chosen.

[*]Equal contribution. Listing order is random.

This research uses the t5 language model as a word embedding layer to design the sarcasm detection model. After T5, the encoder module of the transformer, the Long Short Term Memory (LSTM) (Hochreiter and Schmidhuber, 1997) layer, and scaled dot-product attention (Vaswani et al., 2017) were implemented sequentially for extracting the informative knowledge. Lastly, the model was fed an output from max-pooling. The same model has implemented all three subtasks, changing the input and output layer types.

To participate in Task 6 of SemEval-2022 Abu Farha et al. (2022), we submitted the results of 5 subtasks. The ranking of our model in subtask A ranked 7th in English and 31st[1] in Arabic. Our model placed 9th out of 22 teams in subtask B. In subtask C, our model placed 7th out of 16 teams in English and 3rd out of 13 teams in Arabic. Our code is available at GitHub[2] for researchers.

The remaining of this paper is organized as follows: Section 2 reviews related work. Section 3 describes both tasks and provided dataset. Section 4 presents the theoretical background of the proposed neural model. Implementation details are provided in Section 5, while experiments and results are presented in Section 6. Section 7 presents both quantitative and qualitative error analysis. Section 8 contains paper conclusions.

2 Background

It is pointed out in Javdan et al. (2020) that sarcasm can alter the meaning of a phrase, making opinion analysis error-prone. Subsequently, a model by BERT and aspect-based sentiment analysis is employed to address the issue. Based on the context dialogue sequence, this system can determine whether a response is sarcastic or not, with an F1-score of 0.73 on Twitter.

In Dadu and Pant (2020), as in Javdan et al. (2020), the researcher used two Reddit and Twitter datasets and applied Roberta-large to detect sarcasm in both datasets. González-Ibánez et al. (2011) investigates lexical (like uni-grams and dictionary-based) and pragmatic (like positive or negative emotions) features and compares the performance of machine learning techniques and human judges.

[1]There was an error in submitting this subtask. In the results section, we provide the true results of the proposed model for subtask A .

[2]`https://github.com/MarSanTeam/Sarcasm_Detection`

Since the meaning of sarcasm differs for each individual and may lead to misunderstandings in everyday communications, Hazarika et al. (2018) claims that user embedding can encode the stylistic and personality attributes of users, and combined with Convolutional Neural Networks (CNNs) (LeCun et al., 1999) that extracts localized information, the results are reasonable.

Kumar et al. (2020) introduce a binary classification deep learning model for sarcasm detection. Kumar et al. use Bi-LSTM and Multi-Head Attention Mechanism to obtain sentence embedding and classify input text with a softmax layer.

RoBERTa network architecture is utilized in Potamias et al. (2020) to map words onto a rich embedding space efficiently. To improve RoBERTa performance and capture temporal reliance information, use the RCNN network.

3 Task Description

Task 6 of SemEval-2022 presents a Sarcasm Detection dataset in English and Arabic.

Statistical information on the number of samples in the train, dev, and test data is shown in Table 1. Since there was no official dev set at the evaluation phase, we randomly selected 10% of the dataset as the dev data.

Dataset	train	dev	test
Subtask A (English)	3121	347	1400
Subtask A (Arabic)	2792	310	1400
Subtask B	780	87	1400
Subtask C (English)	780	87	200
Subtask C (Arabic)	670	76	200

Table 1: Statistical information of datasets

A description of the subtasks is provided in the following sections.

3.1 Subtask A

In this subtask, the model should determine the sarcastic or non-sarcastic nature of the text. Arabic and English texts can be submitted for this subtask.

Figure 1 shows the distribution of sarcastic and non-sarcastic classes in subtask A. There is an imbalance with this data, as only 25% of the samples are categorized as sarcasm, making the training process more challenging.

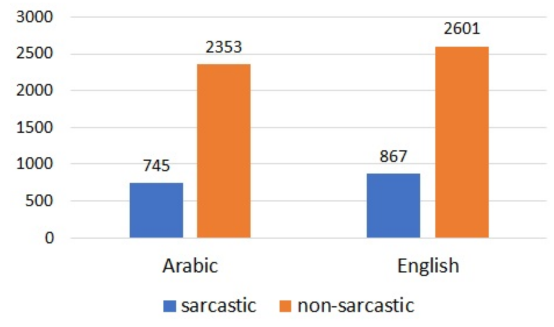

Figure 1: Label distribution in Subtask A

3.2 Subtask B

This subtask is a multi-label binary classification task.

Ideally, the model should predict which category of ironic speech (sarcasm, irony, satire, understatement, overstatement, and rhetorical question) input data falls into. In this subtask, all data is available in English only.

Figure 2 illustrates how irony speech categories (sarcasm, satire, understatement, overstatement, and rhetorical questions) have been distributed. A high percentage of samples are labeled sarcasm, and the lowest, with 10 samples, is for understatement.

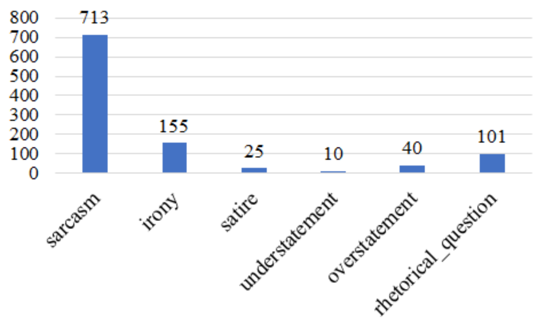

Figure 2: Label distribution in Subtask B

3.3 Subtask C

As part of subtask C, a sarcastic text and its non-sarcastic paraphrase is given to the model. The proposed model should determine which one is sarcastic.

In this Subtask, we have 867 samples in English and 745 samples in Arabic.

4 System overview

Contextual features can be extracted very efficiently with pre-trained language models. In NLP tasks, T5 has proven to be an efficient encoder-decoder framework. Using the encoder layers within the T5 language model, we can fine-tune pre-trained encoder-decoder T5 models efficiently for classification and regression tasks. Pre-trained models ease fine-tuning downstream tasks by reducing the reliance on large task-specific training datasets. Their results can be further enhanced if other deep learning architectures, such as LSTM, CNN, and attention, are applied on top of them (Tavan et al., 2021).

The framework we developed uses the encoder module of T5 and Transformer, Bi-LSTM layer, and scaled dot-product attention to determine whether a text is sarcastic. Also, we apply the same architecture to subtasks B and C but make some changes to the output and input layers, respectively. The proposed model architecture is shown in Figure3.

As part of subtasks A and B, the model gets a sequence of $S = \{s_1, s_2, s_3, ..., s_N\}$, where s_n is the nth token of input text. In subtask C, the inputs are sequence of $P = \{p_1, p_2, p_3, ..., p_I\}$, and $Q = \{q_1, q_2, q_3, ..., q_J\}$, where p_j is the jth token of the first text and q_I is the ith token of the second. The input sequence $S = \{P, < /s >, Q\}$ are the final inputs for subtask C.

Subtask A estimates a sarcastic label based on the probability distribution of $P_r(y|S)$. Within subtask B, the model estimates the probability distribution $P_r(y|S)$ for each category of ironic speech. Finally, subtask C estimates the probability distribution $P_r(y|P, Q)$, predicting whether P indicates sarcasm or Q.

4.1 Word Representation

To obtain vector representations of input tokens, the T5 encoder is used. As mentioned, this model can obtain a contextualized embedding vector for each token in the input text by fine-tuning the T5 encoder.

4.2 Encoder Architecture

The encoder module of the transformer and a Bi-LSTM layer are used sequentially on top of the T5 encoder to extract the contextualized feature.

As a way to extract the relation between tokens, the encoder architecture used in the transformer Vaswani et al. (2017) employs a multi-head attention mechanism. This capability of multi-head attention allows the model to extract relationships between input tokens, which can help identify sarcasm context.

Sarcasm detection can be enhanced by identifying contradictions and long-term dependencies in

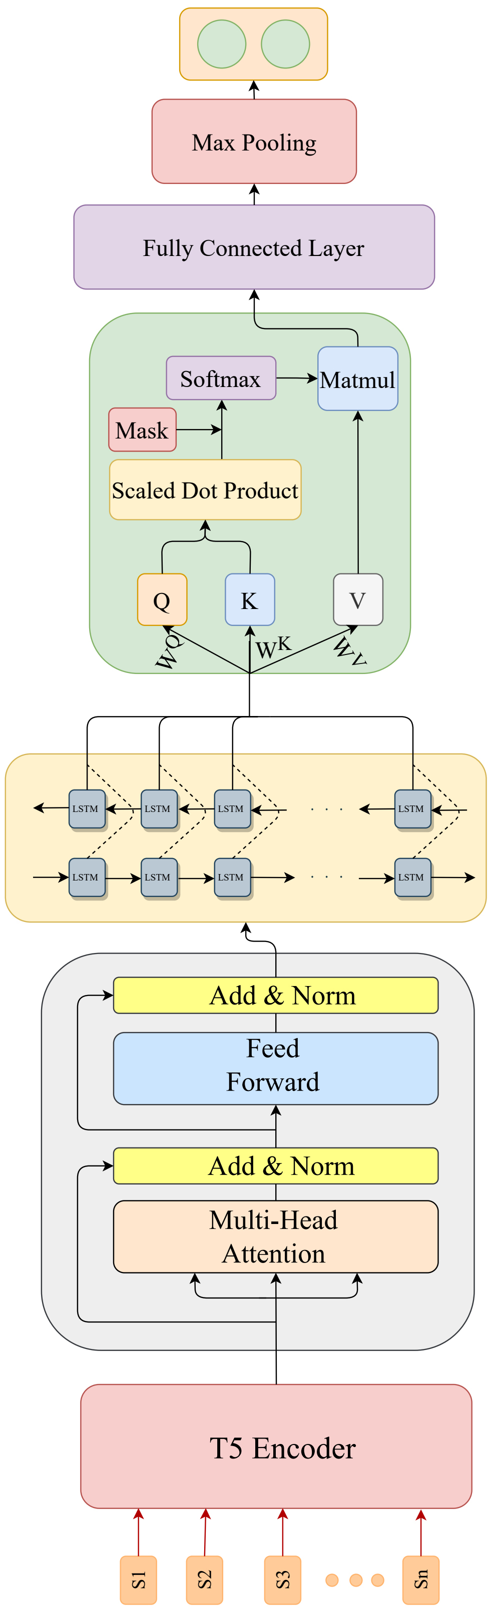

Figure 3: proposed model

a sentence. This information can not be extracted properly from the transformer encoder because of its structure. The challenge can be tackled by using the RNNs layer to extract temporal information and long-term dependencies. Using a Bi-LSTM layer, this can be done in long sequences. The output vector of the encoder layer is calculated by concatenating the Bi-LSTM layer and the transformer encoder output.

4.3 Attention Module

In Bi-LSTM networks, close words are more likely to be correlated with the extracted attribute than words located farther away. In order to extract rich features, scaled dot-product attention assigns different weights to each token. Each token is given a weight based on its importance and relation to a class. Hence, attention can determine the relevance and importance of tokens to identify the label correctly. The scaled dot-product attention above the encoder layer enables the model to capture the importance and relationship between tokens regardless of their distance. The attention module consists of the following components:

$$W_i^Q, W_i^K, W_i^V \in R^{d_{model} \times d_k}$$

$$Q = XW_Q, K = XW_K, V = XW_V \qquad (1)$$

$$Attention(Q, K, V) = softmax(\frac{QK^T}{\sqrt{d_k}})V$$

Among which W_Q, W_K, and W_V are trainable parameters. The input vector X is multiplied by the matrices Q, K, and V in order to create three matrices Q, K, and V. To prevent the dot-product between Q and K from getting too large, the dot-product between Q and K is divided by $\sqrt{d_k}$.

4.4 Prediction Module

To accurately predict sarcasm in a text by utilizing the most relevant and informative extracted features, a fully connected layer with a tanh activity function was first employed. The general representation is then obtained using a max-pooling layer from the same dimensions of different tokens. The max-pooling modules formulate in Equation 2.

$$Z = Max([h_1, ..., h_l]) \qquad (2)$$

Finally, to determine the probabilities of the labels, the softmax classification method is used. The module is a simple softmax classifier that generates probabilities of distributions based on input features. A softmax classifier is used to predict a label $\hat{y}$ from a set of discrete classes(sarcastic or not-sarcastic) for an input sequence S. The softmax classifier takes R as input:

$$P\left(y \mid Z\right) = softmax(WR + b) \tag{3}$$

$$\widehat{y} = argmax P\left(y \mid Z\right) \tag{4}$$

We used six softmax layers to predict the label of each input text in subtask B. The difference between the implementation of the proposed model in single label and multi-label is shown in Figure 4.

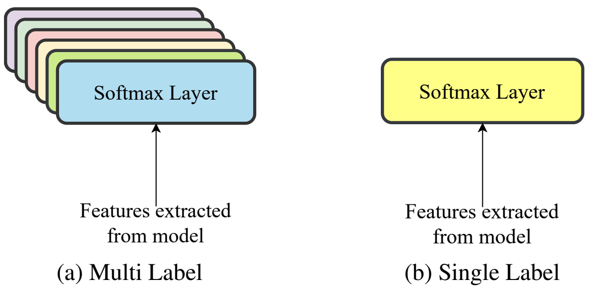

Figure 4: Outline of utput layer used in subtasks.

5 Experimental Setup

In this section, we first describe data pre-processing. Following that, we discuss the implementation details.

Pre-processing Data analysis revealed some samples containing URLs and user mentions. Due to the possibility of these items confusing the model in identifying the correct label, these items were removed in the pre-processing phase. Tokens such as punctuation and emojis were not removed since they could be excellent indicators of sarcasm.

Implementation Details PyTorch was used to implement the model, and we trained it on Nvidia V100 GPUs. Each subtask's hyper-parameters were tuned using the development set. The AdamW optimizer with the learning rate of 2e -5 is used to train the network using the back-propagation algorithm. A training method of early stopping with the patience of 5 and monitoring validation loss of sarcastic class in min mode is used. As for regularization, we evaluate the effect of the dropout on the transformer encoder and the Bi-LSTM layer; the model has a better performance when the dropout rate is set as 0.2, 0.3 respectively.

Each subtask has a batch size of 32. The number of attention heads in the transformer encoder is eight, and the hidden size in the Position-wise feed-forward Layer is 2048. One layer of Bi-LSTM with 128 LSTM units was used. Over the first fully connected layer, we applied tanh, and the output size of this layer was 256. In the case of data imbalance, the cross-entropy loss can be used with class weights. The maximum length used in T5 and MT5 tokenizers is 100. Other parameters are randomly initialized.

6 Results

This section reviews the different baselines and compares them with the proposed model. Due to the success of language models in recent years, we have evaluated different language models to select the most appropriate language model.

Since there was no official test data at the evaluation phase, experiments were conducted on the dev set to select the best architecture. Finally, the performance of the models on the test data is also evaluated.

6.1 Subtask A

Subtask A was evaluated on the F1-score of the sarcastic class. Table 2 Shows the results for subtask A. As can be seen, BERT, T5, and RoBERTa have been evaluated to determine the most appropriate language model. The T5-large and MT5-large achieve a score of 49.47% and 71.53%, respectively, outperforming other language models. It could be caused by the differences in objective learning among the models. In addition, it is worth noting that the BERT-based models predict masked words from the vocabulary and are auto-encoding models, while the T5 uses a text-to-text framework for training, and it is an auto-regressive model.

Table 3 shows the results of implementing the deep learning model. Since T5-large and MT5-large performed well in the initial experiments, they were subsequently used in subtask A. Adding transformer encoders help increase the F1-score on the sarcastic class in subtask A by capturing and focusing the most informative data on top of the language model. In English and Arabic, there was an increase in the F1-score using the transformer encoder due to the presence of multi-head attention in the transformer and the ability of this module to extract the dependencies.

Combining a Bi-LSTM layer results in a higher F1-score. This increase is due to the ability of the recurrent network to extract temporal information

and long-term dependencies. Next, adding scaled dot-product attention improved the F1-score in English and Arabic, reaching 55.11% and 75.16% on the sarcastic class, respectively. A scaled dot-product attention module could improve the model's accuracy by detecting dependencies between words, which is mainly helpful in assisting the Bi-LSTM architecture in identifying spatially spaced apart words.

Finally, as mentioned before, we have also fine-tuned T5 and MT5 on two large datasets in English and Arabic, owing to the deficient number of samples. Using this method, the F1-scores obtained in English and Arabic have reached 58.89% and 76.29%. An improvement in the F1-score can be achieved by the task awareness of the language model.

6.2 Subtask B

The results of different models for subtask B are shown in Table 4. The evaluation metric in this subtask is macro F1-score. As a result of the experiments, it was found that RoBERTa achieves a macro F1-score of 11.34% on test data, which is the highest F1-score. Due to the nature of multi-label binary classification, each of the six classes in this subtask is classified by a separate classifier within the same architecture as subtask A. Our T5-based implemented model in the competition achieved the rank of 9 and F1-score of 7.43%.

Model	Dev	Test

ours in competition	**24.67**	7.43(9)

Table 4: Subtask B: Evaluation result of Language models. Our rank is shown in parentheses.

6.3 Subtask C

Several experiments were performed to select the most appropriate language model for subtask C. Table 5 shows the results of implementing different models on English and Arabic. For this subtask, the evaluation metric is accuracy. Among the tested language models, on dev, the T5 and MT5 reach the highest accuracy among other language models.

For this reason, these models have been used in subsequent experiments. The results of language models are shown in Table 5.

7 Error And Performance Analysis

In this section, we analyze the performance of several components of our system. This section will examine our model's ability to correctly label samples in sarcastic or non-sarcastic contexts.

7.1 Subtask A

There are 1400 samples in the English test set. The model correctly identified 924 samples as non-sarcasm, which means True Negative (TN), and correctly identified 132 samples as sarcasm, known as True Positive(TP). Despite this, 68 sarcasm samples were incorrectly predicted as non-sarcasm, resulting in False Negatives(FN). Lastly, the False Positive(FP) value is very high. There were 276 input samples in this case that were incorrectly predicted as sarcasm samples. According to the results, since about 75% of the data is the negative sample, Data imbalance leads to an FP error rate of about 276 among all predictions.

Error analysis Some samples of post-evaluation on the model's output were examined, in Table 7. According to studies, the most significant effect on the accurate prediction of sarcasm samples is obtained from sentiment and emoji in samples (Type A, B). According to the implemented architecture, the model is more robust for long samples. However, in very short samples (Type C), weaknesses in the estimation are observed.

In addition to analyzing the strengths of the model and the factors that affected them, this section also examined its weaknesses in predicting the sample and the factors that affected them. As mentioned, a major reason is the short length of the input sample. Another reason could be the presence of misspellings (Type D) in the data and the unfamiliarity of the model with the incorrect word. A major reason for the error in estimation can be found in the absence of sentiment and emotion in the text and the fact that the sample is completely based on "human knowledge" (Type E).

As a result, the model has weaknesses in short, humane, and emotionless examples.

7.2 Subtask B

Detailed model results on test data for each label are presented in Table 8. Since the dataset only included one sample of the "understatement" class, the model could not correctly identify the sample's label. The "overstatement" class contains only ten samples, and due to its scarcity and complexity, the model could not predict any of these, so the F1-score on the "understatement" and "overstatement" classes is 0.

Among the remaining 4 classes, the recall value is much higher than the precision of the model, which indicates that the model performed well at

Sample	Prediction type
Type A: Emoji	
Love it when someone with no mask chooses to sit next to me on the bus...😑	TP
Weathers wonderful today! 🌂🌂🌂	TP
Type B: Sentiment	
Wow the Prime Minister is so good at the telling the truth	TP
You on your best behaviour is me on my worst	TP
It makes me feel a lot safer knowing the MET Police don't investigate crimes after they happen.	TP
Yeah, feeding children sweets before bedtime is an awesome way of getting lots of sleep	TP
I swear stupid people were put on this earth to test my anger management skills	TP
Type C: Short samples	
Proof of unjustified victimisation!	FP
Rubbish	FP
Type D: Misspellings	
if you listen carefully, you can hear me not carig	FP
Type E: Human Speech	
Masks work, that's why we don't have to wear them in pubs but do in shops!	FP
Boris Johnson is a great leader and all his team stick to the covid rules rules	FP
I was waiting at the bus stop when the driver pulled up and said you waiting for a bus? I said no mate im waiting for a plane. He drove off.	FP

Table 7: subtask A: Result analysis

Class	Number of samples	TP	FP	FN	TN	Precision	Recall	F1-Score
sarcasm	180	102	748	78	472	12.00	56.67	19.81(19)
irony	20	13	365	7	1015	3.44	65.00	6.53(8)
satire	49	7	135	42	1216	4.93	14.29	7.33(5)
understatement	1	0	10	1	1389	0	0	0(3)
overstatement	10	0	203	10	1187	0	0	0(6)
rhetorical-question	11	9	145	2	1244	5.84	81.82	10.91(3)

Table 8: Subtask B: Error analysis. Our rank is shown in parentheses.

identifying samples that belong to each class. The precision value is very low, which indicates that a significant number of positive predictions are incorrectly categorized as positive.

7.3 Subtask C

Table 9 provides detailed information results for English test data. According to the three evaluation metrics, the model performed well in distinguishing sarcasm samples from non-sarcasm paraphrases.

We have decided not to explain further in this section due to the model's acceptable performance and space limitation.

Sarcasm-id	Precision	Recall	F1-Score
0	79.82	81.31	80.56
1	78.02	76.34	77.17

Table 9: Subtask C: Error analysis

8 Conclusion

We implement a novel deep learning approach based on language models. The last hidden state of T5 is used as an embedding layer in this architecture. On top of this layer, a bidirectional LSTM is used to extract future and past contexts as representations of the input text. LSTM output is processed using an attention mechanism, which focuses more on the valuable tokens to predict.

The main challenge in this study was that there were not enough samples in the dataset. To solve this, we fine-tuned the T5 language model with other large open-source datasets to have a language model that had a pre-awareness of the task and a higher accuracy. This fine-tuned language model was then used as an embedding representation in our deep architecture.

To evaluate the performance of the developed model and find the best language model, many experiments were conducted. The experimental results show that the T5 language model covers a reasonable range of results and is most appropriate for our architecture.

The same architecture was used in all three subtasks, as mentioned earlier. Due to the multi-label nature of subtask B, six separate classifiers were used instead of one to produce the output. We identified specific sarcasm challenges through error analysis, creating immediate future tasks.

As a final point, our architecture has already been created for English and Arabic, but it could be easily extended to other languages.

Abstract

This paper describes the approach developed by the LT3 team in the Intended Sarcasm Detection task at SemEval-2022 Task 6. We considered the binary classification subtask A for English data. The presented system is based on the fuzzy-rough nearest neighbor classification method using various text embedding techniques. Our solution reached 9th place in the official leader-board for English subtask A.

1 Introduction

Sarcasm (or irony) can be defined as a trope or figurative language use whose actual meaning is different from what is literally enunciated (Chandler and Munday, 2011). The task of sarcasm detection can be connected with various challenges in the Natural Language Processing (NLP) field, from sentiment analysis to hate speech detection. However, this task is more complicated by its nature. Even for a human, sarcasm detection could be a challenging issue. It can be represented in different shapes, with voice, gestures, mimic, etc. So, text alone may not be sufficient to detect whether a given utterance is sarcastic or not. It makes the labeling of such datasets quite complicated (Ghanem et al., 2020).

The SemEval competition is an annual event that provides a set of challenges for researchers in different aspects of the NLP field. This year we participated in SemEval-2022 Task 6 called "iSarcasmEval" that considers sarcasm detection in two languages: English and Arabic (Abu Farha et al., 2022). We tackled subtask A for English, where for a given text, we should determine whether it is sarcastic. As described by the authors of the dataset, text writers provided the labels by themselves to exclude subjective labeling. The dataset contains text, its binary label for subtask A (sarcastic or not), a non-ironical rephrase of the provided text with an explanation of why is it sarcastic for subtask C (we did not use it in our experiments), and a set of binary classes for six types of sarcasm (irony, satire, rhetorical question, etc.) for subtask B. We note that the size of the non-irony class for subtask A is three times bigger than the size of the irony class (2,601 instances and 867 instances).

A task related to sarcasm detection is emotion detection issue, which we considered in our previous papers. In (Kaminska et al., 2021b) and (Kaminska et al., 2021a), we addressed the intensity task provided by SemEval-2018 Task 1 (Mohammad et al., 2018). Our first paper used the weighted k Nearest Neighbor (wkNN) classification approach with corresponding text cleaning and embedding steps. In the second paper, we tuned the preprocessing steps and, instead of wkNN, we considered the Fuzzy-Rough Nearest Neighbor (FRNN) classification model with Ordered Weighted Average (OWA) operators ((Jensen and Cornelis, 2011), (Vluymans et al., 2019), (Lenz et al., 2019)). The final approach has the shape of an ensemble of FRNN models based on several strong embedding techniques. The solution described in this paper is based on the methodology presented in (Kaminska et al., 2021a), but it is fine-tuned for the iSarcasmEval dataset and task. Our code is provided at the GitHub repository[1].

The remainder of this paper has the following parts: in Section 2 we provide a step-by-step description of our system, including text preprocessing and the used embedding methods, the classification model and its ensemble, and the evaluation metric. In Section 3 we provide results obtained by cross-validation, and identify the best setup ap-

plied on the test data. It also provides an error analysis of the output and post-competition experiments for model improvement. Section 4 presents conclusions and future steps.

2 System Description

Figure 1 gives an overview of our full method, which encompasses the following steps: we embed the raw text with the Twitter-roBERTa-base for Irony Detection model (Barbieri et al., 2020), then we use the output vectors in the OWA-FRNN classification method to obtain a prediction of classes.

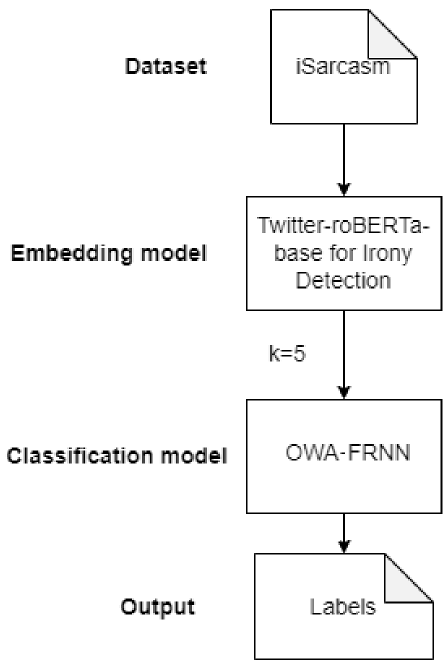

Figure 1: Schematical overview of our architecture.

2.1 Text preprocessing

We manually explored part of the provided dataset and concluded that it has attributes of regular social media posts, like tweets, including user tags, emojis, hashtags, etc. Hence, the first step in our experiments was text preprocessing before we applied text embedding techniques. Initially, we considered three options: no preprocessing, basic cleaning, and extra stop-words removal.

The basic cleaning included deleting the "#" symbol before hashtags and emojis transformation. We did not delete the text of hashtags because it could contain important information about the whole text. Similarly, we kept emojis but replaced them with textual descriptions provided by *"emoji"* package[2].

The third approach of text preprocessing involves the same steps, additionally deleting the stop-words using the *"NLTK"* package[3].

We tried all three text preprocessing setups for each text embedding technique in order to detect the most suitable for each.

2.2 Embedding methods

As a next step of text preparation before classification we investigate different text embedding methods. This technique represents a fragment of text (symbol, word, collocation, sentence, or even paragraph) as a vector (or a set of them). The obtained vector corresponds to the actual text in multi-dimensional vector space with the idea that neighboring vectors represent similar text pieces.

Embedding techniques came a long way from simple bag-of-words and pre-trained dictionaries in a word-vector format to the current state-of-the-art transformer-based solutions and context-based language models. In our method, we explored various types of text embedding techniques: vocabulary Word2Vec from Gensim package[4], sentiment-based DeepMoji[5], Universal Sentence Encoder (USE) by the TensorFlow[6], Bidirectional Encoder Representations from Transformers (BERT), as proposed by (Devlin et al., 2019) and two methods related to BERT - Sentence-BERT (SBERT) by (Reimers and Gurevych, 2019) and the Twitter-roBERTa-based model for irony recognition presented by (Barbieri et al., 2020). As we will see in Section 3.1, the latter performed much better than the others, hence we will describe it in more detail.

The robustly optimized BERT pre-training approach (roBERTa) is comparable to the original BERT model but has a few training technique and architecture differences. In (Barbieri et al., 2020), the authors described several roBERTa-based models for different tasks, for example, hate speech recognition and emotion detection. We considered the one for irony classification[7] that was trained on nearly 58M tweets and fine-tuned on the dataset from Subtask A of the SemEval2018 challenge for Irony Detection presented by (Van Hee et al., 2018).

[2]https://pypi.org/project/emoji/

[6]https://www.tensorflow.org/hub/tutorials/semantic_similarity_with_tf_hub_universal_encoder

[7]https://huggingface.co/cardiffnlp/twitter-roberta-base-irony

This model can perform classification directly, but instead we used it to extract tweets' weights from the inner model's layer as their embedding vectors. We will discuss this further in Section 2.3.

2.3 OWA-FRNN classifier

Most state-of-the-art approaches for tasks such as irony detection belong to the deep learning family, and therefore remain black-box solutions. Our idea was to try a more explainable technique based on the Fuzzy-Rough Nearest Neighbor (FRNN) method that already showed promising results in our previous work (Kaminska et al., 2021a).

The FRNN classification model was introduced in (Jensen and Cornelis, 2011). It is an instance-based approach that uses lower (L) and upper (U) fuzzy-rough approximations inside the classification process. In (Vluymans et al., 2019) and (Lenz et al., 2019), FRNN extensions were described based on the Ordered Weighted Average (OWA) operators with the aim of making the method more robust. OWA operators are used to define the membership of a data instance to the lower and upper approximation through an aggregation process.

We will use the following notation: V is the set of OWA aggregation values, where $v_{(i)}$ is the i^{th} largest element of the set V; the weight vector is denoted as $\overrightarrow{W} = \langle w_1, w_2, ..., w_{|V|}\rangle$, where $(\forall i)(w_i \in [0,1])$ and $\sum_{i=1}^{|V|} w_i = 1$. Then, we will have the following formula for the OWA operator:

$$OWA_{\overrightarrow{W}}(V) = \sum_{i=1}^{|V|}(w_i v_{(i)}) \quad (1)$$

We used additive OWA operators (Vluymans et al., 2019), as they performed the best in our previous paper. They are linearly increasing for lower and linearly decreasing for upper approximations. Additive weights are presented by the Formulas (2) and (3), where p denotes the length of the vector ($p > 1$).

$$\overrightarrow{W}_L^{add} = \langle \frac{2}{p(p+1)}, \frac{4}{p(p+1)}, ..., \frac{2(p-1)}{p(p+1)}, \frac{2}{p+1} \rangle \quad (2)$$

$$\overrightarrow{W}_U^{add} = \langle \frac{2}{p+1}, \frac{2(p-1)}{p(p+1)}, ..., \frac{4}{p(p+1)}, \frac{2}{p(p+1)} \rangle \quad (3)$$

OWA-FRNN assigns a test instance y to the class C with the highest sum of $\underline{C}(y)$ and $\overline{C}(y)$:

$$\underline{C}(y) = OWA_{\overrightarrow{W}_L}\{1 - R(x,y) \mid x \in X \setminus C\} \quad (4)$$

$$\overline{C}(y) = OWA_{\overrightarrow{W}_U}\{R(x,y) \mid x \in C\} \quad (5)$$

Here, $R(x,y)$ corresponds to the similarity between vectors x and y. In our experiments, we used cosine similarity:

$$cos\_similarity(A,B) = \frac{1 + cos(A,B)}{2}. \quad (6)$$

Where $cos(A,B)$ is the cosine distance between elements A and B:

$$\cos(A,B) = \frac{A \cdot B}{||A|| \times ||B||} \quad (7)$$

For our setup, A and B denote tweet embedding vectors, $A \cdot B$ is their scalar product, and $||A||$ is the vector norm of A. We considered similarity instead of distance because Formula (6) provides values that fit our classification method: 0 for opposite vectors and 1 for identical ones.

One more parameter that we need for Formulas (4) and (5) is k - the number of nearest neighbors of test instance y. The difference between k in Formulas (4) and (5) is that for the first, it corresponds to the amount of training samples that are y's neighbors outside class C and for the second - those inside class C. The parameter k is used to limit the calculations and, just as for wkNN, there are no general rules on how to choose it. Hence, we will tune this parameter for each model separately.

We used the OWA-FRNN approach as the primary classification technique, with a Python implementation[8] provided by (Lenz et al., 2020).

2.4 Ensembles

To improve our results, we considered the usage of models' ensembles. The ensemble combines several classification models' outputs to provide the final prediction. The idea behind it is to improve the performance of a single model by combining it with other models to fuse their advantages.

We tuned the best setup for each embedding method separately (with parameters as text preprocessing and a number of neighbors k) and then united them in an ensemble. As a combination method for models outputs, or in other words, "a

[8] `https://github.com/oulenz/fuzzy-rough-learn`

voting function", we used the mean. We tuned the set of the models used in the ensemble to prevent weak models from decreasing the final score. All obtained results are presented in Section 3.

2.5 Evaluation

To compare different approaches on the train data, we used a 5-fold cross-validation technique by splitting the provided dataset into train and test data with an 80/20 ratio.

As an evaluation metric for predicted labels and actual labels, we used the F1-score (Formula (8)) calculated for the sarcastic class, as was suggested by the competition organizers.

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall}, \qquad (8)$$

where by $Precision$ we mean the fraction of accurately predicted sarcastic labels from all predicted test labels, and by $Recall$ we refer to the fraction of accurately predicted sarcastic labels from all actual sarcastic test labels. The highest value of the F1-score corresponds to the best model.

3 Results

This section consists of several parts. In Subsection 3.1 we provide an overview of our experiments, using cross-validation on the train data to identify the best model for irony detection and evaluate its result for test data. In Subsection 3.2, we describe error analysis and illustrate the explainability of our approach. We also performed additional experiments after the competition was finished and labels for the test data released to improve our scores and present this process in Subsection 3.3.

3.1 The best setup

Firstly, we evaluated the OWA-FRNN classification model on each embedding method separately by tuning the number of neighbors k and text preprocessing techniques. The best setup for each embedding method with the best parameters and corresponding F1-score for the sarcastic class is shown in Table 1.

Table 1 lists all methods in decreasing order by F1-score. The best result was obtained with the roBERTa-based model with a noticeable gap for the next method - DeepMoji. It can be seen that for almost all embedding techniques, the value of k is equal to 5, whereas for text preprocessing, no particular pattern was observed.

Table 1: Cross-validation best F1-scores for different embedding methods and corresponding setups.

Method	**Text**	**k**	**F1 sarcastic**
roBERTa	raw	5	**0.3722**
DeepMoji	cleaned	5	0.3157
USE	raw	5	0.2808
BERT	cleaned, no stop-words	5	0.2351
Word2Vec	cleaned, no stop-words	5	0.2050
SBERT	raw	7	0.1618

Table 2: Cross-validation F1-scores for ensembles of embedding methods.

Embeddings	**F1-score**
All six	0.0995
TOP-5	0.1866
TOP-4	0.1317
TOP-3	0.2941
TOP-2	0.1866

Secondly, we combined different embedding methods with their best setups as an ensemble. We calculated the mean for all embedding methods, then for the top-5 (excluding the weakest one - SBERT), top-4 (excluding Word2Vec and SBERT), and so on, until the single top model roBERTa is left. The results are presented in Table 2.

From Table 2 we can see that ensembles provided lower scores than single models. The standalone roBERTa performed better than in ensembles with others, which could already be expected from Table 1, where the gap between the roBERTa method and the rest is remarkable.

Hence, we can conclude that the best setup has the following components: no text preprocessing, roBERTa-based embedding technique for vectors extraction, and an OWA-FRNN classification model with a number of neighbors $k = 5$. This setup was applied to the test dataset.

We calculated labels for the test data using this setup and submitted them to the competition to obtain **F1-score = 0.4242** for the sarcastic class, leading to a **9th place** in the leader-board. Meanwhile, we received higher places for some other metrics: 7th place for averaged F-score = 0.6552 and precision = 0.6422, and 8th place for accuracy = 0.8100.

3.2 Error analysis

For the error analysis, we could rely on the fact that the OWA-FRNN classifier we experimented with has the advantage of being more explainable compared to many other black box approaches. In our case, we mean that we can trace back the test instance and see which five instances from the train data determined its class.

Initially, we traced back several correctly predicted test tweets to see if it was possible to notice any patterns. For example, for the sarcastic test tweet *"So the Scottish Government want people to get their booster shots so badly that the website doesn't even work"*, we got four sarcastic training neighbors out of five. Four neighbors were connected to the health topic and contained collocations such as *"mental health"*, *"health insurance"*, *"covid vaccine"*, and *"healthcare"*. The fifth neighbor was about emails that could be connected to *"website"* word from the test tweet. From this sample, we could conclude that having a common topic is an important feature for neighbors detection and our model deals well with it, as we also noticed from exploring other test samples.

As for wrong predictions, we also found an illustrative example for the sarcastic test tweet: *"Sometimes I lay in bed and think about how today will be the day I make my life better. Exercise, drinking water, eating healthy. Then I wake up."* It has four training neighbors about daily routine and lifestyle with mostly non-sarcastic labels, leading to the wrong prediction. For example, the closest training neighbor *"me: I'm gonna wash my hair and shave my legs! Me instead: I'm gonna dissociate in the shower for 45 minutes"* looks pretty similar to the test sample but has a non-sarcastic label. Here, we could highlight again the difficulty of sarcasm dataset labeling and how subjective it could be.

In general, we can see that topic could be a strong feature. However, the same concept could have different meanings in different topics (for example, *"temperature"* in weather or fever). Also, some neighbors have the same emojis as a test instance that can give a hint about emojis importance.

3.3 Model improvements

After the test labels were released, we experimented with more setups to improve our final F1-score.

First, we used other values of the parameter k that showed mediocre results on cross-validation to see how they perform on the test data. For example, we observed that for $k = 17$, we receive an F1-score with cross-validation equal to 0.3408, which is lower than our best setup. However, on the test data, this value of k provided us an F1-score equal to 0.5, which is more than what we got in the leader-board and would lead us to fourth place.

Secondly, we considered the usage of the weighted k Nearest Neighbors (wkNN) algorithm (Dudani, 1976). This approach is close to OWA-FRNN, and we already worked with it in our previous paper (Kaminska et al., 2021b) for the emotion detection task. The wkNN works with k closest neighbors and puts weights based not on the OWA operator but on the neighbors' distances. As a similarity function, we used cosine again.

To test the wkNN method, we applied it inside our best setup - roBERTa-based embedding vectors obtained from the raw tweets and $k = 5$. We got an F1-score for the sarcastic class of 0.3569 with cross-validation and 0.4299 for the test data. We can see a minor improvement for the test data, compared to our final scores from the leader-board.We also checked this setup for $k = 17$ and obtained a sarcastic F1-score for cross-validation equal to 0.2790 and 0.4969 for the test data. It would also top us up to the fourth place, and so in general, we can see that results for the OWA-FRNN and the wkNN methods in our setups are pretty close.

4 Conclusion & Future Work

In this paper, we presented our model for the iSarcasmEval competition. Our solution uses the instance-based classification method OWA-FRNN and a roBERTa-based model for Irony Recognition as an embedding method. We fine-tuned the best setup on the train data with cross-validation and obtained the ninth place on the test data in the competition leader-board.

Our approach is explainable in a way that we can trace back the test instance and find the training instances that determined the predicted class to explore some patterns. For example, we observe the significance of the tweet topic and even of particular keywords.

In the future, the provided solution may be improved by additional text preprocessing techniques or roBERTa-based model fine-tuning using additional datasets.

Abstract

In this paper, we present our system and findings for SemEval-2022 Task 6 - iSarcasmEval: Intended Sarcasm Detection in English. The main objective of this task was to identify sarcastic tweets. This task was challenging mainly due to (1) the small training dataset that contains only 3468 tweets and (2) the imbalanced class distribution (25% sarcastic and 75% non-sarcastic). Our submitted model (ranked eighth on Sub-Task A and fifth on Sub-Task C) consists of a Transformer-based approach (BERTweet model).

1 Introduction

The Cambridge Dictionary [1] defines sarcasm as *"the use of remarks that clearly mean the opposite of what they say, made in order to hurt someone's feelings or to criticize something in a humorous way."*

Due to the Web openness, sarcastic content becomes very frequent in social media and e-commerce platforms, which may cause misunderstandings. Furthermore, identifying such content is a very challenging task even for humans (Farias and Rosso, 2017). Also, it could impact some natural language processing tasks such as sentiment analysis (Farias and Rosso, 2017; Do et al., 2019; Tubishat et al., 2018; Balazs and Velásquez, 2016; Maynard and Greenwood, 2014; Ptáček et al., 2014; Bouazizi and Otsuki Ohtsuki, 2016; Ren et al., 2018).

We introduce the following example: *"The movie was enjoyable to the point that I clapped because it is finished."* For an opinion mining system, this sentence could be considered positive. However, the author expresses a negative judgment against the movie since the expression *"I clapped because it is finished"* means that it was boring.

For this reason, SemEval 2022 set up Task 6: iSarcasmEval - Intended Sarcasm Detection in English and Arabic to detect sarcastic and non-sarcastic tweets (Abu Farha et al., 2022). Our submitted system consisted of a pre-trained transformer model for English Tweets named BERTweet (Nguyen et al., 2020), secured 8th and 5th positions respectively on Sub-Task A and Sub-Task C leaderboard.

The rest of the paper is structured in the following manner: Section 2 provides the data structure and the main objective of each Sub-Task. Section 3 describes our system. Section 4 details the experiments. And finally, Section 5 concludes this paper.

2 Task Description

The organizers of this task introduced two tweet datasets for both English and Arabic languages that contain:

- a label specifying whether a tweet is sarcastic or non-sarcastic, provided by its author.
- a non-sarcastic rephrase of a sarcastic tweet provided by its author.
- a label specifying the category of ironic speech that it reflects, provided by a linguistic expert (English only).
- a label specifying the dialect (Arabic only).

This task consists mainly of three sub-tasks for the English dataset and two sub-tasks for the Arabic dataset where Sub-Task A aims at determining whether a tweet is sarcastic or non-sarcastic, Sub-Task B, which is available for English only, is a binary multi-label classification task that intends to determine which ironic speech category a sarcastic tweet belongs to if any, and finally, Sub-Task C that takes two inputs: a sarcastic tweet and its non-sarcastic rephrase, and focuses on identifying the sarcastic one between them.

[*] contributed equally
[1] https://dictionary.cambridge.org/fr/dictionnaire/anglais/sarcasm

3 System Description

In this section, we describe our proposed system that tackles Sub-Task A and Sub-Task C English.

3.1 Sub-Task A

In order to tackle Sub-Task A, we adopted a transformer-based (Vaswani et al., 2017) approach that consists of fine-tuning BERTweet [2], which is a language model pre-trained on 850M English Tweets, and it has the same architecture as BERT-base (Devlin et al., 2019), as well as it is was trained using the RoBERTa pre-training procedure (Liu et al., 2019).

Before feeding the training data to BERTweet model, we preprocessed them by removing URLs and then replacing emojis with their English textual meaning (Alami et al., 2020) using BERTweet demojizer [3]. Figure 1 depicts the Tweets preprocessing pipeline.

After the preprocessing phase, we fine-tuned BERTweet model on the training dataset that contains 3468 tweets (867 sarcastic tweets and 2601 non-sarcastic tweets).

3.2 Sub-Task C

The same model of Sub-Task A was used to handle Sub-Task C by feeding two texts to the BERTWeet model that was already fine-tuned on the training dataset. The text with the highest probability of being sarcastic is considered the sarcastic one.

4 Experimental Results

We experimented our model on the SemEval 2022 Task 6: iSarcasmEval - Intended Sarcasm Detection in English Sub-Task A and Sub-Task C datasets. All our experiments have been conducted in Google Colab environment[4], The following libraries: Transformers - Hugging Face[5] (Wolf et al., 2020), Scikit-Learn[6] (Pedregosa et al., 2011), and Keras[7] were used to train and to asses the performance of our model.

[4]https://colab.research.google.com/

[5]https://huggingface.co/docs/transformers/index

[6]https://scikit-learn.org/stable/

[7]https://keras.io/

4.1 Datasets

Since we have participated in Sub-Task A and Sub-Task C for English, we will only describe the English dataset. The training set contains 867 sarcastic tweets and 2601 non-sarcastic tweets, the test set of Sub-Task A contains 200 sarcastic tweets and 1200 non-sarcastic tweets, and the test set of Sub-Task C contains 200 sarcastic tweets and their rephrases. Figure 2 depicts the class distribution of the English tweets in the training and test set for Sub-Task A.

4.2 Evaluation Metric

To evaluate the performance of the submitted results, the organizers adopted the F1-score for the sarcastic class as the main metric for Sub-Task A as well as the accuracy for Sub-Task C. The F1-score and accuracy are computed in the following manner where $P_{sarcastic}$ and $R_{sarcastic}$ are respectively the precision and recall of the sarcastic class, and TP, TN, FP and FN are respectively the true positive, true negative, false positive and false negative.

$$Accuracy = \frac{TP + TN}{TP + TN + FP + FN} \quad (1)$$

$$P_{sarcastic} = \frac{TP_{sarcastic}}{TP_{sarcastic} + FP_{sarcastic}} \quad (2)$$

$$R_{sarcastic} = \frac{TP_{sarcastic}}{TP_{sarcastic} + FN_{sarcastic}} \quad (3)$$

$$F1_{sarcastic} = \frac{2 \times P_{sarcastic} \times R_{sarcastic}}{P_{sarcastic} + R_{sarcastic}} \quad (4)$$

4.3 Experimental Settings

During the fine-tuning of BERTWeet model, we set the hyper-parameters as follows: 10^{-5} as the learning rate, 15 epochs, 128 as the max sequence length, and 32 as batch size. The same settings were adopted for DistilBERT (Sanh et al., 2019) and BERT base uncased. Table 1 summarizes the hyperparameters settings of BERTWeet model.

For the Bidirectional Long Short-Term Memory (Bi-LSTM) (Hochreiter and Schmidhuber, 1997) and Bidirectional Gated Recurrent Unit (Bi-GRU) (Cho et al., 2014), we set 10 epochs, 128 as the max sequence length, and 16 as batch size.

Loss	Cross-Entropy

Table 1: Hyperparameters settings for BERTWeet model in the experiments

4.4 System Performance

We evaluated various models on Sub-Task A test set including Linear Support Vector Classification (LinearSVC) (Boser et al., 1992), Logistic Regression, Multinomial Naive Bayes (MultinomialNB), Bi-LSTM, Bi-GRU, DistilBERT, BERT base uncased, RoBERTa base, and BERTweet base. We picked the combination of unigrams, bigrams, and trigrams of token counts as features for LinearSVC, Logistic Regression, and MultinomialNB since this combination delivered the best results in terms of the F-1 sarcastic metric.

For non-transformer-based models, we preprocessed the data by removing stop words and special characters. For transformer-based models, two approaches were adopted during the evaluation phase. In the first approach, we preprocessed the data as described in Figure 1. In the second one, we fine-tuned the model without applying any preprocessing to the data. Table 2 depicts the obtained results of various models on Sub-Task A - English.

We can see from Table 2 that BERTweet base model achieved the best results in detecting sarcastic tweets succeeded by RoBERTa base. Surprisingly, LinearSVC achieved better results than BERT base and DistilBERT.

We evaluated various models on Sub-Task C test set including LinearSVC, Logistic Regression, MultinomialNB, Bi-LSTM, Bi-GRU, RoBERTa base, and BERTweet base. Table 3 depicts the obtained results of various models on Sub-Task C - English. We mention that the same preprocessing approaches applied on Sub-Task A tweets were applied on Sub-Task C test set.

According to the reported results in Table 3, we can see that BERTweet base model achieved the best results succeeded by RoBERTa base. Moreover, we notice that traditional machine learning approaches such as LinearSVC, Logistic Regression, and MultinomialNB outperformed Recurrent Neural Networks: Bi-LSTM and Bi-GRU.

5 Conclusion

In this paper, we described our approach for tackling Sub-Task A and Sub-Task C of SemEval 2022 Task 6: iSarcasmEval - Intended Sarcasm Detection in English. Our submitted system consisted of a pre-trained transformer model for English Tweets named BERTweet, secured 8th and 5th positions respectively on Sub-Task A and Sub-Task C leaderboard.

Since the top-ranked system for the English Sub-Task A scored about 0.6052 F1-score for the sarcastic class, future studies and works will focus on improving the performance of sarcasm detection tasks by adopting other approaches such as data augmentation and oversampling.

Abstract

Detecting sarcasm and verbal irony from people's subjective statements is crucial to understanding their intended meanings and real sentiments and positions in social scenarios. This paper describes the X-PuDu system that participated in SemEval-2022 Task 6, *iSarcasmEval - Intended Sarcasm Detection in English and Arabic*, which aims at detecting intended sarcasm in various settings of natural language understanding. Our solution finetunes pre-trained language models, such as ERNIE-M and DeBERTa, under the multilingual settings to recognize the irony from Arabic and English texts. Our system ranked second out of 43, and ninth out of 32 in Task A: one-sentence detection in English and Arabic; fifth out of 22 in Task B: binary multi-label classification in English; first out of 16, and fifth out of 13 in Task C: sentence-pair detection in English and Arabic.

1 Introduction

Sarcasm is the use of language that typically signifies the opposite to mock or convey contempt. As a narrow research field in natural language processing (NLP), sarcasm detection is a particular case in the spectrum of sentiment analysis, with important implications for a slew of NLP tasks, such as sentiment analysis, opinion mining, author profiling, and harassment detection. In the textual data, these tonal and gestural clues like heaving tonal stress and rolling of the eyes are missing, making it more difficult for machines.

The sarcastic intention of human annotators has potentially hindered the training and evaluation process in detecting the genuine emotions and positions of the natural language. Thus, this task (Abu Farha et al., 2022) adopted a novel data collection method (Oprea and Magdy, 2020), where authors themselves label the training samples. For sarcastic texts, the authors also rephrase them into non-sarcastic ones. Then, linguistic experts further checked the scathing pieces and labeled them into sub-categories of sarcasm defined by (Leggitt and Gibbs, 2000): sarcasm, irony, satire, understatement, overstatement, and rhetorical question.

This SemEval task requires the identification of sarcasm in either one sentence or sentence pairs in various language settings, which consists of three subtasks:

(1) Task A (English and Arabic): Given a text, determine whether it is sarcastic or non-sarcastic;

(2) Task B (English only): A binary multi-label classification task. Given a text, determine which ironic speech category it belongs to, if any;

(3) Task C (English and Arabic): Given a sarcastic text and its non-sarcastic rephrase, i.e. two texts that convey the same meaning, determine which is the sarcastic one.

Our method employed various multilingual or mono-lingual pre-trained language models, such as ERNIE-M (Ouyang et al., 2020) and DeBERTa (He et al., 2021) to address each component of this task, with a bunch of fine-tuning and ensemble techniques. Our system finally achieved

- 2nd out of 43 and 9th out of 32 in English and Arabic subtasks in *Task A*;
- 5th out of 22 in *Task B*;
- 1st out of 16 and 5th out of 13 in English and Arabic subtasks in *Task C*.

2 Previous Work

After detecting sarcasm in the speech was firstly proposed in (Tepperman et al., 2006), sarcasm detection has attracted extensive attention in the NLP community. Afterward, sarcasm detection in the

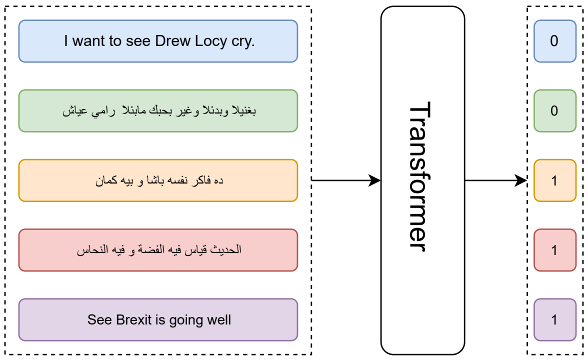
text has been extended to a broad range of data forms in social media, such as tweets, comments, and TV dialogues, due to their public availability. Sarcasm detection spanned several approaches like rule-based, supervised, and semi-supervised (Joshi et al., 2016) methods, resulting in further development for automatic sarcasm detection. Rule-based methods mainly rely on linguistic information, and their classification accuracy is often not very high due to the presence of noisy data. Most previous work on sarcasm detection based on supervised machine learning tends to rely on different types of features, including sentence length, the number of capitalized words, punctuation (Davidov et al., 2010), pragmatic factors such as emoticons (González-Ibáñez et al., 2011), turn-level sentiment lexicon (Wilson et al., 2005), sarcasm markers (Ghosh and Muresan, 2018), and so on. Meanwhile, neural models have been applied to this task, relying on semantic relatedness (Amir et al., 2016) and neural intra-attention mechanism to capture the sarcasm (Tay et al., 2018) and thus reducing feature engineering efforts.

Recently, pre-trained language models such as BERT (Devlin et al., 2018), ERNIE (Sun et al., 2019), and GPT-3 (Brown et al., 2020), have set the new state-of-the-art in a wide range of NLP benchmarks, such as GLUE (Wang et al., 2018). Khatri et al. (2020) evaluated the performance of pre-trained model using feature-based and fine-tuning methods on irony detection in English tweets, finding the latter is better. Meanwhile, there is also a surge of applying pre-trained models in sarcasm detection (Dadu and Pant, 2020; Potamias et al., 2020; Javdan et al., 2020). Our system explored the multilingual and monolingual pre-trained language models to testify their fine-tuning performance on English and Arabic sarcasm detection tasks.

3 Approach

3.1 Pre-trained Language Models

We adopt *pretrain-then-finetune* paradigm for better leveraging the performance of large-scale pre-trained models. As illustrated in Figure 1, for all tasks, we utilize pre-trained models to extract the input representations, followed by a fully-connected feed-forward layer and a softmax/sigmoid activation after the `[CLS]` token for prediction. For sub-task A and B that input samples only contain one sentence, we directly fine-tune the pre-trained Transformers. For sub-tasks with two sentences, *i.e.*, sub-task C, we employ the multi-layer pre-trained Transformer blocks as the cross-encoder by concatenating sentence pairs and separating them with a `[SEP]` token.



I want to see Drew Locy cry.
بغنيلا وبدنلا وغير بحبك مابنلا رامي عياش
ده فاكر نفسه باشا و بيه كمان

0
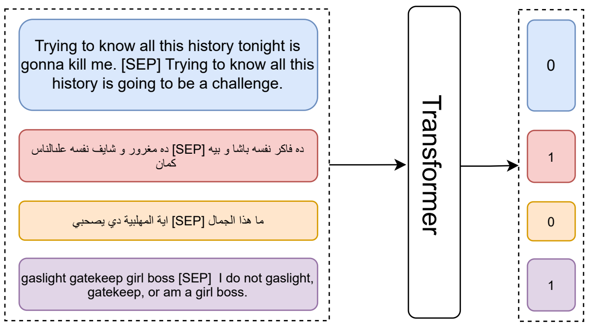
1
1
1

Figure 2: Multilingual learning on Task A. “0/1” indicate the non-sarcastic and sarcastic class.

3.2 Multilingual Learning

By observing that subtasks in task A and task C, we found that both subtasks in Task A and C are for the same objective but in different languages, *i.e.*, Arabic and English. Therefore, we adopt multilingual learning method by simultaneously fine-tuning the pre-trained models on both Arabic and



Trying to know all this history tonight is gonna kill me. [SEP] Trying to know all this history is going to be a challenge.
ده فاكر نفسه باشا و بيه [SEP] ده مغرور و شايف نفسه علىالناس كمان

Figure 3: Multilingual learning on Task C. "0/1" indicate the first or second sentence belongs to sarcasm.

English training data based on multilingual pre-trained models, *i.e.*, ERNIE-M. Specifically, we combine both tasks in Task A or C as a single task, that is, training on Arabic and English sarcasm detection within the same subtask at the same time. As shown in Figure 2, we combine the one-sentence binary sarcasm detection subtasks in English and Arabic together and fine-tune the multilingual pre-trained models in one forward pass. Similarly, as illustrated in Figure 3, we conduct the identical settings for Task C. We found that this approach can achieve obvious performance gain on some specific settings and will discuss it in Secion 4.5.

3.3 Ensemble Learning

Considering the limited training data, we split the training data into k-fold with disparate random seeds, selecting one out of k data blocks for evaluation and using the rest $k-1$ for data training, as shown in Figure 4. Then, we choose the optimal model evaluated on various folds and random seeds. Finally, we apply ensemble techniques by averaging all outputs of test sets using optimal models.

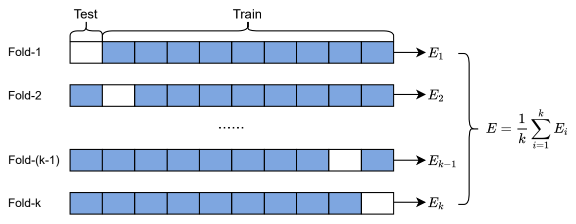

Figure 4: Illustration of ensemble learning. E_i indicates the prediction of the i-th model on the test set.

4 Experiments

4.1 Task Description

4.1.1 Task A: Binary Sarcasm Detection

The first task is binary text classification: given a tweet sample, the system needs to predict whether it is sarcastic or non-sarcastic. The following examples respectively present a sarcastic and non-sarcastic tweet.

(1) `The only thing I got from college is a caffeine addiction. (#sarcastic)`

(2) `I want to see Drew Lock cry. (#non-sarcastic)`

Example 1 is a sarcastic tweet where the author's true intention is "College is really hard, expensive, and exhausting, and I often wonder if the degree is worth the stress."

4.1.2 Task B: Multi-label Sarcasm Detection

The second task is a multi-label classification task, where the system requires to predict multiple categories out of six labels, such as `#Sarcasm`, `#Irony`, `#Satire`, `#Understatement`, `#Overstatement`, and `#Rhetorical_question`. The following examples provide examples for multiple sub-categories:

(1) `Falling asleep at your laptop is always fun. (#Sarcastic)`

(2) `Wow Bdubs can bench press 150 kilometers. (#Irony)`

(3) `Lil Pump is the Nelson Mandela of our generation. (#Satire #Sarcastic)`

(4) `Lucky for 2nd placed Brentford that there's no stand out team like Leeds this year, or they might have no chance of winning the league. (#Understatement #Sarcastic)`

(5) `6 more hours and then a whoppingly massive 2days off work! wowzers! (#Overstatement #Irony)`

(6) `wait what the fuck that solo yolo is mad?` `(#Rhetorical_question #Sarcastic)`

In the above examples, the types of sarcasm are subdivided into six categories. `#Sarcasm`, which is an ironic remark meant to mock by saying something different than what the speaker really means. For example, in example 1, the speaker hates falling asleep on his laptop. `#Irony` is when something happens that is the opposite of what was expected. As shown in example 2, the fact is that Bdubs cannot bench press 150 kilometers. `#Satire` is a type of wit that is meant to mock human vices or mistakes, often through hyperbole, understatement and sarcasm, as shown in Example 3. `#Understatement` is often a way of being critical. In example 4, because Norwich is the standout this year, Brentford cannot win the league. `#Overstatement` is an act of stating something more profound than it actually is, to make the point more serious, important, or beautiful. In example 5, a whoppingly massive two days off work means regret, and the genuine emotion ought not to require overstatement. `#Rhetorical_question` is a question that is asked even if the person doing the asking knows what the answer is. The solos in example 6 was truly expressed to be awful.

4.1.3 Task C: Binary Irony Classification on Two Sentences

The third subtask is binary classification: given a sarcastic tweet and its non-sarcastic rephrase (i.e., two tweets that convey the same meaning), the system needs to predict the sarcastic one. The following examples present a sarcastic sentence and its non-sarcastic paraphrase.

(1) `Trying to know all this history tonight is gonna kill me.` `(#Sarcastic)`

(2) `Trying to know all this history is going to be be a challenge.` `(#Rephrase)`

4.2 Evaluation Metrics

For these three sub-tasks, standard evaluation metrics including accuracy and F1 score are used to evaluate the participating system, calculated as follows:

$$accuracy = \frac{TP + TN}{TP + FP + TN + FN} \tag{1}$$

Task	#Instances	#Metric
`Task A`	1400	F1-score
`Task B`	1400	Macro-F1 score
`Task C`	200	accuracy

Table 1: Summary of official test set in SemEval-2022 Task6.

Class Label	#Instances
`sarcastic`	867
`non-sarcastic`	2601
`total`	3468

Table 2: Satirical and non-satirical categories in training data.

$$precision = \frac{TP}{TP + FP} \tag{2}$$

$$recall = \frac{TP}{TP + FN} \tag{3}$$

$$F_1 = 2 \cdot \frac{precision \cdot recall}{precision + recall} \tag{4}$$

where TP, FP, TN, FN represent true positive, false positive, true negative, and false negative, respectively.

As shown in Table 1, task A, B and C use the F1-score for the sarcastic class, the Macro-F1 score over all classes, and accuracy, respectively. The Macro-F1 score implies that all class labels have equal weights in the final score.

4.3 Data

The detailed statistics of the sarcasm detection dataset are summarized in Table 2 and 3. As shown in Table 2, the training data are shown to be imbalanced, with 867 positive samples vs. 2601 negative ones. We only remove extra spaces, tabs, and line breaks for pre-processing. All emojis that contain emotional factors in training texts are kept without any change.

Multi-class Label	#Instances
`sarcasm`	713
`irony`	155
`satire`	25
`understatement`	10
`overstatement`	40
`rhetorical_question`	101

Table 3: Six satirical sub-categories in Task B.

4.4 Experiment Details

Due to the long-tailed nature of training data, we tried to use outside data[1] for data augmentation. Particularly, we merge the classes of "figurative""irony" in the exta data into a "sarcasm" class, but found it of no benefit. We conjecture that this is due to manual annotators' subjective intention can give the same samples various interpretations and therefore introduce some noise.

Still, the training data is relatively small and insufficient to achieve an unbiased performance estimate with a random train/test split. Instead, we use a k-fold cross-validation procedure ($k = 10$), a common model evaluation scheme in machine learning. The k-fold cross-validation procedure involves splitting the training dataset into k folds. In which $k - 1$ folds are used to train a model, and the rest one fold is used as the evaluation set. Finally, the final output of k models is the mean of these runs.

For English tasks, we compare ERNIE-M (Ouyang et al., 2020) and DeBERTa (He et al., 2021) as the pre-trained workhorse, while for Arabic tasks, we only consider ERNIE-M. We use the AdamW optimizer (Loshchilov and Hutter, 2017) and weight decay of 0.01. We warm up the learning rate for the first 10% of the update to a peak value of 1e-5 and 5e-6, respectively, and then linearly decay it afterward. We also use dropout (Srivastava et al., 2014) with a rate of 0.15 to prevent overfitting. We adopt a total batch size of 64 by running gradient accumulation on each GPU device with a step size of 8 and a batch size of 1, sharded across 8 NVIDIA V100 GPU chips. Our final solution is to ensemble all the model results obtained using a 10-fold cross-validation strategy with different learning rates (1e-5 and 5e-6) and training epochs (20 and 30), respectively.

4.5 Results

Table 4 compares the final performance on the official test set of task A,B,C under proposed model settings. It is obvious that DeBERTa outperforms ERNIE-M on English task since it is pre-trained only on English corpus. As to the multilingual learning in Task A and C, we observe the significant performance gain (*i.e.*, +6 absolute percentage point on F1 measure) on Task C while find it on par with monolingual fine-tuning on Task A. We guess

[1] https://www.kaggle.com/c/gse002/data?select=test.csv

Task	Lang	ERNIE-M (multilingual)	ERNIE-M (monolingual)	DeBERTa	Rank
Task A	en	36.75	38.46	**56.91**($*$)	2/43
	ar	40.36	**41.87**($*$)	-	9/32
Task B	en	N/A	-	**7.99**($*$)	5/22
Task C	en	82.50	75.00	**87.00** ($*$)	1/16
	ar	**90.50**	84.00($*$)	-	5/13

Table 4: Official test-set performance under various experimental settings. The "ERNIE-M (multilingual)" column indicates the performance of multilingual learning in Task A and C. Scores with asterisk indicate final submitted results. The official evaluation metrics for Task A,B,C are F1-score, macro F1-score, and accuracy, respectively.

this is because Task C are given two sentences for comparison, which is more straightforward than Task A (single sentence) to capture the ironic pattern for sarcasm detection. Due to the time limit, we only submit the monolingual fine-tuning results of ERNIE-M (*i.e.*, 84% acc.), which ranks 5th out of 13 in the Arabic subtask of Task C. Instead, the performance of our multilingual learning can achieve 2nd in Task C (Arabic). We contend that it would be worthwhile further exploring multilingual learning methods in various language settings in the future.

5 Conclusion

We present our system that participated in SemEval Task 6 and employ the multilingual learning method to train the English and Arabic tasks jointly. We empirically find that it confers benefits in specific scenarios and outranks the monolingual pre-trained models on Arabic tasks. However, we do not adopt other Arabic-specific pre-trained models, which is also worth comparing. In the future, it is a promising direction to explore different sarcasm detection approaches under multilingual settings.

Abstract

This paper describes the participation of team DUCS at SemEval 2022 Task 6: iSarcasmEval - Intended Sarcasm Detection in English and Arabic. Team DUCS participated in SubTask A of iSarcasmEval which was to determine if the given English text was sarcastic or not. In this work, emojis were utilized to capture how they contributed to the sarcastic nature of a text. It is observed that emojis can augment or reverse the polarity of a given statement. Thus sentiment polarities and intensities of emojis, as well as those of text, were computed to determine sarcasm. Use of capitalization, word repetition, and use of punctuation marks like '!' were factored in as sentiment intensifiers. An NLP augmenter was used to tackle the imbalanced nature of the sarcasm dataset. Several architectures comprising of various ML and DL classifiers, and transformer models like BERT and Multimodal BERT were experimented with. It was observed that Multimodal BERT outperformed other architectures tested and achieved an F1-score of 30.71%. The key takeaway of this study was that sarcastic texts are usually positive sentences. In general emojis with positive polarity are used more than those with negative polarities in sarcastic texts.

1 Introduction

According to the Collins Dictionary [1]

> "Sarcasm is speech or writing which actually means the opposite of what it seems to say".

Fox Tree et al. (2020) report that sarcasm is challenging to identify, even for humans. People often use gestures like rolling of eyes or heavy tonal stress to express sarcasm (Pandey et al., 2019), in speech or in-person communication. Intonation and stress in speech, too, are strong indicators of sarcasm (Castro et al., 2019). Also, the context in the form of shared knowledge between the speaker and the audience can be leveraged to detect sarcasm (Amir et al., 2016). But most of the time the tone or the context is missing in text data, especially tweet data. Some users attempt to use capitalization like "OH YEAH" or repetitions like "woowww" to indicate tonal intensity. But, most of the time these cues are not enough, especially in absence of context to gauge sarcasm. This makes sarcasm detection a challenging task.

In this work, team DUCS participated in *SemEval 2022 Task 6 : iSarcasmEval* Subtask A, (Abu Farha et al., 2022), to determine if the given text is sarcastic or not. The English text training dataset contains 3468 sentences. Each text is labeled as sarcastic or non-sarcastic by the text-author. Of the 3468 sentences 867 are sarcastic and 2601 are non-sarcastic. In the dataset corresponding to a sarcastic text, a rephrased non-sarcastic version has also been provided. These sarcastic texts are labeled as one of sarcasm, irony, satire, understatement, overstatement, and rhetorical question. These ironic speech categories are determined by a linguist expert. The target task is to determine whether a text is sarcastic or not on the Test dataset which contains 1400 sentences.

For sarcasm detection in the above-discussed dataset, an attempt was made to derive cues from the text itself. It is observed that in real scenarios, the absence of labels by users like #not or #sarcasm or any other contextual information makes sarcasm detection challenging (Chaudhari and Chandankhede, 2017). Thus, in this work, the authors attempted to use the information available in the text itself. Emoji occurrences in the text are captured to study their impact in discerning sarcasm. Sentiment intensity and polarity of both the emojis and the text were computed to train the classifiers

[1]https://www.collinsdictionary.com/dictionary/english/sarcasm

for sarcasm classification.
This paper is organized as follows. Section 2 discusses related work in sarcasm detection. In Section 3, System Overview, the proposed approach to incorporate polarity and intensity of emojis along with text sentiment polarity and intensity is discussed. Section 4, describes the Experimental Setup and the data augmentation approach used for the given dataset. The results of the experiments conducted are reported in Section 5. In the last section Conclusion, the key takeaways and learnings are discussed.

2 Related work

The sarcastic nature of the text can deceive classifiers as well as humans, given it conveys the opposite of what it means. Many researchers have attempted to use text sentiment and emojis for sarcasm detection.
Subramanian et al. (2019) use word and emoji embeddings simultaneously to train deep learning models with attention layer for sarcasm detection. Pamungkas and Patti (2018) utilize structural features and affective features of tweets for irony detection. Structural features include the presence of hashtags, links, emojis, quotes, etc. The counts of mentions, exclamations, upper-case, intensifiers, links, along with the counts of verbs, nouns, and adjectives are also used along with the use various affective resources to capture sentiment polarity and emotions. Lemmens et al. (2020) used an ensemble approach with LSTM for representing emojis and hashtags, CNN-LSTM for representation of cases, stop-words, punctuation, and sentiments. MLP was trained with Facebook's InferSent embeddings (Conneau et al., 2017) while SVM was trained with emotion and stylometric features. A decision tree with Adaboost served as the base estimator for the ensemble. This ensemble was used to predict sarcasm on the conversational text where context was available. Sundararajan and Palanisamy (2020) propose a rule-based classifier with an ensemble of 20 different features. They observed that the features based on sentiment can predict sarcasm better in combination with contradictory features.
In most work so far researchers have tried to capture sentiment and linguistic features to identify sarcasm. A few researchers have attempted to include emojis in sarcasm classification. But, how the usage of emojis with text impacts or conveys sarcasm is yet to be explored in depth. It needs to be studied how frequent is sentiment incongruence of emojis in the text they are used with and can the polarity of emojis and text help deduce sarcasm. Hence in this work, the authors focus on these features - emoji sentiment and text sentiment as well as their polarities to understand how this combination impacts sarcasm. This approach is discussed in the next section.

3 System overview

In the given dataset, situational context is not available. Although linguistic markers are provided, they may not be available in real scenarios, eg when the users post on social media. In the absence of context, it is important to take into account other factors that may point to sarcasm. For instance, the surface sentiment of a text is often used in many sarcasm classifiers (Joshi et al., 2016). Sulis et al. (2016), report that most often sarcasm is used with an apparently positive statement to produce a negative impact. It is noted that the users may use intensity in the form of capitalization, repeated letters, etc. to express sarcasm (Chaudhari and Chandankhede, 2017). In this work, to identify sarcasm, the sentiment polarity of the text and intensity in the form of sentiment score was incorporated for the sarcasm classification task. Intensity as a feature is used as it may help capture intonation or stress a user may want to express.
It has been reported that features like emojis can augment as well as alter the sentiment polarity (Grover, 2021).
Pamungkas and Patti (2018) observed that emoji incongruity with the text may help improve the irony classification. Thus, this work investigates whether in sarcastic texts users use in-congruent emojis with the text to express sarcasm. And whether the use of emojis in the text helps in detecting sarcasm?

Data preparation The text dataset was cleaned to remove URLs as they do not contribute to the text sentiment. Most text preprocessing approaches in sentiment classification convert characters to lower case, reduce repeating letters, and perform lemmatization. To compute the sentiment score and polarities, special care was taken to not remove repetition of letters, capitalization or punctuation as they may serve as intensifiers. These special usages can later be removed during the experimentation while training the classifiers.

Emoji extraction In the next step, the emojis are separated from text. The training dataset for this task contained 672 text sentences with emojis of which 195 were sarcastic. The *demoji 1.1.0* Python package [2], is used for emoji extraction.

Text sentiment polarity and intensity To evaluate intensity or the sentiment score of the text and text polarity the VADER sentiment analyzer (Hutto and Gilbert, 2014), available in Python's natural language toolkit is employed. VADER is observed to work better in the language used by the users on social media (Illia et al., 2021), (Bonta and Janardhan, 2019). Users tend to communicate informally, using slang, abbreviations, capitalization and punctuation marks, etc. on social media. VADER can capture these components while computing sentiment polarity and sentiment scores. The compound scores provided by VADER are used as the sentiment score. If the compound score is $\leq$ -0.5 the sentiment polarity is considered negative, between (-0.5, 0.5), the polarity is considered as neutral, while the score $\geq$ = 0.5 is considered to be positive.

Emoji sentiment polarity As discussed above, since emojis are known to contribute to text sentiment and in many cases, they may even reverse the sentiment polarity, the emojis extracted for each text are stored separately in the list. A total of 672 texts have emojis in the provided dataset.
For extracting emoji sentiment, Emoji Sentiment Ranking (Novak et al., 2015) is employed. Emoji Sentiment Ranking gives the sentiment score of the emojis.
A text may contain numerous emojis which is an indicator of both the context as well as associated emotion with the text. For example, a single emoji used several times with a text may be considered as a sentiment intensifier. Thus, all the emojis in the text were considered while computing emoji polarity and emoji sentiment score.
Emoji sentiment scores were captured for all emojis. If an emoji did not appear in the Emoji Sentiment Ranking, it was demojized using the *emoji 1.6.3* Python package[3]. Demojizing here means replacing the emojis with their Unicode Consortium description in English, (Unicode, 2022). These emoji descriptions are passed to the VADER sentiment analyzer to compute the sentiment score of the emojis. Again the compound score provided by VADER is used to compute the final score. Scores of all the emojis are then added to compute the total emoji score for all the emoji scores associated with the text. These emojis are then normalized as done in VADER and corresponding emoji polarities are computed.

$$normalizedScore = \frac{score}{\sqrt{score^2 + \alpha}} \quad (1)$$

where default value of α is 15.
Each text with emojis is labeled with the computed emoji score and emoji polarity. For the text with no emojis, the emoji sentiment score is assigned to zero, and polarity is assigned as neutral.
For example if the text is *"@AsdaServiceTeam imagine your delivery being 2 hours late, and imagine calling up your service team only for them to hang up at 10pm, coincidentally the same time the office closes. But it's okay, my £3 delivery fee is being refunded though 👊"*. The VADER text score is computed as 0.2263 with "+" text polarity. The VADER emoji sentiment score is computed as 0.0150371002692231 with "+" emoji polarity. The prepared dataset with the derived features of text sentiment scores, text polarity, emoji sentiment score, and emoji polarity is now used to train the different classifiers discussed in the next section.

4 Experimental setup

For sarcasm detection, this work employs various machine and deep learning classifiers. The proposed set up is also tested with transformer models like BERT and Multimodal BERT.
First, the text is cleaned to remove stop words, newlines, and spaces. The cleaned text is then converted to lower case and then tokenized to prepare for loading the word embeddings. Pre-trained GloVe embeddings, (Pennington et al., 2014) of 100 dimensions are used to represent the tokenized text.
80% of the dataset was used for training while the remaining 20% was used for validation.

Data augmentation This dataset was highly imbalanced with 867 sarcastic and 2601 non-sarcastic texts, i.e. (3:1 ratio for non-sarcastic: sarcastic texts). So the dataset was augmented to improve this ratio of sarcastic and non-sarcastic texts. The sarcastic texts were oversampled with *nlpaug* python library [4] for text augmentation.

[2]https://pypi.org/project/demoji/
[3]https://pypi.org/project/emoji/
[4]https://nlpaug.readthedocs.io/en/latest/index.html

The contextual BERT embeddings were used to synthesize new texts from existing texts in the dataset. Two different augmented datasets were created. In the first augmented dataset (Aug1 Training Set), each sarcastic text was synthesized once to create one more text. In this set, the ratio of non-sarcastic: sarcastic texts was 2:1. In the next augmented dataset (Aug2 Training Set), each sarcastic text was synthesized to create two more texts, thus resulting in the ratio of 1:1 for non-sarcastic to sarcastic texts.
For example, if the tweet was, "See Brexit is going well". Then in the first augmented text (Aug1 Training Set) the original tweet (mentioned above) was retained and a synthesized tweet in the form "can see brexit negotiations is going extremely well" was added to the dataset. This was done for every sarcastic tweet, making the ratio of non-sarcastic:sarcastic texts as 2:1.
In the Aug2 Training Set) the number of synthesized texts was increased to two. So two synthesized tweets apart from the original tweet were appended to the dataset making the ratio of non-sarcastic:sarcastic as 1:1.
The computed sentiment polarity, text sentiment score, emoji sentiment polarity, and emoji sentiment score were replicated from the original texts in the synthesized texts.

Model architecture The different architectures experimented with are as follows:

- Gaussian Naive Bayes (Perez et al., 2006)
- Support Vector Machine with Linear Kernel (Wang, 2005)
- Logistic Regression (Wright, 1995)
- Sequential model with 1 dense fully connected layer (Sutskever et al., 2014)
- LSTM with Adadelta optimiser, 128 batch size, run over 10 epochs (Sundermeyer et al., 2012)
- Bi-LSTM (Graves and Schmidhuber, 2005) with Adadelta optimiser, 128 batch size, run over 10 epochs
- BERT (Devlin et al., 2018) with the learning rate of 1e-5, batch size 32 run over 4 epochs with the base uncased classifier
- Multimodal BERT with the batch size 32 run over 6 epochs with the base uncased classifier

5 Results

This section reports the results of various classifiers on which the proposed approach was tested with.
The original training set (Original Training Set) provided for the competition is an imbalanced dataset contains 2601 non-sarcastic and 867 sarcastic texts. The training set augmented with 1X sarcastic tweets (Aug1 Training Set) contains 1734 sarcastic and 2601 non-sarcastic texts. 867 sarcastic texts were synthesized to create 867 more sarcastic texts, resulting in a total of 1734 sarcastic texts. The training set augmented with 2X sarcastic tweets (Aug2 Training Set) contains 2601 sarcastic and 2601 non-sarcastic texts. In this set, each of the 867 sarcastic texts were synthesized twice. Hence the total number of sarcastic texts were 867(original) and 1734(each original tweet synthesized twice).
Validation-F1 reports F1 score (%) that were obtained during the validation. Results obtained on the test dataset, (Abu Farha et al., 2022), provided during the competition are reported in Test-F1.
The results of models trained without sentiment scores and polarities on the original training set in Table 1, training set augmented with 1X sarcastic tweets in Table 2, and training set augmented with 2X sarcastic tweets in Table 3 are reported.

Classifier	**Validation-F1**	**Test-F1**
Gaussian Naive Bayes	25.87	14.52
Logistic Regression	7.03	5.45
SVM	7.11	4.65
Sequential	44.09	24.53
LSTM	44	25
Bi-LSTM	44	25
BERT	77.56	22.46

Table 1: Original Training Set without Sentiment Scores and Polarities

The results of models trained with text and emoji sentiment scores and their respective polarities on Original, Aug1, and Aug2 are reported in 4, 5, 6 respectively.

The Multimodal BERT trained with 1736 sarcastic and 2601 non-sarcastic sentences was eventually used to determine sarcastic text in the test data. With this work the authors achieved an overall F1-Score of 30.71% on the test dataset and was ranked 24 out of the 43 participating teams.

Classifier	Validation-F1	Test-F1
Gaussian Naive Bayes	50.73	19.39
Logistic Regression	19.13	16.18
SVM	19.5	16.42
Sequential	56.48	24.53
LSTM	56.48	25
Bi-LSTM	56.48	24.53
BERT	64	23.94

Table 2: Aug1 Training Set without Sentiment Scores and Polarities

Classifier	Validation-F1	Test-F1
Gaussian Naive Bayes	59.04	16.58
Logistic Regression	61.4	22.5
SVM	61.57	22.58
Sequential	66.71	25
LSTM	66.71	25
Bi-LSTM	66.71	25
BERT	64	23.94

Table 3: Aug2 Training Set without Sentiment Scores and Polarities

It was observed that in general, models trained with sentiment scores of text and emojis alongwith their polarities performed better than those trained only with text
Figure 1 shows the distribution of emojis across sarcastic text in the train and test dataset. From Figure 1 of iSarcasmEval dataset

- It is observed that sarcastic texts mostly have emojis with positive polarity.
- Sarcastic texts generally demonstrate positive sentiment.

Some other observations noted during the experiments are reported as follows.

- Sarcastic text when augmented twice results in overfitting and results are not satisfactory on the test set. The best F1-score on the test dataset is achieved when each sarcastic text is augmented once.

Classifier	Validation-F1	Test-F1
Gaussian Naive Bayes	21.3	15.72
Logistic Regression	6.41	2.84
SVM	6.52	2.87
Sequential	37.57	24.53
LSTM	47.03	28.47
Bi-LSTM	47.03	28.48
BERT	35.29	23.28
MultiModal BERT	50.00	25.12

Table 4: Original Training Set with Text and Emoji Sentiment Scores and Polarities

Classifier	Validation-F1	Test-F1
Gaussian Naive Bayes	32.0	18.5
Logistic Regression	17.56	11.11
SVM	17.53	10.89
Sequential	56.75	24.52
LSTM	40.73	28.49
Bi-LSTM	40.51	28.49
BERT	73.184	29.27
MultiModal BERT	75.22	**30.71**

Table 5: Aug1 Training Set with Text and Emoji Sentiment Scores and Polarities

Classifier	Validation-F1	Test-F1
Gaussian Naive Bayes	57.51	20.93
Logistic Regression	54.3	20.62
SVM	54.77	20.75
Sequential	64.26	24.52
LSTM	49.82	28.50
Bi-LSTM	49.82	28.50
BERT	78.36	24.31
MultiModal BERT	81.22	24.69

Table 6: Aug2 Training Set with Text and Emoji Sentiment Scores and Polarities

- Overall the Multi-modal BERT, which can handle tabular data, performs the best.
- Models trained with sentiment scores and polarities of text and emojis performed slightly better than those trained with only text.
- In the test dataset only 18 sarcastic sentences had emojis.
- F1-score on test dataset for text with emojis was found to be 21.05% while that of text without emojis was 31.02%. This performance may be improved if more sentences with emojis are available.

6 Conclusion

In this work, the authors took their first steps in understanding how the sentiment of emojis alongwith the text sentiment helps in detecting sarcasm. Since sarcasm is difficult to detect without context, authors attempted to uncover information implicit in the text. For this the intensity and polarity of both the available emojis and the text itself were used to identify sarcasm.
It was observed that sarcastic texts generally have positive polarity. Sarcastic texts employed emojis with positive polarities more than the negative emojis. This information can be used further to improve results of sarcasm classification. The given dataset

Figure 1: Distribiution of Emojis in Sarcastic Text in Train and Test Datasets of iSarcasmEval

had relatively fewer texts with emojis, thus, more work is required to fully capitalize on the proposed approach. This motivates the authors to explore more sarcasm datasets with emojis to exhaustively study the impact of emojis in identifying sarcasm.

Abstract

In this manuscript we detail the participation of the UMUTeam in the iSarcasm shared task (SemEval-2022). This shared task is related to the identification of sarcasm in English and Arabic documents. Our team achieve in the first challenge, a binary classification task, a F1 score of the sarcastic class of 17.97 for English and 31.75 for Arabic. For the second challenge, a multi-label classification, our results are not recorded due to an unknown problem. Therefore, we report the results of each sarcastic mechanism with the validation split. For our proposal, several neural networks that combine language-independent linguistic features with pre-trained embeddings are trained. The embeddings are based on different schemes, such as word and sentence embeddings, and contextual and non-contextual embeddings. Besides, we evaluate different techniques for the integration of the feature sets, such as ensemble learning and knowledge integration. In general, our best results are achieved using the knowledge integration strategy.

1 Introduction

Sarcasm is a form of rhetorical device based on biting humour to *disarm* an opponent during a dialog (Wilson, 2006). On the Web and, specially in social networks and opinion forums, sarcasm is very popular because it is funny to read and helps to stimulate the viral phenomenon of social media content (Peng et al., 2019). As sarcasm usually relies on figurative language and wordplay, in which words diverts from their conventional meaning, sarcastic statements hinder the ability of automatic classification tasks to perform sentiment analysis, hate-speech detection, or author analysis among other tasks.

From a Natural Language Processing (NLP) perspective, sarcasm, among other forms of figurative speech, such as irony or satire, has been explored in (del Pilar Salas-Zárate et al., 2020). In this work, the authors explored what stands out the most discriminant features for satire and irony detection. The authors identified a total of 25 feature sets. Apart from lexicon-based features and word-n-grams features, such as unigrams or bigrams, the authors identified style features, sentiment and emotional features, pragmatic features, and punctuation features, to name a few. Our proposal for solving sarcasm detection includes language-independent feature sets extracted with a custom tool, UMUTextStats (García-Díaz et al., 2021; García-Díaz and Valencia-García, 2022; García-Díaz et al., 2022a,b).

In this work, we describe the participation of the UMUTeam at SemEval 2022 task 6, concerning sarcasm identification in Arabic and English (Abu Farha et al., 2022). In this edition, three challenges are proposed. The first one is a binary classification problem to determine whether a document is sarcastic or not. This challenge is for English and Arabic. The second challenge is available only in English, and consists in a multi-label classification task discerning among different types of ironic speech. Finally, the last challenge consists of the identification of a sarcastic document between itself and a non-sarcastic rephrase, but with the same meaning. Our team attemted to participate in the first and second challenge. We achieve a F1 score of the sarcastic class of 17.97% for English, and 31.75% for Arabic in the first challenge. However, our results are not considered in the official leader board for the second challenge due to an unknown error. Therefore, we report the results for the second challenge with the validation split of dataset.

2 Dataset

The dataset proposed at iSarcasm 2022 was annotated by the authors themselves. Besides, each author was asked to rephrase their sarcastic texts without the usage of sarcasm. Finally, some linguistic

sarcasm	565	148
satire	19	6
understatement	9	1

Table 2: Corpus statistics per sarcastic mechanism (subtask 2, English)

experts were asked to perform the multi-label annotations based on the following ironic speech labels: sarcasm, irony, satire, understatement, overstatement, and rhetorical question (Leggitt and Gibbs, 2000).

The statistics of the dataset concerning the first challenge are shown in Table 1. There is a significant imbalance between the labels. The relationship between the sarcasm and non-sarcasm texts is a 1:3 for English and 1:6 for Arabic. The statistics concerning the second challenge are shown in Table 2. There are 713 documents annotated as sarcasm, 155 as irony, 101 as rhetorical questions, 40 as overstatement, 25 as satire, and 10 as understatement.

From the training set, we select a 20% of instances to build the validation set using stratified sampling, in order to keep the balance.

3 System architecture

Figure 1 depicts the architecture of our proposal. Basically, we build two systems: one for English and one for Arabic, so we could apply different preprocessing techniques and apply language-specific pretrained embeddings. In a nutshell, this pipeline can be described as follows. First, is the preprocessing step module. For both languages, we ensure that the dataset does not contains hyperlinks, hashtags, quotations or emojis. Plus, for the English dataset we expand acronyms. Second, is the datasplitter, to divide the iSarcasm dataset into training and validation. As there was a strong imbalance in the dataset, we keep this imbalance in both splits. Third, is the feature extraction module, for extracting the language-independent linguistic features and the sentence embeddings. Forth, is the training of several neural networks using hyperparameter selection. Finally, is the feature integration module, in which we evaluate ensemble learning and knowledge integration in order to combine the results of each neural network.

Next, the feature extraction module is described. The first feature set is a subset of language-independent linguistic features (LF) from UMUTextStats. This feature sets includes Part-of-Speech (PoS) features and stylometric features concerning several linguistic metrics such as Type Token Ratio (TTR), punctuation symbols and corpus length. The second and third feature sets are, respectively, non-contextual word and sentence embeddings from FastText (Mikolov et al., 2018). For this, we use the Arabic and English pretrained models. The word embeddings allow to evaluate convolutional and recurrent neural network architectures, apart from multi-layer perceptrons that suitable for feature sets of fixed size. The forth feature set is contextual sentence embeddings. We use BERT (Devlin et al., 2018) for English, and Arabic BERT (Safaya et al., 2020) for Arabic. To extract these embeddings, we applied a similar method as described at (Reimers and Gurevych, 2019). Before extracting the sentence embeddings, we used RayTune (Bergstra et al., 2013) to fine tune BERT and Arabic BERT. For this, we used Tree of Parzen Estimators (TPE) to select the best hyperparameters from a total of 10 trials. The hyperparameters evaluated are: (1) the weight decay (between 0 and 0.3); (2) two training batch sizes: 8 and 16 (we were limited to the GPU); (3) four warm-up steps: 0, 250, 500, 1000; (4) the number of training epochs, between 1 and 5; and (5) a learning rate between 1e–5 and 5e–5.

Once the feature sets are extracted, the next step in the pipeline is the training of the neural networks. We train a neural network per feature set and a neural network combining all the feature sets, using a knowledge integration strategy. Each training is performed with an hyperparameter optimisation stage. This evaluation includes 20 shallow neural networks, in which one or two hidden layers are stacked and that contains the same number of neurons. For the shallow neural networks we evaluate the following activation functions: (`linear`,

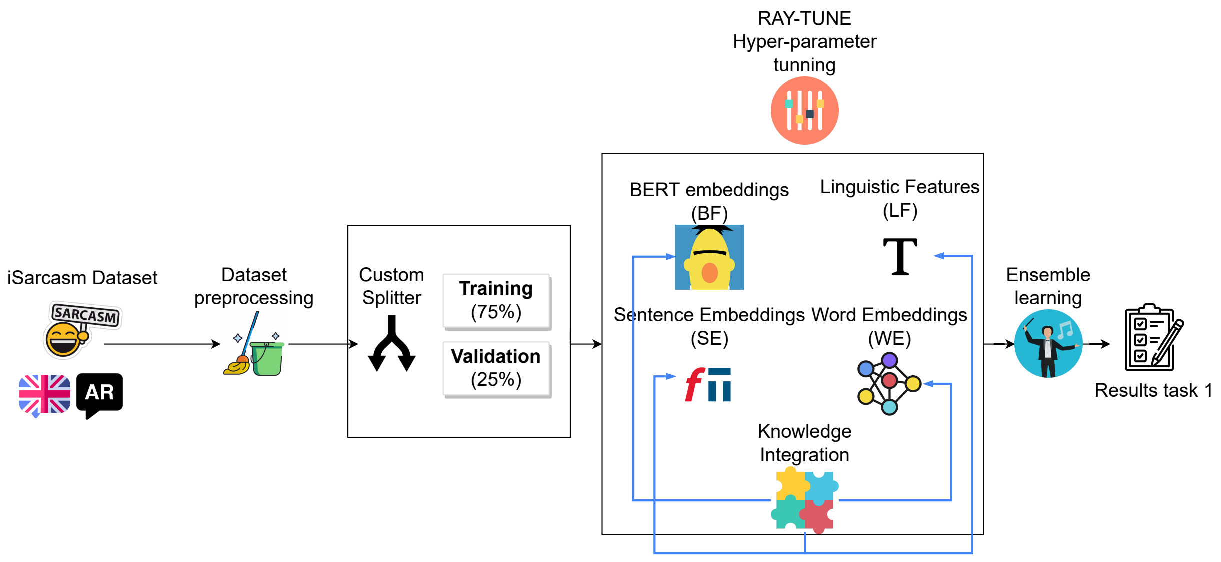

Figure 1: System architecture for solving the iSarcasm 2022 shared tasks

`ReLU`, `sigmoid`, and `tanh`). We also evaluate 5 deep-learning networks, composed from 3 to 8 hidden layers, in which the number of neurons per layer are arranged different shapes (brick, triangle, diamond, rhombus, and funnel). The activation functions evaluated for the deep-learning networks are the `sigmoid`, `tanh`, `SELU` and `ELU`. We also adjust the learning rate to evaluate `10e-03` or `10e-04`. As commented above, the word embeddings from fastText allow us to evaluate 10 convolutional and 10 bidirectional recurrent neural networks. As the dataset was heavily imbalanced, we evaluate large batch sizes, so in all the experiments, we evaluate large batch sizes: `128`, `256`, and `512`. We apply these large batch sizes for ensuring all batches contains sufficient number of instances of both classes. In addition, we apply regularisation by using a dropout mechanism (`[False, .1, .2, .3]`).

Besides, we evaluate two ensemble learning strategies to combine all the features. One method consisting of hard voting the labels predicted by each model (mode) and another method consisting of averaging the probabilities of the label of each model (mean).

It is worth mentioning that one of the tasks of English language is a multi-label problem. To solve it, we trained several binary classification models, one per ironic speech label.

4 Results and validation

During the development stage, we evaluate our models with a custom validation split. The results for the first task are depicted in Table 3, both for English and Arabic. We can observe that there is a strong difference between the results of the English and the Arabic datasets.

First, in case of English, we can observe that the results for identifying sarcasm (F1-pos) are limited, reaching a F1-score of 45.82% with the knowledge integration strategy. We focus on this metric because the validation split is unbalanced, containing 173 sarcastic documents and 521 non-sarcastic documents. The results of the LF are limited in case of English. LF are based mostly on stylometric and PoS features, which are not enough for the correct identification of sarcasm in English. Moreover, the results concerning the sarcasm label achieved with the non-contextual word embeddings (WE) are similar to the ones achieved with the LF (40.10% vs 40.08%), both slightly worse than non-contextual sentence embeddings (SE, 42.27%). The results achieved with transformers (BF) are the best results achieved with the feature sets evaluated in isolation (F1-pos of 45.10%). When combining the results, we observe that we achieve slightly superior results by the knowledgte integration approach, improving to a F1-pos of 45.82%. However, the results are more limited with the the ensemble strategies, achieving the lower results of 38.06% (mode) and 37.96% (mean). The identification of the non-sarcasm label (F1-neg) is more similar (and even slightly superior) compared with the rest of the strategies.

Second, in case of Arabic, we observe astonishing results for all feature sets. We reviewed the

	English			Arabic		
Strategy	**F1-neg**	**F1-pos**	**F1-score**	**F1-neg**	**F1-pos**	**F1-score**
LF	67.92	40.08	54.00	98.14	90.00	94.07
SE	73.21	42.27	57.74	97.99	88.35	93.17
WE	76.68	40.10	58.39	98.07	89.00	93.53
BF	82.40	45.10	63.75	99.08	94.69	96.88
LF-SE-WE-BF (K.I.)	83.57	**45.82**	**64.69**	99.08	94.69	96.88
LF-SE-WE-BF (mode)	**83.71**	38.06	60.89	**99.17**	**95.05**	**97.11**
LF-SE-WE-BF (mean)	78.84	37.96	58.40	96.71	81.86	89.28

Table 3: Results for the custom validation split in the first challenge for English and Arabic. We show F1-neg for non-sarcasm, F1-pos for sarcasm, and the macro F1-score (F1-score) for the neural networks evaluated with a feature set, and the combinations of features by using knowledge integration and two ensemble learning strategies.

dataset in order to find duplicates but we could not identify a relevant number of them. The identification of a large number of duplicates could indicate that some of the instances of the training split were present in our custom dataset. In this case and due to our lack of understanding of Arabic, we could not identify in the validation split the high performance achieved. After the competition, the ground truth labels of the test set were released for the development of the working notes. We observed that the results with the test split are more limited. For example, the F1-score falls from 94.07% with LF with the custom validation split to 33.82% with the official test split. The drop in the results cannot be explained by class imbalance, as we performed a stratified split in order to build the validation split. In fact, our validation split has 102 sarcasm documents whereas the rest (598) are non-sarcasm. The official test contains 1400 documents, 200 labelled as sarcasm whereas the rest were labelled as non-sarcasm. The results achieved with the rest of the feature sets SE, WE, and BF are in the same line, achieving the best result with a macro F1-score of 44.85% with the knowledge integration strategy.

Next, we report the results achieved for each trait separately in Table 4. This table reports the overall macro F1-score. The limited results achieved are caused by the strong imbalance among the validation split. From a total of 694 samples of the validation split of the English dataset, there are 25 samples of irony, 5 of overstatement, 20 rhetorical questions, 148 based on pure sarcasm, 6 based on satire, and 1 for understatement. These results indicate that one of the main drawbacks of our proposal is related to handle class imbalance, as the majority of the neural networks developed does not behave better than a random classifier. Moreover, some surprising results are achieved for the rhetorical questions and understatements, with the ensemble strategy of averaging the probabilities (mean).

Concerning the official results, we achieved very limited results for the binary classification challenge in English, achieving position 41 with a F1-score of the sarcastic class of 17.97% (see Table 5). The best result was achieved by user *stce* with a F1-score over the sarcastic label of 60.52%, which indicates that our system is far from the best results. The average F1-score of the sarcastic label of the rest of the participants is 32% with a standard deviation of 11.24%.

The results achieved with the Arabic dataset for the binary classification were better, with a F1-score of the sarcastic label of 31.75%, reaching position 22 of a total of 32 participants. (see Table 6). In this case, the best result was achieved by user *Abdelkader* with an F1-score over the sarcastic label of 56.32%. The average F1-score of the sarcastic label of the rest of the participants is 35% with a standard deviation of 10.04%.

5 Conclusions and further research lines

In this working notes we have described the participation of the UMUTeam in the iSarcasm shared task of SemEval 2022. In this shared task, the participants were required to solve a binary and a multi-label classification task regarding sarcasm identification in English and Arabic. We achieved a F1 score of the sarcastic class of 17.97% for English, and 31.75% for Arabic in the first challenge.

After sending the official results, we received the annotated test set. Although we are happy with our participation in this shared task, as we have evaluated some of our methods, such as a subset of language-independent feature sets in Arabic, we

Strategy	F1-trait-1	F1-trait-2	F1-trait-3	F1-trait-4	F1-trait-5	F1-trait-6
LF	52.39	66.52	68.18	56.30	55.46	49.96
SE	52.85	64.10	60.34	58.23	64.10	49.96

are aware that our results are limited. Our preliminary experiments with the official annotated test suggests that our major weakness is the class imbalance. As we already include some techniques to address this problem, as weighting the classes and evaluating larger batch sizes, we will explore methods for performing data-augmentation and try to increase the performance of our models.

Abstract

This paper describes our system used for SemEval 2022 Task 6: iSarcasmEval: Intended Sarcasm Detection in English and Arabic. We participated in all subtasks based on only English datasets. Pre-trained Language Models (PLMs) have become a de-facto approach for most natural language processing tasks. In our work, we evaluate the performance of these models for identifying sarcasm. For Subtask A and Subtask B, we used simple finetuning on PLMs. For Subtask C, we propose a Siamese network architecture trained using a combination of cross-entropy and distance-maximisation loss. Our model was ranked 7^{th} in Subtask B, 8^{th} in Subtask C (English), and performed well in Subtask A (English). In our work, we also present the comparative performance of different PLMs for each Subtask.

1 Introduction

Sarcasm, a form of figurative speech, allows people to express contempt or mock using irony. The irony is used to communicate the opposite of the intended meaning to express humour or mock something. Sarcasm plays an essential role in people's daily conversation and finds its use across social media to express thoughts. Recently, social media has drawn in millions of users around the world. Owing to its figurative nature, sarcasm poses a significant challenge to systems performing sentiment analysis on these social media platforms. Therefore, it is essential to design and develop systems that efficiently identify sarcasm. The most challenging aspect of sarcasm is the different socio-cultural backgrounds of people who drive it. Therefore, sarcasm intended by the author may not always be perceived by the audience from different backgrounds. Most datasets on sarcasm detection are collected using predefined criteria or human annotators (Oprea and Magdy, 2020). This is a sub-optimal approach that may not always capture the sarcasm intended by the author leading to noise in the models trained on it. SemEval 2022 Task 6: iSarcasmEval: Intended Sarcasm Detection in English and Arabic (Abu Farha et al., 2022) draws attention to the problem of identifying sarcasm using a dataset of intended sarcasm.

Our proposed approach for Subtask A and Subtask B approach uses a classification objective to finetune PLMs. PLMs learn semantic and syntactic features via training on large amounts of a text corpus. This information is used in downstream tasks by simply finetuning task-specific datasets. PLMs have shown remarkable performance on such downstream tasks using the simple finetuning approach (Sharma et al., 2021b). We extend the same idea to identify sarcasm (Subtask A) and identify the type of irony (Subtask B). Subtask C aimed at identifying sarcastic text from its non-sarcastic counterpart. We propose a Siamese network-based architecture using PLMs trained on a combination of cross-entropy and distance-maximisation loss. The classification objective(cross-entropy) identifies the sarcastic/non-sarcastic text, while the distance-maximisation loss maximises the distance between sarcastic/non-sarcastic features learnt by the model during training. We experimented with different PLMs, namely BERT, RoBERTa, MPNet, DeBERTa, to present a comparative study of their performance for the task of sarcasm detection.

Our final submissions for Subtask A and Subtask B used finetuning on MPNet, while we used an ELECTRA-based model for Subtask C. Our proposed system performed well in Subtask B and Subtask C(English), attaining a 7^{th} and 8^{th} rank, respectively on the official leaderboard and performed well in Subtask A. Our experiments show that all PLMs had almost similar performance with slight variation in results. The overall scores were low for Subtask A and Subtask B, indicating that sarcasm detection and identifying the type of irony is a difficult task for PLMs. However, Subtask C results show that the models can efficiently differentiate between a sarcastic text and its non-sarcastic rephrase. Our code available at GitHub[1] for method replicability.

2 Background

Identifying sarcasm is an essential task in Natural Language Processing (NLP). Owing to its figurative nature, it affects the performance of sentiment analysis systems whose performance have significantly improved over the years (Rosenthal et al., 2017) (Sharma et al., 2021a). In social media, sarcasm is mainly used for humour but can hide hateful content, making the identification of sarcasm a vital topic. Methods to deal with sarcasm detection can be separated into two categories, i.e. content-based models and context-based models (Hazarika et al., 2018). Text-based models model the problem as a classification task using pragmatic and lexical features to identify sarcasm. (Riloff et al., 2013) shows sarcasm is expressed as a combination of positive sentiment words and negative situations. Work done in(Joshi et al., 2015) uses the concept of context incongruity for sarcasm detection. Contextual methods use information about the text and the context in which the text is used. (Khattri et al., 2015) uses the sentiment of the tweet as well as the history of the author's previous tweets on similar topics to identify sarcasm. Work done in (Wallace et al., 2015) uses nouns and sentiments presented in a forum towards irony/sarcasm detection. (Hazarika et al., 2018) worked on using both content as well as contextual information for identifying sarcasm. (Castro et al., 2019) presents work done to identify sarcasm from TV shows in a multimodal setting. (Sharma et al., 2020) used a multimodal feature fusion model using attention (Bahdanau et al., 2016) for identifying sarcasm in internet memes. (Felbo et al., 2017) use models trained on emoji using distant supervision to identify sentiment, sarcasm, and emotion. Another challenge in sarcasm detection is the availability of data. Due to the highly subjective nature of sarcasm, it is challenging to collect high-quality data. (Oprea and Magdy, 2020) tries to solve this problem by introducing a dataset of intended sarcasm where the sarcastic data is labelled by the authors removing any noise or ambiguity in labels. The subjective and figurative nature of sarcasm makes it a formidable task, and it poses a challenge for affective systems performing sentiment analysis (Satapathy et al., 2017). Therefore, the task of sarcasm detection is essential to advance state-of-the-art sentiment analysis systems. Moreover, most datasets for sarcasm detection contain much noise and are sub-optimal in capturing the sarcasm intended by the author of the text. SemEval 2022 Task 6: iSarcasmEval: Intended Sarcasm Detection In English and Arabic (Abu Farha et al., 2022) aims to use a dataset of intended sarcasm for identifying sarcasm in text. The task has three subtasks which we define as:

Subtask A (English and Arabic): Given a labelled dataset D of texts, the task aims to learn a classification function that can identify sarcastic/non-sarcastic texts.

Subtask B (English only): For a given labelled dataset D of texts, the objective of the task is to learn a multilabel classification function that can predict the type of irony I where $I \in \{$ Sarcasm, Irony, Satire, Understatement, Overstatement, Rhetorical $\}$.

Subtask C (English and Arabic): Given a dataset D of sarcastic texts and their non-sarcastic rephrase, i.e. both texts convey the same meaning, the objective of the task is to learn a classification function that can identify the sarcastic text from its non-sarcastic rephrase.

Our team participated in Subtask A(English), Subtask B, and Subtask C(English).

Dataset statistics: Table 1 and Table 2 contain the dataset statistics for all Subtasks (English). Dataset statistics for Subtask A and Subtask B show a clear data imbalance problem. To overcome the class imbalance, we used sklearn to compute class weights which are defined as: Let X be the vector containing counts of each class X_i where $i \in X$ and N be the total number of samples. Then the weights for each class were given as: $weight_i = N/(length(X) * X_i)$ where length function computes the number of classes in vector X. There was no imbalance for Subtask C for each sarcastic sample, the corresponding non-sarcastic rephrase was given.

3 System overview

3.1 *Pre-trained language models (PLMs):*

NLP, a diverse field, contains an array of tasks, but most datasets for these tasks contain only a few hundred or thousand human labelled samples. This makes training large models for these tasks

Table 2: Dataset statistics for Subtask A and Subtask C.

a challenging task. Transfer learning using GloVe (Pennington et al., 2014) and FastText (Bojanowski et al., 2017) is one of the popular choices for solving this problem. Most recently, researchers came up with a method called pre-training (Qiu et al., 2020), which involves training general-purpose models from unannotated text data. This allows models to learn syntactic and semantic features in the text in an unsupervised setting. Transformer architecture proposed in (Vaswani et al., 2017) is the most common choice for training PLMs. These models can be finetuned on various downstream tasks using task-specific datasets. Finetuning allows models to adapt to small task-specific datasets easily and shows promising results (Sharma et al., 2021b). Next, we provide a summary of PLMs used in our approach.

3.2 *Brief overview of used PLMs:*

BERT: It is a bidirectional language model developed by Google that uses transformers. BERT (Devlin et al., 2019) stands for Bidirectional Encoder Representation using Transformer. It uses the auto-encoding modelling technique. It uses Masked Language Modelling (MLM) and the Next Sentence Prediction (NSP) objective for pre-training the model.

RoBERTa: A Robustly Optimized BERT Pre-training Approach was proposed by Facebook in (Liu et al., 2019) and used the BERT architecture with slight modifications to improve its performance. They replaced MLM with dynamic masking and removed the NSP objective during pre-training. They also found that BERT was undertrained, so they trained the model for longer durations with more data and bigger batch size. RoBERTa outperformed BERT on several downstream tasks.

ELECTRA: It was inspired by generative adversarial networks and introduced a new pre-training objective called Replaced Token Detection (RTD) (Clark et al., 2020). Unlike MLM, which introduces <MASK> tokens, ELECTRA replaces specific tokens with plausible fakes. The pre-training objective is to identify if the given token is replaced or the original one. Unlike BERT, where only prediction for the masked token is done, replaced token detection objective is applied to all tokens in ELECTRA, making RTD more efficient than MLM.

MPNet: It was proposed by Microsoft in (Song et al., 2020) and uses a combination of auto-regressive and auto-encoding strategies for pre-training. It solves the problem of MLM in BERT and permuted language modelling in XLNet (Yang et al., 2019) and achieves better performance. It models dependency between tokens using permuted language modelling (vs MLM in BERT) and uses the auxiliary position information to allow the model to see complete sentence reducing position discrepancy (vs permuted language modelling in XLNet). Thus, it uses a combination of masked language modelling and permuted language modelling to jointly model the dependency among predicted tokens and use positional information of complete sentences.

3.3 *Finetuning (Subtask A and Subtask B):*

For Subtask A and Subtask B, we finetuned the pre-trained models defined above. Subtask A was a binary classification task. We added a simple classification head on top of PLMs for Subtask A. It consisted of a 64-neuron dense layer followed by a batch normalisation layer and a final 1-neuron

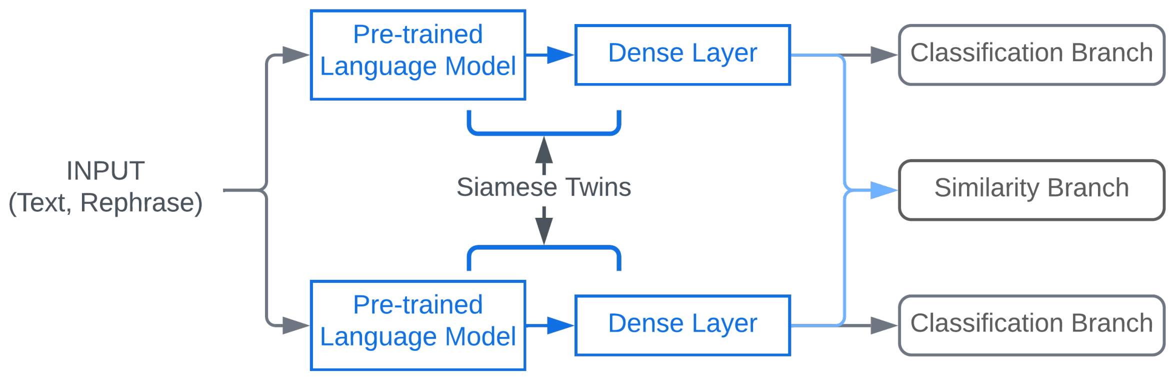

Figure 1: Overview of our Siamese network architecture for Subtask C.

layer with sigmoid activation. Subtask B was a multilabel task aimed at identifying the type of irony. We used a multi-branch model using features from the PLMs, with each branch trying to identify one of the given categories of irony. We used the same classification head for each branch defined in Subtask A.

3.4 *Siamese Network (Subtask C):*

The goal of Subtask C was to identify a sarcastic text from its non-sarcastic rephrase. We use a model based on Siamese network trained using a combination of cross-entropy and distance maximisation loss. Figure 1 shows our Siamese network architecture. A Siamese neural network comprises twin networks that can accept distinct inputs. These twin networks share the same weights, which is known as weight tying (Koch, 2015). Weight tying ensures that the features generated for distinct input are in the same feature space because each network calculates the same function. We use the PLMs to define the twin network of our Siamese architecture. We use the twin network to generate features corresponding to sarcastic text and its non-sarcastic rephrase. Next, these features are separated into two different branches, which we define as:

Distance Maximisation (Similarity branch): Since we want to separate the sarcastic text from its non-sarcastic rephrase, we want to maximise the distance between their features learned by the twin network. We merge the features generated from the twin network using Euclidean distance. It is then passed through a single neuron layer with sigmoid activation, which helps to normalise the distance within a known range of 0-1. We maximise this distance using the distance maximisation loss function, which we define as: Let d_i be the output from the final layer(1-neuron with sigmoid activation), then the loss function L is defined as:

$$L_i = (max[1 - d_i, 0])^2$$

and $L = \sum L_i$ for i belongs to N (Total samples). This ensures that sarcastic/non-sarcastic texts with similar meanings learn different sets of features.

Classification Branch: The primary role of this branch is to classify the generated features as sarcastic/non-sarcastic. It contains two classification heads, each using features generated from the twin network. The classification head comprises a 64-neuron dense layer followed by a batch normalisation layer and a final 1-neuron classification layer with sigmoid activation. Each head independently classifies the features from the respective outputs of the twin network. The classification head with the best performance on the development set was used for making predictions on the test set.

4 Experimental Setup

Text pre-processing: The text was first passed through a pre-processing pipeline to remove noise and normalize into standard features. We removed any website names in the text as they add noise to the data. We also found certain chat words like LOL (laugh out loud) present in the data and converted them into their respective full forms. Emojis are converted to their actual meanings. We used the emoji[2] library for emoji conversion. Lastly, we used ekphrasis (Baziotis et al., 2017) to normalize date, numbers to a standard format and perform spelling correction. PLMs require the text to be tokenized as part of pre-processing step. We use

hugging face's implementation of Fast tokenizers[3] for each pre-trained model. Sequence length was fixed to 70 tokens. Samples greater/smaller than the defined length were truncated or padded.

Data preparation for Siamese network (Subtask C): The dataset for Subtask C consisted of sarcastic texts and their rephrase. We rearranged this data to make sure the input to the Siamese network contains samples in the form of (sarcastic, rephrase) and (rephrase, sarcastic). This is important because the classification layers on top of the Siamese network are used to make predictions on the inputs of the twin network independently using two classification heads. If we do not rearrange the data, each of the two heads will learn to simply predict the output as always sarcastic and non-sarcastic, thereby not learning from training data.

Finetuning: Our approach for all subtasks involves finetuning PLMs and using their features. We used features of [CLS] token for BERT, ELECTRA and start token (<s>) features for MPNet and RoBERTa. These features are then passed to further layers of models as per the architecture we defined above.

Hyperparameters and Training: We developed our models on Keras[4] (Chollet et al., 2015) and used Hugging Face's[5] implementation of transformer[6](Wolf et al., 2020) models. Finetuning was performed on Colab using TPUs. For finetuning we used Adam (Kingma and Ba, 2015) optimiser. We experimented with learning rates ranging from 2e-5 to 5e-5. For Subtask A and Subtask B, we used a binary cross-entropy loss. For Subtask C, we used a binary cross-entropy loss on the classification branch and distance maximization objective on the similarity branch. We finetuned the models for ten epochs and used the weights with the best performance on the development set to make predictions on the test set.

Evaluation metric: Subtask A uses the F1 score of the sarcastic class as an evaluation metric. For Subtask B, the macro averaged F1 score is the official metric, while for Subtask C, accuracy is used as the evaluation metric.

5 Results

Table 3 and Table 4 describe the results of our experiments using different pre-trained models. Our official submission for the task used MPNet for Subtask A, Subtask B and ELECTRA for Subtask C. Our system was ranked 7th in Subtask B, attaining a macro F1 score of 0.076 with the highest F1 score for satire and second highest score for sarcasm and understatement category. Our Siamese architecture-based system also performed well, attaining accuracy of 75% and ranked 8th on the leaderboard for Subtask C.

We performed experiments using BERT, RoBERTa, MPNet, and ELECTRA during the

[3]Hugging Face's Fast Tokenizers

[5]https://huggingface.co
[6]https://huggingface.co/transformers

evaluation phase. We evaluated these models using the validation set, and the model with the best performance was used to make a submission on the test data. Table 3 and Tabel 4 summarise results using different pre-trained models. We have highlighted the official test submissions in bold while underlined the best performing metric across different models. Subtask A results show that all PLMs have similar performance for sarcasm detection. They perform well, but there is considerable scope for improvement. PLMs are trained on general text corpus making it difficult for them to understand figurative content like sarcasm. For Subtask B, RoBERTa performs better than other PLMs. Results for Subtask B show that it is comparatively easy to identify sarcasm and satire compared to other types of irony, which have very low performance on evaluation metrics. Another reason for this could be the high imbalance in the dataset, making it difficult for models to identify different types of irony. For Subtask C, all models have similar performance with slight variations. The models perform significantly better on evaluation metrics when compared to Subtask A and Subtask B, indicating that models can distinguish between sarcastic and non-sarcastic content having similar meanings.

6 Conclusion

This paper describes our proposed model used for SemEval 2022 Task 6: iSarcasmEval: Intended Sarcasm Detection In English and Arabic. Different PLMs were used to do a comparative analysis of their performance for the sarcasm detection task. Our fine-tuning approach worked well for Subtask B, with the best score for satire and second-best performance for the sarcasm and understatement category. For Subtask C, we proposed a novel Siamese network architecture to identify sarcastic content from it's non-sarcastic rephrase. It performed well, attaining 8^{th} rank on the leaderboard. Our comparative analysis shows that sarcasm detection is a difficult task for the PLMs, and there is scope for further improvements, which we will take up in future works.

Abstract

This paper presents solution systems for task 6 at SemEval2022, iSarcasmEval: Intended Sarcasm Detection In English and Arabic. The shared task 6 consists of three sub-task. We participated in subtask A for both languages, Arabic and English. The goal of subtask A is to predict if a tweet would be considered sarcastic or not. The proposed solution SarcasmDet has been developed using the state-of-the-art Arabic and English pre-trained models AraBERT, MARBERT, BERT, and RoBERTa with ensemble techniques. The paper describes the SarcasmDet architecture with the fine-tuning of the best hyperparameter that led to this superior system. Our model ranked seventh out of 32 teams in subtask A- Arabic with an f1-sarcastic of 0.4305 and Seventeen out of 42 teams with f1-sarcastic 0.3561. However, we built another model to score f-1 sarcastic with 0.43 in English after the deadline. Both Models (Arabic and English scored 0.43 as f-1 sarcastic with ranking seventh).

1 Introduction

In recent years, sarcasm has received remarkable research attention due to its importance and extraordinary impact on society, especially with the significant increase in its use in social media (Ghosh et al., 2020; Van Hee et al., 2018; Faraj and Abdullah, 2021). However, sarcasm is saying something, and what is meant is the opposite. Adding to the difficulty of detecting sarcasm is that all the words in the sentence are positive, but the intended meaning is just the opposite (Channon et al., 2005). Therefore, the detection of sarcasm depends mainly on the general meaning of the sentence, which makes us move away from traditional methods and use artificial intelligence, especially natural language processing.

Natural Language Processing (NLP) is a branch of artificial intelligence that gives machines the ability to read and understand the meanings of humans (Nadkarni et al., 2011). As a result, machines became able to understand the underlying meanings of words and not just rely on keywords. Moreover, it helps reveal forms of speech, such as emotion analysis, humor, ridicule, abuse, etc (Abujaber et al., 2021; Qarqaz et al., 2021).

Task 6 at SemEval-2022, "iSarcasmEval: Intended Sarcasm Detection In English and Arabic" (Abu Farha et al., 2022) suggested three main subtasks in both Arabic and English languages: SubTask A is a binary classification problem that determines whether a tweet is sarcastic or not, SubTask B is a multi-label classification problem which determines the category of tweets sarcastic if it is found in English only, SubTask C is two sentences, one sarcastic and the other paraphrased to be non-sarcastic, define which one is sarcastic.

We only participated in subtask A. Our solution combines four state-of-the-art pre-trained NLP models: AraBERT and MARBERT for Arabic and BERT and RoBERTa for English. SarcasmDet placed seventh out of 32 teams in the subtask A-Arabic and seventh (after the competition deadline) out of 42 teams. We have experimented with the pre-trained language models with different hyperparameters using the simple transformers library. It is worth mentioning that using the ensemble technique has increased our score remarkably.

The paper is constructed as follows: Section 2 provides the related works. Section 3 describes the shared task and the provided dataset. Section 4 describes our system solution. Section 5 shows our experiments. Section 6 provides the results, and finally, the conclusion is in Section 7.

2 Related Work

Sarcastic texts over social media are among the most researched issues of importance for sentiment analysis. Authors of (Rajadesingan et al., 2015) proposed Sarcasm Classification Using a Behavioral modeling Approach. They investigate users' past tweets and use psychological studies to better sarcasm detection of tweets. They used three models to perform their evaluation (Logistic Regression (LR) Decision Tree (DT) and support vector machine (SVM)). The evaluation is performed on a dataset obtained from Twitter and provided on Kaggle with 9104 sarcastic tweets. They used different class distributions (1:1, 10:90, and 20:80) and 10-fold cross-validation techniques. The best performance was obtained from the LR model and class distribution (1:1) with 83.46% accuracy. In 2016, researchers of (Bouazizi and Ohtsuki, 2016) provided pattern-based features approach to detect sarcasm expressions posted on Twitter which extracted with the hashtag sarcasm. They applied four models (Random Forest (RF), SVM, K-Nearest Neighbour (KNN), and Max-Entropy (Max.Ent.)) on three different balanced datasets with different sizes (1000, 2256, and 6000 instances). RF model outperformed the rest with 81.3% in terms of F1-score. In this paper (Pawar and Bhingarkar, 2020), researchers almost did the same work; they used the Pattern-based approach and the same classifiers (RF, SVM, and KNN). The used dataset consists of 9104 sarcastic tweets. RF outperforms the rest in accuracy and F1-score with 81% and 79%, respectively.

The focus on detecting sarcasm in Arabic has emerged in recent years, and researchers have become increasingly interested in this field. In (Karoui et al., 2017), the authors were among the beginning people to supply a dataset to detect sarcasm in Arabic. First, they collected the dataset from Twitter of the Arabic tweets with different Arabic dialects, such as the Egyptian, Syrian, and Saudi dialects. Then, they cleaned the dataset, 5,479 tweets, including 1733 irony, and added four features for each tweet: surface, sentiment, shifter, and internal context features. Finally, they applied several machine learning algorithms, and experiments showed that the Random Forest classifier achieved a high accuracy of 72.76% for detecting sarcasm in Arabic tweets.

On the other hand, another dataset is provided for sarcasm in Arabic by (Farha and Magdy, 2020). This dataset contains three topics: sarcasm, sentiment, and dialect labels include 10,547 rows of tweets where 16% are sarcastic tweets. The researchers applied a Bidirectional LSTM deep learning approach (biLSTM) to achieve an F1-score of 0.46, which indicates the difficulty of detecting sarcasm in the Arabic language.

The researchers in (Faraj and Abdullah, 2021) participated in the WANLP 2021 Shared Task for subtask 1 (Sarcasm Detection) competition. First, they used the AraSarcasm-v2 dataset and then cleaned data by using NLTK library (Bird, 2006), such as normalized and removed emojis, links, and Html tags. Next, they implemented several pre-trained models such as AraBERt, multilingual BERT cased and uncased, and XLM-Roberta. Their solution, called SarcasmDet, is based on fine-tuning of the large AraBERT and base AraBERT, and they got first place with an accuracy of 0.7830 and fourth place with f1-sarcastic 0.5989.

3 Task and Data Description

In Shared Task on SemEval 2022 - Task 6 (iSarcasmEval): Intended Sarcasm Detection In English and Arabic (Abu Farha et al., 2022), has three subtasks in two languages: Arabic and English, and each task solves different requirements. We participated in SubTask A: a binary classification problem that determined whether a tweet contains sarcasm or not.

The dataset consists of nine columns: the tweet, the rephrase, sarcastic, which defines whether the tweet is sarcastic or non-sarcastic, irony, stair, understatement, overstatement, and the rhetorical question. The last five columns are the type of sarcasm contained in the tweets. Moreover, the dataset contains 3467 non-null rows. Regarding our task, a binary sarcasm classification of the tweets, the tweet, and the sarcasm are the only required columns to solve the task. Table 1 shows a sample of the utilized dataset in English subtask A.

Table 1: Sample of English data

Tweet	**Sarcastic**
The only thing I got from college is a caffeine addiction	1
I love it when professors draw a big questionmark next to my answer on an exam becauseI'm always like yeah I don't either	1
The population spike in Chicago in 9 months is about to be ridiculous	0
You'd think in the second to last English classof the year my prof would stop calling meSean	0

The data is highly imbalanced as there are 2600 tweets classified as non-sarcastic and 867 as sarcastic.

id	tweet	Sarcastic	rephrase	dialect
3	اية المهلبية دي يصحي	1	ما هذا الجمال	nile
2805	أينما وجد العدل فثم شرع الله	0	NaN	msa

Table 2: sample from the training Arabic dataset

The Arabic training dataset contains 3102 tweets and five columns: id, tweet, sarcastic, rephrase, and dialect. They have categorized the text into sarcastic or non-sarcastic based on the author himself. Table 2 shows an example of training the Arabic dataset for subtask A- Arabic. The Arabic dataset in subtask A- Arabic is imbalanced due to class sarcasm and a clear difference between sarcastic and non-sarcasm tweets. The number of sarcastic tweets was 745, and the number of non-sarcastic tweets was 2357.

4 SarcasmDet Description

Texts are sequential, so they must be trained by models supporting data in which the order of its features is an important factor. Transformers are deep learning techniques that utilize the idea of self-attention mechanism (Potamias et al., 2020). In this work, two transformer-based pre-trained models are fine-tuned to achieve the requirements of the sarcasm detection task for each language. The two models are the BERT and the RoBERTa for English, where we combined two pre-trained models, AraBERT and MARBERT, for Arabic.

Subtask A - English Figure 1 shows the architecture of the proposed model for English. The ensemble technique is adopted by performing a weighted sum for the predictions of BERT and RoBERTa. One BERT machine with weight one and four RoBERTa machines, each with weight one, is deployed except for one machine with a weight of 0.5.

Regarding the BERT model, the dataset is tokenized by a pre-defined tokenizer of the model. The BERT model originally consists of 12 layers, the first ten layers are chosen to be untrainable and the last two layers to be trainable. Moreover, the model is trained using a batch size equal to 6 and the number of epochs equal to 3. As to the RoBERTa model, the dataset is tokenized using its pre-defined tokenizer. The layers are fine-tuned. The first nine layers are untrainable, the last three layers are trainable, and the model is trained using a batch size equal to 12 and the number of epochs equal to 3.

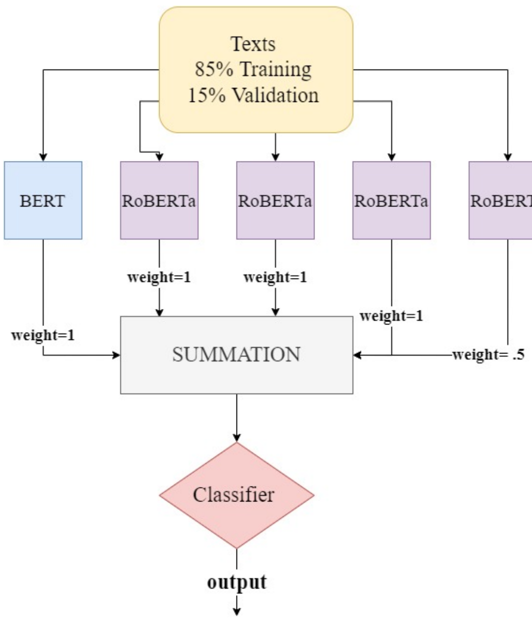

Figure 1: Architecture of SarcasmDet-English

Subtask A - Arabic The ensemble is a technique of combining several different models in the prediction process. In addition, we used hard voting that depends on the highest vote from all the model predictions. We combined two pre-trained models, AraBERT and MARBERT. The Arabic pre-trained model called AraBERT (Antoun et al.). AraBert is a pre-trained model that focuses directly on the Arabic language, and it is based on the BERT architecture (Devlin et al., 2018). There are two versions of AraBERT(v01 and v02). The first version, AraBERT-v01, was trained on 77M sentences, with a size of 23GB and 2.7B of words. The second version, AraBERT-v02, was trained on 200M sentences with 77GB and 8.6B words. MARBERT (Abdul-Mageed et al., 2020) is also based on the BERT architecture without the next sentence prediction and focuses on Dialectal Arabic and MSA.

In SarcasmDet, tweets are fed to the AraBERT and MARBERT. Next, we added the final layer, which is fine-tuning with the best hyperparameters as shown in **table 3** to classify the Arabic tweet into a sarcastic tweet or not. Then we applied the

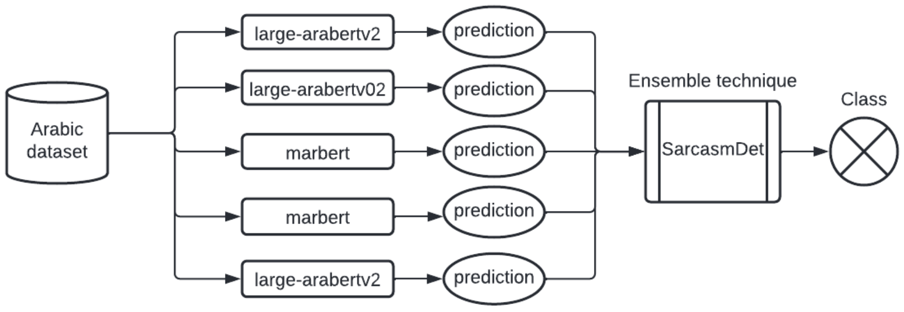

Figure 2: Architecture of SarcasmDet-Arabic

hard voting technique to select the final label in all tweets, as shown in Figure 2.

Model	LR	Epoch	Batch Size
large-arabertv2	2e-5	5	8
marbert	1e-5	5	8

Table 3: Best the hyperparameter that we used in our models

5 Experiments

5.1 English

Unfortunately, the number of sarcastic sentences is much smaller than the number of the non-sarcastic ones, so using the accuracy to evaluate the model performance is not a good choice. Thus, the metric used to describe the version of the model is the F1-Score. F1-score is the harmonic mean of the precision and the recall. It is the average of the model's ability to find all sarcastic sentences and how accurate it is when classifying sentences as sarcastic.

The transformer-based models, BERT and RoBERTa, are trained using different hyperparameters. Table 4 and Table 5 show the results of the models with different fine-tuning.

Table 4: Result of Bert Model

BERT Parameters	Results F1-sarcastic
Batch size: 6 Number of epochs: 3 Number of trainable layers:4	0.38
Batch size: 6 Number of epochs: 3 Number of trainable layers:1	0.35
Batch size: 6 Number of epochs: 3 Number of trainable layers:2	0.39

Table 5: Result of RoBert Model

RoBERTa Parameters	Results f1-sarcastic
Batch size: 6 Number of epochs: 3 Number of trainable layers:3	0.36
Batch size: 4 Number of epochs: 2 Number of trainable layers:4	0.29
Batch size: 7 Number of epochs: 3 Number of trainable layers:4	0.37

5.2 Arabic

We have experimented with fine-tuning for two pre-trained models: AraBERT and MARBERT with different hyperparameters. Also, we attempted to increase the dataset using the augmentation technique with the ArSarcasm-v2 dataset to improve the results. We used the data set after the increment and fed the tweet to AraBERT and MARBERT, then fine-tune with hyperparameters to classify the Arabic tweet into a sarcastic tweet or not. **table 6** shows the hyper-parameters we have used in our experiments for the tested models.All of the models have been implemented using the HuggingFace library and SimpleTransforner pre-trained package.

6 Results

6.1 English

The model achieved a recall value equal to 0.37, a precision value equal to .51, and an F1-Score equal to 0.43. Table 7 shows the parameters and the results of the BERT model, RoBERTa model, and the ensemble model. It is noteworthy that the higher F1-Score in the SemEval competition in subtask A of task 6 is 0.6052, and the seventh rank is 0.4342. So the proposed architecture results, which is 0.4322, are equivalent to the eighth rank

Experiment	Model	LR	Epoch	Batch Size
1	large-arabertv2	1e-5	5	8
2	large-arabertv2	2e-5	5	8
3	large-arabertv02	2e-5	5	8

6	large-arabertv2	2e-5	5	8
7	marbert	1e-5	5	8

Table 6: all the hyper-parameter that we used in our experiments

in the competition.

Table 7: Best Parameters of BERT, RoBERTa and Ensembling.

Model	Parameters	Results (F1-Score)
BERT	Batch size: 6 Number of epochs: 3 Number of trainable layers: 2	.39
RoBERTa	Batch size: 12 Number of epochs: 3 Number of trainable layers: 3	.41
Ensemble	BERT model with weight :13 RoBERTa models with weight:11 RoBERTa with weight : .5	.43

6.2 Arabic

First, we applied AraBERT and MARBERT with different finetuning. AraBERT outperformed on MARBERT with a score of an f1-sarcastic 0.4255. Then, we augmentation the dataset and applied AraBERT and MARBERT, in this case, MARBERT outperformed AraBERT with a score of an f1-sarcastic 0.4065, although the data size increased, this did not lead to an improvement in the results, the best result was for ARABERT using Arabic data for the task. But SarcasmDet using the ensemble technique specifically hard vote significantly outperformed both AraBERT and MARBERT with an f1-sarcastic score of 0.4304, Table **table 8** shows the organizers' final result and table **table 9** shows all experiments that we have implemented.

7 Conclusion

Sarcasm is an influential issue in human life, whether written or spoken. However, sarcasm detection in texts is a challenging task. This paper presented our model SarcasmDet for solving subtask A- English and Arabic in task6 at SemEval 2021 - iSarcasmEval: Intended Sarcasm Detection in English and Arabic. SarcasmDet is based on the fine-tuning of two pre-trained NLP models for each language and then applied ensemble technique to improve the model. The models trained on a dataset obtained from a competition SemEval 2022 subtask A of task 6. For English subtask A, the dataset consists of 3467 records, 866 of them are sarcastic, and the rest are non-sarcastic. The results showed that the RoBERTa model outperformed the BERT model, where the Ensembling technique outperformed both in the f1-sarcastic score, which was 0.43. On the other hand, the Arabic dataset consists of 8K tweets divided into training and testing sets. Our solution SarcasmDet is ranked 7th out of 32 teams with an f1-sarcastic score of 0.4305.

Abstract

In this paper, we describe our submissions to SemEval-2022 contest. We tackled subtask 6-A - "iSarcasmEval: Intended Sarcasm Detection In English and Arabic – Binary Classification". We developed different models for two languages: English and Arabic. We applied 4 supervised machine learning methods, 6 preprocessing methods for English and 3 for Arabic, and 3 oversampling methods. Our best submitted model for the English test dataset was an SVC model that balanced the dataset using SMOTE and removed stop words. For the Arabic test dataset, our best submitted model was an SVC model that preprocessed removed longation.

1 Introduction

The rapid development of various types of social networks allows the development of increasingly offensive language in general and sarcasm in particular. Sarcasm is the use of words that mean the opposite of what you want to say especially to insult someone, show irritation, or be funny[1].

Sarcastic language can harm individuals or groups of people and may cause harmful effects on society. Thus, it is important to develop high-quality systems capable of detecting sarcastic expressions automatically.

Sarcasm detection is a difficult task not only for a computer but even for a human being. High-quality performance of this task requires understanding the context of the situation, the relevant culture, and in some cases the specific issue or people involved in this situation (Maynard and Greenwood, 2014).

Moreover, the noisy nature of social media texts especially Twitter messages make the detection task even harder. Therefore, it is an interesting and challenging task to detect sarcasm using supervised machine learning (ML) methods and natural language processing (NLP) tools.

Furthermore, Rosenthal et al. (2014) show a significant drop in sentiment polarity classification performance when processing sarcastic tweets, compared to non-sarcastic ones.

In this paper, we describe our research and participation in subtask 6-A for sarcasm detection in tweets written in two languages: English and Arabic. The full description of task 6 in general and 6-A in particular including the datasets and the participating teams is given in Abu Farha et al. (2022).

The structure of the rest of the paper is as follows. Section 2 introduces a background concerning sarcasm detection, text preprocessing, and text classification with imbalanced classes. Section 3 describes subtask 6-A and its datasets. In Section 4, we present the submitted models and their experimental results. Section 5 summarizes and suggests ideas for future research.

2 Related Research

Most prior textual sarcasm detection datasets have been annotated by using either manual labeling or a weak supervision method. In the first approach, sarcasm labels are provided by human annotators (e.g., Filatova, 2012; Riloff et al., 2013; Abercrombie and Hovy, 2016). However, such labels represent annotator perception, which

[1] www.merriam-webster.com. Retrieved 9-Feb-2022.

may differ from the author intention, as further pointed out by Oprea and Magdy (2020).

In the second approach, texts are labeled as sarcastic if they meet predefined criteria, e.g., including specific tags (e.g. #irony, #sarcastic, #sarcasm) (Ptáček et al., 2014; Khodak et al., 2018). However, this method can lead to noisy labels because of various reasons (Oprea and Magdy, 2020).

To overcome these disadvantages, Oprea and Magdy (2019) introduced another method. In their method, the sarcasm labels for texts are provided by the authors themselves.

Most of the sarcasm detection studies are in the English language (Campbell and Katz, 2012; Riloff et al., 2013; Bamman and Smith, 2015; Rajadesingan et al., 2015; Wallace et al., 2015; Amir et al., 2016; Joshi et al., 2016; Hazarika et al., 2018; Oprea and Magdy, 2019).

There are also some studies in Arabic (Karoui et al., 2017; Ghanem et al.,2019; Abbes et al., 2020; Abu-Farha and Magdy, 2020).

For more information about various issues concerning sarcasm detection please refer to survey papers such as Joshi et al. (2017), Sarsam et al. (2020), Verma et al. (2021), and Moores and Mago (2022).

2.1 Text preprocessing

Text preprocessing is an important step in many NLP domains such as ML, sentiment analysis, text mining, and text classification (TC). In text documents in general and in social text documents in particular, it is common to find various types of noise, e.g., typos, emojis, slang, HTML tags, spelling mistakes, and repetitive letters. Analysis of text that has not been carefully cleaned or preprocessed might lead to misleading results.

Not all of the preprocessing types are considered effective for TC tasks. For instance, HaCohen-Kerner et al. (2008) demonstrated that the use of word unigrams including stop words leads to improved results compared to the results obtained using word unigrams excluding stop words.

HaCohen-Kerner et al. (2019) investigated the impact of all possible combinations of six preprocessing methods (spelling correction, HTML tag removal, converting uppercase letters into lowercase letters, punctuation mark removal, reduction of repeated characters, and stopword removal) on TC in three benchmark mental disorder datasets. In another study, HaCohen-Kerner et al. (2020) explored the influence of various combinations of the same six basic preprocessing methods mentioned in the previous paragraph on TC in four general benchmark text corpora using a bag-of-words representation. The general conclusion was that it is always advisable to perform an extensive and systematic variety of preprocessing methods, combined with TC experiments because this contributes to improving TC accuracy.

2.2 Text classification with imbalanced classes

The problem of TC with imbalanced classes is that there are too few examples of the minority class to effectively learn a good predictive TC model. There are various methods to cope with this problem. The main idea is to change the dataset until a more balanced distribution is reached. Two well-known sampling methods that enable such a change are oversampling and undersampling. Random oversampling means randomly duplicating examples in the minority class. Random undersampling means randomly deleting examples in the majority class.

An additional frequent method is to generate synthetic samples which means randomly sampling the attributes from instances in the minority class. There are several algorithms that support the generation of synthetic samples. The most popular is called the Synthetic Minority Oversampling Technique (SMOTE) (Chawla, 2002). This method is an oversampling method that creates synthetic samples from the minor class instead of creating copies. This method selects two or more similar instances and perturbs an instance one attribute at a time by a random amount within the difference to the similar instances. We used also two other oversampling methods BorderlineSMOTE and ADASYN that work similarly.

Readers interested in expanding and deepening the topic of solutions to TC with imbalanced classes are referred to the following articles (Chawla et al., 2002; He and Ma, 2013; Krawczyk, 2016; Brownlee, 2020, Shaikh et al., 2021).

3 Task and Datasets Description

Tables 1-4 present various statistical details about the training and test sets for English and Arabic**.**

The analysis of the details presented in Tables 1 and 2 show that the training and test sets for English are highly imbalanced, with a ratio of about 25:75 and 14:86 (non-sarcastic:sarcastic), respectively. We tried to balance the dataset in our experiments using the oversampling methods that we have mentioned above.

Table 4: details of the test set for Arabic.

The analysis of the details presented in Tables 3 and 4 show a similar picture. The training and test sets for Arabic are highly imbalanced, with a ratio of about 39:61 and 14:86 (non-sarcastic:sarcastic), respectively. Also, for Arabic, we tried to balance the dataset in our experiments using the oversampling methods that we have mentioned above. Both for English and Arabic, the test datasets are even more imbalanced than the compatible training datasets.

4 The Submitted Models and Experimental Results

We applied 4 supervised ML methods on the training datasets: Random Forest (RF), Support Vector Classifier (SVC), Logistic regression (LR), and Decision Tree (DT).

RF is an ensemble learning method for classification and regression (Breiman, 2001). Ensemble methods use multiple learning algorithms to obtain improved predictive performance compared to what can be obtained from any of the constituent learning algorithms. RF operates by constructing a multitude of decision trees at training time and outputting classification for the case at hand. RF combines Breiman's "bagging" (Bootstrap aggregating) idea in Breiman (1996) and a random selection of features introduced by Ho (1995) to construct a forest of decision trees.

SVC is a variant of the support vector machine (SVM) ML method (Cortes and Vapnik, 1995) implemented in SciKit-Learn. SVC uses LibSVM (Chang & Lin, 2011), which is a fast implementation of the SVM method. SVM classifies vectors in a feature space into one of two sets, given training data. It operates by constructing the optimal hyperplane dividing the two sets, either in the original feature space or in higher dimensional kernel space.

LR (Cox, 1958; Hosmer et al., 2013) is a linear classification model. It is known also as maximum entropy regression (MaxEnt), logit regression, and the log-linear classifier. In this model, the probabilities describing the possible outcome of a single trial are modeled using a logistic function.

DT (Song and Ying, 2015) is a flowchart-like structure method in which each internal node represents a "test" on an attribute (e.g. whether a coin flip comes up heads or tails), each branch represents the outcome of the test, and each leaf node represents a class label (decision taken after computing all attributes).

These ML methods were applied using the following tools and information sources:

- The Python 3.7.3 programming language[2].
- Scikit-learn – a Python library for ML methods[3].
- Numpy – a Python library that provides fast algebraic calculous processing, especially for multidimensional objects[4].

We applied six preprocessing methods for English:

1. change to lower-case
2. stop words removal
3. numbers removal
4. emojis removal
5. HTML tags removal
6. punctuations removal

For Arabic we applied three preprocessing methods:

1. punctuations removal
2. Tashkeel removal[5]
3. longation removal[6,7]

We applied three oversampling methods to balance the data:

4. SMOTE
5. BorderlineSMOTE
6. ADASYN

Tables 5 and 6 present the F1-scores over the PCL class of our models for English and Arabic, respectively. The analysis of the details presented in Tables 5 and 6 show that there is a big impact on the longation in the Arabic language, and removing it improved the models. In the English language, we do not see a specific preprocess method that is the most effective method (mark in bold – the three highest results in each language for different number of word unigrams).

Table 6: F1-scores over the PCL class of our models for Arabic.

Table 7 presents the F1-Scores over the PCL class of our best models for English and Arabic that were submitted to the competition. The F1-scorer over the PCL class on the training dataset of our best model for English and Arabic were 0.4183 and 0.6791 respectively while the F1-scores over the PCL class on the test dataset of our best model were only 0.215 and 0.29515 respectively.

Possible explanations might be: (1) The training dataset is different in its balance rate than the balance rate of the competition test datasets and (2) the content of a relatively high number of Tweeter messages in the competition test dataset are fundamentally different from the content of the Twitter messages in the training dataset.

5 Summary and Future Research

In this paper, we describe our models and submissions to subtask 6-A of SemEval-2022: sarcasm detection in Twitter messages written in English and Arabic using preprocessing methods and word n-grams.

Language	Model name and split mode	ML Method	Applied text preprocessing and oversampling methods	F1-score over the PCL class on the training dataset	F1-score over the PCL class on the test dataset	Place in the competition
English	Ilan_SVC 80-20	SVC	Balance with SMOTE, removed stop words	0.418	0.215	33-35
Arabic	Matan_SVC 80-20	SVC	No balance method, removed longation	0.679	0.295	24

Table 7: F1-scores over the PCL class of our best models for English and Arabic that were submitted to the competition.

We applied 4 supervised ML methods, 6 preprocessing methods for English and 3 for Arabic, and 3 oversampling methods.

Our best submitted model for the English test dataset was an SVC model that balanced the dataset using SMOTE and removed stop words. For the Arabic test dataset, our best submitted model was an SVC model that preprocessed longation removal.

There are various ideas for future research that are connected to the nature of Twitter messages as follows: (1) the use of skip character n-grams because they serve as generalized n-grams that allow us to overcome problems such as noise and sparse data (HaCohen-Kerner et al., 2017), which are common to Twitter messages and (2) Many Twitter messages contain acronyms. Acronym disambiguation might enable better classification (HaCohen-Kerner et al., 2010A).

Another idea that may lead to better classification is to use additional feature sets such as stylistic feature sets (HaCohen-Kerner et al., 2010B).

SemEval-2022 Task 7: Identifying Plausible Clarifications of Implicit and Underspecified Phrases in Instructional Texts

Michael Roth **Talita Anthonio** **Anna Sauer**
University of Stuttgart
Institute for Natural Language Processing
{michael.roth,talita.anthonio,anna.sauer}@ims.uni-stuttgart.de

Abstract

We describe SemEval-2022 Task 7, a shared task on rating the plausibility of clarifications in English-language instructional texts. The dataset for this task consists of manually clarified how-to guides for which we generated alternative clarifications and collected human plausibility judgements.[1] The task of participating systems was to automatically determine the plausibility of a clarification in the respective context. In total, 21 participants took part in this task, with the best system achieving an accuracy of 68.9%. This report summarizes the results and findings from 8 teams and their system descriptions. Finally, we show in an additional evaluation that predictions by the top participating team make it possible to identify contexts with multiple plausible clarifications with an accuracy of 75.2%.

1 Introduction

Understanding texts in natural language requires that both explicit text components as well as implicit references and relationships are interpreted correctly. This applies in particular to instructional texts, which demand a clear understanding of individual instruction steps in order to reach the desired goal. Possible uncertainties should therefore already be clarified in the text. In principle, such clarifications can also be generated automatically. In that case, however, it will be necessary to investigate the circumstances under which a clarification is plausible and unambiguous.

As a first step towards such an investigation, this shared task evaluates the ability of NLP systems to distinguish between plausible and implausible clarifications of an instruction. Inspired by the success of previous cloze-based evaluations (see Section 2), we set up our task as a cloze task, in which clarifications are presented as fillers and systems have to identify which fillers plausibly fit in a given context (see Table 1). Our focus in this task is on different types of referring expressions that are either underspecified or not realized explicitly at all, and we consider possible clarifications in the form of additional specification or explicitation.

Choose a Hair Salon			
(1)	Check ratings of different salons.		
(2)	Visit the salon's website.		
(3)	Call __$\emptyset$__ and ask questions.		
✓	the salon	✗	a friend
✓	the number	✗	your stylist
✓	the owner		

Table 1: Simplified example from a pilot study: the top shows a sentence (3) and shortened version of its discourse context (1–2). In the clarified version of this sentence, the phrase *the salon* was inserted. Other phrases shown in the bottom part are automatically generated fillers, annotated as plausible (✓) or implausible (✗).

Research in linguistics and psychology has shown that individuals use language differently (Pennebaker and King, 1999; Heylighen and Dewaele, 2002). In particular when it comes to implicit and underspecified language, individual differences can also lead to different interpretations (Scholman and Demberg, 2017; Poesio et al., 2019). As a result, worst case scenarios include medical instructions being followed incorrectly or news being passed on inaccurately. In view of the fact that language is inherently ambiguous, however, it is neither sensible nor expedient to produce clarifications for all occurrences of underspecification. Avoiding worst-case scenarios therefore goes beyond ranking individual clarifications by plausibility and must take into account whether multiple (incompatible) clarifications are perceived as plausible, thus reflecting possible misunderstandings.

We discuss our task and data in more detail in

[1]The task data is available at https://github.com/acidAnn/claire.

Sections 3 and 4, respectively. The participating teams are summarized in Section 5 and their results on the task and additional evaluations in Section 6.

2 Related Work

Cloze tasks have become a standard framework for evaluating various discourse-level phenomena in NLP. Some prominent examples include the narrative cloze test (Chambers and Jurafsky, 2008), the story cloze test (Mostafazadeh et al., 2016), and the LAMBADA word prediction task (Paperno et al., 2016). In these tasks, NLP systems are required to make a prediction about the filler of a cloze that is most likely to continue the discourse. However, it is not always clear whether exactly one likely filler exists. Evaluations typically circumvent this issue by requiring systems only to distinguish between a correct and an incorrect filler, or by evaluating predictions only with a relative measure. Both of these options ignore the more general challenge that multiple fillers can be plausible. Our shared task addresses this challenge explicitly, by requiring systems to classify different clarifying fillers as either plausible or implausible. This is a natural extension of previous cloze tasks to discourse contexts in which multiple interpretations are plausible. This extension makes it possible to evaluate in how far NLP systems can reflect cases of underspecification and uncertainty as well as possible sources of misunderstanding.

Our task is based on manual text revisions that can be traced through revision histories and by which possible needs for clarification can be identified. Thus, the task follows a number of existing research contributions that deal with text revisions. A number of previous works examine reasons for and types of revisions in, for example, Wikipedia (Bronner and Monz, 2012; Daxenberger and Gurevych, 2012; Yang et al., 2017; Faruqui et al., 2018) and the essay-based corpus ArgRewrite (Zhang and Litman, 2015, 2016; Afrin and Litman, 2019; Kashefi et al., 2022). In this work, we use revision histories of instructional texts because clarifications seem particularly relevant in this domain.

The starting point of our task is the data set wikiHowToImprove (Anthonio et al., 2020), which comprises revision histories of more than 250,000 how-to guides from the online platform wikiHow.[2] In our own previous work, we investigated the extent to which these histories are useful for examining textual improvements (Anthonio and Roth, 2020), predicting revision requirements (Bhat et al., 2020), modeling cases of lexical vagueness (Debnath and Roth, 2021), and resolving implicit references (Anthonio and Roth, 2021). The last two studies in particular have shown that wikiHowToImprove is well suited as a resource for studying clarifications of semantic phenomena. We describe one of these studies and how we build upon it in more detail in Section 3.

[2]www.wikihow.org

3 Task and Background

The general idea of the present shared task is to use revisions of English-language instructional texts as a basis to identify potential clarifications and to rate them regarding their plausibility. We assume that at least certain cases of clarifying revisions follow patterns that can be recognized automatically, by comparing the text before/after revision. An example of such a pattern is the insertion of a nominal phrase mentioned in context that makes an implicit reference explicit (see Table 1). We consider additional patterns as part of this shared task (see Section 4), but only consider cases of insertion for simplicity.

The focus on insertions allows us to consider clarifications as solutions to a cloze test, since the revision always fills in a text segment that previously was not present. Compared to previous cloze tasks, we do not assume that the revision observed is always unique and plausible. Instead, we also consider alternative clarification options and obtain plausibility judgments for all options.

As background, we first summarize findings from a pilot study that we conducted before setting up the present task (§3.1). Based on this, we then describe the settings of the shared task (§3.2).

3.1 Pilot Study

In our pilot study (Anthonio and Roth, 2021), we constructed a dataset of implicit references and potential clarifications in three steps: (1) heuristically identifying insertions of nominal phrases mentioned in the previous context, (2) automatically generating alternative clarifications using generative language modeling (GPT; Radford et al., 2018), and (3) collecting human plausibility judgements for each clarification option.

The first step of our pilot showed that it is possible to extract about 6,000 relevant clarifications from the revisions in wikiHowToImprove. We further found that most noisy instances can be filtered by the application of linguistic constraints and that remaining cases can be identified during the manual verification in the final step. In the second step, we found GPT to produce completions for many sentences that seem sensible on the surface level. Using our best strategy, namely re-ranking based on paragraph-level perplexity, the best sequence generated by the model was identical to the human-inserted clarification in over 56% of cases, and the clarification appeared in the top-10 generated sequences in 78% of cases.

A crucial finding in the third step was that the annotator indicated a preference for the human-inserted clarification in most cases (68%), but different, model-generated clarifications were judged as equally good in many cases (24%). In some cases, the annotator actually preferred a generated clarification over the human-edited insertion (8%).

The framework for the shared task is strongly motivated by the finding that alternative clarifications, generated by a computational model, can be as good or even better than human-produced clarifications. In some cases, we simply found different verbalizations of the same proposition. In other cases, like examples (a) and (b) below, we found plausible alternatives that are not fully compatible semantically.

(a) Call <u>the salon</u> and ask questions.

(b) Call <u>each salon</u> and ask questions.

When multiple incompatible readings exist, there is a risk that instructions will be misunderstood and not lead to the desired goal. To identify potential occurrences of such cases, we consider different fillers in the shared task and rate the plausibility of each filler independently.

3.2 Shared Task Settings

The SemEval shared task is set up as follows: Systems are provided with a cloze sentence, surrounding sentences and a potential clarifying filler as input, and are required to make a prediction regarding the plausibility of the filler in the given context. For evaluation, predicted labels are compared against the manually collected plausibility judgements described in Section 4. We define two subtasks with different labels and evaluation measures.

Task 1: Classification. In the classification task, systems need to distinguish between three labels (IMPLAUSIBLE, NEUTRAL and PLAUSIBLE). We use *accuracy* as the main evaluation measure, calculated as the proportion of correct predictions among all predictions of a system.

Task 2: Ranking. In the ranking task, systems need to predict a continuous plausibility score. We evaluate the predictions based on their *correlation* with human judgements, calculated as Spearman's rank correlation coefficient between all predictions and all judgements.

We describe the selection of data and collection of human judgements in the next section. In Section 6, we discuss additional evaluations performed to assess system performance with regard to the presence of multiple plausible clarifications.

4 Data

We closely follow the three steps of our pilot study, described in Section 3.1, to construct the data for this shared task. Our starting point is the dataset wikiHowToImprove (Anthonio et al., 2020), a resource of sentence-level revisions and their contexts based on wikiHow. In the first two steps, we create relevant data from this resource automatically; in the final step, we collect manual annotations to form a gold standard. In step 1, we apply a pattern-based approach to identify revisions that involve insertions that serve specific clarifying functions (§4.1). In step 2, we use transformer-based language models to produce sets of alternate clarifications that may or may not be compatible with an observed insertion (§4.2). In step 3, we collect human plausibility judgements on each clarification independently (§4.3).

4.1 Data Extraction

We collect relevant revisions by identifying cases in which a single *contiguous* insertion and no other change was made within a sentence. We compute differences and extract cases automatically based on the Python library `difflib`[3] and the following preprocessing tools: `spaCy`[4] for sentence splitting and tokenization, the Berkeley Neural Parser (Kitaev and Klein, 2018) for constituency parsing and `Stanza` (Qi et al., 2020) for POS tagging, dependency parsing and co-reference resolution. For the shared task, we focus on four types of phenomena, which are summarized in Table 2.

[3]https://docs.python.org/3/library/difflib.html

[4]https://github.com/explosion/spaCy

Phenomenon	Clarification pattern	Example	Potential filler
Implicit Reference	$\emptyset \rightarrow$ [DET] NOUN	Lift your toes up while keeping your leg straight. Hold __ $\emptyset$ __ for a few seconds, then release. Incorporate calf stretches into your yoga routine.	✓ your pose ✓ the stretch ? a leg ? the chair ✗ your head
Fused head	DET/JJ $\emptyset \rightarrow$ DET/JJ NOUN	Traditionally, the groom waits for the bride at the altar, the bride tosses the bouquet and (...). Since this is your wedding, feel free to change these __ $\emptyset$ __.	✓ ideas ✓ plans ? symbols ? characters ✗ changes
Noun compound	$\emptyset$ NOUN $\rightarrow$ NOUN NOUN	Heating for cold water tanks isn't quite of an issue as for tropicals. In fact, you can keep a __ $\emptyset$ __ tank without a heater.	✓ goldfish ✓ freshwater ✓ water ? fishing ✗ soup
Metonymy	NP $\emptyset \rightarrow$ NP's NP $\emptyset$ NP $\rightarrow$ NP of NP	Look at the __ $\emptyset$ __ of the teeth. If you're unsure of your dog's age, or want to determine if they are already entering into the senior territory, try the teeth.	✓ condition ✓ color ✓ thickness ? layout ? points

Table 2: Phenomena, extraction patterns and example clarifications (✓ plausible, ? neutral, ✗ implausible).

Implicit references. Instances with a non-verbalized reference in the original sentence which was clarified in the revised sentence through insertion. We select the cases from Anthonio and Roth (2021) with insertions containing a single noun or a determiner followed by a noun.

Fused heads. Instances of noun phrases for which the head noun was implicit in the original sentence and clarified in the revised sentence through insertion. We search for noun phrases with a determiner or adjective head in the original sentence and select those instances where a single noun was inserted in the revision.

Noun compounds. Instances of underspecified noun phrases, which were clarified in the revised sentence through the insertion of a dependent noun to form a more specific compound. We select instances of single noun insertions in which the inserted noun is a `compound` dependent of another noun that has already been present in the original sentence.

Metonymy. Instances in which a revision adds a noun y to a noun x to make explicit to which component or aspect of x the text refers. For the genitive pattern x*'(s)* y, we select insertions including an apostrophe and a noun y that is in a dependency relation `nmod:poss` with a noun x. For the y *of* x pattern, we select insertions that consist of a noun y and the token *of* added right in front of a noun x, allowing for intervening determiners and adjectives.

4.2 Constructing Clarifications

We produce a set of possible clarifications for each instance as follows: First, we generate the top-100 fillers in place of an observed insertion using language modeling. Second, we select a subset of potentially suitable clarifications by filtering and clustering the top-100.

Filler generation. For the implicit references, we take the top-100 generated clarifications from Anthonio and Roth (2021). For the other phenomena, we generate alternative clarifications automatically using the same approach as Anthonio and Roth (2021). That is, we feed the original sentence s with the surrounding sentences from the same paragraph to a language model. We then compute the top-100 completions for the token position(s) where an insertion was added in the revised sentence. We use BERT (Devlin et al., 2019) instead of GPT (Radford et al., 2018) to generate the clarifications, as the required insertions consist of only one token and BERT makes it possible to also consider follow-up context directly. The BERT checkpoint `bert-base-uncasedbert-base-uncased`[5] in `Transformers` (Wolf et al., 2020) was used without additional pre-training.

Filler selection. From the top-100 clarifications provided by the language model, we select four fillers with the goal of producing a semantically diverse set of clarifications. First, we remove unsuitable fillers from the top-100, including cases that only consist of digits or non-alphanumerical characters and fillers that do not have the right part of speech based on `Stanza` (retaining only *NOUN* for fused heads and metonymy and *NN* for noun compounds to exclude plural nouns).

For all instances with ≥ 4 candidate fillers, we select the observed insertion from the revised sentence as one filler. To select semantically different fillers as alternate candidates, we apply k-means clustering with $k = 4$ to the remaining candidates, using the algorithm by Elkan (2003) as implemented in `sklearn` (Pedregosa et al., 2011). We obtain vector representations for clustering from BERT (`bert-base-uncased`) by averaging over the last hidden state for all tokens in a filler. After clustering, we select the fillers closest to the four cluster centroids based on cosine similarity.

4.3 Plausibility Annotation

Task. After selecting fillers for each sentence, we collect plausibility judgements on Amazon Mechanical Turk for our train set (19,975 instances, i.e. 3995 sentences with 1 human and 4 generated fillers each[6]), development and test sets (2,500 instances each, i.e., 125 sentences per phenomenon with 5 fillers per sentence). Each clarification in the training set is annotated by 2 crowdworkers. For the development and test set, we collected annotations from 4 crowdworkers to ensure a consistently high quality. In each annotation task, we ask participants to indicate on a scale from 1 to 5 whether the clarification made sense in the given how-to-guide. A screenshot of the interface for our Human Intelligence Task (HIT) is provided in Appendix A.

[5]We also tried `bert-base-cased` in preliminary experiments but observed no improvements.

[6]1000 each for noun compounds and metonymy, 996 for implicit references and 999 for fused heads.

	Train	Dev	Test
IMPLAUSIBLE	5,474 (27%)	982 (39%)	858 (34%)
NEUTRAL	7,162 (36%)	602 (24%)	672 (27%)
PLAUSIBLE	7,339 (37%)	916 (37%)	970 (39%)
Total	19,975	2,500	2,500

Table 3: Distribution of class labels in our training, development and test sets.

Qualifications. We use several qualifications to increase the annotation quality. First, we require participants to be located in the United States or in the United Kingdom, to increase the chance that the participants are native speakers of English. Secondly, participants need to have a HIT approval rate $\geq 95\%$ and their number of approved HITS has to be ≥ 1000. Finally, annotators are required to pass a qualification test in which they are asked to judge a list of clearly plausible and implausible cases that were pre-selected unanimously by the authors.

Class labels. For Task 1 (classification), we average over the real-valued judgements collected for a clarification and map this plausibility score to one of the three classes labels. Specifically, we label clarifications with an average score ≤ 2.5 as IMPLAUSIBLE, clarifications with a score ≥ 4.0 as PLAUSIBLE, and all clarifications between these thresholds as NEUTRAL. The thresholds have been selected based on manual inspection of the data and mathematical considerations: in particular, the threshold for PLAUSIBLE requires scores to be substantially above average (in case of two judgements, $\geq$3&5 or $\geq$4&4), whereas the IMPLAUSIBLE threshold allows for a slightly wider range of judgements. The NEUTRAL label covers cases that received inconclusive individual scores as well as cases of disagreement (e.g. 3&3 as well as 2&5).

Statistics. We show the frequency distribution of the labels in the train, development and test set in Table 3. It is noteworthy that development and test set proportionally includes fewer NEUTRAL and more IMPLAUSIBLE clarifications than the training set. Presumably, this is because we increased the number of qualification questions from 4 to 6 after collecting the training data to ensure the quality of the evaluation data.

Since we are particularly interested in cases with

Team	Model type	Pre-trained model components	Additional comments

multiple plausible clarifications, we also compute the average number of PLAUSIBLE clarifications per sentence s, which we found to be 1.84, 1.87 and 1.84 in the training, development and test set, respectively. This means that, on average, each annotated sentence in the dataset has between 1 and 2 clarifications that the annotators rated as plausible.

5 Participants

A total of 21 users participated in the CodaLab competition set up for the shared task and 8 teams submitted system description papers. An overview of the best model by each team is shown in Table 4.[7] We observe that all systems are based on Transformer architectures, using one or more of the following pre-trained models: BERT (Devlin et al., 2019), DeBERTa (He et al., 2020), ELECTRA (Clark et al., 2019), ERNIE (Sun et al., 2019), RoBERTa (Liu et al., 2019), S-BERT (Reimers and Gurevych, 2019), T5 (Raffel et al., 2020), XLM-R (Conneau et al., 2020).

In addition to fine-tuning a single or multiple Transformer models in an ensemble, some teams have taken additional steps to adapt their system to the task. We summarize some of these steps below.

Consideration of phenomena. At least two teams took into account that the data set consists of four phenomena that were identified using different patterns (*pattern-aware*): PALI used the phenomenon description that applies to a classification instance as additional model input; X-PuDu developed an ensemble architecture that consists of different individual models and hyperparamters for each phenomenon.

[7]A table with the official results of the CodaLab competition, including participants who did not submit system descriptions, is shown in Appendix B.

Adapted loss functions. Several teams adapted the loss functions of their models to better account for various properties of the task. This includes the use of classification and regression based loss functions in a multi-task learning set-up (*multi-loss*) as well as the use of specific loss functions that consider the ordinal nature of labels (*ordinal regression*) or differences in label distributions (*class weighting*) in the classification task.

Unsupervised components. Given the similarity of our task to general cloze tasks, several teams experimented with models that were merely self-supervised and not fine-tuned on task-specific training data. In case of one team, HW-TSC, such an unsupervised component is also part of the ensemble model that produced the best results.

6 Results and Discussion

The results for Task 1 and 2 are shown in Table 5 and 6, respectively. We focus our discussion on Task 1: Classification, as the participants of Task 2 form only a subset of the Task 1 participants and the system results rank, with exception of the last two teams, in the same order. In addition to showing results by participants, we also provide a human upper bound as well as results by our own BERT-based baseline model. The upper bound was computed as the accuracy over all individual annotations when compared against the (averaged) class label of each test instance.

The human upper bound has an accuracy of 79.4%, indicating that the task is challenging and potentially involves a number of disagreements. The winning team of the competition, X-PuDu, achieves an accuracy of 68.9%, only 10.5 percentage points below the human upper bound. The results of all teams lies substantially above a naive majority class baseline of 39%. All teams but one

Rank	Team	Accuracy
–	Human (upper bound)	79.4%
1	X-PuDu	68.9%
2	HW-TSC	66.1%
3	PALI	65.4%
4	Nowruz	62.4%
5	JBNU-CCLab	61.4%
6	DuluthNLP	53.3%
7	Stanford MLab	46.6%
8	niksss	44.2%
–	BERT (baseline)	45.7%

Table 5: Results for Task 1 (classification).

Rank	Team	Spearman's ρ
1	X-PuDu	0.807
2	PALI	0.785
3	HW-TSC	0.774
4	Nowruz	0.707
5	niksss	0.252
6	Stanford MLab	0.194

Table 6: Results for Task 2 (ranking).

Rank	Team	F1 (all)	F1 (w/o N)
1	X-PuDu	0.689	0.773
2	HW-TSC	0.661	0.749
3	PALI	0.654	0.749
4	Nowruz	0.624	0.714
5	JBNU-CCLab	0.551	0.627
6	DuluthNLP	0.533	0.608
7	Stanford MLab	0.466	0.514
8	niksss	0.442	0.494

Table 7: Classification results with/without NEUTRAL.

Rank	Team	Accuracy (#P$\geq$2)
1	X-PuDu	75.2%
2	HW-TSC	73.2%

also outperform our BERT-based baseline, which is a linear classification model based on the checkpoint provided by the Transformer library (Wolf et al., 2020) and fine-tuned on our training data.

6.1 Findings by Participants

In the following, we briefly summarize a couple of findings by task participants. More details can be found in the individual task description papers.

Different phenomena. The winning team, X-PuDu, found that different hyperparameters worked best depending on the phenomenon/extraction pattern. Based on this finding, different individual models were trained and combined in an ensemble.

Label distribution. Some teams, including DuluthNLP, noticed performance issues related to the distribution of labels in the development data. As a dedicated solution, DuluthNLP uses a decreased weight for the NEUTRAL label in the loss function.

NEUTRAL label. Team JBNU-CCLab reported that the NEUTRAL label is generally difficult to distinguish from other labels by different models. An underlying problem could be that the label represents instances that are seen as somewhat plausible by multiple annotators as well as instances that are seen as plausible by some annotators and implausible by others (see Section 4).

Noisy data. Team HW-TSC found that isolated training instances have the label NEUTRAL rather than PLAUSIBLE, even though the respective filler represents a human insertion (i.e., the filler can be found in the final version of the text in wikiHow). As the results of our human upper bound in Table 5 show, this is partly because the right label is sometimes not clear cut even for humans. We discuss this aspect in more detail in the next section.

6.2 Additional Evaluations

We perform two additional evaluations to assess the impact of the NEUTRAL label on system performance and to investigate the possibility of identifying whether multiple plausible clarifications exist by aggregating the predictions regarding individual clarifications.

Excluding NEUTRAL. For the evaluation without the NEUTRAL label, we calculate micro-averaged precision, recall and F_1-scores for the two labels PLAUSIBLE and IMPLAUSIBLE. The results in

Correct	#P≥2	Text	Fillers
8 (all)	✓	Galette des rois—or "King Cake" in English—is traditionally made to celebrate the __∅__ of Epiphany. Especially popular in France during the Christmas season, it is enjoyed elsewhere too.	✓ holidays ✓ Feast ? hours ? celebration ? proclamation
	✗	Let the __∅__ of shoes air dry. You can put them in front of a dehumidifier, a fan, or an open window, but avoid putting them in front of any type of heat source.	✓ pair ? pile ✗ shoes ✗ color ✗ end
0 (none)	✓	If you want a smoother surface, try a __∅__ of paper with a higher amount of grains, if you want a faster job but a rougher surface try a paper with a lower amount of grains.	✓ thickness ✓ piece ? fabric ? product ✗ pile
	✗	Your cucumber plant will also grow thin, light green shoots that help the plant grasp onto a surface and grow vertically. These __∅__ grow immediately next to the suckers.	✓ shoots ? fibers ? tendrils ? foliage ✗ bushes

Table 9: Examples of difficult and easy instances, selected based on how many systems classified them correctly.

terms of F_1-score are shown in Table 7. The results indicate that all systems perform substantially better in the evaluation setting that ignores NEUTRAL labels. The ranking is identical to the ranking in the evaluation including all labels. Considering only the PLAUSIBLE and IMPLAUSIBLE, Team X-PuDu achieves the highest micro-averaged F_1-score of 0.773. In the cases where their system predicts a non-NEUTRAL label, it is correct in 72.7% of cases (precision), and 82.5% of all non-NEUTRAL instances in the data received the correct prediction (recall).

Multiple clarifications. In our final evaluation, we examine whether system predictions can also be used to determine whether multiple plausible clarifications for a given context exist. For this, we consider the labels of each individual clarification and compare system outputs and annotations in terms of whether two or more clarifications for a cloze and its context received the label PLAUSIBLE. We show the result of this evaluation in terms of accuracy for each team in Table 8. Apart from the last two places, the teams rank in the same order as in the other evaluations. The best performing team, X-PuDu, correctly predicts whether two or more plausible clarifications exist for 75.2% of all cases. Table 9 shows examples that were correctly classified by all or none of the systems.

7 Conclusion

In this paper, we presented the task, data, participating systems, and results of the shared task on clarifying implicit and underspecified phrases in instructional texts. Our motivation for this task was to explore the possibility of testing different clarifications for plausibility. In particular, we were concerned with the question of whether two or more clarifications can be plausible and whether such cases can be detected automatically. To create a suitable dataset, we worked with and identified a set of revisions with manual clarifications, automatically generated possible alternatives, and then collected human plausibility ratings.

In total, 21 users participated in our shared task. We summarized the systems and results of 8 teams that submitted descriptions of their systems. The best systems from each group have in common that they are based on Transformer architectures or combine them in an ensemble. The best system achieved 68.9% accuracy, only 10.5 percentage points below a human upper bound. In additional evaluations, we have shown that an accuracy of up to 75.2% is achieved with respect to the detection of multiple plausible clarifications.

The results show that the presented task is a difficult one, but that many cases can already be modeled well by current state-of-the-art methods. There is further room for improvement with respect to both the data set and models: with respect to the data, it should be noted that the training set with less than 20k instances is relatively small and that there are many instances with a underspecified NEUTRAL label (36%). On the model side, we found that the participating teams make complementary contributions that may allow for additional improvements in combination.

One shortcoming of the task as presented and performed is that we only considered four forms of clarifications related to referring expressions. In addition, clarifications were assessed individually and judgements by different annotators were aggregated. In the long term, we believe that more forms of clarifications as well as individual differences regarding their plausibility need to be considered. Finally, future work will have to investigate under which circumstances multiple different clarifications are actually incompatible and can thus reveal potential sources of misunderstanding.

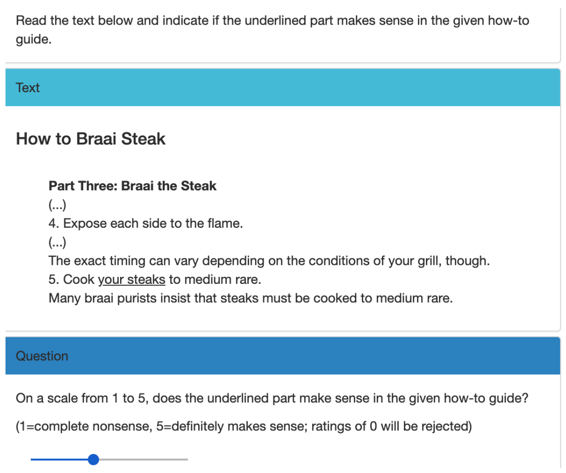
A Annotation Interface

The annotation interface for our crowdsourcing task is depicted in Figure 1. Annotators see and have to rate a single underlined clarification in its context.



Read the text below and indicate if the underlined part makes sense in the given how-to guide.

Text

How to Braai Steak

Part Three: Braai the Steak
(...)
4. Expose each side to the flame.
(...)
The exact timing can vary depending on the conditions of your grill, though.
5. Cook your steaks to medium rare.
Many braai purists insist that steaks must be cooked to medium rare.

Question

On a scale from 1 to 5, does the underlined part make sense in the given how-to guide?
(1=complete nonsense, 5=definitely makes sense; ratings of 0 will be rejected)

JBNU-CCLab at SemEval-2022 Task 7: DeBERTa for Identifying Plausible Clarifications in Instructional Texts

Daewook Kang, Sung-Min Lee, Eunhwan Park, Seung-Hoon Na
Computer Science and Engineering, Jeonbuk National University, South Korea
{dwkng, cap1232, judepark, nash}@jbnu.ac.kr

Abstract

In this study, we examine the ability of *contextualized representations* of pretrained language model to distinguish whether sequences from instructional articles are plausible or implausible. Towards this end, we compare the BERT, RoBERTa, and DeBERTa models using simple classifiers based on the sentence representations of the [CLS] tokens and perform a detailed analysis by visualizing the representations of the [CLS] tokens of the models. In the experimental results of Subtask A: *Multi-Class Classification*, DeBERTa exhibits the best performance and produces a more distinguishable representation across different labels. Submitting an ensemble of 10 DeBERTa-based models, our final system achieves an accuracy of 61.4% and is ranked fifth out of models submitted by eight teams. Further in-depth results suggest that the abilities of pretrained language models for the plausibility detection task are more strongly affected by their model structures or attention designs than by their model sizes.

1 Introduction

WikiHow[1] is the largest how-to website with more than 300,000 articles and over 2.5M registered users that help user improve their knowledge of specific areas. However, these instructional articles have grammatical errors and ambiguous content that cause misunderstandings. To enhance the clarity of instructional texts, *clarification* is required as a revision that makes implicit elements explicit, resolves ambiguities, or replaces underspecified phrases with a clearer and more precise expressions.

SemEval-2022 Task 7 (Roth et al., 2022) evaluates the ability of an NLP system to distinguish between plausible and implausible clarifications of an instruction. The task is formulated as a CLOZE task in which clarification is presented as a *filler* in a blanked sentence. Given a context with a filler option (i.e., a sentence X and filler option O), the system should determine the plausibility of a sequence, that is whether a sequence is "plausible," "neutral," and "implausible."

Our work is motivated by the recent successes of pretrained language models such as BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), and DeBERTa (He et al., 2021a,b), which have effectively induced *contextualized representations*, achieving remarkable fine-tuning performance on downstream tasks.

To explore the plausibility detection of clarifications in SemEval-2022 Task 7, we compare the plausibility detection abilities of three pretrained language models (BERT, RoBERTa, and DeBERTa) in Subtask A, *Multi-Class Classification*. Our main observations of the development set are highlighted as follows.

- Among the three models, DeBERTa exhibits the best performance in the plausibility classification task[2].
- Visualization analysis of the representations of the [CLS] tokens of BERT, RoBERTa, and DeBERTa, reveals that the best distinguishable representations among different classes are achieved with DeBERTa.
- A comparison of base and large models confirms that large models are always better than base models for all the types: BERT, RoBERTa and DeBERTa.
- Given the comparative results among various models, we hypothesize that the abilities of pretrained language models for the plausibility detection task are more strongly affected

[1] https://www.wikihow.com/Main-Page

[2] Note that we used BERT-{base, large}, RoBERTa-{base, large}, and DeBERTa-{base, large}. DeBERTa V3 model of (He et al., 2021a) was used for DeBERTa models.

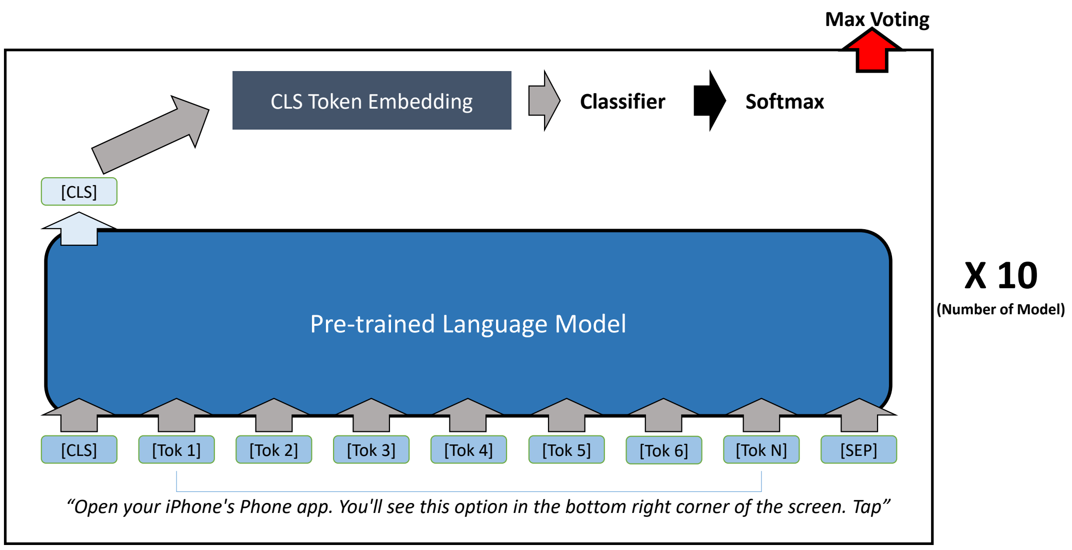

Figure 1: Architecture of the proposed system for plausibility classification using pretrained language models

by their model structures or attention designs rather than their parameter sizes.

By ensembling 10 different DeBERTa-based models, our final submitted system achieves an accuracy of 61.4% on the test data and is ranked the 8th place among 21 systems[3], that is, 5thth place among the 8 teams who submitted their papers on Subtask A.

The remainder of this paper is organized as follows: Section 2 presents related work. Section 3 describes the system architecture in detail. Section 4 describes the experimental settings, results, and analyses. Our concluding remarks and a description of future work are presented in Section 5.

2 Related work

Since the success of BERT (Devlin et al., 2019), it has been used for numerous natural language processing (NLP) tasks and has inspired the emergence of many other pretrained models. In RoBERTa (Liu et al., 2019), dynamic masking in the masked language modeling (MLM) objective dynamically while revisiting the next sentence prediction owing to its uncertain effectiveness has achieved promising results on GLUE (Wang et al., 2018), RACE (Lai et al., 2017), and SQuAD (Rajpurkar et al., 2016). DeBERTa (He et al., 2021b) further advanced BERT based on two major extensions, *disentangled attention* and *enhanced mask decoder*, by combining both the relative and absolute positions of words. DeBERTa V3 (He et al., 2021a) replaces the MLM objective in DeBERTa with the replaced token detection (RTD) objective proposed by ELECTRA (Clark et al., 2020) and further proposes *gradient-disentangled embedding sharing* to alleviate the *tug-of-war* problem between the generator and discriminator [4] as an improvement of the embedding sharing method used in ELECTRA.

3 System description

Figure 1 presents the architecture of our system, which uses pretrained language models equipped with ensemble inference.

3.1 Methods with pretrained language models

Let X^p, X^c and X^n be the previous, main, and follow-up context, respectively. As in Section 4.1, we concatenate these sentences for the i-th training example as follows: $X_i = X^p \oplus X^c \oplus X^n$, where X_c is unmasked by filling each possible filler option O_{ij}. We use $Y_i \in \{0, 1, 2\}$ to refer to the ground truth of the i-th example, where Y_0, Y_1, and Y_1 refer to *implausible*, *neutral*, and *plausible* sequences, respectively. Finally, we denote a training set as $\mathcal{D} = \{X_i, Y_i\}_{i=1}^{N}$, where N is the total number of training examples obtained by unmasking all the main sentences with their possible filler options.

We feed X_i into a pretrained language model denoted as LM to encode contextualized represen-

[3]https://competitions.codalab.org/competitions/35210

[4]Because the generator and discriminator have different objectives, they tend to pull shared word embeddings in different directions, resulting in degradation of the training speed.

tations $\mathbf{M}_i \in \mathbb{R}^{|X_i| \times d}$ as follows:

$$\mathbf{M}_i = \mathsf{LM}(X_i)$$

where $|X_i|$ is the length of the concatenated sentence X_i and d is the dimensionality of the hidden representation of LM. As mentioned, we use BERT, RoBERTa, and DeBERTa for LM.

Let $\mathbf{M}_{i,[CLS]}$ be the representation of the [CLS] token of X_i. To perform a plausibility prediction, we feed $\mathbf{M}_{i,[CLS]}$ to a linear layer as follows:

$$f(X_i) = \mathbf{W}^T \mathbf{M}_{i,[CLS]} + \mathbf{b}, \qquad (1)$$

where $\mathbf{W} \in \mathbb{R}^{d \times 3}$ and $\mathbf{b} \in \mathbb{R}^3$ are task-specific parameters of the linear layer. The loss function $\mathcal{L}$ used to optimize our system is formulated as follows:

$$\mathcal{L} = - \sum_{(X_i, Y_i) \in \mathcal{D}} \mathbf{y}_i \cdot \log \text{softmax}(f(X_i)) \qquad (2)$$

where $\mathbf{y}_i \in \{0, 1\}^3$ is the one-hot vector for Y_i.

Table 1: Results of our system on the test dataset (Official Leaderboard)

4.1 Experimental setting

Dataset We used the data and labels from SemEval-2022 Task 7 (Roth et al., 2022). The data consists of the article title, sub-heading, masked sentence, previous and follow-up context, and possible filler options with corresponding labels (Subtask A) and ratings (Subtask B). During our preprocessing step, the placeholder in the main sentence is filled with each possible filler option O_i.

Preprocessing We concatenate the previous context, main context, and follow-up context without using the article name and section header; any parenthesis and the content inside, special characters, and redundant whitespaces are removed. No truncation is applied because none of the concatenated data exceeds the maximum token length of the pretrained language models.

For example, suppose that a masked sentence is given as *"You'll see this ______ in the bottom right corner of the screen."* and is filled with each filler text "*option*." Assume that the sentence that precedes it is *"1. Open your iPhone's Phone app. (...),"* and the sentence that follows it *"3. Tap ."* The concatenated input looks like *"Open your iPhone's Phone app. You'll see this option in the bottom right corner of the screen. Tap"*.

Training We fine-tune the model on the training data with a batch size of 32 and 20 of epochs. We use the AdamW optimizer (Loshchilov and Hutter, 2019) and a cosine scheduler with warm-up steps for the initial 5% of the total steps at a learning rate of $1e-5$.

We also create a DeBERTa-based ensemble model using ten models trained on different seeds to obtain the final submission result.

4.2 Official results

For each model, we select the checkpoint with the best accuracy on the validation data as the finetuned model.

As mentioned in Section 4.1, we ensemble 10 finetuned DeBERTa-v3-large models by *max-voting* their outputs to further improve our DeBERTa-based model.

Table 1 shows the official results of our DeBERTa-based ensemble model compared with the other participants' systems.

4.3 Analysis

4.3.1 Comparison of the results on the development set

Table 2 presents the results of the validation data using three different pretrained language models without an ensemble [5]

As shown in Table 2, DeBERTa-large outperforms the baseline models by a decent margin.

Furthermore, Figure 2 shows the detailed confusion matrix of the finetuned DeBERTa-large model for the development set. As shown in Figure 2, DeBERTa-large distinguishes between plausible and implausible sequences reasonably well but has difficulty identifying neutral sequences. In our ex-

[5]While the official evaluation only measures the accuracy of the system, Table 2 lists the precision, recall and f1 score for analysis in detail.

Model	Parameters	Metric			
		Accuracy	**Precision**	**Recall**	**F1-score**
BERT-base	110M	45.36	43.32	43.06	42.67
BERT-large	340M	48.00	43.06	43.32	38.89
RoBERTa-base	125M	51.48	50.20	48.22	46.32
RoBERTa-large	355M	53.12	49.39	49.50	48.28
DeBERTa-v3-base	86M	55.92	49.19	50.84	48.36
DeBERTa-v3-large	304M	**59.88**	**52.92**	**54.20**	**50.81**

Table 2: Comparative results of BERT, RoBERTa, and DeBERTa on the validation dataset. The precision, recall, and F1-score are calculated via macro-average.

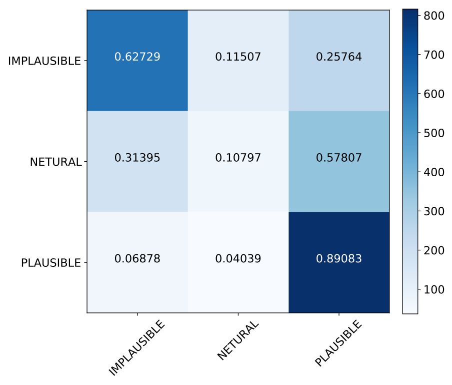

Figure 2: Illustration of the confusion matrix of our DeBERTa-based model on the validation dataset

periment, a similar tendency was also observed on BERT- and RoBERTa-based models.

Overall, from these results, we hypothesize that the ability of a pretrained language model to contextualize representations for the plausibility detection task is more strongly affected by its model structures, such as attention design or refining positional embeddings, rather than its parameter size.

4.3.2 Visualization of [CLS] representation

Figure 3 shows the visualization of the representations of [CLS] tokens using T-SNE (van der Maaten and Hinton, 2008) to compare the abilities of pretrained language models to distinguish between plausible, neutral and implausible sequences. As shown in Figure 3, the context representation distributions of the two DeBERTa models are more coherent and distinctive that those of BERT and RoBERTa. In contrast, no significant differences are observed between the BERT and RoBERTa models.

5 Conclusion

In this study, we compare BERT, RoBERTa and DeBERTa in SemEval-2022 Task 7 Subtask A: Multi-Class Classification. The results show that DeBERTa presents the best performances with improved distinguishable representations. We assume that the substantial changes made to the model structure of DeBERTa, such as disentangled attention, enhanced mask decoder, and RTD objective, would give DeBERTa a significant advantage in the addressed task.

Our final submission, based on an ensemble model comprising 10 fine-tuned DeBERTa-based models, achieved an accuracy of 61.4% on the test data. Our proposed model is ranked fifth out of eight models of teams who reported their papers.

In future studies, it would be worthwhile to explore other pretrained language models, such as ELECTRA, or models resulting from task-specific pretraining.

Abstract

This paper describes the system for the identifying Plausible Clarifications of Implicit and Underspecified Phrases. This task was set up as an English cloze task, in which clarifications are presented as possible fillers and systems have to score how well each filler plausibly fits in a given context. For this shared task, we propose our own solutions, including supervised approaches, unsupervised approaches with pretrained models, and then we use these models to build an ensemble model. Finally we get the 2nd best result in the subtask1 which is a classification task, and the 3rd best result in the subtask2 which is a regression task.

1 Introduction

The rapid development of artificial intelligence has also been reflected in the field of NLP, and there have been many heavyweight achievements, such as word2Vec (Mikolov, et al., 2013), Glove (Pennington, et al., 2014), Transformer (Vaswani, et al., 2017). Natural language processing is an important branch of artificial intelligence. Cloze tasks have become a standard framework for evaluating various discourse-level phenomena in NLP, which is an important field in artificial intelligence, many researchers have long been committed to the development of this field. Some prominent examples include the narrative cloze test (Chambers and Jurafksy, 2008), the story cloze test (Mostafazadeh et al., 2016), and the LAMBADA word prediction task (Paperno et al., 2016). Cloze requires the testee to infer from the context, which is very difficult for machines.

The goal of this shared task is to evaluate the ability of NLP systems to distinguish between plausible and implausible clarifications of an instruction. Such clarifications can be critical to ensure that instructions describe clearly enough what steps must be followed to achieve a specific goal. This task was set up as a cloze task. However, different from regular cloze task, there may be zero or more than one correct candidates out of the five options. This presents new challenges for cloze systems.

For subtask 1, it is a classification task that requires the system to classify five candidates into corresponding categories, which are plausible, neutral, or implausible, and the number of each category is not fixed. This means that there may be zero or more than one correct candidates out of the five options, and the same applies to the other two categories. This situation creates new challenges for cloze tasks.

For subtask 2, it is a regression task ask annotators to rate for each clarification option whether it "makes sense in the given how-to guide" (on a scale from 1 to 5) to assess the plausibility of different clarification options.

In this paper, we analyze the characteristics of the shared task and describe out contribution to this cloze task. We build an ensemble model with Deberta-v3 (He P, et al., 2020), Roberta-large (Liu Y, et al., 2019), SBERT (Reimers and Gurevych, 2019), including supervised approaches and unsupervised approaches. Our model had the 2nd best performance in the subtask1 (66.1% Accuracy Score) and the 3rd best performance in the subtask2 (77.4% Ranking Score). The results are encouraging for evaluating various discourse-level phenomena in NLP, although there is much room for improvement.

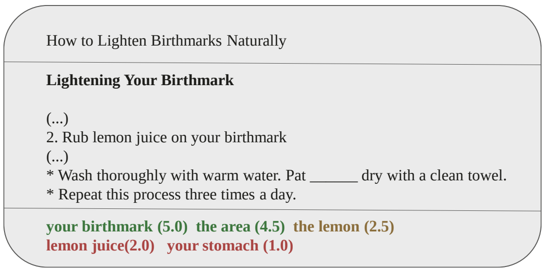
The rest of this paper is organized as follows. Section 2 introduce our approach for the shared task. Section 3 shows the experimental results of our approach and do some analysis. In Section 3, experimental results are compared and discussed. Finally, the whole paper is summarized with a brief conclusion in Section 4.

2 System Overview

In this section, we first describe our data processing steps. We experimented with different ways of processing the data, trying to find the one that worked best for the task. And then, we discuss our solutions with pre-trained models for the shared task, including unsupervised approaches, supervised approaches, and an ensemble model.

2.1 Data Processing

The participants of the shared task were provided a collection of revisions of instructional texts from the how-to website wikiHow. The dataset contains sentences that need to be filled in and its previous context, follow-up context, five options, etc. The data example is as shown in the Figure 1 below:



How to Lighten Birthmarks Naturally

Lightening Your Birthmark

(...)
2. Rub lemon juice on your birthmark
(...)
* Wash thoroughly with warm water. Pat ______ dry with a clean towel.
* Repeat this process three times a day.

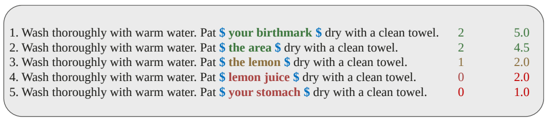
your birthmark (5.0) the area (4.5) the lemon (2.5)
lemon juice(2.0) your stomach (1.0)

Figure 1: Data example

We bring the five options into the positions that need to be filled in, and get a dataset that is five times the size of the original.

For subtask1, a label file was gave which contains the corresponding category of each option of each piece of data, which category does it belong to, plausible, neutral or implausible? We map these three categories to numbers 2, 1, 0, corresponding to plausible, neutral and implausible.

For subtask2, a score file was gave to assess the plausibility of different clarification options. For the score file, we keep it in its native state. In addition, in order to make the model focus on the positions that need to be filled in, we have added special symbols $ on both sides of the blank. After data processing, the data example is as shown in the Figure 2 below:



1. Wash thoroughly with warm water. Pat $ **your birthmark** $ dry with a clean towel.	2	5.0
2. Wash thoroughly with warm water. Pat $ **the area** $ dry with a clean towel.	2	4.5
3. Wash thoroughly with warm water. Pat $ **the lemon** $ dry with a clean towel.	1	2.0
4. Wash thoroughly with warm water. Pat $ **lemon juice** $ dry with a clean towel.	0	2.0
5. Wash thoroughly with warm water. Pat $ **your stomach** $ dry with a clean towel.	0	1.0

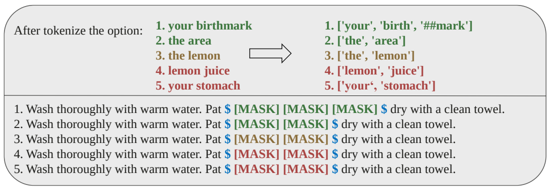
Figure 2: Data example after processing

To get more information that might be useful, we tried a variety of sentence concatenations using different columns in the data. Our experiments show that this is necessary and effective.

2.2 Unsupervised approach

First, in order to get a reliable benchmark on this task, we use unsupervised methods to try to solve the task with BERT. Because the pre-training process of BERT includes masked language model, that is, to replace a small part of words in the text with [MASK], and let the model predict the words replaced by [MASK]. This task is very similar to cloze, so we can use cloze to test BERT's masked language model capability in longer and more [MASK] texts (Ding et al., 2021).

For this task, we tokenize each option to get the number of tokens, and then fill in the blank with the same [MASK] as the number of tokens. We do this because multiple [MASK] work better than a single one. The processing process is shown in the following Figure 3:



After tokenize the option:

1. your birthmark	**1. ['your', 'birth', '##mark']**
2. the area	**2. ['the', 'area']**
3. the lemon	**3. ['the', 'lemon']**
4. lemon juice	**4. ['lemon', 'juice']**
5. your stomach	**5. ['your‘, 'stomach']**

1. Wash thoroughly with warm water. Pat $ **[MASK] [MASK] [MASK]** $ dry with a clean towel.
2. Wash thoroughly with warm water. Pat $ **[MASK] [MASK]** $ dry with a clean towel.
3. Wash thoroughly with warm water. Pat $ **[MASK] [MASK]** $ dry with a clean towel.
4. Wash thoroughly with warm water. Pat $ **[MASK] [MASK]** $ dry with a clean towel.
5. Wash thoroughly with warm water. Pat $ **[MASK] [MASK]** $ dry with a clean towel.

Figure 3: Data example after filled with [MASK]

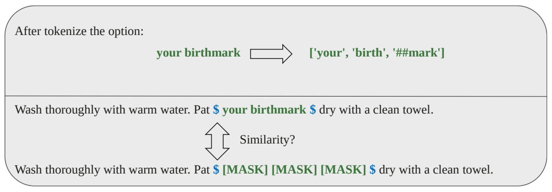
A pooling operation is added to the output of BERT to generate a fixed-size sentence embedding vector. The tokens embedding of [MASK] obtained from the pre-trained model would be used for classification with different pooling strategies. In our experiment, three pooling strategies were used for comparison:

- MEAN strategy
  Calculate the average value of each token output vector of option to represent the sentence vector.
- MAX strategy
  Take the maximum value of each dimension of all output vectors of option to represent the sentence vector.
- SUM strategy
  Take the sum value of each dimension of all output vectors of option to represent the sentence vector.

2.3 Supervised approach

After getting a benchmark with an unsupervised method, we want to get some experimental results with a supervised method. First, we still conduct some experiments to screen out the model with better performance from several models. The models we use include Deberta-v3, Roberta-large, SBERT, BERT (Devlin et al., 2018), etc. The final experimental results will be displayed in the experimental section.

And then, in the above part, we mentioned filling in the blanks with [MASK], and using the embedding of [MASK] is directly used for classification. This is naturally associated with the similarity between [MASK] and options. Intuitively, [MASK] should be the most similar to the plausible option, and the least similar to the implausible option. So we use SBERT to calculate the similarity between the sentences after filling in [MASK] and filling in the options. After getting the similarity, we classify it by threshold optimization. The schematic diagram of the data process is shown in the following Figure 4:



After tokenize the option:
your birthmark
['your', 'birth', '##mark']
Wash thoroughly with warm water. Pat $ your birthmark $ dry with a clean towel.
Similarity?
Wash thoroughly with warm water. Pat $ [MASK] [MASK] [MASK] $ dry with a clean towel.

Figure 4: Data process for calculate

The sentence obtained by filling [MASK] into the blank part and the sentence obtained by filling the option into the blank part are used as the input of the model, and then the embedding representation of [MASK] and the option is obtained by average pooling, as u and v respectively. We concatenate the values of u and v and the absolute value of their differences for classification tasks, and we also calculate the similarity between u and v for the task. The process is shown in Figure 5.

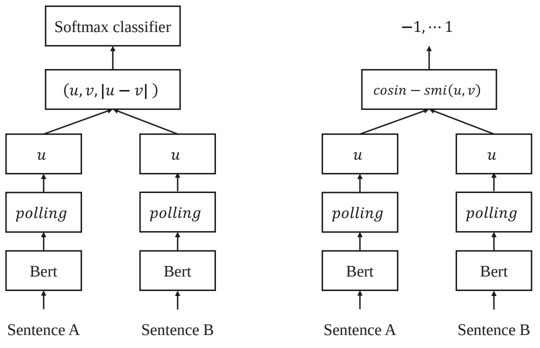


Figure 5: The process of SBERT

2.4 Model ensemble

Through Sections 2.3.1 and 2.3.2, we have obtained the results of several models. By comparing the classification results between different models, there are large differences, which means that for the classification results of the same data, the Model I may classify it into IMPLAUSE, but the Model II may classify it as NEUTRAL. This makes it possible for us to further improve the classification effect through the model ensemble.

The voting method is an ensemble learning model that follows the majority principle, and reduces variance through the integration of multiple models, thereby improving the robustness and generalization ability of the model. We adopt the voting method commonly used in ensemble learning, which is an ensemble learning model that follows the principle of majority rule by the minority, and reduces variance through the integration of multiple models, thereby improving the robustness and generalization ability of the model. We used four models (Roberta based on unsupervised method, and Roberta-large, Deberta-v3, SBERT based on supervised method) as benchmarks for ensemble learning. The structure of ensemble model is shown in the Figure 6.

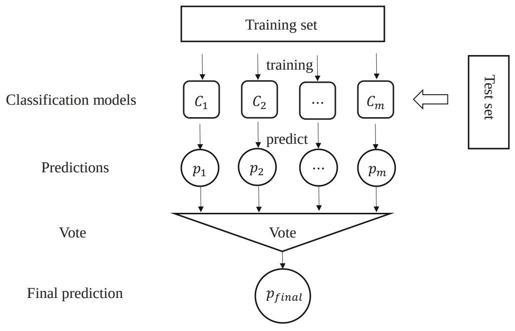

Figure 6: The structure of ensemble model

3 Experimental Results

In the following experimental part, all the data used for the experiment adopts the data processing method we introduced in Section 2.1.

3.1 Unsupervised approach results

We propose an attempt to use an unsupervised approach to benchmark this task in Section 2.2, and propose three strategies for dealing with [MASK]. The experimental comparison of the three strategies is gave by Table 1, there is little

Model	Pooling	Train Accuracy	Dev Accuracy
Bert-large	Mean	0.4373	**0.5152**
Bert-large	Sum	0.4434	0.4920
Bert-large	Max	0.4330	0.5150
Roberta-large	Mean	0.4678	**0.5788**

Table 1: Pooling strategy for unsupervised approach

Roberta-large supervised	--	0.6370	--
Deberta-v3	0.6137	**0.7784**	0.747
SBERT(Roberta-large)	--	0.6560	--
Ensemble	--	0.7752	**0.774**

Table 5: Results for subtask2 with ensemble model

difference between MEAN strategy and Max strategy. We ended up using MEAN strategy to get a benchmark (57.88% Accuracy Score) with Roberta-large.

3.2 Supervised approach results

For supervised methods, although we did some experiments to try to find a better embedding than [CLS] for this task, we didn't get it. So we still ended up screening out the model with better performance from several models with [CLS] embedding. The results of model screening are given in Table 2.

In Section 2.3 we propose to use SBERT to try to solve this task. We conduct experiments with direct classification and computing similarity respectively. Table 3 gave the experimental results of SEBRT.

3.3 Model ensemble results

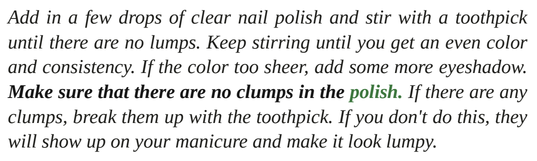
After obtaining several benchmarks using the unsupervised method and the supervised method, respectively, in the supervised method, by adjusting the parameters of several models, such as adjusting the batch size, learning rate or freezing some parameters in the model. We end up with 11 results including the above for ensemble learning。Due to space limitations, we no longer list the training results after adjusting the model parameters or freezing some parameters here. For each model, we list its best results. The results are given in Table 4.

For subtask 2, we just converted the above model from a classification task to a regression task, and also adjusted the training parameters, froze some model parameters, and obtained eleven kinds of results. The ensemble learning is carried out by the method of averaging, and the final result is obtained and shown in Table 5.

3.4 Discussion

A phenomenon can be observed from the experimental results: when the model has not fully converged on the training set, the best result of the model on the validation set has already appeared. Especially when using Deberta-v3, when the best results (63.26%) appear on the validation set, the model's accuracy score on the training set is only 44.03% in the classification task. This phenomenon also occurs in the regression task. But the difference is that the difference between the results of the training set and the validation set of the model in the classification task is much smaller than that in the regression task.

We therefore consider that there is noise in the training set, which is especially evident in classification tasks. To verify that there is really noise in the data, we compared part of the data in the training set with the data on the wikiHow website, as shown in the figure below. It can be seen that the sentences that appear in the original text in time are still marked as Neutral or Implausible in the training set. Figure 7 shows an example of original data with id-20 that may be incorrect.



Add in a few drops of clear nail polish and stir with a toothpick until there are no lumps. Keep stirring until you get an even color and consistency. If the color too sheer, add some more eyeshadow. ***Make sure that there are no clumps in the polish.*** *If there are any clumps, break them up with the toothpick. If you don't do this, they will show up on your manicure and make it look lumpy.*

Figure 7: Data in the original paragraph

We tried Label Smoothing (Müller et al., 2019) and Self-Adaptive Training (Huang et al., 2020) to solve the problem of data noise. Although there is no significant improvement in the model's performance, it speeds up the model Convergence rate during training.

4 Conclusion

In this paper, we describe the Identifying Plausible Clarifications of Implicit and Underspecified Phrases shared task held within SemEval-2022 and present the design, the data, the results, and the systems for the shared task. The participants of the shared task were provided a collection of revisions of instructional texts from the how-to website wikiHow. The shared task is challenging, partly due to the relatively small training data and label noise.

We develop an ensemble model of NLP to distinguish between plausible and implausible clarifications of an instruction, achieving the 2nd best performance in the subtask1 and the 3rd best performance in the subtask2. For some of the problems reflected in this task, such as data noise, non-identically distributed data, there is still a lot of research space.

{akrah001, tpederse}@d.umn.edu

Abstract

This paper describes the DuluthNLP system that participated in Task 7 of SemEval-2022 on Identifying Plausible Clarifications of Implicit and Underspecified Phrases in Instructional Texts. Given an instructional text with an omitted token, the task requires models to classify or rank the plausibility of potential fillers. To solve the task, we fine–tuned the models BERT, RoBERTa, and ELECTRA on training data where potential fillers are rated for plausibility. This is a challenging problem, as shown by BERT-based models achieving accuracy less than 45%. However, our ELECTRA model with tuned class weights on CrossEntropyLoss achieves an accuracy of 53.3% on the official evaluation test data, which ranks 6 out of the 8 total submissions for Subtask A.

1 Introduction

Instructional texts (e.g., How To Guides) describe how to accomplish a given goal and are integral to our daily lives. One popular source is WikiHow[1] which is an online platform that allows users to collaborate to create and maintain such guides. This kind of documentation must be clear, and if it is not then this is a key reason that prompts revisions of underspecified instructions in WikiHow (Anthonio et al., 2020a).

One important problem for NLP is to determine if a given instructional text is in need of clarification or revision. SemEval-2021 Task 7 (Roth et al., 2022) extends this problem by requiring models to score five possible fillers based on how well they can plausibly fit a given context. Task 7 includes two subtasks. Subtask A classifies the possible fillers as IMPLAUSIBLE, NEURAL, and PLAUSIBLE. Subtask B requires systems to rank the fillers on a scale of 1 to 5, where a higher score means more plausible. We only participated in Subtask A and used a variety of BERT-based methods.

[1]https://www.wikihow.com

2 Task Data

The training, development and test data were supplied by the organizers of SemEval–2022 Task 7 (Roth et al., 2022). The dataset is based on the WikiHowToImprove Corpus (Anthonio et al., 2020b) which consists of edits of 2.5 million sentences from WikiHow. The authors show that edits are primarily made to clarify instructional texts and that the distinction between older and revised versions of sentences can be modelled computationally.

Each instance in the data is divided into an Article title, a Section header, and a Sentence nested between a Previous and Future context. Each instance also includes five potential fillers, each of which is annotated as IMPLAUSIBLE, NEUTRAL, or PLAUSIBLE, which serves as the basis of Subtask A. There is a also a plausibility score of 1 to 5 which is the basis of Subtask B (which we did not participate in).

Table 1 shows 3 training example templates made up of the concatenation of the Previous context, the Sentence with the blank to be filled, and the Future context. Each template is filled with each of the five possible fillers to generate the training examples (5 per template). We start with 3,995 training templates where the filler is not specified. We create an instance for each of the five possible fillers for each template, giving us a total of 19,975 training examples. We remove extraneous content such as bullet points and numbers in order to make the examples more readable. In a later approach, we highlight each filler in the generated instance with a special "[filler]" token, a step that yields further performance gains on the development data (Table 3) but achieves no corresponding gains on the official test results.

3 Methodology

We experimented on three large pre–trained language models for Subtask A, including BERT,

Previous context	Sentence	Followup context
State what you have contributed to the company. By doing it this way, it is going to show that you have done your job and been an asset, thus the raise is well-deserved. *	**P:** If you believe your [...] of time working at this company warrants a raise or promotion, say that as well. **Fillers: A. continuity B. window C. abundance D. length E. appreciation**	It is best to tell them all the reasons you believe you deserve this increase.
An all weather strategy often keeps you always afloat compared to one planned for normal market behavior. Table 1: Training Example Templates for SemEval–2022 Task 7. Each possible replacement (filler) for the omitted token [...] must be ranked as PLAUSIBLE (blue), NEUTRAL(orange), or IMPLAUSIBLE (RED).

RoBERTa and ELECTRA. BERT (Bidirectional Encoder Representational from Transformers) (Devlin et al., 2018), is a Transformer-based language model trained using Masked Language Modeling (MLM) to predict the masked tokens based on the surrounding context. In MLM, a given percentage of the tokens of an input sequence is masked, and BERT is tasked to predict the orginal tokens. With the MLM approach, BERT was able to produce good results when transferred to downstream NLP tasks, becoming the new benchmark for other pre–trained models. The authors of the ELECTRA paper (Clark et al., 2020), however, note that the MLM approach only learns from the masked tokens (about 15%) of any given example, thus requiring substantial compute resources to train a language model using MLM.

The next model we used was RoBERTa, which is essentially a replication of BERT (Liu et al., 2019) which adjusts key hyperparameters and uses larger amounts of data during pre–training. RoBERTa improves upon BERT when trained longer, using larger mini–batches over more data.

Similarly, we experimented with ELECTRA (Clark et al., 2020), a pre–trained model that uses Replaced Token Detection as a pre–training objective. This distinguishes real inputs from plausible but synthetically generated ones coming from a small masked language model. The authors argue that ELECTRA improves compute efficiency during pre–training, and can match or exceed the performance of BERT and its variants when fine–tuned on downstream tasks.

The ELECTRA model includes two Transformer models, a generator and a discriminator. The generator emulates a small Masked Language Model by predicting the original token of a masked-out token. Like the Masked Language Model in BERT, some samples of the input sequence to the generator are replaced with [MASK]. The predicted results of the generator are fed as inputs to the discriminator.

For each token in the sequence, the discriminator predicts whether it is the original or the generated one. This means that the discriminator is able to learn from all input tokens for any given example, with the model loss calculated over all the tokens. This is what sets ELECTRA apart from BERT, and a major reason for ELECTRA's greater compute efficiency.

ELECTRA addresses a drawback of Masked Language Models, which is that the masked tokens are only used during pre–training and are omitted during fine–tuning. This pre–train fine-tune mismatch contributes to a loss in performance. Replaced Token Detection, in which ELECTRA distinguishes between real tokens and their plausible fakes, is easily transferable to fine–tuning. This is particularly true for Subtask A of SemEval-2022 Task 7, which requires a model to classify how fillers will plausibly fit an omitted token.

4 System Description

This section introduces DuluthNLP's approach which relied on BERT, RoBERTa, and ELECTRA.

Hyperparameter	Value
Learning Rate	4e-5
Adam ϵ	1e-8
Optimizer	AdamW
Learning rate decay	Linear
Weight Decay	0
Batch Size	16
Train Epochs	10

Table 2: Hyperparameter Values for Fine-Tuning.

Model	Accuracy
ELECTRA with class weights	0.556
RoBERTa with class weights	0.552
BERT with class weights	0.522
ELECTRA	0.443
BERT	0.441
Logistic Regression	0.348
Random Guessing	0.267
RoBERTa	0.177

Table 3: Experimental Results on Development Data.

We discuss our fine–tuning process, and then how class weights were tuned.

4.1 System Description

We first fine–tune BERT on Subtask A. Using our pre–processed dataset as inputs, we build and train a classifier on top of the BERT model to learn how plausible each filler fits the blank in each sentence.

Using the BERT-base uncased tokenizer on our inputs, we then train our BERT model using the Adam Optimizer with a linear scheduler with warmup; a CrossEtropy Loss with adjusted class weights; and a learning rate of 4e-5 for 10 epochs (see Table 2). We train our model twice, once without class weight tuning, and a second time with tuned class weights.

We used these same hyperparameters for fine-tuning RoBERTa (Liu et al., 2019) and ELECTRA (Clark et al., 2020). As our experimental results will show, the most accurate results were obtained with ELECTRA.

We used the HuggingFace PyTorch implementations of the BERT, RoBERTa, and ELECTRA (Wolf et al., 2019). We fine-tuned our models using 2 Nvidia Quadro RTX 8000 GPUs.

4.2 Class Weights

Class imbalances for classification tasks are often caused by imbalances in the dataset. However, for Subtask A the training data is reasonably balanced and includes 7339 (36%) PLAUSIBLE labels, 7162 (36%) NEUTRAL labels, and 5474 (27%) IMPLAUSIBLE labels.

While the task training data does not have significant imbalances, our model predictions on the development set initially skewed towards NEUTRAL. Over 52% of all the predictions were NEUTRAL, as shown in Table 4.

Our model corrects these imbalances by applying class weights that penalize NEUTRAL labels. This helped to reduce predictions for NEUTRAL labels to 28%, as shown in Table 5. This is at least closer to the actual distribution of 18% NEUTRAL in the development data and helps to improve accuracy.

The selection of optimal weights was based on random search, which has been shown to be more efficient for parameter optimization than grid search (Bergstra and Bengio, 2012). To achieve this, we initially defined a 3-tuple list of random weights, and for each tuple, we set the class weights for the CrossEntropy Loss function and trained our model. From the list, we selected the class weights with the best performance for further tuning.

5 Experimental Results

In this section we present the results of our models on both the development data and the test data as used in the official evaluation scored by the task organizers.

We used the Logistic Regression model from scikit-learn[2] as a baseline method. It incorporates binarized Ngram counts (Wang and Manning, 2012).This obtained an accuracy of 34.8% on the development data for Subtask A.

As shown in Table 3, accuracy on the development data without class weights were lower. The RoBERTa model, in particular, achieved accuracy of 17.7%, the lowest among the three language models, and even lower than random guessing.

However, with tuned class weights, all three of the pre–trained models achieved accuracy above 50%. ELECTRA and RoBERTa obtained nearly identical scores of 55.2% versus 55.6%. We decided to use ELECTRA as our official evaluation

method because of its very consistent performance with the class weights adjustment and its somewhat lower energy consumption as compared to other large language models.

Our official results on the Subtask A evaluation data for Task 7 Subtask A were 53.3% with our ELECTRA model with class weights. The top ranked system in the task obtained accuracy of 68%. DuluthNLP ranked 6 among 8 systems.

6 Error Analysis

The classes predicted by our model on the development data prior to the official evaluation were skewed to NEUTRAL, as discussed earlier. We observed this with various different pre–trained models including BERT, RoBERTa, and ELECTRA with various different hyperparameter settings. Despite our best efforts the DuluthNLP system never reached accuracy above 45%.

We addressed this by adding class weights to CrossEntropyLoss function used in our models. When we assigned class weights of [1.5, 0.03, 0.7] for the IMPLAUSIBLE, NEUTRAL, and PLAUSIBLE labels, the wrongly predicted scores for the NEUTRAL label reduced to 28%, as shown in Table 5.

What is curious, though, is the difficulty in correctly classifying the IMPLAUSIBLE label. This represents 38% of the actual labels but is 14% of the predicted labels. Even after class weights are set as described above, only 18% of the labels are predicted to be IMPLAUSIBLE, which is still a difference of 20% from the actual IMPLAUSIBLE labels.

We achieved further performance gains on the devset across all the models by highlighting the filler in each data instance with a special "[]" symbol, and this forms the basis for our results in Table 3. This approach did not distribute well over the test data, however.

7 Ethical Considerations

The training of large language models has a dark side: demands for large amounts of compute power and the corresponding energy consumption. Training BERT with the Masked Language Model requires a lot of computational resources.This raises concerns over the accessibility, cost, and environmental impact of such methods (Bender et al., 2021). Whilst we experimented with three BERT-variants, we sought to limit model fine–tuning to the base models (Bert-base, RoBERTa-base, and ELECTRA-base), which require less compute resources than their larger versions. The ELECTRA model, which we used for our official evaluation test results, is computationally efficient, which partly informed our choosing it over the other models for use as our official method during the evaluation stage.

The accuracy of our models are, at best, a little above 50%. This means that roughly half of any of these predictions may be wrong. This is clearly not accurate enough to deploy in a real setting without potentially causing harm. It is easy to imagine the negative impacts of automatically clarified instructions that prove to be inaccurate.

Similarly, the test data and the training set are from the same sample distribution, and we cannot guarantee that our model will achieve similar results for any out-of-distribution test data. In other words, our model, reliant as it is on the contextual representations provided by the pre–trained models, cannot perform well on a completely new task or distribution.

We relied on large language models which were trained on very large corpora. Such text may include stereotypes and biases which are then carried over into the resulting model (Bender et al., 2021). This locks the model to older, less–inclusive understandings that may not reflect more modern views of gender, race, or other questions of identify. To minimize the potential harms of such misrepresentations it would be best if candidate predictions were verified by a human editor.

However, if models like these were deployed and used to auto–suggest revisions to WikiHow, they may constrain the choices of human editors (Miller and Record, 2017). This could create a mindset that uncritically accepts the framed options of the model as legitimate (Alfano et al., 2018). The reviewer may then abandon their own edits because the auto–suggestion seems to provide an answer. One way to minimize such risk is the deployment of Reflection Machines (Cornelissen et al., 2022), a decision support system that will compel users to give reasons for accepting or rejecting suggestions from the model.

Acknowledgements

The authors would like to thank the organizers for the opportunity to participate in SemEval-2021 Task 7. We are also grateful to the three anonymous reviewers for their thoughtful comments and feedback. Finally, we would like to thank Dr. Alexis Elder for her contributions regarding the ethical considerations of this work.

Abstract

In this paper, we detail the methods we used to determine the idiomaticity and plausibility of candidate words or phrases into an instructional text as part of the SemEval Task 7: Identifying Plausible Clarifications of Implicit and Underspecified Phrases in Instructional Texts. Given a set of steps in an instructional text, there are certain phrases that most plausibly fill that spot. We explored various possible architectures, including tree-based methods over GloVe embeddings, ensembled BERT and ELECTRA models, and GPT 2-based infilling methods.

1 Introduction

The internet is filled with instructional texts from websites like wikiHow that detail how to perform a variety of tasks (from tying a bow tie to building a deck of stairs). With this increase of quantity and use of instructional texts, it has become increasingly important for them to be clear and unambiguously worded. To this end, we evaluate whether lightweight and neural models are capable of detecting which phrases most plausibly fit into a given series of instructions.

The current revision process requires that a reader potentially identify something wrong about the content, and they report it to the website for alterations. A system such as the one described could automatically identify candidates that are unlikely to exist and report them for human verification.

In this paper, we describe our lightweight and transformer-based models that rank the plausibility of candidate phrases given some previous context.

2 Background

2.1 Task Setup

The data for this task was provided by SemEval Task 7 (Roth et al., 2022). This dataset is an augmented version of WikiHowToImprove (Anthonio et al., 2020), which consists of 2.7 million sentences and their revision histories extracted from the instructional website WikiHow. The dataset extracts over 4000 sentences and revision that represent clarifications of the original text. Each sentence is masked and presented with 5 possible fillers that may represent a clarification. The article title, subsection, previous context, and future context are also provided. Each filler is annotated with a plausibility class label (either IMPLAUSIBLE, NEUTRAL, or PLAUSIBLE), whose prediction is the basis of Subtask A, and a plausibility score on a scale from 1 to 5, whose prediction is the basis of Subtask B.

The plausibility of a given filler is highly dependent on the context. For example, the clarification *birthday* is annotated as implausible for the sentence

2. Send a _____ card. Even if you're able to have the conversation in person, it's worth sending a card.

given the previous context

1. Ask in person whenever possible. Receiving an invitation to be a groomsman is exciting.

as the previous context implies a wedding.

Given this, we simply concatenate each of the provided data inputs into a single string as input for our models.

3 System overview

3.1 Word Embeddings

We first implemented a GloVe-based method (Pennington et al., 2014). To embed all the words, we used the Python Natural Language Toolkit (nltk) library to handle tokenizing all words. These words were pre-processed using a Punkt sentence tokenizer that can handle stripping punctuation from boundaries that would not affect the semantics of the phrase or sentence. We then fit various classical ML models, as listed in Section 3.2, to make

[*]Co-first authors.
[†]Co-senior authors.

predictions on the word vector inputs.

3.2 Lightweight models

- **Ridge regression** is a classification algorithm that minimizes the residual sum of squares.
- **Random forest** is a supervised learning technique that ensembles independent decision trees to yield a result.
- **Gradient Boosting** is a technique that ensembles a number of weak learners (typically decision trees) and optimizes based on a differentiable loss function.
- **Discriminant analysis** is a generative learning algorithm that assumes the data is distributed according to a Gaussian distribution.
- **Multilayer Perceptron** is a multi-layer artificial neural network.

3.3 BERT-like models

BERT is a language representation model first introduced in 2018 that has achieved state-of-the-art results in NLP experiments (Devlin et al., 2018). The model follows a multi-layer transformer-based encoder architecure. It leverages bidirectional self-attention, which enables it to learn context from both preceding and following sentences. Furthermore, it was trained on language modeling tasks – predicting masked tokens from context – which makes it an ideal model for this task. We fine-tune the BERT model to learn the plausibility of various possible fillers.

To do so, we input both the masked sentence with context information (chosen out of resolved pattern, article title, section header, previous context, and follow-up context) and the possible filler, with each element separated by a special separator token. We then train a shallow neural network on top of BERT to recognize the plausibility or implausibility of the filler based on BERT's encoded representation.

In our data set, we used the pre-trained bert-base-uncased tokenizer to prepare the words for the model. In our BERT Class, we used the Sigmoid activation function and added dropout to prevent over-fitting of the model. We froze the first 8 layers of the BERT model and then trained using Cross Entropy Loss, an Adam optimizer function, and a learning rate scheduler. As the model was trained, the program kept track of the best models with the highest performance accuracy. It would check with each epoch and save the model if it improved.

Alongside BERT, we also experiment with other similar BERT-based language models, like ALBERT (Lan et al., 2019) and RoBERTa (Liu et al., 2019). ELECTRA uses the same underlying model as BERT, but through a different pre-training mechanism. This approach corrupts the input by replacing tokens with alternatives, rather than masking it, and trains the model to determine which tokens were corrupted versus part of the original sentence (Clark et al., 2020). This makes ELECTRA another ideal candidate for determining the plausibility of certain fillers. Each of these models was fine-tuned and evaluated in the same manner as the original BERT.

The ELECTRA model of the highest accuracy was achieved using the ELECTRA-small discriminator, two linear layers, a hyperbolic tangent activation function, and a dropout rate of 0.5 before each linear layer. The context information used was the previous and follow-up context.

3.4 Infilling by Language Modeling

This approach is taken from (Donahue et al., 2020). Training data for this model was created by randomly masking words or phrases in a body of text and fine-tuning the GPT-2 model on those masked sentences. We combined the Article Title, Section Header, Previous Context, Sentence, and Follow-up Context into a single string and added an infill mask token where we are predicting the word or phrase. Then, given the surrounding the context, the model returned a set of logits and softmaxed probabilities that ranked the probability of all possible tokens. To handle multitoken words such as "jalapenos" ([474, 282, 499, 28380]), the logits were summed and the probabilities were mutliplied for each individual token. There were additionally phrases like "your hands" ([14108, 2832]) that were multi-token as well.

For the example "How to Store Jalapenos," the sentence needing clarification was "Make sure to wear latex gloves when handling jalapenos or wash [INFILL-WORD] thoroughly after handling." As follows are the options and their returned logits: "your hands": -6.1058 "the jalapenos": -70.2685 "the sun": -22.6745 "the floor": -19.1986 "your underwear": -18.6225. The model accurately determined "your hands" to be more probable than the other options like "the sun", "the floor", and "your underwear" which make little sense in this context. However, "the jalapenos", which received a medium plausible score of 3.0 in the training data was found to be extremely improbable with this model due to the high number of tokens. This was a flaw that was pervasive throughout the usage of this model and is why we decided to continue with the BERT and ELECTRA ensemble models instead.

After the logits were calculated for all the possible infills in the training data, we trained a Ridge linear model to convert from logits to our 1-5 scoring scale. Unfortunately, because of the inaccurate probabilities generated by multi-token words and phrases, there appeared to be no correlation between logits and their labeled scores, leading the Ridge model to predict around 3.33 as a baseline score for most words.

4 Experimental setup

We merge the provided train and dev sets, perform random 75:25 splits of the merged data to use for training and validation. We noted little difference in performance between different random splits.

Predictions were evaluated on accuracy for Subtask A and Spearman correlation for Subtask B. Although we also calculated other metrics such as macro-averaged F1 for Subtask A and mean squared error for Subtask B, we standardized on accuracy and Spearman correlation for consistency in comparing results. In particular, since the classes were close to balanced for Subtask A, using accuracy was not a big issue in overfitting to certain classes.

5 Results

As shown in Table 1, here was some variation in dev set performance between the lightweight models that we experimented with; in particular, Linear and Quadratic Discriminant Analysis performed better than the other models. However, even these performances are very low, achieving a maximal dev set accuracy of only 0.389 with Linear Discriminant Analysis.

After switching to BERT-like models, we generally achieve a significant improvement in classification accuracy. In particular, ELECTRA achieves the highest accuracy across all of our models, with a dev set accuracy of 0.465. An exception is RoBERTa, with which we achieve an accuracy close to that of Linear Discriminant Analysis.

The ILM-based models ultimately failed to improve upon the accuracy of the lightweight models. While the ILM approach might initially seem to be the most promising given the task, it seems that the model's ability to generate the top few most likely options did not correlate with its ability to compare relatively more unlikely potential infills. The model was also pre-trained on a stories database, which may not reflect the context appropriate for instructional texts like WikiHow articles.

For the regression subtask, we only experiment with BERT with a regression head. We find that BERT achieves a Spearman correlation of 0.149 on the dev dev set.

Our final evaluation results on both subtasks are shown in Table 2. Surprisingly, our evaluation scores are slightly higher than our development scores.

6 Conclusion

BERT-like models are the highest performing models for this type of instructional clarifications task. Because BERT has been trained to predict masked tokens, it is naturally better at finding words or phrases that most plausibly fit with the surrounding context. Simple GloVe word embedding models were unable to learn to the requisite complexity of this meta-linguistic task and were unable to break the level of 0.389 accuracy. Meanwhile, ILM-based approaches seemed promising, but in practice failed to accommodate phrases or long words. This method is more effective at generating text and not necessarily determining how plausible an infill sounds in that context.

In terms of future work, we believe that our system may be improved by the usage of large pretrained models such as SpanBERT (Joshi et al., 2019), which are trained using tasks involving multi-token span prediction, which may be more fit to the given task. Despite our lack of results, we believe that the infilling approach is still promising, and hope that it can be adapted to this task going forward.

Abstract

This paper outlines the system using which team Nowruz participated in SemEval 2022 Task 7 "Identifying Plausible Clarifications of Implicit and Underspecified Phrases" for both subtasks A and B (Roth et al., 2022). Using a pre-trained transformer as a backbone, the model targeted the task of multi-task classification and ranking in the context of finding the best fillers for a cloze task related to instructional texts on the website Wikihow.

The system employed a combination of two ordinal regression components to tackle this task in a multi-task learning scenario. According to the official leaderboard of the shared task, this system was ranked 4th in both classification and ranking subtasks out of 21 participating teams. With additional experiments, the models have since been further optimised. The code used in the experiments is going to be freely available at https://github.com/mohammadmahdinoori/Nowruz-at-SemEval-2022-Task-7.

1 Introduction

Oxford dictionary defines cloze test as "a test of readability or comprehension in which a person is required to supply words which have been deliberately omitted from a passage" (Oxford University Press, 2022). In the context of NLP, a cloze format task is one in which the context is one or more sentences with masked spans and the model is expected to predict a suitable filler for each span. Cloze-format datasets have become popular in NLP recently as they are relatively easy to create automatically and provide high quality resources for model training (Rogers et al., 2021).

SemEval 2022 task 7 is framed as a cloze task in which the goal is to rank or classify fillers within a given context based on their suitability. The texts are taken from actual articles on an instructional website and the masked spans are placed at locations of edits made by users. We participated in this shared task in both ranking and classification parts and developed a transformer-based model that utilises both classification and regression components at the top layer. The code and the data used in these experiments are publicly available.

2 Related Work

Cloze tasks have been a subject of interest in Natural Language Understanding (NLU) in recent years, especially within the context of reading comprehension, story understanding, and summarisation (Deutsch and Roth, 2019; Sharma et al., 2018; Mostafazadeh et al., 2016). There is evidence that cloze tasks can be used to effectively pretrain or finetune language models in order to perform few shot learning (Schick and Schütze, 2021; Liu et al., 2021).

WikiHow is a community-edited open domain repository that hosts how-to articles on a variety of different subjects. It is possible to track edits made by users and compare different versions. There have been some recent computational works exploring this resource, including modelling of revision requirements (Bhat et al., 2020), and the effect of edits on fluency (Anthonio and Roth, 2020) and vagueness (Debnath and Roth, 2021).

2.1 Masked Language Modelling

Masked Language Modeling (MLM) is a pretraining task which is widely used in transformer-based models. This task forms a self-supervised

[0]National Organization For Development of Exceptional Talents

cloze test by randomly removing some of the tokens of the sentence which will be further filled by the model during training. Prominent transformers including BERT (Devlin et al., 2019) , RoBERTa (Liu et al., 2019), DeBERTa (He et al., 2020) and T5 (Raffel et al., 2019) are trained using MLM as an auxiliary objective. Given the successes of transformers in most areas of machine learning and NLP, it is standard practice to fine-tune them for various down-stream tasks.

2.2 Ordinal Regression

Ordinal Regression (also known as Ordinal Classification) is a type of classification in which labels have order with respect to each other. Examples of ordinal regression tasks include age estimation (Niu et al., 2016), assessment of damage (Ci et al., 2019), and monocular depth estimation (Fu et al., 2018). In ordinal regression, performance of the model is sensitive to the order of the predictions with regards to the labels. For instance, in the age estimation task, the error of the model should be higher when it incorrectly predicts the age of 30 as 10, as opposed to when it predicts the age of 30 as 20. Ordinal Regression is commonly done by breaking the multi-class classification task into several binary classification subtasks within a multi-task learning scenario. The output of these binary classification subtasks should be rank-consistent to achieve good performance.

3 System Description

Figure 1 shows the overall architecture of our model. A pre-trained transformer sits at the base of the architecture. Different variations of this transformer are tried and reported in Sec 5. These include BERT (Devlin et al., 2019), RoBERTa (Liu et al., 2019), DeBERTa (v1 & 3) (He et al., 2020, 2021), and T5[1] (Raffel et al., 2019) in different configurations.

At the bottom of the network, there are two components, one for regression and the other for classification. At training time, both of these are trained in tandem using ordinal regression and a combined loss. The loss function ensures that the ranks of the labels are kept consistent across these task (Sec. 3.6).

[1]Since T5 is originally an encoder-decoder language model, we only use its pre-trained encoder for our experiments

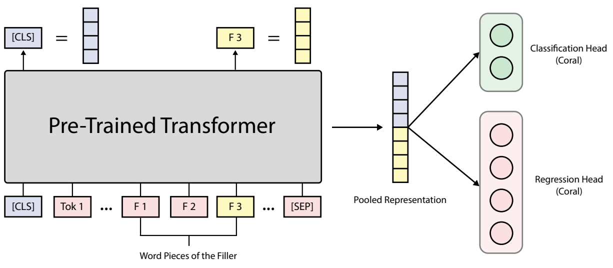

Figure 1: Overall architecture of the model. Note how a pooled representation is produced using the last token of the filler and the CLS token

3.1 Representing the Filler

To classify each filler, it is first placed in the location of the blank in the text to form a full context. The pre-trained transformer is equipped with a word-piece tokeniser that breaks down the filler to subword units and also uses a [CLS] token to represent the entire context [2]. To build a pooled representation for the filler, the contextualised representations for the last word piece and the entire context (i.e. representation of [CLS]) are concatenated and passed on to the next layer.

3.2 Multi-task learning with Ordinal Regression

Once a combined contextualised representation is obtained from concatenation of [CLS] and the filler, we address both subtasks of the shared task in a single multi-task learning architecture. The objective of this model is to predict both the class and the suitability score for each provided filler. The concatenated representation is fed to a fully connected feed-forward layer followed by a GELU activation function (Hendrycks and Gimpel, 2016). This layer projects the representation to a lower dimensional space. Subsequently, the output is passed on to two separate classification and regression heads.

3.3 Decomposing the Problem into Binary Classification tasks

As mentioned in Sec. 3, our model uses a special loss function named coral to perform ordinal regression. This loss function and the training procedure it requires are explained in Cao et al. (2020). Coral layers break a K-class classification problem into $K - 1$ binary classification tasks as part of a multi-task learning scenario. For a coral layer with $K - 1$

[2]T5 does not use CLS for context representation. In that case we just classify the last word-piece with no additional concatenation

units [3], the value of loss is constructed from the sum of $\mathrm{K}-1$ separate binary cross entropy losses belonging to each unit.

To train a coral layer, it is necessary to first transform the original labels to sets of binary labels. This is the step where the notion of order is introduced into the model. Given K classes, we convert each label to a collection of binary labels as follows:

$$f(y,k)=\begin{cases}1 & \text{if}\, k<y\\ 0 & \text{if}\, k\geq y\end{cases} \tag{1}$$

$$Y^{(i)}_{ordinal}=\{f(y^{(i)},k)|k\in\mathbb{W}\wedge k<\mathrm{K}-1\}$$

where $y^{(i)}$ is the original label for the ith training instance and $0\leq y^{(i)}\leq \mathrm{K}-1$.

3.4 Classification and Regression Heads

At the top end of the architecture there are two components for classification and regression. The classification head is a coral layer with two units which is used to address the classification subtask where we have three labels, namely, `Implausible`, `Neutral`, and `Plausible`. Note that the labels in the classification task have inherent order and for the model to be trained effectively, it is important that the training objective penalises misclassifications based on this underlying assumption. For instance, the error of the model should be more when it predicts an `Implausible` sample as `Plausible` compared to when it predicts an `Implausible` sample as `Neutral`. This is the motivation to use ordinal regression losses like coral.

The other head is assigned to the regression subtask and rates each filler for suitability. We converted continuous scores in the $1-5$ range to labels with discrete values in the $0-4$ range by either rounding or flooring the scores. For example, the original scores of $\{1.333, 1.75, 2.5, 3.75, 4.25\}$ are mapped to $\{0,1,2,3,3\}$ by rounding and $\{0,0,1,2,3\}$ by flooring. We can frame the regression task as ordinal classification with five labels by binning the values. A 4-unit coral layer is used to perform this classification. These heads are jointly trained using a combined loss.

[3]A T-unit coral layer, is comprised of T binary classification units which share the same weights but have different biases.

3.5 Constructing Labels and Ranks from Heads

Since coral layers differ from normal dense layers, their output can not be directly converted to labels. Furthermore, the regression subtask is also framed as an additional classification task in our methodology. However, since the purpose is to report continuous scores rather than discrete labels, a unique conversion is necessary for the output of the regression head.

For the classification head, the goal is to output discrete labels in range of $0-2$. Given the output of the classification head for one sample $\hat{C}$, the conversion to the label is defined as follows:

$$f(y)=\begin{cases}1 & \text{if}\, y>0.5\\ 0 & \text{if}\, y\leq 0.5\end{cases} \tag{2}$$

$$c=\sum_{k=1}^{2}f(\sigma(\hat{C}_k))$$

where c is the final label and σ is the sigmoid function.

For the regression head, the goal is to output continuous scores in range of $1-5$. Given the output of the regression head for one sample $\hat{R}$, the conversion to the continuous scores in range of $1-5$ is defined as follows:

$$r=(\sum_{k=1}^{4}\sigma(\hat{R}_k))+1 \tag{3}$$

3.6 Computation of Loss

Since we have three labels for the classification task, ordinal labels would be sets of binary values with the length of two. Given $C^{(i)}$ as the converted classification label for the i_{th} training sample and the $\hat{C}^{(i)}$ as the output of the classification head for the i_{th} training sample, we can define the classification loss as:

$$\begin{aligned} l^{(i)}_c=\sum_{k=1}^{2}&-C^{(i)}_k\log(\sigma(\hat{C}^{(i)}_k))\\ &-(1-C^{(i)}_k)\log(1-\sigma(\hat{C}^{(i)}_k))\end{aligned} \tag{4}$$

For the regression task there are 5 different labels, and accordingly, ordinal labels would be sets of binary values with the length of four. Given $R^{(i)}$ as the converted regression label for the i_{th} training sample and the $\hat{R}^{(i)}$ as the output of the regression head for the i_{th} training sample we can define the regression loss in a similar way:

$$l_r^{(i)} = \sum_{k=1}^{4} -R_k^{(i)} \log(\sigma(\hat{R}_k^{(i)})) \\ -(1 - R_k^{(i)}) \log(1 - \sigma(\hat{R}_k^{(i)})) \quad (5)$$

Since we are aiming to perform both classification and regression, a joint loss is needed to combine losses from the two heads. For a given training batch of size n:

$$L_{total} = \frac{1}{n} \sum_{i=1}^{n} \lambda_c l_c^{(i)} + \lambda_r l_r^{(i)} \quad (6)$$

where λ_c is the weight associated with the classification loss and the λ_r is associated with regression.

4 Dataset and Experimental Setup

The shared task is based on Anthonio et al. (2020), where instructional texts from the website Wikihow [4] are used to create training instances for a cloze task. The deletions in the dataset are based on actual edits made by online users and they are assumed to represent certain types of clarifications to make a point more clear or disambiguate a sentence. Based on the actual edits, alternative fillers are automatically extracted and added to build a number of possible fillers. These texts along with the fillers were later annotated by humans and given plausibility scores from 1 to 5. There is also a separate type of annotation available in which there are 3 labels with discrete plausibility values. The shared task was organised in two separate tracks of classification and regression, depending on what kind of annotation was used for modelling the task. Table 2 & 3 show the basic statistics of the dataset in the shared task.

The dataset for this task consists of six features, named Resolved Pattern, Article title, Section header, Previous context, Sentence, and Follow-up context along with five different fillers for each sample. Resolved Pattern is one of the four following categories: `IMPLICIT REFERENCE`, `ADDED COMPOUND`, `METONYMIC REFERENCE`, and `FUSED HEAD` which indicates the relationship of the fillers with the context. Article title is the name of the article from which the paragraph is selected. Section header is the section from which the article is selected. Previous context is a few sentences before the sentence that contains the filler. Sentence is the sentence that contains the filler.

We obtained our best results when we used a custom formatting using which we can feed all the features to the model as textual input. Table 1 is an example of how we represent each training instance. Note how the 'Text' feature is constructed by concatenating previous and follow-up contexts with the target sentence.

Example input while using all features
Resolved pattern: ADDED COMPOUND Section header: Following a Basic Routine Article title: How to Get Rid of Peeling Skin Text: (...) 6. Never tear away loose skin. (...) 7. Protect your skin from sunlight. Exposure to direct sunlight can weaken your skin further and complicate the [Filler] problem. This is true regardless of whether your skin is peeling due to a sunburn or due to dryness.

Table 1: An example of how each input is formatted for training and inference. Each identifier followed by ":" represents a feature of the dataset represented in textual format.

Variation	implausible	neutral	plausible	total
train	5474 (27.40%)	7162 (35.85%)	7339 (36.75%)	19975 (100%)

5 Results and Discussion

The official test results for both subtasks are presented in Table 5. These are the best results that we have obtained on the test set prior to the end of the competition. On the official leaderboard of the shared task, our system was ranked 4th in both the ranking and classification tasks.

We have since performed extensive analyses on the effect of hyperparameters on different varia-
