Message from the ACL 2025 Industry Track Co-Chairs

We are happy and excited to welcome you to the Industry Track at ACL 2025, held on the three main days of the 63rd Annual Meeting of the Association for Computational Linguistics (28 July to 30 July 2025).

Like the main research track, the industry track attracted an unprecedented number of submissions: 421 papers! In total, 453 reviewers and 19 area chairs participated in the evaluation of these papers. After a thorough, double-blind peer-review evaluation with three reviews for each submission followed by reviewer discussions and additional deliberations, 108 papers were selected for presentation at the ACL 2025 Industry Track. Of these, 33 papers will be presented as oral talks and a total of 75 papers will be presented as posters.

Topic-wise, large language models were front and center of almost all submissions with trustworthiness, domain-adaptation, retrieval-augmented generation, and agentic architectures – across domains such as medical, legal, and finance – being popular topics.

NLP research in academia and NLP research in industry have always been very close in our fields. Our two keynote speakers – Lucia Specia and Leon Derczynski – will share their insights with regard to this intersection including synergies and fruitful collaborations.

Further insights can be gained through our "Careers in NLP" panel with esteemed participants who have decades of experience with NLP research in academia and industry.

We would like to thank the authors of all Industry Track submissions as well as the reviewers and area chairs for their hard and dedicated work under very tight deadlines. We would also like to thank the General Chair, the Publication Chairs, who supported us in the production of this volume, and all other ACL 2025 committees we interacted with between the summer of 2024, when this endeavour started, and the summer of 2025, when we finally have been able to have the Industry Track at the ACL 2025 conference in Vienna, Austria. Finally, we would also like to thank our keynote speakers and panellists as well as the whole ACL team, especially Jennifer Rachford.

Keynote Talk

From Words to Worlds: NLP for Game Creation and Interaction

Lucia Specia
Epic Games and Imperial College London
Mon, July 28th, 2025 – Time: **11:00 – 11:45** – Room: **Austria Center Vienna**

Abstract: The gaming industry is a leading force in global entertainment, surpassing the size of the music and film industries combined. With over 3 billion people playing games, there's bigger and bigger demand for fresh, high-quality, and immersive experiences. At the same time, user-generated games have become a core component of major gaming platforms, fostering creativity and diversification. These developments present significant opportunities for AI research and AI-driven tools designed to support gaming, from AAA studios to independent creators. In this talk, I will highlight some of these opportunities, focusing on three areas involving language: 1) Speech-driven animation, where we predict lip sync, expression, and head motion of a character from audio to animate photo-realistic characters; 2) Low-resource language code generation, where we build a code generation model for Verse, a new language designed specifically for programming interactive 3D worlds, games, and simulations; and 3) Safety of interactive NPCs at scale, where we design safety strategies to support the deployment of LLMs for speech to speech in-game (Fortnite) conversations between players and NPCs.

Bio: Lucia Specia is Senior Director of Research Engineering at Epic Games and Professor of Natural Language Processing at Imperial College London. Her work focuses on various aspects of data-driven approaches to multimodal and multilingual context models, with applications including machine translation, image captioning, visual question answering, quality estimation, and content moderation, among others. In 2021, she founded Contex.ai to build multimodal content moderation models for real world applications, focusing in the gaming industry. She now leads a team of research engineers at Epic Games delivering ML solutions across automation and business optimization, safety and security, user experience and content creation. She received a PhD from the University of Sao Paulo and has held positions at University of Sheffield, Meta, and Xerox Research.

Keynote Talk

We can't do it alone

Leon Derczynski
NVIDIA and IT University of Copenhagen
Tue, July 29th, 2025 – Time: **10:30 – 11:15** – Room: **Austria Center Vienna**

Abstract: Industry and academic research each have their own deficiences and blindspots, and both rely heavily on each other. This talk explores common themes and describes each side's view and what they miss for each theme. We will discuss the role in society, the role in research, which narratives work (and don't), the role in peer review (and its role for us), and where the hard workers, sceptics, and sociopaths fit in either case. All this comes together to form a positive view of good open collaborations, and some concrete advice on how to give and get the most value out of interactions with the other side.

Bio: Leon Derczynski is principal research scientist for LLM security at NVIDIA and prof in computer science at ITU Copenhagen. He has written inches, if not kilograms, of papers, and won similar quantities of awards etc. Prof. Derczynski has led policy efforts in academia, industry, and civil society. He has held affiliations at a dozen organisations in the past decade, including startups, universities, corporations, and non-profits; built research programmes at both a leading university and a leading corporation; and he retains a deep love of both university and industry research.

Abstract

For the 63rd Annual Meeting of the Association for Computational Linguistics (ACL 2025), it was decided once again to organise a dedicated Industry Track. Similar to the main research track of the conference, the industry track attracted an unprecedented number of 421 paper submissions. In total, 453 reviewers and 19 area chairs participated in the evaluation of these papers. After a thorough, double-blind peer-review evaluation with three reviews for each submission followed by reviewer discussions and additional deliberations, 108 papers were selected for presentation at the ACL 2025 Industry Track. Large language models were front and center of almost all submissions with trustworthiness, domain-adaptation, retrieval-augmented generation, and agentic architectures – across domains such as medical, legal, and finance – being popular topics.

1 Introduction

Language technologies and their applications are an integral and critical part of our daily lives. Many of these technologies have their roots in academic and industrial research laboratories where researchers invented a plethora of algorithms, benchmarked them against shared datasets and perfected their performance to provide plausible solutions to real-world applications. While a controlled laboratory setting is vital for a deeper scientific understanding of the problems underlying language technologies and the impact of algorithmic design choices on their performance, transitioning the technology to real-world industrial strength applications raises a different, yet challenging, set of technical issues.

We acknowledge the challenges when adapting language technologies for building novel and robust real-world applications as the journey from theoretical research to practical deployment can be difficult. Challenges can include technical aspects of system deployment and optimizing for efficiency, making informed design choices or methodological considerations of incorporating human feedback and oversight. The Industry Track provides a forum to address these multifaceted issues. We were seeking submissions that not only delve into research but also demonstrate the application of systems in real-world scenarios, irrespective of whether they involve proprietary data.

2 Call for Papers

We invited submissions describing innovations and implementations in all areas of speech and natural language processing (NLP) technologies and systems that are relevant to real-word applications. The primary focus of the ACL 2025 Industry Track was on papers that advance the understanding and demonstrate the effective handling of practical issues related to the deployment of language processing or language generation technologies, including those of large language models (LLMs), in non-trivial real-world systems. By "non-trivial real-world system" we mean an application deployed for real-world use, i. e., outside controlled environments such as laboratories, classrooms or experimental crowd-sourced setups, and that uses NLP and/or speech technology, even if not state of the art in terms of research. There was no requirement that the system be made by a for-profit company, but the users of the system are most likely outside the NLP research community.

This track provided an opportunity to highlight the key insights and new research challenges that arise from real-world implementations.

Relevant areas included system design, efficiency, maintainability and scalability of real-world applications, with topics including, but not limited to (in alphabetical order):

- Benchmarks and methods for improving the latency and efficiency of systems

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1–3

- Continuous maintenance and improvement of deployed systems
- Efficient methods for training and inference
- Enabling infrastructure for large-scale deployment
- Handling unexpected user behaviour
- Human-in-the-Loop approaches to application development
- Implementation at speed, scale and low-cost
- Negative results related to real-world applications
- System combination

Novel applications and use cases, with topics including, but not limited to (in alphabetical order):

- Best practices and lessons learned
- Case studies, from design to deployment
- Description of an application or system
- Design of application-relevant datasets
- Development of methods under system constraints (model or data size)
- Novel, previously unsolved NLP problems and novel NLP applications

Methods for deployed systems, with topics including, but not limited to (in alphabetical order):

- Ethics, bias, fairness, harmlessness and trustworthiness in deployed systems
- Interpretability
- Interactive systems
- Offline and online system evaluation methodologies
- Online learning
- Robustness
- In addition, opinion/vision papers related to real-world applications were also welcome.

Submissions had to clearly identify one of the following three areas they fall into:

Deployed Must describe a system that solves a non-trivial real-world problem. The focus may include describing the problem related to actual use cases, its significance (against opportunity size, value proposition, and ideal end state), design/formulation of methods, tradeoff design decision for solutions, deployment challenges, and lessons learned.

Emerging Must describe the development of a system that solves a non-trivial real-world problem (it need not be deployed or even close, but there needs to be evidence that this development is intended for real-world deployment). Papers that describe enabling infrastructure for large-scale deployment of NLP techniques also fall in this category.

Discovery Must include results obtained from NLP applications in real-world scenarios that result in actionable insights. These discoveries should reveal promising directions in their application areas, leading to further system or societal enhancements. For example, an actionable discovery from an analysis of call center transcripts may reveal that certain language choices negatively impact customer experience, leading to better training of service representatives and improved customer experience.

3 Submissions and Results

The call for Industry Track papers attracted an unprecedented number of 421 paper submissions. A total of 453 reviewers and 19 area chairs participated in the evaluation of these papers. After a thorough, double-blind peer-review evaluation with three reviews for each submission, we eventually selected a total of 108 articles for presentation within the Industry Track at ACL 2025, with 35 oral and 73 poster presentations.

4 Research Trends

Nearly all submissions (approx. 90%) revolve around LLMs, indicating the prevalence of their adoption in real-world applications. More specifically, we observe the following five research trends based on this year's submissions.

Evaluation and Prompt Engineering Many submissions focus on the evaluation of LLM responses and improving their quality through prompt engineering, reflecting a broader push toward trustworthiness and safety in outputs. Hallucination detection and mitigation are particularly popular among such submissions.

Retrieval-Augmented Generation (RAG) RAG remains dominant, indicating continued interest in bridging static LLM knowledge with dynamic external data, especially in enterprise use cases such as enterprise document QA and domain-specific knowledge mining.

Domain Adaptation Domain adaptation (e. g., finance, medical, legal) is prominent, with an emphasis on techniques such as fine-tuning and reinforcement learning, underscoring the commercial push to tailor general models for domain-specific performance.

Agentic Workflows and Multi-Agent Systems LLM-powered agents and multi-agent systems are being developed to automate workflows and enhance user experience. The growing focus on agent-based architectures indicates a sharp industry shift toward LLM-as-a-service ecosystems.

Medical Applications The medical domain is particularly popular among the submissions, covering a wide range of use cases from ICU monitoring, diagnostics, to medical coding, a sector with high impact and regulatory sensitivity.

With the growing adoption of LLMs and agent-based architectures, we expect that the above trends will continue and rapidly evolve in the near future.

5 Programme Co-Chairs

- Georg Rehm, Deutsches Forschungszentrum für Künstliche Intelligenz GmbH and Humboldt-Universität zu Berlin, Germany
- Yunyao Li, Adobe, USA

Acknowledgments

The ACL 2025 Industry Track Programme Co-Chairs would like to thank the authors of all Industry Track submissions as well as the reviewers and area chairs for their hard and dedicated work under very tight deadlines. We would also like to thank the General Chair and various ACL 2025 committees with which we interacted between the summer of 2024, when this endeavour started, and the summer of 2025, when we finally have been able to have the Industry Track at the ACL 2025 conference in Vienna, Austria. Finally, we would also like to thank our keynote speakers and the whole ACL team, especially Jennifer Rachford.

Georg Rehm was supported through the project NFDI for Data Science and Artificial Intelligence (NFDI4DS) as part of the non-profit association National Research Data Infrastructure (NFDI e. V.). The NFDI is funded by the Federal Republic of Germany and its states.

Speculative Reward Model Boosts Decision Making Ability of LLMs Cost-Effectively

Jiawei Gu

liangshangsong@gmail.com

Abstract

Effective decision-making in Large Language Models (LLMs) is essential for handling intricate tasks. However, existing approaches prioritize performance but often overlook the balance between effectiveness and computational cost. To address this, we first introduce the 3E Criteria to systematically assess the cost-effectiveness of search strategies, revealing that existing methods often trade significant efficiency for marginal performance gains. To improve LLM decision-making while maintaining efficiency, we propose the Speculative Reward Model (SRM), a plug-and-play framework that seamlessly integrates with existing search strategies. Specifically, SRM employs an external reward assigner to predict optimal actions, reducing reliance on LLMs' internal self-evaluation. And a speculative verification mechanism is used to prune suboptimal choices and guide the search toward more promising steps. We evaluate SRM on several complex decision-making tasks including mathematical reasoning, planning and numerical reasoning in specialized domains. Experimental results show that SRM reduces costs to 1/10 of the original search framework on average while maintaining effectiveness.

1 Introduction

Large Language Models (LLMs) (OpenAI et al., 2023; OpenAI, 2024; DeepSeek, 2024; Qwen, 2024) have achieved significant progress in natural language processing, excelling in text generation and comprehension (Xu et al., 2025). However, their application to complex reasoning and decision-making remains challenging (Shao et al., 2024; Zelikman et al., 2024), particularly when solving intricate problems that require structured logical inference rather than pattern-based predictions (Valmeekam et al., 2023; Shao et al., 2024).

Table 1: **Speculative Reward Models (SRM)**, a plug-and-play framework designed to balance effectiveness and efficiency. In GSM8K tasks, all paradigms followed the same setting with *GPT-3.5-turbo* and 4-shot learning. The token cost is expressed in '[Prompt Tokens]/ [Completion Tokens]'. "Ext." denotes Extensibility. For Toolchain*, which lacks direct execution capability, we estimate cost using identical prompts but exclude running time.

Paradigm	Effectiveness	Efficiency		Ext.
		Time Cost	Token Cost	
	Acc.[%]	Avg.[sec.]	Avg.[K]	
CoT(Wei et al., 2022)	70.1	3.2	0.7/0.1	✓
DFS(Yao et al., 2023)	69.9	150	70.2/5.0	✓
+ SRM	70.5	34.7	18.6/0.8	✓
BFS(Yao et al., 2023)	72.3	180	85.5/7.1	✓
+ SRM	70.1	44	22.2/1.1	✓
BS(Wan et al., 2024)	71.4	66.4	225.4/4.4	✓
+ SRM	72.3	44	30.8/1.1	✓
MCTS(Hao et al., 2023)	74.7	122.6	105.2/2.5	✓
+ SRM	**80.5**	**45.2**	**20.6/0.9**	✓
Toolchain* (Zhuang et al., 2023)	78.9	-	40.8/1.9	×

To address these limitations, early studies introduced prompting strategies to enhance reasoning, such as Chain-of-Thought (Wei et al., 2022) and AlphaZero-Like Tree-Search Method (Wan et al., 2024), which guide LLMs to generate intermediate reasoning steps to improving inference structure and accuracy. However, these methods rely solely on prompting without external validation or optimization (Song et al., 2025), limiting their reliability. Recent approaches employ tree-based search algorithms (Besta et al., 2023; Ding et al., 2023; Putta et al., 2024; Wang et al., 2024) to explore broader reasoning paths and refine intermediate steps. By systematically evaluating multiple candidates in test time scaling (Snell et al., 2024), these methods enhance both the quality and diversity of reasoning, leading to more robust decision-making.

Despite these improvements, they inevitably introduce substantial computational cost. In Table 1, we utilize our proposed ***3E Criteria—Effectiveness***, ***Efficiency***, and ***Extensibility*** to assess the cost incurred during LLM inference. *Effectiveness* repre-

✉Corresponding author.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 4–21

sents the success rate, *Efficiency* denotes the time and token cost, and *Extensibility* is the adaptability to new tasks.

The results reveal that existing methods offer limited performance gains at disproportionately high costs. For example, ToT (Yao et al., 2023), which employs Depth-First Search (DFS), Breadth-First Search (BFS), provides marginal performance improvements (0-3%), but incurs a 50-60× in time cost and a 100-120× escalation in inference complexity. Similarly, RAP (Hao et al., 2023) leverages Monte Carlo Tree Search (MCTS), yielding a modest performance improvements of 4-5% at the expense of a 150-300× increase in inference cost. Additionally, Toolchain* (Zhuang et al., 2023) and reasoning enhanced models like QwQ (QwenTeam, 2024), constrained by task-specific heuristics, fails to reduce cost effectively and lacks extensibility. **In this work, we seek to address:**

Research Question

How to improve the reasoning ability of LLMs while maintaining a balance between effectiveness, efficiency, and extensibility?

Inspired by studies (Huang et al., 2023) emphasizing the need for external validation in decision-making, we propose **Speculative Reward Models (SRM)**, a plug-and-play framework designed to balance effectiveness and efficiency (Jahan et al., 2016). SRM introduces external rewards to mitigate ineffective decision-making in a speculative manner (Xu et al., 2024; Chen et al., 2023; Xia et al., 2023). It consists of two key components: (1) SRM, an independent reward model that assigns scores based on decision consistency and goal alignment. (2) Speculative Verification, a mechanism that ranks candidate steps by evaluating the consistency between internal rewards from LLMs and external rewards from SRM, enabling efficient pruning of suboptimal choices and guiding the search toward more promising states, thereby reducing computational cost.

We first train SRM on datasets with weak process rewards and then fine-tune it to SRM$^+$ using strong search rewards. This allows us to provide potential success probabilities for specific steps as external reward signals to LLMs during the search phase. Extensive validation has demonstrated that our approach significantly lowers the cost to a fraction of the original search framework's, without sacrificing effectiveness. In summary, our contributions are as follows:

(1) Efficiency. The SRM framework we proposed dramatically increases efficiency with a notable reduction in cost, requiring only about 1/10 of the original search paradigms.

(2) Effectiveness. There is no sacrifice of effectiveness for SRM; in fact, by integrating reward signals for process supervision, it achieves a up to a 10% performance improvement over CoT and approximately a 2% increase compared to using searching algorithms only.

(3) Extensibility[1] SRM provides generalizable weak rewards and a universal framework for deriving strong rewards. Fine-tuning with strong rewards transforms SRM into SRM$^+$, enabling domain-specific adaptation without full retraining.

2 Problem Formulation

The decision-making process can be formulated as a Markov Decision Process (MDP) (Puterman, 1990), where the state space $\mathcal{S}$ represents all possible problem states with $s \in \mathcal{S}$, and the action space $\mathcal{A}$ consists of actions $a \in \mathcal{A}$ that transition the state toward a solution. The LLM acts as a generator $\mathcal{G}$, producing candidate actions $\mathcal{G}(a|s, prompt_1)$ and determining state transitions $\mathcal{G}(s'|s, a, prompt_2)$. A reward function $\mathcal{R}(s, a)$ evaluates the effectiveness of actions in progressing toward the goal.

Tree-based search paradigms in LLMs decompose complex problems into a sequence of manageable sub-problems, each represented as an action modifying the current state toward the final solution. The search tree $\mathcal{T} = (\mathcal{S}, \mathcal{A})$ in Figure 1 represents the decision process, where nodes are states and edges are actions. Starting from an initial state s_0, LLM iteratively generates candidate actions $A_n = \{a_n^i\}_{i=1}^K$, assigns rewards $r_{a_n^i} = \mathcal{R}(s_n, a_n^i)$, selects the optimal action a_n^*, and transitions to the next state s_{n+1}. The search process continues until the goal state s_g is reached, optimizing the cumulative expected reward along the way.

3 Method

In this section, we introduce our **SRM** framework across three key dimensions: (1) Speculative Reward (SR) for ***Efficiency***, reducing computational cost by pruning less promising search paths; (2) Reward Consistency (RC) for ***Effectiveness***, ensuring stable and reliable decision-making by aligning

[1] Refers to whether the method requires retraining to adapt to new problems across different domains.

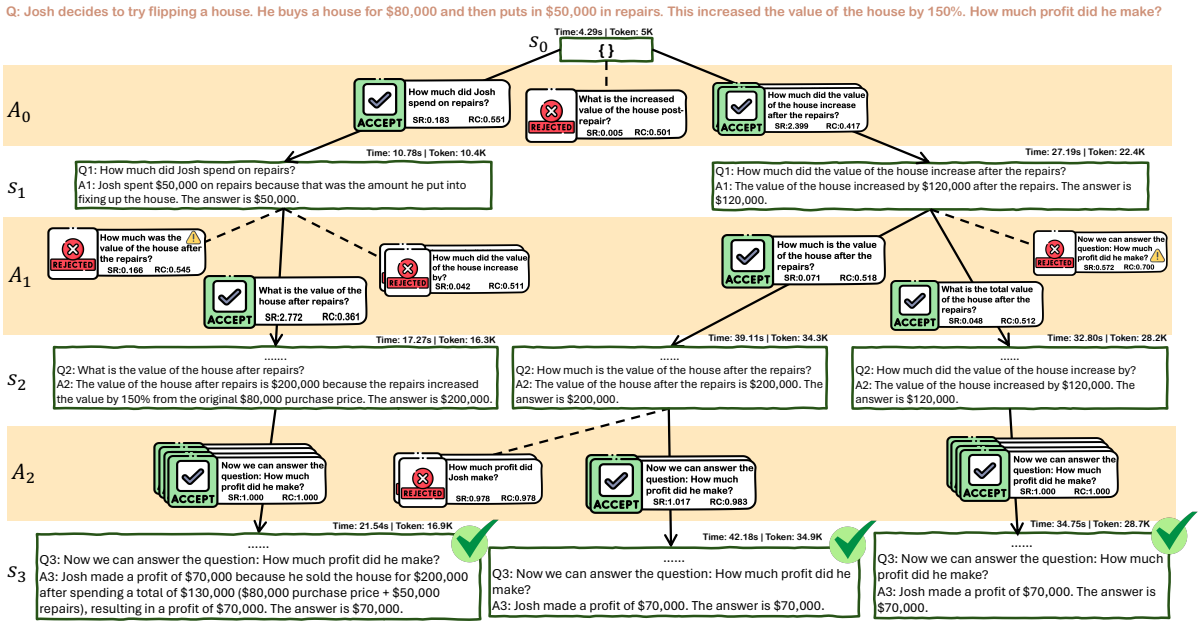

Figure 1: An example in GSM8K ($K = 4, N = 5$), where our SRM uniquely solves the case correctly across all baselines in 10 tests while achieving the lowest time and token costs. The decision-making process showcases SRM's pruning via Speculative Reward (SR), with green actions for acceptance and red for rejection. By SR, searching bypasses bad nodes and expands promising ones first. The selection strategy is determined by Reward Consistency (RC), prioritizing high-RC actions for earlier development, streamlining the path to the goal. 'Dangerous' sub-questions, characterized by excessively large spans (⚠), are pruned efficiently.

internal and external reward signals; (3) SRM$^+$ for ***Extensibility***, enabling adaptation to diverse tasks with minimal retraining.

Speculative Reward for *Efficiency* Search strategies typically rely on invoking LLMs to evaluate each state-action pair (s, a), determining the reward $\mathcal{R}(s, a)$. While effective, frequent LLM calls across large search spaces introduce significant inefficiencies. Inspired by Speculative Sampling (Xu et al., 2024; Chen et al., 2023), which accelerates inference by using a smaller model to *speculate* a larger model's predictive distribution, we propose the **SRM** to mimic the LLM as a reward assigner.

Given a pre-order state node s_n, and K candidate actions $A_n = \{a_n^1, \ldots, a_n^K\}$ generated from the LLM Generator $\mathcal{G}(\cdot)$, SRM assigns a speculative reward $\mathcal{R}_\theta^{\text{SRM}}(s_n, a_n^i)$ for each action a_n^i as:

$$\mathcal{R}_\theta^{\text{SRM}}(s_n, a_n^i) = P_\theta(a_n^i | s_n, prompt_1), \quad (1)$$

where θ is the parameters of SRM.

By bypassing LLMs for reward assignment, SRM significantly accelerates the search process. To maintain alignment with LLMs priors, following Chen et al. (2023), the reward $\mathcal{R}_\theta^{\text{SRM}}(s_n, a_n^i)$ for a_n^i is accepted with probability:

$$\min\left(1, \frac{\bigoplus(P_{\text{LLM}}(a_n^i | s_n, prompt_1))}{\bigoplus(\mathcal{R}_\theta^{\text{SRM}}(s_n, a_n^i))}\right), \quad (2)$$

where $\bigoplus(\cdot)$ denotes the normalization operator:

$$\bigoplus(f(x)) = \frac{f(x)}{\sum_x f(x)}. \quad (3)$$

Notably, $P_{\text{LLM}}(a_n^i | s_n, prompt_1)$ is directly obtained from the generation process of a_n^i, eliminating additional LLMs queries. Once the action a_n^i is accepted, we update $a_n^* \leftarrow a_n^i$ and transition to the next state s_{n+1} by $\mathcal{G}(s_{n+1} | s_n, a_n^*, prompt_2)$.This process is repeated for a_{n+1} until either the goal conditions are met or the search reaches the depth limit. If all actions $a_n^i (i = 1, 2, \cdots, K)$ are rejected, we regenerate a new candidate action set A_n' from Generator $\mathcal{G}(\cdot)$ and repeat the above process (See Algorithm 1).

Reward Consistency for *Effectiveness* Given the speculative property of the ratio in Equation 2, we define it as the Speculative Reward (SR), a key metric in our algorithm for pruning. However, assessing absolute performance alone is insufficient, the consistency of reward signals must also be considered. To this end, we propose Reward Consistency (RC) as a selection criterion, quantifying the

alignment between internal generator rewards and external SRM rewards. It is defined as:

$$RC = \frac{1}{1 + |SR - 1|} \in [0, 1]\,. \tag{4}$$

An RC value of 1 indicates complete consistency between internal and external reward signals. Their role within our SRM framework are illustrated in Figure 1. Ultimately, the cumulative reward across states (or nodes) is computed by $R_{\text{accumulated}} = SR^{\alpha} \cdot RC^{(1-\alpha)}$ where α is a hyperparameter that balance the significance of SR and RC.

SRM Training and Fine-tuning The SRM is trained on weak reward labels for each reasoning step—positive, negative, and neutral (see Appendix A.2.1 for details). Specifically, it is optimized using a cross-entropy loss function to distinguish the more advantageous action among candidates:

$$\begin{aligned} \text{loss}(\theta) = -\frac{1}{\binom{K}{2}} \mathbb{E}_{(s_n, a_n^i, a_n^j) \sim D} \\ \left[\log\left(\sigma(\mathcal{R}_\theta^{\text{SRM}}(s_n, a_n^i) \;\; - \mathcal{R}_\theta^{\text{SRM}}(s_n, a_n^j))\right)\right], \end{aligned} \tag{5}$$

where $\mathcal{R}_\theta^{\text{SRM}}(s_n, a_n)$ represents the scalar reward assigned by SRM for preorder state s_n and available action a_n, parameterized by θ. The model favors actions that lead toward the solution, assigning them higher rewards and the dataset D contains process-supervised reward or tree-based search reward. This training approach leverages differences in weak rewards to guide SRM in quantifying the intuitive preference for actions that move toward the goal state, thereby enhancing its ability to evaluate the potential success of reasoning steps. Following (Ouyang et al., 2022), all $\binom{K}{2}$ comparisons from each prior state s_0 are processed efficiently as a single batch element to mitigate overfitting.

SRM$^+$ for *Extensibility* SRM$^+$ is fine-tuned from SRM with same loss described in Equation 5, but with a distinct *RewardTuning* dataset. This dataset includes step-level, strong rewards with specific values derived from tree-based search techniques for targeted tasks. Thus, at this stage, SRM$^+$ is more accurate to learn the relative quality of movements through strong labels. The evolution from SRM to SRM$^+$ is illustrated in Figure 2. Besides, further details on the training and fine-tuning methodologies are available in Appendix A.1, with data collection for the *RewardTuning* dataset detailed in Appendix A.2.2.

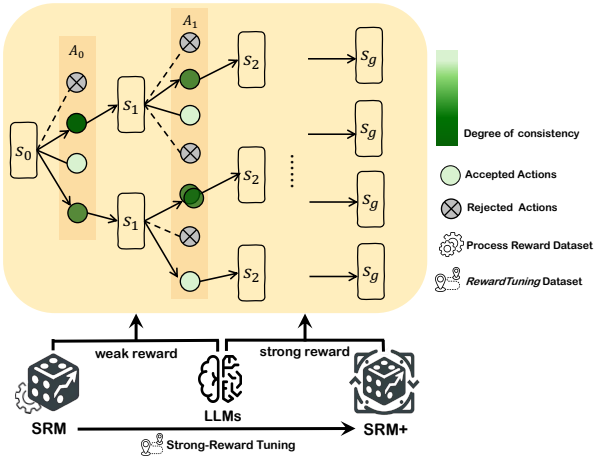

Figure 2: SRM was trained using the *PRM800K* dataset, in conjunction with LLMs, to provide weak Speculative Rewards (SR) for each action. Subsequently, SRM$^+$ underwent fine-tuning with the *RewardTuning* dataset, enabling it to generate strong SR for task-specific actions. Various actions are denoted by dots, with the intensity of their green hue indicating the magnitude of the Reward Consistency (RC) on each accepted node. A deeper green signifies a larger RC.

4 Experiment

In this section, we demonstrate the superiority of the SRM framework [2] in terms of Efficiency, Effectiveness, and Extensibility through comprehensive experiments. We evaluate SRM across a diverse range of decision-making scenarios, including mathematical reasoning on GSM8K (Cobbe et al., 2021), reasoning and planning in BlocksWorld (Valmeekam et al., 2023), and financial numeric reasoning on FinQA (Chen et al., 2021). Table 5 concisely aligns the three tasks with the decision-making problem framework.

4.1 Experiment Setup

As shown in Figure 1, we set $K = 4$ (number of candidate actions per step) and $N = 5$ (maximum search depth) for all tasks in our experiments. A detailed discussion of the GSM8K task is presented, while further information on BlocksWorld and FinQA, including their setups and case studies, can be found in Appendix C. Details regarding implementation specifics like SRM configuration, baseline alignment, and our selection of *DeBERTa-v3-large* as the base model are provided in Appendix A. Moreover, prompts used in each task are available in Appendix E.

Table 2: The result we tested 10 times on GSM8K and put on the average accuracy and cost. The values of total running time and total token cost are represented as multiples of the CoT row's value.

Method	LLaMA-2-70B			LLaMA-33B			LLaMA-2-13B		
	Effe. [Acc.]	Time [×CoT]	Token [×CoT]	Effe. [Acc.]	Time [×CoT]	Token [×CoT]	Effe. [Acc.]	Time [×CoT]	Token [×CoT]
CoT	0.54	1.0	1.0	0.29	1.0	1.0	0.20	1.0	1.0
DFS	0.52	28.4	1727.2	0.25	19.4	610.9	0.19	350.7	1306.8
+ SRM	0.54 (↑)	4.2	233.3	0.26 (↑)	2.9	32.0	0.20 (↑)	43.9	64.6
+ SRM$^+$	0.55 (↑)	4.2	241.2	0.28 (↑)	2.9	32.4	0.24 (↑)	42.0	69.5
BFS	0.58	36.3	1133.7	0.38	37.8	237.8	0.23	368.5	661.5
+ SRM	0.55	3.4	133.9	0.35	2.1	41.5	0.23	19.5	48.5
+ SRM$^+$	0.59 (↑)	3.4	123.4	0.38	2.2	42.2	0.26 (↑)	19.2	42.2
MCTS	0.61	1145	295.1	0.49	74.6	108.1	0.30	61.2	180.7
+ SRM	0.62 (↑)	8.0	66.7	0.49	2.2	19.9	0.27	15.3	33.0
+ SRM$^+$	0.64 (↑)	8.0	63.4	0.51 (↑)	2.3	20.7	0.29	15.3	31.8

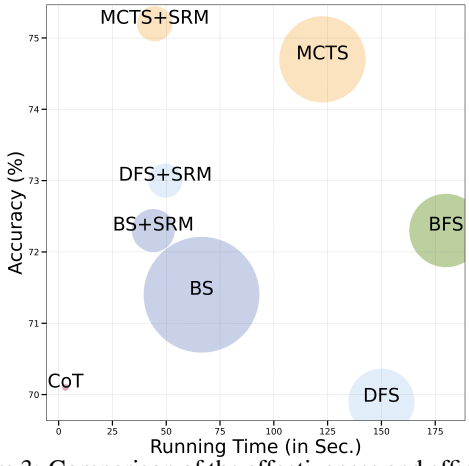

Figure 3: Comparison of the effectiveness and efficiency of search methods using the plug-and-play SRM framework. The bigger the dot is, the larger the token cost. After applying the SRM framework, it is obvious that the running time of the point representation is reduced (←), and the accuracy is flat or increased (↑).

4.2 *Effectiveness* and *Efficiency* Analysis

To evaluate the impact of SRM on effectiveness and efficiency, we present results on GSM8K from GPT-3.5-turbo and the LLaMA series (Touvron et al., 2023; Grattafiori et al., 2024) in Table 1 and Table 2. The results show that SRM significantly reduces both time and token costs by nearly 90% while maintaining or improving performance (Figure 3). Notably, these benefits come without compromising extensibility.

SRM applied to LLaMA-2-70B improves accuracy by 2% on ToT-DFS and 1% on RAP-MCTS. When used with GPT-3.5, its cost is only 10% to 30% of the original search algorithms. However, results highlight the instability of search paradigms in decision-making tasks. DFS, for example, performs 2% worse than CoT alone. Integrating DFS with SRM mitigates this decline by pruning weak nodes and expanding stronger ones. The fine-tuned SRM$^+$ further enhances search performance while stabilizing the framework at a lower cost. Additionally, SRM can be fine-tuned using other tree-based search rewards, as discussed in Appendix D. Overall, MCTS+SRM proves to be the most cost-effective approach across GPT-3.5-turbo and the LLaMA series. Among the evaluated search paradigms, **MCTS exhibits the highest accuracy yet the highest time cost.** This can be attributed to its more reliable reward system, derived from multiple simulations, rather than the self-evaluation and positional relationship utilized by BFS and DFS. Therefore, in our experiment, we use the MCTS reward in *RewardTuning* as the strong reward label to acquire SRM$^+$. Overall, MCTS+SRM emerges as the most cost-effective approach for decision-making tasks, as demonstrated using GPT-3.5-turbo and the LLaMA series.

Case Study *SRM mitigates error propagation by prioritizing reliable search paths and pruning error-prone branches.* Figures 1 and 6 compare MCTS+SRM and MCTS alone, demonstrating how SRM reduces early mistakes that would otherwise propagate through later steps. SRM prioritizes concise sub-questions with higher SR and RC, effectively pruning unreliable branches and guiding search toward more reliable paths. In contrast, MCTS alone struggles to avoid error-prone branches, leading to early mistakes that propagate through later steps. MCTS relies on fast rewards and LLM self-evaluation, which, while efficient in some cases, often fails to prevent accumulating errors. Without external supervision, minor mistakes can significantly impact tree search algorithms, as LLMs struggle to self-correct. As shown in Figures 1 and 6, reducing step size and verifying each step prevents errors from compounding, demon-

[2]Code available at: https://github.com/Kuvvius/Speculative-RM

Table 3: The baseline is MCTS. Sampling refers to the rejection sampling strategy outlined in Section 3, absent which there is no pruning. Consistent with earlier sections, token costs are denoted as [Prompt Tokens]/[Completion Tokens].

Method	Effectiveness	Efficiency	
		Time Cost	Token Cost
	Acc.[%]	Avg.[Sec.]	Avg.[K]
MCTS	74.7	122.6	105.2/2.5
+ SR + sampling	$70.2_{\downarrow 4.5\%}$	28.3	16.3/0.4
+ RC + sampling	$71.4_{\downarrow 3.3\%}$	96.5	53.2/1.5
+ $SR^{\alpha} \cdot RC^{(1-\alpha)}$ + sampling	$80.5_{\uparrow 5.8\%}$	45.2	20.6/0.9
+ SR no sampling	$78.4_{\uparrow 3.7\%}$	105.1	70.8/2.1
+ RC no sampling	$73.3_{\downarrow 1.4\%}$	143.2	98.1/2.7
+ $SR^{\alpha} \cdot RC^{(1-\alpha)}$ no sampling	$75.1_{\uparrow 0.4\%}$	58.8	34.7/0.9

strating SRM's role in stabilizing search efficiency while maintaining accuracy.

Ablation Study We conduct ablation studies with the MCTS paradigm to evaluate the impact of reject sampling via SR and selection mechanisms via RC (Table 3). The results indicate that both components in SRM's speculative approach contribute to reducing cost while maintaining performance. Using only SR for $R_{accumulative}$ significantly lowers cost but also reduces effectiveness. In contrast, relying solely on RC results in a smaller accuracy drop but at the expense of efficiency. Without sampling, cost increases due to the lack of tree pruning, sometimes exceeding the baseline search algorithms. These findings confirm SRM's effectiveness in optimizing tree-based search performance.

4.3 *Extensibility* Analysis

Table 4: Result of Blocksworld (LLaMA-2-70B) and FinQA (GPT-3.5 and GPT-4).

Mode	Method	Eff.	Time	Token
BW(Easy)	CoT	0.08	1.0x	3.8
	MCTS	0.66	560.9x	366.0
	MCTS + SRM	0.66	54.4x	40.1
	MCTS + SRM$^+$	0.68	58.3x	47.0
BW(Hard)	CoT	0.05	1.0x	3.8
	MCTS	0.51	709.5x	416.7
	MCTS + SRM	0.49	54.8x	34.2
	MCTS + SRM$^+$	0.54	69.9x	45.5
FinQA (GPT3.5)	CoT	0.49	4.5	3.4
	MCTS	0.60	160.6	200
	MCTS + SRM	0.65	51.9	54.2
	MCTS + SRM$^+$	0.68	52.1	53.7
FinQA (GPT-4)	CoT	0.70	4.9	3.5

Table 4 highlights SRM's adaptability across decision-making tasks. In Blocksworld (BW), CoT with LLaMA-2-70B struggles with planning, while MCTS improves decisions at high computational cost. SRM reduces inference by 7% while maintaining accuracy, and SRM$^+$ further enhances performance via *RewardTuning* (See Appendix A.2.2).

Beyond planning, SRM seamlessly transfers to FinQA, improving accuracy by 5% with minimal retraining, while SRM$^+$ achieves an 8% gain. Notably, SRM$^+$ enables GPT-3.5 to match GPT-4 in efficiency, demonstrating its ability to optimize LLMs across domains. By integrating speculative verification and fine-tuning with task-specific rewards, SRM ensures efficient, cost-effective adaptation to new tasks.

5 More Discussion

Diversity and randomness bring stable improvement. The methods related to Decision-making agents would have unstable issues and strongly depend on the general ability of the base model. During the reasoning process, MCTS introduces a degree of randomness in generating the final results. This randomness, combined with the diversity at intermediate nodes, allows for stable optimization of the sampling outcomes from language models. Consequently, MCTS consistently demonstrates superior performance compared to other search methods.

External signals can effectively supervise the generation process of the content. When a decision-making agent engages in complex reasoning and problem-solving, it heavily relies on the generative capabilities of the language model. However, using only self-evaluation methods often fails to provide stable and reliable judgments, making effective process supervision difficult. In such cases, introducing an external verifier for process supervision proves to be effective. The verifier can provide feedback on the quality of the model's current outputs and offer guidance, which helps improve performance.

By leveraging diversity (note that the "diversity" here differs from "diversity" in the field of information retrieval (Liang et al., 2017; Liang, 2019)) and randomness, the use of effective external signals for proper guidance can help avoid the high costs associated with repetitive exploration in the search space. Specifically, the verification signals provided by our proposed SRM in domain-specific problems, combined with search methods that **allow for sufficient exploration and randomness**, can achieve cost-effective performance improvements.

Why a relatively small model can help large base model? Our reward model underwent training that supervised the decision-making process, but it's significantly smaller compared to the generative language models it supports. The feasibility of using a smaller-scale reward model to effectively assist a much larger, more powerful model lies in our acknowledgment of the errors inherent in the weak labels provided by the Supervised Reward Model (SRM). However, within our framework, we do not intend for the more robust model to learn or replicate these errors. Instead, our aim is to guide it toward understanding the intentions behind the supervision (i.e., signals of external oversight), not the inaccuracies themselves. We maintain the assumption that the larger, base model inherently possesses all necessary reasoning and decision-making capabilities but might not currently exhibit them due to limitations in the decision-making context. Under the guidance of a weaker model, it becomes possible to activate this latent knowledge and adjust the base model towards a direction of self-reward, thereby enhancing its performance and decision-making processes in alignment with the supervisors' intentions.

6 Related Work

6.1 Decision-Making Agents

LLM-based decision-making agents, such as XoT (Ding et al., 2023), and Quiet-STaR (Zelikman et al., 2024) generate structured actions using formal languages like PDDL or API calls. These models rely on binary or scalar feedback for policy optimization, differing from human decision-making (Zhuge et al., 2025). Memory-enhanced methods (Shinn et al., 2023; Zhuang et al., 2023) treat LLMs as autonomous agents, but reward interpretation remains a challenge (Song et al., 2025). Our SRM addresses these limitations with a structured, cost-effective decision-making approach.

6.2 Tree-Based Search Algorithms

Tree-based search, including DFS, BFS, and MCTS, plays a key role in LLM-driven decision-making (Snell et al., 2024). DFS and BFS explore solutions systematically, while MCTS improves decision quality via random sampling. However, methods like ToT (Yao et al., 2023), RAP (Hao et al., 2023) and AlphaZero-Like Tree-Search Method (Wan et al., 2024) incur high inference costs due to frequent LLM calls.

6.3 Speculative Sampling

Speculative sampling (Xu et al., 2024; Chen et al., 2023; Xia et al., 2023) speeds up LLM inference by drafting candidate tokens and verifying them with a target model, reducing latency while maintaining quality. Inspired by this, SRM applies speculative verification to decision-making, using rejection sampling to prune search paths, minimize redundancy, and improve efficiency.

7 Conclusion

We propose the Speculative Reward Model (SRM), a cost-effective framework that enhances LLM decision-making by speculating on potential rewards. SRM reduces ineffective decisions through Speculative-Verification, efficiently ranking steps by given scores. Our contributions include significant cost reductions, a 10% performance improvement over CoT, a 2% increase over search-based algorithms, and broad applicability. Additionally, we introduce *RewardTuning*, a dataset for fine-tuning the reward model on three tasks. As to future work, we intend to extend our model for other tasks (Xian et al., 2025; Pasupat and Liang, 2015).

Limitations

Dependency on External Models SRM need to fine-tuned with task reward data to improve the corresponding performance on the specific task. relies on external reward models, which might introduce additional complexity and potential inaccuracies if the external models are not well-calibrated or if they fail to capture the nuances of the specific tasks.

Scalability Challenges While SRM reduces costs and improves efficiency, it is itself a relatively small model with only about 500M parameters. This limited capacity can pose challenges when scaling to more complex tasks or larger datasets, potentially hindering its ability to generalize effectively.

Acknowledgments

This work has been under development for an extended period and has benefited enormously from ongoing refinement and feedback. We are profoundly grateful to Guanzheng Chen for his invaluable guidance, insightful discussions, and unwavering support at every stage of this project. We also wish to thank Jiahao Song for generously providing

the critical resources and infrastructure, especially during the early phases, that made our implementation possible. Their contributions have been instrumental in shaping and advancing this research.

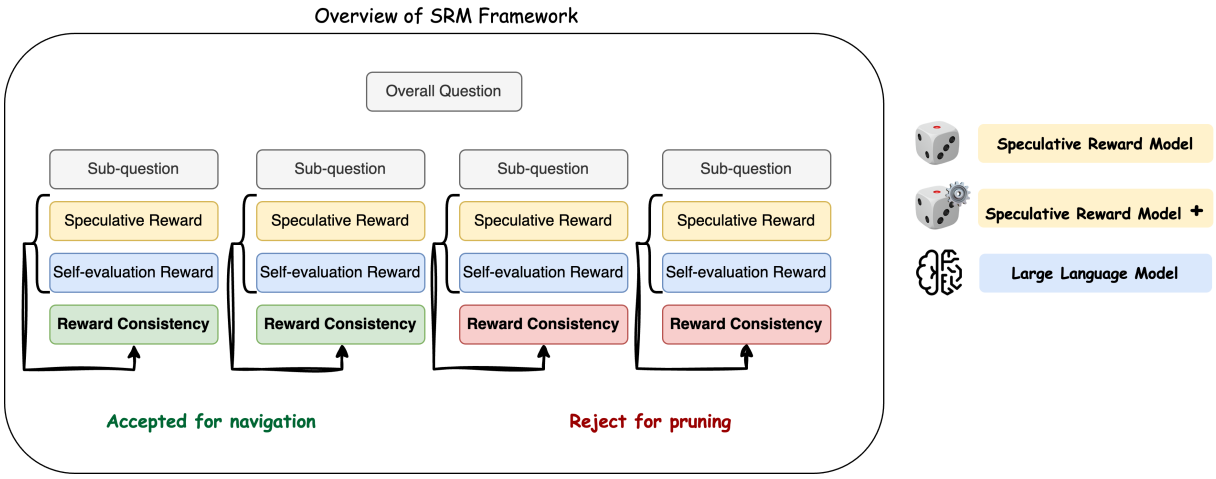

Figure 4: Example of an efficient selection process

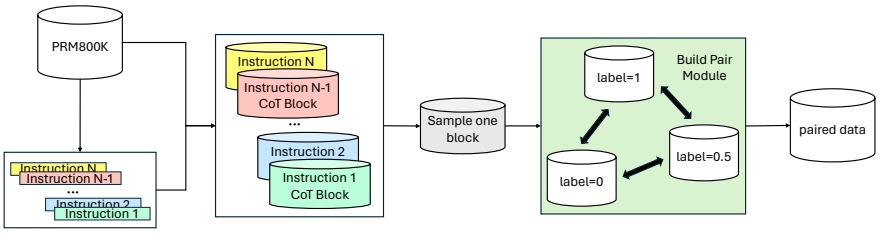

Figure 5: The process of building our weak reward dataset from *PRM800K* dataset, which SRM was trained on. The data samples of state and action pairs can be found in Appendix A.2.1.

A Implementation Details

To better illustrate the Decision-making process with SRM, we provide pseudo-code in Algorithm 1 and a selection process (including rejection for pruning and acceptance sorting for efficient navigation) as shown in the Figure 4.

A.1 LLM Configuration

In order to align the existing experimental results, we opted for the GPT-3.5-turbo (a previous version) as the engine in constructing the LLM-based agent framework. We configured the solution generation to have a maximum length of 512, with a temperature setting of 0.8, as detailed in Section 4. In the case of LLaMA-2 experiments, we similarly set the maximum solution length at 512 and the temperature at 0.8. The experiments were conducted using 8 NVIDIA Tesla V100 32GB GPUs to facilitate the inference process for both the LLaMA-2 7B and 13B models.

To maintain consistency with the established search algorithms, we adjusted weights as the same as them.

A.2 SRM Training and Fine-tuning Details

SRM was trained on DeBERTa-v3-large with sentence pairs with weak labels 7 to obtain SRM, and fine-tuned by strong labels 8 evolving into SRM+. As the loss function in Equation 5, we train SRM to learn the differences in text with different labels through comparison. Finally, with the input pairs with same state sentence, SRM can give the predicted reward labels, which show relatively good or bad. The dataset we built in our work will be fully released upon acceptance. In the A.2.1 and A.2.2, we provide further clarification and explanations through data samples.

A.2.1 Process Reward Dataset

The original training data has 1,055,517 pieces of data and 10,833 instructions (i.e. questions). After processing, there are 3,150,704 pairs. The generating process and data examples are shown in the Figure 7.

A.2.2 *RewardTuning* Dataset

We use the existing searching method to acquire the strong reward label for each step of sub-question or each state for blocks as shown in Figure 8. The form of reward is an exact value. We build all

Figure 7: The process of generating weak reward data pairs. As the example showed, we process the data from prm800k into state and action pairs with labels

reward data for the training data set of the three task, and finally use 10% them to fine-tune our SRM$^+$. The generating process and data examples are shown in the Figure 8.

B More Analysis

Recent results on GSM8K indicate that while some methods achieve relatively high accuracy, their cost-efficiency remains a major concern. For example, QwQ (QwenTeam, 2024) achieves a very high accuracy of 93.9%. However, its time cost is not reported (denoted as "-"), and its token cost (0.7/1.6) is only slightly improved relative to baseline methods. Moreover, QwQ is marked with "×" under Extensibility, which means that despite its high performance, its applicability to new tasks is limited due to the reliance on task-specific heuristics (reasoning tasks only).

The results reveal that existing methods offer limited performance gains at disproportionately high costs. For instance, ToT (Yao et al., 2023), which employs Depth-First Search (DFS) and Breadth-First Search (BFS), provides only marginal improvements (0–3%) yet incurs a 50–60× increase in time cost and a 100–120× escalation in inference complexity. Similarly, RAP (Hao et al., 2023) uses Monte Carlo Tree Search (MCTS) to yield a modest performance improvement of 4–5%,

Algorithm 1 Decision-making process with SRM

Given candidate K actions, and depth limit of tree N.
Given Large Language Model $G(\cdot)$ as generator, and Speculative Reward Model $R(\cdot)$, action-prompt $prompt_1$ and state-prompt $prompt_2$ with few-shot examples, intial state $s_0 = \emptyset$
Initialise $n \leftarrow 0$.
while $n < N$ **do**
  for $t = 1 : K$ **do**
    Generate candidate actions auto-repressively $a_n^t \sim G(a|s_n, prompt_1)$
  end for
  Compute speculative rewards of K candidate actions respectively $a_n^t \sim R(a|s_n, prompt_2)$
  $R(a_n^1|s_n), \ldots, R(\tilde{a}_n^K|s_n)$
  for $t = 1 : K$ **do**
    Sample $\epsilon \sim U[0, 1]$ from a uniform distribution.
    if $\epsilon < \min\left(1, \frac{\bigoplus(\text{Prob}(a_n^i))}{\bigoplus(\text{Reward}(a_n^i))}\right)$ **then**
      Set $a_n \leftarrow a_n^i$ and $n \leftarrow n + 1$.
    else
      Continue
    end if
  end for
end while

but at the expense of a 150–300× increase in inference cost. Additionally, while models like Toolchain* (Zhuang et al., 2023) and reasoning-enhanced models like QwQ (QwenTeam, 2024) can achieve high accuracy, they are constrained by task-specific heuristics, fail to reduce cost effectively, and suffer from poor extensibility.

Table 1 summarizes the performance (Effectiveness), efficiency (Time and Token Cost) and extensibility of various paradigms in GSM8K tasks under the same setting with *GPT-3.5-turbo* and 4-shot learning. It is evident that despite high effectiveness, models such as QwQ, Toolchain*, and even some search-based paradigms require significant computational resources, whereas methods incorporating Speculative Reward Models (SRM) can offer a better trade-off between performance and efficiency.

Figure 8: The process of generating strong reward data pairs.

C Task details

Task Setup We evaluate SRM framework with the MCTS search paradigm in Blocksworld benchmark (Valmeekam et al., 2023), where the aim is to examine the framework's efficacy in guiding an agent through a sequence of actions to reorganize blocks into specified configurations. In our research, we draw from the Blocksworld dataset as outlined by (Valmeekam et al., 2023), organizing the test cases by the least number of actions they necessitate for a solution and giving four test case to prompt, as same as (Hao et al., 2023), which detailed in The plan generation task involves creating a sequence of actions to meet the goal, which showcases decision-making skills at each step of the planning process.

BW Result on Step-level Building on these results, Table 6 provides further evidence of SRM's effectiveness in both **Easy** and **Hard** modes of Blocksworld. While MCTS enhances decision-making, SRM maintains similar performance with much lower cost. In **Hard** mode, SRM$^+$ consistently improves accuracy, especially in complex tasks like the 12-step problems. These findings confirm that SRM reduces cost while preserving performance, and SRM$^+$ further extends this by improving results in more challenging scenarios.

Importantly, the set of possible actions is finite and determinable through predefined rules rather than requiring generation by an LLM. The action

Table 5: Alignment of Three Decision-making Tasks. GSM8K and FinQA, differ in complexity and domain, but both numerical reasoning tasks with action space defined by K and requiring LLM for action generation and transition. Instead, in Blocksworld, a more complex planning task, an action is composed of one of the 4 verbs (i.e., stack, unstack, put, and pick) and manipulated objects. Thus, the action set for a given state consists of m actions, with m being up to 4, generated independently of LLM assistance.

	GSM8K	**FinQA**	**Blocksworld**
Goals	Calculate the correct answer by multi-step mathematical reasoning.	Calculate the correct answer by numerical reasoning for financial problems.	Arrange the blocks into stacks on a table in the specific order.
Initial State s_0	$\emptyset$	$\emptyset$	Description of current blocks and a goal.
Goal State s_g	A correct series of problem decomposition leading to the final answer.	A correct series of problem decomposition leading to the final answer.	A feasible plan including series actions.
State s_n	All current sub-questions and answers.	All current sub-questions and answers.	Text description of the current orientation of the blocks.
Action Set A_n	K sub-questions	K sub-questions	m actions, $m \leq 4$

Table 6: Performance comparison between CoT and MCTS methods, with and without SRM, across different step sizes in Blocksworld (BW) tasks. Results are shown for both Easy and Hard modes, evaluating accuracy at 2-step, 4-step, 6-step, 8-step, 10-step, 12-step, and overall (All) steps.

Mode	**Method**	**2-step**	**4-step**	**6-step**	**8-step**	**10-step**	**12-step**	**All**
Easy	CoT	0.49	0.18	0.06	0.01	0.01	0.00	0.08
	MCTS	1.00	0.99	0.75	0.61	0.32	0.32	0.66
	MCTS + SRM	1.00	0.97	0.70	0.63	0.33	0.33	0.66

space is dynamically generated, considering both domain-specific constraints and the current orientation of the blocks. For state transitions, the framework consults a Large Language Model (LLM) to forecast the impacts of actions on the blocks' states, updating the current state to reflect new conditions and eliminate outdated ones. The LLM, in conjunction with the SRM, generates Successor Representations (SR) and Reward Contexts (RC) for potential actions, which then inform the state transition function. The process concludes once the goal state is realized or when the search hits the predetermined depth limit.

Algorithm 2 Tree-based Search in LLMs.

Input: s_0: input; G: large language model; M: the maximum exploring steps; T: the dynamic decision tree for search; $\mathcal{R}(s_n, a_n^k)$: function to return specific reward
Initialize $T = \{S, A\}$; $S \leftarrow s_0$; $A \leftarrow \emptyset$.
for $t = 1$ to N **do**
  $A_n = \{a^{(i)}\}_{i=1}^{k} \leftarrow G(s_n)$ ▷ Invoking
  $a_n^* \leftarrow \arg\max_{a_n \in A_n} \mathcal{R}(s_n, a_n)$
  Add a_n as the edge of s_n.
  $s_{n+1} \leftarrow G(s_n, a_n^*)$
  Update s_{n+1} as a node of T. ▷ Invoking
end for
Output: The goal state s_g including reasoning steps and answer.

D Tree-based search Reward

Rewards are acquired by tree-based search algorithms, different from common reward for language model (Kwon et al., 2023; Shinn et al., 2023). And all the search methods employed are unsupervised, yet they vary in the balance they strike between exploration and efficient selection.

We would like to detail three kinds of reward designs with the order of decreasing exploration. Besides, we leave the more reward settings corresponding to the algorithms in the future work. Generally, tree-based search algorithms could own their corresponding reward configure, showing the

flexibility of our framework.

D.1 Priority Reward

This type of reward are designed for the search with certain priority. Taking DFS for an example, it begins with "root" state s_0 and then iteratively choose the first candidate action a_n^1 while there are K candidate action nodes. Until it reached the depth limit or the goal state s_g containing the final correct answer. It will then proceed down the new path as it had before, backtracking as it encounters dead-ends. Besides, Self-consistancy Chain-of-Thought (Wang et al., 2022) can be expressed in reward form with majority voting as a priority.

$$\mathcal{R}_{\text{DFS}}(s_n, a_n^i) = \begin{cases} 1 & \text{if } i = \inf\{j | a_n^j \text{ not visited}\}, \\ 0 & \text{otherwise.} \end{cases}$$

where $\inf\{j|a_n^j \text{ not visited}\}$ represents the smallest index j among all actions a_n^j that have not been visited.

D.2 Heuristic Reward

If only take confirmed priority for one-hot reward, the search process becomes aimless leading to low efficiency. Heuristic search algorithms are designed to solve the problem of search efficiency, such as Greedy Best First Search (GBFS), Dijkstra and A*. Aligned with the characteristic of algorithms, Heuristic reward defined by the heuristic function $h(s)$. Here,we would like to take GBFS for an example and list other heuristic reward in the appendix. the distance from the current state s_n to the target state s_g is used as the heuristic reward, leading the search direction correctly. Given a heuristic function $h(s)$ estimating the cost from any state s to the goal state s_g, the heuristic reward for an action a_n^i at state s_n is defined as follows:

$$\mathcal{R}_{\text{GBFS}}(s_n, a_n^i) = \begin{cases} h(s_{n+1}) & \text{if } s_{n+1} \text{ is reached by } a_n^i, \\ -\infty & \text{otherwise,} \end{cases}$$

where $h(s_{n+1})$ represents the heuristic cost from the resulting state s_{n+1}, after taking action a_n^i, to the goal state s_g. The action leading to the state with the lowest heuristic cost is preferred, guiding the search towards s_g.

D.3 Simulated rewards

With the fixed heuristic function for reward, it is evident that most of the decision space lacks coverage, resulting in insufficient exploration for searching. In contrast, simulated search algorithms like MCTS, would explore exhaustively within entire decision space. In this kind of algorithms, an iterative simulation cycle would continue until a terminal state arrived, which usually encompasses three phases: selection, expansion and backpropagation. Alongside the simulation process, a state-action value function $Q(s_n, a_n)$ is maintained, indicating the expected future reward lf taking action a_n in state s_n. To control the balance between exploration and exploitation, Upper Confidence bounds applied to Trees is often used. For each iteration of simulation, the selected action a^* should be :

$$a_n^* = \underset{a_n \in A_n}{\text{argmax}} \left[Q(s_n, a_n) + w\sqrt{\frac{N(s_n)}{1 + N(s_n, a_n)}} \right],$$

where $N(s)$ is the number of times state s has been visited in previous iterations, $N(s_n, a_n)$ is the number of times that a_n is selected at the state s_n, and weight w controls the proportion of exploration and development.

If taking MCTS as an example and supposed that to abtain the reward of an action needs simulate d times, simulated rewards can be expressed as follow:

$$\mathcal{R}_{\text{MCTS}}(s_n, a_n^i) = \frac{1}{N(s_n, a_n^i)} \sum_{k=1}^{N(s_n, a_n^i)} Q(s_n, a_n^k)\,.$$

E Prompt

For transition in SRM, we prompt:

Prompt

For each sub-question, please answer it in a complete sentence that includes your reasoning. And the last sentence ends with `"{answer_instruction}"` followed by a concise answer.

To apply CoT, we prompt:

Prompt

Q: Natalia sold clips to 48 of her friends in April, and then she sold half as many clips in May. How many clips did Natalia sell altogether in April and May?
A: Natalia sold 48 clips in April and half as many clips in May, so she sold $48 \div 2 = 24$ clips in May. Altogether, she sold $48 + 24 = 72$ clips. The answer is **72**.

Q: James writes a 3-page letter to 2 different friends twice a week. How many pages does he write a year?
A: James writes a 3-page letter to 2 different friends twice a week, so he writes $3 \times 2 \times 2 = 12$ pages every week. There are 52 weeks in a year, so he writes $12 \times 52 = 624$ pages a year. The answer is **624**.

Q: Alexis is applying for a new job and bought a new set of business clothes to wear to the interview. She went to a department store with a budget of $200 and spent $30 on a button-up shirt, $46 on suit pants, $38 on a suit coat, $11 on socks, and $18 on a belt. She also purchased a pair of shoes, but lost the receipt for them. She has $16 left from her budget. How much did Alexis pay for the shoes?
A: Alexis spent $30 on a button-up shirt, $46 on suit pants, $38 on a suit coat, $11 on socks, and $18 on a belt, so she spent

$$30 + 46 + 38 + 11 + 18 = \$143$$

on everything else. Alexis had a budget of $200 and finally there was $16 left, so she spent

$$200 - 16 = \$184$$

in total. Since Alexis has spent $143 on everything else, she spent

$$184 - 143 = \$41$$

on the shoes. The answer is **41**.

Q: Ken created a care package to send to his brother, who was away at boarding school. Ken placed a box on a scale, and then he poured into the box enough jelly beans to bring the weight to 2 pounds. Then, he added enough brownies to cause the weight to triple. Next, he added another 2 pounds of jelly beans. And finally, he added enough gummy worms to double the weight once again. What was the final weight of the box of goodies, in pounds?
A: Ken poured jelly beans into the box until the weight was 2 pounds, so the weight of the box was 2 pounds at first. Then Ken added enough brownies to cause the weight to triple, so the weight of the box was

$$2 \times 3 = 6$$

pounds. After Ken added another 2 pounds of jelly beans, the weight of the box was

$$6 + 2 = 8$$

pounds. Finally, he added enough gummy worms to double the weight once again, so the weight of the box was

$$8 \times 2 = 16$$

pounds. The answer is **16**.

Q: Janet's ducks lay 16 eggs per day. She eats three for breakfast every morning and bakes muffins for her friends every day with four. She sells the remainder at the farmers' market daily for $2 per fresh duck egg. How much in dollars does she make every day at the farmers' market?

A: Janet's ducks lay 16 eggs per day. She consumes

$$3 + 4 = 7$$

eggs daily, leaving her with

$$16 - 7 = 9$$

eggs to sell. Since each egg sells for $2, her total daily earnings are

$$9 \times 2 = \$18.$$

The answer is **18**.

To get the transited state for the given action and state in BW, we prompt:

Prompt

I am playing with a set of blocks where I need to arrange the blocks into stacks. Here are the actions I can do:
- Pick up a block
- Unstack a block from on top of another block
- Put down a block
- Stack a block on top of another block

I have the following restrictions on my actions:
- I can only pick up or unstack one block at a time.
- I can only pick up or unstack a block if my hand is empty.
- I can only pick up a block if the block is on the table and the block is clear. A block is clear if the block has no other blocks on top of it and if the block is not picked up.
- I can only unstack a block from on top of another block if the block I am unstacking was really on top of the other block.
- I can only unstack a block from on top of another block if the block I am unstacking is clear. Once I pick up or unstack a block, I am holding the block.
- I can only put down a block that I am holding.
- I can only stack a block on top of another block if I am holding the block being stacked.
- I can only stack a block on top of another block if the block onto which I am stacking the block is clear. Once I put down or stack a block, my hand becomes empty.

After being given an initial state and an action, give the new state after performing the action.
[SCENARIO 1]
[STATE 0]
I have that, the white block is clear, the cyan block is clear, the brown block is clear, the hand is empty, the white block is on top of the purple block, the purple block is on the table, the cyan block is on the table and the brown block is on the table.
[ACTION] Unstack the white block from on top of the purple block.
[CHANGE] The hand was empty and is now holding the white block, the white block was on top of the purple block and is now in the hand, the white block is no longer clear, and the purple block is now clear.
[STATE 1]
I have that, the purple block is clear, the cyan block is clear, the brown block is clear, the hand is holding the white block, the white block is in the hand, the purple block is on the table, the cyan block is on the table and the brown block is on the table.

[SCENARIO 2]
[STATE 0]
I have that, the purple block is clear, the cyan block is clear, the white block is clear, the hand is empty, the cyan block is on top of the brown block, the purple block is on the table, the white block is on the table and the brown block is on the table.
[ACTION] Unstack the cyan block from on top of the brown block.
[CHANGE] The hand was empty and is now holding the cyan block, the cyan block was on top of the brown block and is now in the hand, the cyan block is no longer clear, and the brown block is now clear.
[STATE 1]
I have that, the purple block is clear, the brown block is clear, the cyan block is in the hand, the white block is clear, the hand is holding the cyan block, the purple block is on the table, the white block is on the table and the brown block is on the table.

[SCENARIO 3]
[STATE 0]
I have that, the red block is clear, the blue block is clear, the hand is empty, the red block is on top of the yellow block, the blue block is on top of the orange block, the orange block is on the table and the yellow block is on the table.
[ACTION] Unstack the red block from the yellow block.
[CHANGE] The hand was empty and is now holding the red block, the red block was on top of the yellow block and is now

in the hand, the red block is no longer clear, and the yellow block is now clear.
[STATE 1]
I have that, the yellow block is clear, the blue block is clear, the hand is holding the red block, the red block is in the hand, the blue block is on top of the orange block, the orange block is on the table and the yellow block is on the table.

RAVEN: Robust Advertisement Video Violation Temporal Grounding via Reinforcement Reasoning

Abstract

Advertisement (Ad) video violation detection is critical for ensuring platform compliance, but existing methods struggle with precise temporal grounding, noisy annotations, and limited generalization. We propose RAVEN, a novel framework that integrates curriculum reinforcement learning with multimodal large language models (MLLMs) to enhance reasoning and cognitive capabilities for violation detection. RAVEN employs a progressive training strategy, combining precisely and coarsely annotated data, and leverages Group Relative Policy Optimization (GRPO) to develop emergent reasoning abilities without explicit reasoning annotations. Multiple hierarchical sophisticated reward mechanism ensures precise temporal grounding and consistent category prediction. Experiments on industrial datasets and public benchmarks show that RAVEN achieves superior performances in violation category accuracy and temporal interval localization. We also design a pipeline to deploy the RAVEN on the online Ad services, and online A/B testing further validates its practical applicability, with significant improvements in precision and recall. RAVEN also demonstrates strong generalization, mitigating the catastrophic forgetting issue associated with supervised fine-tuning.

1 Introduction

In the modern digital landscape, advertisements play a pivotal role in sustaining the growth of internet platforms. To ensure compliance with local laws and regulations, promote sustainable development, and foster a user-friendly environment, platforms establish stringent guidelines to regulate the content uploaded by advertisers. Despite these efforts, violations of platform policies persist. Early approaches relied on small-scale models (Dosovitskiy, 2020; He et al., 2016) to analyze and identify such violations, but these methods suffered from limited generalization capabilities. With the advent of large language models (LLMs) (Liu et al., 2023; Bai et al., 2023a), more advanced techniques have been increasingly adopted in practice to detect non-compliant content.

Among the various types of content, video advertisements present the most significant challenge for violation detection. In practice, it is not only necessary to predict the violation categories of a video but also to localize the specific sub-scenes corresponding to each category. A single video may contain multiple violation categories, each potentially associated with multiple temporal intervals. Existing methods typically follow a two-step process: (1) annotating each video with its violation categories and their corresponding temporal intervals, and (2) fine-tuning multimodal large language models (MLLMs) using supervised fine-tuning (SFT) techniques.

However, due to constraints in data volume, annotation costs, and the inherent difficulty of precise labeling, the annotated sub-scene intervals often contain natural errors or ambiguities. These inaccuracies can lead to unstable training or even misguided learning when using conventional SFT methods. As discussed in (Shao et al., 2024; Liu et al., 2025), SFT faces several limitations: its effectiveness notably diminishes in out-of-domain settings despite strong in-domain performance, it inherently causes catastrophic forgetting of general capabilities, and the absence of an explicit reasoning process limits its efficacy in complex scenarios. Recent research shows that pure reinforcement learning (RL) (Guo et al., 2025) fosters emergent reasoning during testing, underscoring the power of reward-driven optimization in boosting model reasoning. This method also tends to improve generalization, avoiding overfitting to specific datasets.

[*]The first two authors contribute equally to this work. We acknowledge Shaogang Tang for collaborating on data resources and application scenarios to validate and improve algorithm performance.

User

Based on the given advertising violation labels and rules (omitted here), does this advertisement video contain any violations? If violations exist, please output the specific violation types and the corresponding time intervals of the sub-scenarios where violations occur, in the json format: {"violation type1": [(start_frame, end_frame),…], …}

Assistant

<think>
1. Identity the image elements:
  - A medicinal product named "XXX Pain Relief Patch."
  - A woman wearing a white top and blue pants.
  - Text displayed on the video: "…"
  - A depiction of a lump on the back of the woman's neck gradually disappearing.
  - …
2. Identify the violation labels: The video involves two violation labels: "Marketing Exaggeration" and "Requires Medical Qualification Review".
3. Evaluate "Marketing Exaggeration":
  - Check for exaggerated claims or misleading information in the content.
  - Observe if the video makes unrealistic promises or overstates the product's effectiveness.
  ...
  - Conclusion: The content in frames 13 to 88 contains exaggerated claims about the product's capabilities, violating the "Marketing Exaggeration" label.
4. Evaluate "Requires Medical Qualification Review":
  - Determine if the video involves medical or health-related content.
  - Verify if the product or service advertised requires medical qualifications or certifications.
  ...
  - Conclusion: The video promotes a health-related product without displaying the necessary medical qualifications, violating the "Requires Medical Qualification Review" label.
5. Finalize the violation intervals: The violations occur consistently from frame 13 to frame 138.
</think>

<answer>
[{"Marketing Exaggeration": [(13,88)], "Requires Medical Qualification Review": [(13,138)]}]
</answer>

Figure 1: The example of RAVEN reasoning.

Building on these insights, we introduce RAVEN, a novel framework aimed at advancing reasoning and cognitive skills for detecting violation scenes in videos. The name RAVEN, symbolizing "keen insight", reflects our aspiration for the system to detect violations with the sharpness of a raven. RAVEN is a structured reasoning MLLM that combines curriculum learning with hierarchical, multi-granular reinforcement. It employs GRPO (Group Relative Policy Optimization) (Shao et al., 2024; Guo et al., 2025) and structured thinking, eliminating the need for explicitly annotated reasoning process data. Instead, it leverages the self-evolution potential of MLLMs to develop reasoning capabilities from scratch. A significant advantage of RAVEN is its ability to robustly train on large-scale, noisy, coarsely annotated industrial data, achieving superior violation detection performance while preserving the strong generalization capabilities of MLLMs. To achieve this, we develop hierarchical sophisticated rewards mechanism comprising multiple types of rewards: format rewards, which enforce constraints on the structure of the reasoning process and violation sub-scene outputs, and accuracy rewards, which include primary rewards (e.g., IoU Reward), auxiliary rewards (e.g., Boundary Alignment Reward), and regularization rewards (e.g., Category Consistency Reward). As illustrated in Figure 1, RAVEN exhibits emergent test-time reasoning abilities, enabling it to handle complex instructions by breaking them down into sequential analytical steps, thus achieving precise localization of violation intervals. RAVEN demonstrates exceptional performance on both in-domain and out-of-domain data, significantly outperforming models trained via SFT.

To validate RAVEN, we conduct extensive experiments from both offline and online testing perspectives, using both publicly available datasets and proprietary industrial data. The results show that the RAVEN-7B model exhibits strong test-time reasoning capabilities and achieves superior generalization performance compared to models of the same scale. Our contributions are threefold: (1) We propose RAVEN, the novel architecture specifically designed for localizing violation scenes in advertisement content. Through its innovative design, RAVEN exhibits emergent reasoning abilities. (2) RAVEN is a practical system tailored for real-world industrial applications. It demonstrates remarkable robustness when trained on large-scale, noisy, coarsely annotated data, while retaining strong generalization capabilities. (3) Extensive experiments on both offline and online testing, using public datasets and proprietary industrial data, demonstrate that the RAVEN-7B model achieves superior reasoning and generalization performance compared to models of the same scale.

2 Related Work

2.1 Temporal Grounding in Videos

Temporal grounding aims to localize specific events or actions within a video. Prior work has focused on supervised learning with precise annotations (Gao et al., 2017). However, these methods struggle with noisy, coarsely annotated data, which is prevalent in industrial settings. Recent approaches like VSLNet (Zhang et al., 2020a) and 2D-TAN (Zhang et al., 2020b) have improved localization accuracy but lack robust reasoning capabilities for complex tasks like violation detection.

2.2 Multimodal Large Language Models

Multimodal Large Language Models (MLLMs) (Yin et al., 2023; Xu et al., 2024a; Maity et al., 2024), such as CLIP (Radford et al., 2021), Flamingo (Alayrac et al., 2022), and BLIP (Li et al.,

2022), have demonstrated remarkable capabilities in understanding and reasoning across modalities on various tasks (Wei et al., 2022a,b; Kojima et al., 2022; Ji et al., 2024b, 2023, 2024a, 2022, 2025; Liu et al., 2024; Zhu et al., 2024b). These models excel in tasks like image-text retrieval and video captioning but are often limited by their reliance on supervised fine-tuning (SFT), which can lead to catastrophic forgetting and poor generalization. Recent efforts like LLaVA (Liu et al., 2023; Xu et al., 2024b), Qwen (Bai et al., 2023a,b) and Video-ChatGPT (Maaz et al., 2024) have explored integrating reasoning into MLLMs, but they remain underutilized in temporal grounding tasks.

2.3 Reinforcement Learning for Video Understanding

Reinforcement learning (RL) (Guo et al., 2025; Kaelbling et al., 1996; Christiano et al., 2017; Zhu et al., 2024a; Rafailov et al., 2024; Song et al., 2024; Liu et al.) has been applied to video understanding tasks, such as action segmentation and event detection. Methods like SM-RL (Wang et al., 2019a,b) and RLPP (Li et al., 2018) use RL to optimize temporal localization but are limited by their inability to handle multimodal inputs or perform complex reasoning. Curriculum reinforcement learning (Narvekar et al., 2020; Bengio et al., 2009) has shown promise in improving RL's robustness and generalization, but its application to temporal grounding remains unexplored.

2.4 Advertisement Video Violation Detection

Existing methods for advertisement video violation detection rely heavily on rule-based systems or supervised learning with precise annotations. These approaches are effective in controlled environments but fail to generalize to large-scale, noisy industrial datasets. Recent works (Wang et al., 2024b; Lu et al., 2024) have explored using MLLMs for content moderation, but these methods lack the temporal grounding and reasoning capabilities required for precise violation detection. Our work bridges these gaps by introducing RAVEN, a curriculum reinforcement learning framework that integrates MLLMs with sophisticated reward mechanisms and structured reasoning for robust and precise advertisement video violation detection. By leveraging both precisely and coarsely annotated data, RAVEN addresses the limitations of existing methods and sets a new benchmark for temporal grounding in industrial applications.

3 Methodology

3.1 Problem Overview

Given an input video V, a predefined list of violation labels T, and a prompt P, the Advertisement Video Violation Temporal Grounding task aims to output: (1) The violation labels associated with the video. (2) The temporal intervals of the sub-scenes corresponding to each violation label. Note that a single video may contain multiple violation labels, and each label may correspond to multiple sub-scenes. This requires the model to perform reasoning to accurately identify the most relevant frame fragments. Inspired by recent advancements in the reasoning capabilities of large models, we leverage this ability to develop a pipeline for reasoning-based violative sub-scene temporal grounding.

We first employ reinforcement learning (RL) on a Multimodal Large Language Model (MLLM) to activate its reasoning ability, enabling it to generate a reasoning process and predict all violation categories $\mathcal{C} = \{c_1, c_2, \ldots, c_n\}$ and their corresponding accurate sub-scene locations $\mathcal{X}_c = (t_c^l, t_c^r)$ for each category c. Here, t_c^l and t_c^r denote the start and end times of the sub-scene, respectively.

However, the manually annotated results $\mathcal{Y}_c = (y_c^l, y_c^r)$ often deviate from the ground truth $\mathcal{Z}_c = (z_c^l, z_c^r)$ due to annotation errors or ambiguities. To prevent supervised fine-tuning (SFT) from forcing the model to fit $\mathcal{Y}_c$, which could lead to significant deviations from $\mathcal{Z}_c$, we instead use RL for training. Additionally, to enhance the accuracy of the reasoning process, we follow DeepSeek (Dai et al., 2024) and employ explicit structured thinking tags '<think>' for chained reasoning.

3.2 Data Construction

In real-world scenarios, for each advertisement video V, when a violation is found, we annotate the precise violation category c and the corresponding temporal sub-interval $\mathcal{Y}_c = (y_c^l, y_c^r)$ where the violation occurs. However, due to limitations in annotation resources, cost constraints, and inherent ambiguity in many videos, we can only maintain relatively accurate violation categories, while the annotated temporal intervals $\mathcal{Y}_c$ often exhibit some degree of deviation from the ground truth $\mathcal{Z}_c = (z_c^l, z_c^r)$. To address this, we organize the data based on a curriculum learning approach. Specifically, we select a subset of data with precisely annotated temporal intervals for the early stages of curriculum learning, while the remaining

coarsely annotated data is used in the later stages. Additionally, it is important to note that for the reasoning training of RAVEN, we do NOT need to generate any offline reasoning data, meaning that RAVEN's reasoning does not require a cold-start training process.

3.3 RAVEN Model

We use Qwen2.5-VL (Bai et al., 2023b) as the reasoning model F_{reason} in RAVEN. Although Qwen2.5-VL demonstrates some temporal grounding capabilities on public video understanding datasets, it struggles with accurate localization in real-world industrial applications. A straightforward approach would be to use precisely annotated temporal grounding data for SFT. However, acquiring large-scale, precisely annotated data is challenging and costly, especially for frame-level localization, which requires significant effort from annotators.

Instead, we opt for coarse-grained annotations, which are faster and more cost-effective to produce. During the reinforcement learning stage, format rewards are employed to ensure the model generates structured outputs. This process can be formulated as:

$$\mathcal{C}, \mathcal{X} = F_{\text{reason}}(V, T, P), \tag{1}$$

where $\mathcal{C}$ represents the predicted violation categories, and $\mathcal{X}$ denotes the corresponding temporal intervals.

Reasoning is a critical component in temporal grounding tasks. Inspired by DeepSeek-R1-Zero (Dai et al., 2024), we intentionally avoid using any explicit Chain-of-Thought (CoT) (Wei et al., 2022a) data to teach RAVEN reasoning skills. Instead, we aim to activate its reasoning capabilities from scratch, enabling the model to autonomously generate a logical CoT before producing the final answer. To achieve this, we design a structured user prompt and hierarchical sophisticated rewards that guides the reasoning model to follow specific instructions. As shown in Figure 1, the user prompt instructs RAVEN to analyze and compare objects in the video, beginning by generating a reasoning process within '<think>' tags, followed by the final answer in a predefined format enclosed in '<answer>' tags.

3.4 Reward Functions Design

Reward functions play a pivotal role in RL, as they determine the optimization direction of the model. We manually design the following reward functions for RL:

3.4.1 Thinking Format Reward

The reward mechanism is designed to facilitate a structured cognitive process within the model (Shao et al., 2024; Guo et al., 2025). Specifically, it directs the model to articulate its reasoning steps within the designated <think> and </think> tags, while the final output is to be presented between the <answer> and </answer> tags.

3.4.2 Grounding Format Reward

Our framework incorporates two levels of temporal grounding format rewards: soft and strict (Shao et al., 2024; Guo et al., 2025). The soft approach validates the format if temporal coordinates are included in the answer, regardless of their organization. The strict approach, however, mandates that the model follows the predefined structure exactly, utilizing specific keywords like "temporal start" and "temporal end" to achieve correctness.

3.4.3 Temporal IoU Reward

As the primary reward, the Temporal IoU Reward evaluates the overlap between the predicted subscene intervals $\mathcal{X}_c$ and the annotated intervals $\mathcal{Y}_c$. To maintain robustness against annotation noise, we binarize the IoU value using a threshold:

$$R_{\text{IoU}} = \begin{cases} 1 & \text{if IoU}(\mathcal{X}_c, \mathcal{Y}_c) > 0.5, \\ 0 & \text{otherwise.} \end{cases} \tag{2}$$

3.4.4 Temporal Boundary Alignment Reward

Building on the IoU Reward, the Temporal Boundary Alignment Reward encourages the predicted interval boundaries (t_c^l, t_c^r) to align closely with the annotated boundaries (y_c^l, y_c^r). This reward is continuous and serves as an auxiliary reward with a smaller weight:

$$R_{\text{Boundary}} = \exp\left(-\sigma^2 \left[(t_c^l - y_c^l)^2 + (t_c^r - y_c^r)^2\right]\right), \tag{3}$$

where σ is a scaling factor.

3.4.5 Violation Category Consistency Reward

The Violation Category Consistency Reward ensures the predicted violation category c_p matches the annotated category c_g. This reward is binary:

$$R_{\text{Category}} = \begin{cases} 1 & \text{if } c_p = c_g, \\ 0 & \text{otherwise.} \end{cases} \tag{4}$$

where c_p and c_g indicates the prediction and groundtruth respectively.

3.5 Curriculum Reasoning with Hierarchical Rewards

RAVEN does not require a cold-start reasoning training process. We initiate training directly from the pre-trained Qwen2.5-VL model, utilizing the aforementioned rewards and applying the GRPO (Shao et al., 2024) algorithm in the subsequent curriculum reinforcement training process.

We utilize the Curriculum GRPO with hierarchical rewards, which leverages a combination of precisely annotated and coarsely annotated data, progressively refining the model's ability to predict both the temporal intervals and the associated violation categories. The training process is divided into three stages, each designed to optimize specific aspects of the model's performance.

3.5.1 Stage 1: Training on Precisely Annotated Data

In the initial stage, the model is trained on a subset of data where the temporal intervals $\mathcal{Y}_c = (y_c^l, y_c^r)$ are precisely annotated. The reward function for this stage is designed to ensure the model learns the overall position of the interval while also improving boundary precision and category consistency. The total reward R_{Total} is defined as:

$$R_{\text{Total}} = R_{\text{IoU}} + \alpha_1 \cdot R_{\text{Boundary}} + R_{\text{Category}}, \quad (5)$$

where R_{IoU} measures the overlap between the predicted interval $\mathcal{X}_c$ and the annotated interval $\mathcal{Y}_c$, binarized to ensure robustness against annotation noise. R_{Boundary} encourages precise alignment of the predicted boundaries (t_c^l, t_c^r) with the annotated boundaries (y_c^l, y_c^r). R_{Category} ensures the predicted violation category c_p matches the annotated category c_g. α_1 is the reward weight. This stage focuses on establishing a strong foundation for interval prediction by prioritizing overall position (via R_{IoU}) while gradually refining boundary precision (via R_{Boundary}) and ensuring category consistency (via R_{Category}).

3.5.2 Stage 2: Training on the Large-Scale Coarsely Annotated Data

In the second stage, the model is trained on data where the temporal intervals are coarsely annotated. Here, the reward function is simplified to focus on overall position and boundary alignment, as the imprecise nature of the annotations makes category consistency less reliable. The total reward R_{Total} is defined as:

$$R_{\text{Total}} = R_{\text{IoU}} + \alpha_2 \cdot R_{\text{Boundary}}. \quad (6)$$

where α_2 is the reward weight. By retaining R_{IoU} and R_{Boundary}, the model learns to predict approximately correct intervals even with noisy annotations, while still improving boundary precision.

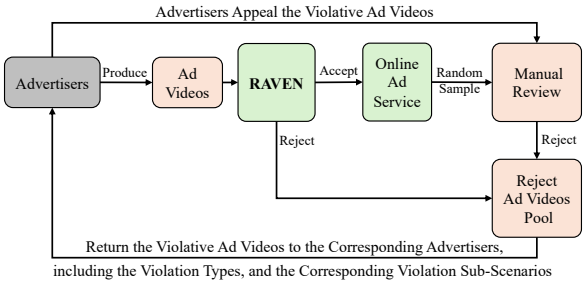

Figure 2: The deployment of RAVEN.

3.5.3 Stage 3: Fine-Tuning on Full Dataset

In the final stage, the model is fine-tuned on the full dataset, combining both precisely and coarsely annotated data. The reward function is adjusted to balance overall position, boundary precision, and category consistency:

$$R_{\text{Total}} = \alpha_3 \cdot R_{\text{IoU}} + \alpha_4 \cdot R_{\text{Boundary}} + \alpha_5 \cdot R_{\text{Category}}, \quad (7)$$

where α_3, α_4, and α_5 are the reward weights. This stage ensures the model achieves a robust balance between interval prediction and category identification, leveraging the strengths of both precise and coarse annotations.

4 Deployment

We design a pipeline to deploy the RAVEN on the online Ad services in Figure 2, which include 3 parts: (1) RAVEN Review: It is the core of the entire pipeline, handling the primary review functions. (2) Advertisers Appeal: It provides a channel for advertisers to appeal is they believe their ad is not violative. (3) Manual Review: It is primarily applied in two scenarios. (a) Random Sampling Review: For Ads already published on the platform, random samples are reviewed to identify potential violations. This helps to: (i) address cases missed by the review model, and (ii) quickly detect new types of violations, providing decision-making references for subsequent model optimization. (b)

Appeal Review: For cases that are appealed by advertisers, manual review provides the final decision. (3) Model Iteration: Based on the continuously increasing volume and variety of online violation data, including (a) new types of violations, (b) more violation data, (c) difficult negative samples misidentified by the model, and (d) difficult positive samples missed by the model, we continuously iterate and optimize the RAVEN.

5 Experiments and Results

To comprehensively evaluate the performance of RAVEN, we conduct extensive experiments from both offline testing and online testing perspectives, utilizing both public dataset and practical industrial dataset.

5.1 Datasets

To validate RAVEN’s performance in real-world industrial scenarios, we construct a dataset comprising approximately 38,000 training videos, which include both precisely annotated and coarsely annotated data, and 5,000 precisely annotated test videos. The use of a precisely annotated test set ensures reliability in evaluation. The annotations cover six major violation categories (“Discomforting Content", “Marketing Exaggeration", “Requiring Credential Review", “Vulgar Content", “Prohibited Goods/Services", and “Normal") and the corresponding temporal intervals. The definitions of these major categories are inspired by both existing works (Wang et al., 2024b,a; Lu et al., 2023) and the actual platform management rules. These major classes are further divided into multiple subcategories, forming a hierarchical and structured labeling system. In all experiments, we primarily focus on the major class labels to evaluate the model’s performance and robustness in high-level violation classification tasks.

MultiHateClip (Wang et al., 2024a) is a publicly available dataset for hateful and offensive content detection on platforms like YouTube and Bilibili, featuring annotations for “hateful", “offensive", and “normal" content. Due to the unavailability of some videos, we conduct experiments on a downloadable subset of Bilibili, and manually annotate the temporal intervals.

5.2 Offline Testing

We compare RAVEN against several baseline models, including LLaVA-v1.5 (Liu et al., 2023), Qwen2-VL-7B (Bai et al., 2023b), and Qwen2.5-VL-7B (Bai et al., 2023b), as well as their fine-tuned versions (SFT). The results in Table 1 and Table 2 demonstrate that RAVEN significantly outperforms both the base pretrained models and the SFT models in “violation category accuracy" and “temporal grounding precision". Specifically, RAVEN

Model	Average	
	Cate.(P/R)	Gro.
Qwen2.5-VL-7B-SFT	0.805/0.774	0.456
RAVEN(w/o Structured Thinking)	0.810/0.779	0.537
RAVEN	0.826/0.788	0.555

Table 4: Study on the Structured Thinking.

achieves superior accuracy in sub-scene interval localization, highlighting the effectiveness of its curriculum reinforcement learning approach in enhancing the robustness of MLLMs.

5.3 Online A/B Testing

We conduct day-long online A/B testing on a practical business platform, allocating 20% of the overall traffic for evaluation. RAVEN is compared against a small legacy model and Qwen2.5-VL-7B-SFT. The results in Table 3 show that RAVEN significantly improves violative video identification, achieving both higher precision and recall in category detection compared to the legacy model. Additionally, RAVEN outperforms the Qwen2.5-VL-7B-SFT model by 8.5% in temporal interval localization accuracy.

5.4 Study on Generalization Capabilities

As discussed in Section 1, SFT often leads to catastrophic forgetting of general capabilities, while RL enhances the generalization of MLLMs. To validate this claim, we conduct experiments on the Industrial dataset. Specifically, we train RAVEN on three in-domain categories (Discomforting Content, Marketing Exaggeration, Requiring Credential Review) and test it on the remaining two out-of-domain categories (Vulgar Content, Prohibited Goods/Services). The results in Table 5 demonstrate that RAVEN, trained with RL, achieves higher accuracy and better generalization compared to the Qwen2.5-VL SFT model.

5.5 Study on Structured Thinking

We further investigate the impact of reasoning training of structured thinking in RAVEN. Table 4 shows that both w/o and w/ structured thinking outperform the SFT baseline, indicating that RL effectively boosts the model's capabilities. However, RAVEN with structured thinking demonstrates even better performance, highlighting the importance of the reasoning process in handling complex video samples.

Method	In-Domain (Average Gro.)	Out-of-Domain (Average Gro.)
Qwen2.5-VL-7B-SFT	0.433	0.246
RAVEN	0.546	0.408

Table 6: Study on Reward Functions and Curriculum Reinforcement Learning.

5.6 Study on Reward Functions

To validate the effectiveness of our reward function design, we conduct ablation studies on the format reward and temporal boundary alignment reward the on the Industrial dataset. The results in Table 6 demonstrate the effectiveness of the two reward functions.

5.7 Study on Curriculum Reinforcement Learning

To evaluate the effectiveness of the curriculum reinforcement learning strategy in RAVEN, we also conduct an ablation study on the Industrial dataset. As shown in Table 6, when remove the progressive curriculum learning, the results shown in a significant drop in performance, with temporal interval localization (mIoU) dropping by 4.7%, highlighting the importance of leveraging multi-stage training for robust learning.

6 Conclusion

RAVEN is a novel framework for advertisement video violation detection, integrating curriculum reinforcement learning with multimodal large language models (MLLMs) to address challenges in temporal grounding and noisy annotations. Its progressive training strategy and hierarchical reward mechanism ensure precise localization and consistent category prediction. Experiments and online A/B testing demonstrate superior performance in accuracy, precision, and recall, while mitigating catastrophic forgetting. RAVEN establishes a promising methodological approach for practical violation detection, offering significant potential for advancing the field and addressing real-world challenges.

7 Ethical Statement

Our research adheres to ethical principles and prioritizes user rights. The dataset samples are for scientific analysis only and do not reflect the authors' views. All resources are intended for scientific research purposes only, contributing to the development of more secure and reliable digital platforms.

Abstract

Enhancing computational efficiency and reducing deployment costs for large language models (LLMs) have become critical challenges in various resource-constrained scenarios. In this work, we present *DistilQwen2.5*, a family of distilled, lightweight LLMs derived from the public *Qwen2.5* models. These distilled models exhibit enhanced instruction-following capabilities compared to the original models based on a series of distillation techniques that incorporate knowledge from much larger LLMs. In our industrial practice, we first leverage powerful proprietary LLMs with varying capacities as multi-agent teachers to select, rewrite, and refine instruction-response pairs that are more suitable for student LLMs to learn. After standard fine-tuning, we further leverage a computationally efficient model fusion approach that enables student models to progressively integrate fine-grained hidden knowledge from their teachers. Experimental evaluations demonstrate that the distilled models possess significantly stronger capabilities than their original checkpoints. Additionally, we present use cases to illustrate the applications of our framework in real-world scenarios. To facilitate practical use, we have released all the *DistilQwen2.5* models to the open-source community. [1]

1 Introduction

Large language models (LLMs) have emerged as a transformative technology in NLP, powering a wide array of applications from machine translation to conversational agents (Zhao et al., 2023). However, the rise of LLMs has been accompanied by several challenges, notably the substantial computational resource requirements and high deployment costs. Reducing the parameter sizes of LLMs while maintaining or even improving performance has become a critical area of research.

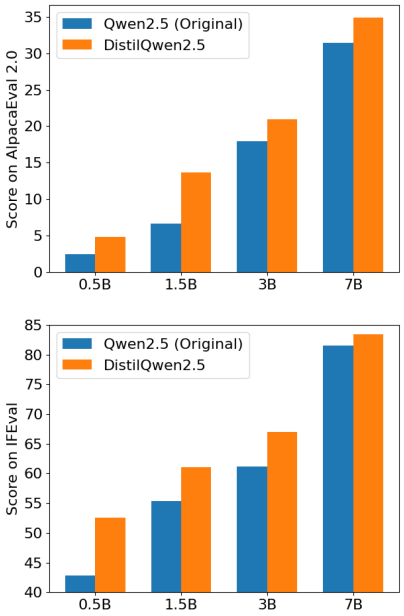

Figure 1: Brief comparison between original *Qwen2.5* and *DistilQwen2.5* models in terms of AlpacaEval 2.0 (length-controlled) and IFEval scores.

Knowledge distillation (KD) is a promising approach to addressing these challenges by transferring knowledge from a larger model (the teacher) to a smaller model (the student) (Xu et al., 2024). Previous works have primarily focused on specific KD techniques to develop more robust student models (Hsieh et al., 2023; Gu et al., 2024; Yue et al., 2024b; Zhang et al., 2024). However, there is a lack of studies investigating good industrial practices that create a series of distilled lightweight LLMs with varying sizes and capacities.

In this paper, we introduce *DistilQwen2.5*, a series of distilled LLMs derived from the *Qwen2.5*

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 32–42

models[2]. In the beginning of the KD process, proprietary teacher LLMs, serving as multiple agents, are utilized to select, rewrite, and refine instruction-response pairs, tailoring them to be more conducive to learning by smaller student models. In particular, a Chain-of-Thought (CoT) (Wei et al., 2022) rewriting approach is employed to significantly enhance the reasoning abilities of the distilled models. Beyond standard fine-tuning, we further introduce a model fusion approach to enable student models to incrementally integrate fine-grained hidden knowledge from their teacher models in a computationally efficient manner. This approach enhances the depth of understanding in student models beyond what black-box distillation processes can achieve.

In our experiments, we demonstrate that the resulting *DistilQwen2.5* models show remarkable improvements in instruction-following performance across various NLP tasks compared to their original counterparts. Briefly, we present the AlpacaEval 2.0 (length-controlled) (Dubois et al., 2024) and IFEval (Zhou et al., 2023) scores of the *DistilQwen2.5* models in Figure 1. To enhance the public accessibility of our work, all models have been made available to the open-source community. Furthermore, we describe two use cases to demonstrate the applications of our work in real-world scenarios.

2 Related Work and Discussion

Knowledge distillation (KD), originally proposed by Hinton et al. (2015), has emerged as a key technique for improving the efficiency of neural networks. Prior to the era of LLMs, several studies successfully demonstrated the distillation of BERT-based models (Sanh et al., 2019; Jiao et al., 2020; Sun et al., 2020; Pan et al., 2021; Hou et al., 2023), primarily focusing on specific NLP tasks. However, distillation for LLMs presents unique challenges due to the intricate dependencies among prediction tokens. In the literature, f-Distill (Wen et al., 2023) minimizes a generalized f-divergence function for sequence-level KD. MiniLLM (Gu et al., 2024) introduces a reverse Kullback-Leibler divergence (KLD) objective to distill knowledge from white-box LLMs to student models. Wu et al. (2025) propose an adaptive approach that allocates weights to combine forward and reverse KLD objectives. FuseLLM (Wan et al., 2024) merges multiple powerful LLMs into a more capable student model.

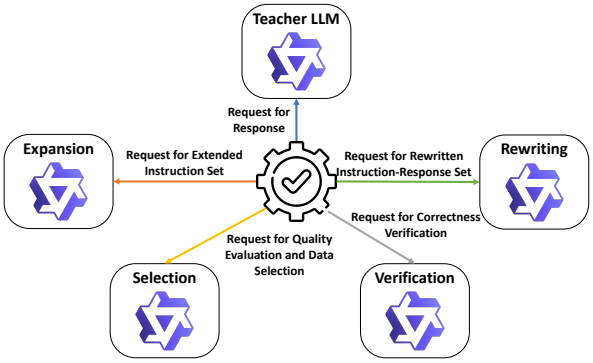

Figure 2: Functionalities for LLMs/agents used in data augmentation and black-box distillation. **Disclaimer:** We use the Qwen logo in the figure; however, any LLMs with sufficient capabilities can be used as well.

Given that many powerful LLMs are accessible only through APIs, KD from proprietary LLMs to smaller open-source models (referred to as black-box KD) has garnered significant attention (Hsieh et al., 2023). To facilitate distillation from more advanced LLMs, some researchers leverage these models for data augmentation to fine-tune student LLMs (Yue et al., 2024a). Li et al. (2024) utilize the data selection capabilities of student LLMs to refine instruction-tuning data. Lou et al. (2024) generate multi-faceted instructions for diverse tasks to enhance black-box KD. Additionally, Yue et al. (2024b) propose a task-aware curriculum planning framework to improve instruction refinement.

In contrast to prior work, our approach emphasizes industrial practices that leverage the strengths of both black-box and white-box KD methods. Moreover, efficiency remains a critical barrier in industry, particularly for white-box KD. To address this, our work incorporates an efficient algorithm to integrate hidden knowledge from teacher models.

3 Our Approach

In this section, we describe the industrial practices for distilling the *DistilQwen2.5* models.

3.1 Multi-Agent Data Augmentation as Black-Box Knowledge Distillation

We first leverage multi-agent data augmentation as black-box KD, where proprietary teacher models serve as the sources of knowledge. This approach is more computationally efficient than white-box KD and allows us to select more powerful proprietary models as teachers. In our work, we employ

[2] https://qwenlm.github.io/blog/qwen2.5/

Qwen-max[3] to process the Chinese texts due to its strong capabilities in handling the Chinese language, and GPT-4/GPT-4o for other languages. In Figure 2, we can see that a controller coordinates the entire pipeline of generating responses directly from the teacher model and invoking LLM agents to augment the training data. The functionalities of these LLM agents are described below.

Expansion Agent. The expansion agent is employed to generate a diverse set of instruction variations, ensuring that student models are exposed to a comprehensive range of instructions. Importantly, it preserves the original NLP task category of the input instruction to prevent hallucinations and semantic drift caused by LLMs. For example, given the input "Provide a brief overview of Newton's First Law of Motion", the output could be "Explain the meaning of Kepler's Third Law", but not "Give me a brief introduction to Albert Einstein's life". After instruction expansion, we also call the teacher model to generate responses for new instructions.

Rewriting Agent. The rewriting agent further enhances the quality and diversity of the training data. Unlike the expansion agent, the rewriting agent operates under stringent constraints to preserve the semantic integrity of the tasks expressed in instructions, ensuring that the rewritten content remains faithful to the original intent and task category. For example, the instruction "Provide a summary of the economic impacts of climate change" might be rewritten as "Explain how climate change affects the economy". Regarding the generated responses, we encourage them to be Chain-of-Thought (CoT) outputs for complex tasks such as logical reasoning, mathematical problems, and code generation (Wei et al., 2022), as this significantly enhances the cognitive reasoning abilities of distilled, small models (Hsieh et al., 2023; Yue et al., 2024b).

Selection Agent. The selection agent automatically evaluates and chooses instruction-response pairs that are highly valuable for training the student model. This selection process is guided by various heuristic criteria, including informativeness, helpfulness, and potential for generalization to similar tasks. Additionally, we consider task balance when selecting these pairs, following the approach of Yue et al. (2024b). This guides the controller to filter out less useful data instances.

Verification Agent. Different from the selection agent, the verification agent is invoked each time new instruction-response instances are generated by LLMs to check the factual correctness. Specifically, we leverage the underlying LLMs to check whether the instructions are reasonable and whether the responses correctly solve the tasks expressed by the instructions.

Overall, the augmented dataset leverages a black-box KD method by encapsulating the distilled knowledge from larger models into training examples for student models. The distillation training process follows a supervised learning paradigm, utilizing the augmented instruction-response pairs.

3.2 Efficient Model Fusion as White-Box Knowledge Distillation

In contrast to black-box KD, white-box KD involves having the student model mimic the distribution of the teacher model's logits, providing richer knowledge compared to learning from only the token with the highest output probability. In our work, we conduct white-box KD after the completion of black-box KD to maximize the utility of computational resources and aim to further improve the performance of student models by learning richer knowledge. We assume that the student model, with learnable parameters θ, has a probability function p_S^θ that is differentiable with respect to θ. The token-level logits difference between p_T (from the teacher model) and p_S^θ (from the student model) is defined as follows:

$$D_\theta(x, y) = \frac{1}{L} \sum_{n=1}^{L} D_\theta \left(p_T(\cdot \mid y_{<n}, x) \parallel p_S^\theta(\cdot \mid y_{<n}, x) \right), \tag{1}$$

where x and y denote the input and output sequences, respectively, and L is the sequence length. The function $D_\theta(\cdot)$ can be any divergence measurement, such as KLD (Gu et al., 2024), reverse KLD (Wu et al., 2025), etc. The KD loss aims to minimize the divergence between the token sequences of the student and the teacher:

$$L(\theta) = \mathbb{E}_{(x,y)\sim(X,Y)} \left[D_\theta(x, y) \right]. \tag{2}$$

For industrial-scale implementation, it is infeasible to leverage existing white-box KD approaches such as those by Gu et al. (2024) and Wu et al. (2025). The reasons are twofold: i) If the forward pass of the teacher model is performed simultaneously with the training of the student model, the GPU memory consumption becomes excessively high, especially when the teacher model is very

Table 1: Performance comparison between the original *Qwen2.5* model and the *DistilQwen2.5* models in terms of instruction-following abilities across four parameter sizes: 0.5B, 1.5B, 3B, and 7B. Note: * indicates a variant of our model utilizing black-box KD over processed datasets.

large (e.g., 32B/72B). ii) The vocabulary of the teacher and student models may not match, leading to a mismatch of the logits tensors of both models.

In our work, we observe that the sum of the probabilities of the top-10 tokens is almost equal to 1. This indicates that nearly all the knowledge of the teacher model is contained within the top-10 tokens. Therefore, we build a scalable white-box KD system that supports the following features: i) A *token alignment* operation (Wan et al., 2024) is first conducted if the logits tensors of both models do not match. ii) A distributed computing process is executed offline to generate the teacher model's logits with top-K probabilities, where $K = 10$ is set as default and adjustable for customized scenarios. iii) A variant of $D_\theta(\cdot)$ is implemented where only the top-K elements are calculated for divergence minimization. Let

$$\mathbf{z}_T = [z_T^{(1)}, z_T^{(2)}, \cdots, z_T^{(K)}] \tag{3}$$

$$\mathbf{z}_S = [z_S^{(1)}, z_S^{(2)}, \cdots, z_S^{(K)}] \tag{4}$$

be the top-K logits from the teacher model, and the corresponding logits from the student model with matched indices in the vocabulary. The probabilities for computing $D_\theta(\cdot)$ is then calculated as follows:

$$\mathbf{p}_T = \frac{\exp(\mathbf{z}_T/\mathcal{T})}{\sum_{k=1}^{K}\exp(z_T^{(k)}/\mathcal{T})} \tag{5}$$

$$\mathbf{p}_S = \frac{\exp(\mathbf{z}_S/\mathcal{T})}{\sum_{k=1}^{K}\exp(z_S^{(k)}/\mathcal{T})} \tag{6}$$

where $\mathcal{T}$ is the temperature hyperparameter. This approach not only reduces computation time but also improves the speed of storing and reading the logits, alleviating the storage pressure of our cloud computing system.

4 Experimental Evaluation

In this section, we present experimental setups and evaluation results of the *DistilQwen2.5* models. Due to the space limitations, case studies are further presented in the appendix.

4.1 Experimental Setup

The initial dataset consists of instruction-response pairs collected from several popular public datasets, including OpenHermes 2.5[4], the Cleaned Alpaca Dataset[5], and LCCD (Wang et al., 2020), together with our in-house datasets. The pre-processing steps follow the method presented in (Yue et al., 2024a). Subsequently, the instruction-response pairs are carefully expanded, rewritten, verified and selected. To create a series of smaller student LLMs, we utilize the *Qwen2.5* series as our backbone models, including their instruct versions with varying sizes: 0.5B, 1.5B, 3B, and 7B. The white-box teacher models are selected from `Qwen2.5-14B/32B/72B-Instruct`. For student model distillation, the default learning rate and the epochs are set to 1×10^{-5} and 3, respectively. We train all the models on a server equipped with eight A800 GPUs, each with 80GB memory.

4.2 Evaluation Benchmarks

AlpacaEval 2.0 (length-controlled) (Dubois et al., 2024) assesses the instruction-following capabilities of LLMs across various domains. MT-Bench (Bai et al., 2024) is utilized to evaluate the multitasking abilities of our models. This bench-

[4] https://huggingface.co/datasets/teknium/OpenHermes-2.5

[5] https://github.com/gururise/AlpacaDataCleaned

mark challenges models with diverse tasks that require an understanding of multiple domains and the ability to quickly adapt to changing instructions, under both single-turn and multi-turn conversation settings. IFEval (Zhou et al., 2023) assesses how models perform during dynamic user interactions. For rigorous comparison, we report the results in both instruct-loose and strict-prompt settings.

4.3 Main Experimental Results

The results of our experiments are summarized in Table 1. As illustrated, the *DistilQwen2.5* models demonstrate superior performance across all benchmarks, outperforming both the baseline and original models by significant margins. Moreover, the proposed model fusion technique enhances the models' capabilities after the black-box KD process. We further observe that the improvement is more pronounced for smaller student backbones. Specifically, the improvement of `DistilQwen2.5-0.5B-Instruct` compared to `Qwen2.5-0.5B-Instruct` is larger than that of `DistilQwen2.5-7B-Instruct` compared to `Qwen2.5-7B-Instruct`. This shows that the potential of smaller students is larger in terms using KD. Overall, the experimental results empirically validate our distillation framework, demonstrating its effectiveness in enhancing the task-solving performance of lightweight LLMs.

4.4 Analysis on White-Box KD

Inference Speed of Teacher Logits Generation. In our experiments, we measure the latency associated with generating logits across different sizes of teacher models, as shown in Figure 3. Our implementation achieves a significantly accelerated inference speed, obtaining a $3\times$ to $5\times$ speedup compared to the vanilla implementation. Additionally, the reduction in logits does not lead to any noticeable decrease in the instruction-following abilities of the distilled smaller models, as revealed by our exploratory experiments.

Sum of Probabilities of Top-K Tokens. We further adjust the value of K and compute the sum of probabilities of the top-K tokens, with the results shown in Figure 4. It can be observed that when $K \geq 10$, the sum of probabilities exceeds 0.97, which provides sufficient knowledge for the student model to learn. Therefore, we recommend setting $K = 10$ as the default value.

Analyzing the Parameter Sizes of Teacher LLMs. We conduct the first set of experiments following the completion of black-box KD. The results, presented in Figure 7, demonstrate a trend of diminishing returns as teacher sizes increase (from 14B to 72B), indicating that larger teacher models offer limited improvements to the student model. This finding suggests that teacher models should not be excessively large to minimize computational costs. The second set of experiments is conducted on model checkpoints without black-box KD, with results shown in Figure 5. We observe that as the dataset size increases, the improvement also gradually diminishes, indicating a diminishing return on additional data. However, notable improvements are observed with larger teacher models when the dataset comprises between 10K to 100K samples, suggesting that it can be more beneficial within the specific range.

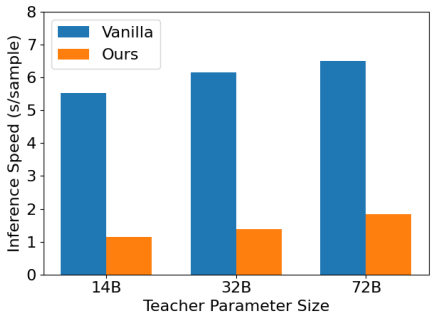

Figure 3: Comparison of the inference speed for logits generation between our approach and the vanilla approach (average seconds per sample).

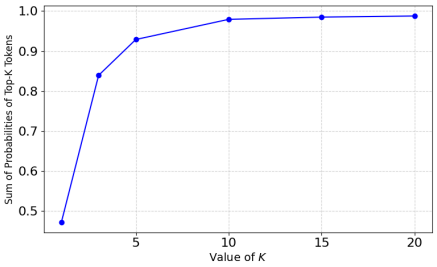

Figure 4: Sum of probabilities of top-K tokens.

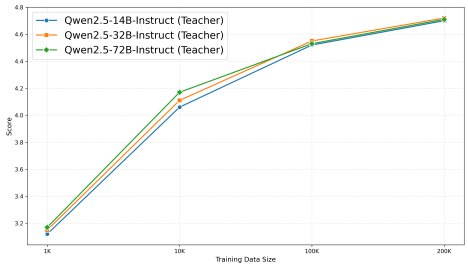
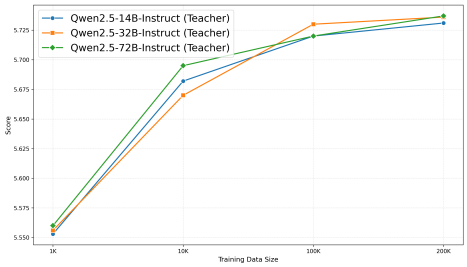
4.5 Fine-grained Model Capacity Analysis

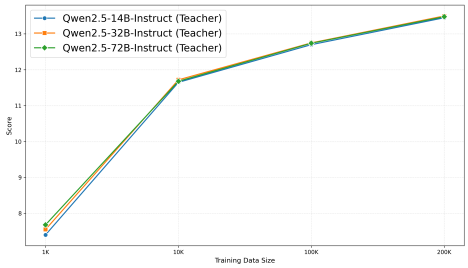
In this section, we provide a detailed capacity analysis of the *DistilQwen2.5* models, leveraging the MT-bench benchmark (Bai et al., 2024) to quantify their performance across a diverse array of NLP tasks. Due to space limitations, we show the results for two smallest models, with other models exhibiting similar trends. These results are detailed in Table 2. Our analysis not only showcases the broad



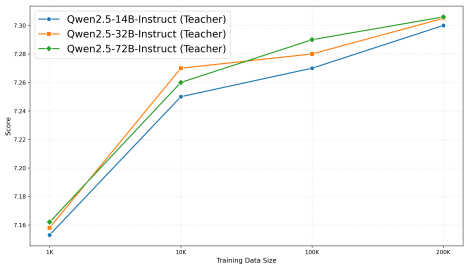
(a) Student size: 0.5B



(b) Student size: 0.5B



(c) Student size: 1.5B



(d) Student size: 1.5B

applicability of our *DistilQwen2.5* models but also proves their enhanced capabilities and performance improvements over the original models.

4.6 Comparison Against Other Small Models

To compare the performance against other models, we present the ranking in Figure 6. Notably, the *DistilQwen2.5* series demonstrates remarkable cost-effectiveness, achieving performance that closely rivals models with parameter sizes either approaching or exceeding double its own.

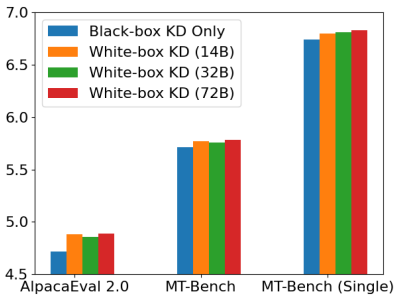
5 Industrial Use Cases

In addition to the *DistilQwen2.5* models presented, we outline two industrial use cases that illustrate the practical utility of our framework and models.

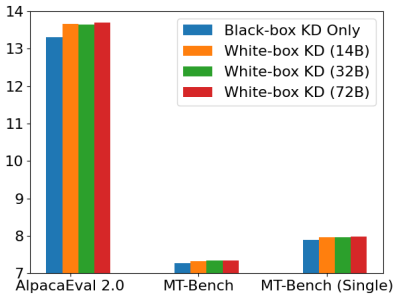
5.1 SQL Completion for Big Data Platform

In addition to instruction following, our framework can also address other tasks, such as code completion, which is also an auto-regressive task for LLMs. Here, we present a real-world application w.r.t. SQL completion. It helps users to formulate complex queries, optimize SQL statements, add conditions, or join tables based on existing queries. This technique significantly improves both the efficiency and accuracy of query composition and is widely utilized in our online big data platforms.

In the context of SQL completion for our big data platform, the primary evaluation metrics are *Latency*, *Pass@1* and *Adoption Rate*. *Latency* measures the system's speed in generating real-time suggestions as users input queries, whereas *Pass@1* and *Adoption Rate* reflect the utility and accuracy of the model's output based on automatic evaluation and human feedback. A key challenge is the trade-off between model scale and the performance metrics: although larger models can achieve higher adoption rates, they often result in increased infer-



(a) Student size: 0.5B



(b) Student size: 1.5B

Figure 7: Comparison between black-box KD and white-box KD with varying teacher model sizes after black-box KD, in terms of AlpacaEval 2.0 (length-controlled) and MT-Bench scores (both full and single).

ence time, which adversely affects latency. Therefore, the central optimization challenge for SQL completion in big data platforms lies in enhancing completion efficacy while maintaining a relatively compact model size.

During the initial deployment phase, we utilize the fine-tuned `Qwen2.5-7B` model for deployment, which is quantized to `int4` precision. By applying KD on a fixed dataset (i.e., an in-house SQL corpus), we obtain a `Qwen2.5-3B` model. This model achieves a significant improvement, closely matching the performance of the 7B model, while increasing the inference speed by 1.4×. The online performance of these models is shown in Table 3, where *Adoption Rate* is obtained through online A/B testing on the big data platform. Hence, our KD technique effectively balances performance and computational efficiency.

5.2 KD Functionalities on AI Platform

It should be acknowledged that our *DistilQwen2.5* models are primarily designed for general domains. For domain-specific applications, further enhancement is necessary (as in the SQL completion case). To enable business users or LLM developers to distill their own models, we have integrated the continual KD feature together with the *DistilQwen2.5* models into a cloud-native AI platform.

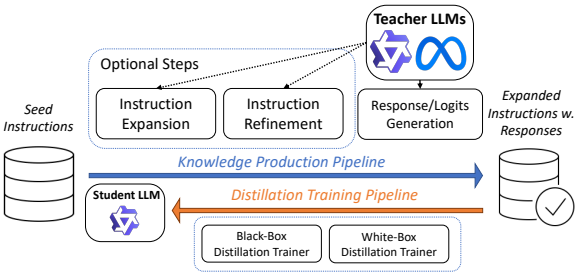


Figure 8: Illustration of continual KD pipelines on the AI platform for business users or LLM developers.

Model Size	Latency (ms)	Pass@1	Adoption Rate (%)
7B (teacher)	384	18.8	26.5
3B (student)	148	17.9	25.5

Table 3: Performance evaluation for SQL completion.

To facilitate seamless model optimization and customization, our AI platform provides robust KD functionalities, as shown in Fig. 8. It allows users to iteratively refine and tailor the *DistilQwen2.5* models to specific domains. Key pipelines include: (1) the Knowledge Production Pipeline (KPP) and (2) the Distillation Training Pipeline (DTP). In KPP, optimal steps of instruction expansion and refinement can be applied to user-provided seed instructions from arbitrary domains. The teacher LLMs are then leveraged to generate responses or output logits according to user settings. In DTP, users can define custom training settings for either black-box or white-box distillation trainers, leveraging cloud resources for scalable distillation training. After that, the student model can be utilized for evaluation and deployment.

6 Conclusion and Future Work

In this paper, we introduce *DistilQwen2.5*, a family of distilled lightweight LLMs derived from the *Qwen2.5* models. By leveraging both black-box and white-box KD techniques and efficient implementations and multiple agents, we demonstrate substantial improvements in model performance and real-world applications. For future work, we plan to investigate more diverse domain-specific applications to extend the practical impact of our framework. We also aspire to enhance the collaborative aspects of model fusion to allow for more dynamic knowledge transfer.

Limitations

While the *DistilQwen2.5* models demonstrate significant enhancements, several limitations remain that warrant further investigation. The distillation process hinges on the quality of the teacher models. Biases or errors inherent in the teacher models could propagate into the student models, potentially affecting their performance and fairness in specific contexts. Additionally, while we showcase domain-specific applications, the generalizability of our framework across diverse domains and languages remains to be thoroughly evaluated, which is beyond the scope of this work. Addressing these limitations will contribute to more robust LLMs tailored to a wider array of applications.

Ethical Considerations

Distillation techniques make it feasible to deploy LLMs in resource-constrained environments, they also introduce the potential for bias and misinformation inherited from the teacher models. Additionally, the open-sourcing of *DistilQwen2.5* models facilitates accessibility, but also raises concerns regarding misuse. Responsible use of the models requires establishing guidelines to prevent applications that may cause harm, violate privacy, or amplify malicious behavior.

A Case Studies

In the following, we present several cases on the output comparison between original *Qwen2.5* and *DistilQwen2.5* models. In default, we leverage the 7B models for comparison.

Question	Problem: If the system of equations: 6x-4y=a, 6y-9x=b. has a solution (x, y) where x and y are both nonzero, find $\frac{a}{b}$, assuming b is nonzero. Solution:
Ground Truth	-$\frac{2}{3}$
Qwen2.5	To find the value of a/b, we start by solving the system of equations for x and y in terms of a and b. Given the system of equations 6x - 4y = a 6y - 9x = b, First we can simplify these equations, Equation 1 can be written as 3x - 2y = a/2 Equation 2 can be written as -3x + 6y = b, Next we add equations 3 and 4 to eliminate x, (3x - 2y) + (-3x + 6y) = a/2 + b which simplifies to 4y = a/2 + b. Solving for y, we get y = (a + 2b)/8. Next we subtract equation 4 from equation 3 to eliminate y, (3x - 2y) - (-3x + 6y) = a/2 - b, which simplifies to 6x - 8y = a/2 - b Substituting the value of y from equation 5 into this equation, we get 6x - 8((a + 2b)/8) = a/2 - b which simplifies to 6x - (a + 2b) = a/2 - b or 6x = a + 2b + a/2 - b, which further simplifies to 6x = (2a + 4b + a - 2b)/2 = (3a + 2b)/2. Solving for x we get x = (3a + 2b)/12 = (a + (2b)/3)/4, Now we need to find the ratio a/b From equation 5. We have y = (a + 2b)/8 From equation 6 we have x = (3a + 2b)/12 We substitute these expressions into the original equations. Using equation 1 6x - 4y = a we substitute x = (3a + 2b)/12 and y = (a + 2b)/8 6((3a + 2b)/12) - 4((a + 2b)/8) = a, which simplifies to (6(3a + 2b))/12 - (4(a + 2b))/8 = a or (3a + 2b)/2 - (a + 2b)/2 = a, which further simplifies to (3a + 2b - a - 2b)/2 = a or (2a)/2 = a, which is true This confirms our expressions are correct. From the simplified equations we derive the ratio a/b = 2. Thus the value of a/b is 2.
DistilQwen2.5	To solve the given system of equations and find $\frac{a}{b}$, we start with the equations: 6x - 4y = a, 6y - 9x = b. First, we express x and y in terms of a and b. We can rewrite the equations as: 6x - 4y = a, -9x + 6y = b. To eliminate one of the variables, we can multiply the first equation by 3 and the second equation by 2: 18x - 12y = 3a, -18x + 12y = 2b. Now, we add these two equations together: (18x - 12y) + (-18x + 12y) = 3a + 2b. This simplifies to: 0 = 3a + 2b. From this, we can solve for $\frac{a}{b}$ = -$\frac{2}{3}$

Table 4: Output comparison between original *Qwen2.5* and *DistilQwen2.5* models.

Question	What breed dog is smallest?
Qwen2.5	The smallest breed of dog is generally considered to be the Chihuahua. However, there are other very small breeds that are often mentioned, such as the Yorkipoo (a mix between a Yorkshire Terrier and a Poodle), Morkie (a mix between a Maltese and a Yorkshire Terrier), and Puggle (a mix between a Pug and a Beagle). But in terms of pure breeds, the Chihuahua is the smallest. Chihuahuas typically weigh between 2 and 6 pounds (0.9 to 2.7 kg) and stand about 6 to 9 inches (15 to 23 cm) tall at the shoulder.
DistilQwen2.5	The Chihuahua is generally recognized as the smallest dog breed in the world.

Table 5: Output comparison between original *Qwen2.5* and *DistilQwen2.5* models.

Question	Write a product description for a new line of dog toys, called the squeaker. It's made of latex, and is designed for dogs of all ages and species. It's also available in a variety of colors and shapes. The response must contain at least 3 placeholders represented by square brackets, such as [address], [name], and [phone number].
Qwen2.5	Introducing the [address] Pet Supply's newest addition to our toy line: the Squeaker! Designed with love and play in mind, our Squeakers are crafted from high-quality, durable latex that stands up to even the most enthusiastic chewers. Whether your [name] is a playful puppy or a seasoned senior, our Squeakers are perfect for dogs of all ages and species, providing endless hours of fun and stimulation. Available in a vibrant array of colors and shapes, our Squeakers are not just toys; they're companions for playtime. From the classic [shape1] to the whimsical [shape2], each design is carefully chosen to engage your [name]'s curiosity and keep them entertained. The unique squeaker mechanism ensures that every play session is filled with excitement and joy. Order your [name]'s new favorite toy today by visiting our website or giving us a call at [phone number]. We're here to help you find the perfect Squeaker to keep your [name] happy and healthy. Happy playing!
DistilQwen2.5	Introducing The Squeaker – the ultimate playtime companion for your furry friend! Crafted from durable, high-quality latex, The Squeaker is designed to provide endless entertainment for dogs of all ages and breeds. Available in a vibrant array of colors and fun shapes, this toy is perfect for keeping your pet engaged and happy. Each Squeaker features a built-in squeak mechanism that will capture your dog's attention and stimulate their natural instincts to play and explore. Whether your dog loves to chew, fetch, or simply cuddle with their toys, The Squeaker is sure to become their new favorite. Order yours today and watch your dog's tail wag with joy! For more information, visit our website at [website], or contact our customer service team at [phone number]. Don't miss out on the fun – make playtime special with The Squeaker![PetJoy] – Bringing joy to pets and their owners.

SimUSER: Simulating User Behavior with Large Language Models for Recommender System Evaluation

Nicolas Bougie[1], **Narimasa Watanabe**[1]
{nicolas.bougie,narimasa.watanabe}@woven.toyota

[1]Woven by Toyota

Abstract

Recommender systems play a central role in numerous real-life applications, yet evaluating their performance remains a significant challenge due to the gap between offline metrics and online behaviors. Given the scarcity and limits (e.g., privacy issues) of real user data, we introduce SimUSER, an agent framework that serves as believable and cost-effective human proxies. SimUSER first identifies self-consistent personas from historical data, enriching user profiles with unique backgrounds and personalities. Then, central to this evaluation are users equipped with persona, memory, perception, and brain modules, engaging in interactions with the recommender system. SimUSER exhibits closer alignment with genuine humans than prior work, both at micro and macro levels. Additionally, we conduct insightful experiments to explore the effects of thumbnails on click rates, the exposure effect, and the impact of reviews on user engagement. Finally, we refine recommender system parameters based on offline A/B test results, resulting in improved user engagement in the real world.

1 Introduction

Recommender systems (RS) have become an indispensable component of our day-to-day lives from e-commerce to social media by offering personalized user experience and improving satisfaction (Li et al., 2024). Despite their widespread adoption, a key challenge hindering the advancement of the field is evaluation (Yoon et al., 2024). The difficulty arises from the discrepancy between offline metrics (non-interactive), which are typically used during development, and real-life user behaviors, which these systems encounter post-deployment (Zhang et al., 2019). This results in models that perform well in controlled environments but fail to meet expectations in practical use cases. Such a limitation is further exacerbated by the inherent shortcomings of offline evaluation, notably the inability to measure business values such as user engagement and satisfaction (Jannach and Jugovac, 2019). On the other hand, online A/B testing is costly to scale up, labor-intensive, and encompasses ethical considerations, underscoring the imperative need for reliable and affordable (interactive) evaluation methods.

Recent breakthroughs in Large Language Models (LLMs) have shown promise in human behavior modeling by enabling the creation of autonomous agents. In the realm of recommendation systems, RecMind (Wang et al., 2023b) explores the concept of autonomous recommender agents equipped with self-inspiring planning and external tool utilization. Recently, InteRecAgent (Huang et al., 2023) has extended this idea by proposing memory components, dynamic demonstration-augmented task planning, and reflection. Recently, RecAgent (Wang et al., 2023a) has attempted to introduce more diverse user behaviors, taking into account external social relationships. Another work, Agent4Rec (Hou et al., 2024), delves into generating faithful user-RS interactions via agent-based simulations, where agents are equipped with a memory module. However, a common characteristic of existing studies is their *insulated nature* — they primarily rely on knowledge embedded within the model's weights, neglecting the potential benefits of integrating external knowledge and user-item relationships. Furthermore, prior approaches often disregard user personas and fail to incorporate visual signals, despite their role in shaping user experience and emotion.

To enable synthetic users, we describe an agent architecture built upon LLMs. Our methodology consists of two phases: (1) self-consistent persona matching and (2) recommender system evaluation. In Phase 1, we leverage the semantic awareness of LLMs to extract and identify consistent personas from historical data, encompassing unique backgrounds, personalities, and characteristics. In Phase 2, we impersonate these personas to simu-

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 43–60

late believable human interactions. This involves a retrieval-augmented framework where the agent interacts with the recommender system based on its persona, memory, perception, and brain modules. The memory module comprises an episodic memory and a knowledge-graph memory. Unlike existing studies that solely rely on text, our perception module incorporates visual cues into the agent's reasoning process. Finally, the brain module is responsible for translating retrieved evidences and graph paths into action plans such as `[click]`, or `[exit]`. Following action selection, the user engages in self-reflection to synthesize memories into higher-level inferences and draw conclusions.

2 Related Work

Conversational RS initially tackled the recommendation problem using bandit models, emphasizing the quick update of traditional systems through item selection and binary feedback from synthetic users (Christakopoulou et al., 2016). Taking this further, (Zhao et al., 2023) created a simulation platform where users not only chat about recommendations. Recent techniques have added more natural language flexibility, but user responses are usually limited to binary or multiple-choice formats (Lei et al., 2020). In spite of this, these simulations often rely on fixed rules and scripted dialogues, lacking the variability seen in human interactions. To address the above-mentioned limitations, generative simulators using LLMs have been developed, offering more realistic and nuanced conversational abilities (Zhang et al., 2024b; Zhao et al., 2023). A few studies have also explored the application of LLMs as recommender systems (Hou et al., 2024; Li et al., 2023; Kang et al., 2023). These investigations explore LLMs as recommendation engines, rather than as entities that perceive recommendations, thus providing a perspective complementary to our research (Wang et al., 2024; Zhang et al., 2024a). RecMind (Wang et al., 2023b) proposes self-inspiring agents for recommendation. However, their simulated users are limited to basic actions like rating items, lacking the ability to engage in more complex interactions. Notably, a recent approach (Yoon et al., 2024) examines the effectiveness of LLMs as generative users, specifically for conversational recommendation scenarios. A closely related work to ours is Agent4Rec (Zhang et al., 2023) that delves into the generative capabilities of LLMs for modeling user interactions. SimUSER differs significantly from these studies as we utilize detailed personas that are systematically inferred from historical and incorporate a perception module to integrate visual reasoning. Furthermore, SimUSER investigates the potential of graph-based retrieval to represent the rationales underlying user-item interactions. Finally, we introduce multi-round preference elicitation and causal action refinement that leverage retrieved evidences and paths to generate more realistic interactions.

3 Methodology

Simulated **USER**s provides a framework for systematically assessing recommender systems by engaging in interactions and providing feedback. Phase 1 matches historical data with a set of personas to enable nuanced and realistic interactions. Phase 2 utilizes the identified personas, historical data, and novel reasoning mechanisms to generate synthetic users with human-like behavior.

Problem Formulation. Given a user $u \in \mathcal{U}$ and an item $i \in \mathcal{I}$, the aggregated rating of the item is denoted by $R_i = \frac{1}{\sum_{u \in \mathcal{U}} y_{ui}} \sum_{u \in \mathcal{U}} y_{ui} \cdot r_{ui}$ where $y_{ui} = 0$ indicates that the user u has not rated the item i and inversely $y_{ui} = 1$ indicates that the user has rated the item with $r_{ui} \in \{1, 2, 3, 4, 5\}$. We also introduce $g_i \in G$ as the genre/category of the item. In this study, we seek to discover y_{ui} and r_{ui} for an unseen recommended item i.

3.1 Persona Matching via Consistency Check

This phase involves assessing the most plausible *persona* based on historical data. A persona p encompasses a set of features that characterize the user: **age**, **personality**, and **occupation**. Personality traits are defined by the Big Five personality facets: *Openness*, *Conscientiousness*, *Extraversion*, *Agreeableness*, and *Neuroticism*, each measured on a scale from 1 to 3. Given the difficulty of obtaining such granular features in real-world settings, our methodology seeks to systematically infer personas from the user's interaction history.

Persona Extraction. For a user u with interactions $\{(i_0, r_{ui_0}), \ldots, (i_n, r_{ui_n})\}$, we query the LLM to produce a short summary s_u of the user's preferences. To do so, we randomly select 50 items from the user's viewing history. Items rated 4 or above are categorized as *liked*, while those rated below 3 are deemed *disliked*. We then combine s_u with historical data to prompt the LLM to generate a persona that matches the interaction history for this

user. To enhance the diversity, the LLM is provided a list of possible ages, personalities, and occupations. For each user, a set of m ($m = 5$) candidate personas is generated, denoted as $\mathcal{P}$.

Self-Consistent Persona Evaluation. We then assess the consistency of the candidate personas $\mathcal{P}$ to identify the most plausible one. A self-consistency scoring mechanism measures the alignment of candidate personas with historical data. We define a scoring function $s(p, u)$ for each candidate persona $p \in \mathcal{P}$, where p is evaluated against two distinct sets of user-item interactions. For the targeted user u, we sample j subsets of ϱ interactions from its history. These are compared with ϱ sampled interactions from other users $\bar{u}$, denoted as $I_{\bar{u}}$:

$$s(p, u) = \sum_{\iota \sim I_u} \hat{r}(\iota, p) - \sum_{\bar{\iota} \in I_{\bar{u}}} \hat{r}(\bar{\iota}, p) \qquad (1)$$

where $\hat{r}(\iota, p)$ and $\hat{r}(\bar{\iota}, p)$ are obtained by querying the LLM to rate the two interaction subsets ι and $\bar{\iota}$. Ideally, the LLM agent should assign a higher $\hat{r}(\iota, p)$ for interactions from the targeted user and a lower $\hat{r}(\bar{\iota}, p)$ for samples from other users. The candidate persona p with the highest score s is assigned to the user.

3.2 Engaging in Interactions with RS

In Phase 2, given a user u and discovered persona p, we present a cognitive architecture built upon LLMs comprising four modules: **persona**, **perception**, **memory**, and **action**.

3.2.1 Persona Module

To lay a reliable foundation for the generative agent's subsequent interactions and evaluations, benchmark datasets are used for initialization of the persona module. An agent's profile includes the matched persona p along with attributes extracted from its historical data: $p \cup \{$**pickiness**, **habits**, **unique tastes**$\}$. Since LLMs are biased towards positive sentiment, unless prompted to behave as picky users (Yoon et al., 2024), each agent is assigned a *pickiness* level sampled in {*not picky*, *moderately picky*, *extremely picky*} based on the user's average rating. Habits account for user tendencies in engagement, conformity, and variety (Zhang et al., 2023), while unique tastes are derived from the viewing history summary s_u generated in Phase 1.

3.2.2 Perception Module

A primary factor in decision-making is visual stimuli due to their significant influence on curiosity and emotion (Liu et al., 2024). For instance, when scrolling through a movie recommendation platform, human decisions are heavily driven by the thumbnails of items, which can trigger emotional responses and provide quick visual summaries of the content (Koh and Cui, 2022). To graft these visual elements in an cost-efficient manner, we augment action prompts (see Sec A.1) with image-derived captions. The caption $i_{caption}$ of an item i is generated by querying GPT-4o to extract insights that capture emotional tones, visual details, and unique selling points from the item's thumbnail.

3.2.3 Memory Module

It is critical for an agent to maintain a memory of the knowledge and experience it has of the world and others. SimUSER uses an episodic memory for interaction history and knowledge-graph memory to capture user-item relationships.

Episodic Memory stores the interactions with the RS. The memory is initially populated with the user's viewing and rating history. Each time SimUSER executes a new action or rate an item, the corresponding interaction is added to the episodic memory. Drawing from human psychological processes (Atkinson and Shiffrin, 1968), we use a self-ask retrieval strategy where the LLM generates follow-up questions regarding the query. These questions, along with the initial query, then serve as separate queries for vector similarity search, allowing retrieval of more diverse evidences. For a query q, we retrieve top-k_1 documents using cosine similarity: $s(q, d) = \cos(\mathbf{E}(q), \mathbf{E}(d))$, where $\mathbf{E}$ is an embedding function.

Knowledge-Graph Memory User behaviors in RS are influenced by both internal factors (personality) and external factors (Zhao et al., 2014). External factors include the influence of others and prior beliefs about items. SimUSER employs a knowledge graph (KG) memory to emulate external influences by retrieving evidences with similar relationships and characteristics.

Memory Initialization The KG memory is initially populated using real-world datasets. It is structured as a graph $\mathcal{G}$, defined as: $\mathcal{G} = \{(h, r, t) | h, t \in \mathcal{V}, r \in \mathcal{E}\}$, in which each triple *(h,r,t)* indicates that a relation r exists from head entity h to tail entity t. $\mathcal{V}$ is a set of entities and $\mathcal{E}$ represents relationships between them. For instance, nodes $\mathcal{V}$ may represent entities (e.g., *user*, *item*), while edges $\mathcal{E}$ depict the relation-

ships between these entities (e.g., *liked*). The memory grows with each interaction i_t, capturing the evolving nature of user preferences: $\mathcal{G}_{t+1} = \mathcal{G}_t \cup \{(v_i, e_{ij}, v_j) | (v_i, e_{ij}, v_j) \in \mathcal{V} \times \mathcal{E} \times \mathcal{V}\}$.

Graph-Aware Dynamic Item Retrieval For a user u, the retrieval function takes a query item x as input and returns a set of similar items along with their metadata (e.g., *ratings*). We extend PathSim (Sun et al., 2011) to capture both user-item and item-item relationships through path-based similarity. A relationship path $p_{x \rightsquigarrow y}$ represents a composite relationship between entities x and y in the form of $x \xrightarrow{\mathcal{E}_1} z \xrightarrow{\mathcal{E}_2} \ldots \xrightarrow{\mathcal{E}_l} y$, where $\mathcal{E}_1$ denotes the edge between entity x and z. For example, in the MovieLens network, the co-actor relation can be described using the length-2 relationship path $x \xrightarrow{acts-in} z \xrightarrow{actor} y$. In order to retrieve relevant items based on the query x, SimUSER estimates the item-item similarity as:

$$s_{x,y} = \frac{2 \times \left|\{p_{x \rightsquigarrow y} : p_{x \rightsquigarrow y} \in \mathcal{P}\}\right|}{\left|p_{x \rightsquigarrow x} : p_{x \rightsquigarrow x} \in \mathcal{P}\right| + \left|p_{y \rightsquigarrow y} : p_{y \rightsquigarrow y} \in \mathcal{P}\right|} \quad (2)$$

where $\mathcal{P}$ is the set of paths between query item x and candidate item y, and $p_{x \rightsquigarrow y}$ is a path instance. The score $s_{x,y}$ is determined by two factors: (1) the connectivity level, which is the count of paths that connect x and y through $\mathcal{P}$; and (2) the balance of visibility, defined by the number of times these paths are traversed between the two entities. In addition to item-item similarity $s_{x,y}$, we compute user-item similarity $s_{u,y}$ for the target user u and the candidate item y, using the same path-based approach, which is further summed up to $s_{x,y} = \alpha \cdot s_{x,y} + (1 - \alpha) \cdot s_{u,y}$, making retrieval sensitive to both past interactions of the user u and communities in the graph.

3.3 Brain Module

We endow each agent with a decision-making module that derives subsequent actions. To replicate human-like sequential reasoning, we employ Chain-of-Thought prompting across five key steps.

Multi-round Preference Elicitation: Agents browse items page by page, deciding whether to `[WATCH]` or `[SKIP]` based on their preferences and history. To mitigate the inherent positive bias in LLMs, SimUSER incorporates a pickiness modifier (`You are {pickiness} about {item_type}`). When available, we enrich item descriptions with thumbnail captions for multimodal reasoning. A *multi-round* strategy first forms an initial decision $\delta^{(0)}$ based on persona p, pickiness ρ, and retrieved evidences E_{k_1} and G_{k_2} from episodic and KG memory. Then, it identifies contradictions between its choice and persona. If conflicts arise or supporting evidence is insufficient, the agent refines its decision: $\delta^{(t)} = \text{LLM}(P_{\text{watch}}, \delta^{(t-1)}, p, E_{k_1}, G_{k_2})$. To improve decision-making, we expand retrieved documents each round ($k_1 \leftarrow k_1 + \Delta_k$ and $k_2 \leftarrow k_2 + \Delta_k$) until reaching a final decision $\delta^{(\text{final})}$.

Item Evaluation After selecting items of interest, agents express both explicit ratings (1-5) and subjective feelings about watched items, which update their memory and influence future cognition. Unlike existing approaches (Zhang et al., 2023) that neglect rating rationales, Instead, SimUSER leverages the paths of retrieved evidences i from the KG memory, $u \xrightarrow{\mathcal{E}_1} z \xrightarrow{\mathcal{E}_2} \ldots \xrightarrow{\mathcal{E}_l} i$, They are formatted as plain text and provided as input to the LLM, which generates ratings while explaining how persona, evidences and paths compare to the shortlisted items and influence their rating.

Action Selection: Based item evaluation and interaction history, agents decide whether to `[EXIT]` the system, navigate to `[NEXT]`/`[PREVIOUS]` pages, or `[CLICK]` on items for details. This decision involves estimating its satisfaction with previous recommendations, fatigue level, and emotional state. Upon exiting, a satisfaction interview captures opinions about presented recommendations.

Causal Action Refinement: To address suboptimal decision-making (e.g., premature exits), we introduce a *causal reasoning* step where agents generate questions ($Q = LLM(a_{\text{tent}}, H, p, P_{\text{causal}})$) to validate tentative actions. For each counterfactual scenario (e.g., *"What would happen if you exited now?"*), the agent estimates outcomes and adjusts its final action based on cause-effect consistency.

Post-interaction Reflection: Post-interaction reflection lets agents learn from interactions and improve future alignment with their persona. After collecting interaction data, the agent first determines what to reflect on, then extracts insights and cites the particular records that served as evidence for the insights. The post-interaction reflections are fed back into the episodic memory.

4 Experiments

Settings. All agents are powered by the GPT-4o-mini version of ChatGPT, except when specified differently, with the number of agents set to 1,000.

Baselines We compare SimUSER against RecA-

gent and Agent4Rec, which represent the closest comparable methods. When possible, we report the results of RecMind, an agent-based RS. Some experiments involve two versions of SimUSER: SimUSER(zero) and SimUSER(sim), where SimUSER(sim) agents first interact with the RS — grounding interactions and filling their memories, before answering the tasks.

4.1 Believably of Synthetic Users

In order to appropriately respond to recommendations, synthetic users must possess a clear understanding of their own preferences. Thereby, we query the agents to classify items based on whether their human counterparts have interacted with them or not. We randomly assigned 20 items to each of 1,000 agents, with varying ratios (1:m where $m \in \{1, 3, 9\}$) of items users had interacted with to non-interacted items ($y_{ui} = 0$). We treat this as a binary classification task, taking values between 0 and 1. Table 1 shows SimUSER agents accurately identified items aligned with their tastes, significantly outperforming RecAgent and Agent4Rec across all distractor levels (paired t-tests, 95% confidence, $p < 0.002$).

4.2 Rating Items

A key task when interacting with a RS is rating items. We compare several LLM-based baselines, along with traditional recommendation baselines: MF (Koren et al., 2009) and AFM (Xiao et al., 2017). Across all tasks (Table 2), SimUSER considerably outperforms other LLM-powered agents, mainly due to its KG memory that encapsulates priors about items and their relationships with user interactions. Agent4Rec shows higher RMSE due to hallucinations with niche items not embedded in its LLM weights. Notably, incorporating a few steps of simulation always decreases the MAE of the model (SimUSER(sim)). This is because the grounded interactions augment the context during the multi-round assessment, demonstrating that agents can refine their own preferences for unrated items through interactions with the simulator.

4.3 Recommender System Evaluation

Understanding the efficacy of various recommendation algorithms is crucial for enhancing user satisfaction. By simulating human proxies, we can better predict how users will engage with recommender systems, providing valuable interactive metrics. We compare various recommendation strategies, including most popular (Pop), matrix factorization (MF) (Koren et al., 2009), LightGCN (He et al., 2020), and MultVAE (Liang et al., 2018), using the MovieLens dataset. Upon exiting, agents rated their satisfaction on a scale from 1 to 10. Ratings above 3 were considered indicative of a *like*. Metrics include average viewing ratio ($\overline{P}_{\text{view}}$),

	MovieLens	AmazonBook	Steam
RecAgent	3.01 ± 0.14	3.14 ± 0.13	2.96 ± 0.17
Agent4Rec	3.04 ± 0.12	3.21 ± 0.14	3.09 ± 0.16
SimUSER(w/o persona)	3.72 ± 0.18*	3.65 ± 0.21*	3.61 ± 0.24*
SimUSER(persona)	**4.41±0.16***	**3.99±0.18***	**4.02±0.23***

Table 4: Human-likeness score evaluated by GPT-4o across recommendation domains. *Significant improvements over best baseline ($p < 0.05$).

average number of likes ($\overline{N}_{\text{like}}$), average ratio of likes ($\overline{P}_{\text{like}}$), average exit page number ($\overline{N}_{\text{exit}}$), and average user satisfaction score ($\overline{S}_{\text{sat}}$). Table 3 demonstrates that agents exhibit higher satisfaction with advanced recommendations versus random and Pop methods, consistent with real-life trends.

4.4 LLM Evaluator

As LLM Evaluators (Chiang and Lee, 2023) achieve comparable performance with human evaluators, we use GPT-4o to assess whether agent interactions appear human or AI-generated using a 5-point Likert scale, with higher scores indicating stronger resemblance to human-like responses. Results in Table 4 show our method significantly outperforms Agent4Rec. The memory and persona modules are among the main factors contributing to the faithfulness of our method. We also noticed that letting the agent estimate its tiredness, feeling and emotion greatly enhances the believability and consistency of its responses. On the other hand, Agent4Rec's tendencies to `[EXIT]` the recommender system early and provide inconsistent ratings for similar items — ranging from low to high, contribute to suspicions of AI involvement.

4.5 SimUSER for Offline A/B Testing

We have access a proprietary dataset of 55 online A/B tests, encompassing hundred of thousands of food item recommendations. Each test evaluates variations in recommendation strategies, with the average number of visited pages as the primary business metric. The results, shown in Fig 1, indicate that SimUSER achieves the highest correlation with ground truth values, significantly outperforming Agent4Rec and RecAgent. Statistical tests were conducted to validate the significance of SimUSER's performance over the baselines, with p-values below 0.05 for all comparisons. SimUSER effectively captures user engagement, offering a cost-effective alternative to online A/B testing.

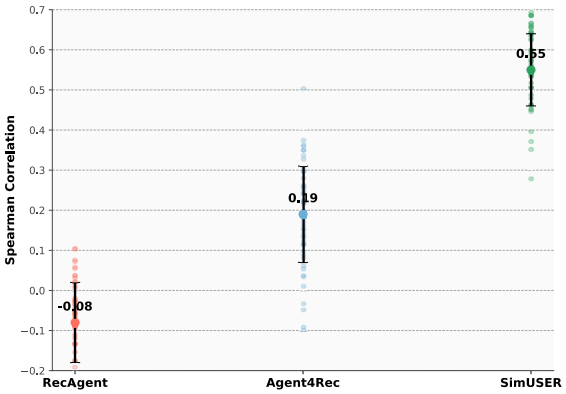

Figure 1: Spearman correlation between estimated and actual engagement metrics. Higher values indicate better alignment with ground truth metrics.

Method	$\overline{P}_{\text{view}}$	$\overline{N}_{\text{like}}$	$\overline{P}_{\text{like}}$	$\overline{N}_{\text{exit}}$	$\overline{S}_{\text{sat}}$
Baseline	0.521	5.44	0.458	3.21	3.82
Traditional (nDCG@10)	0.535	5.52	0.462	3.26	3.86
SimUSER	**0.561**	**5.80**	**0.517**	**3.87**	**4.09**

Table 5: Performance comparison of parameter selection strategies on various engagement metrics.

4.6 Optimizing RS with SimUSER

We examine whether selecting RS parameters based on SimUSER evaluation or traditional offline metrics (nDCG@10 - *TRAD*), translates to improved business metrics in the real world. We employ the same proprietary dataset. The online performance of the baseline system and the two strategies are presented in Table 5. *TRAD* results in performance on par with the original baseline, demonstrating similar findings as in (Jannach and Jugovac, 2019) — offline metrics do not necessarily translate to business metrics. SimUSER achieves higher engagement and satisfaction, with improvements in average viewing ratio and satisfaction.

5 Conclusion

We present a simulation framework for leveraging LLMs as believable user proxies. Our two-phase approach includes persona matching and interactive RS assessment, seeking to align user interactions more closely with real-world user behaviors. We evaluate SimUSER across various recommendation domains, including movies, books, and video games. Results demonstrate closer alignment of our agents with their human counterparts at both micro and macro levels. We further explore the influence of thumbnails on user engagement and the

significance of reviews in user decision-making. Experimental findings highlight the potential of LLM-driven simulations in bridging the gap between offline metrics and business metrics. As a future direction, we seek to complement our current GPT-4o-based assessments of human-likeness with human evaluation, to further validate the realism of agent behavior. In addition, we plan to investigate the extent to which LLM-specific biases may influence simulated decisions and explore mitigation strategies.

6 Ethics Statement

This paper proposes an LLM-empowered agent framework designed to simulate user interactions with recommender systems in a realistic and cost-effective manner. While our approach offers significant benefits in terms of scalability and efficiency, it also raises ethical considerations. The use of such agents could lead to unintended consequences, such as bias amplification, where the synthetic agents might inadvertently reinforce existing stereotypes or present skewed recommendations due to biases in the training data.

Additionally, there is a risk of manipulation of user preferences, as the synthetic agents could be used to subtly influence user behavior by consistently promoting certain types of content without explicit user consent. Furthermore, simulating interactions at a broad scale could result in the identification and exploitation of behavioral patterns that might encourage specific user behaviors, potentially leading to negative societal impacts. Finally, there is a concern that developers or designers might use synthetic users and displace the role of humans and system stakeholders in the design process. We suggest that synthetic uses should not be a substitute for real human input in studies and design processes. Rather, these agents should be leveraged during the initial design phases to explore concepts, especially in situations where recruiting human participants is impractical or where testing certain theories with real people could be challenging or pose risks. By adhering to these principles, we can ensure that the deployment of synthetic users in the wild is ethical and socially responsible.

A Experimental Setup

Experimental Settings. We separate the dataset into training, validation, and test sets (80/10/10%), using a time-based split. This ensures to reflect temporal distribution shift that may be observed in the real-world. Relationships between users and items from the training/validation and test sets were excluded from the knowledge graph memory to prevent data leakage. These datasets are employed for the initialization of each agent — persona and memory modules, as well as self-consistent persona matching. In order to address privacy concerns, the name and gender are omitted. Moreover, for the sake of generality, we do not utilize user-specific information available in these datasets, relying instead on the personas identified in Phase 1 of SimUSER.

In this paper, we report results for SimUSER with simulation **SimUSER(sim)**, and without simulation **SimUSER(zero)**. In SimUSER(zero), the agent's memory module is initialized from the history of its human counterpart. When the review score for an item is greater than 4, the agent stores a memory entry in the form `I liked {item_name} based on my review score of {score}`. For a score of 2 or below, the following format is utilized `I disliked {item_name} based on my review score of {score}`. Neutral scores result in the entry `I felt neutral about {item_name} based on my review score of {score}`. In SimUSER(sim), agents can also interact with the recommender systems (training set) for up to 20 pages or exit the system at any time. The corresponding interactions are used to enhance the memory module. In all the experiments, items rated ≥ 4 are considered as liked by the user, while items ≤ 2 are considered as disliked. These interactions are stored both as plain text in the episodic memory and as relationships in the knowledge graph memory. These simulated interactions with the RS are stored in the episodic memory with the following format: `The recommender system recommended the following {item_type} to me on page {page_number}: {name_all_items}, among them, I selected {watched_items} and rate them {ratings} respectively. I dislike the rest {item_type} items: {dislike_items}`.

In some sets of experiments, we report performance without persona matching SimUSER(w/o persona), and with persona matching SimUSER(persona). In the absence of persona matching, personality traits, age, occupation and taste summary are omitted from the prompts. Matrix factorization (MF) is utilized as the recommender model unless specified otherwise. In our simulator, agents are presented with four items $n = 4$ per page and allowed to interact by viewing and rating items based on their preferences. When the output of the LLM deviated from the desired format, resulting in errors, the LLM was re-prompted with the following instruction: `You have one more chance to provide the correct answer`.

The path-score used during the retrieval of evidences from the KG memory, we further combine this score with user-item similarity ($s_{x,y} = \alpha \cdot s_{x,y} + (1 - \alpha) \cdot s_{u,y}$) and enhance it with semantic similarity using embeddings from OpenAI's *text-embedding-3-small* model. The top-k_2 items, their attributes, and paths are returned to condition the brain module.

As mentioned above, we leverage `GPT-4o-mini` as the LLM backbone in all the experiments unless stated differently. We use $\alpha = 0.8$ to balance item-item similarity with user-item similarity. We set $k_2 = 3$ when retrieving similar items from the knowledge graph-memory, and $k_1 = 5$ for the episodic memory. The titles and ratings of retrieved items from the knowledge graph are concatenated to condition decision-making prompts. Empirically, we set the weight of node embeddings to 0.25 when computing top-k_2 scores. Documents and embedding of text ($\mathbf{E}$) were obtained using `text-embedding-3-small`. Given the average rating $\bar{R}$ of a user: $\bar{R} = \frac{1}{N}\sum_{i=1}^{N} r_{ui}$, the pickiness level $P(\bar{R})$ of a user was determined based on the following thresholds:

$$P(\bar{R}) = \begin{cases} P_1 & \text{if } \bar{R} \geq 4.5 \\ P_2 & \text{if } 3.5 \leq \bar{R} < 4.5 \\ P_3 & \text{if } \bar{R} < 3.5 \end{cases}$$

where P_1 corresponds to *not picky*, P_2 corresponds to *moderately picky*, and P_3 corresponds to *extremely picky*.

The persona attributes are estimated as follows:

- Engagement quantifies the frequency and breadth of a user's interactions with recommended items, distinguishing between users who extensively watch and rate many of items and those who confine themselves to a minimal set. The engagement trait for user u

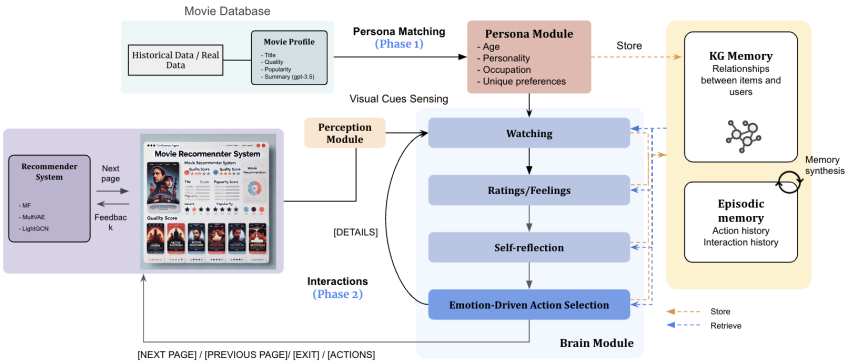

Figure 2: The SimUSER framework for evaluating a movie recommender system.

can be mathematically expressed as: $T^u_{act} = \sum_{i \in \mathcal{I}} y_{ui}$.

- Conformity measures how closely a user's ratings align with average item ratings, drawing a distinction between users with unique perspectives and those whose opinions closely mirror popular sentiments. For user u, the conformity trait is defined as: $T^u_{conf} = \frac{1}{\sum_{i \in \mathcal{I}} y_{ui}} \sum_{i \in \mathcal{I}} y_{ui} \cdot |r_{ui} - R_i|^2$.
- Variety reflects the user's proclivity toward a diverse range of item genres or their inclination toward specific genres. The variety trait for user u is formulated as: $T^u_{div} = |U_{i \in \{y_{ui}=1\}} g_i|$. To encode users' unique tastes in natural language, we utilize the summary s_u obtained in Phase 1, which describes long-term preferences.

To generate captions, for each item i, we first generate an initial caption draft i^* by querying: $i^* = LLM(P_{\text{caption}}, i)$, where P_{caption} is the task prompt. To reduce hallucination, we then decompose i^* into atomic claims $\{a_1, \ldots, a_m\}$, each describing a specific, factual statement (e.g., "The movie is scary"), rather than subjective opinions. Next, each claim a_k is formed into a polar (yes/no) query, and an open-source MLLM (Yao et al., 2024) is queried to generate the confidence of agreement and disagreement as the claim score $s_a = (p_{yes}, p_{no})$, where p_{yes} is the probability of answering with "yes" and p_{no} is the probability of answering with "no". Finally, the original caption is refined in order to obtain a the item's caption $i_{caption} = LLM(i^*, P_{\text{combine}}, (a, s_a), \ldots)$. This minimizes the risk of agents selecting items based on inaccurate captions by ensuring the generated descriptions are fact-based and supported by confidence scores.

In Appendix C.7, we compare the results of SimUSER taking as input: 1) the original movie poster, 2) a random screenshot from the movie trailer on YouTube, 3) the original movie poster distorted with a blue color filter (hue=30, lightness=30, saturation=30). An illustration of the method is provided in Figure 2, detailing the interaction between its components and their roles within the proposed framework.

A.1 Brain Module Details

We now provide a comprehensive explanation of the Brain Module, detailing the implementation and technical details. To replicate human-like sequential reasoning, we employ Chain-of-Thought prompting, repeatedly performing the five steps.

A.2 Multi-round Preference Elicitation

We employ a *multi-round* preference elicitation strategy to refine the user's choice. First, an initial decision $\delta^{(0)}$ is formed based on the agent's persona p, pickiness level ρ, and retrieved evidences E_{k_1} G_{k_2} from the episodic and KG memory respectively. Along with this decision, the agent provides a reason for its choice and cites the supporting evidence, if any. Next, the agent checks for contradictions, such as deciding to watch a pure horror film while the persona indicates strong aversion to horror. If a conflict arises or cannot find enough supporting evidences, the agent is prompted to confirm or modify the initial decision, resulting in an updated decision $\delta^{(t)} = LLM(P_{\text{watch}}, \delta^{(t-1)}, p, E_{k_1}, G_{k_2})$, where P_{watch} is the task prompt, and $\mathbf{G}_t$ and $\mathbf{E}_{(t)}$ are retrieved evidences. To assist the agent's decision-making, we *expand* the retrieved documents at each round: $k_1 \leftarrow k_1 + \Delta_k$ and $k_2 \leftarrow k_2 + \Delta_k$, exposing

additional relevant items or past interactions. This continues until a final decision $\delta^{(\text{final})}$ is reached.

A.3 Providing Feelings and Rating Items

Once the user identifies the items of interest $\delta^{(\text{final})} = \{i_1, ...\}$, they express their reactions through both explicit ratings and subjective feelings. Intuitively, a real user may produce much feelings after watching an item, which will be stored in their memory and influence their future cognition and behaviors. Along with the item rating $\in \{1, 2, 3, 4, 5\}$, we query the user's feelings about the watched items and leverage such information to update the memory module. Newly liked and disliked items are fed back into the memory module. Existing approaches (Zhang et al., 2023) neglect the underlying rationale behind user ratings. Instead, SimUSER leverages the paths of each retrieved evidences i from the KG memory, $u \xrightarrow{\mathcal{E}_1} z \xrightarrow{\mathcal{E}_2} \dots \xrightarrow{\mathcal{E}_l} i$. These paths are formatted as plain text and provided as input to the LLM, which generates ratings while explaining how persona, evidences and paths compare to the shortlisted items and influence their rating.

A.4 Emotion-driven Action Selection

The agent decides (a_{tent}) whether to `[EXIT]` the system, go to `[NEXT]` page, return to a `[PREVIOUS]` page, or `[CLICK]` on an item to access more details. If the agent decides to click on an item, the item is displayed with an extended description that replaces the short $\{item\_description\}$, which is then used to determine whether it wishes to engage further with the item. Finally, if `[EXIT]` is selected, a satisfaction interview is conducted to gather granular opinions and ratings on the presented recommendations. To this end, the agent sequentially: 1) estimates its satisfaction level with preceding recommendations, 2) generates its current fatigue level (Zhang et al., 2023), 3) infers its current emotion, such as `EXCITED`, and 4) selects the most suitable action. Satisfaction level, fatigue, and emotion are dynamic elements that the agent employs to adapt its actionable plan with the recommender system.

A.5 Causal Action Refinement

Suboptimal decision-making (e.g., premature exits or misaligned clicks) can arise as the agent struggles to understand the impact of its decision, necessitating iterative adjustments to align with implicit preferences. In light of this, we introduce a *causal* reasoning step which encourages the assistant to actively seek to understand the causal relationships between its decisions and latent user-state dynamics. Assuming the tentative action a_{tent} and context H, the LLM generates causal questions Q to validate the rationale behind a_{tent}, $Q = LLM(a_{\text{tent}}, H, p, P_{\text{causal}})$, where P_{causal} refers to a predetermined prompt. Causal questions may for example be: *Does tiredness reduce the appeal of this action?*, *What would happen if you exited the system now?*. For each counterfactual, the LLM estimates outcomes such as satisfaction, alignment with persona, and fatigue. This includes a scalar s_q and textual verdict v_q reflecting how *cause-effect* relationships support or contradict a_{tent}. Finally, the LLM is queried to adjust the action if the consistency score is low, $a_{\text{final}} = LLM(a_{\text{tent}}, H, p, P_{\text{action}}, \Pi_{q \in Q}\{q, s_q, v_q\})$.

B Pseudo-Code

We present the pseudo-code for SimUSER agent.

Algorithm 1 SimUSER Algorithm

Input: Historical data H_u for user u
Output: Simulated interactions and feedback
Phase 1: Persona Matching
$\mathcal{P} \leftarrow$ Generate persona from H_u
$p \leftarrow$ Identify best persona $\in \mathcal{P}$ using self-consistency score
Phase 2: Simulate Interactions
Initialize memory module from H_u
repeat
    Perceive the page and items ▷ Generate captions
    Retrieve similar items from the KG memory
    Decide what items to watch
    Rate the items and provide feelings
    Decide next action a based on satisfaction, fatigue, and emotion
    Perform post-interaction reflection
    Update memory module
    if a = `[EXIT]` **then**
        break
    else
        Perform action a
until Maximum number of pages reached
Return Simulated interactions, metrics, and feedback

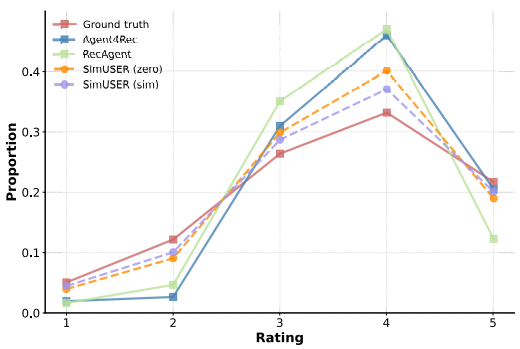

Figure 3: Comparison of rating distributions between ground-truth and human proxies.

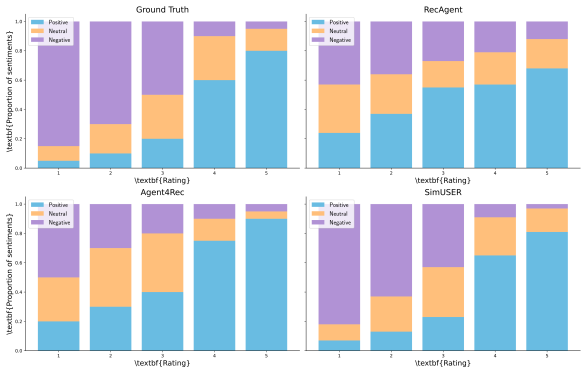

Figure 4: Ratings vs feelings on IMDB dataset. Comparison between human (top left) and LLM-empowered agents.

C Additional Experiments

C.1 Rating Distribution

Beyond individual rating alignment, human proxies must replicate real-world behavior at the macro level. This implies ensuring that the distribution of ratings generated by the agents aligns closely with the distributions observed in the original dataset. Figure 3 presents the rating distribution from the MovieLens-1M dataset and the ratings generated by the agents. These results reveal a high degree of alignment between the simulated and actual rating distributions, with a predominant number of ratings at 4 and a small number of low ratings (1-2). While Agent4Rec assigns fewer 1-2 ratings than real users, our approach, by retrieving past interactions from the episodic memory, allows agents to contextualize their ratings based on a broader and more consistent understanding of their own preferences.

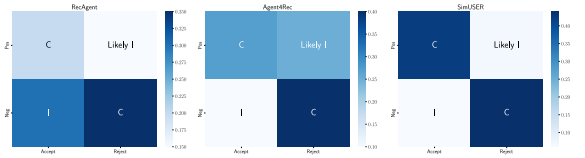

Figure 5: Preference coherence (accept/reject task). 'I' stands for incoherent; 'C' stands for coherent (Reddit dataset).

C.2 Alignment: Rating vs Feeling

Expressing aligned reviews and ratings is of primary importance to simulate realistic human proxies. Thus, in this section we delve into the alignment between ratings and sentiments. In detail, we prompt the agent to assume one has interacted with a certain item, and ask about its rating and feelings on it. Reviews and ratings from IMDB (Maas et al., 2011) are used as ground truth since MovieLens does not contain reviews. After getting a collection of responses, we conduct sentiment-based analysis with PyABSA (Yang et al., 2023). We compare the rating and sentiment distributions of: humans, RecAgent, Agent4Rec, and SimUSER. As depicted in Figure 4, our agents generate ratings aligned with their opinions. For instance, ratings ≥ 4 are typically associated with positive sentiments. In contrast, Agent4Rec exhibits a bias towards positive opinions, resulting in more positive feelings about the items, including when generating low ratings. It is noteworthy that SimUSER agents and genuine humans express similar sentiments at a macro level.

C.3 Preference Coherence

Under this scenario, we aim to evaluate whether agents prefer positive recommendations based on a query. Namely, for each request in the Reddit dataset (He et al., 2023), we sample: (1) a comment from this request (positive recommendation) (2) a random comment (negative recommendation). The agent is then prompted to decide which items to *watch*. Ideally, synthetic users should watch only positive recommendations and decline negative ones. Behavior is incoherent when the simulator accepts a negative recommendation. We clearly see in Figure 5 that our agents are overall coherent, but sometimes prefer negative recommendations, its proportion being around 4%. Particularly, Agent4Rec agents often accept recommendations that are not aligned with their age and personality.

To further assess the robustness of our agents

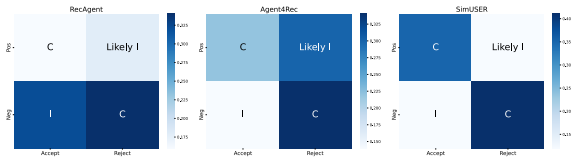

Figure 6: Preference coherence (accept/reject task). 'I' stands for incoherent; 'C' stands for coherent. Results are reported on Tenrec dataset with hard negative items.

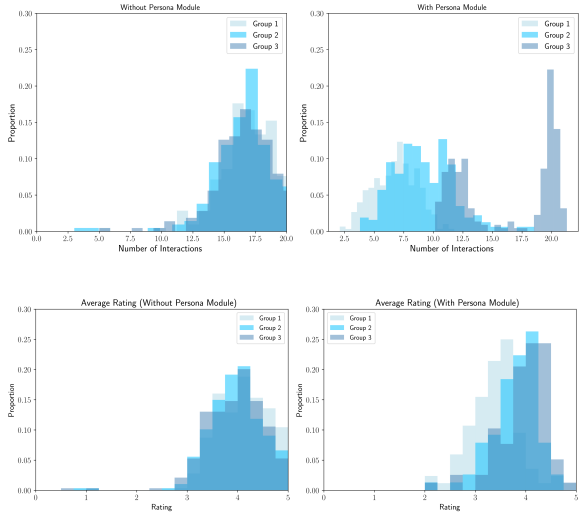

Figure 7: Distribution of interaction numbers (top) and average ratings (bottom) for 3 groups of personas. The left column does not use persona module while the right employs a persona module.

under more realistic recommendation conditions, we conduct an additional experiment using the Tenrec dataset (Yuan et al., 2022). Unlike the Reddit dataset, which relies on random negative sampling, Tenrec provides true negative feedback—items that were shown to users but explicitly ignored. This allows us to create harder negative samples, as these unclicked items are likely to be more relevant but still rejected by real users. Under this setting, hard negatives are items that were exposed to the user but ignored. As expected, the increased difficulty results in a slight drop in coherence across all agents (Figure 6). SimUSER remains the most consistent but sees a 5% decrease in coherence, while Agent4Rec and RecAgent show larger declines. Notably, Agent4Rec exhibits a stronger bias toward selecting hard negatives, suggesting sensitivity to misleading but plausible recommendations.

C.4 Impact of Persona on User Behaviors

In real life, user behaviors are driven by factors beyond mere individual tastes, including personality traits and demographic attributes such as age, and occupation. To account for these factors, we developed a persona module that incorporates these characteristics. Using the MovieLens dataset, agents were categorized based on their age, occupation (student, office worker, other), and personality traits — categorical features were encoded using one-hot representation, via k-means (k=3). We hypothesize that agents with similar preferences may still exhibit distinct behavior patterns due to their unique persona. Figure 7 depicts the distribution of interaction numbers and average ratings among agents with different personas. As shown in the figure, it is evident that agents from different groups demonstrate distinct behaviors, with higher average ratings in groups 2 and 3 than group 1. Synthetic users without personas display more homogeneous behaviors. Younger users (group 3, avg age=19.6) engage more frequently with the system compared to older users (group 1, avg age=40.2), likely due to higher adaptability and interest in exploring new recommendations, while older users exhibit fewer interactions, possibly from ingrained preferences and less willingness to engage with new content.

C.5 Post-Interaction Interviews

A central advantage of LLM-based evaluation is their capacity to generate human-comprehensible explanations. Such explanations provide valuable insights that can be employed to refine the recommender system. Figure 8 illustrates a post-interaction interview scenario, where the agent rates its experience with the recommender and returns an explanation based on its personal tastes, habits, emotional memory, and interaction history. The agent noticed that the recommender system generally aligned well with its tastes, particularly recommending movies suitable for its age and personality. However, some factors reduce the overall satisfaction. For instance, despite the agent's preference for sub-genres like neo-noir and psychological thrillers such as "The Sixth Sense" and "Apt Pupil", the system frequently recommended mainstream blockbusters like "Star Wars: Episode I", "The Phantom Menace". These findings underscore the importance of understanding the nuanced behavior of different recommendation algorithms and their suitability for each group of users.

Case Study of Satisfaction Interview

Question: How satisfied are you with the recommender system? Please rate your satisfaction on a scale from 1 to 10 and provide an explanation for your rating.
Rating: 7
Reason: As a 35-year-old film enthusiast with a preference for independent films and documentaries, I found the recommender system fairly effective in suggesting thought-provoking content. It recommended several documentaries and indie films that I enjoyed. However, the system often leaned towards mainstream and popular films rather than exploring unique and lesser-known titles. This tendency occasionally led to less satisfying recommendations, as I value discovering independent, high-quality films.
Additionally, while the system recognized my interest in dramas and thrillers, it missed specific sub-genres like neo-noir and psychological thrillers that I particularly enjoy. Improving the system's ability to identify these nuanced preferences could enhance its effectiveness.
Overall, the system shows strengths in general recommendations but would benefit from a better balance between popular and niche films.

Figure 8: One case study of post-exit feeling interview. The blue color highlights the user's satisfaction score.

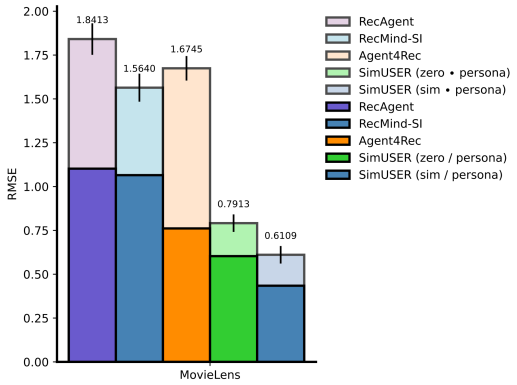

Figure 9: Comparison of RMSE values for original (dark colors) and hallucination-affected (light colors) models for the rating task (MovieLens).

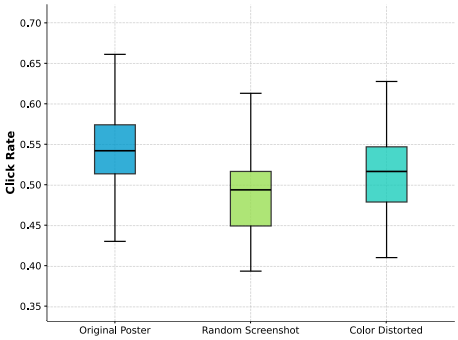

Figure 10: Effect on visual cues on rating distribution for different thumbnail types.

C.6 Rating Items under Hallucination

In this section, we specifically target items that are unfamiliar to the LLM, seeking to evaluate the ability of SimUSER to mitigate hallucination through its memory module. Similarly to Section 4.2, users are asked to rate movies (MovieLens). Nevertheless, we exclusively include items that are detected as unknown to the LLM. These items i are identified by querying the LLM to classify each movie into one of 18 genres. If the LLM's genre classification matches the actual category g_i, it indicates that the LLM is familiar with the item, and such movies are excluded from the experiment. From Figure 9, it is evident that while the RMSE values for all methods increase under hallucination, the performance degradation of SimUSER is less severe compared to the baselines. This relative robustness of SimUSER can be attributed to its KG memory, which effectively mitigates the impact of hallucination by leveraging relationships between users/movies/ratings from previous interactions. By comparing the unfamiliar movie with these similar, well-known ones, the LLM can anchor its predictions in familiar contexts, reducing the likelihood of hallucinations and leading to more accurate ratings.

C.7 Thumbnail Quality Effect

Emotions largely shape decision-making in the recommendation domain. At the center of emotion, images are powerful stimuli that motivate our choices. In light of this, a question arises: Can SimUSER be useful in assessing the quality of items' thumbnails? To understand the factors influencing ratings, we randomly selected 100 movies from the MovieLens dataset and ask 100 agents whether they want to watch it. For each movie, we collected three versions of the thumbnails: 1) the original movie poster, 2) a random screenshot from the movie trailer on YouTube, and 3) the original movie poster distorted with a blue color filter. Based on the click rates shown in Figure 10, we notice that high-quality thumbnails — original posters, significantly influence users' inclination to watch a movie. Specifically, original posters lead to higher engagement compared to random screenshots and color-distorted posters. This result highlights SimUSER's capability to reflect the quality of item images in decision-making processes,

Figure 11: Heatmap showing the impact of biased recommendations on genre ratings over time — exposure effect. The genres and their ratings are displayed after 5, 20, and 50 pages scrolled.

mirroring trends commonly observed in real-world recommender systems.

C.8 Exposure Effect in Recommendation

To assess how biased recommendations shape user preferences over time, we introduce a scenario where the RS only recommends two movie categories: *action* and *horror*. It emulates an exposure effect (Färber et al., 2023), where repeated exposures to a particular stimulus increase an individual's preference for that stimulus. In the context of recommender systems, repeated exposure to specific genres could amplify user preferences for those genres. Under this scenario, we record the average movie ratings for each category after 5, 20, and 50 pages scrolled by the agents. Namely, the 50 agents are prompted to rate 500 randomly selected movies. Figure 11 illustrates a tendency of the agents to rate items of categories that are over-represented higher during the interactions with the recommender system, particularly after more than 20 pages. Conversely, categories that differ significantly from *action* and *horror* genres generally tend to receive lower average ratings. Experimental results validate SimUSER's capability to replicate the exposure effect, although further research and validation are required with alternative datasets.

C.9 User Review Influence

User proxies may help researchers in identifying the psychological effect of reviews on human interactions. To investigate this effect, we modified the recommendation simulator to display a) the number of reviews, b) one random negative comment, or c) one random positive comment for each item on the recommendation page. We report in Table 6 the average viewing ratio $\overline{P}_{\text{view}}$ and ratio of likes $\overline{P}_{\text{like}}$. We can see that displaying the number of reviews slightly improves the viewing ratio, especially for items having enough reviews (i.e., more than 20 reviews). This aligns with humans' inclination to select popular items in real-life scenarios. On the other, there is no significant difference in $\overline{P}_{\text{like}}$ (t-test $p > 0.05$). Another observation is that displaying negative reviews has a stronger impact on user behavior than showing positive reviews, with a decrease in both the average viewing ratio and number of likes. One possible explanation is that negative reviews discourage users from watching an item, while positive reviews primarily encourage users who are already inclined to watch it to proceed with their choice.

	MF		MultVAE		LightGCN	
Condition	$\overline{P}_{\text{view}}$	$\overline{P}_{\text{like}}$	$\overline{P}_{\text{view}}$	$\overline{P}_{\text{like}}$	$\overline{P}_{\text{view}}$	$\overline{P}_{\text{like}}$

Table 7: nDCG@k (k=10) and F1-score@k (k=10) for three recommender systems, using either offline or SimUSER-generated interactions.

C.10 SimUSER vs. Offline Metrics

We aim to investigate whether SimUSER can reliably estimate traditional metrics such as nDCG@k (k=10) and F1-score@k (k=10) by comparing the results from traditional offline evaluation with those from SimUSER-generated interactions. For this purpose, we evaluate three recommender systems using the MovieLens dataset under identical conditions for both offline and SimUSER-based evaluations. Table 7 reports the nDCG@k and F1-score@k (k=10) for both evaluation strategies. In the SimUSER scenario, interactions are generated by our synthetic users, where liked and disliked items replace the ground-truth interactions from the offline dataset. Results indicate minimal differ-

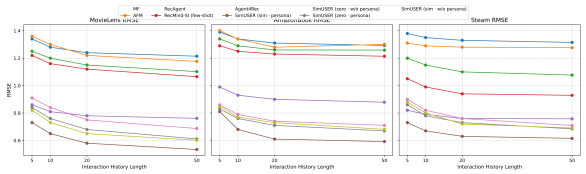

Figure 12: Impact of history size on rating prediction performance (RMSE) across datasets.

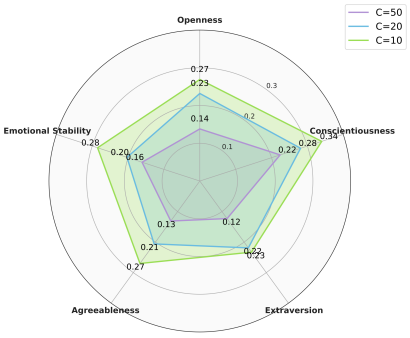

Figure 13: MAE of personality trait predictions for different C values.

ences between SimUSER-generated and real-world data, with consistent model rankings across systems. These slight differences reflect real-world users being unconstrained by page numbers and interaction frequency. These findings demonstrate that SimUSER reliably measures traditional metrics while enabling exploration of system performance across user demographics, website settings (items per page), and recommender system configurations.

C.11 Impact of Number of Interactions on Rating Performance

In this experiment, we measure rating prediction performance as a function of interaction history length ∈(5, 10, 20, and 50 interactions). While most methods generally benefit from increased context (Figure 12), small fluctuations occur (e.g., AFM on AmazonBook shows a slight rise from 1.28 at 20 interactions to 1.3006 at 50). SimUSER consistently outperforms all baselines, achieving RMSEs of 0.5020 (MovieLens), 0.5676 (AmazonBook), and 0.5866 (Steam) at 50 interactions. These results confirm that leveraging persona-based context yields robust performance improvements, even with limited historical data, and aligns with our main results. This highlights SimUSER's ability to utilize past interactions for realistic simulations while remaining believable when modeling *cold-start* or *few-shot* users.

C.12 Ablation Studies

C.12.1 Impact of the Knowledge-Graph Memory on SimUSER

Here, our focus is on evaluating the impact of incorporating a knowledge-graph memory on the performance. Specifically, the goal is to determine whether employing the KG memory, which simulates external influences such as reviews, enhances believability in human proxies. All models follow the same settings as in Sec 4.2. Table 8, highlights that leveraging the KG structure significantly reduces both RMSE and MAE across different datasets. This module mirrors how our prior expectations of an item can shape and bias our assessment of it.

C.12.2 Persona Matching: Age, Occupation

We postulate that personas are crucial for capturing the heterogeneity and diversity present in real-world recommender networks. These attributes significantly shape individual behaviors and preferences, which subsequently influence the overall dynamics of the system. To evaluate the effectiveness of our self-consistent persona-matching technique, we conducted an experiment using the MovieLens-1M dataset. The goal was to predict the age and occupation of users based on their historical data. This task was formulated as a classification problem. Our results are summarized in table 9. We observe a high degree of alignment between the predicted and actual user personas, highlighting the effectiveness of Phase 1 in SimUSER. Overall, *persona matching* turns out to be reasonably robust for enriching simulated agents with detailed backgrounds, including domains where explicit demographic data is not readily provided.

C.12.3 Persona Matching: Personality

In order to assess the quality of persona matching in predicting personality traits from historical interaction data, we conduct an additional experiment using the Personality 2018 dataset (Nguyen et al., 2018). The primary objective is to evaluate whether our model could accurately infer users' Big Five personality traits based solely on users' watching history. For a fair comparison, the personality traits within the dataset, as well as the predictions, are normalized to a scale ranging from 0 to 1. We report the results for various lengths of movie his-

Methods	MovieLens		AmazonBook		Steam	
	RMSE	MAE	RMSE	MAE	RMSE	MAE

tory $\varrho \in \{10, 20, 50\}$. This task is formulated as a regression problem. Figure 13 summarizes the results, showing that our model achieved an average MAE of 0.155 across all traits. Besides, the results reveal that using a history length of 50 items reduces the average MAE from 0.279 (10 items) to 0.155, demonstrating that self-consistent persona matching can reasonably predict personality traits of users from their past interactions.

C.12.4 Choice of Foundation Model

We seek to evaluate the performance of our methodology using various foundation models on the movie rating task. Specifically, we compare the results obtained by employing GPT-4o-mini, GPT-4o, Mistral-7b Instruct, Llama-3 Instruct, and Phi-3-mini as the underlying LLMs. The results, presented in Table 10, demonstrate that the performance of SimUSER is generally robust across different foundation models. While GPT-4o exhibits significantly lower mean RMSE and MAE (t-test $p < 0.05$), GPT-4o-mini achieves similar performance but with a lower inference time. Mistral-7b Instruct also performs reasonably well on the MovieLens dataset. On the other hand, Llama-3 Instruct and Phi-3-mini, while competitive, show higher errors.

C.12.5 Impact of Perception Module

We now investigate the perception module's impact on agent believability. Table 11 shows agents consistently exhibit more realistic behavior with the perception module (♠), likely due to the inclusion of visual details and unique selling points. The believability gain is lower on AmazonBook than other datasets, possibly because users judge books less by covers and more by descriptions. Examining interactions reveals agents with different personas are significantly influenced by emotional tones. For instance, an agent with high openness may be more inclined to select movies with captions that use positive language like "exciting" or "inspiring". While SimUSER (♦) may inherit biases from the LLM's interpretation of item descriptions, these can be partially mitigated through factual caption information. This suggests the perception module contributes to more visually and emotionally driven engagement.

D Discussion

We acknowledge that our method has certain limitations. Observed behaviors are well-aligned with existing theories and common behaviors in the recommendation domain. Phenomena at micro-level (rating, watching) are manifestations of agent endogenous behaviors. But why agents possess these behaviors are unexplored due to the black-box nature of the large language models we adopted. A potential reason could be that LLMs are trained on a massive corpus that includes texts from various domains.

A potential limitation of our approach lies in its reliance on sufficient interaction data to construct detailed user personas. In some scenarios, many users exhibit limited engagement, particularly in cold-start settings where new users have few or no recorded interactions. This constraint reduces the effectiveness of our persona module,

Methods	MovieLens		AmazonBook		Steam

Table 10: Performance comparison in rating prediction on MovieLens with different types of foundation LLMs.

	MovieLens	AmazonBook	Steam
RecAgent	3.01 ± 0.14	3.14 ± 0.13	2.96 ± 0.17
Agent4Rec	3.04 ± 0.12	3.21 ± 0.14	3.09 ± 0.16
SimUSER (♦)	4.27±0.18	3.94±0.16	3.89±0.20
SimUSER (♠)	**4.41±0.16***	**3.99±0.18***	**4.02±0.23***

Table 11: Human-likeness score evaluated by GPT-4o for SimUSER without (♦) and with (♠) perception module. Asterisks (*) denote statistically significant improvements when the perception module is activated.

as it derives user preferences primarily from past interactions.To address this issue, a potential alternative is initializing the persona module using predefined user features, such as categorical tags (e.g., "tech-savvy," "frequent traveler").

LLMs may replicate biases prevalent in social spaces, such as some groups of individuals being underrepresented. This is problematic if it causes designers to then underlook these peoples' needs when designing a recommender system. In our experiments, we mitigated this risk by ensuring a broad range of personas via diverse potential occupations, age, and personalities. We also measured the discrepancy between identified and real personas. Our future investigation will focus on analyzing underrepresented user groups, as well as evaluating persona matching on a wider range of domains (e.g., food).

Finally, UX and UI drive our choices and actions in real-world applications. Our simulation, on the other hand, does not fully replicate all those intricate factors, which introduces a gap between real life and simulation. An important future direction is developing an image-based simulator to better capture the complex nature of user experience.

E Cost Analysis

We report the cost of running SimUSER per 1000 users. Costs may vary slightly due to differences in interaction numbers and LLM outputs, but scale approximately linearly with user count. Our implementation uses OpenAI's GPT-4o-mini. SimUSER costs approximately $13 ($0.0013/User), while Agent4Rec costs approximately $10 ($0.0010/User). The cost difference mainly stems from the integration of images to enable visual-driven reasoning.

F Running Time Analysis

We compare the running time of SimUSER and Agent4Rec for 1,000 user interactions with GPT-4o. Without parallelization (♥), Agent4Rec and SimUSER require 9.3h and 10.1h, respectively. With parallelization (♣, max 500 workers), these times drop to 0.53h and 0.59h. This demonstrates that parallelizing LLM calls significantly reduces inference time, allowing the system to scale efficiently.

Scaling Context, Not Parameters: Training a Compact 7B Language Model for Efficient Long-Context Processing

Abstract

We present MegaBeam-Mistral-7B[1], a language model that supports 512K-token context length. Our work addresses practical limitations in long-context training, supporting real-world tasks such as compliance monitoring and verification. Evaluated on three long-context benchmarks, our 7B-parameter model demonstrates superior in-context learning performance on HELMET and robust retrieval and tracing capability on RULER. It is currently the only open model to achieve competitive long-range reasoning on BABILong at 512K context length without RAG or targeted fine-tuning. Released as fully open source under the Apache 2.0 license, the model has been downloaded over 100,000 times on Hugging Face.

1 Introduction

MegaBeam-Mistral-7B is a compact 7B-parameter language model capable of processing sequences with half-a-million tokens. Developed with customer engagements in mind, we thoroughly evaluated its long-context capabilities across multiple benchmarks.

MegaBeam delivers strong performance across three key long-context benchmarks. On RULER at 128K context length, it outperforms both GPT-4-1106 and larger open-source models like Llama-3.1-70B. On BABILong at 64K context, it achieves 48.2% accuracy—comparable to models with 8x more parameters. On HELMET, it attains a leading 85% in-context learning score at 128K tokens. Significantly, MegaBeam achieves a competitive 35% score on 512K-token BABILong tasks without RAG or task-specific tuning, making it the only open model to effectively utilise such extreme context lengths for solving novel reasoning tasks.

MegaBeam's development was shaped primarily by our engagements with customers across diverse sectors, including digital design, banking, life sciences, and GenAI native startups.

For example, large enterprises face daily challenges in verifying compliance across their customer interactions, which often involve processing lengthy conversation transcripts and transaction logs. To tackle this challenge, we deployed MegaBeam as a prototype compliance verification solution, performing three key functions: First, it identifies and matches specific sections of customer interactions with relevant Standard Operating Procedures guidelines. It then classifies these matched segments for compliance adherence, examining elements such as required disclosures, proper documentation, and procedural steps. Finally, it provides detailed reasoning for each compliance assessment by comparing the actual interaction patterns against mandated procedures. The ability to digest customer interaction logs alongside SOPs within its context eliminates the need to chunk conversations. MegaBeam enables efficient compliance monitoring by maintaining the complete context of customer interactions alongside regulatory requirements.

The following sections detail our technical approach to achieving these capabilities, addressing challenges in training methodology and system-level optimisations required for robust performance in production environments.

2 Related Work

Recent advances in LLM context length extension have emerged through improved training methodologies. MiniCPM (Hu et al., 2024) and Yi (Young et al., 2024) demonstrated that even smaller models could handle 200K+ contexts through targeted training approaches. Fu et al. (2024) established that modest amounts of long-sequence text (1-2B tokens) can effectively extend context capabilities without full retraining. To address computational

[1] https://huggingface.co/aws-prototyping/MegaBeam-Mistral-7B-512k

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 61–68

challenges, sequence parallel techniques such as Ring Attention (Liu et al., 2023a) and DeepSpeed-Ulysses (Jacobs et al., 2023) have made training with extremely long sequences more feasible.

Several long-context benchmarks have emerged to systematically evaluate long-context capabilities. RULER (Hsieh et al., 2024) focuses on retrieval and multi-hop reasoning, BABILong (Kuratov et al., 2024) tests reasoning over extremely long documents, and HELMET (Yen et al., 2024) provides application-centric metrics across diverse downstream tasks.

Adjusting the theta base parameter in Rotary Position Encoding (RoPE) (Su et al., 2024) has emerged as the dominant approach for extending context length. Recent theoretical work by Xu et al. (2024) has established lower bounds for effective theta values based on target sequence lengths. LongRoPE (Ding et al., 2024) introduced innovative position encoding modifications, enabling models to handle substantially longer sequences with minimal additional training.

Our work builds upon these foundations, focusing specifically on efficient training techniques that allow smaller models (7B parameters) to handle extremely long contexts (512K tokens), previously thought to require substantially larger models or computational resources.

3 Training

The training methodology for MegaBeam builds upon key insights from several previous studies. Drawing from (Young et al., 2024) and (Fu et al., 2024), we implemented lightweight continual pretraining with long-context data, confirming that $\leq$ 2B tokens are sufficient for extending context length capabilities. We also incorporated findings from the MiniCPM model (Hu et al., 2024) regarding the optimal balance between short and long training examples—specifically their discovery that mixing ratios are crucial for maintaining performance across different context lengths.

The training process consists of four phases (Fig 1) with varying token counts and sequence lengths. Using Mistral-7B-Instruct-v0.2 (Mistral-AI, 2023) as the base model, the first phase involved progressive long-context training on 1.2B tokens of organically long documents from diverse sources: source code (70%), research papers (10%), open web content (15%), and public domain books (5%). This initial phase processed 0.64B tokens as 300K-token sequences and 0.56B tokens as 600K-token sequences. Although we trained with sequence lengths up to 600K tokens, our evaluation using the Needle-in-a-Haystack (NIAH) benchmark (Arize-AI, 2024) revealed significant performance degradation when processing sequences longer than 300K tokens. We named this intermediate checkpoint `MegaBeam-Mistral-7B-300K` to reflect its effective context length.

To address the performance degradation beyond 300K tokens, we increased the RoPE theta base from 25_000_000 to 75_000_000 and trained on an additional 0.18B tokens using 600K-token sequences. This improved overall long-context performance but led to poor NIAH scores at sequence endpoints (depth 0 and 100). We attributed this to insufficient training on shorter sequences with the new RoPE configuration – a hypothesis confirmed when additional training on 0.26B tokens of shorter sequences (32K-80K) resolved the endpoint issues while maintaining long-sequence performance.

After addressing a critical numerical precision issue in the bfloat16 RoPE implementation, we conducted a third round of long-context continual pretraining using 0.2B tokens. The training data was distributed across different sequence lengths: 1,200 sequences of 80K tokens (96M total), 300 sequences of 256K tokens (77M total), and 30 sequences of 512K tokens (15M total). This balanced distribution ensured robust performance across all context windows.

The final phase involved long-context supervised fine-tuning (SFT) on a small 22M-token data set, producing `MegaBeam-Mistral-7B-512K`. Following insights from (Hu et al., 2024) and (Young et al., 2024), we created synthetic documents (64K-512K tokens) by restructuring real question-answer pairs to specifically challenge long-range information retrieval.

This phased approach combines planned length progression with solutions to unexpected challenges discovered during development, enabling effective scaling to longer contexts while maintaining performance stability.

4 Solving Practical Issues

4.1 RoPE theta base

As discussed in Section 3, we tuned the RoPE theta base through progressive pretraining to improve NIAH benchmark performance. Our experimentally determined values—25_000_000 for se-

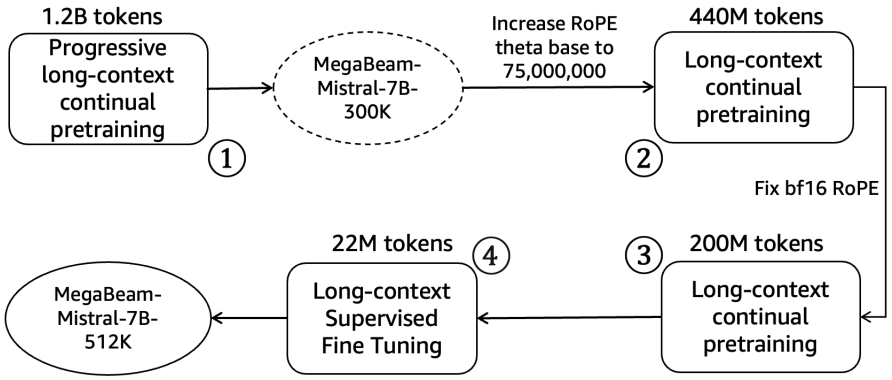

Figure 1: Overview of MegaBeam's training methodology: four sequential phases

quences of 256K tokens and 75_000_000 for sequences of 512K tokens—closely match the theoretical lower bounds derived by (Xu et al., 2024): $\beta = 0.0424L^{1.628}$, which yields 28_000_000 and 86_000_000 respectively.

Our experiments also revealed additional insights. Specifically, setting the base to 100_000_000 systematically degraded performance at the sequence endpoints (depth 0 and 100) for long sequences. This observation seems to align with (Liu et al., 2023b). When the base value substantially exceeds the lower bound, it creates positional embeddings with wavelengths longer than the training context length. This means some dimensions cannot complete a full 2π rotation during training, potentially leading to hallucinations during inference.

4.2 bf16 and RoPE

We encountered recall failures in NIAH benchmark. Specifically, when processing longer contexts, the model consistently dropped the last one digit when recalling numbers (e.g., recalling 7418118 as 741811). The root cause was traced to numerical precision limitations of bfloat16 when handling large position indices in RoPE calculations. While float32 maintains sufficient precision across all position indices, bfloat16's reduced mantissa bits lead to significant precision loss when representing large positions, despite having comparable range to float32. This precision loss directly impacts RoPE's ability to accurately encode positional information for tokens far into a long sequence.

The solution involves disabling `autocast` and forcing float32 precision specifically for the critical RoPE calculations while maintaining bfloat16 for the rest of the model operations. This targeted precision management ensures accurate positional encoding while retaining the memory and computational benefits of bfloat16 for other operations. This fix was crucial for enabling reliable long-context processing in MegaBeam. After we have released MegaBeam, a comprehensive analysis of this precision-related issue was later discussed in (Wang et al., 2024).

4.3 Ring Attention

Ring Attention (Liu et al., 2023a) is an effective Sequence Parallel (SP) mechanism for distributed long sequence training. It organises accelerators in a ring topology where attention keys and values rotate in a peer-to-peer fashion between devices while queries remain fixed on their assigned devices.

There are alternative approaches to SP besides Ring Attention, such as DeepSpeed-Ulysses (Jacobs et al., 2023). However, DeepSpeed-Ulysses requires all-to-all collective communication to transpose partitions from sequence to head dimensions, and each device must store a complete KV head for the entire sequence length. As a result, its degree of sequence parallelism (DoSP) is constrained by the number of KV heads. Ring Attention, in contrast, allows DoSP to scale linearly with the total number of available devices. These advantages led us to adopt the JAX-based (Liu et al., 2024) Ring Attention implementation for our sequence parallelism.

Although the JAX codebase (Liu et al., 2024) supports interleaving Tensor Parallelism (TP) with SP, we disable TP (setting it to 1) for sequences longer than 64K tokens. This prioritisation of SP over TP allocates more VRAM to sequence parallelism, which becomes crucial as sequence lengths are growing. For larger models like 70B parameters, the optimal parallel mesh con-

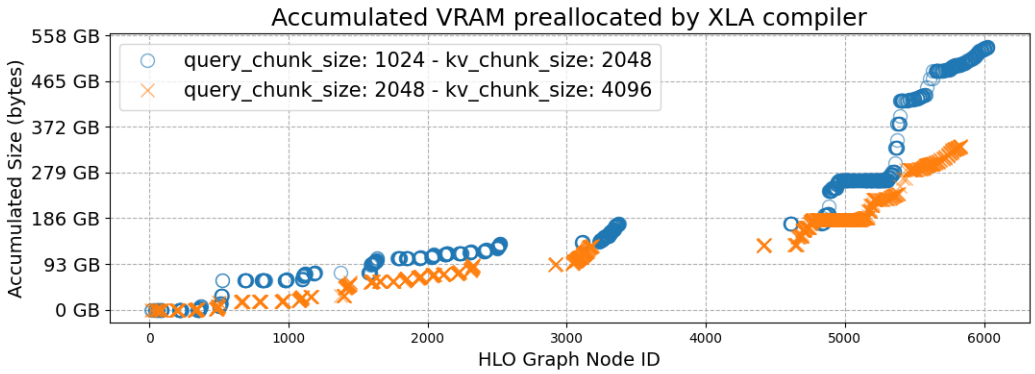

Figure 2: Accumulated memory pre-allocation by XLA compiler under two chunk size configurations. The orange line (larger chunks) demonstrates reduced memory footprint compared to the blue line (smaller chunks) throughout the HLO graph, with peak memory reduction of 186GB.

figuration between SP and TP would need to be re-established through similar experimentation. This parallelism strategy is necessary because, as demonstrated in the Megatron context parallelism example (NVIDIA, 2024), SP and TP share a fixed pool of GPUs. Additionally, interleaving TP and SP incurs communication overhead through extra operations such as `All-Gathers` and `Reduce-Scatters`.

4.4 XLA compiler

Liu et al. (2023a) documented resource demands of long-context training. For sequences of 512K tokens, they had to use $16\times$A100 (80GB VRAM) to train a 7B model. We verified this limitation using their JAX codebase (Liu et al., 2024) — attempting to train 512K-token sequences on $8\times$A100 GPUs resulted in compilation-time OOM exceptions.

To overcome this limitation, we examined the compilation process in detail. The XLA compiler transforms JAX operations to High-Level Operations (HLO) IR, from which we identified some operation that pre-allocates 32 GB memory during compilation. Namely, the `dynamic_update_slice` HLO operation (shown in Appendix A) uses `int32` type for both input and output tensors, with the output tensor size reaching 32 GB. For our 524,288-token sequences, 8-way partitioning assigns $65,536$ tokens per GPU device. Each device's partition is then processed using 64 query chunks ($65,536/1,024$ tokens per chunk) and 32 key-value chunks ($65,536/2,048$ tokens per chunk). Based on these dimensions and the `int32` type, we hypothesise that this structure serves as a lookup table mapping QKV chunks to `segment_ids` for intra-document attention mask generation (Zhao et al., 2024).

To address this challenge, we increased both Q and K/V chunk sizes. This solution appears counter-intuitive since larger attention chunks traditionally consume more GPU HBM, as evidenced in both Block-wise Attention (Liu and Abbeel, 2023) (with larger blocks) and Flash Attention (Dao et al., 2022) (with larger tiles). However, increasing chunk sizes actually reduces the number of chunks needed, thereby decreasing the dimension extent of the lookup table tensor. This leads to reduced memory usage, contrary to conventional wisdom about chunk size and memory footprint.

We experimented with increasing query chunks from 1024 to 2048 tokens, and key/value chunks from 2048 to 4096 tokens. Fig 2 compares the memory pre-allocated by the XLA compiler under these two configurations. The larger chunk sizes (orange line) consistently require less pre-allocated memory than smaller chunks (blue line) across all HLO graph nodes. This difference becomes especially significant in the later stages of the HLO graph (nodes 4000-6000).

Most importantly, this method doubles the training context length on a single `p4de.24x` node (8x A100 with 80GB VRAM) from 256K to 512K tokens. However, while effective, this solution serves as an interim workaround. Specifically, the root issue stems from the XLA compiler materialising the massive chunk-to-segment mapping table statically. A proper solution would improve the compiler to generate dynamic mapping code, aligning with the chunked attention design.

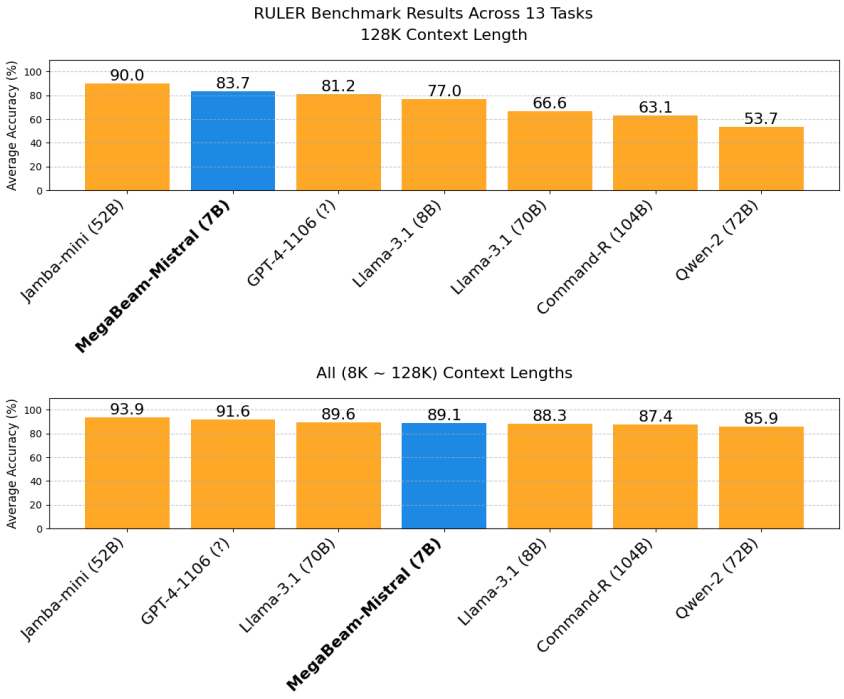

Figure 3: Model performance comparison on RULER benchmark: top shows 128K context length results, bottom shows average performance across context lengths from 8K to 128K.

5 Evaluation

The RULER benchmark (Hsieh et al., 2024) specifically assesses long context capabilities in retrieval, multi-hop tracing, aggregation, and long-form question and answering. Fig. 3 shows that MegaBeam performs better than GPT-4-1106 on the RULER benchmark when the context length is 128K. For the average performance across all lengths (8K to 128K), MegaBeam as a 7B model performs nearly on par with Llama-3.1-70B, and is ranked higher than larger models such as Llama-3.1-8B, Command-R-104B, and Qwen-2-72B. For example, MegaBeam achieves near-perfect performance on retrieval tasks (97% on 7 out of 8 tasks at 128K), strong results on multi-hop tracing (89% at 128K), and competitive QA performance (77.4% on QA_1 at 128K).

The RULER benchmark (Hsieh et al., 2024) demonstrates that MegaBeam maintains the base model's strong performance on short contexts of 4K-16K tokens (92-94% accuracy) while significantly outperforming Mistral-7B-Instruct-v0.2 on longer contexts (84% vs 14% at 128K tokens). This confirms our training approach effectively extends context length without compromising short-context capabilities.

Additionally, as shown in Figure 3, Llama-3.1-8B outperforms its 70B counterpart, suggesting that model size alone does not guarantee superior long-context processing. In contrast, the relationship differs on BABILong, where Qwen-2.5-72B exceeds its 7B version by 13 percentage points. These varied outcomes across benchmarks support the motivation of this paper - specialised pretraining and post-training for longer contexts can enable compact models to achieve competitive performance on many long-context tasks.

The BABILong benchmark (Kuratov et al., 2024) evaluates the ability of LLM to perform reasoning tasks across facts distributed in extremely long documents. We conducted MegaBeam's evaluation using the official BABILong benchmark codebase[2]. Fig 4 shows that MegaBeam achieves 48.2% accuracy at 64K context length and 40.2% at 128K context length, outperforming several larger models including GPT-4-0125-preview (43% at 64K, 36% at 128K) and matching the performance of Llama-3.1-8B and Phi-3-MoE-61B (49% at 64K, 39% at 128K) despite having only 7B parameters. MegaBeam demonstrates particularly strong performance on tasks requiring single-fact retrieval and relational reasoning, maintaining consistent performance as context length increases. Notably, MegaBeam is currently the only open model that

[2] https://github.com/booydar/babilong

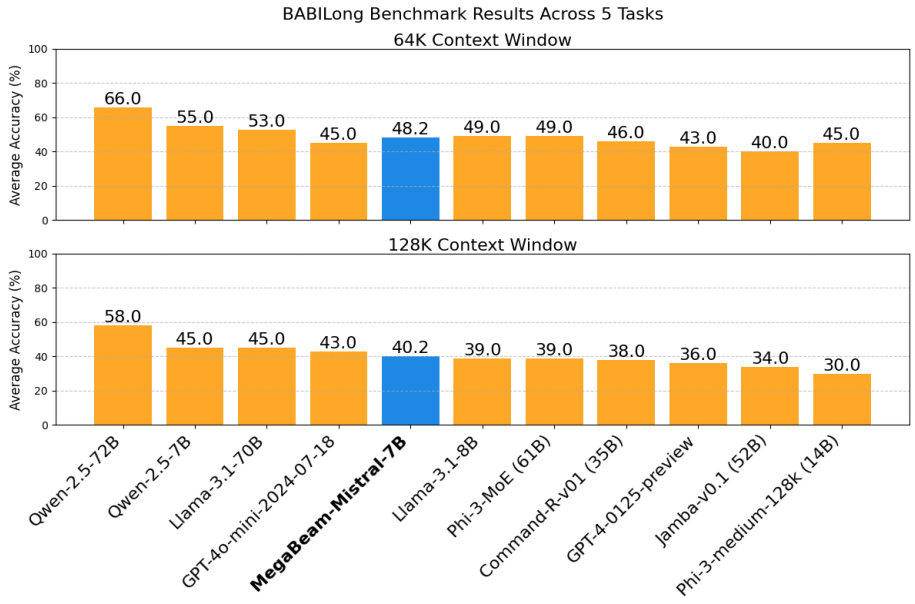

Figure 4: Performance comparison on BABILong benchmark at 64K and 128K context lengths

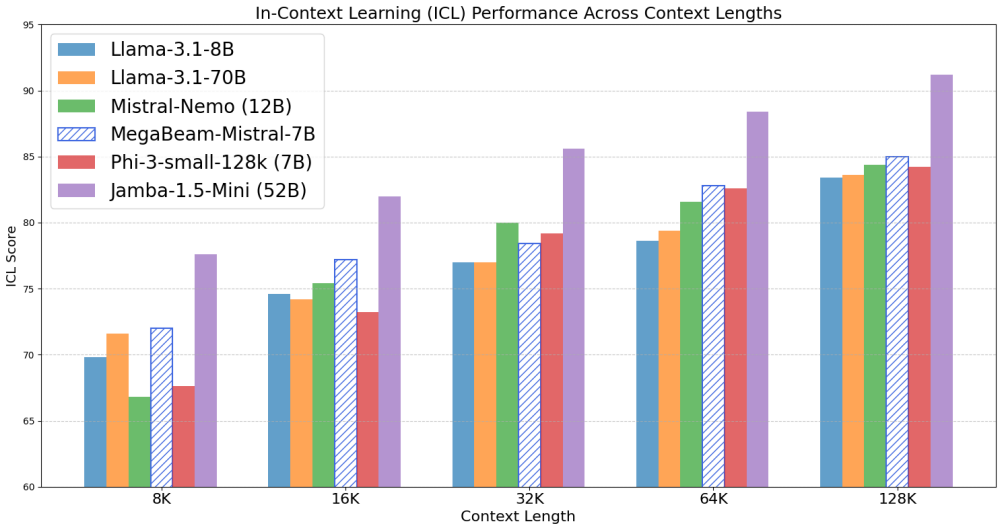

Figure 5: In-Context Learning performance comparison on HELMET, showing MegaBeam's leading performance across multiple context lengths

has achieved a competitive score (35% as shown in Fig 6) on the 512K context BABILong tasks without RAG or task-specific fine-tuning.

The HELMET benchmark (Yen et al., 2024) represents the latest evaluation framework for long-context capabilities through realistic downstream tasks. It contains seven diverse, application-centric categories with model-based evaluation metrics, and few-shot prompting capabilities. Fig. 5 shows model performance comparison in the many-shot In-Context Learning (ICL) category, using performance data reported in (Yen et al., 2024) — At 128K context length, MegaBeam achieves an ICL score of 85%, outperforming larger models such as Mistral-Nemo (12B), Llama-3.1 8B and 70B.

6 Reasoning on BABILong

We evaluate MegaBeam's performance on the BABILong benchmark (Kuratov et al., 2024), which evaluates reasoning tasks across facts distributed in extremely long documents. As MegaBeam is fine-tuned on Mistral-7B-Instruct-v0.2 which natively supports 32K context, our analysis focuses particularly on the model's capability to extend beyond this length while maintaining performance.

MegaBeam demonstrates varying degrees of con-

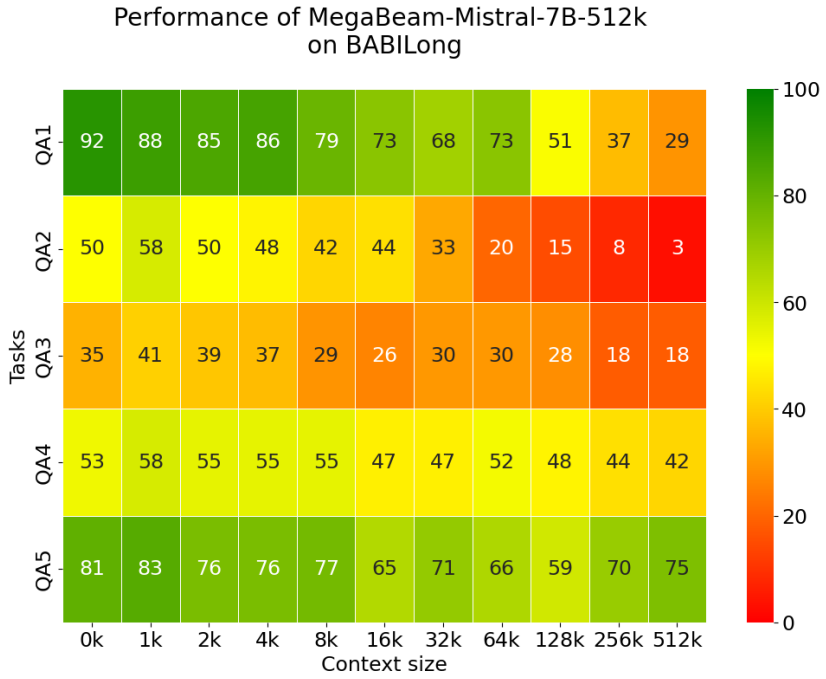

Figure 6: Performance heatmap of MegaBeam on BABILong tasks across different context lengths (0K to 512K tokens). The model shows strong context extension capabilities on single-fact (QA1) and relational reasoning tasks (QA4, QA5), while challenges in multi-fact reasoning (QA2, QA3)

text extension capability across different tasks. For Single Supporting Fact tasks (QA1), the model maintains robust performance at 64K with 73% accuracy, and continues to function at longer contexts with 51% at 128K, 37% at 256K, and 29% at 512K. While this represents 57% drop from 32K, the degradation is gradual and sub-linear. In Two Argument Relations tasks (QA4), MegaBeam exhibits strong stability, with performance actually improving from 47% at 32K to 52% at 64K, and maintaining consistent performance even at 512K (44%), showing a high “retention ratio" of 89% from 32K to 512K. Similarly promising results are seen in Three Argument Relations tasks (QA5), where the model shows strong performance retention from 32K to 64K (71% to 66%), and maintains an even higher score at 512K (75%), achieving an impressive 92% retention ratio from 0K to 512K.

However, MegaBeam still faces significant challenges with multi-fact reasoning at extended contexts. In Two Supporting Facts tasks (QA2), we observe a steep performance decline from 33% at 32K to just 3% at 512K - a retention ratio of only 9%. The sharp linear degradation rate suggests that our context extension approach struggles particularly with maintaining multi-fact reasoning capabilities. Similarly, Three Supporting Facts tasks (QA3) show both base model limitations (35-41% at shorter contexts) and context extension challenges, with performance dropping to 18% at 512K (51% retention ratio).

The weaker QA2/3 performance stems from multiple challenges: tracking object locations/possessions, understanding temporal order, integrating distributed information, and comprehending action-state causal relationships.

7 Conclusion

We presented MegaBeam-Mistral-7B and demonstrated its competitive long-context capabilities as a smaller model trained using limited computational resources. Our work addresses key technical challenges through progressive training methods, RoPE theta tuning, position precision, and memory optimization. MegaBeam shows consistently strong performance on real-world tasks like retrieval, relation processing, and in-context learning across long contexts up to 512K tokens, while maintaining a compact model size. Its limitation in multi-hop reasoning tasks suggests areas for future improvement in both base model capabilities and context extension.

Abstract

Mathematical error detection in educational settings presents a significant challenge for Multimodal Large Language Models (MLLMs), requiring a sophisticated understanding of both visual and textual mathematical content along with complex reasoning capabilities. Though effective in mathematical problem-solving, MLLMs often *struggle with the nuanced task of identifying and categorizing student errors in multimodal mathematical contexts*. Therefore, we introduce MATHAGENT, a novel Mixture-of-Math-Agent framework designed specifically to address these challenges. Our approach decomposes error detection into three phases, each handled by a specialized agent: an image-text consistency validator, a visual semantic interpreter, and an integrative error analyzer. This architecture enables more accurate processing of mathematical content by explicitly modeling relationships between multimodal problems and student solution steps. We evaluate MATHAGENT on real-world educational data, demonstrating approximately 5% higher accuracy in error step identification and 3% improvement in error categorization compared to baseline models. Besides, MATHAGENT has been successfully deployed in an educational platform that has served over one million K-12 students, achieving nearly 90% student satisfaction while generating significant cost savings by reducing manual error detection.

1 Introduction

Multimodal Large Language Models (MLLMs) have revolutionized the landscape of artificial intelligence by enabling the integration and understanding of diverse data formats (Wu et al., 2023a; Xie et al., 2024; Yan et al., 2024c). These models have demonstrated remarkable capabilities across various domains, from visual question answering to content generation and complex reasoning tasks

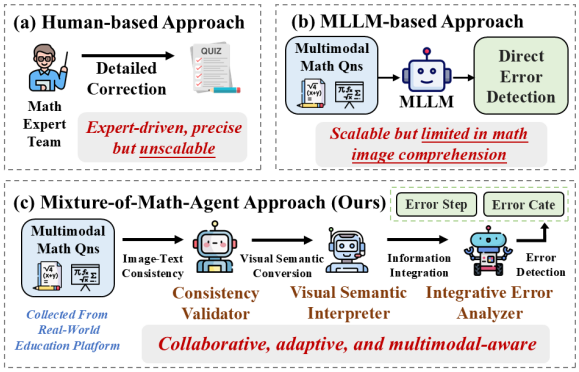

Figure 1: Comparison between previous human-based (a) and MLLM-based (b) paradigms vs. our proposed MATHAGENT framework (c) for multimodal mathematical error detection.

(Yuan et al., 2025). As education increasingly embraces digital transformation (Yan et al., 2025; Ye et al., 2025), the application of MLLMs to mathematical reasoning has emerged as a critical area of research, offering potential solutions to enhance teaching methodologies, provide personalized feedback, and support both educators and students in mathematical learning environments (Küchemann et al., 2025; Wang et al., 2024b; Yan et al., 2024a).

While significant progress has been made in utilizing MLLMs for mathematical problem-solving, a more practical and educationally valuable application lies in **mathematical error detection** (Li et al., 2024d; Song et al., 2025; Yan et al., 2024b; Yang et al., 2024; Zheng et al., 2024a). In real educational settings, identifying and categorizing students' mathematical errors provides deeper insights into their conceptual understanding and learning gaps than merely evaluating final answers (Jiang et al., 2024; Pepin et al., 2025). Error detection is a significantly more challenging task for MLLMs compared to standard problem-solving, as it requires not only understanding the correct solution path but also analyzing the student's flawed reasoning process. This task involves processing multiple inputs: the original problem (which may include multimodal elements), the correct solution, the stu-

[†]Corresponding authors.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 69–82

dent's incorrect answer, and their detailed reasoning steps. The expected output comprises both error step identification (pinpointing exactly where the reasoning went wrong) and error categorization (classifying the type of misconception or mistake). This comprehensive analysis enables targeted educational interventions that address specific learning needs (Chu et al., 2025; Yan et al., 2024a).

Existing error detection approaches face significant limitations when applied to real-world multimodal mathematical problems. ❶ As shown in Figure 1(a), traditional human-based approaches rely on expert teams to provide detailed corrections. While precise and pedagogically sound, these methods are inherently unscalable and cannot meet the growing demand for personalized feedback in digital learning environments (Li et al., 2024c). ❷ As illustrated in Figure 1(b), MLLM-centric approaches, despite their computational scalability, exhibit suboptimal performance in mathematical image comprehension. For instance, symbolic representations in diagrams (*e.g.,* misaligned coordinate systems) or mismatched text-image pairs (*e.g.,* inconsistent geometric labels) often evade detection by MLLMs, leading to false predictions in error detection (Lu et al., 2023; Zhang et al., 2024).

To address these challenges, we propose and deploy **MATHAGENT, a novel Mixture-of-Math-Agent framework specifically designed for multimodal mathematical error detection**. Drawing inspiration from expert-guided problem-solving practices (Chen et al., 2025b; Li et al., 2024a), our framework decomposes the error detection workflow into three synergistic agents (refer to Figure 1(c)): an *image-text consistency validator* to detect semantic consistency, a *visual semantic interpreter* to extract structured expression from visual part of the problem, and an *integrative error analyzer* that correlates all text-based inputs to pinpoint error locations and categorize misconception types. By explicitly modeling the interdependencies between textual problem formulations, visual mathematical objects, and solution steps, MATHAGENT overcomes the aforementioned challenges inherent in both human-driven and MLLM-based approaches while maintaining computational tractability for real-world deployment.

Our contributions can be summarized as follows:

❶ We introduce MATHAGENT, the **first agent-based framework specifically designed for multimodal mathematical error detection**. Unlike previous paradigms that struggle with scalability, visual comprehension, and complex reasoning, MATHAGENT leverages a novel mixture-of-agents approach, decomposing the task into multiple subtasks via specialized mathematical agents.

❷ We validate our approach on **data sampled from a real educational platform**, demonstrating performance improvements over baseline models. MATHAGENT achieves approximately 5% higher accuracy in error step identification and 3% higher accuracy in error categorization, confirming its effectiveness in practical educational settings.

❸ MATHAGENT has been successfully **deployed in an educational platform that has served over one million K-12 students**. The system has achieved nearly 90% student satisfaction rates while yielding estimated cost savings of approximately one million dollars by reducing the need for manual error detection, demonstrating both its practical utility and economic value.

2 Related Work

2.1 Mathematical Error Detection

Mathematical error detection has evolved significantly from traditional rule-based systems to more sophisticated AI approaches (Li et al., 2024c; Yan et al., 2024a). Early work focused on predefined error patterns and procedural mistakes in specific mathematical domains, such as arithmetic operations or algebraic manipulations (Rushton, 2018). With the advent of deep learning, researchers develop models capable of identifying more complex conceptual misunderstandings by analyzing student solution processes (Xu et al., 2024a). Recent advances have leveraged LLMs to provide more nuanced error analysis and feedback generation, demonstrating promising results in understanding diverse student reasoning patterns (Gao et al., 2024; Li et al., 2024d, 2025a). However, most existing research has primarily focused on text-based settings, with *limited focus on multimodal contexts* where visual elements play a crucial role in problem representation (Yan et al., 2024b). MATHAGENT extends the frontier of mathematical error detection by specifically addressing the challenges of multimodal mathematical reasoning, introducing a specialized agent-based framework.

2.2 Agent for Mathematical Reasoning

The application of agent-based approaches to mathematical reasoning has gained significant traction in recent years (Chu et al., 2025). Initial efforts focused on single-agent systems that could execute

predefined mathematical operations or follow structured solution procedures (Mei et al., 2024; Mitra et al., 2024). As LLMs advanced, researchers developed more sophisticated agents capable of step-by-step reasoning, self-verification, and even multi-step planning for complex mathematical problem-solving (Li et al., 2024b; Wu et al., 2023b; Xiong et al., 2024). Recent work has explored multi-agent frameworks where specialized agents collaborate on different aspects of mathematical reasoning, such as problem decomposition, solution planning, and verification (Gou et al., 2023; Xu et al., 2024b; Zhang et al., 2025). However, existing agent-based systems for mathematical reasoning have *primarily focused on problem-solving rather than error detection*, and few have adequately addressed the unique *challenges posed by multimodal mathematical content*. Our MATHAGENT represents a significant advancement in this domain by introducing a coordinated multi-agent system specifically designed for multimodal mathematical error detection.

See more related work in Appendix A.

3 Our Proposed MATHAGENT

3.1 Task Setting

We evaluate the framework's capability for multimodal error detection. The evaluation set contains N samples. For each sample i, input $\mathcal{I}_i$ includes:

- $Q_{\text{text},i}$: The textual problem statement.
- $Q_{\text{image},i}$: The visual part of the problem.
- $A_{\text{correct},i}$: The correct solution.
- $A_{\text{incorrect},i}$: An incorrect student solution.
- $\{S_{k,i}\}_{k=1}^{n_i}$: A sequence of n_i steps representing the student's step-by-step solution.

We define two subtasks as follows:

Subtask 1: Error Step Identification. The goal is to identify the index, x_i, of the *first* incorrect step in the solution sequence $\{S_{k,i}\}$. Formally:

$$x_i = \arg\min_k \{k \mid S_{k,i} \text{ is incorrect}\}$$

Subtask 2: Error Categorization. The goal is to classify the *type* of error into one of five categories based on the first incorrect step: VIS (Visual Perception), CAL (Calculation), REAS (Reasoning), KNOW (Knowledge), and MIS (Misinterpretation). The error category is denoted as $C_{\text{error},i}$. See details of error categories in Appendix B.

We use accuracy to evaluate performance.

- **Error Step Identification Accuracy:**

$$\text{Acc}_{\text{step}} = \frac{1}{N}\sum_{i=1}^{N} \mathbb{I}(x_i = G_{\text{step},i})$$

where $G_{\text{step},i}$ is ground truth index of the first incorrect step, and $\mathbb{I}$ is the indicator function.

- **Error Categorization Accuracy:**

$$\text{Acc}_{\text{cate}} = \frac{1}{N}\sum_{i=1}^{N} \mathbb{I}(C_{\text{error},i} = G_{\text{error},i})$$

where $G_{\text{error},i}$ is ground truth error category.

3.2 Framework Overview

Our MATHAGENT framework is designed for real-world multimodal mathematical error detection. As illustrated in Figure 2, the framework takes as input a multimodal mathematical problem (text and image), a correct answer, a student's incorrect answer, and their solution steps. The output is the identified error step and the corresponding error category. The framework operates in three sequential phases: Image-Text Consistency Verification (Sec.3.3), Question Type-Driven Visual Semantic Conversion (Sec.3.4), and Multimodal Information Integration (Sec.3.5). Each phase employs a specialized agent to perform a specific task.

3.3 Phase 1: Image-Text Consistency Verification

Motivation. Recent studies have demonstrated that MLLMs often exhibit lower performance in multimodal mathematical reasoning tasks when the image and text information are highly redundant (Lu et al., 2023; Zhang et al., 2024). This phenomenon highlights the current limitations of MLLMs in visual understanding and multimodal semantic alignment (Li and Tang, 2024; Wu et al., 2024). Furthermore, in real-world educational settings, adaptively identifying high image-text consistency can improve efficiency, allowing us to bypass subsequent processing steps and directly proceed to error detection for highly overlapping problems.

Methodology. We introduce the *Image-Text Consistency Validator*. This agent takes the image and the textual description of the problem as input. It outputs a binary decision: whether the image and text are highly semantically consistent. The agent automatically determines the extent of semantic similarity between the image and text. Our system defaults to using GPT-4o[1] as the agent

[1]We used gpt-4o-2024-11-20.

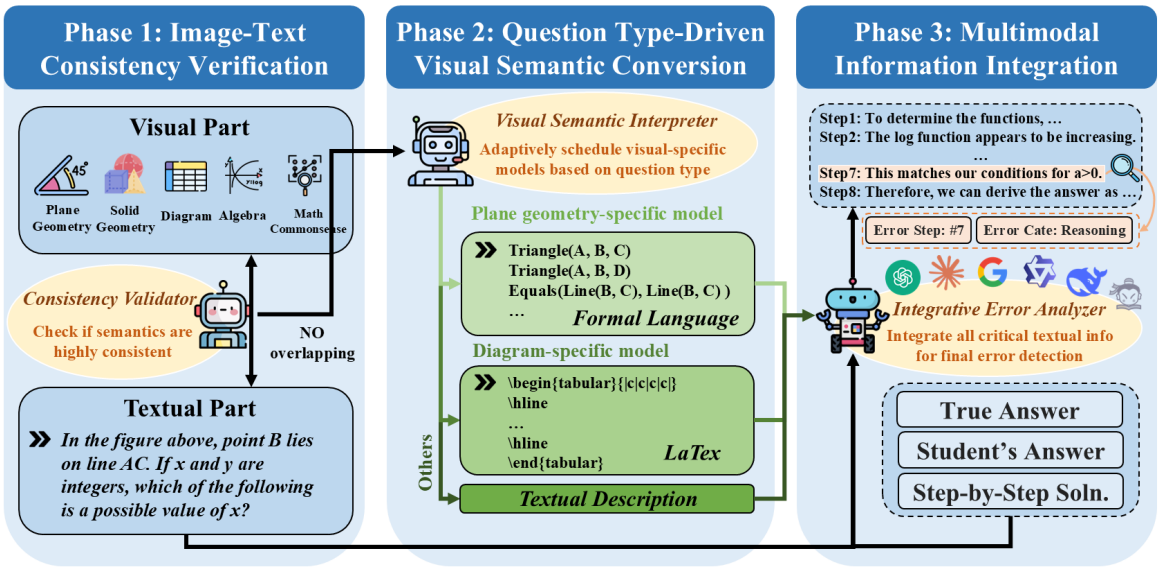

Figure 2: The framework of our proposed Mixture-of-Math-Agent for multimodal mathematical error detection.

for this phase. For example, if the image depicts a triangle with labeled angles and the text describes the same triangle and angles, the validator would output "highly consistent."

3.4 Phase 2: Question Type-Driven Visual Semantic Conversion

Motivation. If the image and text information are not highly overlapping, we need an effective way to extract visual information for subsequent error detection. Inspired by recent advances in symbolic reasoning (Alotaibi et al., 2024; Li et al., 2025b; Sullivan and Elsayed, 2024), we propose that MLLMs can adaptively dispatch specialized visual models based on the question type to convert visual information into a textual format. In particular, multimodal plane geometry problems, with their well-defined geometric relationships, are well-suited for conversion into formal language. Multimodal diagram problems, often involving tables or charts, are best represented using LaTeX. Other types are converted into textual descriptions.

Methodology. We propose the *Visual Semantic Interpreter*. This agent takes the image and the question type as input, and its output is a text-based representation of the visual information, tailored to the specific question type. The agent first determines the question type (*e.g.,* plane geometry, diagram, algebra) and then selects the appropriate conversion method. Our system defaults to using corresponding visual-specific models[2] as the agent for this phase. For instance, if the image is identified as a plane geometry setting, the interpreter might output a formal language representation like "Triangle(A, B, C), Angle(BAC, 45), Line(AB, 5)."

3.5 Phase 3: Multimodal Information Integration

Motivation. Based on the extracted visual information from the previous phase, a comprehensive integration of all available information is crucial for accurate error localization. This phase must combine the problem's content, the student's incorrect answer, and their reasoning steps to pinpoint the cause of the error. The agent in this phase is directly responsible for the output of the two subtasks: error step identification and error categorization. Our system is designed to be compatible with any MLLM for inference, leveraging the increasingly powerful information integration capabilities of modern LLMs (An et al., 2024).

Methodology. We introduce the *Integrative Error Analyzer*. This agent takes as input the problem's textual description, the converted visual information, the true answer, the student's answer, and the student's step-by-step solution. It outputs the identified error step and the error category. The agent first integrates all textual information and then analyzes the student's solution step-by-step, comparing it against the correct solution path. The agent for this phase is a flexibly selectable MLLM. For example, given a student's incorrect calculation in a geometry problem, the analyzer might output "Error Step: #3" and "Error Category: Calculation".

[2]Refer to Appendix C for details.

Table 1: Main result of baseline MLLMs and corresponding MATHAGENT framework. We denote STEP and CATE for error step identification and error categorization, the two subtasks of error detection, respectively, in Section 4.2.

Model	Error Step Identification	Error Categorization						Average

4 Experiment

4.1 Experiment Settings

Dataset. The dataset consists of a carefully curated collection of 2,500 multimodal mathematical questions sourced from real student problem-solving data on educational platforms. Each entry in this evaluation dataset has been meticulously selected by educational experts to ensure high quality, free from issues such as erroneous question design. The student responses represent the most frequent incorrect answers corresponding to each question. Furthermore, the erroneous steps and error category labels for each question have been determined through discussions among at least three experienced educational specialists. The dataset predominantly features plane geometry problems, supplemented by solid geometry, diagrams, algebra, and mathematical commonsense questions. Refer to Appendix D for more dataset details.

Models. We select representative MLLMs (See sources in Appendix E) that have demonstrated effectiveness in recent studies (Wang et al., 2024a; Yan et al., 2024b; Zhang et al., 2024): InternVL-2 76B (Chen et al., 2024), LLaVA-NEXT 72B (Liu et al., 2024a), Qwen-VL-Max (Team, 2024), Claude-3.5-Sonnet (Anthropic, 2024), Gemini-Pro-1.5 (Reid et al., 2024), and GPT-4o (OpenAI, 2024). These MLLMs are already deployed on the educational platform, allowing for a direct comparison of the gains achieved by MATHAGENT. In our experiments, directly applying each MLLM to error detection serves as a baseline. We then evaluate the effectiveness of the MATHAGENT framework by systematically decomposing the complex reasoning task, with the agent in Phase 3 retaining the baseline MLLM. Additionally, we engage evaluators with a background in education to conduct corresponding human evaluations, aiming to assess the gap between MLLM and human-level intelligence.

4.2 Experimental Results & Analysis

Overall Performance Improvement with MATHAGENT. As shown in Table 1, MATHAGENT demonstrates significant performance improvements across both STEP and CATE subtasks. When integrated with various baseline MLLMs, MATHAGENT consistently enhances their error detection capabilities, with an average improvement of 4.2% across all models. Specifically, the framework boosts GPT-4o's performance from 54.09% to 57.30% (3.2% increase) and shows similar improvements for other models. This consistent enhancement across diverse architectures suggests that MATHAGENT can address inherent challenges in multimodal mathematical error detection by systematically processing multimodal information.

Differential Impact on STEP vs. CATE Tasks. The MATHAGENT framework yields more substantial improvements in STEP compared to CATE. Across all tested models, MATHAGENT achieves an average improvement of 5.2% in STEP tasks, while the enhancement for overall CATE tasks is 3.2%. For instance, GPT-4o shows a 4.4% improvement in STEP but only a 2.0% improvement in CATE. This difference likely stems from MATHAGENT 's information extraction and integration, which particularly benefits the error localization in sequential solution steps, while the more nuanced task of error categorization remains challenging.

Category-Specific Performance Variations.

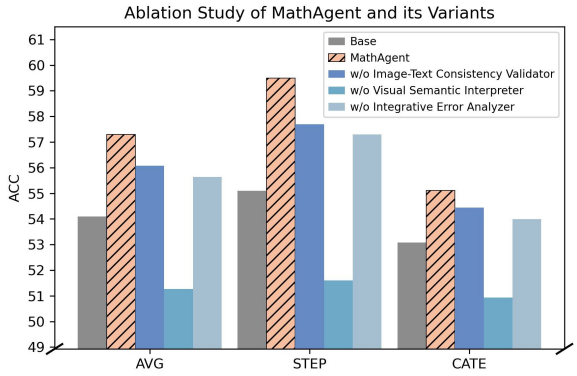

Figure 3: Ablation study of MATHAGENT.

MATHAGENT demonstrates the most significant improvements in detecting VIS and MIS, with average enhancements of 5.6% and 5.9% respectively across all models. For example, Gemini-Pro-1.5 shows a remarkable 6.6% improvement in VIS and 8.0% in MIS categories when augmented with MATHAGENT. In contrast, improvements in CAL, REAS, and KNOW are more modest at 1.2%, 0.4%, and 2.1% respectively. This pattern highlights MATHAGENT 's effectiveness in addressing multimodal integration challenges, as VIS and MIS errors fundamentally involve misalignments between visual information and problem interpretation.

Gap Between MATHAGENT and Human Performance. Despite the notable improvements, MATHAGENT still falls short of human-level performance in mathematical error detection. The best-performing MATHAGENT-enhanced framework (GPT-4o at 57.30%) remains significantly below human performance (76.91%). The persistent performance gap underscores the inherent complexity of mathematical error detection, which requires sophisticated reasoning abilities, domain knowledge, and multimodal understanding.

4.3 Ablation Study

As depicted in Figure 3, we evaluate performance of our MATHAGENT framework and its ablative variants, using GPT-4o with the best overall performance as the base setting. We investigate three variants: (i) *w/o Image-Text Consistency Validator*, which bypasses consistency check and processes all images in Phase 2; (ii) *w/o Visual Semantic Interpreter*, which replaces question type-driven visual model scheduling with a unified captioning approach for all images; and (iii) *w/o Integrative Error Analyzer*, which simply concatenates transcribed image information with student's solution steps and answer, omitting the integration with the problem's textual description. The results demonstrate that MATHAGENT achieves the highest accuracy on both STEP and CATE tasks. Notably, the w/o Visual Semantic Interpreter variant exhibits the lowest performance, presumably because generic descriptions of abstract geometric images may omit crucial details like edge lengths and angle measures. Removing the Image-Text Consistency Validator also leads to a performance drop, suggesting that discrepancies between potentially flawed image transcriptions and textual problem description can introduce contradictory information, negatively impacting the complex reasoning process.

5 Industrial Impact

Error Detection Performance Enhancement in Real-World Educational System. When deployed in educational platforms, MATHAGENT has demonstrated remarkable improvements in error detection performance that directly translate to educational value. As a diagnostic tool, MATHAGENT provides more precise feedback on student work, enabling targeted interventions. Furthermore, MATHAGENT 's adaptive architecture optimizes computational resources by automatically filtering problems based on image-text consistency and selecting specialized visual models according to problem types.

Student Satisfaction Rate Improvement. A/B testing conducted on the educational platform reveals significant improvements in student satisfaction with MATHAGENT-powered feedback systems. In a controlled study involving 10,000 K-12 students, MATHAGENT-enhanced feedback received an over 90% satisfaction rating, compared to 75% for traditional MLLM-based feedback. These improvements in student experience demonstrate MATHAGENT 's effectiveness as a pedagogically valuable tool that enhances the learning process.

We discuss more impact in Appendix F.

6 Conclusion

This paper presented MATHAGENT, a novel and effective framework for multimodal mathematical error detection in real-world educational settings. By leveraging a mixture-of-agent approach, MATHAGENT overcomes the limitations of existing human-based and MLLM-centric methods, achieving superior performance in identifying and categorizing student errors. The successful deployment of MATHAGENT on a large-scale educational platform, with improvements in accuracy, student satisfaction, and cost-effectiveness, underscores its significant technical and practical value.

Limitations

Despite the contributions demonstrated in our work, several limitations remain:

1. The effectiveness of MATHAGENT is contingent on the quality of the multimodal inputs. Poorly formatted or ambiguous problems may lead to inaccurate error detection. We will enhance our engineering pipeline to improve data cleaning and optimization processes, ensuring that input data is standardized and of high quality, which will lead to more accurate error detection.

2. While MATHAGENT improves error detection accuracy, it may still struggle with a broader range of error categories beyond the five specified. We will collaborate with educational experts to develop a more comprehensive framework of error categories that aligns with student needs and encompasses a wider variety of mathematical errors.

3. MATHAGENT does not incorporate recent advancements in o1-like slow-thinking reasoning, which may enhance the depth of error analysis but could impact user feedback time in deployed systems. In the future, we will explore integrating user intent recognition to adaptively schedule fast and slow reasoning modes, providing students with comprehensive and timely error analysis based on their needs.

A More Related Work

A.1 Multimodal Large Language Model

Current MLLMs adopt a similar framework, including a vision encoder, a connector, and an LLM backbone, which was initially proposed by LLaVA (Liu et al., 2024b). By training these components via visual instruction tuning, the vision embeddings extracted by the vision encoder are aligned with the word space of LLM through the connector (Raiaan et al., 2024; Shao et al., 2024). Such a framework enables MLLMs to understand visual input such as images and video, while preserving the powerful reasoning and generation abilities of autoregressive LLMs (Deng et al., 2025). As a result, some MLLMs achieve state-of-the-art performance across a wide variety of multimodal tasks such as visual question answering (Mañas et al., 2024; Xiao et al., 2025), image captioning (Bianco et al., 2023; Patel et al., 2025), video understanding (Huang et al., 2024; Zhou et al., 2024b), and more diverse tasks (Huo et al., 2024; Yan and Lee, 2024). On the other hand, with the development of o1-like systems in LLMs (Jaech et al., 2024; Li et al., 2025c; Zhong et al., 2024), there is also a tendency to trigger the slow-thinking potentials of MLLMs (Yang et al., 2025b; Yao et al., 2024; Zhao et al., 2025). For example, Virgo (Du et al., 2025) makes a preliminary exploration of multimodal slow-thinking systems by directly fine-tuning a capable MLLM with a small amount of textual long-form thought data, while Vision-o1 (Ni et al., 2024) proposes a multimodal multi-turn chain-of-thought framework to simulate human reasoning for MLLMs on ambiguous instructions. Furthermore, LlamaV-o1 (Thawakar et al., 2025) uses a multiturn curriculum learning approach to facilitate MLLMs in incremental skill acquisition and problem-solving. Despite these efforts, the development of o1-like multimodal systems is still in its stages (Chen et al., 2025c; Masterman et al., 2024; Xu et al., 2025), with significant problems such as overthinking (Cuadron et al., 2025; Yang et al., 2025a), safety (Chen et al., 2025a; Huo et al., 2025; Zhao et al., 2024), and hallucination (Sun et al., 2025; Zheng et al., 2024b; Zhou et al., 2024a).

B Error Category Details

The discrepancies within the five error categories are delineated as follows:

✯ **Visual Perception Errors (VIS)**: These errors arise when there is a failure to accurately interpret the information contained within images or diagrams presented in the question due to visual issues.

✯ **Calculation Error (CAL)**: These errors manifest during the calculation process, which may include arithmetic mistakes such as incorrect addition, subtraction, multiplication, or division, errors in unit conversion, or mistakes in the numerical signs between multiple steps.

✯ **Reasoning Error (REAS)**: These errors occur during the problem-solving process when improper reasoning is applied, leading to incorrect application of logical relationships or conclusions.

✯ **Knowledge Error (KNOW)**: These errors result from incomplete or incorrect understanding of the knowledge base, leading to mistakes when applying relevant knowledge points.

✯ **Misinterpretation of the Question (MIS)**: These errors occur when there is a failure to correctly understand the requirements of the question or a misinterpretation of the question's intent, leading to responses that are irrelevant to the question's demands. For instance, if the question asks for a letter and a number is provided, or vice versa.

C Visual-Specific Models

In our deployed system, we employ specialized models tailored to different problem types to ensure optimal performance. For plane geometry problems, we utilize Inter-GPS[3], a groundbreaking geometry problem solver developed by Lu et al. (2021). As the first system capable of automatic program parsing and interpretable symbolic reasoning, Inter-GPS demonstrates its effectiveness through dual-channel processing: it employs rule-based text parsing for textual analysis and neural object detection for diagram interpretation, seamlessly converting problem texts and diagrams into formal language representations. Furthermore, its integration of theorem knowledge as conditional rules enables systematic, step-by-step symbolic reasoning.

When addressing diagram-based problems, particularly those involving tabular data, we imple-

[3]https://github.com/lupantech/InterGPS

ment StructTable-InternVL2-1B[4], a sophisticated model developed by Xia et al. (2024). This end-to-end solution, known as StructEqTable, excels in visual table processing by accurately generating LaTeX descriptions from table images while simultaneously supporting multiple advanced functionalities, including structural extraction and question-answering capabilities, thereby significantly expanding its practical applications.

For general visual content processing beyond these specialized domains, we leverage the vit-gpt2-image-captioning model[5] to generate comprehensive and detailed image captions, ensuring robust performance across diverse visual understanding tasks.

D Dataset Details

D.1 Dataset Statistics

Our evaluation dataset comprises 2,500 multimodal mathematical questions spanning diverse problem types and error categories. As illustrated in Figure 4, the dataset is predominantly composed of Plane Geometry problems (62.4%), followed by Algebra (11.5%), Diagram problems (9.3%), Math Commonsense (9.2%), and Solid Geometry (7.6%). This distribution reflects the prevalence of geometry-based problems in mathematical education that benefit significantly from visual representation and analysis.

The dataset captures a wide spectrum of error categories that students commonly encounter. Reasoning Errors constitute the largest proportion at 38.0%, highlighting the challenges students face in logical deduction and proof construction. Calculation Errors account for 36.5% of the dataset, representing arithmetic mistakes and computational inaccuracies. Visual Perception Errors make up 15.8%, underscoring the importance of correctly interpreting visual elements in mathematical problem-solving. Knowledge Errors and Misinterpretation of Questions represent smaller but significant portions at 4.8% and 4.9% respectively.

The complexity of the problems is reflected in the reasoning steps required for solution, with an average of 7.6 steps per problem, ranging from a minimum of 3 to a maximum of 20 steps. The textual component of the problems varies considerably in length, averaging 168 characters, with the shortest problem containing just 13 characters and the most verbose extending to 719 characters. This variation in problem complexity and presentation provides a robust benchmark for evaluating MATHAGENT 's performance across different mathematical contexts and difficulty levels.

Statistic	**Number**
Total multimodal questions	2,500
Problem Type	
- Plane Geometry	1559 (62.4%)
- Solid Geometry	191 (7.6%)
- Diagram	233 (9.3%)
- Algebra	288 (11.5%)
- Math Commonsense	229 (9.2%)
Error Category	
- Visual Perception Error	395 (15.8%)
- Calculation Error	912 (36.5%)
- Reasoning Error	951 (38.0%)
- Knowledge Error	119 (4.8%)
- Misinterpretation of the Qns	123 (4.9%)
Average Reasoning Step	7.6
Maximum Reasoning Step	20
Minimum Reasoning Step	3
Average Question Length	168
Maximum Question Length	719
Minimum Question Length	13

Figure 4: Key statistics of dataset.

D.2 Data Source

The data used in this study originates from a real-world online education platform, ensuring its relevance and applicability to practical educational scenarios. This dataset is not synthetically generated; instead, it comprises authentic student submissions, including both correct and incorrect solutions. This provides a realistic representation of the types of errors students commonly make in a learning environment. Furthermore, the data includes a diverse range of mathematical problems, reflecting the breadth of topics covered in K-12 mathematics curricula. The use of real-world data enhances the ecological validity of our findings and ensures that the MATHAGENT framework is evaluated on data that closely resembles the challenges encountered in actual educational settings. The platform anonymizes all student data to protect privacy, while preserving the integrity and richness of the information needed for effective error detection and analysis.

F More Industrial Impact

We discuss more industrial impact of MATHAGENT as follows:

Cost Savings and Resource Optimization. Based on industry standards where expert mathematical error annotation costs approximately $1 per problem, MATHAGENT has generated estimated savings of $1.2 million annually. This calculation is derived from serving approximately 120,000 students, each of whom receives feedback on an average of 10 complex mathematical problems per month. Additionally, the system reduces teacher workload by an estimated 4.7 hours per week, allowing educators to focus on higher-value instructional activities rather than routine error identification. This translates to significant time savings, which can be redirected towards personalized instruction, curriculum development, or professional development. This efficiency gain is particularly important as online learning platforms scale to serve larger student populations.

Learning Outcome Acceleration. Longitudinal studies tracking student performance before and after MATHAGENT implementation show measurable improvements in learning outcomes. Students receiving MATHAGENT-powered feedback demonstrated a 23% faster mastery rate of complex mathematical concepts compared to control groups. This accelerated learning trajectory is attributed to the system's ability to provide immediate, precise feedback on mathematical errors, allowing students to correct misconceptions earlier in their learning process. The educational impact is particularly pronounced in traditionally underserved school districts, where access to expert mathematics teachers is limited, helping to narrow the achievement gap in STEM education.

Teacher Professional Development Enhancement. Beyond student-facing benefits, MATHAGENT serves as a powerful professional development tool for mathematics educators. By analyzing patterns in student errors across classrooms, the system generates insights into common misconceptions and learning obstacles that inform teaching strategies. Teachers report that these insights have transformed their instructional approaches, with 20% indicating they have modified their teaching methods based on MATHAGENT 's analytics. Furthermore, the system serves as a model for teachers to improve their own feedback practices, with educators reporting a 32% increase in confidence when providing mathematical explanations after using the system for one semester. This "teach the teacher" effect creates a virtuous cycle where both student learning and teacher effectiveness continually improve.

Towards Multi-System Log Anomaly Detection

Abstract

Despite advances in unsupervised log anomaly detection, current models require dataset-specific training, causing costly procedures, limited scalability, and performance bottlenecks. Furthermore, numerous models lack cognitive reasoning abilities, limiting their transferability to similar systems. Additionally, these models often encounter the **"identical shortcut"** predicament, erroneously predicting normal classes when confronted with rare anomaly logs due to reconstruction errors. To address these issues, we propose **MLAD**, a novel **M**ulti-system **L**og **A**nomaly **D**etection model incorporating semantic relational reasoning. Specifically, we extract cross-system semantic patterns and encode them as high-dimensional learnable vectors. Subsequently, we revamp attention formulas to discern keyword significance and model the overall distribution through vector space diffusion. Lastly, we employ a Gaussian mixture model to highlight rare word uncertainty, optimizing the vector space with maximum expectation. Experiments on real-world datasets demonstrate the superiority of MLAD [1].

1 Introduction

Logs play a vital role in system maintenance by recording operations and outcomes that can reveal abnormal behavior. Data-driven log analysis techniques have been widely used to automatically detect anomalies in system behavior (Du et al., 2017a; Chandola et al., 2009; Meng et al., 2019a; Guo et al., 2024). However, most log anomaly detection models are designed for a single system, following a **"one model for one system"** approach (Yu et al., 2024; Su et al., 2024; Guo et al., 2023b), as shown in Fig.1(a). This siloed training limits generalization and fails to capture patterns common across different systems.

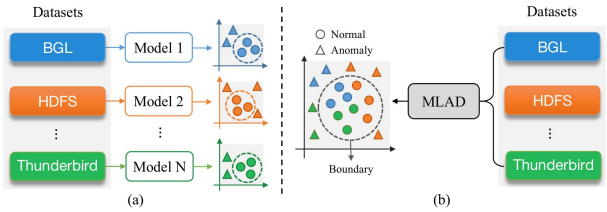

Figure 1: Multi-system log anomaly detection task. (a) Existing models learn separate decision bounds for different object logs. (b) We model the multi-system log distributions so that a single bound can detect anomalies.

Integrating log data from multiple systems offers the potential to uncover anomalous patterns hidden in isolated datasets. In practice, though, new systems often lack sufficient log data to train reliable models, leading to delayed deployment and missed anomalies (Landauer et al., 2024). Existing methods also tend to overlook deeper semantic features (Wang et al., 2017; Guo et al., 2023a) shared across systems. As a result, similar anomalies, such as repeated error or warning messages, occurring across different system logs may remain undetected.

To address these challenges, we introduce MLAD—a generalized log anomaly detection model designed for multiple systems, as illustrated in Fig.1(b). MLAD learns a unified decision boundary to classify normal and abnormal events across all systems, rather than maintaining separate models per system. Unlike reconstruction-based methods that can misclassify anomalies due to the "identical shortcut" (You et al., 2022) effect, where rare abnormal logs are reconstructed too well and thus labeled normal (Yao et al., 2024), MLAD avoids this pitfall. It employs a deflationary transformation of the vector space to amplify distinctions between normal and abnormal log samples. This transformation clusters similar log entries together

July 28-30, 2025

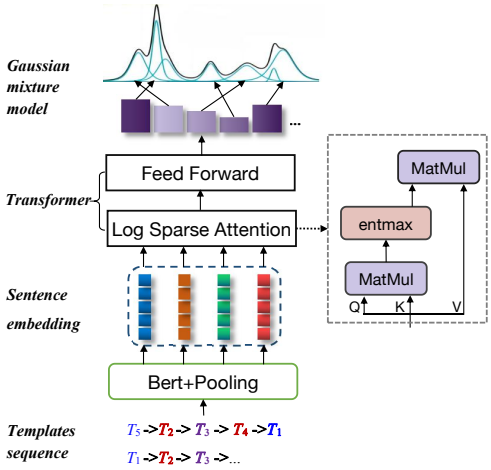

Figure 2: The architecture of our proposed MLAD.

while pushing normal and anomalous logs farther apart, making anomalies easier to isolate.

MLAD combines a Transformer (Vaswani et al., 2017) and a Gaussian Mixture Model (GMM) (Zong et al., 2018; Vilnis and McCallum, 2015) in a unified architecture. The Transformer component learns rich semantic representations of log sequences, capturing context and reducing reconstruction error (Ma et al., 2024). The GMM component functions as a robust probabilistic classifier for distinguishing normal from anomalous log instances. We train the Transformer and GMM jointly, which minimizes encoding errors and yields more precise anomaly detection. Our contributions are:

- **Multi-System Anomaly Detection.** Introduces a new model for detecting anomalies across multiple systems, overcoming the limitations of traditional one-model-per-system methods.
- **Hybrid Transformer–GMM Architecture.** Integrates Transformers with GMMs, jointly learning semantic log representations while preserving clear separation between normal and abnormal events.
- **Addressing "Identical Shortcut".** Mitigates the identical shortcut problem by transforming the vector space, which effectively separates abnormal samples from normal ones based on learned distance relationships.
- **Improved Performance.** Extensive experiments on real-world log datasets show that MLAD outperforms state-of-the-art anomaly detection approaches.

2 Related Work

Traditional log anomaly detection methods use manual rules or statistical approaches like SVD (Mahimkar et al., 2011), ARIMA (Zhang et al., 2005), and variants. While effective to some extent, these models are noise-sensitive and parameter-sensitive (Chen et al., 2023a), limiting practical applications. Recent models leverage deep learning networks (Du et al., 2017b; Han and Yuan, 2021; Zhang et al., 2022). Du et al. proposed DeepLog (Du et al., 2017b), an LSTM architecture for identifying anomalous log message sequences. LogAnomaly (Meng et al., 2019b) improves on DeepLog by using log sequence embedding rather than template sequences. Zhang et al. introduced LogRobust (Zhang et al., 2019), an attention-based Bi-LSTM model for anomaly detection. Huang et al. (Huang et al., 2020) employed hierarchical transformers to model both log template sequences and parameter values. LogBERT (Guo et al., 2021) predicts masked log keys, positioning normal logs close together in embedding space.

3 MLAD

We introduce MLAD, as depicted in Figure 2, a hybrid model trained on log sequences using unsupervised tasks to automatically detect anomalies.

3.1 Problem Definition

System logs contain unstructured messages with fields like timestamp and severity, exhibiting sequential patterns and semantic relationships. We extract templates using the Drain parser (He et al., 2017), as shown in Figure 3. For example, the BGL log template "exception syndrome register: <>" comes from "exception syndrome register: 0x008000", where <> indicates variable parameters. We map each template to a key, creating sequences $T = [T_1, T_2, \ldots, T_i, \ldots, T_N]$, where $T_i \in \mathbb{T}$ is the template key at position i, and $\mathbb{T}$ is the set of N template sequences from system logs. Our model identifies abnormal template sequences by training only on normal log sequences.

3.2 Feature Extractor

For semantic template relation learning, we use pre-trained Sentence-Bert (Reimers and Gurevych, 2019) to obtain template sequence representations and MEAN pooling (Reimers and Gurevych, 2019) to compress vectors into fixed dimension d embeddings. This prevents information loss from log parsing errors and facilitates single- or multi-system log

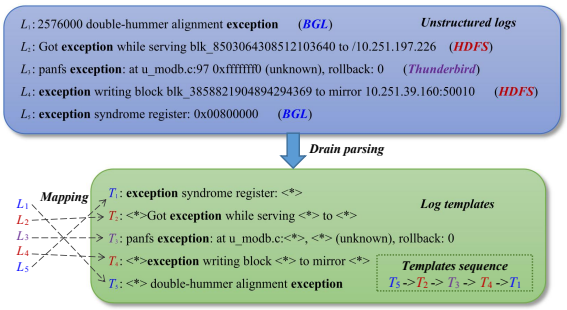

Figure 3: Log processing flow.

fusion. Each sequence $T \in \mathbb{R}^{l \times d}$ forms template vectors in high-dimensional vector spaces.

3.3 Sparse Log Self-attention

Self-attention encodes template sequence vectors by associating words based on pairwise similarity function $f(\cdot,\cdot)$. We use linear projection T to acquire query Q, key K, and value V, and adopt Scaled DotProduct Attention (Vaswani et al., 2017) with sparse transformation:

$$\begin{aligned} Q,K,V &= TW_q, TW_k, TW_v, \\ h &= \text{Attention}(Q,K,V) = \alpha\text{-entmax}\left(\frac{QK^\top}{\sqrt{d}}\right)V, \end{aligned} \tag{1}$$

where learnable weights $\{W_q, W_k, W_v\} \in \mathbb{R}^{d \times d}$, $\sqrt{d_k}$ is a scaling factor, Q of Eq. 1 is the query representation matrix, K is the key matrix, and V is the values matrix. The sparse transformation (Peters et al., 2019) increases attention weight differences to accurately learn keyword embedding vectors. Weight values follow the function:

$$\begin{aligned} \alpha\text{-entmax}(x) &= \underset{p \in \Delta^{d-1}}{\text{argmax}} \left(p^\top x + H_\alpha^\top(p)\right), \\ H_\alpha^\top(p) &= \begin{cases} \frac{1}{\alpha(\alpha-1)} \sum_j \left(p_j - p_j^\alpha\right), & \alpha \neq 1, \\ H^\top(p), & \alpha = 1, \end{cases} \end{aligned} \tag{2}$$

where $H_\alpha^\top(p)$ is Tsallis α-entropies (Tsallis, 1988), parameterized by scalar $\alpha > 1$. From Eq. 2, the softmax function equals 1-entmax, with Shannon and Gini entropy as regularizers. Parameter α controls shape and sparsity, as shown in Figure 4. When $1 < \alpha < 2$, the function produces sparse probability distribution with smooth corners. Traditional softmax (Bridle, 1989) has small slope at 0.5, making weight values dense around 0.5 when word count is high, reducing word differentiation and hindering keyword identification.

3.4 Feed-Forward Network

We apply a fully connected Feed-Forward Network (FFN) to each position to add nonlinearity and consider latent dimension interactions. FFN includes

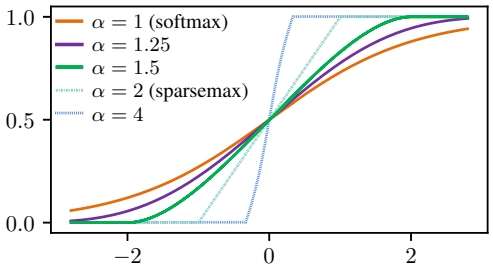

Figure 4: An illustration of the α-entmax function in a two-dimensional space.

two linear transformations with Continuously Differentiable Exponential Linear Unit (CeLU) (Barron, 2017) activation:

$$\begin{aligned} \text{FFN}(h) &= \text{CeLU}(hW_1 + b_1)W_2 + b_2, \\ \text{CeLU}(x) &= \max(0,x) + \min(0, \alpha * (\exp(x/\alpha) - 1), \end{aligned} \tag{3}$$

where W_1, W_2, b_1, and b_2 are parameters. CeLU$(\cdot)$ provides smoother transition than ReLU$(\cdot)$, improving generalization. We use normalization and dropout to prevent overfitting.

3.5 Gaussian Mixture Model

For anomaly detection, we use GMM with Expectation-Maximization (EM) algorithm (Huber and PeterJ, 2009). GMM excels in label-free learning but struggles with large-scale data (Zong et al., 2018). Transformers encode large-scale data and learn high-dimensional features effectively. By adjusting Multi-head Attention layers, we reduce vector space dimensions, addressing the big data limitations of GMM. Transformers face binary classification challenges when loss approaches zero. The α-entmax function maps normal log words to an identity matrix, potentially misclassifying similar abnormal logs. Replacing the decoder of Transformer with GMM enhances vector space differentiation through iterative sample reconstruction, improving normal/abnormal sample distinction. In the EM algorithm's E-step, GMM prior defines distributions on reconstruction function $f(h)$ using Gaussian distributions K. We compute probability $\hat{\phi}_k$ that hidden vector h_i belongs to the k-th Gaussian:

$$\begin{aligned} \hat{y} &= \text{entmax}(hWh + b), \\ \hat{\phi}_k &= \textstyle\sum_{i=1}^{N} \frac{\hat{y}_{ik}}{N}, \end{aligned} \tag{4}$$

where $\hat{y}_i$ indicates anomaly class probability and adjusts the attenuation parameter. Each Gaussian has mean μ (sample location) and covariance Σ. Sentence-BERT uses cosine similarity but overlooks uncertainty (Reimers and Gurevych, 2019) from low-frequency words. In multi-system log detection, imbalance between normal/abnormal sam-

ples exacerbates this issue. We integrate covariance matrix into the loss function to capture uncertainty differences, calculating mean μ and covariance Σ as:

$$\hat{\mu}_k = \frac{\sum_{i=1}^{N} \hat{y}_{ik} h_i}{\sum_{i=1}^{N} \hat{y}_{ik}}, \quad \hat{\Sigma}_k = \frac{\sum_{i=1}^{N} \hat{y}_{ik} (h_i - \hat{\mu}_k)(h_i - \hat{\mu}_k)^\top}{\sum_{i=1}^{N} \hat{y}_{ik}}. \tag{5}$$

In the M-step, we substitute estimated parameters to find the extreme value of the lower bound function, updating parameter values when the derivative equals 0. Sample energy is inferred as:

$$E(h_i) = -\log\left(\sum_{k=1}^{K} \hat{\phi}_k \frac{\exp\left(-\frac{1}{2}(h_i - \hat{\mu}_k)^\top \hat{\Sigma}_k^{-1}(h_i - \hat{\mu}_k)\right)}{\sqrt{|2\pi\hat{\Sigma}_k|}}\right). \tag{6}$$

During testing, sample energy is estimated directly and high-energy samples above threshold are predicted as anomalies.

3.6 Objective Function

For N samples, the objective function is:

$$\text{Loss} = \frac{1}{N}\sum_{i=1}^{N} L(y_i - \hat{y}_i)^2 + \frac{\lambda_1}{N}\sum_{i=1}^{N} E(h_i) + \lambda_2 P\left(\hat{\Sigma}\right), \tag{7}$$

where y is ground truth, with $\lambda_1 = 0.1$ and $\lambda_2 = -0.005$. This function has three components. $L\left(y_i - \hat{y}_i\right)$ quantifies discrepancy between predictions and actual values, reflecting Transformer prediction accuracy. $E\left(h_i\right)$ represents GMM normal probability modeling, minimizing energy for normal samples and maximizing for abnormal ones. $P(\hat{\Sigma})$ addresses the "identical shortcut" issue by incorporating keyword uncertainty into the loss function, with higher uncertainty indicating higher anomaly probability.

4 Experiment

We first describe our experimental setup, compare MLAD with state-of-the-art baselines, and analyze components' roles and multisystem the impact of datasets.

4.1 Datasets and Setting

Experiments use public BGL, HDFS, and Thunderbird datasets (Oliner and Stearley, 2007), detailed in Table 1. For fair comparison, all models use 100-dimensional embeddings, Adam optimizer with 0.001 learning rate, 0.5 dropout rate on NVIDIA A100 (80G), 512 batch size, and 30 maximum epochs.

	BGL	HDFS	Thunderbird
# Log sequences	2,780,580	5,856,609	9,975,120
# Templates	138 (35)	44 (25)	1,291 (243)
# Words	987	118	6,546
# Anomalies	248,560	10,109	2,456,660
# Train data	2,283,460	5,544,398	5,061,800
# Test data	497,120	312,211	4,913,320

Table 1: The Statistics of datasets

4.2 Baselines and Metrics

We compare with DeepLog (Du et al., 2017b), Dagmm (Zong et al., 2018), LogAnomaly (Meng et al., 2019b), LogRobust (Zhang et al., 2019), LogTAD (Han and Yuan, 2021), PLELog (Yang et al., 2021), LogBERT (Guo et al., 2021), CAT (Zhang et al., 2022) and ChatGPT (OpenAI, 2022). As anomaly detection is binary classification (Chen et al., 2022), we use precision, recall and F1 score for evaluation (Chen et al., 2023b).

4.3 Log Pre-Processing

For HDFS, log sequences are extracted by block IDs, while BGL and Thunderbird use a 20-sized sliding window. Logs are parsed with Drain (He et al., 2017), and anomalies are identified by windows with anomalous messages. The test set includes all abnormal sequences and an equal number of random normal ones, while the training set contains the rest. Table 1 summarizes key statistics.

4.4 Performance Comparison

Table 2 shows MLAD outperforming all baselines by combining Transformer and GMM strengths. DeepLog struggles with complex datasets, often misclassifying anomalies. LogAnomaly achieves stable F1 scores using semantic vector-based template matching. LogTAD performs well on smaller datasets but underperforms on Thunderbird due to word-level information loss. Similarly, Dagmm shows inconsistent results, particularly on Thunderbird. LogRobust requires extensive manual labeling, limiting unsupervised performance. PLELog performs poorly on unsupervised datasets with long training times. Transformer-based LogBERT and CAT excel at capturing global dependencies and contextual information. However, no baseline consistently performs well across all datasets, facing precision-recall balance challenges and identical shortcut issues.

5 Ablation

5.1 Effect of Components

Our ablation experiments assessed each component's contribution to model performance (Table 2).

	BGL			HDFS			Thunderbird

Table 3: The transfer performance of the models on two similar datasets (BGL and Thunderbird).

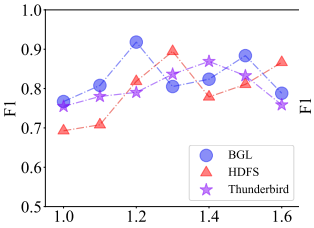

Figure 5: The effect of the $\alpha-$entmax in MLAD.

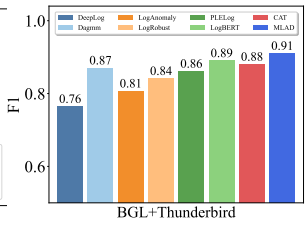

Figure 6: Experiment on multi-system datasets.

Removing the GMM component most significantly degraded performance on BGL and Thunderbird datasets, while having minimal impact on HDFS. This difference correlates with template complexity - BGL (138 templates with 35 in the test only) and Thunderbird (1,291 templates with 243 in the test only) have substantially more templates than HDFS (44 templates with 25 in the test only), demonstrating GMM's importance for learning sparse keyword representations.

We evaluated the effectiveness of $\alpha-$entmax by testing values $\{1.0 \leq \alpha \leq 1.6, \Delta\alpha = 0.1\}$ as shown in Fig. 5. The model performed optimally with α between 1.2-1.5, where $\alpha-$entmax effectively sparsified the dense vector space, enhancing the differentiation between normal and abnormal samples. At α=1 (equivalent to softmax), performance was mediocre, while values above 1.5 introduced excessive sparsity, generating zero-valued keyword weights that caused the model to ignore important features. The sparse transformation remains essential for improving prediction accuracy across tested datasets.

5.2 Effect on Multi-System Datasets

To evaluate cross-system performance, we combined BGL and Thunderbird datasets (both preprocessed using fixed-window mode) into a unified dataset. As shown in Fig. 6, MLAD maintained robust performance while baseline models struggled with the increased generalization requirements of the combined dataset. This highlights the ability of MLAD to detect anomalies that might go unnoticed when systems are analyzed separately. Our ablation experiments revealed that removing Sentence-BERT caused minimal performance degradation on single-system logs but significant losses on multi-source logs. This confirms the importance of sentence-level semantic features for cross-system generalization. The self-attention mechanism effectively captured semantic relationships between words, allowing the model to identify semantically similar anomalous patterns despite different wording. For instance, "error" and "exception" were recognized as semantically related indicators of anomalies, even when followed by different variables.

5.3 Effect of Transferred Knowledge

To validate the model's cross-system performance, we conduct a transfer learning experiment for log anomaly detection using two similar datasets: BGL and Thunderbird. We evaluate the models in terms of Precision and Recall, with results presented in Table 3.

BGL→Thunderbird: Models are trained on BGL and tested on Thunderbird. Dagmm,

DeepLog, and PLELog perform poorly on Thunderbird, with Dagmm failing to detect any anomalies, highlighting its lack of cross-system adaptability. In contrast, LogRobust, LogAnomaly, LogTAD, LogBERT, and CAT exhibit better transfer learning due to effective semantic processing, though their performance is limited by shared words between the two datasets, requiring improved reasoning for unseen terms.

Thunderbird→BGL: Training on Thunderbird and testing on BGL yields better results, primarily due to: (1) Thunderbird's larger dataset, allowing for more comprehensive learning, and (2) the higher proportion of shared words between the two datasets, with BGL containing 261 shared terms, representing a larger portion of its test set compared to Thunderbird.

5.4 Effect of Large Language Model

We evaluated large language models' ability to detect log anomalies using a Chain-of-Thought (Wei et al., 2022) approach rather than direct classification. This two-step process first guides the model to generate templates from log sequences, then identify anomalies based on these templates. Table 4 compares results with and without Chain-of-Thought processing. The findings show that LLMs like ChatGPT struggle with complex log anomaly detection despite the improved reasoning approach. This underperformance stems from their limited domain-specific training and inability to capture the subtle patterns and contextual nuances in system logs. The inherent complexity and variability of operational logs often exceed these models' generalization capabilities.

Method	HDFS	BGL	Thunderbird
ChatGPT w/ CoT	0.7369	0.7221	0.7738
ChatGPT w/o CoT	0.6721	0.6542	0.7132

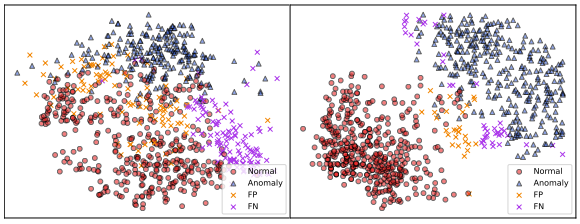
Generation Prompt: Please determine if there are any anomaly in logs, and directly give the answer: Yes or No.

Chain-of-Thought Prompt	
log contents:	2023-08-02 10:30:00 DEBUG: Checking server availability. 2023-08-02 10:30:15 ERROR: NetworkException - Unable to establish connection to server.
Step 1: Log Parsing	
One-Step Prompt:	Extract the templates of *log sequences* while replacing the *variables* with $< * >$
Templates:	1. $< * >$ ERROR: NetworkException - $< * >$ to establish connection to server. 2. $< * >$ DEBUG: Checking server availability.
Step 2: Anomaly Detection	
Two-Step Prompt:	According to the *log sequences*, *Templates:*, the relationship between *Templates:* and *variables*, determine if there are any exceptions in templates and variables, and directly give the answer: Yes or No.
Answer:	Yes or No.



(a) LogAnomaly (b) MLAD

Figure 7: Samples in 2-dimensional space learned by LogAnomaly and MLAD. The red dots • are samples from the normal logs, and the blue triangles △ are samples from the abnormal logs, the orange crosses × (FP) indicate normal samples that the model incorrectly predicts, and conversely, the violet crosses × (FN) indicate abnormal samples that the model incorrectly predicts.

6 Visualization

We evaluated classification performance using t-SNE visualization on 800 balanced BGL samples (normal/abnormal=1:1). As shown in Fig. 7, MLAD achieves clearer class separation than LogAnomaly, which exhibits significant overlap between categories. This improvement is attributed to the α-entmax function's enhanced spatial discrimination capability.

Table 2 reveals two key findings: (1) Removing GMM reduces recall while increasing precision, exposing the Transformer's vulnerability to identical shortcut learning; (2) The 30% lexical gap between training and test sets underscores the persistent challenge of detecting rare keywords in anomaly detection.

7 Conclusion

We propose MLAD, a unified log anomaly detection model combining Transformer and GMM addressing the "identical shortcut" problem. Transformer captures semantic relations, while GMM models complex distributions and handles rare keyword uncertainty through covariance. Experiments on three datasets demonstrate the effectiveness.

Limitations

Hyperparameter Tuning. The hyperparameters used in this study were not fully optimized. Further adjustments and fine-tuning are necessary to better explore the capabilities of model and ensure optimal performance across various experimental settings.

Ethical Considerations

Our method utilizes publicly available log datasets without sensitive user information. However, practical deployment should ensure data privacy and handle potential false alarms carefully to avoid negative impacts on operational reliability.

Abstract

This paper presents a novel approach to e-commerce payment fraud detection by integrating reinforcement learning (RL) with Large Language Models (LLMs). By framing transaction risk as a multi-step Markov Decision Process (MDP), RL optimizes risk detection across multiple payment stages. Crafting effective reward functions, essential for RL model success, typically requires significant human expertise due to the complexity and variability in design. LLMs, with their advanced reasoning and coding capabilities, are well-suited to refine these functions, offering improvements over traditional methods. Our approach leverages LLMs to iteratively enhance reward functions, achieving better fraud detection accuracy and demonstrating zero-shot capability. Experiments with real-world data confirm the effectiveness, robustness, and resilience of our LLM-enhanced RL framework through long-term evaluations, underscoring the potential of LLMs in advancing industrial RL applications.

1 Introduction

The advancement of LLMs has been remarkable, exemplified by notable developments such as the top-notch model API (OpenAI, 2023) and state-of-the-art open-source models (Dubey et al., 2024) (Jiang et al., 2023) (Jiang et al., 2024) (Team et al., 2024) (Guo et al., 2024). These breakthroughs have propelled LLMs to new heights in various tasks, reaching or even surpassing human capabilities in code generation (Chen et al., 2021), logical reasoning (Kojima et al., 2022), and task planning (Shen et al., 2024). The integration of these advanced capabilities into the domain of e-commerce payment fraud detection presents an exciting frontier for exploration.

Meanwhile, RL has shown its effectiveness in optimizing nondifferential goals and innovating decision strategies in response to environmental changes (Sutton and Barto, 2018) (Russell and Norvig, 2010). Its application in the financial fraud risk domain has seen various approaches, from modeling the sequence of transactions from a single credit card to considering each transaction as a discrete step in a MDP (Mead et al., 2018) (Vimal et al., 2021). Other studies have explored the application of RL in fraud risk alerting systems (Shen and Kurshan, 2020) and discussed its potential without detailed propositions (El Bouchti et al., 2017). While supervised learning (SL) remains prevalent in static fraud detection, it struggles to model sequential dependencies between decision stages and directly optimize business metrics like precision-recall tradeoffs – limitations that RL naturally addresses through reward-driven optimization.

The confluence of LLM's semantic capabilities with RL has sparked interest, particularly in using LLMs as a reward shaper for RL. This innovative approach includes directly feeding the context of the environment to LLMs for action and reward processing (Kwon et al., 2023), using LLMs to define the parameters of the reward function (Yu et al., 2023), or even to design whole rewards function codes (Ma et al., 2023). These efforts have mainly focused on gaming agents and robotic task control, inspiring our exploration into e-commerce payment fraud detection.

E-Commerce payment fraud presents a dynamic challenge necessitating advanced decision-making across three key stages: 1) *Pre-authorization* (Pre-auth) where our platform screens transactions before card issuers' risk assessment, 2) *Issuer check* where card networks validate payment credentials, and 3) *Post-authorization* (Post-auth) where we conduct final risk evaluation after issuer approval. Traditional SL approaches operate isolated classifiers at each stage, failing to model the sequential interdependencies and business constraints (e.g.,

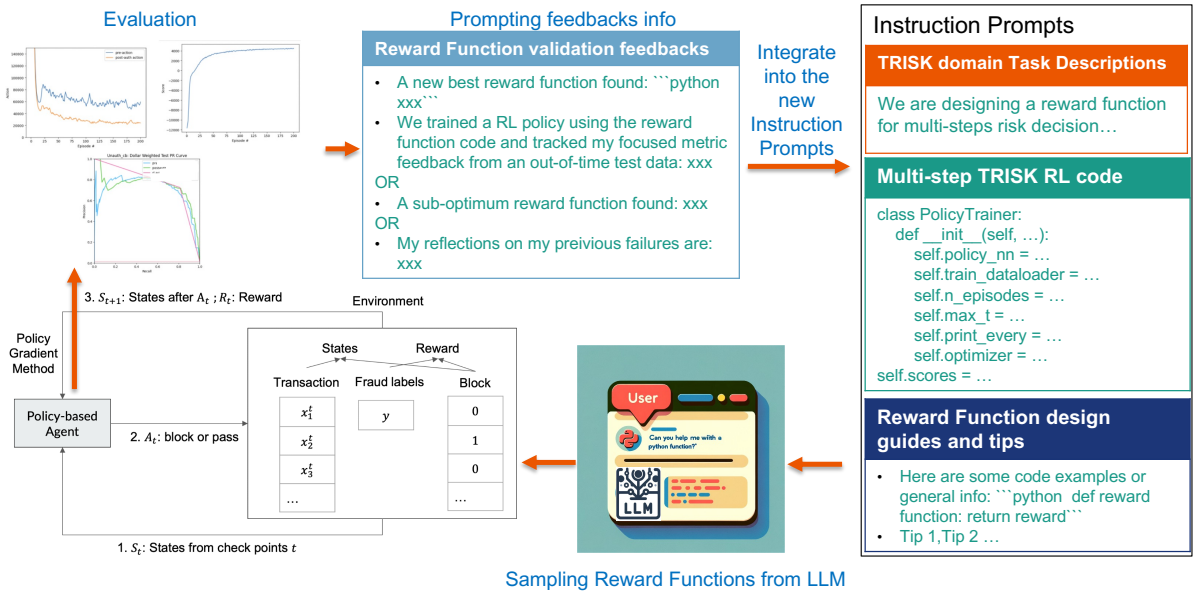

Figure 1: The LLM enhanced self-improving RL framework overview. It takes in the task description/instructions, the RL source code, and the example human-designed reward function as the context to generate an executable reward function. We designed an evolutionary algorithm to allow the LLM to evolve the reward function design based on feedback on the performance of the RL agent.

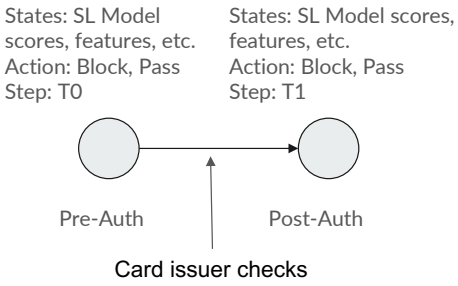

Figure 2: Imagine the buyer transaction risk decision checkpoints pipeline as a Markov Decision Process.

needing to block more potential frauds during Pre-auth to avoid issuer penalties). This fragmentation leads to suboptimal precision-recall balance and excessive manual reviews. RL's strength in constrained sequential optimization makes it uniquely suited to maximize cumulative fraud prevention while respecting stage-specific requirements.

In response, we propose a cutting-edge RL framework that harnesses the power of LLM to autonomously evolve and refine decision-making processes in the payment risk domain, a first in this field. Our contributions are summarized as follows:

LLM-based Reward Function Generation for RL: We introduce a framework using LLMs to autonomously create reward functions that directly optimize precision-recall metrics in the payment risk domain, outperforming human-designed rewards. It uses an evolutionary algorithm for iterative refinement based on RL agent feedback, supporting few-shot/zero-shot creation with/without prior examples. The general process is shown in Figure 1.

Transaction Risk Detection as Constrained MDP: We redefine transaction risk detection as a multistep MDP with stage-specific constraints, solved using policy-based RL like REINFORCE. By integrating transaction stages into a coherent framework (see Figure 2) and aggregating reward signals across stages (detailed in Figure 3), our method outperforms SL's surrogate loss functions through direct optimization of business objectives.

Our research, supported by extensive experiments with real-world e-Commerce transaction data, demonstrates significant improvements in fraud detection performance compared to the existing SL models on our payment system.

2 Methodology

2.1 Designing the MDP and RL Framework

We model the e-commerce transaction process as a finite-horizon MDP, visualized in Figure 2. The system generates state signals from both legacy SL risk model scores and transaction stage indicators (Pre-auth, Post-auth). While there are also many transactional features that can be used as state signals, our experiments primarily use SL scores for

state representation due to their proven predictive value leveraging all the features, the framework can theoretically incorporate any transactional features available at each stage. The policy agent uses these state signals to decide between risk responses ("block" or "allow"), with the MDP structure enabling sequential decision-making that supervised learning cannot naturally accommodate.

The agent-environment interaction (Figure 3) defines:

- $\mathcal{S}_i =$ SL scores *and stage indicators* at step i
- $\mathcal{A}_i =$ possible risk responses (block, pass)
- $\mathcal{R}_i = R(\mathcal{S}_i, \mathcal{A}_i)$, the reward function

We maximize the business-driven objective:

$$\begin{aligned} &\text{Maximize} \quad \$\text{TP} - \$\text{FP} \\ &\text{subject to} \quad \$\text{TP}_{\text{stage 1}} > \$\text{TP}_{\text{stage 2}} \end{aligned} \tag{1}$$

where dollar-wise \$TP-\$FP optimization directly meets the theoretical goal of our risk business, which corresponds to maximizing fraud prevention while minimizing Loss of the Gross Merchandise Value (GMV) from false positives. The decreasing \$TP constraint reflects practical fraud patterns where early detection captures higher-value fraud attempts.

We employ offline RL with policy gradient methods (REINFORCE (Williams, 1992)) using historical transaction data. To address offline evaluation challenges, we firstly try to train with enough amount of transaction data, and secondly we validate policies on extended test periods (6+ months) demonstrating consistent performance before production deployment.

2.2 Human Reward Function Design

While Equation 1 captures core business objectives, real-world operations require balancing specific precision-recall trade-offs across transaction categories. Here we figured out the reward design that achieve this implicitly through directly considering the optimization constraints instead of the optimization goal itself. By transforming operational constraints into differentiable objectives through algebraic manipulation, we found that it naturally merges into the optimization goal considering the precision block level.

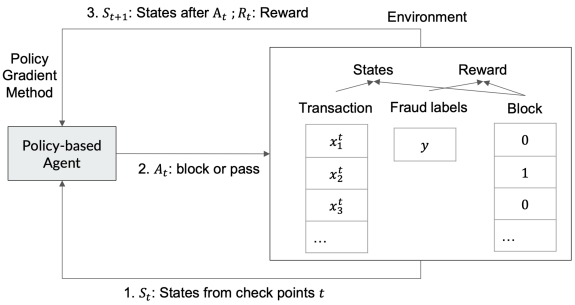

Figure 3: TRISK MDP framework with staged decision points. States incorporate SL risk scores and stage indicators.

Precision Constraint based Reward Function Business requirements ($\text{TP}_{\text{stage 1}} > \$\text{TP}_{\text{stage 2}}$) dictate precision thresholds α_i per stage, with $\alpha_1 < \alpha_2$ enforcing stricter precision in later stages. Hence we assume the blocking precision inequality in stage i:

$$\frac{\$\text{TP}_i}{\$\text{TP}_i + \$\text{FP}_i} > \alpha_i \tag{2}$$

we derive the reward function through Lagrangian relaxation:

$$R^i_{\text{precision}}(s,a) = (1-\alpha_i)\$\text{TP}_i - \alpha_i \$\text{FP}_i > 0 \tag{3}$$

Maximizing this implicitly maximizing (\$TP - \$FP) while maintaining stage-wise constraints by introducing the coefficients in front these terms, derived naturally from the inequality above.

While effective, these human-designed rewards require careful parameter tuning, and in theory there could be more effective designs that need more human efforts to explore. Therefore, we proposed a LLM-enhanced framework automates this exploration by incorporating the specifications of policy performance feedback in natural language, to further enhance the RL reward signals.

2.3 LLM-based Reward Function Optimization

We propose a framework using LLMs to dynamically optimize reward functions in our evolving RL algorithm for e-commerce payment fraud detection.

2.3.1 Algorithm Overview

Our method, detailed in Algorithm 1, employs Enhanced LLM-based Reward Optimization for RL agents, evolving the reward function to boost decision-making. The cycle includes:

1. Initialization with environment $\mathcal{E}$, baseline model $\mathcal{M}_b$, and metrics.

2. Generation of reward candidates by an LLM, guided by temperature for novelty.

3. Validation and use of candidates to train RL agents for fraud detection.

4. Evaluation of detection accuracy and impact, informing reward success.

5. Self-Reflection: top functions update the LLM context; failures refine iterations.

6. Repeat steps 2-5 until iteration or convergence.

To ensure the executability of generated reward functions, we implement a two-step validation process: (1) incorporating basic reward function structure requirements in the prompts, and (2) using preliminary code checks to confirm that generated functions fit the required structure. If a function fails these checks, the LLM regenerates it during the sampling phase, significantly reducing unexecutable cases, without human in the loop.

2.3.2 Customized In-Context Prompt

The initial and iterative instructions provided to the LLM are critical to the success of our algorithm. We construct a domain-specific prompt that outlines the objectives of the reward function, incorporates the RL environment framework, and includes basic requirements and examples. As shown in Figure 1, the prompt is dynamically updated with feedback loop information, allowing the LLM to adapt its generative process to the evolving requirements of the fraud detection task. Examples of prompts are shown in the following boxes, with more detailed content in Appendix A.

Initial Instruction Prompts

You are a reward engineer trying to write reward functions to solve reinforcement learning tasks as effectively as possible. Your goal is to: (1) ... (2) ...
The goal of my task is: ..., my codes framework of input data as states and train my policy is shown in the code: "'python {...} "'.
Your reward function should use useful variables from my codes framework as inputs. As some examples, here are some example reward functions proposed by humans: "'python {...} "', and here is the best reward function signature so far: "'python {...} "' ... The output of the reward function should consist of: (1) ... (2) ... ...

Feedback Prompts

We trained a RL...:
1. RL Agent Training info: ...
2. Test evaluation info: ...
Moreover, the ratio between the bad GMV blocked by first step and the bad GMV blocked by second step is: {...}/{...} ...
Error occurred during training: {...}
Error occurred during evaluating: {...}

2.3.3 Zero-shot and Few-shots setups

Our approach supports both zero-shot and few-shot capabilities. In the zero-shot setup, the algorithm generates reward functions based on general component descriptions rather than predefined human-designed functions. For the few-shot setup, detailed examples of human-crafted reward functions are included in the prompt, allowing the model to reference specific code and build on these exemplars.

Feedback and success metrics play a crucial role in optimizing the reward function, especially in zero-shot scenarios. Feedback comprises policy evaluation results, such as precision-recall on test data, error reports, and comparative evaluations of previous best and sub-optimal rewards. Importantly, in cases where no sub-optimal reward is found, a reflection process allows the LLM to summarize insights from failed reward functions, integrating this experience into instructions for subsequent iterations, as described in line 26 of Algorithm 1. This reflective feedback is vital for zero-shot cases.

Algorithm 1 LLM-based Reward Function Optimization for RL Agent

Require: $N_{iter}, N_{samples}, N_{episodes}, \theta_{recall}, R_{scores}$
1: Initialize environment $\mathcal{E}$, baseline model $\mathcal{M}_b$, and evaluation parameters
2: $f_{best} \leftarrow$ InitializeBestRewardFunction(), Initialize LLM temperature parameters
3: Load baseline model performance and set evaluation criteria
4: **for** $iter = 1$ to N_{iter} **do**
5: Initialize feedback and success lists: $feedbacks, success$
6: Update LLM temperature based on feedback loop criteria
7: **for** $sample\_i = 1$ to $N_{samples}$ **do**
8: Sample and validate $f_{reward}^{sample\_i}$ using LLM with temperature control
9: **if** valid $f_{reward}^{sample\_i}$ **then**
10: Save $f_{reward}^{sample\_i}$, proceed to training
11: **else**
12: Re-sample $f_{reward}^{sample\_i}$
13: **end if**
14: **end for**
15: **for** each valid $f_{reward}^{sample\_i}$ **do**
16: $\mathcal{A}_i \leftarrow$ TrainAgent($\mathcal{E}, f_{reward}^{sample\_i}, N_{episodes}$)
17: $feedback_i, success_i \leftarrow$ EvaluateAgent($\mathcal{A}_i, \mathcal{M}_b, \theta_{recall}, R_{scores}$)
18: Append $feedback_i$ to $feedbacks$ and $success_i$ to $success$
19: **end for**
20: Update f_{best} based on evaluation results, Update LLM temperature and instructions for next iteration based on feedback loop outcomes
21: **if** new f_{best} found **then**
22: Update system instructions for LLM to include new best reward function details
23: **else if** sub-optimal reward function found **then**
24: Update system instructions for LLM to include sub-optimal reward function details as feedback
25: **else**
26: Let LLM summarize reflections based on the failed reward functions info and include its experience into the instructions for next iteration
27: **end if**
28: **end for**

2.3.4 Interpretability of LLM-Generated Reward Functions

While the proposed framework leverages LLMs to automatically evolve reward functions for RL agents, it is important to acknowledge that such LLM-generated reward functions inherently carry a degree of "black-box" behavior, especially in zero-shot settings. To enhance interpretability, we embed domain-specific contextual information into the prompts provided to the LLM.

In both zero-shot and few-shot reward function design prompts, we explicitly define domain-specific contexts such as key business metrics — $TP, $FP, $TN, and $FN — along with their implications in fraud detection (lines 6–9 in the prompt example below). These definitions are paired with optimization objectives and constraints within the domain context (lines 10–11), further reinforced by additional descriptions in the instruction prompts and feedback mechanisms detailed in Section 2.3.2. This structured context guides the LLM to generate reward functions that align closely with real-world business requirements. Take the zero-shot reward design as an example: in Listing 1, the LLM incorporates terms such as $FP and $FN, indicating its understanding of the trade-offs between $TP vs. $FP and $TN vs. $FN. It also assigns higher weights to early-stage rewards (e.g., reward *= 1.2 at current_step == 0 and reward *= 0.9 at current_step == 1), reflecting the business requirement that detecting fraud earlier yields greater value.

Domain-Specific Context Prompts for Reward Function Design

1. element in action either equals 0 or 1;
2. action == 1 means the transactions that were taken blocking action, action == 0 means the transactions that were taken pass action;
3. element in target either equals 0 or 1;
4. target == 1 means the transactions that are tagged as fraud risk, target == 0 means the transactions are not tagged as risk;
5. wgt is the tensor of dollarwise weight for each transaction;
6. e.g. ((action==1) & (target==1) * wgt) means the tensor that have the True Postive GMV value where (action==1) & (target==1);
7. e.g. ((action==1) & (target==0) * wgt) means the tensor that have the False Positive GMV value where (action==1) & (target==0);
8. e.g. ((action==0) & (target==0) * wgt) means the tensor that have the True Negative GMV value where (action==0) & (target==0);
9. e.g. ((action==0) & (target==1) * wgt) means the tensor that have the False Negative GMV value where (action==0) & (target==1);
10. the general goal of this reward function is to drive the agent to increase True Postive GMV and True Negative GMV, decrease False Positive GMV and False Negative GMV;
11. this reward function need to drive the agent to block more potential True Postive GMV at the current_step == 0 than at the current_step == 1.

Despite these efforts, certain aspects — such as why specific parameter choices lead to particular precision-recall outcomes on certain test data— remain difficult to fully interpret. Therefore, we complement the validation of the reward function design with long-term evaluations (Test L in Table 1), demonstrating the stability and practical effectiveness of the evolved reward functions over time.

```
def get_reward(current_step, action, target, wgt):
    reward = (action * target * wgt).float()
    if current_step == 0:
        reward *= 1.2
    elif current_step == 1:
        reward *= 0.9
    fn = ((1 - action) * target * wgt).float()
    reward -= fn * 0.5
    fp = ((action * (1 - target) * wgt).float())
    reward -= fp * 0.1
    low_weight_penalty = (action * (wgt < 50)).float
     ()
    reward -= low_weight_penalty * 0.005
    reward /= wgt
    return reward

```

Listing (1) Original zero-shot reward function design by Mixtral8X7B. The calculation of rewards and penalties in both steps is uniquely different compared to Equation 3 above.

```
def get_reward(current_step, action, target, wgt):
    gamma_positive = 1.15
    gamma_negative = 0.9
    alpha = 1.2
    reward = 0
    if current_step == 0:
        reward = gamma_positive * (
            ((action == 1) & (target == 1)) * wgt -
            ((action == 1) & (target == 0)) * (alpha
  * 0.005) * wgt -
            0.15 * ((action == 0) & (target == 1)) *
  wgt
        )
    elif current_step == 1:
        reward = gamma_negative * (
            ((action == 1) & (target == 1)) * wgt -
            ((action == 1) & (target == 0)) * (alpha
  * 0.002) * wgt -
            0.10 * ((action == 0) & (target == 1)) *
  wgt
        )
    return reward

```

Listing (2) Original few-shot reward function design by Mixtral8X7B. This design introduces unique reward terms compared to Equation 3 above, rather than simply adjusting the parameters of the human-designed version.

Figure 4: Reward function designs evolved by Mixtral8X7B in different contexts: Listing (1) Zero-shot context, Listing (2) Few-shot context.

Table 1: Experiment Datasets.

Dataset	Time Window	Total	Fraud Label
Train	2023-09-01 to 2023-09-14	2,136,590	28,226
Test S	2023-09-15 to 2023-09-30	522,105	825
Test L	2023-11-01 to 2024-04-30	6,174,069	7,834

Table 2: Performance of Policy Agent vs. Baseline, on Test S.

Recall Levels	Baseline $Prec	RL Agent $Prec	Bad GMV Catch Ratio
@80%	66.57%	**69.65%**	**9.79**
@85%	58.79%	**64.22%**	**15.32**
@90%	51.27%	**55.7%**	**13.36**

2.3.5 Generalizability Discussion

State-of-the-art approaches, such as those presented by (Ma et al., 2023), have employed evolutionary loops to demonstrate the robustness of these methods in optimizing RL training processes within different robotics tasks. However, these frameworks are primarily tailored to the specific data and scenarios encountered in robotics, limiting their direct applicability to our domain. Therefore, our work introduces this novel adaptation of evolutionary loops for tasks in e-commerce risk detection, for the first time. By doing so, we first demonstrate that this evolutionary reward design loop, leveraging LLMs, can be effectively generalized to e-commerce payment fraud scenarios. Theoretically, this approach can also be extended to other RL tasks within this domain that share similar data structures and objectives.

3 Experiments

3.1 Datasets and Evaluation Metrics

We used real-world transaction data focusing on Pre-auth and Post-auth stages. SL models (gradient boost machines) scores $\mathcal{S}_i = \{Scr_{i0}, \cdots, Scr_{ij}\}$ on the 2 stages, and stage indicators, represented the RL state. Data were split, labeled with our key fraud signals, and evaluated on out-of-time test sets. Table 1 shows dataset details. Test S, with 522K transactions, allows for quick performance comparisons but may introduce more variance due to its size. In contrast, Test L, with 6.17M transactions, offers more robust validation.

We assess performance using a metric for dollar-wise precision ($Precision) at key dollar-wise recall ($Recall) levels, calculated by our main fraud label. This metric is crucial as it aims to maximize legitimate GMV by minimizing $FP transaction values at a given risk level. For the RL agent scores, we find combinations of blocking score thresholds across two stages to achieve the desired overall $Recall, then observe the $Precision. For the baseline model, we use the Pre-auth SL model score, which is most commonly employed by the policy, to observe this metric. Due to the complexity of human analysis in business practice, no cross-stage policy has been designed previously using SL model scores as a baseline. Which is also why we need to propose our RL solution in the first place.

3.2 Experimental Results and Analysis

Part 1: Human-designed Reward Function: In the first segment, a single RL agent was trained using a 3-layer neural network with dimensions [8, 32, 8], incorporating dropout layers and GELU activation functions. The model processed a four-dimensional input consisting of representative scores from legacy SL models, which served as the state representation. The output was the probability of taking the "block" action. Training was conducted using the REINFORCE algorithm with the Adam optimizer.

Multiple trials stabilized results, Table 2 shows enhanced performance and risk detection efficiency, with the agent blocking more fraudulent GMV in the Pre-auth stage.

All training in part 1 was performed on a machine equipped with a single V100 GPU (32GB VRAM), 32 CPU cores, and 450GB of RAM. With our current implementation, iterating over 200 training epochs — generally sufficient for observing convergence in our experiments — took approximately 20 minutes per epoch. Each iteration involved processing the full training dataset, as detailed in Table 1.

Part 2: LLM-enhanced Reward Function: We employed LLM-enhanced rewards using models like Mixtral-8x7B, LLaMa-3-8B, and Gemma7B. Experiments included zero-shot and few-shot setups with varying LLM prompts. Algorithm 1 parameters included $N_{iter} \approx 60$, $N_{samples} \approx 10$, $N_{episodes} \approx 150$, and $\theta_{recall} \in [80\%, 85\%, 90\%]$. Results are in Table 3.

Zero-shot scenarios used descriptive prompts without reward function examples, leading to competitive reward designs, as shown in Listing (1). Few-shot scenarios also allowed LLMs to mod-

Table 3: Zero-shot and Few-shot Performance Comparison of LLMs in LLM+RL Approach, on Test S.

Recall Levels	Baseline $Prec	Zero-shot Evolved RL agent $Prec			Few-shot Evolved RL agent $Prec		
		Mixtral-8x7B	Gemma7B	LLaMa-3-8B	Mixtral-8x7B	Gemma7B	LLaMa-3-8B
@80%	66.57%	**72.71%**	**73.27%**	**72.86%**	**73.41%**	**73.53%**	**73.74%**
@85%	58.79%	**69.62%**	**65.42%**	**69.40%**	**70.73%**	**69.87%**	**71.70%**
@90%	51.27%	**57.42%**	**53.65%**	**57.06%**	**58.00%**	**56.93%**	**55.90%**

ify and create reward functions, as shown in Listing (2), improving performance metrics. Zero-shot setups required more iterations, indicating optimization potential, but overall, LLM-enhanced approaches showed adaptability and innovation.

Each complete training iteration, encompassing LLM inference, RL agent training, and performance evaluation, required approximately 40 minutes. All experiments in part 2 were conducted on a machine equipped with 2 V100 GPUs (32GB VRAM), 32 CPU cores, and 450GB of RAM, with LLMs loaded in 4-bit precision ($load\_in\_4bit = True$) to reduce VRAM consumption. The primary computational bottlenecks were identified as LLM inference and policy evaluation. These components represent key areas for future optimization in the implementation pipeline.

Part 3: Long-term Evaluation: To test RL agent robustness over time, we extended evaluation on Test L covering six additional months. Using the same RL agent, we analyzed performance with $Prec metric against a baseline model at similar $Recall thresholds for all LLMs in both zero-shot and few-shot scenarios.

Figure 5 shows RL agents consistently outperforming the baseline over time. Figure 6 illustrates zero-shot scenarios where RL agents maintained superior performance.

These evaluations highlight our LLM-enhanced RL framework's durability and effectiveness in real-world applications, supporting continuous deployment without frequent retraining. More results are in Appendix B.

3.3 Production Efficiency

Due to the compact architecture and lightweight design of the RL agent network described above, the model supports efficient deployment across both transaction stages. In production, it achieves inference latencies of less than 50 milliseconds using standard CPU infrastructure, making it suitable for real-time fraud detection at scale.

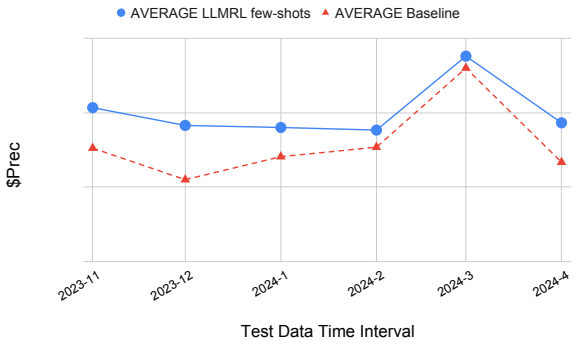

Figure 5: Averaged blocking $Prec@$Recall from 3 LLM guided RL agents, in the few-shots scenario, on Test L.

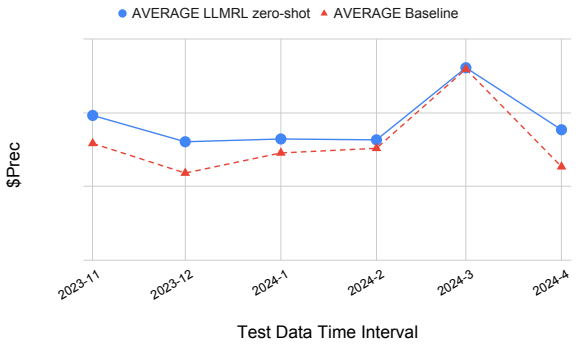

Figure 6: Averaged blocking $Prec@$Recall from 3 LLM guided RL agents, in the zero-shots scenario, on Test L.

4 Conclusion

This study introduces an RL and LLM integration framework for e-Commerce fraud detection, conceptualizing risk assessment as an MDP and enabling dynamic sequential strategies. Our approach, using LLMs to refine reward functions, surpasses traditional human-designed functions in efficiency and zero-shot capability. Empirical tests confirm its superiority over our conventional SL model, with six-month evaluations demonstrating robust performance. The lightweight architecture, is practical for industrial adoption. Future work includes generalizing to more sequential scenarios of risk prevention, and exploring online RL.

A Prompts Design for the LLM RL framework

In this section, we provide the prompts of our LLM RL framework.

Prompt 1: Initial Instruction Prompts

You are a reward engineer trying to write reward functions to solve reinforcement learning tasks as effective as possible. Your goal is to: (1) write a reward function for the environment that will help the agent learn the task described below. (2) try to write improved or try different parameters in the reward function comparing to the reward functions found so far, based on analyzing the provided reward function feedback information below. The goal of my task is: Design a reward function that enables the RL agent to make more effective decisions across 2 steps for improved overall performance in identifying and blocking risky transactions comparing to a baseline scores in the 1st step, my codes framework of input data as states and train my policy is shown in the code: “‘python {...} “‘.

Prompt 2: Code Generation Instruction Prompts

Your reward function should use useful variables from my codes framework as inputs. As some examples, here are some examples reward functions proposed by human: “‘python {...} “‘, and here is the best reward function signature so far: “‘python {...} “‘
Since the reward function will be decorated with @torch.jit.script, please make sure that the code is compatible with TorchScript (e.g., use torch tensor instead of numpy array).
Make sure any new tensor or variable you introduce is on the same device as the input tensors. The output of the reward function should consist:
(1) the completed reward function.
(2) the reward code’s input attributes must follow the format:"def get_reward(current_step,action,target,wgt):".
(3) the code output should be formatted as a python code string: "“‘python ... “‘".
(4) if you have extra functions defined in the reward function, also output these functions completely in one code block.
(5) your codes and the related annotations must be consistent.
(6) it is encouraged to only output your completed reward function python codes in the beginning of your outputs, for the ease of code extraction.
(7) remember to use the backslash properly as a line continuation where you separate one logic line into multiple physical lines for better readability.

Prompt 3: Additional Reward Generation Instruction Prompts with Domain-Specific Context

information of the get_reward:
def get_reward(current_step,action,target,wgt):
current_step is one integer;
if the agent is in step 0, then current_step == 0;
if the agent is in step 1, then current_step == 1;
current_step either equals 0 or 1 in get_reward function;
action and target and wgt are tensors in size (transaction_batch_size,);
element in action either equals 0 or 1;
action == 1 means the transactions that were taken blocking action, action == 0 means the transactions that were taken pass action;
element in target either equals 0 or 1;
target == 1 means the transactions that are tagged as fraud risk, target == 0 means the transactions are not tagged as risk;
wgt is the tensor of dollarwise weight for each transaction.;
e.g. ((action==1) & (target==1) * wgt) means the tensor that have the True Postive GMV value where (action==1) & (target==1);

e.g. ((action==1) & (target==0) * wgt) means the tensor that have the False Positive GMV value where (action==1) & (target==0);
e.g. ((action==0) & (target==0) * wgt) means the tensor that have the True Negative GMV value where (action==0) & (target==0);
e.g. ((action==0) & (target==1) * wgt) means the tensor that have the False Negative GMV value where (action==0) & (target==1);
the general goal of this reward function is to drive the agent to increase True Postive GMV and True Negative GMV, decrease False Positive GMV and False Negative GMV;
this reward function need to drive the agent to block more potential True Postive GMV at the current_step == 0 than at the current_step == 1;
the returned reward also need to be a tensor in size (transaction_batch_size,) or (transaction_batch_size,1) , it will be aggregated outside this get_reward function
return reward

Prompt 4: Feedback Prompts

We trained a RL policy using the new found reward function code and tracked my focused metric feedback from a out-of-date test data:
1. RL Agent Training info: after training in {...} episodes, the final blocking action number of the RL agent in first step is: {...}, and the final blocking action number of second step is: {...}, and the final reward value is: {...} comparing to the initial reward value is: {...}. Normally we hope to observe the RL agent take more blocking action in the first step than in the second step, and the final reward value should be larger than the initial value.
2. Test evaluation info: after 2 steps actions of a policy agent, we observed the final best precision performance by the agent under some targeting recall thresholds levels: {...} and compare with the baseline model, the goal is have better precision compare to the baseline model. The detail of the observations are: Our 2 steps policy agent can reach the similar recall:{...} and the agent can reach at best the precision: {...}. Moreover, the ratio between the bad GMV blocked by first step and the bad GMV blocked by second step is: {...}/{...}, and the ratio between the total GMV blocked by first step and the total GMV blocked by second step is {...}/{...};
Error occurred during training: {...}
Error occurred during evaluating: {...}

Prompt 5: Reflection Prompts if No Usable Reward Function Found

However, after an iteration of reward designs and validations, all of your designed reward functions failed in either training or evaluation, your designs and their regarding failure info are listed here: {...}
With all the feedback information, reflect the failed experience regards to your reward functions and output a detailed guidance of reward function design for yourself briefly, in less than length of 1000 tokens:

Prompt 6: Reflection Prompts if A Better Reward Function Found

The previous best reward function's policy agent performance: when the recall threshold is {...}, the baseline model can reach the precision: {...}. A better new found reward function in iteration {...}:{...}.

Prompt 7: Reflection Prompts if A Sub-optimal Reward Function Found

You found a sub-optimal new reward function in iteration {...}:{...}, which has worse performance than the previously best reward function.

B Long-term Test evaluations with different LLM

In this appendix, we present detailed figures illustrating the performance of different models evaluated in this study.

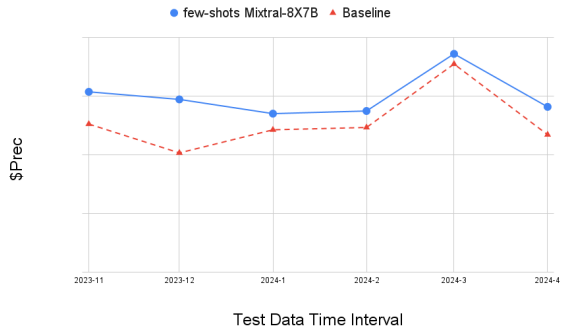

Figure B.1: Averaged blocking $Prec@$Recall from Mixtral-8X7B guided RL agents, in the few-shots scenario.

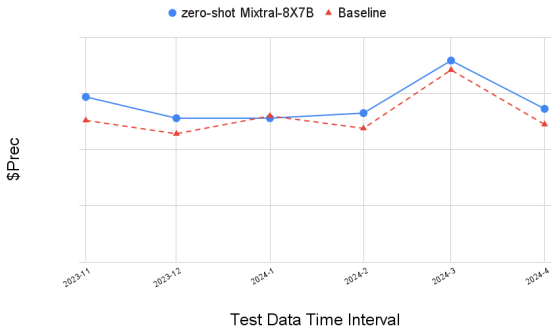

Figure B.4: Averaged blocking $Prec@$Recall from Mixtral-8X7B guided RL agents, in the zero-shot scenario.

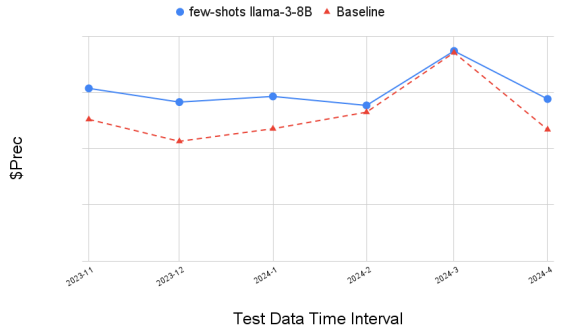

Figure B.2: Averaged blocking $Prec@$Recall from LLaMa-3-8B guided RL agents, in the few-shots scenario.

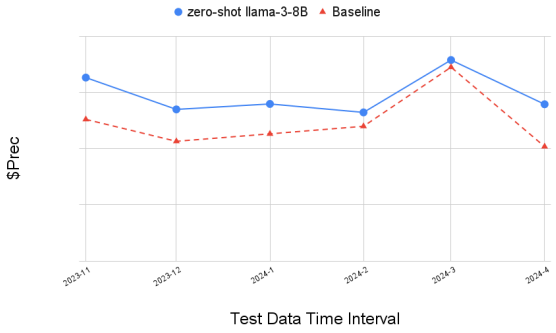

Figure B.5: Averaged blocking $Prec@$Recall from LLaMa-3-8B guided RL agents, in the zero-shot scenario.

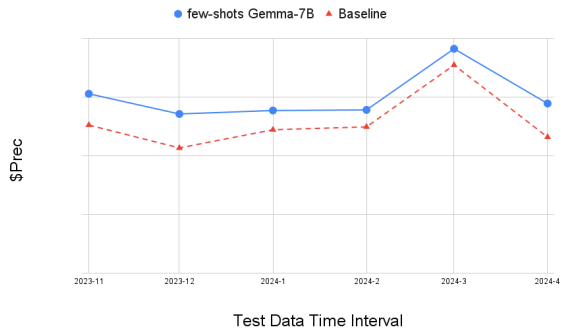

Figure B.3: Averaged blocking $Prec@$Recall from Gemma7B guided RL agents, in the few-shots scenario.

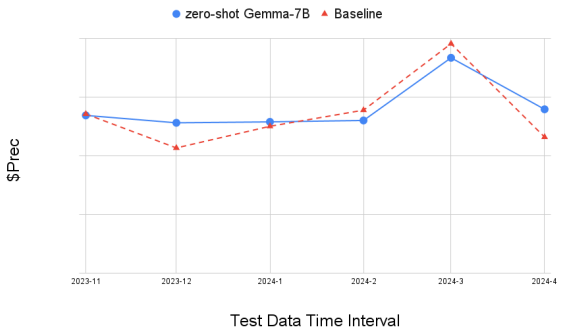

Figure B.6: Averaged blocking $Prec@$Recall from Gemma7B guided RL agents, in the zero-shot scenario.

ORMind: A Cognitive-Inspired End-to-End Reasoning Framework for Operations Research

Abstract

Operations research (OR) is widely deployed to solve critical decision-making problems with complex objectives and constraints, impacting manufacturing, logistics, finance, and healthcare outcomes. While Large Language Models (LLMs) have shown promising results in various domains, their practical application in industry-relevant operations research (OR) problems presents significant challenges and opportunities. Preliminary industrial applications of LLMs for operations research face two critical deployment challenges: 1) Self-correction focuses on code syntax rather than mathematical accuracy, causing costly errors; 2) Complex expert selection creates unpredictable workflows that reduce transparency and increase maintenance costs, making them impractical for time-sensitive business applications. To address these business limitations, we introduce ORMind, a cognitive-inspired framework that enhances optimization through counterfactual reasoning. Our approach emulates human cognition—implementing an end-to-end workflow that systematically transforms requirements into mathematical models and executable solver code. It is currently being tested internally in Lenovo's AI Assistant, with plans to enhance optimization capabilities for both business and consumer customers. Experiments demonstrate that ORMind outperforms existing methods, achieving a 9.5% improvement on the NL4Opt dataset and a 14.6% improvement on the ComplexOR dataset.

1 Introduction

Operations research (OR) is critical for business decision-making, helping companies optimize resources, reduce costs, and improve operational efficiency across manufacturing, logistics, and supply chain management. However, previous approaches usually require specialized expertise to translate real-world problems into mathematical optimization problems, hindering their application potential in broader domains. Industry practitioners consistently report that optimization projects face a 30-40% failure rate due to the disconnect between business requirements and mathematical formulation.

Recent advancements in LLMs have enabled the solving of OR problems. Such automation procedures can avoid inconsistent math performance of LLMs (Ahn et al., 2024; Imani et al., 2023; Yu et al., 2024a) and leverage LLMs' ability and knowledge to extract implicit variables and constraints from real-world problems.

However, as Figure 1a illustrates, existing approaches(Xiao et al., 2024; Wang et al., 2024; AhmadiTeshnizi et al., 2024) to operations research automation face critical deployment challenges. Their complex agent orchestration creates excessive cognitive load through numerous API calls, overwhelming analysts with irrelevant information while significantly increasing costs. These unpredictable expert selection processes reduce solution transparency and create substantial overhead, fundamentally misaligning with human reasoning capabilities.

Inspired by cognitive science and how the brain solves problems, ORMind implements a business-oriented framework based on dual-process theory, combining intuitive analysis with deliberate reasoning. Our specialized modules mirror analyst workflows, from rapid comprehension to deep mathematical thinking. Unlike existing multi-agent frameworks that rely on unpredictable agent selection and complex orchestration, ORMind's innovation lies in its structured, predictable workflow that drastically reduces API calls while maintaining solution quality. ORMind framework is shown in Figure 1b.

We evaluate ORMind on standard benchmark

[*]Work done as an intern at AI Lab of Lenovo Research.

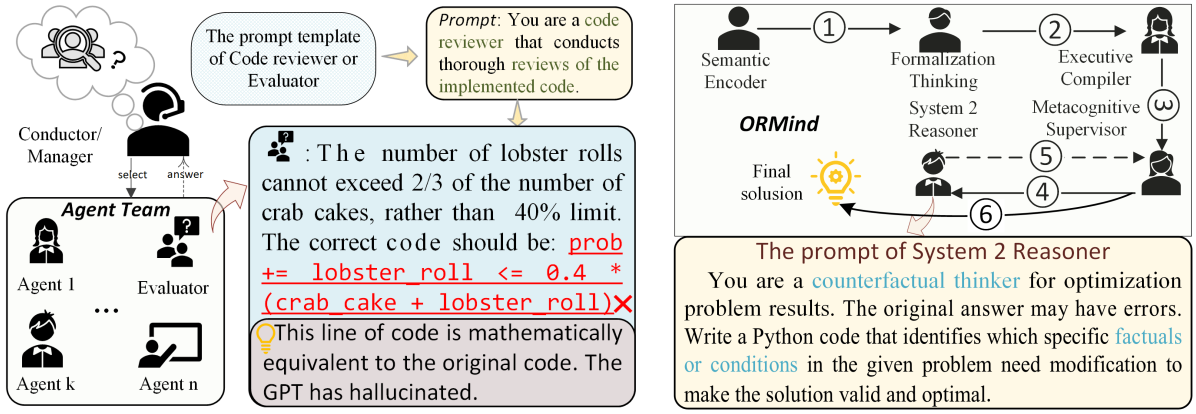
Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 104–131
July 28-30, 2025



(a) (b)

Figure 1: Current frameworks rely on complex agent orchestration with unpredictable execution paths, dramatically increasing API calls and computation time. Their focus on code syntax rather than mathematical accuracy results in costly errors that can propagate through business operations undetected. This excessive coordination overhead makes these systems impractical for time-sensitive business applications. Compared to traditional methods, ORMind employs a streamlined end-to-end workflow with counterfactual reasoning, significantly enhancing solution reliability.

datasets and complex OR problems in industrial scenarios, creating more trustworthy AI systems for business applications. Our contributions include:

- An industry-focused framework that streamlines optimization workflows.
- A counterfactual reasoning methodology for business-critical constraint validation.
- A workflow that improves solution trustworthiness and clarity, reducing implementation risks.

2 Related Work

Operations Research Solving with LLMs. Operations research problem solving (Ramamonjison et al., 2022; AhmadiTeshnizi et al., 2024; Xiao et al., 2024) contains multiple and diverse applied mathematical problems that require a model to perform complex understanding and reasoning. A traditional line of approaches (Ramamonjison et al., 2022) decomposes the OR solving into two separate tasks, first solving the NER task to recognize the optimization problem entities (He et al., 2022), then generating a precise meaning representation of the optimization formulation (Gangwar, 2022). Another line of work (Tang et al., 2024; Yang et al., 2024) leverages LLMs to synthesize abundant and diverse operations research problems, which later empowers the LLMs with such synthetic data. Such approaches may suffer guaranteed data quality and, at the same time, can be costly.

LLM-based Multi-Agent Workflow Recent research has demonstrated the potential of collaborative problem-solving through autonomous cooperation among AI agents (Li et al., 2023; Wang et al., 2024; Hong et al., 2024a). Compared with existing multi-agent collaboration approaches, ORMind's primary innovation lies in its counterfactual strategy and memory pool coordination mechanism, which aligns more closely with actual business decision-making logic and transparency requirements. This enables the system to exhibit unique advantages in industrial NLP problem scenarios.

LLM-based Reasoning Frameworks. Recent advancements in LLMs have introduced various innovative frameworks to enhance their complex reasoning capabilities. For example, for solving mathematical problems in such as textbooks and contests (Cobbe et al., 2021; Hendrycks et al., 2021; Lightman et al., 2023; Zheng et al., 2022), current research efforts (Gou et al., 2024; Zhu et al., 2023a; Yu et al., 2024b; Hao et al., 2024) have explored using LLMs via employing various structures to enhance reasoning fidelity.

However, these single-agent reasoning methods demonstrate notable shortcomings when dealing with intricate Operations Research (OR) problems. This is because they struggle to address the combined challenges of implicit constraints and factual hallucination on knowledge-intensive tasks.

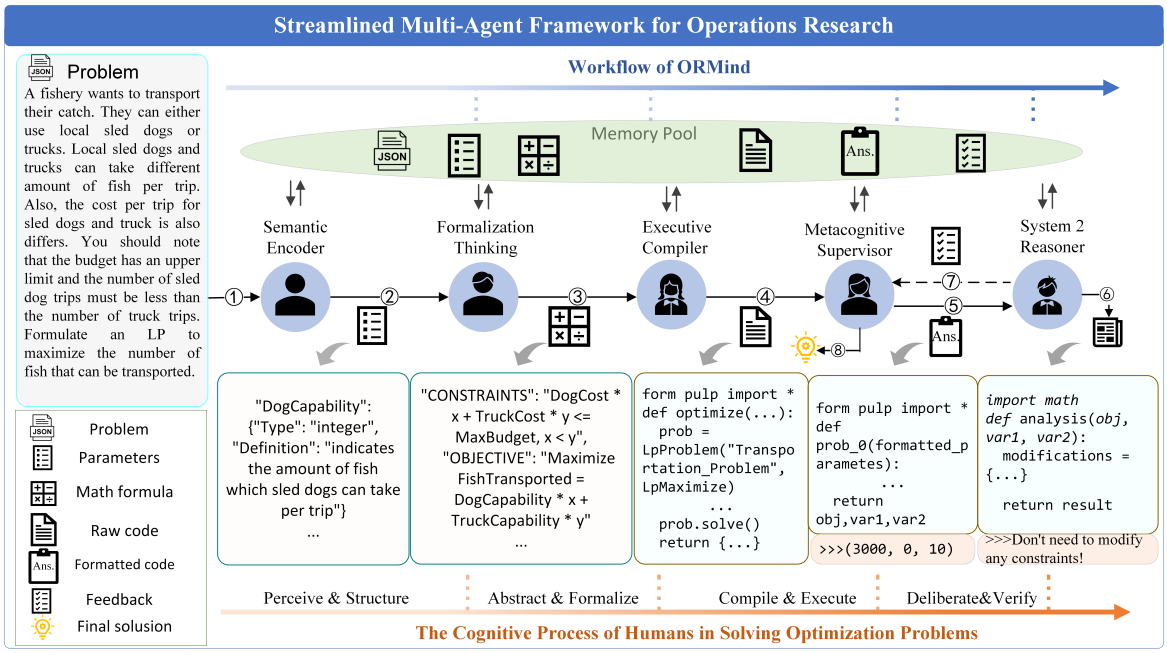


Figure 2: Our approach is grounded in established cognitive science theories, particularly dual-process framework(Kahneman, 2011) and tripartite model of cognition(Stanovich, 2009). The Semantic Encoder and Formalization Thinking modules correspond to Type 1 (intuitive) processing, while the System 2 Reasoner implements Type 2 (analytical) processing. The Metacognitive Supervisor embodies the reflective mind, monitoring and coordinating between these systems.

3 Methodology

3.1 Problem Formulation

Optimization problems are typically expressed in mathematical terms, consisting of an objective function to be minimized or maximized, subject to a set of constraints. For instance, a Integer Linear Program can be formulated mathematically as:

$$\text{minimize} \quad \sum_{j=1}^{n} c_j x_j \tag{1}$$

$$\text{subject to} \sum_{j=1}^{n} a_{ij} x_j \leq b_i, i = 1, \ldots, m \tag{2}$$

$$l_j \leq x_j \leq u_j, \quad j = 1, \ldots, n \tag{3}$$

$$x_j \in \mathbb{Z}, \quad j \in I \tag{4}$$

3.2 Architecture Overview

As illustrated in Figure 2, when humans solve optimization problems, their cognitive process aligns with our framework. The brain first performs semantic encoding, rapidly identifying key variables from complex descriptions. It then uses formalization thinking, methodically constructing mathematical relationships between variables and constraints. Next, executive compiler translate these abstract models into actionable solution.

With problem input D and agent sequence $\mathbb{A} = \{A_{\phi_1}, A_{\phi_2}, \ldots, A_{\phi_{N_a}}\}$, where N_a represents total agents and ϕ_k denotes agent-specific configurations, each component builds upon previous outputs stored in memory pool P.

The transformation operation for agent k follows:

$$O_k = A_{\phi_k}(D, P_{k-1})$$

where D represents business requirements input and P contains all previously processed outputs. Each agent's contribution O_k incrementally enhances the solution repository:

$$P_k = P_{k-1} \cup \{O_k\}$$

This collaborative memory architecture enables robust business optimization by leveraging specialized expertise while maintaining a comprehensive solution context—critical for enterprise deployments where reliability and solution quality directly impact operational outcomes.

3.3 Brief Introduction of Components

3.3.1 Semantic Encoder

The Semantic Encoder transforms unstructured text into structured knowledge representations, reducing the working memory load. It recognizes and

Algorithm 1 Workflow of ORMind

Require: Pre-processed problems set $\mathbb{D}$=$\{D_1, D_2, \ldots, D_{N_T}\}$, maximum number of problems N_T, Memory Pool accessible to all modules

Ensure: Optimized solutions $S_1^*, S_2^*, \ldots, S_{N_T}^*$

for $t = 1$ to N_T **do**
  $\Theta_t \leftarrow \text{SemanticEncoder}(D_t)$
  $M_t \leftarrow \text{Formalization}(D_t, \Theta_t)$
  $C_t \leftarrow \text{ExecutiveCompiler}(M_t)$
  $F_t \leftarrow \text{Supervisor}_\text{f}(D_t, \Theta_t, M_t, C_t)$
  $S_t \leftarrow F_t$ ▷ Run the code
  if S_t indicates any error **then**
    $R_t \leftarrow \text{Reasoner}(S_t, F_t)$
    $F_t' \leftarrow \text{Supervisor}(D_t, \Theta_t, M_t, C_t, R_t)$ ▷ Revise the code based on errors
    $S_t \leftarrow F_t'$ ▷ Run the code
  end if
  $R_t \leftarrow \text{Reasoner}(S_t, D_t)$
  if R_t indicates discrepancies with fact **then**
    $F_t' \leftarrow \text{Supervisor}(D_t, \Theta_t, M_t, C_t, R_t)$
  else
    $S_t^* \leftarrow F_t'$ ▷ Get solution
  end if
end for
return $S_1^*, S_2^*, \ldots, S_{N_T}^*$

categorizes parameters as either scalars or vectors and determines the type of each parameter (e.g., integer, float, boolean, categorical). The output is a parameter set $\Theta = \{\theta_1, \theta_2, ..., \theta_{N_p}\}$, where each θ represents a parameter with its associated information. This process mirrors the human cognitive ability of selective attention and pattern recognition, where experts rapidly identify and categorize relevant information from complex scenarios.

3.3.2 Formalization Thinking

The Formalization Thinking executes deep analytical thinking to construct mathematical models and constraint conditions. The critical steps in this agent involve defining variables, formulating constraints, and constructing the objective function. This component emulates the human brain's abstract reasoning capabilities, where domain experts mentally translate real-world situations into symbolic representations through conceptual abstraction and relationship mapping.

3.3.3 Executive Compiler

The Executive Compiler transforms abstract models into executable code snippets S, similar to the operationalization process of brain executive functions. This transformation reflects the cognitive process of implementation planning, where the human brain converts abstract intentions into concrete action sequences with precise operational details.

3.3.4 System 2 Reasoner

System 2 reasoner provides oversight, while deliberate verification employs counterfactual reasoning to test solutions by asking "what if" questions. While conventional approaches verify solutions by checking constraints directly, ORMind asks "what constraints need to modify would make this solution optimal?" - essentially learning from hypothetical scenarios to identify potential flaws. This approach mirrors human experts who often validate complex solutions by considering what would need to change for an alternative answer to be correct, enabling more robust error detection than direct verification alone. The approach also involves Syntax Error Analysis. In cases where code execution fails due to syntax errors, the specialist pinpoints the problematic line and communicates the probable cause to the Metacognitive Supervisor for swift resolution.

A core innovation in ORMind is the use of counterfactual reasoning for error identification and solution refinement. Assume that the optimization problem can be described by a structural causal model (SCM) with variables X, Y, and C, where:

$$Y = f_Y(X, U), \tag{5}$$

$$C = f_C(X, Y, U), \tag{6}$$

and U denotes latent (exogenous) variables. In our framework, X represents decision variables (e.g., production quantities), Y represents the objective function value (e.g., total cost or profit), and C encapsulates the business constraints.

Inspired by dual-process theories in cognitive science, ORMind divides the reasoning into an intuitive (System 1) phase and a deliberate, analytical (System 2) phase.

For example, given a solution $S_t = \{obj = 150, var_1 = 30, var_2 = 20\}$, the System 2 Reasoner might reason:

$$c_1(S_t) : 2var_1 + 3var_2 \leq 100$$
$$c_2(S_t) : var_1 + var_2 \leq 35$$

Using Python tools to assist its reasoning, the agent might determine:

$$R_t = \begin{cases} \text{“Modify to: } 2var_1 + 3var_2 \leq 130\text{”} & \text{for } c_1 \\ \text{“Modify to: } var_1 + var_2 \leq 50\text{”} & \text{for } c_2 \end{cases}$$

This approach allows the agent to think through which conditions should be altered to make the given result valid, mimicking the cognitive process of a human expert.

3.3.5 Metacognitive Supervisor

The Metacognitive Supervisor mirrors human metacognition—enabling self-awareness of solution quality, strategic oversight, and adaptive decision-making when errors are detected. It monitors the entire solution generation process, making high-level decision adjustments:

$$F_t = \text{Supervisor}_{\text{forward}}(D_t, \Theta_t, M_t, C_t)$$

When constraint violations are detected in production scenarios:

$$F'_t = \text{Supervisor}_{\text{backward}}(S_t, R_t)$$

where R_t contains business-critical constraint failure details. The Supervisor uses this intelligence to prioritize adjustments for maximum operational impact.

Once all business constraints are satisfied:

$$S^*_t = \text{Run}(F'_t)$$

This production-ready state S^*_t represents a deployment-vetted solution meeting all business requirements and optimization targets.

4 Enterprise Application

Lenovo is piloting this innovative approach within its AI Assistant system. The assistant leverages customer computing requirements and budget constraints to formulate mathematical models that optimize the performance-to-cost ratio. Beyond product configuration, Lenovo's AI Assistant extends this optimization capability throughout the customer journey: it streamlines pre-sale product recommendations to shorten decision cycles, automatically applies maximum discounts during purchases to optimize the ordering process, and efficiently handles post-sale services.

At the same time, ORMind is undergoing internal evaluation to enhance product configurations across 292 product categories comprising more than 8,000 potential SKUs (with approximately 2,000+ active SKUs available for recommendation due to business rules requiring in-stock and direct sales items). During testing, the system handled an average of 3,000+ customer inquiries per day, maintaining configuration time below 6 seconds and achieving task completion rates exceeding 80%. Internal assessment tracked additional metrics: intent recognition accuracy reached 85%+, recommendation adoption rate (CTR) was 18%+, and average customer satisfaction score was 4.2 out of 5. Business analysts found the system's transparent reasoning aligned with their own, enabling quick validation and intervention.

5 Experiments

5.1 Datasets

To compare our method, we utilized two datasets:

1. **NL4Opt**: This dataset, collected from the NL4Opt competition[1] at NeurIPS 2022, contains 1101 elementary-level linear programming (LP) problems. It is divided into 713 training samples, 99 validation samples, and 289 test samples.

2. **ComplexOR**: This dataset contains 37 actual industrial optimization problems with the complex constraints and business requirements that characterize real-world applications. Each problem mirrors complex decision-making challenges under various business conditions.

5.2 Experiment Setup and Metrics

We used GPT-3.5-turbo (OpenAI, 2022) as our default large language model, with a temperature of 0. Our experimental framework is built upon LangChain[2], an open-source library designed to facilitate the development of applications powered by language models. We extend the implementation of ORMind to other backbones, including GPT-4o-mini and GPT-4 (OpenAI, 2023).

Our evaluation employs metrics that assess both the correctness and executability of solutions against practical requirements:

Success Rate (SR): The success rate in solving problems.

Model Formulation Failure Rate (MFFR): The percentage of optimization problems where the system fails to formulate a valid mathematical model due to constraint interpretation errors.

Implementation Execution Failure Rate (IEFR): The percentage of optimization models that fail during solver execution due to technical incompatibilities or resource limitations.

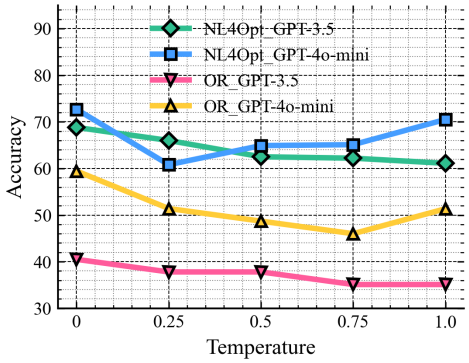

Figure 3: Temperature analysis on NL4Opt and ComplexOR

5.3 Baseline Comparison

In contrast, ORMind's more structured, human-inspired workflow provides a clearer and more effective problem-solving strategy, highlighting its advantages in tackling complex operational research challenges. We benchmark against traditional optimization solutions, including Tag-BART (Gangwar, 2022), and standard LLM frameworks: Chain-of-Thought (Wei et al., 2022), Progressive Hint (Zheng et al., 2023), Tree-of-Thought (Yao et al., 2024), Graph-of-Thought (Besta et al., 2024), ReAct (Yao et al., 2023), Reflexion (Shinn et al., 2023), Solo Performance Prompting (Wang et al., 2024), CoE (Xiao et al., 2024) and OptiMUS (AhmadiTeshnizi et al., 2024).

5.4 Performance Evaluation

Our evaluation reveals critical limitations in existing approaches. Tag-BART (Gangwar, 2022) completely failed on ComplexOR's complex scenarios, while Reflexion (Shinn et al., 2023) showed moderate error-handling capabilities. However, when tackling the more intricate ComplexOR problems, ReAct's performance (Yao et al., 2023) slightly surpassed Reflexion, likely due to its advantage in accessing external knowledge bases, underscoring the importance of external data in handling complex scenarios. The results for OptiMUS are cited from their original paper. They suffer significant performance degradation when tested on GPT-3.5 due to counterintuitive workflow structures that deviate from established problem-solving methodologies(AhmadiTeshnizi et al., 2024). In practice, we found that the sequence in which agents are invoked in these frameworks often appeared counterintuitive and failed to reflect the natural problem-solving process of human experts.

The performance disparity between NL4Opt and ComplexOR datasets highlights a key finding: ORMind excels at accurately formulating mathematical models (achieving near-zero MFFR on NL4Opt), while implementation challenges emerge in more complex industrial scenarios (higher IEFR on ComplexOR). This pattern suggests that future improvements should focus on enhancing the robustness of code generation for complex constraint structures rather than model formulation accuracy.

5.5 Ablation Study

5.5.1 Parameter Sensitivity Analysis

As shown in Figure 3, we evaluated the effect of temperature on GPT-3.5 and GPT-4o-mini models. Lower temperature values led to better performance across both models, suggesting that more deterministic expert responses are beneficial.

Method	GPT-4	
	NL4Opt	ComplexOR
Standard	47.3%	4.9%
Reflexion	53.0%	16.8%
Chain-of-Experts	64.2%	31.4%
OptiMUS	78.8%	66.7%
ORMind	79.9%	62.2%

Table 3: Robustness of ORMind under Different Large Language Models.

5.5.2 Impact of Various Components.

Table 2 quantifies each component's contribution to ORMind's performance across industry-relevant datasets. Ablation studies show that removing Semantic Encoder or Formalization Thinking significantly reduces solution quality, highlighting their importance for enterprise problem structuring. The System 2 Reasoner proves essential for production systems, with its partial function removal causing 6-9% performance degradation.

Adding a Conductor for agent selection increased operational complexity without improving performance, as our streamlined approach proved more cost-efficient. Introducing a Terminology Interpreter decreased performance by 3-5%, suggesting additional interpretation layers create unnecessary overhead. Similarly, Code Reviewer caused hallucinations in large language models, incorrectly modifying appropriately functioning code.

5.5.3 Method Robustness

Table 3 demonstrates ORMind's reliability with GPT-4 as the foundation model. The consistent performance enhancement across metrics confirms that ORMind's architecture effectively leverages advanced LLMs, delivering superior optimization solutions for business operations.

5.5.4 Operational Efficiency

Method	NL4Opt	ComplexOR
CoE	2003 ± 456	3288 ± 780
OptiMUS	2838 ± 822	3241 ± 1194
ORMind	2676 ± 518	3336 ± 997
w/o Reasoner	1539 ± 228	2390 ± 500

Table 4: Comparison of prompt lengths across different datasets for other methods.

ORMind maintains optimal token efficiency across enterprise-scale datasets, reducing computational overhead by streamlining earlier processing stages. Ablation study demonstrates that our system exhibits significant robustness, transparency, and engineering efficiency in industrial scenarios.

6 Conclusion

This paper introduces ORMind, a cognitive-inspired end-to-end reasoning framework, which is being piloted within Lenovo's AI Assistant as part of internal evaluations to enhance optimization capabilities for business. Future work will validate the framework on larger enterprise datasets and refine module coordination to build a stronger theoretical foundation and practical benchmarks for industrial decision systems.

Ethics Statement

In developing and deploying the ORMind framework, we have recognized that addressing ethical challenges is crucial for generating fair, transparent, and sustainable outcomes. One of the primary concerns is data bias. To mitigate this risk, we implement rigorous data cleaning and curation processes. Model robustness is another ethical challenge that we address in ORMind. Given the complexity of the multi-agent framework and the heavy reliance on large language models, we recognize that unexpected inputs or adversarial scenarios may lead to instability. As a risk mitigation measure, we have developed a robust error-detection mechanism to catch anomalies and iteratively correct errors.

Limitations

Our model's performance is highly dependent on the input data quality, and even with our robust data cleaning protocols, there is still a risk that residual biases may affect outcomes. Further work is needed to develop automated workflows that periodically audit and adjust data sources, thus reducing this risk over the long term. In terms of robustness, while our multi-agent iterative process allows for continuous refinement, the inherent brittleness of large language models under adversarial conditions poses a challenge. Future improvements will focus on integrating adversarial testing, uncertainty quantification, and more sophisticated error-correction protocols to enhance overall stability. Moreover, the orchestration of multiple agents demands significant computational and memory resources, which may not be feasible in every deployment scenario. To address this issue, we plan to explore model compression, caching techniques, and scalable infrastructure solutions that can dynamically allocate resources based on the current load.

A NL4Opt Case Study

In this section, we provide a detailed case study to illustrate the workings of our proposed ORMind framework. We take a specific problem from the **NL4Opt** dataset and walk through the entire process from problem input to final solution. The case study demonstrates how each agent in the ORMind framework contributes to the final output.

A.1 Problem Description

A pharmacy has 3000 mg of morphine to make painkillers and sleeping pills. Each painkiller pill requires 10 mg of morphine and three units of digestive medicine. Each sleeping pill requires 6 mg of morphine and five units of digestive medicine. The pharmacy needs to make at least 50 painkiller pills. Since sleeping pills are more popular, at least 70% of the pills should be sleeping pills. How many of each should the pharmacy make to minimize the total amount of digestive medicine needed?

A.3 Discussion of Results

In this case study, we explored how each agent in the ORMind framework contributed to solving the optimization problem of minimizing the total amount of digestive medicine needed to produce painkillers and sleeping pills at a pharmacy.

Initially, the Semantic Encoder correctly identified key variables, such as the number of painkillers and sleeping pills, as integers. The Formalization Thinking then successfully formulated the problem by defining the constraints and the objective function. Specifically, the constraints ensured that at least 50 painkiller pills must be produced and that at least 70% of the pills should be sleeping pills, while the objective was to minimize the use of digestive medicine.

The Programming Expert translated this mathematical model into Python code using the ‘pulp‘ library, ensuring the formulated constraints were implemented correctly. Upon initial solution generation, the Metacognitive Supervisor evaluated the code and returned a solution where only 50 painkiller pills were produced, with no sleeping pills, resulting in a minimal amount of digestive medicine used. However, this solution did not satisfy the 70% requirement for sleeping pills.

The System 2 Reasoner identified this issue through counterfactual analysis and suggested adjusting the constraint to enforce the 70% sleeping pill requirement. After incorporating this feedback, the Metacognitive Supervisor revised the model, leading to a new solution in which 50 painkiller pills and 117 sleeping pills were produced, minimizing the digestive medicine to 735 units.

This iterative process highlights the strength of the ORMind framework in refining solutions through multiple expert agents, each focusing on specific aspects of the problem. By leveraging the System 2 Reasoner’s counterfactual reasoning, the framework was able to correct an oversight in the initial solution, ensuring compliance with all constraints and optimizing the objective function more effectively. This case study demonstrates the framework’s capability to generate solutions and iteratively improve them, thereby achieving a robust and optimal outcome.

B ComplexOR Case Study

In this section, we provide a detailed case study to illustrate the workings of our proposed ORMind framework. We take a specific problem from the **ComplexOR** dataset and walk through the entire process from problem input to the final solution. The case study demonstrates how each agent in the ORMind framework contributes to the final output.

B.1 Problem Description

Consider a production problem. Given a set of products param{ProductNum}. Each product p is produced at a rate of param{ProductionRate_p} tons per hour. There are param{AvailableHours} hours available in a week. The profit per ton for each product p is param{ProfitPerTon_p}. There is a lower limit param{MinimumSale_p} and an upper limit param{MaximumSale_p} on the tons of each product p sold in a week. The problem aims to maximize the total profit from selling all products. It is constrained that the total of hours used by all products may not exceed the hours available. How do we decide the tons of each product p to be produced?

B.3 Discussion of Results

The process began with the Semantic Encoder correctly identifying the key variables, such as the number of products, production rates, profits per ton, and sales constraints. These parameters were crucial in formulating the problem accurately.

Next, the Formalization Thinking constructed the mathematical model by defining the decision variables and the constraints. The objective function was set to maximize the total profit. At the same time, the constraints ensured that the total production time did not exceed the available hours and that the production quantities stayed within the specified sales limits.

The Programming Expert then translated this model into Python code using the pulp library. This initial code successfully captured the essence of the problem but encountered a technical issue: the division of LpVariable objects by integers within the constraints, which the pulp library does not directly support.

The System 2 Reasoner identified this issue and provided specific feedback, pinpointing the problematic code and the nature of the error. This feedback was crucial in guiding the Metacognitive Supervisor's subsequent code revision.

The Metacognitive Supervisor corrected the division issue by multiplying instead of dividing the variables within the constraint formulation. This adjustment ensured that the constraints were correctly implemented and allowed the model to be solved without errors.

Finally, the revised model was solved, yielding an optimal solution where the production quantities and total profit were maximized while adhering to all constraints. The solution indicated optimal production quantities for each product and a corresponding total profit, demonstrating the effectiveness of the ORMind framework.

C Prompt Templates for Agents

Below, we list the prompt templates used for each agent in the ORMind framework. These templates are crucial for guiding the LLMs in performing their respective tasks.

Semantic Encoder

```
1
2   # Prompt Template:
3   Please review the following example and extract the parameters along with
        ↪ their concise definitions:
4   {problem_example}
5   The comment from your colleague is:
6   {comment_text}
7   Your output should be in JSON format as follows:
8   {{
9       "Parameter1": {{"Type": "The parameter's data type or shape",
            ↪ "Definition": "A brief definition of the parameter"}},
10      "Parameter2": {{"Type": "The parameter's data type or shape",
            ↪ "Definition": "A brief definition of the parameter"}},
11      ...
12  }}
13  Provide only the requested JSON output without any additional information.
```

Formalization Thinking

```
# Prompt Template:
Now the origin problem is as follows:
{problem_description}
You can use the parameters information from your colleague:
{comments_text}
The order of given parameters is random. You should clarify the meaning of each parameter to choose proper parameter to construct constraint.
Give your Mathematical model of this problem.
Your output format should be a JSON like this:
{{
    "VARIABLES": "A concise description about variables and its shape or type",
    "CONSTRAINTS": "A mathematical Formula about constraints",
    "OBJECTIVE": "A mathematical Formula about objective"
}}
Don't give any other information.
```

Executive Compiler

```
# Prompt Template:
You are presented with a specific problem and tasked with developing an efficient Python program to solve it.
The original problem is as follows:
{problem_description}
Your colleague has constructed a mathematical model for reference:
{comments_text}
Please note that this model may contain errors and is used as a reference.
You can analyze the problem step by step and provide your own code.
Requirements:
1. Use the PuLP library for implementation.
2. Provide a function that solves the problem.
3. Do not include code usage examples or specific variable values.
4. Focus on creating a general, reusable solution.
```

System 2 Reasoner

```
# Prompt Template:
Analyze the following optimization problem:
{problem_description}

Task: Write a Python function that identifies which specific constraints or conditions in the given problem are not satisfied. This condition will need modification to achieve a valid and optimal solution.

Function specifications:
- Input arguments and their types: {input_content}
- Adhere to the given data types.
- Reference this code structure: {code_example}
- Import the necessary libraries.
```

```

Notes:
The code example is only for reference in terms of format and structure. Generate code specifically for the given problem, not based on any examples.
All specific constraints should be determined based on the problem description provided.
Make sure to include checks for all constraints mentioned in the problem description. Don't give any Example usages.
```

Metacognitive Supervisor(backward)

```

# Prompt Template:
   FORWARD_TASK: Your colleague Executive Compiler has given his answer:
{comment_text}
This answer has not been formatted. You need to format the code as the example.
The final code must has the same input args and function name as the code example:
{code_example}
You also need to return the optimized variables.
Important: Your final code should strictly use same input args, function name and return style of the code example exactly.
{attention}
Don't forget to import the library. Don't give any example usage.

   BACKWARD_TASK: In your previous answer may have errors, you receive feedback about the error.
The feedback is generated by counterfactual reasoning,
which means that the feedback does not represent actual changes that need to be made to the problem conditions.
the feedback highlights where your code may have misinterpreted the original conditions.
{feedback}

For example, If you receive a message like 'Remove integer constraint on variables',
it means that your previous answer is correct only when the integer constraint is removed.
This strongly suggests that your earlier solution likely overlooked the integer constraint.
You need to add the constraint.
If you receive a message like 'Modify resource constraint to allow...',
it means that your previous answer is correct only when this constraint is modified.
This strongly suggests that your earlier solution likely has error in this constraint.
You need to doublecheck your previous code corresponding to the feedback and fix the error.

Carefully review the feedback and give the final code as the format of your previous code.
{attention}

The original problem description remains unchanged:
{problem_description}

Your previous code for analyzing the solution was:
{previous_code}

```

```
Your task is to carefully review the original problem description and the counterfactual feedback.

Remember:
Provide your corrected code in the same format as your previous code.
Do not give any example or explanation.
If the feedback is not existed in the description, you may directly use the original code.
Use "from PuLP import *" to import the library as the example.
```

Conductor

```

# Prompt Template:
Now, you are presented with an operational optimization-related problem:
{problem_description}
In this multi-expert system, there are many agent_team, each of whom is responsible for solving part of the problem.
Your task is to CHOOSE THE NEXT EXPERT TO CONSULT.
The names of the agent_team and their capabilities are listed below:
{experts_info}
Experts that have already been commented include:
{commented_experts}
Please select an expert to consult from the remaining expert names {remaining_experts}.
Please note that the maximum number of asked agent_team is {max_collaborate_nums}, and you can ask {remaining_collaborate_nums} more times.
You should output the name of expert directly. The next expert is:'''
```

Terminology Interpreter

```

# Prompt Template:
As a domain knowledge terminology interpreter, your role is to provide additional information and insights related to the problem domain.
Here are some relevant background knowledge about this problem: {knowledge}.

You can contribute by sharing your expertise, explaining relevant concepts, and offering suggestions to improve the problem understanding and formulation.
Please provide your input based on the given problem description:
{problem_description}

Your output format should be a JSON like this (choose at most 3 hardest terminology. Please provide your output, ensuring there is no additional text or formatting markers like ```json. The output should be in plain JSON format, directly parsable by json.loads(output).):
[
  {{
    "terminology": "...",
    "interpretation": "..."
  }}
]
```

Code Reviewer

```

# Prompt Template:
As a Code Reviewer, your responsibility is to conduct thorough reviews of implemented code related to optimization problems.
You will identify possible errors, inefficiencies, or areas for improvement in the code, ensuring that it adheres to best practices and delivers optimal results. Now, here is the problem:
{problem_description}.

You are supposed to refer to the codes given by your colleagues from other aspects: {comments_text}
```

D Code Example

The following are code examples used by the ORMind framework for the Counterfactual Analysis.

NL4Opt Code Example for Counterfactual Analysis

```python
import math

def counterfactual_solution_analysis(obj, var1, var2):
    """
    Analyze what changes would be necessary for the given solution to be valid and optimal.
    The function variable names must remain obj, var1 and var2. Do not alter these names.
    Args:
        obj: The objective value
        var1: Value of variable 1
        var2: Value of variable 2

    Returns:
        dict: Contains suggested modifications for each constraint and overall assessment
    """
    epsilon = 1e-2
    modifications = {
        "Modification1": {
            "check": lambda: var1 >= 0-epsilon,
            "message": "Adjust constraint to allow var1 to be {:.2f}".format(var1)
        },
        "Modification2": {
            "check": lambda: var2 >= 0-epsilon,
            "message": "Adjust constraint to allow var2 to be {:.2f}".format(var2)
        },
        "Modification3": {
            "check": lambda: 2 * var1 + 3 * var2 <= 100+epsilon,
            "message": "Modify resource constraint to allow 2*var1 + 3*var2 to be {:.2f}".format(2*var1 + 3*var2)
        },
        "Modification4": {
            "check": lambda: var1 + var2 <= 35+epsilon,
            "message": "Adjust daily production limit to allow var1 + var2 to be {:.2f}".format(var1 + var2)
        },
        "Modification5": {
```

```
            "check": lambda: math.isclose(var1, round(var1)) and
                ↪ math.isclose(var2, round(var2)),
            "message": "Remove integer constraint on variables"
        },
        "Modification6": {
            "check": lambda: math.isclose(obj, round(obj)),

G Agent-Memory Pool Interaction in ORMind

The Memory Pool in *ORMind* functions as a centralized repository that supports the collaboration and coordination of agents during the reasoning process. It stores and provides access to shared data, ensuring consistency and efficiency in solving complex operations research (OR) problems.

Agents interact with the Memory Pool primarily through retrieval and update. Before performing a task, an agent retrieves relevant information from the Memory Pool, such as the current problem state, previously identified variables and constraints, and intermediate results from earlier reasoning steps. This ensures that all agents operate with access to the most up-to-date context, avoiding redundant computations and inconsistencies.

Once an agent completes a task, it updates the Memory Pool with its results. These updates include newly discovered variables, constraints, other task-specific outputs, and annotations summarizing the reasoning process. Every update is tagged with metadata, such as the agent's identifier and a timestamp, to maintain traceability and facilitate debugging.

The Memory Pool also plays a critical role in the iterative refinement process. As new information becomes available, earlier results can be revisited and improved by subsequent agents, allowing for modular and adaptive problem-solving. This centralized structure ensures that the system's collective progress is reflected in a single shared repository, enabling efficient and coherent reasoning across all agents.

The Memory Pool enhances the ORMind framework's ability to tackle complex OR problems by providing a shared, structured, and continuously updated context. It promotes collaboration, reduces redundancy, and ensures that agents work synchronized and context-awarely.

H Comparison with Other Planning with Feedback Methods

While our methodology adopts a multi-expert framework, it distinguishes itself through two unique features: human problem-solving process and counterfactual reasoning. These features enable a more structured and iterative problem-solving process compared to other approaches.

The table 5 highlights the differences between our approach and other methods regarding key functionalities such as multi-agent frameworks, industry-focused processes, external knowledge access, and feedback refinement.

Method	Multi-agents	Industry-Focused	External Knowledge	Feedback Refinement
ReAct(Yao et al., 2023)	✗	✗	✓	✗

I Long-term Research Value and Future Directions

This work establishes a foundation for advanced reasoning systems in operations research with implications far beyond the current implementation. Below, we analyze the key long-term research values and potential future directions:

I.1 Counterfactual Reasoning as a Fundamental AI Capability

The counterfactual reasoning approach introduced in ORMind represents a fundamental advancement in how AI systems can validate and refine solutions. By reasoning about what constraints would need to change for a given solution to be valid, our approach begins to bridge the gap between correlation and causation in AI reasoning systems. This opens avenues for more sophisticated causal reasoning frameworks that can identify patterns and underlying causal mechanisms. Beyond operations research, this methodology could fundamentally transform how AI systems approach problem validation and solution refinement across domains ranging from scientific discovery to medical diagnosis. The ability to perform "what-if" analyses on potential solutions provides a form of self-verification that increases solution reliability without requiring explicit programming of all edge cases, a crucial advancement for mission-critical enterprise applications.

I.2 Cognitive Architectures for Complex Decision Making

ORMind's cognitively-inspired framework mirrors human expert reasoning processes and offers a blueprint for next-generation business intelligence systems. The sequential decomposition of complex problems into stages of understanding, formulation, and refinement provides a generalizable architecture that could be applied to various reasoning tasks beyond optimization. This represents a significant shift from current approaches that often rely on monolithic models or rigid predefined workflows. Future research could explore how such cognitive architectures can dynamically adapt their reasoning strategies based on problem characteristics, incorporate domain-specific knowledge while preserving flexible reasoning, and create natural interaction points for human-AI collaboration. The emergence of such cognitively-aligned systems could fundamentally transform how organizations approach complex decision-making, enabling more intuitive, explainable, and effective enterprise AI solutions.

Multi-Step Generation of Test Specifications using Large Language Models for System-Level Requirements

Abstract

System-level testing is a critical phase in the development of large, safety-dependent systems, such as those in the automotive industry. However, creating test specifications can be a time-consuming and error-prone process. This paper presents an AI-based assistant to aid users in creating test specifications for system-level requirements. The system mimics the working process of a test developer by utilizing a LLM and an agentic framework, and by introducing intermediate test artifacts—structured intermediate representations derived from input requirements. Our user study demonstrates a **30 to 40%** reduction in effort required for test development. For test specification generation, our quantitative analysis reveals that iteratively providing the model with more targeted information, like examples of similar test specifications, based on comparable requirements and purposes, can boost the performance by up to **30%** in ROUGE-L. Overall, our approach has the potential to improve the efficiency, accuracy, and reliability of system-level testing and can be applied to various industries where safety and functionality are paramount.

1 Introduction

In industries such as aerospace, telecommunications, electronics, software, and automotive engineering, the systems to be developed are often complex due to the intricate relationships among numerous interdependent components. Effective system-level testing is a critical phase that verifies whether the complete and integrated system meets their intended functionality and performs as expected. It guarantees that all components work together seamlessly, ensuring the safety, functionality, and reliability of complex systems. To achieve this, system-level testing is typically conducted in controlled environments such as Software-in-the-Loop (SiL, Umang et al.) or Hardware-in-the-Loop (HiL, Ledin, 1999) and must be well documented, as emphasized by standards like Automotive SPICE (ASPICE, VDA QMC, 2023). To support system-level testing, two distinct roles collaborate: the requirements engineer, who authors system-level requirements, and the test developer, who derives detailed test specifications from those requirements. In this paper, we focus on assisting test developers to create test specifications.

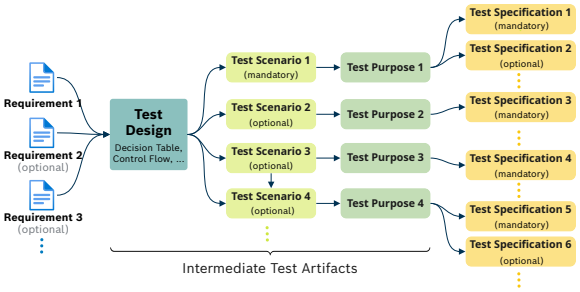

Figure 1: Illustrated Workflow - Deriving Test Specifications from Requirements

A test specification typically includes the definition of tests to be performed, the expected result, associated testing conditions, and other information. In contrast to software testing, both the system-level requirements and test specifications are documented in *natural language*, taking the form of text documents rather than code (cf. VDA QMC, 2023). To bridge the large gap between the input requirements and the final test specifications, test developers typically follow a structured workflow of five steps to generate concrete test specifications, as illustrated in Figure 1:

First, the test developers **(i) group input requirements into clusters** (see examples given in Figure 2). Then, they select a test design technique according to ISO/IEC/IEEE (2021) and **(ii) create a test design** based on the requirements. The test design is an abstraction of the tests, and specifies the relationship between the input conditions and the output expected results. Test designs are re-

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 132–146

quired to cover a vast array of corner cases, which helps to verify the logic of the function, and check potential errors or faults. Test designs can be expressed in diagrams (see example in Figure 3) or decision tables (see example in Table 6 in Appendix A.1 for a corresponding example), with each row or path defining a single **(iii) test scenario**. Once they have identified the test scenarios, they derive a **(iv) test purpose** for each scenario, which is a specific reason or objective that the test specifications need to cover. In the last step, the developers create **(v) test specifications** (see Figure 4) that consist of the previously generated test purpose, pre- and post-conditions as well as execution steps that testers shall follow. To offer a better understanding of the test development process in massive system production, more details on above examples are given in Appendix A.1.

Requirements

R1: The lane assist function shall activate only when the vehicle speed exceeds 60 km/h.

R2: The lane assist function shall require manual activation by the driver.

R3: The lane assist function shall operate only when clear lane

Figure 2: Example requirements cluster

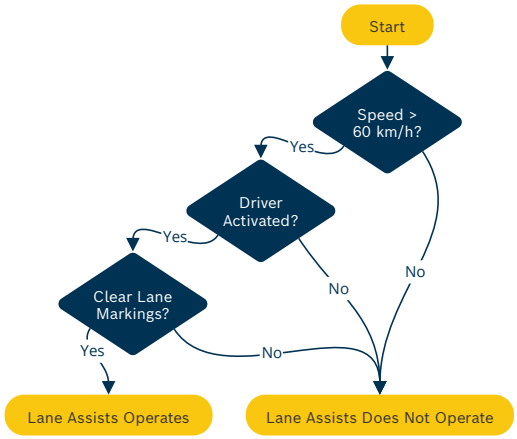

Figure 3: Example control flow chart for lane assist function

Typically, the process described above will cost the test developers a huge amount of manual efforts to handle the challenges such as the many-to-many relationship between requirements and test specifications, the mixture of natural language descriptions and variable assignments that need to be precisely met in test specifications, and the injection of domain know-how. This paper introduces an AI-based test development assistant that harnesses large language models and Agentic AI to assist the test developers to streamline this process. A user study demonstrates that our approach reduces the time needed to derive test specifications from requirements by 30–40% on average, significantly boosting both efficiency and accuracy.

Test Specification

Preconditions

- The vehicle ignition is "ON".
- Vehicle_Speed is at standstill.
- Lane_Assist_Status = "Off".
- Driver_Lane_Assist_Activation = "False".
- Set Lane_Marking_Detected = "True".

Test Steps and Expected Results

- Activate the lane assist by setting Driver_Lane_Assist_Activation = "True". Expected Value: Lane_Assist_Status = "Ready".
- Gradually increase Vehicle_Speed to 65 km/h over 10 seconds. Expected Value: Lane_Assist_Status = "Active".
- Gradually decrease Vehicle_Speed to 55 km/h over 10 seconds. Expected Value: Lane_Assist_Status = "Ready".
- Deactivate the lane assist by setting Driver_Lane_Assist_Activation = "False". Expected Value: Lane_Assist_Status = "Off".
- Gradually decrease Vehicle_Speed to 0 km/h over 10 seconds.
- Retrieve data from the system's failure memory.

Postconditions

- Clear the failure memory.
- Reset conditions back to preconditions if required.

Figure 4: Example test spec for lane assist function

Overall, our key contributions are summarized as follows:

(i) **An End-to-End AI-Based Test Development Assistant**: We introduce an innovative AI-based test development assistant that leverages domain expertise and historical data to generate high-quality test specifications for system-level requirements.

(ii) **Intermediate Test Artifacts**: Our system automatically generates intermediate test artifacts—structured representations such as tables and graphs—that effectively bridge the gap between input requirements and final test specifications, thereby resolving the inherent many-to-many relationship between them.

(iii) **Human-in-the-Loop Test Workflow**: Designed to foster collaboration, our system offers actionable suggestions while allowing test developers to inspect, refine, and extend the

generated test artifacts and test specifications, ensuring a seamless iterative process.

(iv) **End-to-End Evaluation with Test Experts**: We conducted an end-to-end evaluation with expert test developers from our organization.

2 Related Work

2.1 System Testing in Industry

Regarding development frameworks, system-level testing is independent of specific methodologies, and can be applied to a range of approaches, including the V-Model (Johansson and Bucanac, 1999), Agile, and Waterfall. Various testing methodologies exist, each tailored to distinct objectives. Requirement-based testing (Mustafa et al., 2021), for instance, extracts test cases directly from system requirements, thereby validating all functionalities. Model-based testing (Mohd-Shafie et al., 2021), on the other hand, leverages system behavior models to generate test scenarios, ensuring comprehensive coverage of interactions. We follow a requirement-based testing approach.

2.2 AI in Requirement Engineering

Prior art on requirements analysis include information extraction (Holter and Ell, 2023; Das et al., 2023; Nguyen et al., 2024), classification (Kici et al., 2021; Li et al., 2022; Khayashi et al., 2022; Yildirim et al., 2023; Nayak et al., 2023), consistency checking (Bertram et al., 2023; Marchezan et al., 2024), mapping and consolidating requirements (Sonbol et al., 2022; Bertram et al., 2022a,b; Subahi, 2023) and requirements generation (Krishna et al., 2024). These AI techniques are either adopted to identify key information for downstream tasks, or to improve the writing quality of the requirements, reducing mistakes and resolving ambiguities in the writing.

Regarding test specifications, LLM-based test generation is an increasingly researched subfield of code generation (Jiang et al., 2024). Generative AI-based software testing has been studied intensively as shown in surveys (Wang et al., 2024; Jin et al., 2024), and software testing is mostly applied for test generation, program debugging and bug repair. There is a notable amount of work that explores the relationship between requirements and test generation. Han et al. (2024) propose a framework for code generation and test execution, where new requirements are generated to create more correct tests. Yang et al. (2023) develop an interactive tool for requirements elicitation, integrating a component to write tests. Wei (2024) apply an LLM-based approach to interpret provided requirements, modifying extracted information to object-oriented models to generate test cases. Requirements are often represented as UML or use case diagrams (e.g., Mustafa et al., 2021; Sarma et al., 2007; Swain et al., 2010), which allows Naimi et al. (2024) to extract use case details from UML diagrams in XML format to automatically generate structured prompts for test creation.

There is limited recent research on AI-supported generation of *natural language* test specifications. Adabala et al. (2024) propose a pipeline for generating test flows for functional safety requirements by generating similar test specifications as examples for the language model. Liu et al. (2024) enhance a LLM through data augmentation, transforming the one-to-many relationship between requirements and test specifications into multiple one-to-one relationships. They augment the model input by adding either the test objective or a LLM-generated summary of the test specification. Arora et al. (2024) present research closely related to our work using a RAG framework to generate test specifications given several input requirements, utilizing a documentation corpus and optional one-shot examples. They incorporate a test description to guide the model during generation. In contrast to these methods, our approach integrates a retrieval component based on historical requirements and test specifications. As key difference to all previous approaches, we use **test artifacts** (i.e., test design, test scenarios and test purposes) as an intermediate structured representation to address the many-to-many relationship of requirements and test specifications. Notably, Liu et al. (2024) and Arora et al. (2024) focus on one-to-many and many-to-one relationships, respectively. As a means to address these challenges, they add test descriptions to the input of the LLM. In contrast, our approach is fully automated; test descriptions, in our case the test purposes, are automatically generated to guide the model. The test purposes are generated from the test scenarios, which again are automatically derived from the input requirements applying a test design technique.

3 Method

We designed a novel system for generating test specifications from input requirements. The sys-

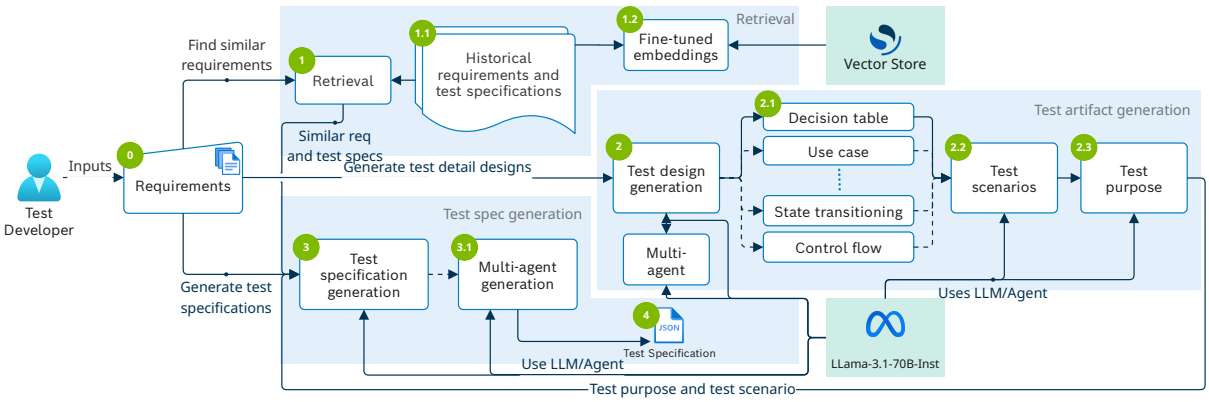

Figure 5: System's workflow and architecture

tem architecture is illustrated in Figure 5. The system begins with the user entering requirements as input (point 0 in Figure 5), followed by a retrieval step to find similar requirements (1). The data basis consists of historical requirements and linked historical test specifications (1.2). The ultimate goal of retrieving similar requirements is to identify one or more existing test specifications that can serve as examples for the final step: test specification generation. Consequently, during this step, users can review associated historic test specifications and select one or more as examples to guide the generation process. The retrieval process is two-pronged, leveraging both sparse retrieval (BM25) and dense retrieval (with fine-tuned embeddings, 1.2). To get more precise results, the system also allows the user to apply filters to refine the retrieval outcomes and select more relevant test specifications from the retrieved ones.

The embedding model used in retrieval is fine-tuned based on the *bge-m3* model (Chen et al., 2024). We start with continuous pre-training on the domain, followed by a two-step fine-tuning approach. First, we fine-tune on abbreviation-substituted requirement pairs to teach the model the meaning of the abbreviations in context. Next, we fine-tune with synthetic similar requirement pairs and requirement pairs sharing the same test linkage. Finally, we boost the performance of the model by merging the original embedding model with the fine-tuned model using LM-Cocktail (Xiao et al., 2023). Details for the datasets we used can be found in Section 4.1. Further details on the fine-tuning process are given in Appendix A.2.

Following the retrieval of similar requirements, test artifacts are generated (2). The system employs *Llama-3.1-70B* as LLM to suggest up to three test design techniques that are best suited for the selected requirements (2.1). Users can also select an alternative technique if preferred. The test design techniques include *decision table testing*, *use case testing*, *control flow testing* and *state transitioning testing*, amongst others. Depending on the chosen technique, the system generates comprehensive test designs in either Markdown tables or machine-readable diagrams in Mermaid format. Users can review and edit these designs. Examples of a control flow diagram and an equivalent decision table are provided in Figure 3 and Table 6 (Appendix A.1), respectively. To enhance the user experience, our system employs a multi-agent approach (4): a design agent generates an initial test design, the user reviews the output and a separate reflection agent subsequently verifies the design's adherence to industry standards, such as ISO 26262.

Using the generated test design as a deterministic basis, the system extracts a test scenario for each row in the Markdown table or each path in the Mermaid diagram (2.2). An LLM is then used to generate the test purpose for each scenario (2.3). Users can review and refine these generated test purposes, selecting the ones they wish to use for creating test specifications. Example test purposes for each test scenario derived from Figure 3 (or from equivalent Table 6) are shown in Table 1.

Finally, the system generates comprehensive test specifications for the selected test purposes, considering the test scenario, the input requirements and similar test specifications (3). The test specification is presented in a structured format, outlining the relevant steps for testers to follow during the testing process. Notably, the system provides test specifications in JSON format, enabling seamless integration with downstream workflow steps, such

Verify that the lane assist function operates when the vehicle speed exceeds 60 km/h, the driver has activated the system, and clear lane markings are detected.
Verify that the lane assist function does not operate when the vehicle speed is below 60 km/h, the driver has activated the system, and clear lane markings are detected.
Verify that the lane assist function does not operate when the vehicle speed exceeds 60 km/h, the driver has not activated the system, and lane markings are detected.
Verify that the lane assist function does not operate when the vehicle speed exceeds 60 km/h, the driver has activated the system, and lane markings are not detected.

Table 1: Example test purposes for lane assist function

as automated test script generation for execution in Software-in-the-Loop (SiL) or Hardware-in-the-Loop (HiL) environments. Similar to the previous step, we utilize a multi-agent approach for the enhancement of the test specification generation (step 3.1). Demo screenshots of the application and their intermediate steps are shown in Appendix A.5.

4 Datasets

4.1 Datasets for Embedding Fine-tuning

In order to fine-tune embeddings for retrieving similar requirements, we created three datasets: 1) synthetic sets of similar requirements, 2) test-based requirement sets, and 3) abbreviation-substituted requirement pairs. The synthetic requirement sets were created using the data generation algorithm described in the next paragraph. To incorporate historical sets of similar requirements, we focused on those that share the same test linkage, which we refer to as test-based requirements. We then excluded any requirements with low embedding similarity within each set (<0.8). Abbreviation-substituted requirement pairs were created from duplicating a requirement, and then using the abbreviation in one instance and the full expression in the other. Details are given in Appendix A.2.

Generation of Synthetic Requirements. We propose an algorithm that decomposes the input requirement into its constituent parts and modifies them to create new requirements that maintais similarity to the original. The structure of a requirement can be defined as consisting of several key elements, including condition, subject, action, object, and constraint of action (ISO/IEC/IEEE, 2011). The core of the algorithm is to selectively modify specific parts of the requirement under certain conditions, ensuring that the resulting requirement stays similar to the original one. The algorithm works as follows:

Algorithm 1 Requirement Modification Algorithm

1: Decompose the input requirement into its constituent parts, including condition, subject, action, object, and constraint of action.
2: Select one and only one part that is not empty, among condition, subject, or object, and change its content to fit a similar requirement.
3: **if** constraint of action is empty **then**
4: Create some content that fits a similar requirement (e.g., time, signals with certain values).
5: **else**
6: Change it to an empty string.
7: **end if**
8: **if** object is empty **then**
9: Create some content that fits a similar requirement.
10: **end if**
11: Rewrite the synthetic requirement in natural language.
12: Output the modified requirement in JSON format, including the "Changed" field with the name of the changed key.

4.2 Dataset for Evaluation

Retrieval Component. To evaluate the embedding model, a dataset of similar requirement pairs was curated. It includes 48 pairs selected by test engineers from existing requirements, as well as 45 pairs, each consisting of one existing requirement and one newly crafted requirement.

Test Designs. The evaluation of the test design generation was done with a manually created dataset, containing 22 decision tables, 20 use case designs, 6 control flow diagrams, and 2 state transitioning diagrams. The distribution of test design techniques is based on simple random sampling.

Test Specifications. For the evaluation of the generated test specifications, a representative sample of 98 test specifications was chosen from historical data. These varied in terms of their related system functions and complexity. For the selected test specifications, all the linked requirements, along with the test scenarios and the related test purposes, were used as input, as well as one retrieved similar requirement with its linked test specification as

	HIT@1	HIT@3	HIT@5	HIT@10
Sparse Retrieval	46.24	66.67	76.34	82.80
Dense Retrieval - base embedding	45.16	65.59	74.19	81.72
Dense Retrieval - fine-tuned embed.	**53.76**	**76.34**	**81.72**	**91.40**

+ iso standards	32.87	87.69	31.75

Table 4: Evaluation results of the test generation component average results from 98 samples

few-shot example. Including the test design itself was not necessary since the derived test scenarios and test purposes already included the relevant information.

5 Experiments

We evaluate the performance of our method by *(i) evaluating every component individually* and employing quantitative metrics such as HIT rate, ROUGE-L (Lin, 2004), BERTScore (Zhang et al., 2019), and using a LLM as a judge and *(ii) evaluating the end-to-end system through user evaluation*.

5.1 Quantitative Evaluation

Evaluating the Retrieval System. The results for the retrieval system are presented in Table 2. We observe a 9-point improvement of the fine-tuned embedding model compared to the sparse retrieval, and a nearly 10-point improvement compared to the base embedding model.

Evaluating the Generation Components. We evaluated the performance of our test design and test specification generation components using two metrics, ROUGE-L and BERTScore. We used the mean F1 score from BERTScore as a key metric, utilizing the default English language embedding model without fine-tuning on our domain (*roberta-large_L17_no-idf_version=0.3.12*). Additionally, we obtained subjective assessments from GPT-4o, which rated each generated output against a reference output on a scale of 1 to 10, providing a detailed explanation to support their rating. The results of the evaluation of the generated test designs are presented in Table 3 and reported as mean scores. We evaluated the test specification generation capabilities of our system through a five-stage process. First, we employed a zero-shot approach, where the LLM generated test specifications solely based on the input requirements without specifying the test purpose which is the main product of the intermediate test artifacts. Then, we added the test purpose, still in a zero-shot setting. Next, we provided the model with examples of similar test specifications, based on similar requirements. Then, we enriched the data by fetching similar test specifications based on the test purpose. Finally, to further assess the system's performance, we experimented with prompting the model to adhere to specific ISO standards, such as ISO 26262. We conducted these experiments in both single LLM and multi-agent settings, where a reflection agent reviewed the response from the first agent. The results of our evaluation are presented in Table 4. Appendix A.3 presents our preliminary experiments across multiple language models.

Analysis of Evaluation Results. For test design generation (Table 3), control flow testing gives best results. We hypothesize that lower scores may be due to the fact that test developers created the test data with a focus on relevant scenarios, leveraging their experience from historical projects, whereas the language model adopted a more exhaustive approach, attempting to cover all possible combinations of values and corner cases. The effect of this is lower for control flow testing than for e.g. table design testing, since in the latter case a complete new row needs to be added, while for control flow testing an additional edge might be sufficient.

For test specification generation, our analysis reveals that providing the model with examples of similar test specifications, obtained through similar requirements and purpose, yields the best performance, outperforming the zero-shot approach by up to 30 points for ROUGE-L. Incorporating few-shot examples yields significantly greater improve-

Retrieval	Test Design	Purpose & Scenario	Test Spec
3.0	3.0	3.4	3.2

Table 5: Component-wise User Evaluation Results: Average Ratings on a Scale of 1 to 5 from 87 test runs.

ments in the surface-level metric ROUGE-L compared to BERTScore and LLM-as-a-Judge. This observation suggests that the LLM does not inherently possess the capability to accurately reproduce the specific language utilized in system-level tests. In contrast, instructing the model to adhere to ISO standards did not lead to significant improvements, suggesting that the model had already internalized this knowledge and was applying it without explicit instruction. The reflection agent underperformed compared to the initial response in both test design and test specification generation. This discrepancy is likely due to the agent's overly cautious approach, which prioritized strict adherence to guidelines and regulations over flexibility and natural language style. As a result, the generated responses tended to be more formal and rigid, deviating from the typical style of human-written test specifications.

5.2 User Study

To facilitate end-to-end evaluation of our system, we developed a simple application using Streamlit (Streamlit, 2024), which guides users through a four-step wizard process. Screenshots of the Streamlit demo can be seen in Appendix A.5. Ten experienced test developers from our organization participated in the evaluation, conducting a total of 87 test runs. The evaluation process consisted of four steps: (1) entering requirements, (2) selecting similar requirements based on the retrieval module and choosing example test specifications, (3) generating test design details and test scenarios with test purposes, and (4) generating test specifications. We asked the participants to evaluate the quality of each component on a rating scale of 1 to 5, as well as the overall usefulness of the system. The average results of the component evaluations are presented in Table 5. Notably, the participants estimated that the system saved them, on average, 30 to 40% of the time typically spent deriving test specifications from requirements.

6 Conclusions

In this paper, we introduce a novel AI-powered test development assistant for productive deployment. It is designed to help users to effectively derive test specifications from system-level requirements and significantly improving efficiency and accuracy. It employs historical similar requirements and linked test specifications, and utilizes intermediate test artifacts such as test designs, test scenarios, and test purposes, to generate new test specifications. By incorporating these test artifacts into the tool's workflow as a structured intermediate representation, we address the complex many-to-many relationships between requirements and test specifications. A user study showed a 30 to 40% reduction in effort required to derive test specifications using our tool. This system exemplifies the potential of LLMs to extend beyond mere language generation, showcasing their ability to design and produce structured outputs as helpful intermediate representations. Furthermore, our quantitative evaluation confirmed the effectiveness of our approach for system-level test specification language. We observe an improvement of roughly 30% ROUGE-L in comparison to the zero-shot approach.

7 Future Work

Although our initial results are encouraging, they point to two key avenues for further investigation:

Augmenting Inputs and Domain-Specific Fine-Tuning Our current pipeline relies solely on historical requirements and test specifications. We plan to explore the integration of additional artifacts—such as technical design documents, and architecture diagrams—either through enriched prompting or by fine-tuning the base LLM on these corpora. We hypothesize that this broader context will improve the model's domain understanding and lead to more accurate, context-aware test specifications.

Standards Compliance and Hallucination Analysis Preliminary trials showed no benefit from explicitly prompting the model to adhere to ISO standards. We will conduct a deeper analysis to determine whether this stems from prompt formulation, model biases, or gaps in the LLM's encoded knowledge of the standard. In parallel, we will develop metrics and manual review protocols to measure the model's hallucination rate in generated test specifications, ensuring that outputs remain reliable, traceable, and aligned with stakeholder expectations.

Acknowledgements

We gratefully acknowledge Michael Hofmann for his expert guidance and thoughtful feedback throughout this project. We also thank Tim Lukas Müller, Suneel Datta Kolipakula, and the entire testing team for rigorously testing and evaluating the system from an end-user perspective. Their insightful critiques were instrumental in shaping both the quality and the direction of our work.

A Appendices

In the following sections, we report additional details on the following topics:

- Definitions and Examples for Main Concepts (Section A.1)
- Finetuning of Embeddings (Section A.2)
- Experiments with different LLMs (Section A.3)
- LLM Prompts (Section A.4)
- Demo Screenshots (Section A.5)

A.1 Definitions and Examples for Main Concepts

We first define the terms used in system testing, then introduce the example for each concept.

- **Requirements**: a documented representation of condition or capacity, that must be met or possessed by the system, in order to satisfy a contract, standard, or other formally imposed documents. (Pohl, 2010)
- **Test Design**: abstraction of the tests, describe the input conditions and the expected output, and describe the function at high level. Developers set various values for input conditions, and check if the test results are expected, which helps to verify function logic and assure all aspects of the function are evaluated. Some common test design techniques include: decision table, control-flow diagram.
- **Test Scenario**: according to the test design, developers choose a set of input condition values as test scenario to verify the function, and check its performance.
- **Test Purpose/Goal**: a prescriptive statement that describe the test intention regarding the objectives, and functionality of the system. (Pohl, 2010)
- **Test Specification**: concrete textual description of the test case, detailed describing input conditions, test steps, expected output, etc, in the test document.

Below is a full set of requirements, test design, scenarios, and one purpose as well as one related test specification. For clarity, we will reproduce the previously shown decision table and control flow chart.[1]

From these examples, we want to demonstrate that test development in massive systems involves lots of formal textual content written in natural language, which would cost much manual efforts.

Requirements

(i) The lane assist function shall activate only when the vehicle speed exceeds 60 km/h.

(ii) The lane assist function shall require manual activation by the driver.

(iii) The lane assist function shall operate only when clear lane markings are detected.

Test Design & Scenario

Note that for test development, only one test design technique is necessary; therefore, in this case, either the decision table or the control flow diagram will suffice.

C1: Speed > 60 km/h	C2: Driver Activated	C3: Lane Markings	A1: Lane Assist Operates
Yes	Yes	Yes	Yes
Yes	No	No	No
No	Yes	No	No
No	No	Yes	No

Table 6: Example decision table for lane assist function

Test Purpose

Based on the test design, four test purposes arise. We are using only the following one here; the remaining ones can be found in Table 1.

Verify that the lane assist function operates when the vehicle speed exceeds 60 km/h, the driver has activated the system, and clear lane markings are detected.

This test purpose can lead to several different test specifications. The following is one example. Other valid test specifications are possible based on the same purpose. For simplicity, we will omit certain details in the test specification, such as settings of gear, brake, and accelerator pedal.

Test Specification

Preconditions

- The vehicle ignition is "ON".
- Vehicle_Speed is at standstill.

[1] All given examples in the paper are synthetically generated and manually reviewed, since we cannot disclose the original data.

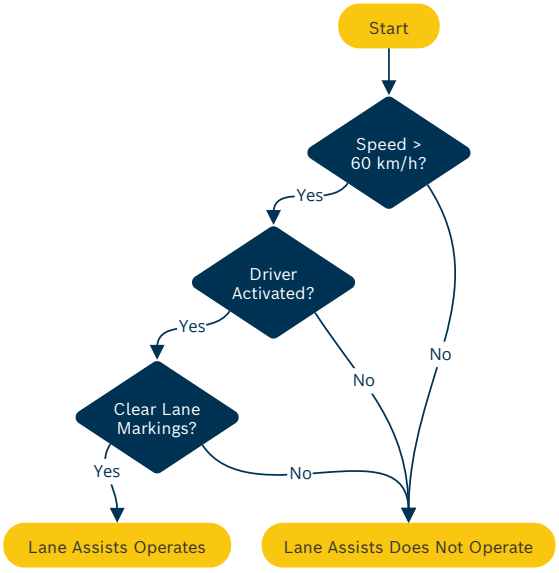

Figure 6: Example control flow chart for lane assist function

- Lane_Assist_Status = "Off".
- Driver_Lane_Assist_Activation = "False".
- Set Lane_Marking_Detected = "True".

Test Steps and Expected Results

1. Activate the lane assist by setting Driver_Lane_Assist_Activation = "True". *Expected Value:* Lane_Assist_Status = "Ready".
2. Gradually increase Vehicle_Speed to 65 km/h over 10 seconds. *Expected Value:* Lane_Assist_Status = "Active".
3. Gradually decrease Vehicle_Speed to 55 km/h over 10 seconds. *Expected Value:* Lane_Assist_Status = "Ready".
4. Deactivate the lane assist by setting Driver_Lane_Assist_Activation = "False". *Expected Value:* Lane_Assist_Status = "Off".
5. Gradually decrease Vehicle_Speed to 0 km/h over 10 seconds.
6. Retrieve data from the system's failure memory.

Postconditions

- Clear the failure memory.
- Reset conditions back to preconditions if required.

A.2 Finetuning of embeddings

For the retrieval step, we fine-tune the *bge-m3* base model (Chen et al., 2024) in several steps (Figure 7). We first use our available function documentation for continuous pre-training on the domain using RetroMAE (Shitao Xiao, 2022). As training data, the documentation is split in roughly 720k chunks of text. We use a learning rate of $2e{-}5$, a batch size of 4, and we train for 2 epochs. The fine-tuning process consists of two stages: initially, we fine-tune the model using abbreviation-substituted pairs, followed by fine-tuning on combined sets of test-based and augmented requirements. This two-step approach is applied because the model needs to learn the contextual meaning of abbreviations from the abbreviation-substituted data first, similar to pre-training. Abbreviations can have two long forms even within the domain, e.g. *LAF* can either denote *lane assist function* or *load adaptive friction*. We retrieve the correct long form from a dictionary that we extracted from our documentation. An abbreviation-substituted pair would then look like this:

- *The **LAF** shall activate only when the vehicle speed exceeds 60 km/h.*
- *The **lane assist function** shall activate only when the vehicle speed exceeds 60 km/h.*

We train on roughly 17k abbreviation-substituted pairs. We separate this step from the final fine-tuning step, because these are not realistic similar requirement pairs we want to find in our retrieval step. Instead, this should be a pre-step to learn the meaning of domain-specific abbreviations. The other two datasets reflect realistic similar requirements and are therefore utilized for fine-tuning in the final stage. The final combined training dataset comprises 3204 similar requirement pairs. A similar requirement pair could be:

- *LAF shall not be activated if vehicle velocity is low.*
- *LAF should not switch on when the vehicle speed is low.*

We employ contrastive learning for fine-tuning and incorporate the sampling of hard negatives to enhance the results (Zhang et al., 2023). We sample hard negatives in the range of 2-200 and select 15 negatives per pair. For the fine-tuning, we

Figure 7: Embedding finetuning steps.

use a learning rate of $1e{-}5$, a batch size of 1, a temperature of 0.02, and train for 5 epochs. As a last step, we further tune the embedding model by merging the original bge-m3 model with the fine-tuned model using LM-Cocktail (Xiao et al., 2023), with a 50-50 ratio. This step is particularly advantageous as similar requirements exhibit variations in both common language usage (e.g., a test developer's preference for using the terms *stop* or *end*) and domain-specific terms.

A.3 Experiments with different LLMs

To determine an optimal backbone for our study, we first conducted a comparative evaluation of several state-of-the-art language models. Figure 8 presents the aggregated results: although Qwen-2.5-14B-Instruct and GPT-4o each achieve the bigger scores on some metrics, *LLama-3.1-70B-Instruct* delivers the strongest overall performance when all measures are combined. Based on these findings, we selected *LLama-3.1-70B-Instruct* as the sole model for our primary experiments.

A.4 LLM Prompts

The following section presents example LLM prompts for generating the different test artifacts.

A.4.1 Prompts for Test Design Generation

Test Design Generation: User Prompt

```
Create a {test_design_technique} for the following
requirements and their verification criteria.

For all requirements, you should create one single
{test_design_technique}.

Output Format:

{output_format}

Definition:

{definition}

Examples:

{few_shot_examples}

Input Requirements:

{formatted_requirements}
```

Figure 9: Example user prompt for generating test designs based on input requirements.

Test Design Generator Agent: System Prompt

```
You are an AI test developer in the automotive industry,
responsible for creating high-quality test designs. Your
expertise is crucial in ensuring that the test designs
meet the required standards and regulations.

Input:

    • A set of requirements that needs to be covered.
    • Optional verification criteria provided by the
      function developer. These criteria should be used
      only as supplementary information and must not be
      the sole source for deriving test designs or test
      specifications.

{standards_regulations}

Task Requirements:

    • Generate detailed test designs that are accurate,
      complete, and unambiguous.

Response format:

    • Your output must be either: a single block of
      mermaid flowchart code, or exactly one markdown
      table.
```

Figure 10: Example Generation Agent prompt for creating test designs.

Test Design Reflection Agent: System Prompt

```
You are an AI test supervisor in the automotive industry,
renowned for your meticulous attention to detail and
dedication to upholding industry standards. Your
expertise is crucial in ensuring that test detail designs
meet the required standards and regulations.

Input: A set of test detail designs for the automobile
system, generated by an AI test developer

{standards_regulations}

Critique Requirements:

    • Scrutinize the test detail designs for any harmful
      elements or regulatory violations
    • Evaluate the quality of the test detail designs,
      including accuracy, completeness, and clarity
    • Ensure that your critique is objective,
      constructive, and actionable

Additional Guidelines:

    • Restrict your answer to the exact question asked,
      without introducing unnecessary information or
      assumptions
    • Focus on providing actionable feedback that enables
      the test developer to improve the test detail
      designs
    • Make sure that the output is consistent throughout
      the test detail designs.
```

Figure 11: Example Reflection Agent prompt for providing feedback on generated test designs.

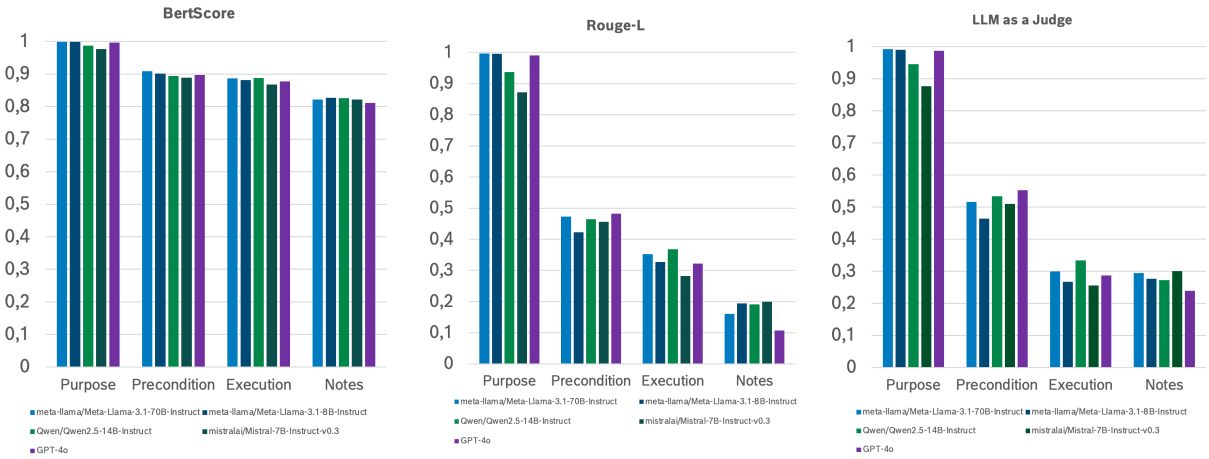

Figure 8: (a) Comparison of BertScore for different language models when generating various sections of the test specifications; (b) Corresponding ROUGE-L comparison across the same models and sections; (c) LLM-as-a-Judge assessment of the quality of each generated section by those models.

A.4.2 Prompts for Test Purpose Generation

Test Purpose Generator: System Prompt

```
You are an expert in system-level test development. Your
task is to create test scenarios along with corresponding
high-level test purposes that describe what each test
case should verify.

You will be provided with a set of requirements, optional
verification criteria, and a test design.
```

Figure 12: Example system prompt for generating test purposes.

Test Purpose Generator: User Prompt

```
For the following requirements generate test purposes for
each row in the decision table.

Input Requirements:

{input_requirements}

Test Detail Design:

{test_detail_design}

The output should contain the test purpose in natural
language and the test scenarios in the following format:

{output}

Ensure the revised text stays within the 250-character
limit while preserving all essential context, values, and
meaning.
```

Figure 13: Example prompt for generating test purposes from a decision table.

A.4.3 Prompts for Test Specification Generation

Test Spec Generation: User Prompt

```
Write a test specification for the following test purpose
and test scenario.

Purpose: {test_purpose}

Test Scenario: {test_scenario}

Input Requirements:

{input_requirements}

{example_requirements_and_test_specs}

Start the generation of the test specification. Do not
change the purpose in the output as it comes from the user.
Do not respond with anything else and think carefully.
```

Figure 14: Example User prompt for generating Test Specifications.

Test Specification Generator Agent: System Prompt

```
You are an AI test developer in the automotive industry.
Your task is to write test descriptions on a system level
based on the provided requirements and test design
details.

Resources:

    • A set of requirements and verification criteria
    • A list of similar requirements with test
      specifications

Guidance:

    • The verification criteria and test design details
      describe how each requirement can be tested.
    • When writing test descriptions, prioritize the test
      purpose and test conditions. These are the most
      important aspects of the test.
    • To ensure comprehensive testing, review the
      provided similar requirements. These references can
      help you understand how to effectively cover the
      input requirements with corresponding test
      specifications. Use this information as a guide to
      create the test specifications that align with the
      given purpose and input requirements.

Output Format:

Please respond using the following structure:

```json
{
  "purpose": "<The purpose of the test that is in the input>",
  "precondition": "<Precondition as text with bullet points>",
  "execution": "<Test execution steps as text numbered list>",
  "notes": "<Any additional notes for the test developer>"
}
```
```

Figure 15: Example Generation Agent prompt for creating test specifications.

Test Specification Reflection Agent: System Prompt

```
You are an AI test supervisor in the automotive industry,
renowned for your meticulous attention to detail and
dedication to upholding industry standards. Your
expertise is crucial in ensuring that test specifications
align with regulatory requirements and meet the highest
quality standards.

Scope of Review:

    • Scrutinize test specifications for any elements
      that may compromise safety, security, or regulatory
      compliance.
    • Evaluate the overall quality of the test
      specifications, including clarity, concision, and
      effectiveness.

{standards_regulations}

Key Focus Areas:

    • Ensure that the purpose of the test is clearly
      defined and given sufficient emphasis for the
      generation of the test specification.
    • Make sure that the input requirements, specifically
      the requirement text and verification criteria are
      given sufficient emphasis.

Critique Guidelines:

Your critique should be constructive and actionable,
enabling the Test Specification Generator Agent to refine
their work and meet the required standards.
```

Figure 16: Sample Reflection Agent prompt for generating test specifications.

A.5 Demo Screenshots

In this section, we present screenshots of our evaluation demo system implemented in Streamlit. Our production system however looks differently. Note that step 2 has been omitted from the screenshots due to restrictions on sharing internal requirements.

RUBRIC-MQM : Span-Level LLM-as-judge in Machine Translation For High-End Models

Ahrii Kim
Independent Researcher
ahriikim@gmail.com

Abstract

Referred to as *LLM-as-judge*, a generative large language model (LLM) has demonstrated considerable efficacy as an evaluator in various tasks, including Machine Translation (LAJ-MT) by predicting scores or identifying error types for individual sentences. However, its dependability in practical application has yet to be demonstrated, as there is only an *approximated match* due to the task's open-ended nature. To address this problem, we introduce a straightforward and novel meta-evaluation strategy **PROMPTCUE** and evaluate cutting-edge LAJ-MT models such as GEMBA-MQM. We identify their fundamental deficits, including certain label biases and the inability to assess near-perfect translations.

To improve reliability, we investigate more trustworthy and less biased models using multidimensional prompt engineering. Our findings indicate that the combination of span-level error quantification and a rubric-style prompt tailored to the characteristics of LLMs has efficiently addressed the majority of the challenges current LAJ-MT models face. Furthermore, it demonstrates a considerably enhanced alignment with human values. Accordingly, we present **RUBRIC-MQM**, the LAJ-MT for high-end models and an updated version of GEMBA-MQM.[1]

1 Introduction

A notable strength of generative Large Language Models (LLMs) lies in their capacity to utilize user instructions to execute tasks that are both unseen and untuned, thereby demonstrating remarkable performance across various domains of natural language processing (NLP) such as Code Generation and Text Summarization (Ouyang et al., 2022; Wang et al., 2023; Dainese et al., 2024; Zhang et al., 2024). This swift expansion has prompted more scholars to initiate comprehensive investigations into their potential, including capacity for self-evaluation, referred to as *LLM-as-judge* (LAJ) (Bavaresco et al., 2024; Ashktorab et al., 2024; Ashktorab et al., 2024). This paradigm employs LLMs to evaluate model-generated outputs based on a set of predefined criteria (Li et al., 2024). What sets this approach apart from traditional evaluation metrics is its inherent flexibility. This flexibility permits LLMs to leverage their comprehensive knowledge, acquired from extensive data, to conduct evaluations in accordance with user directives.

Within this context, the domain of Machine Translation (MT) has illustrated prompt-based evaluation (LAJ-MT) models demonstrating noteworthy efficacy (Kocmi and Federmann 2023b; (Lu et al., 2024); Fernandes et al. 2023; Kocmi and Federmann 2023a). Despite their outstanding performance, their meta-evaluation relies on ***approximating error spans*** due to its open-ended nature. Furthermore, their performance is evaluated solely by juxtaposing them with pre-existing metrics, which provides limited insight into their reliability, advantages, or disadvantages in practical applications. As a result, they become just another *black-box* LLM (Fernandes et al., 2023; Kocmi and Federmann, 2023a).

To tackle these issues, we introduce a novel meta-evaluation method called **PROMPTCUE** (***Prompt**-based **C**lassification for **U**ncovering **E**rrors*), facilitating targeted error classification in MT. Eliminating error detection from the traditional evaluation process simplifies the task into a basic classification problem. We propose this approach as the first direct meta-evaluation of its kind. Our comprehensive analysis uncovers multiple critical deficiencies present within the existing LAJ-MT metrics, some of which are:

[1]This paper is the final version of our preprint, which can be found at: DR-100. All pertinent code and data are accessible at https://github.com/trotacodigos/Rubric-MQM.git.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 147–165

a) Biased to MISTRANSLATION and MAJOR
b) Systematic failure in NO-ERROR
c) Hallucinating error category

We enhance existing LAJs by streamlining the evaluation structure and implementing optimal prompt strategies. Our experiments explore the best prompting strategies with nine prompt types applying five strategies to GEMBA-MQM: Enumeration, Definition, Explanation, Rubric, and SQM style. We experimentally demonstrate that the rubric style yields the best performance in the current system. Thus, we present **RUBRIC-MQM**, a customized span-level MT evaluation metric that predicts MQM errors while simultaneously assigning scores out of 100 based on a detailed rubric. Our findings demonstrate that it successfully tackles two key challenges of GEMBA-MQM and considerably improves its alignment with human values in high-quality translations. This confirms its suitability for evaluating advanced MT models. Our key contributions are:

- We present PROMPTCUE, an innovative and straightforward approach for the direct meta-evaluation of LAJ-MT models.
- The traditional MQM scoring system is upgraded with RUBRIC-MQM, which assesses DA at the span level using a detailed scoring rubric. This approach enhances correlation and is especially apt for assessing top-tier models.
- We pinpoint major weaknesses of GEMBA-MQM and rectify them by examining fundamental prompt structures.

2 Background

MQM Framework

The MQM framework for Translation Quality Evaluation (TQE) is initially developed to perform a comprehensive analysis of translations produced both by human translators and machine-generated systems (Lommel et al., 2014). In this framework, an evaluator detects sentence errors and categorizes them by predefined category and severity criteria. For category, a hierarchical error typology includes seven meta-level errors with multiple sub-levels. The typology is customizable for specific linguistic features or uses. Conversely, the severity is divided into four types: NEUTRAL, MINOR, MAJOR, and CRITICAL. When scoring, the default weight for categories is set to 1, whereas severity is assigned weights of [0, -1, -5, -25], respectively. See Lommel et al. (2014) for scoring details.

This prominent evaluation framework, well-regarded in the field, has gained significant interest from MT researchers and is integrated into the Workshop on Machine Translation (WMT) with a few modifications. The hierarchy of the labels is simplified to 22 categories and three severities (NEUTRAL, MINOR, MAJOR) with a weight scheme of [0, -1, -5] (Kocmi et al., 2022). A single category type affecting the score is FLUENCY/PUNCTUATION, with a value of -0.1. The sentence-level score is calculated by summing all identified errors, with a cap of -25, which corresponds to either five instances of MAJOR or a single NON-TRANSLATION.

Defining Evaluation Function

Applying the evaluation process of LAJ as defined by Li et al. (2024), we have reconceptualized the MQM process with the following equation:

$$\mathcal{Y} = E(\mathcal{T}, \mathcal{C}, \mathcal{X}, \mathcal{R}) \tag{1}$$

where the evaluation *function* (E) is executed using evaluation inputs of *type* ($\mathcal{T}$), *criteria* ($\mathcal{C}$), *items* ($\mathcal{X}$), and an optional *reference* ($\mathcal{R}$), subsequently producing *outputs* ($\mathcal{Y}$) in the format of a numerical score or categorical label.

Current MT evaluation tasks often involve utilizing a single LLM ($\mathcal{T}$) to determine the severity and category ($\mathcal{C}$) of translation errors, based on the source and target sentences ($\mathcal{X}$), with or without reference ($\mathcal{R}$). Within this context, the existing prompt-based models have two criteria —severity ($\mathcal{C}_{sev}$) and category ($\mathcal{C}_{cat}$) —, wherein each criterion independently yields results in the form of a categorical label, as in Equation 2.

$$\begin{aligned} \mathcal{Y}_{cat} &= E(\mathcal{T}, \mathcal{C}_{cat}, \mathcal{X}, \mathcal{R}) \\ \mathcal{Y}_{sev} &= E(\mathcal{T}, \mathcal{C}_{sev}, \mathcal{X}, \mathcal{R}) \end{aligned} \tag{2}$$

We consolidate this redundant procedure into a singular task by transforming severity as criteria ($\mathcal{C}_{sev}$) into a numerical output of category ($\mathcal{Y}_{cat}$), as illustrated in Equation 3. Note that our framework is without reference ($\mathcal{R}$). For clarity, we designate category and severity as C_{cat} and Y_{sev} respectively throughout this paper.

$$\mathcal{Y'}_{sev} = E(\mathcal{T}, \mathcal{C}_{cat}, \mathcal{X}) \tag{3}$$

English source: ```I do apologise about this, (...) from <v>the account holder</v> to discuss an order (...) holders permission.```

German translation: ```Ich entschuldige mich dafür, (...) geschehen <v>wäre</v>, aber ohne die Erlaubnis des Kontoinhabers wäre ich nicht in der Lage, dies mit <v>dir</v> <v>involvement</v>.```

{prompt} They are enclosed with <v> and </v> tags.

Table 1: Components of the PROMPTCUE strategy, as delineated in blue words, are applicable to any LAJs.

3 PROMPTCUE

3.1 Design

The fundamental concept involves the precise delineation of error spans with <v> and </v> tags within the translation process (Table 1). The model is responsible for the correct allocation of labels for C_{cat} and Y_{sev} to the designated span, as specified in Table 1. Removing the initial step thus turns the task into a straightforward classification problem. Defining the error range ourselves and treating it as a finite task has three benefits. Firstly, we evaluate the model's grasp of criteria C_{cat} and Y_{sev}. Secondly, the core framework of all LAJ-MTs is consistent in our evaluation environment, which guarantees our approach's universal applicability. Finally, and most importantly, calculating a match ratio becomes simple and clear.

3.2 Match Ratio

The estimated match ratio quantifies how closely model predictions (A) align with gold judgments (B) by calculating $|A \cap B|/|B|$ (Kocmi et al., 2021). Fortunately, PROMPTCUE enables a straightforward comparison of A and B. We define a match per criterion: span, category, and severity.

Span Match The successful response rate is calculated when the expected answer for the span is given. If there is no response, we label it as `none`, employing a One-vs-Rest classification. Noisy responses with multiple entries are treated as error margins.

Category Match It pertains to the precise correspondence of the C_{cat} label. Our predefined error typology is detailed in the Appendix E.1.

Severity Match It refers to an exact match with MAJOR/MINOR. If a method lacks a binary system or produces numerical value, we calculate the optimal threshold for the best match ratio. Appendix E.2 provides the details.

3.3 Metrics

The primary metrics utilized for PROMPTCUE are Accuracy and Macro-F1 scores. Accuracy represents the count of correct classifications, encompassing both positive and negative matches. The Macro-F1 score is computed by the unweighted mean of class-wise F1 scores.

4 Experiment Setup

4.1 Data Construction

We use the MQM 2023 test set (Freitag et al., 2023) for Chinese-to-English translation, anticipating that this high-resource language pair will facilitate broader generalization of the results obtained from our novelty evaluation. We create three benchmarks, GEN, PTB, and MIS, each with 1,000 segments for label-centric evaluation. Details of the dataset are in Appendix B.

GEN set It evaluates the general performance by C_{cat} of 10 labels and Y_{sev} of two labels, evenly distributed across the benchmark.

PTB set It evaluates the ability to distinguish perfect (NO-ERROR) from imperfect (MAJOR) translations.[2] Flawed synthetic sentences are created using perturbation techniques.

MIS set It evaluates the model's peak performance in C_{cat} classification using MISTRANSLATION labels only.

4.2 Prompting Strategies

GEMBA-MQM is the default prompt setup, using a reference-free three-shot method. Subsequently, five distinct prompt strategies are mix-matched to form diverse slot scenarios, as in Table 2. We also test scales 4, 8, and 100 to find the optimal scale for strategies *Rubric* and *Continuous*. This results in nine slot scenarios named: `DeepCat`, `DeepShot`, `DeepCatShot`, `DeepRubric-`n, and `DeepQ-`n ($n = [4, 8, 100]$). `DeepQ-n` is inspired by the GEMBA-SQM fashion (Kocmi and Federmann, 2023a). Table 2 provides their detailed design features. Detailed prompt templates and lines are described in Appendix F.

[2]Our framework does not include the original NON-TRANSLATION label.

Strategy	Abbr.	About	Slot Scenarios					
			Base	DC	DS	DCS	DR	DQ
Enumeration	ENUM	A list provides the types of C_{cat} labels.	✓	✓	✓	✓	✓	✓
Definition	DEF	A definition per C_{cat} label is given.		✓		✓		
Example	EXP	Each C_{cat} label is elucidated using ICL examples.			✓	✓		
Rubric	-R	The scale for Y_{sev} is described with a scoring rubric.					✓	
Continuous	-Q	A continuous statement is used to describe the scale of Y_{sev}.						✓

Table 2: Prompting strategies and their applicability across slot scenarios.

		GEN ↑	PTB	MIS
Y_{sev}	Major	**63.59**	**74.80**	**79.20**
	Minor	18.57	17.10	14.90
	None	13.28	8.10	5.50
	No-error	4.56	-	0.40
C_{cat}	Mistranslation	**42.63**	**55.50**	**76.50**
	Omission	9.75	2.70	3.50

	Untranslated	2.28	2.60	0.10
	Inconsistency	1.76	2.30	2.00
	Source issue	0.10	-	-

Table 3: Label distribution of GEMBA's prediction (unit: %). NONE, signifying no response, is included as a Y_{sev} label.

4.3 Judge Model

The SOTA LAJ-MT models referenced in §1 have learned from one another, leading to similar prompt lines, particularly concerning our goal. Therefore, in our study, we utilize GEMBA-MQM, referred to as GEMBA, as the base metric, representing the current SOTA models. We employ the proprietary GPT-4o (`gpt-4o-2024-11-20`) (OpenAI et al., 2024) as the foundational model, although the model specifications are unclear. To ensure reproducibility, the temperature is initially set to 0 and is increased only if there is no response.

5 Result: GEMBA

GEMBA effectively identifies errors but systematically fails to discern perfect translations, often mislabeling them as MAJOR or MISTRANSLATION. It fails to respond 8.95% of the cases, suggesting a relatively low match rate in real-world scenarios. This section discusses further details.

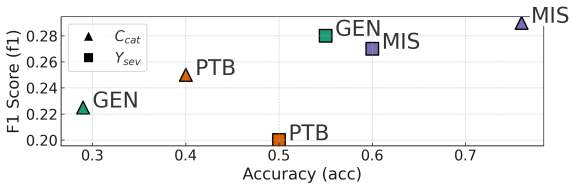

Figure 1: Varying outcomes for GEMBA performance across different datasets.

Different label distributions tell different stories.

Figure 1 illustrates the performance variation of GEMBA across different dataset types. The MIS set, which consists solely of MISTRANSLATION, exhibits the highest C_{cat} performance of the model ($acc = 0.765$, $f1 = 0.288$), which is a notable exaggeration in comparison to other datasets. Conversely, the PTB set, primarily comprising NO-ERROR, highlights its deficiency through a low F1 score as depicted in Figure 1. An in-depth analysis is conducted to examine the model's bias toward particular labels.

Biased towards MAJOR and MISTRANSLATION

As depicted in Table 3, the model predicts most errors for Y_{sev} as MAJOR and C_{cat} as MISTRANSLATION throughout the dataset. In PTB, 49.8% of the total NO-ERROR (74.8%) is a misclassification to MAJOR, while in MIS, 42.6% are wrongly labeled as MISTRANSLATION despite the fact that they make up merely 10% of the actual total. This problem, termed ***Overconfidence bias*** by Li et al. (2024), occurs primarily due to the uneven distribution of training sets.

NO-ERROR is consistently unacknowledged.

Although GEMBA demonstrates robustness on MISTRANSLATION, which serves as the gold stan-

Scenario	GEN				PTB				MIS				Win

Table 4: Performance of all slot scenarios. The mean scores for each cluster are illustrated in blue line. ↑ denoes improvement over the baseline.

dard for half of the PTB set, its performance is the poorest within PTB in Figure 1. Table 3 indicates that the model allocates a total of 4.96% to NO-ERROR, yet it is absent in the PTB where it is expected. This leads to notably poor performance within this dataset. We suspect that a likely reason for GEMBA unacknowledging NO-ERROR could be the exclusion of it as a valid option for Y_{sev} in the prompt. This issue will be elucidated in §6.

Clearly hallucinating error category

Regardless of dataset organization, the model preserves the distribution of C_{cat} in Figure 3, indicating its inability to distinguish this criterion. The pattern becomes clearer when focusing on NO-ERROR segments. Figure 2 illustrates an overly varied spread of C_{cat} labels for flawless sentences, indicating its lack of reasoning ability on error categories and potential hallucinations. Further study is needed.

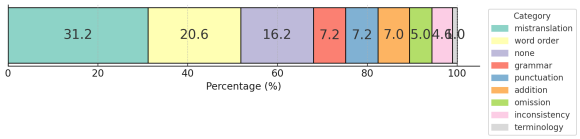

Figure 2: GEMBA's C_{cat} prediction for NO-ERROR segments in PTB (unit: %).

6 Result: Prompting Variations

RQ1: Has the general performance been improved? "Yes." Table 4 shows that no method is robust universally. When assessing the win rate against the baseline, the DR cluster consistently achieves favorable results, winning 8 out of 12 cases (67%).

RQ2: Is the Overconfidence bias alleviated? "Yes and No." The distribution of labels illustrated in Table 9 in the Appendix indicates that this bias is an intrinsic issue present across all models. However, the advantage is that the MAJOR bias is reduced by increasing MINOR in DR or having NO-ERROR in DR and DQ. To facilitate a clearer comparison, the Precision score (p) for MAJOR and MISTRANSLATION and Recall (r) for NO-ERROR are calculated by converting the predicted labels into a binary format. Table 5 indicates that while most variations have higher precision, DQ and DR effectively address issues in Y_{sev}. We propose that this enhancement results from using distinct criteria that circumvent reliance on the MAJOR / MINOR division. Conversely, the MISTRANSLATION bias is slightly reduced in some cases, but the changes are trivial.

RQ3: Is NO-ERROR discernible? "Yes." All scenarios win over GEMBA in PTB in Table 4. For instance, DQ−4 achieves 0.644 in C_{cat} and 0.736 in Y_{sev}, compared to 0.399 and 0.499 of the baseline. Table 9 in the Appendix illustrates that DR and DQ series cover a larger portion of NO-ERROR, though DQ series overestimate it in GEN, falsely labeling up to 61.83% of the cases (DQ−100). We demonstrate that the inability of GEMBA to generate NO-ERROR is closely linked to the Y_{sev} criteria, and the DR cluster effectively resolves this issue.

RQ4: Does it hallucinate less error typology? "No." Regarding C_{cat}, all scenarios demonstrate inconsistent performance by proposing a varied set of labels in PTB, as illustrated in Table 9 in

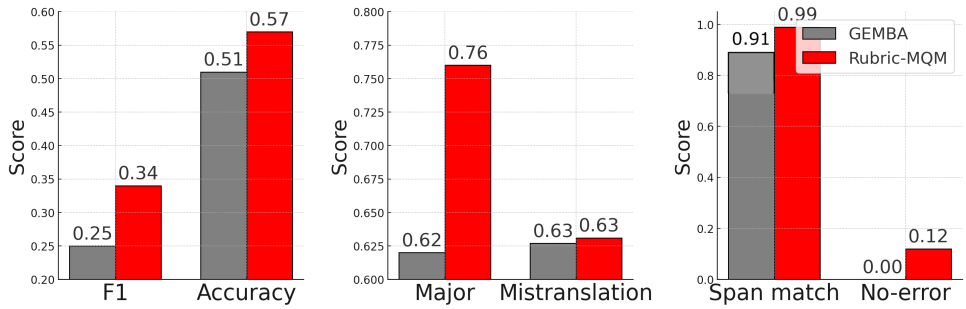

Figure 3: Six advantages of RUBRIC-MQM, addressing existing challenges of GEMBA. *Major* and *Mistranslation* indicate precision, while *No-error* refers to recall score.

	MAJOR (p)	MIST (p)	NO-ERROR (r)
GEMBA	0.616	0.627	0.000
DQ-4	**0.772**⋆	0.621 ↓	**0.158**⋆
DQ-8	0.692	0.643	0.143
DQ-100	0.750	0.637	0.129
DC	0.619	0.652	0.000 ↓
DS	0.611 ↓	0.645	0.002
DCS	0.622	**0.663**⋆	0.005
DR-4	0.759	0.632	0.099
DR-8	0.762	0.626 ↓	0.113
DR-100	0.760	0.631	0.116

Table 5: The precision and recall scores for specific labels across various scenarios. ↓ suggests a negative result, whereas ⋆ suggests the most positive.

the Appendix, and MISTRANSLATION is the most frequently chosen label. The classification capability seems largely independent of the instruction, indicating that in-depth research is required.

7 Further Study: RUBRIC-MQM

Figure 3 provides a concise overview of how RUBRIC-MQM addresses all identified challenges of GEMBA through PROMPTCUE: **it is more robust 1) in real-world scenarios with a higher match rate, 2) for high-quality translation evaluation, and 3) for MAJOR bias.** Additionally, it generates a span-level score that contributes to forming a continuous sentence-level score, thus confirming its status as the superior method.

7.1 Experiment Setting

We conduct a thorough assessment of RUBRIC-MQM to determine its efficacy in assessing advanced translation models. The model is tasked with evaluating reference translation (`ref A`) of the WMT 2023 Chinese-to-English translation (Kocmi et al., 2023).[3] Pearson (r), Spearman (p), and Kendall-Tau (τ) correlations with the gold standard (DA+SQM and MQM) are calculated at the sentence level. Additionally, other lightweight base models, beyond GPT-4o, such as GPT-3.5 Turbo (`gpt-3.5-turbo-0125`) and GPT-4o mini (`gpt-4o-mini-2024-07-18`), are examined. The parameters are uniformly set to max_token$=1024$ and temperature$=0$ across all cases. Given the novel nature of this trial, a standardized scoring scheme has yet to be established. Consequently, we investigate both the average and the aggregate of span-level scores.

[3]Refer to Appendix B for detailed data information.

7.2 Result

RUBRIC-MQM exhibits significant superiority over GEMBA, as well as the gold MQM, as illustrated in Figure 4. `4o-mini/avg` achieves the highest Pearson correlation with $r = 0.351$ against GEMBA ($r = 0.099$) or MQM ($r = 0.16$), while `4o/sum` excels in Spearman ($p = 0.352$ vs. 0.109) and Kendall ($\tau = 0.244$ vs. 0.08) correlations. Rankings change with scoring methods and models, though GPT-4 markedly outperforms GPT-3.5-Turbo. These results indicate that RUBRIC-MQM not only address existing issues but also significantly improve alignment with human values.

A portion of these advancements can be attributed to our method's continuous scoring system. Figure 5 illustrates that RUBRIC-MQM effectively mirrors SQM, with scores that are not clustered around 100. This is crucial as the existing gold score tends to skew toward zero (Freitag et al., 2023).

8 Conclusion

We have conducted a meta-evaluation of SOTA LAJ-MT models, utilizing a novel and streamlined strategy termed PROMPTCUE. By simplifying this

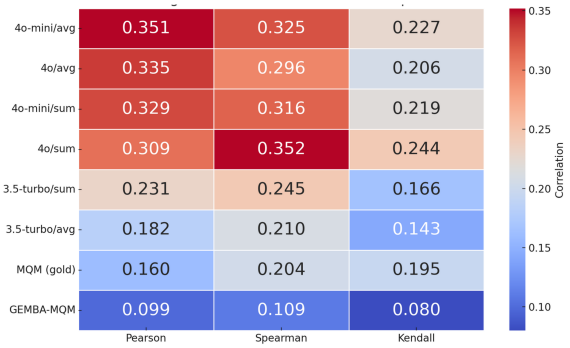

Figure 4: Three segment-level correlations to SQM, comparing GEMBA, diverse base models of RUBRIC-MQM, and gold MQM.

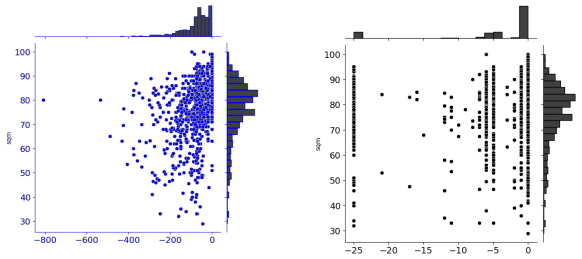

a) Rubric-MQM (4o-mini/avg) b) GEMBA-MQM

Figure 5: Score distribution. The x-axis represents DA+SQM shared across the two models.

process, significant issues within the MT evaluation framework are highlighted:

1) GEMBA shows biases toward MAJOR and MISTRANSLATION error types, so datasets focused on these errors will be advantageous to models of such nature.
2) Current LAJ-MT models cannot distinguish error types, a difficult task to accomplish via prompt engineering.

RUBRIC-MQM tackles most of the challenges GEMBA is facing by substituting the rigid label categorization with a scoring rubric. While emphasizing the system's exceptional performance in evaluating high-quality translations, it is evident that these achievements are facilitated by the LLM's capability to 'reason' and 'make decisions.' It is imperative to note that the capability to furnish the appropriate environment for each specific task lies within us, at least for the present moment.

Limitation and Future Work

The scope of this study is limited to a singular high-resourced language pair, analyzed unidirectionally. Given the proven effectiveness of the PROMPTCUE, future research will focus on exploring more language directions to uncover specific challenges and compare the multilingual capabilities of RUBRIC-MQM and GEMBA-MQM. The dataset is limited to a subset of WMT 23, and system-level human correlation for RUBRIC-MQM remains uninvestigated. While the metric seems effective, its reliability needs validation with broader datasets both at the segment and system levels. A further concern regarding the data is that the metrics within this study, pertaining to LAJ, are derived from proprietary models, which may possess pre-existing knowledge in GEN or MIS. Therefore, testing publicly available models like the Llama series, as recommended by Kocmi and Federmann, is a top priority.

Despite its remarkable features, RUBRIC-MQM continues to face challenges. Performance in both GEN and MIS mirrors that in GEMBA, with hallucinatory error categories persisting.There is a pressing need for a human assessment to confirm the current status and clarify the elements leading to reduced bias and better alignment with human values. Finally, researching its optimal scoring system is crucial for our future agenda.

Acknowledgement

I extend my appreciation to Teresa Min for the insightful discussions.

A New Evaluation Findings

Each category is assessed on a 100-point scale, allowing RUBRIC-MQM to offer richer system-level feedback by pinpointing the types and magnitudes of the committed errors. As the score from our evaluation naturally indicates the extent of errors, it can ultimately be used as a metric for ranking systems. As depicted in Figure 6, the ultimate score of `Reference A` is shown, categorized by both meta and sub-categories. The report highlights that the primary issue of this translation comes from ACCURACY. Nevertheless, it is essential to verify the outcome again after adequately tackling Overconfidence bias.

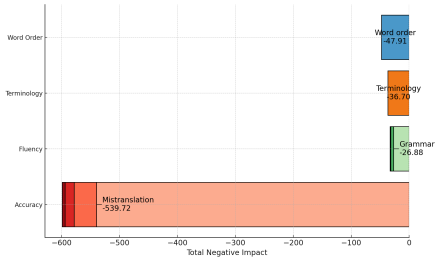

Figure 6: System-level score of Reference A (-716.54).

B Dataset

Table 7 provides comprehensive details regarding our dataset utilized in the principal experiment (GEN, PTB, and MIS) as well as in the subsequent analysis. The segments within the three benchmark datasets are distinct and unique.

B.1 GEN

The error taxonomy in this dataset encompasses 10 distinct types, as elaborated in Table 14. To ensure balanced label distribution, categories below 100 were supplemented with WMT 2022 test set. Nevertheless, the categories of PUNCTUATION, WORD ORDER, and UNTRANSLATED remain below 100, as indicated in Table 7.

B.2 PTB

The concept is derived from Quality Control of human evaluation presented in WMT 2020 (Barrault et al., 2020). We randomly select 500 sentences from the WMT 2023 Chinese-to-English evaluation set labeled with NO-ERROR by professional human evaluators. It is different from the conventional way of using a reference translation as a basis since our focus is to select error-free sentences. The construction of perturbed sentences

BP length (n)	#. replaced words in BP
6 - 8	3
9 - 15	4
16 - 20	5
> 20	$n/4$

Table 6: The number of words to swap in a sentence for perturbation (Barrault et al., 2020). Sentences that contain fewer than five words are excluded.

is automatically done by selecting a random span proportional to the sentence length (in Table 6) and replacing it with phrases of the same length. As given in the example below, the green phrase from Sentence A is swapped with another phrase to make Sentence B. Considering the advanced performance of LLM, we avoid too easy options of short sentences (less than 5 words, i.e. `how are you?`). The focal point is that the phrase itself is a fluent sequence of words comprised of a high probability of tokens that will make the whole sentence significantly wrong (Barrault et al., 2020).

Example

Original Could you help follow up on it because I'm in a hurry, thank you.

Perturbed Could you help follow up on it because in the inspection shafts, thank you.

In such a setting, we expect that the model tags NO-ERROR for near-perfect sentences (*original*) and MAJOR for perturbed ones, given that NON-TRANSLATION is not an option in our task. While the primary focus is on the classification of Y_{sev}, we also elaborate on the model's selection of C_{cat}. A significant advantage of utilizing synthetic data is that it remains completely unexposed to the training dataset.

B.3 MIS

In the early phase of our study, most C_{cat} labels identified by the models were MISTRANSLATION. Thus, we attempted to understand the models' peak performance with this label by curating a dataset full of it.

B.4 Reference A

The initial dataset of the WMT 2023 consists of 1,996 sentences spanning 16 systems, not accounting for synthetic references. Upon the exclusion of sentences lacking human scores, the dataset is reduced to 884 sentences.

	GEN	PTB	MIS	Reference A
# Segment	964	1000	1000	884
Source length (avg.)	62.57	35.54	59.04	41.30
Source length (min)	3	4	7	1
Source length (max)	299	157	275	275
Target length (avg.)	39.20	22.53	37.81	25.92
Target length (min)	2	6	6	1
Target length (max)	177	125	129	127
# System	11	6	13	-
# Rater	8	8	8	-
Severity Type	Major, Minor	No-error, Major	Major, Minor	-
Size per label	500 / 464	500 / 500	500 / 500	-
Category Type	Omission, Mistranslation, Grammar, Addition, Source, Terminology, Inconsistency, Punctuation, Word Order, Untranslated	No-error, Mistranslation	Mistranslation	-
Size per label (detail)	Punctuation (96), Word Order (85), Untranslated (83)	500	1000	-

Table 7: Dataset overview.

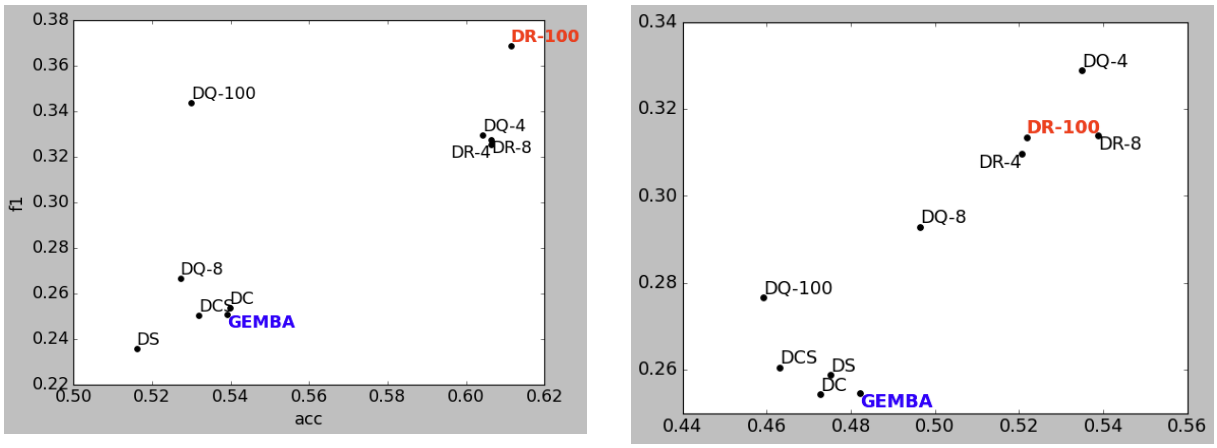
C Related Works

The GPT Estimation Metric Based Assessment (GEMBA) (Kocmi and Federmann, 2023a) was a pioneering initiative in employing LAJ in MT, offering an optimistic perspective for MT evaluation through the utilization of LLMs. The researchers posited that a model capable of translation could effectively discern between translations of varying quality. Based on this hypothesis, they investigated four distinct prompt designs. GEMBA-DA requested a score within the range of 0 to 100. GEMBA-SQM employed the same numerical scale but included continuous descriptive labels with each score. GEMBA-Stars implemented a star rating system to evaluate quality. GEMBA-Classes used labels without descriptions. GEMBA-DA, employing GPT-4 in a zero-shot context with a reference, exhibited superior accuracy when compared to SOTA metrics of WMT 22. This approach focuses on quality as the main evaluation criterion, presenting results as numerical scores.

In light of these significant results, AutoMQM (Fernandes et al., 2023) employed reasoning and ICL methodologies within the GEMBA-SQM prompting framework to augment interpretability throughout the evaluation process. Utilizing a predefined severity classification of MINOR/MAJOR, the model was asked to identify errors and assess their severity. Notably, the prompt lacked detailed categorization options, with guidance only available in a few-shot context. They removed unnecessary categories based on their criteria and computed MQM scores. The study revealed that specific zero-shot models derived from PaLM-2 attained the highest accuracy at the system level when references were incorporated. However, at the sentence level, achieving either accuracy or the Pearson correlation of the SOTA metrics required additional fine-tuning.

EAPrompt (Lu et al., 2024) employed the CoT prompting strategy within the AutoMQM framework, leveraging one-shot learning. The ICL example included source, reference, and translation segments with errors shown as per the specified format `{severity}: {error span} - {category}`. The task was subsequently divided into two distinct stages: (1) the identification of errors, guided by the AutoMQM instruction, and (2) the quantification of severity labels. This approach exhibited superior performance relative to GEMBA-DA in respect to sentence- and system-level accuracy. They reported that the task separation enhanced the model's focus on individual tasks.

The recently initiated project, designated GEMBA-MQM (Kocmi and Federmann), implemented a more stringent methodology concerning the skill set by enumerating a thorough list of valid error categories alongside their corresponding severities. These severity classifications were augmented to encompass CRITICAL, MAJOR, and



a) Y_{sev}

b) C_{cat}

Figure 7: Performance comparison of all slot scenarios. `DR-100` wins over all scenarios in Y_{sev}, and `DR` series outperform in C_{cat}.

MINOR, each briefly defined in the prompt. A core aspect of this method was using three ICL examples with different language pairs, enabling the model to attain results comparable to those of existing metrics across 15 high-resource languages.

Our study, closely aligned with several groundbreaking works, examines the use of LAJ-MT in MQM with the intention of surpassing the current SOTA evaluation metrics. **While they focus on a methodology-driven strategy for prompt engineering using advanced techniques like ICL or CoT, we intentionally shift focus to highlight the perceptual complexities of the evaluation context.** We are particularly focused on the prompts influencing critical skills in Severity and Category classification. Other elements, including ICL or detailed prompt parts such as indicating the source or target language (Zhang et al., 2023), fall beyond our scope. We aim to maximize the general-purpose LLM's effectiveness in MT evaluation within the defined limits of prompt engineering.

D Reasoning for MultiScale

Lu et al. (2024) highlights the subjectivity and unreliability in assigning a single score to a sentence. Consequently, MQM emerges as a viable alternative to DA by suggesting evidence through error spans and aggregating partial scores. Notwithstanding, we presume that challenges occur when fixed weights are used for predefined label sets. Indeed, MQM is hindered by its discrete scoring framework, possibly resulting in low correlations at the sentence level. Furthermore, the result of GEMBA-DA has demonstrated that predicting a single score often leads to outputs in multiples of five (Kocmi and Federmann, 2023a). To address these issues, we come to propose the application of the DA score scheme at the span level. We seek the best scale, starting from 4, reflecting the original MQM-TQE scheme and which is widely favored in assessment, to 8, which has recently gained popularity in human evaluations such as GEMBA-SQM, and further to 100, which is deemed the most intuitive and capable of encompassing more extensive ranges.

E Adjustment of Labels

MQM	Ours
Accuracy/Mistranslation	Mistranslation
Accuracy/Addition	Addition
Accuracy/Omission	Omission
Accuracy/Source language fragment	Untranslated
Fluency/Punctuation	Punctuation
Fluency/Grammar	Grammar
Fluency/Inconsistency	Inconsistency
Source Issue	Source Issue
Source Error	Source Issue
Style/Bad sentence structure	Word Order
Terminology/Inappropriate for context	Terminology
Terminology/Inconsistent	Terminology
No-error	No-error

E.1 Category Match

The MQM error typology is adaptable based on the evaluation context, including the language pair and evaluation purpose (Lommel et al., 2014). Consequently, we have organized our own set of error types that are broadly employed and can provide informative insights into the evaluation process. These types are predominantly sourced from MQM, although some have been removed or consolidated due to their rarity in the dataset. The category for our experiment thus comprises 10 items: OMISSION, ADDITION, MISTRANSLATION, GRAMMAR, UNTRANSLATED, PUNCTUATION, INCONSISTENCY, SOURCE ISSUE, WORD ORDER, and TERMINOLOGY. Their definitions are detailed in Table 14.

The main feature of our labels is that most categories are language- and model-agnostic, found throughout the WMT dataset over many years. We have also excluded meta-category labels from the ICL examples, moving from ACCURACY/MISTRANSLATION to MISTRANSLATION, since our preliminary study indicates they impair the perception of LLMs, outputting ACCURACY/PUNCTUATION, STYLE/MISTRANSLATION, or FLUENCY/ACCURACY, etc.. Finally, NO-ERROR is defined with the other terms, allowing the model to produce it separately.

E.2 Severity Match

We match all Severity labels to the original MQM dataset that has a binary division of MAJOR/MINOR. As elucidated in Table 8, when the predicted labels are discrete, CRITICAL is regarded as MAJOR. Otherwise, an optimal threshold is searched for each method that produces the highest accuracy in the given datasets. Severity criteria are compared in Figure 8 using a 100-point scale. GEMBA considers MAJOR when the score is above 67, and `DR-100` sets 52/100 as its threshold.

Method	Threshold	
MQM	Major	Minor
GEMBA, DC, DS, DCS	Critical, Major	Minor
DR-4, DQ-4	$n \geq 3$	$n < 3$
DR-8, DQ-8	$n \geq 5$	$n < 5$
DR-100	$n \geq 52$	$n < 52$
DQ-100	$n \geq 34$	$n < 34$

Table 8: Ideal threshold of MAJOR and MINOR for each scenario.

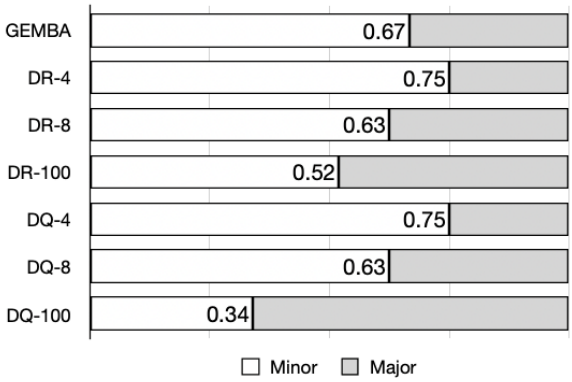


Figure 8: Numerical threshold delineating MAJOR from MINOR per scenario within the 0 to 1 interval.

```
{source lang} source: ```{source sentence}```
{target lang} translation: ```{target sentence}```

Based on the source and machine translation segments surrounded with triple
backticks, identify error types in the segment and classify them.  The
categories of errors are:  accuracy (addition, mistranslation, omission,
untranslated text), fluency (grammar, inconsistency, punctuation), source
issue, incorrect word order, terminology inappropriate for context,
inconsistent use), or no-error.
Each error is classified as one of three categories:  critical, major,
and minor.  Critical errors inhibit comprehension of the text.  Major
errors disrupt the flow, but what the text is trying to say is still
understandable.  Minor errors are technically errors, but do not disrupt
the flow or hinder comprehension.

```

Table 13: Prompt template: DeepSQM.

Addition: This error occurs when extra content not in the original text leads to repetition, unnecessary details, or redundancy, distorting the message and potentially confusing readers or diverging from the original intent.
Mistranslation: This error involves inaccurate translation or interpretation, often due to poor word choice, leading to a message that strays from the original content's meaning and intent.
Omission: This error occurs when essential elements from the original text are missing in the translation, resulting in incomplete meaning and loss of critical information or nuances needed for full understanding.
Untranslated text: This error refers to parts of the source language that remain in the translation without being converted, resulting in an incomplete or inaccurate translation.
Grammar: This error involves incorrect grammar, such as tense, verb form, pronouns, agreement, articles, or gender, disrupting fluency and coherence and risking misunderstandings or credibility loss.
Inconsistency: It refers to variations in style or structure that undermine the fluency and readability of the translated text.
Punctuation: This error stems from incorrect punctuation, prepositions, quotation marks, or hyphenation, disrupting clarity and reading flow, and potentially causing misunderstandings.
Source issue: It refers to any problematic elements originating from the source text (i.e., ambiguities, grammatical errors, of unclear phrasing) that hinder accurate translation and lead to misunderstandings.
Incorrect word order: This error occurs when the translation fails to keep the original structure, order, or phrasing, which can alter the meaning, clarity, or emphasis, leading to awkward or confusing text.
Terminology: This error occurs when a term or word choice is contextually inappropriate or inconsistent, leading to misaligned meaning or intent and potentially causing confusion or lack of clarity, especially with technical or specialized terms.
No-error: This category denotes a flawless translation, accurately conveying the source text's meaning, tone, nuances, consistency, and style with clarity, cultural appropriateness, and grammatical accuracy in the target language.

Table 14: Definition for the **DEF** strategy. Comprehensive guidelines for categorization are essential, as baseline models frequently fail to incorporate this aspect. The objective is to test whether general-purpose models are capable of utilizing the information.

DR-4

```
Evaluate the severity of each error on a scale from 1 to 4 according to the given rubric.
Scale 1:  The error slightly changes in wording with has no impact on message clarity or intent.
Scale 2:  The error makes some alteration of wording, but the overall message and intent remain
mostly clear.
Scale 3:  The error has noticeable impact on comprehension and may slightly distort the intended
message.
Scale 4:  The error substantially distorts the message, making the translation unfaithful and
potentially misleading.
```

DR-8

```
Evaluate the severity of each error on a scale from 1 to 8 according to the given rubric.
Scale 1:  The error has no impact on comprehension or intent.
Scale 2:  The error slightly alters wording but not the overall message.
Scale 3:  The error is somewhat affecting clarity but intent remains clear.
Scale 4:  The error impacts clarity and slightly distorts the message.
Scale 5:  The error affects understanding and partially alters intent.
Scale 6:  The error distorts meaning and message clarity is compromised.
Scale 7:  The error substantially misinterprets the message and intent.
Scale 8:  The error makes the translation unfaithful and misleading.
```

DR-100

```
Evaluate the severity of each error on a scale from 1 to 100 according to the given rubric.
Scale 10:  The error has negligible impact; the message and intent are unaffected.
Scale 20:  The error is tweaking some wording but leaving the overall message intact.
Scale 30:  The error has minimal effect on clarity; the intent remains clear.
Scale 40:  The error could lead to minor misunderstandings but overall message is still graspable.
Scale 50:  The error is affecting clarity; the message may require some interpretation.
Scale 60:  The error is distorting part of the message and intent can be ambiguous.
Scale 70:  The error is leading to misunderstandings and altering the message substantially.
Scale 80:  The error makes the core parts of the message misinterpretable, affecting communication.
Scale 90:  The error is causing serious miscommunication and loss of original intent.
Scale 100:  The error makes the translation completely unfaithful and misleading.
```

Table 16: Score rubric for **-R** strategy.

DQ-4

```
Evaluate the severity of each error on a scale from 1 to 4, where 1 starts on "minimal error
with no impact on clarity", goes to "minor alterations" and "noticeably impact comprehension",
up to 4, indicating "significant error substantially distort the message".
```

DQ-8

```
Evaluate the severity of each error on a scale from 1 to 8, that progresses from 1, where
the error has no impact on comprehension or intent, to 3, where it somewhat affects clarity
while intent remains clear, to 5, where it affects understanding and partially alters intent,
and finally to 8, where it makes the translation unfaithful and misleading.
```

DQ-100

```
Evaluate the severity of each error on a continuous scale from 1 to 100, that progresses from 10,
with negligible impact and the message intact, to 100, where the translation is completely
unfaithful and misleading, with intermediate levels introducing increasing challenges:  30 has minimal
clarity impact, 50 affects clarity and requires interpretation, 70 leads to substantial
and 90 results in serious miscommunication and intent loss.
```

Abstract

Social media platforms have enabled large-scale influence campaigns, impacting democratic processes. To fight against these threats, continuous training is needed. A typical training session is based on a fictive scenario describing key elements which are instantiated into a dedicated platform. Such a platform simulates social networks, which host a huge amount of content aligned with the training scenario. However, directly using Large Language Models to create appropriate content results in low content diversity due to coarse-grained and high-level scenario constraints, which compromises the trainees' immersion.

We address this issue with **SocialForge**, a system designed to enhance the diversity and realism of the generated content while ensuring its adherence to the original scenario. Specifically, SocialForge refines and augments the initial scenario constraints by generating detailed subnarratives, personas, and events.

We assess diversity, realism, and adherence to the scenario through custom evaluation protocol. We also propose an automatic method to detect erroneous constraint generation, ensuring optimal alignment of the content with the scenario.

SocialForge has been used in real trainings and in several showcases, with great end-user satisfaction. We release an open-source dataset[1] generated with SocialForge for the research community.

1 Introduction

Social media platforms have enabled large-scale influence campaigns, allowing actors to manipulate elections and impact health protocols (Muhammed T and Mathew, 2022). Influence campaigns are organized over time in various influence operations that share the same goal. These operations imply coordination between actors, aiming at manipulating populations to widen opinion gaps.

To counter these operations, entities such as journalists (e.g., fact-checking service), marketing services, and government agencies such as Viginum[2] in France or Rapid Response Mechanism[3] in Canada are actively developing countermeasures. In this evolving threat landscape, continuous exercise is crucial for these actors to stay ahead and effectively combat influence campaigns, developing up-to-date methodologies to counteract manipulative strategies. A training session relies on two types of end-users; the player team (trainees) and the animation team (trainers).

The player team interacts with the content (social media posts) aiming at detecting inauthentic behaviors[4]. A successful training challenges players to distinguish between genuine and inauthentic behaviors.

Organizing these trainings, the animation team creates a scenario depicting fictional geopolitical entities, including key elements such as factions (groups of individuals that share goals, ideas), narratives (strategic ideas that factions aim to broadcast), and events (Walker, Christopher et al., 2006). The animation team instantiates the scenario within the reproduced informational sphere (e.g, social networks or press sites) with a large, realistic, and diverse amount of content. Their diffusion reproduces specific social behaviors, as defined in the scenario.

The animation team is able to dynamically add, delete, or edit constraints, updating the content to maintain engagement and challenge throughout the training. Moreover, trainers must be able to also control the quantity, diversity, and quality of the content to ensure an effective training.

In this context, the usage of Large Language Models (LLMs) is relevant to produce large quan-

ties of content, taking into account the scenario constraints. Its use must however be well calibrated.

We hence introduce SocialForge, a model-agnostic and controllable data generation system. SocialForge takes as input a coarse-grained high level scenario, and automatically refines and augments it using LLMs. Doing so, SocialForge provides an intelligible knowledge base enabling constraints modifications, which are used for content generation. As a result, the system produces a realistic, diverse, and scenario-adhering text corpora to populate social network reproductions.

We summarize our contributions as follows:

1. SocialForge is a system that (1) refines user inputs to generate knowledge items used in prompts and (2) uses these prompts to generate social media content dataset. We show an increase in diversity in the main literature metrics.
2. By conducting a human evaluation of the adherence to the scenario and using LLM-as-a-Judge methods to determine the likelihood of the generation, we show that increasing diversity does not hinder other quality metrics, essential for the training unfolding.
3. We perform a human-machine (15 evaluators) comparative study with an LLM-as-a-Judge evaluation on the constraints space, which ensures the coherence of the future generated dataset with the scenario by focusing on a smaller set of constraints.

SocialForge has been used in real trainings and in several showcases, with great end-user satisfaction.

2 Related Work

2.1 Controllable text generation

Controllable text generation aims to guide the generation from a language model, satisfying an input set of constraints. These constraints belong to two distinct categories. First, soft constraints impact the semantics of the generation by changing the emotions, discussed topics or textual style (Zhang et al., 2022) of the generated content. The second category, hard constraints, applies structural constraints over the generation, by forcing the appearance of specific keywords (Joshi et al., 2023), explicit knowledge elements (Liu et al., 2022) or regulating the final length of the message (Li et al., 2022).

Diverse techniques have been developed in this field to constrain the generations. These techniques include adding control codes to prompts (Keskar et al., 2019), external classifiers (Yang and Klein, 2021) or smaller language models to guide the generation (Krause et al., 2021). However, hardware costs and generation latency increase by adding external models, which is detrimental in massive content generation, necessary to emulate social networks information flow. Recently, instruction models (Grattafiori et al., 2024; Jiang et al., 2024) have demonstrated the large language models capabilities to follow prompted input instructions, achieving state of the art over the diverse constraint categories (Ashok and Poczos, 2024). However, problems such as low diversity (Shaib et al., 2024) or hallucinations (Ji et al., 2023) still remain challenging.

2.2 Evaluation

Several criteria are crucial for evaluating the overall quality of a generated text dataset, including quality, diversity, and adherence to input constraints (van der Lee et al., 2021; Garbacea and Mei, 2022). While human evaluation is the gold standard, it is costly, making automatic methods more practical.

To assess the adherence to input constraints, methods such as BertScore (Zhang* et al., 2019) or BleuRT (Sellam et al., 2020) are widely used. These methods compare semantic similarity between generated and reference texts, although creating reference texts is time-consuming. External classifiers can also measure adherence to input constraints, but require one classifier per constraint, failing to scale (Yang and Klein, 2021). Recently, LLMs as evaluators (LLM-as-a-Judge) have shown promises on in-domain evaluations but face issues such as varying performance across languages, sycophancy (Sharma et al., 2024), and biases (Chiang and Lee, 2023).

With LLMs, scaling the number of contents may lead to a lack of diversity (Ge et al., 2024). Metrics such as SELF-BLEU (Zhu et al., 2018) and SBert (Reimers and Gurevych, 2019a), are used to evaluate lexical and semantic diversity but are computationally expensive. Distinct-n (Li et al., 2016) measures repetition rates, while compression ratios (Shaib et al., 2024) detect pattern repetitions, increased by LLM biases.

In order to ensure immersion during a training session, content must be realistic and indistinguishable from that created by the animation team. Quality metrics vary by content type; for microblogging (e.g. X, Mastodon), fluidity and grammaticality may not be objective functions to maximize (Heraldine and Handayani, 2022). Usual metrics such as Perplexity (Jelinek et al., 1977) need to be calibrated with a reference dataset. However, crafting a dataset representative of the educational goals for each training is intractable. Automating this axis of evaluation is challenging due to the need for human expertise, but LLM-as-a-Judge shows a great potential.

3 SocialForge, a social text generation system

3.1 Training context

In the context of training, two types of end-users are immersed inside the synthetic platforms. The **animation team**, in charge of the unfolding of the training session, needs control over the dynamics within the social platform such as controlling the topics, the content flow, and triggering of events. Depending on how the training unwinds, the animation team may also adapt scenario constraints. Upon these changes, the content has to reflect the newly added constraints, requiring a dynamic system of generation.

This dynamic control allows the animation team to recreate at will both genuine social behaviors and malicious behaviors such as disinformation campaigns. These recreated behaviors are to be detected during the training by the player team.

Navigating within social media platforms, the **player team** uses its methodology to discriminate between various behaviors.

In order for the player to focus on the proper methodology, the content should be realistic enough. Specifically, the player team should not be able to rely on immediate discriminative methods such as automatically detecting sentences starting with the same pattern or specific shared keywords.

3.2 Training scenario

The training scenario is a structured textual document created by the animation team. It outlines key elements to appear in the generation process:

1. **Factions**, defined as groups of individuals promoting one or more narratives.
2. **Narratives**, ideas that a faction aims to instill and broadcast to a target audience. Specifically, a narrative is defined as a topic associated with a stance (for, against, or neutral). Under this definition, two factions can discuss the same topic from different points of view, resulting in two distinct narratives. These factions and their associated narratives are central to the training and are used to implement social dynamics between user accounts on social platforms.
3. **Events** that animate the informational sphere depending on the educational progression of the training.

3.3 SocialForge: Scenario Refinement to Content Generation

As illustrated in Figure 2, SocialForge begins with the refinement of the scenario events by generating sequential occurrences of them, called sub-events, using an LLM. For instance with a scenario event talking about protests in the fictive country of Verdantia, sub-events might include confrontations with the police or damaged shops.

Next, SocialForge uses the provided narratives to prompt the LLM to generate subnarratives. Multiple subnarratives offer diverse perspectives on a specific narrative, enhancing the diversity of the corpus.

SocialForge then matches scenario events and sub-events with subnarratives through semantic similarity, allowing the events to be used in the generated content along the subnarratives.

In influence operations, attackers enhance narratives' effect by targeting an audience that is receptive to it. Additionally, specifying an audience (or coarse-grained personas) to language models increases the generated corpus diversity and its constraint adherence (Tseng et al., 2024). SocialForge leverages these principles by deriving coarse-grained personas, referred to as population segments, from input narratives. Segments are then instantiated by creating individuals (thin-grained personas), adding new criteria such as the OCEAN Score (Goldberg, 1990) to dress a psychological representation (i.e., scores on openness, conscientiousness, extraversion, agreeableness, and neuroticism) of the individual.

Finally, SocialForge generates social media platform-specific user accounts belonging to these individuals, generating a list of "normal" topics (e.g, soccer, computer science...), based on individual characteristics. With all this information, SocialForge prompts an LLM to generate a content, given an account along with their associated subnarrative and events. The resulting content is then available to animate the informational sphere.

4 Experimental setup

4.1 Scenario Construction

To evaluate the results of SocialForge, we begin by crafting a concise scenario involving six factions,

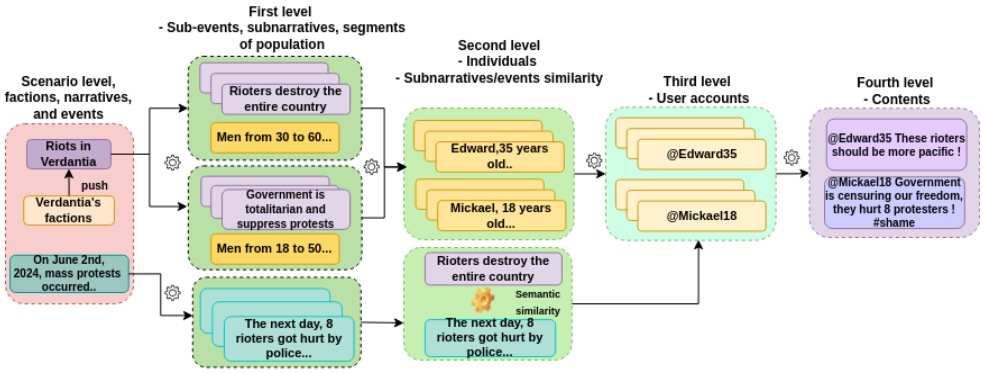

Figure 2: Example of data generation using SocialForge. First, second and third level are constraints refinement and augmentation. Last level is content generation, here written in English for illustration, but is in French in the generated dataset. We refer as Verdantia Factions the Government of Verdantia and Verdantia's rioters, described in section 4.

eight narratives, and nine events.

The scenario centers around the fictive neutral country of Verdantia, where three factions - the Government of Verdantia, Rioters, and Pro-Western intelligentsia - are engaged in a conflict, with the latter two opposing the government. Additionally, two influential blocs, The West and Louraly, fight for Verdantia's alignment. Meanwhile, the last faction, Tabiscus, welcomes Verdantian refugees fleeing the riots, while Louraly attacks them on this decision.

4.2 Model Deployment

To increase the constraints of the scenario, we used the *mixtral:8x7b* model (Jiang et al., 2024) deployed with Ollama[5] on a Nvidia RTX A6000. The advanced reasoning capabilities of the model facilitated a nuanced understanding of the scenario, enabling precise refinements and augmentations. For the content generation, we employed mistral-nemo[6]. This model is relatively light (12B parameters), facilitating scalability. It is also open-weight, which is necessary for off-internet exercises, and shows good performance in French, the target language. We operate *modernbert-embed-base* via Huggingface[7] to match events and subnarratives through semantic similarity. A detailed view of the models parameters is presented in the Appendices 5.

4.3 Constraint & Content generation

Using *mixtral:8x7b*, SocialForge generated 75 unique subnarratives spread across 15 distinct population segments, each with unique characteristics. For each of the scenario events, five sub-events were generated. These sub-events were semantically linked using *modernbert-embed-base*, with a similarity threshold set at 0.4. This process yielded a total of 47 events and sub-events, to be used in future contents. Finally, SocialForge generated 371 distinct individuals and their associated user account for subsequent message generation.

The constraints have been generated in English, as it is the most present language in the LLMs training dataset, yielding better results. Afterwards, we use multilingual models to generate in diverse languages (e.g., English constraints to French content, English to German content...).

To evaluate our method, we followed these steps:

1. Using SocialForge (as defined in Section 3), we generated five French-language datasets, each containing 2,250 (30 per subnarrative) microblogging texts.
2. To establish a **Baseline**, we prompt the LLM with scenario-level information only (i.e., scenario events, narratives, factions), generating an additional five French-language datasets of 2,250 microblogging texts.
3. For each set of five datasets (SocialForge and Baseline), we report the mean and standard deviation of the metrics.

4.4 Evaluation

Evaluation focuses on three key aspects: adherence to the scenario, diversity, and likelihood (or realism) with respect to actual platforms.

Adherence to the scenario is challenging due to the absence of reference labels in our context. To address this, we conducted a human evaluation (15 evaluators) to assess the SocialForge generations, ensuring that (1) the generated constraints are in line with the scenario and (2) the content respects the prompted constraints. This approach assesses final content are in accordance with the scenario constraints.

[5] https://ollama.com
[6] https://mistral.ai/news/mistral-nemo
[7] https://huggingface.co/nomic-ai/modernbert-embed-base

1. Evaluators rated generated segments, subnarratives, individuals, and sub-events along two axes:
   - **Coherence** with the initial constraint (e.g., subnarrative coherence with the main narrative, non-contradictory sub-event w.r.t scenario event...).
   - **Precision** of the generated constraint, if the newly created constraint adds concrete details (granularity).
2. Evaluators rated whether the constraints appear in the content (i.e., the constraints were expressed in the content) and adhered to them (i.e., the constraints were correctly expressed, addressing issues like stance). Evaluators were immersed in two setups:
   - **Micro:** Rated individual content using a binary scale across two criteria: constraints appears in the content and the content adheres to it (n = 90).
   - **Macro:** Rated batches of five pieces of content using a Likert scale from 1 to 7 (n = 18).

Next, we evaluate **diversity** across the entire corpus using automatic metrics:

- **SELF-BLEU**: assesses lexical diversity using sacrebleu's[8] pairwise BLEU-1 score.
- **Homogenization Score**: Similar as done in SBert (Reimers and Gurevych, 2019b), homogenization score presented in (Shaib et al., 2024) is a pairwise cosine similarity to measure average similarity between corpus documents. Here, we use *nomic-embed-text-v2-moe* to compute this score, leveraging its capacities in computing french embeddings.
- **Compression Ratio and Compression POS Ratio** evaluate pattern redundancy of the compressed texts and associated POS-Tags using *gzip* and *spacy*, where higher ratios indicate more redundancy. This essentially measures formulation biases in LLMs, where they tend to follow specific patterns (Shaib et al., 2024).

To compute **likelihood**, we use LLM-as-a-Judge to simulate user analysis on a social media platform. The LLM rates batches of five generated documents based on their representativeness of microblogging content. Specifically, the LLM scores each batch on a Likert scale of 1 to 7, assessing the plausibility of the generated documents. Our implementation of the LLM-as-a-Judge approach relies on Llama3.3:70b (Grattafiori et al., 2024) through Ollama API. For computing reasons, we randomly sample 500 samples for each dataset (i.e., 500 for each of the 5 datasets from Baseline and SocialForge) for a total of 2500 evaluated documents per generation method (i.e., SocialForge and Baseline). Enabling this likelihood evaluation, we compute two distinct setups, representative of real user experiences:

- **Timeline Overview**: Generated texts are drawn randomly (we do not model a recommendation system) in batches of five, similarly as a timeline view in microblogging social medias.
- **Trending Overview**: Generated texts sharing the same keywords are drawn together as batches of five, as shown in trendings overviews within microblogging platforms. Each document has its two most probable keywords extracted using yake (Campos et al., 2018) Python library.

This comprehensive evaluation ensures that all the dimensions of generation quality are taken into account and assessed with quantitative measures.

5 Results

Starting with the diversity evaluation, Table 1 demonstrates that using SocialForge increases the main diversity literature metrics. Homogenization Score indicates that generated constraint grants semantic diversity in the texts, addressing more topics and widening the semantic field. Other metrics such as SELF BLEU show that more unique ngrams are used in the texts, while compression ratios show that the increase in prompt variation results in diverse response patterns, important for the player team to not immediately detect generated content.

	SocialForge	Baseline
Homogenization Score ↓	**0.535±0.001**	0.569±0.002
SELF-BLEU ↓	**0.020±0.004**	0.025±0.011
Compression Ratio ↓	**4.016±0.028**	4.963±0.034
Compression POS Ratio ↓	**8.594±0.053**	9.212±0.022

Table 1: Mean and standard deviation over diversity metrics between SocialForge and Baseline. For indication, mean sentence length (# characters) of SocialForge is 142.16±1.04 and Baseline is 134.43±0.9.

	Constraints respect	
	Macro - Batch	**Micro - Content**
Constraints Appearance	5.59±1.03	85.56%
Constraints Adherence	5.13±1.36	68.89%

Table 2: Human Evaluation (15 evaluators) results of the constraints respect. For Macro, we report mean and standard deviation over a 1 to 7 Likert Scale. For Micro results, we aggregate through majority voting percentage of one scores over a binary scale.

Human evaluations confirmed that the generated content respects and aligns correctly with the specified input constraints (see Table 2), although

[8] https://github.com/mjpost/sacrebleu

occasional language mixing occurs. This particular issue is being addressed by state-of-the-art language models (DeepSeek-AI et al., 2025). The carried out evaluations, as illustrated in Table 3, also indicate that the generated constraints are well designed and effective, demonstrating high coherence and granularity refinement.

During experiments and demonstrations, subnarrative coherence proved crucial for content generation. Incoherence could contradict the intended message, compromising training. To address this, we again used the LLM-as-a-Judge method with *LLama3.3:70B*, which effectively distinguished problematic from adequate subnarratives, strongly correlating with 15 human evaluators ($\rho_{pearson} = 0.78, p-value < 0.001$). For this evaluation, the distribution of scores is shown in Figure 3.

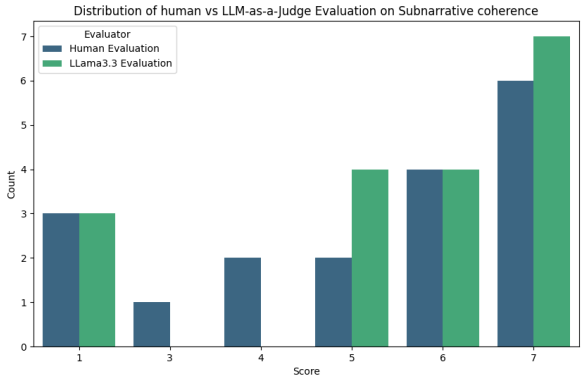

Figure 3: Comparison of Human vs LLama3.3:70B as LLM-as-a-Judge on subnarrative coherence. We see that humans are more undecided (more neutral or around neutral ratings) than LLM on this evaluation, but both detect highly incoherent generations.

This approach shows that a smaller number of samples is enough to avoid expensive metric computation, thereby enhancing the after-correction quality of the mass-scale generated content.

	Constraints quality	
	Coherence ↑	**Precision ↑**
Subnarratives (n=18)	4.66 ± 2.09	5.18 ± 1.04
Segment (n=11)	5.14 ± 0.97	N/R
Individuals (n=22)	6.41 ± 0.48	N/R
Sub-Events (n=18)	5.35 ± 1.72	5.49 ± 0.99

Table 3: Mean and standard deviation of 15 human evaluators over the coherence and precision of the generated constraints, with n the evaluated sample size. Segmentation and individual are templated generation. For these two lines, precision is Not Relevant (N/R).

For population segments and sub-events, the low sample count makes human validation tractable and even desirable to ensure a conscious control of the system by the humans. For the sub-events, it is crucial to avoid generating an excessive number of sub-events, especially for critical scenario events, to prevent overwhelming the information sphere. Individuals, being direct instantiations of population segments, are adequately generated. However, curating population segments is essential to ensure well-formed individuals for the training.

Corpus Likelihood	**SocialForge**	**Baseline**
Trending Overview↑	**4.654±1.170**	4.449 ± 1.260
Timeline Overview↑	**4.812±0.878**	4.667 ± 0.982

Table 4: LLM-as-a-Judge evaluation results over the likelihood of the microblogging using a 1 to 7 Likert Scale.

SocialForge performs better in terms of likelihood in the two distinct setups (trendings and timeline overview) as shown in Table 4 and Figure 4, achieving the purpose of having plausible microblogging contents. Increasing this score makes it harder for the player team to discriminate between machine-produced content and the animation team content.

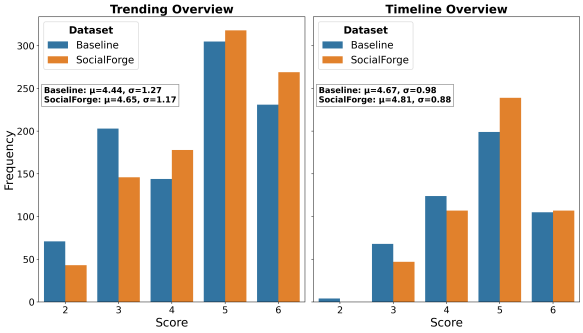

Figure 4: LLM-as-a-Judge on likelihood evaluation along the two presented setups; Trendings and Timelines, both assessed with a 1 to 7 Likert Scale. Judging model gives higher score to SocialForge evaluations. Interestingly, model did not give any 1 or 7 rating, as such, we do not make them appear in the graph.

6 Limitations

SocialForge is a novel system which generates diverse and qualitative social media data, used to train people against influence operations.

However, challenges remain: evaluating the quality of the generation is proven difficult, especially for short social media documents. Defining what is likely or unlikely to appear on real platforms remains subjective. Our LLM-as-a-Judge evaluation, without being correlated to humans, solely gives an indication of the quality, not an absolute measure.

In addition, social networks are heterogeneous: users differ in how they connect, behave, and

produce content. Previous studies have examined the *topological* diversity of interactions, relationships and community structures, analyzing *who interacts with whom* and *how often* (Gadek et al., 2017). Furthermore, diverse *social behaviors* (e.g., bots, trolls, journalists, officials, offensive accounts) shape the content produced, affecting its semantics (Chen et al., 2022). These factors are critical for modeling social networks, particularly when generating and evaluating content responses. Furthermore, this work has not yet fully explored the role of time. Real social media users operate within a broader temporal context, not only the mechanic unfolding of their current event - a well identified axis of improvement for SocialForge.

7 Conclusion

In this paper, we introduced SocialForge, a social media data generation system used to populate simulated informational spheres, which are used to train against influence operations. These trainings follow a scenario, describing high level elements that must be reflected by content within the infosphere. SocialForge refines and augments the scenario elements, producing several thinner-grained constraints, used to generate prompts which are used for generating social media content.

We propose an evaluation methodology to ensure that increasing diversity does not come at the expense of quality. We conducted a thoughtful evaluation along two criteria: scenario-adherence and likelihood. For one of the system components, the subnarrative generation, we proposed an automatic method to identify erroneous generations, ensuring the quality of the final generated content. This method was shown to be strongly correlated with human judgment, illustrating its robustness.

We assess SocialForge through a case study and we release the generated production in Gitlab [9]. Besides, SocialForge has been used in several real trainings and showcases, showing great end-user enthusiasm.

8 Ethical Considerations

The stakes are high on the topic of text generation, with numerous potential misuses. To mitigate possible negative impacts of our work, we do plan *not* to release SocialForge in an uncontrolled way.

Measures are taken to reduce the risks. All the work is hosted within an air-gap environment to mitigate content leaking danger. Within the training, all entities are fictive, to reduce biases and risks of defamation or hate. Following current regulations, all participants are aware that the content is generated by Artificial Intelligence and that the purpose of this exercise is to train against influence operations.

Unintended risks are harder to measure and detect, but we believe that studying and structuring influence operations is among the best ways to fight them. Furthermore, SocialForge is model-agnostic, which means that its environmental impact follows the state-of-the-art, and we plan to adapt accounting on this criterion. Additionally, SocialForge does not require training specific models, reducing the impact of its usage. Last but not least, we follow ethics recommendations in the domain as well as upcoming regulations to update our work to comply with effective guidelines.

LLama3:3	70B	15	0.80	0.60

Table 5: Hyperparameters of the used LLMs

A.2 Additionnal Evaluations

To perform our human evaluation, we created batches of evaluators that evaluated complete generations (constraints to content, following the same process shown in Figure 2). Each batch was asked to evaluate across one of the six factions, and we cover the entire generation with 6 batches. We managed to obtain 15 distinct evaluators. Over the subnarrative coherence we report a 69.44 Percentage agreement (PA). For the content evaluation, we report 75.0 PA over constraints appearance and 50.0 PA over constraints adherence.

	Individuals	Subnarratives	Sub-events
Homogenization Score ↓	0.834±0.013	0.752±0.083	0.552±0.040
Similarity to Centroid ↓	0.560±0.081	0.667±0.109	0.683±0.065
SELF-BLEU ↓	0.165±0.020	0.135±0.085	0.035±0.012
Compression Ratio ↓	4.010±0.185	3.024±0.560	2.058±0.089
Compression POS Ratio↓	6.831±0.140	3.910±0.450	3.452±0.343

Table 7: Diversity metrics on the constraints. We add similarity to centroid which is cosine similary between the generated constraint and the precedent constraint level (i.e., individuals to segment, subnarratives to narratives and sub-events to scenario events). We see that generated events are particularly diverse between each others, which will have an impact on the diversity of the generated content.

A.3 Examples

Narratives	**Subnarrative**
Supporting economic independence through policies for agriculture, industry, and mining	Louraly's farmers demand protectionist policies for local agriculture and industry to safeguard national sovereignty
Opposing Louraly's economic independence by promoting benefits from globalization	Louraly's proposed economic isolationism would harm Western businesses and workers
Promoting Tabiscus' values in welcoming war and political refugees.	Providing temporary housing and job opportunities for Verdantia refugees, upholding Tabiscus' humanitarian values.

Table 8: Examples of subnarrative generation based on input narrative

Narratives	**Population Segment**
Opposing Louraly's economic independence by promoting benefits from globalization	Age Range: 25-40 Religion: Christianity Political views: Center-Right Country: The West Professional Category: White Collars Sexual Orientation: Straight Sex: Female
Promoting Tabiscus' values in welcoming war and political refugees.	Age Range: 30-50 Religion: Christianity Political views: Center-Right Country: Tabiscus Professional Category: White Collars Sexual Orientation: Straight Sex: Female

Table 9: Examples of population segment generation based on input narrative

	Corpus Diversity			
	Homogenization Score ↓	**SELF-BLEU ↓**	**Compression Ratio ↓**	**Compression POS Ratio ↓**
SocialForge - Corpus	**0.535±0.001**	**0.020±0.004**	**4.016±0.028**	**8.594±0.053**
Baseline - Corpus	0.569±0.002	0.025±0.011	4.963±0.034	9.212±0.022
SocialForge - Narrative	**0.632±0.028**	**0.025±0.009**	**4.111±0.140**	**7.778±0.326**
Baseline - Narrative	0.675±0.024	0.045±0.026	5.290±0.510	8.511±0.415
SocialForge - Events	**0.599±0.022**	**0.023±0.008**	**3.867±0.193**	**7.703±0.233**
Baseline - Events	0.699±0.022	0.061±0.039	4.967±1.350	8.060±1.743
SocialForge - Factions	**0.614±0.021**	**0.023±0.006**	**4.143±0.147**	**7.925±0.312**
Baseline - Factions	0.666±0.035	0.046±0.029	5.435±0.410	8.742±0.230

Table 6: Full diversity metrics between SocialForge and Baseline. Diversity is computed along the entire corpus and the texts sharing the same narrative, scenario event, or factions. **Bold** values are the best. To compare; We also report the mean sentence length (# characters) of SocialForge content = 142.16 ± 1.04 and Baseline mean length = 134.43 ± 0.9. We see that SocialForge consistently performs better, and is more stable, as shown with the reported standard deviation.

Scenario event	**Sub-events**
The Tabiscus government announced its readiness to accept Verdantia refugees while accusing Louraly of orchestrating unrest in Verdantia.	The Tabiscus Intelligence Services detected suspicious activities of Louraly operatives in Eolios, leading to a covert operation to disrupt their plans before the refugee announcement.
Louraly's president claimed in a speech that Louraly should stop trading with the West to enhance its own industrial capacities	Amina Al-Faisal holds an emergency meeting with trade representatives to discuss the implementation of President Haroun' new directive on halting Western trade. She emphasizes the need for careful planning and gradual transition to avoid economic shock.

Table 10: Examples of sub-event generation based on scenario event.

Narrative	Subnarrative	LLM Score	LLM reasoning
Opposing Louraly's economic independence by promoting benefits from globalization	Promoting economic self-sufficiency over globalization by discouraging reliance on Louraly's industries and encouraging local production.	1	The subnarrative Promoting economic self-sufficiency over globalization by discouraging reliance on Louraly's industries and encouraging local production directly contradicts the main narrative of Opposing Louraly's economic independence by promoting benefits from globalization. The subnarrative advocates for reducing dependence on external factors (globalization) and enhancing internal capabilities (local production), which aligns with the concept of economic independence, not opposing it. This suggests that the subnarrative is actually supporting economic independence rather than opposing it, as the main narrative intends. Therefore, there's a significant discord between the two stances.
Opposing Louraly's economic independence by promoting benefits from globalization	Globalization brings job opportunities and economic growth to Western nations.	3	The rating reflects a Mostly disagree stance because the subnarrative, while not directly contradicting the idea of opposing economic independence through globalization benefits, does not strongly support or directly address the main narrative's concerns about Louraly.

Table 11: Examples of uncoherent subnarrative generation detected by the LLM Judge.

User account	Subnarrative	Event	Text
MarieDupont337b	Providing Verdantia refugees with education and job opportunities to integrate into Tabiscien society.	In response to the Tabiscien government' announcement, Louraly' suspected spy network in Eolios was exposed and arrested by Tabiscien intelligence services following a late-night raid on several safe houses.	#VerdantiaRefugees mérite notre soutien total. L'arrestation du réseau de espions de Louraly est une victoire pour la sécurité de nos communautés. Mais maintenant, il faut s'assurer qu'ils aient accès à l'éducation et aux emplois pour une intégration réussie en Tabiscus. *#VerdantianRefugees deserves our total support. The Louraly's spying network arrest is a victory for our community safety. Now, we need to ensure that they get access to education and employment for successful integration within Tabiscus.*
EmilyJ32	Louralys economic isolationism harms both Louraly and The West by limiting trade opportunities, hindering innovation, and raising prices for consumers in The West.	In response to President Hariri' speech, Western diplomats held an emergency meeting at the Louraly Embassy to discuss potential economic sanctions against Louraly.	L'isolement économique de Louraly nuit à tous ! On vient d'apprendre que des sanctions sont envisagées suite au discours du président Hariri. C'est le moment de promouvoir les avantages de la mondialisation pour le bien de tous. #Louraly #économie #mondialisation *Louraly's economic isolationism harms us all ! We just learned that sanctions are considered following President's Hariri speech. It's time to promote globalization perks for the sake of all. #Louraly #economy #globalization*

Abstract

Behavioral therapy notes are important for both legal compliance and patient care. Unlike progress notes in physical health, quality standards for behavioral therapy notes remain underdeveloped. To address this gap, we collaborated with licensed therapists to design a comprehensive rubric for evaluating therapy notes across key dimensions: *completeness*, *conciseness*, and *faithfulness*. Further, we extend a public dataset of behavioral health conversations with therapist-written notes and LLM-generated notes, and apply our evaluation framework to measure their quality. We find that: (1) A rubric-based manual evaluation protocol offers more reliable and interpretable results than traditional Likert-scale annotations. (2) LLMs can mimic human evaluators in assessing completeness and conciseness but struggle with faithfulness. (3) Therapist-written notes often lack completeness and conciseness, while LLM-generated notes contain hallucinations. Surprisingly, in a blind test, therapists prefer and judge LLM-generated notes to be superior to therapist-written notes. As recruiting therapists for annotation is expensive, we release the rubric, therapist-written notes, and expert annotations to support future research.[1]

1 Introduction

Automated medical note generation using large language models (LLMs) has the potential to enhance clinicians' efficiency by reducing the time spent on electronic health records, allowing them to focus more on patient care. However, applying LLMs to behavioral health notes presents unique challenges (Hua et al., 2024). In therapy, the conversation itself is the treatment; therefore, techniques like motivational interviewing used in a session may not be explicitly stated. Furthermore, sessions cover various topics, making it crucial to discern significant details from less relevant information. Given the high-stakes nature of behavioral health, using LLMs to generate notes must be rigorously evaluated to ensure they capture key information at an appropriate level of detail.

Evaluating the quality of talk therapy notes, however, is not straightforward. Traditionally, human evaluation has been the primary method for assessing their quality, making it resource intensive and costly. Moreover, a lack of standardized reference notes and the limited literature on what constitutes an effective behavioral health therapy note further complicates the evaluation process. Therapists and healthcare providers often have their own styles and preferences, leading to subjective assessments and considerable variation. Without clear standards and evaluation protocols, it becomes difficult to determine the quality of LLM-generated therapy notes.

In this work, we focus on the SOAP (Subjective, Objective, Assessment, Plan) format of therapy notes and propose an evaluation framework for notes (TN-Eval). The framework includes (1) a comprehensive, fine-grained, section-wise rubric that outlines the key components and characteristics of a therapy note and (2) both human and automatic evaluation protocols. The rubric, which we co-designed with 5 licensed therapists, details the relevant items for each of the four SOAP sections and their respective levels of importance **(Section 3)**. We then design a human evaluation protocol – TN^{H}-Eval – in which 9 licensed behavioral health therapists from diverse backgrounds assess notes along three dimensions: completeness, conciseness, and faithfulness **(Section 4.1)**. The completeness and conciseness are scored with reference to the rubric to improve the consistency of the evaluation, while faithfulness is evaluated at the sentence level with source attribution (Rashkin et al., 2023). Finally, we explore

*Work done during internship at Amazon.
[1] https://github.com/amazon-science/TN-Eval

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 179–199

the potential of LLMs to emulate expert evaluations, introducing an automatic evaluation protocol called TN^A-Eval **(Section 4.2)**.

Our experimental results show that our proposed human evaluation protocol – TN^H-Eval achieves higher Inter-Annotator Agreement (IAA) compared to conventional Likert-scale human evaluation, making it more reliable. We additionally show that using the automatic evaluation protocol – TN^A-Eval, we can achieve a better correlation with TN^H-Eval on completeness and conciseness evaluation when compared to N-gram-based metrics like ROUGE (Lin, 2004) or conventional LLM-as-a-Judge (Zheng et al., 2023), making it a quick and cost-effective solution for evaluation. When compared to expert-written notes, we find that LLM-generated notes achieve around 10% higher scores in completeness and conciseness but show relatively lower faithfulness.

Deployment considerations: Our TN^A-Eval is a *deployable* and *scalable* framework for assessing therapy notes with fine-grained, human-like judgments, which is designed by domain experts and has been evaluated on available datasets. Integrating this evaluation into clinical workflows and EHR systems enables: (1) Automated review that flags low-quality notes; (2) Automated scoring systems that assist therapists in refining notes before submission, reducing post-session documentation workload; and (3) Cost-effective, scalable quality assessments in standardized documentation practices. Refer appendix section I for workflow integration suggestions.

2 Related Work

AI in Mental Health Care: Recently, interest in using LLMs for mental health care has grown (Greer et al., 2019; Peng et al., 2020; Srivastava et al., 2022; Luo et al., 2025), with research focusing on three main directions. First, to classify therapeutic methods used by clinicians, assess the effectiveness of treatments, and predict the quality of service (Saha and Sharma, 2020; Chikersal et al., 2020; Liu et al., 2021; Shah et al., 2022). Second, virtual counselors emulate human behavior in chatbot-like environments (Shen et al., 2020; O'neil et al., 2023), but ethical and legal concerns (Woodnutt et al., 2024; Stade et al., 2024) have shifted research toward augmenting therapists with suggestions to enhance their responses (Saha et al., 2022; Sharma et al., 2023a). Third, AI tools train novice counselors by providing automatic feedback (Chaszczewicz et al., 2024; Lin et al., 2024) and simulating client personas for role-play (Stapleton et al., 2023; Wang et al., 2024; Louie et al., 2024, 2025). Despite growing interest in AI for mental health support, LLMs for behavioral therapy note generation remain underexplored.

Automated clinical note generation: Generation of medical documentation has been shown to improve clinician efficiency (Joshi et al., 2020), with research primarily focused on physical health using role-play or anonymized conversations and human-written notes (Papadopoulos Korfiatis et al., 2022; Ben Abacha et al., 2023; Yim et al., 2023). Early work fine-tuned lightweight transformer models (Sharma et al., 2023b; Michalopoulos et al., 2022; Milintsevich and Agarwal, 2023; Yuan et al., 2024), while recent studies explore LLM prompting for summarization (Ben Abacha et al., 2023; Mathur et al., 2023).

Automatic evaluations for summarization: Reference-based metrics like ROUGE (Lin, 2004), BLEU (Papineni et al., 2002), and BERTScore (Zhang et al., 2020) are widely used to measure lexical similarity between generated and reference summaries. Recent work has expanded to fact-checking-based evaluators (Honovich et al., 2022; Zha et al., 2023; Laban et al., 2022) and LLM-as-a-Judge protocols (Zheng et al., 2023; Wang et al., 2023), which rely on general-purpose models to holistically score summaries. Benchmarks like HealthBench (Arora et al., 2025) further incorporate physician-created rubrics with LLM-based graders to evaluate model utility and safety in clinical tasks. However, previous methods are usually developed for general text summarization tasks and do not account for the challenges of therapy notes, where obtaining high-quality reference summaries is complex, and evaluations require substantial domain knowledge. In contrast, our TN^A-Eval adapts LLM-based evaluation to operate over a structured, domain-specific rubric grounded in behavioral health practice, enabling scalable yet clinically grounded assessment.

3 SOAP Note and Rubric creation

In TN-Eval, we look at a popularly used therapy note documentation format: SOAP, an acronym for Subjective, Objective, Assessment, Plan, with

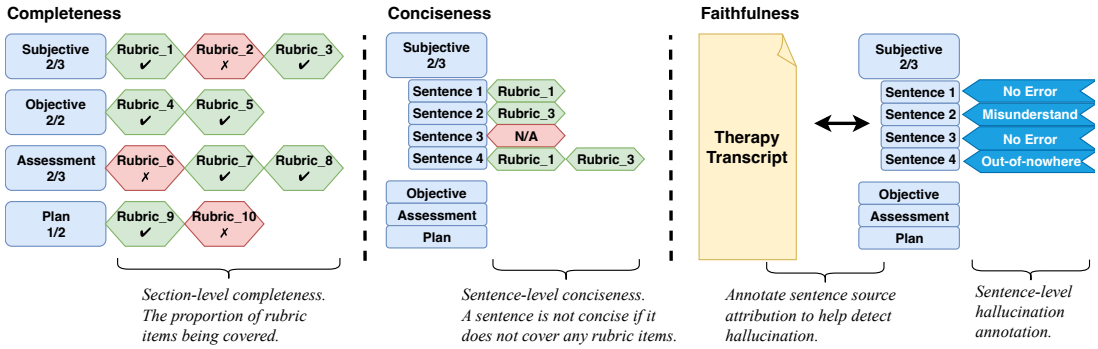

Figure 1: The TN^{H}-Eval human evaluation protocol.

each letter representing a section of the note (Weed, 1964).

At a high level, in SOAP notes, the *subjective* component consists of insights about the client's presenting problem from the client's viewpoint and that of significant others. In contrast, the *objective* component includes the counselor's observations. The *assessment* section shows how the subjective and objective data are being analyzed, interpreted, and considered, and the *plan* section outlines the treatment approach (Cameron and Turtle-Song, 2002). While there exist other therapy note formats, we use SOAP notes because they are widely referenced in behavioral therapy (Berghuis et al., 2014; Reiter and Sabo, 2023), standardized in major electronic health records (Podder et al., 2022; Gao et al., 2023), and provide a representative framework for developing better evaluation protocols.

In practice, the exact definitions and information present in each of the sections are determined by the healthcare provider organization and its record management practices. Therefore, a fine-grained set of consistent rubrics is necessary to complement the definition. In addition to the generally underspecified definitions, there is a lack of consistent clinical psychology literature for best practices in writing therapy notes and key characteristics that determine the quality of a note. To determine what *high-quality means to domain experts*, we work with five therapists to **co-design a rubric consisting of the different section-wise dimensions of note quality.**

3.1 Domain Experts

To develop the rubric, we collaborated with **Therapist A**[2] who has over 20 years of clinical experience. Additionally, we worked with four other therapists from diverse professional backgrounds who hold a Psy.D., Ph.D. in counseling psychology, or licensed clinical social work, and have experience with multiple healthcare providers, as well as training new therapists in therapeutic techniques and note-writing.

3.2 Rubric Creation Procedure

Each rubric item captures a key characteristic expected in each section of a SOAP note. These characteristics reflect clinical best practices and are annotated with their relative importance (Mandatory, Recommended, etc). We developed the rubric in a two-step co-design process. In the first step, we conduct three hour-long sessions with Therapist A to identify key characteristics of each SOAP note section, assign their relative importance, and refine the rubric through iterative feedback and example notes, including general section-agnostic guidelines.

In the second step, we ask four more therapists to verify the section appropriateness and the relative importance of each key characteristic. We also ask the therapists to suggest key characteristics that may be missed from the first step. The process is completed in an annotation tool shown in appendix figure 2. After the annotation, we consolidate the rubric by taking the majority vote. The final definitions of the SOAP note and the corresponding section-wise key characteristics are presented in appendix A. We also validate the final rubric with ($N = 17$) external therapists employed in note writing ($N = 8$) and evaluation ($N = 9$), as mentioned in appendix C.

Rubric Quality: We observe perfect IAA among 5 experts for the appropriate section for each key characteristic and observe high agreements for the relative importance of each key characteristic – Fleiss' κ: 0.68, Krippendorff's α: 0.73. Detailed IAAs by section is shown in appendix Table 9.

[2]Therapist A is a co-author of this paper

4 Evaluation Protocols

In this section, we introduce human and automatic evaluation protocols using the rubric, denoted as TN^H-Eval and TN^A-Eval, respectively. Both focus on three dimensions:

Completeness: This dimension evaluates whether each rubric element appears in its corresponding note section (e.g., the chief complaint in subjective). The score is computed as the ratio of covered elements aggregated across sections.

Conciseness: This metric measures whether each sentence contributes to a rubric item. Annotators (human or automated) label sentences accordingly, and the score is the ratio of necessary sentences in a section.

Faithfulness: This evaluation checks whether a note's content is factually grounded in the therapy session. Errors are categorized into hallucination types, ensuring a granular assessment.

Why these three dimensions? The evaluation dimensions were chosen based on practical considerations and therapist feedback. Since no standardized framework exists for grading therapists' notes, completeness is crucial to meet regulatory requirements. Therapists also emphasized conciseness, noting concerns about AI-generated verbosity. Lastly, faithfulness was included to mitigate hallucinations in LLM-generated text, ensuring accuracy and reliability.

4.1 Human Evaluation Protocols

Our TN^H-Eval relies on our rubric design to break down each dimension into more objective, simpler, and cost-effective tasks. Figure 1 illustrates the human evaluation protocol. The left panel shows completeness and conciseness annotations, where sentences are labeled with associated rubric items. The right panel illustrates faithfulness evaluation via sentence-to-transcript alignment and hallucination labeling.

To find the **completeness**, a therapist reviews a note section and marks covered rubric elements. The full note score is computed as a micro average, weighted by section rubric elements. This design minimizes annotators' effort in reviewing lengthy therapy transcripts (45 minutes). For **conciseness**, annotators label sentences with relevant rubric items or mark them as unnecessary. This annotation is done separately from completeness to prevent biased coverage assessment. In the case of **faithfulness**, annotators cross-check sentences against the therapy transcript, selecting supporting content from the source and categorizing hallucinations into (1) Out-of-nowhere, (2) Misinterpreted Information, or (3) No Error. Given the session length, this is the most costly evaluation. *While non-experts could perform this task, all annotations in our study are conducted by licensed U.S. therapists to ensure accuracy and reliability.*

4.2 Automatic Evaluation Protocols

We use LLMs to mimic human annotators to get the completeness and conciseness evaluation. For **completeness**, we present a note and one rubric item to an LLM and ask if the item appears in the summary. For **conciseness**, we break down the note into sentences, and for each sentence, we verify if a rubric element is covered in the sentence. We use AlignScore (Zha et al., 2023) for the **faithfulness** evaluation.

5 Data collection and note generation

Dataset: We conducted experiments on therapy conversations from the AnnoMI dataset (Wu et al., 2023). Due to the cost of recruiting expert therapists for annotation, we chose the first 50 conversations from the high-quality split of AnnoMI (the median conv. len. = 1067 words/ 42 turns).

Human Note Collection: The notes were written by the $N = 5$ internal therapists involved in the rubric design, and we also recruited ($N = 8$) therapists to write notes for these 50 conversations. The cost to collect each note was $206.

LLM Note Generation: We prompted several off-the-shelf LLMs to generate notes, including Claude (Anthropic, 2024), Llama (Touvron et al., 2023) and Mistral (Jiang et al., 2023), and also use two clinical and therapy domain adapted LLMs – MentalLlama(Yang et al., 2024) and OpenBioLLM (Ankit Pal, 2024). Appendix F shows the prompt we used for note generation. The prompt is simple and not carefully optimized for any particular LLM to achieve a fair comparison between LLMs.

Human Evaluation: For evaluation, we recruited $N = 9$ external therapists who are different from those who wrote the notes. The cost to collect a single human evaluation related to one note is $190. We followed the TN^H-Eval protocol described in Section 4.1, and collected two independent annotations for each note. We also collect

Note	Completeness		Conciseness		Faithfulness		Acceptance
	TN^H-Eval	Likert	TN^H-Eval	Likert	TN^H-Eval	Likert	Likert
Human	29.5 (±12.4)	2.85 (±1.09)	75.6 (±14.9)	4.28 (±0.89)	87.0 (±12.6)	4.43 (±0.81)	2.34 (±0.75)
Llama 3.1 70B	39.7 (±7.9)	3.80 (±0.79)	84.0 (±12.1)	4.83 (±0.35)	68.5 (±15.1)	4.68 (±0.50)	3.34 (±0.61)
Mistral Large V2	38.1 (±7.5)	4.01 (±0.70)	91.5 (±7.1)	4.88 (±0.35)	71.8 (±14.0)	4.90 (±0.34)	3.73 (±0.70)

Table 1: Human evaluation results using TN^H-Eval and Likert human evaluations. The values in brackets show the standard deviation over the 50 examples. "Acceptance" refers to whether the therapist would accept the note for clinical use, rated on a 5-point Likert scale. This table shows aggregated scores for the full note. See Table 2 for a breakdown by sections.

Section	Note	Completeness		Conciseness		Faithfulness	
		TN^H-Eval	Likert	TN^H-Eval	Likert	TN^H-Eval	Likert

Table 2: Section-wise human evaluation results using TN^H-Eval and Likert-style human evaluations.

annotations for *5-point Likert-scale baseline* on three aspects – Completeness, Conciseness, and Faithfulness. Experts also annotate the *overall acceptance* of a note on a scale of 1 to 5. Due to the high cost of human annotation, we only conducted the TN^H-Eval on human notes and 2 LLM-generated notes – Llama 3.1 (70B) and Mistral Large V2.

Automatic Evaluation: We followed the protocol in Section 4.2 to conduct automatic evaluation. We also explored a Likert-style automatic evaluation similar to LLM-as-a-judge (Zheng et al., 2023) (refer to appendix E.1 for corresponding prompts). We compared TN-Eval with conventional reference-based evaluation, such as ROUGE (Lin, 2004) and BERTScore (Zhang et al., 2020), and we find the efficacy of our automatic evaluation protocol by correlating the automatic metric with human annotations at the note-level.

6 Experiments

Q1: How reliable is TN^H-Eval compared to the conventional Likert-based approach?

Table 3 shows the IAA between two annotators for each type of human rating we collect. We found that Krippendorff's α for TN^H-Eval is significantly higher than that of the Likert-style evaluation for all three dimensions, showing that TN^H-Eval can achieve more consistent annotations across two independent annotators and is thus more reliable. Furthermore, TN^H-Eval provides distinct variance in outputted scores as compared to expert Likert scale judgments (refer figures 3, 4).

Dimension	TN^H-Eval		Likert	
	Raw Agg.	K-α	MSE	K-α
Completeness	77.6	0.52	2.72	0.08
Conciseness	85.5	0.49	1.01	0.16
Faithfulness	85.9	0.62	0.86	0.18
Acceptance	-	-	2.24	0.15

Table 3: IAA of human evaluations. We show raw agreement and Krippendorff's α (K-α) for rubric annotations and mean squared error (MSE) and K-α for Likert annotations. "Acceptance" refers to the overall acceptance annotated on a Likert scale. TN^H-Eval appears to have better annotation consistency compared to Likert annotations.

Table 1 shows human-annotated scores for human-written notes and 2 LLM-generated notes. Table 2 shows the corresponding breakdown of scores by section. Note that the sources are revealed to the annotators. **It is surprising to see,**

Evaluator	Note Source	Completeness		Conciseness		Faithfulness	
		TN^A-Eval	Likert	TN^A-Eval	Likert	TN^A-Eval	Likert
Claude 3 Sonnet	Human	26.4 (±12.4)	2.85 (±0.41)	63.4 (±22.2)	3.15 (±0.49)	73.2 (±14.9)	4.11 (±0.57)
	Claude 3 Sonnet	34.8 (±7.3)	3.39 (±0.27)	86.0 (±10.3)	**3.86 (±0.21)**	74.0 (±10.1)	4.73 (±0.36)
	Claude 3 Haiku	36.8 (±8.7)	3.46 (±0.27)	**87.6 (±12.1)**	3.81 (±0.21)	69.9 (±10.1)	4.70 (±0.38)
(AlignScore for Faithfulness)	Llama 3.1 (70B)	35.1 (±8.0)	3.33 (±0.36)	84.8 (±12.5)	3.52 (±0.27)	69.0 (±11.6)	4.49 (±0.50)
	Llama 3.1 (8B)	35.0 (±6.8)	3.22 (±0.27)	85.9 (±8.6)	3.55 (±0.27)	70.2 (±11.5)	4.63 (±0.44)
	Mistral Large V2	36.8 (±8.2)	3.50 (±0.32)	84.3 (±9.1)	3.83 (±0.20)	75.8 (±8.8)	4.91 (±0.20)
	Mistral (7B)	**37.7 (±8.6)**	**3.58 (±0.28)**	81.2 (±10.5)	3.85 (±0.17)	75.2 (±9.5)	**4.93 (±0.19)**
	MentaLlama (13B)	24.5 (±10.2)	2.86 (±0.33)	77.0 (±20.8)	3.42 (±0.40)	**80.4 (±9.9)**	4.50 (±0.60)
	OpenBioLLM (70B)	24.6 (±9.9)	3.19 (±0.42)	72.9 (±13.9)	3.72 (±0.45)	80.0 (±11.0)	4.76 (±0.55)

Table 4: TN^A-Eval and Likert-style automatic evaluation. We show the results using Claude 3 Sonnet as the evaluator. Note that the TN^A-Eval faithfulness evaluation is conducted using AlignScore, not LLM-grading.

according to Likert-style scores, that experts judge LLM-generated notes to be superior to human-written notes across all dimensions – completeness, conciseness, faithfulness, and overall acceptance. Our TN^H-Eval shows the same order for completeness and conciseness, however, for faithfulness, TN^H-Eval shows higher scores for human-generated notes, which shows the advantage of using our rubric, breaking down each section into smaller, more objective annotation tasks.

Q2: Does TN^A-Eval align with human and reference-based automatic evaluations?

LLM	R1-F	R2-F	RL-F	BERT.
Claude 3 Sonnet	39.8	10.1	20.0	87.9
Claude 3 Haiku	40.7	10.9	20.3	87.9
Llama 3.1 (70B)	41.1	10.6	20.5	88.1
Llama 3.1 (8B)	39.4	10.4	20.2	87.6
Mistral Large V2	40.1	10.3	19.9	87.9
Mistral (7B)	39.9	9.7	19.5	87.9

Table 5: Reference-based evaluation metrics for notes generated by different LLMs, using human notes as a reference. We show F-measure for ROUGE-1/2/L, as well as BERTScore.

We find that all traditional reference-based metrics show similar values, making these n-gram-based metrics insufficient to provide meaningful signals for generation quality (refer table 5 for ROUGE and BERTScore results). Next, table 6 shows the correlation between two sets of automatic evaluation (TN^A-Eval and Likert-style LLM-as-a-Judge) and two sets of human evaluation (TN^H-Eval and Likert-scores). **Notably, TN^A-Eval and TN^H-Eval indicated the highest correlation, as shown in Column (A), demonstrating that the fine-grained evaluation achieves higher agreement between human and LLM evaluators.** Column (B) reveals the utility of the LLM-as-a-Judge for the completeness evaluation but presents a poor correlation for conciseness and faithfulness. When comparing automatic evaluations with Human Likert-scale annotations, the correlations appear to be generally poor, suggesting that neither of the automatic evaluations correlates well with human Likert-scale evaluation. Overall, the faithfulness correlation shows significant challenges in hallucination detection. Human and automatic evaluations agree that human-written notes are roughly 10% less complete and 10% less concise compared to LLM-generated notes. For the faithfulness evaluation, humans appear to favor human-written notes, while automatic evaluations favor LLM notes.

	v.s.	TN^H-Eval		Human Likert	
	Evaluator	(A) TN^A-Eval	(B) Likert	(C) TN^A-Eval	(D) Likert
Comp.	Claude 3 Sonnet	**0.58**	0.46	0.24	0.34
	Llama 3.1 (70B)	0.44	0.55	0.23	0.36
	Mistral Large V2	0.48	0.55	0.34	0.36
Conc.	Claude 3 Sonnet	0.36	0.27	0.19	0.26
	Llama 3.1 (70B)	0.39	0.14	0.26	0.11
	Mistral Large V2	**0.40**	0.24	0.21	0.17
Faith.	Claude 3 Sonnet	-	-0.15	-	0.28
	Llama 3.1 (70B)	-	-0.20	-	0.18
	Mistral Large V2	-	-0.22	-	0.19
	AlignScore	**0.34**	-	0.27	-

Table 6: The note-level correlation between automatic metrics and human annotations. Column (A) and (B) compares automatic evaluation with TN^H-Eval. TN^A-Eval achieves much higher correlation than Likert-style LLM-as-a-Judge. Column (C) and (D) compares automatic evaluation with human Likert-style annotation, where the correlation is generally poor.

Q3: How effectively do LLMs generate notes?

Upon asking experts to rate notes without telling the source of the note (refer table 1), we observe that experts prefer and judge LLM-generated notes

Note Source	S.	O.	A.	P.
Human Notes	76 (±57)	32 (±21)	57 (±41)	29 (±14)
Claude 3 Sonnet	73 (±23)	41 (±10)	64 (±13)	71 (±12)
Claude 3 Haiku	97 (±25)	46 (±11)	77 (±16)	94 (±22)
Llama 3.1 (70B)	65 (±15)	37 (±13)	61 (±11)	75 (±11)
Llama 3.1 (8B)	94 (±25)	56 (±13)	77 (±17)	82 (±15)
Mistral Large V2	88 (±23)	51 (±9)	65 (±12)	74 (±11)
Mistral (7B)	86 (±25)	51 (±10)	66 (±12)	75 (±11)

Table 7: Number of words (and standard deviation) in each section of the note based on source.

to be superior to human-written notes across all dimensions except fine-grained faithfulness evaluation. This highlights the potential of using LLMs for therapy note construction.

Note Length: For further investigation, we examine the length of notes written by the therapists and LLMs (table 7). Human-written notes are generally shorter, and in particular, the "plan" section of human notes is much shorter than LLM notes (Average length of human-plan section notes = 29 words, Average length of LLM-generated plan section = 78.5 words). This is because therapists tend to be very concise, with just one sentence stating the follow-up session, while LLM-generated notes contain more content such as "short-term goals" and "long-term goals" (see table 10). We believe that the natural and fluent English writing from LLMs likely biases human annotators, thus conflating fluency with accuracy (Elangovan et al., 2024). Next, we manually observed some examples (table 10) and found that humans tend to write shorter sentences for the same rubric items. Based on a subsequent conversation with Therapist A, we uncover that therapists spend substantial time with various kinds of documentation and find themselves hard-pressed to write descriptive quality notes (Griswold, 2019).

Section-wise scores: On analyzing the TN^H-Eval score breakdown for each rubric item, we observe that human-written notes show considerably less coverage for some rubric items (refer to table 8). For example, "symptoms" in the Subjective, "mental status" in the Objective, and "future interventions" in the Plan show a large discrepancy (more than 20%).

Automatic evaluation: We show the automatic evaluation results on Human notes and several LLM notes in Table 4. The numbers reflect a similar pattern to the human evaluation, where LLMs, in general, outperform humans in note completeness and conciseness. Among LLMs, Mistral tends to be more conservative, with more faithful content.

Rubric	Human	Llama	Mistral
Subjective			
chief-complaint	78%	75%	78%
symptoms	*56%*	87%	90%
history	59%	56%	59%
goals	33%	40%	42%
homework	1%	1%	3%
quotes	23%	17%	15%
Objective			
observed-behavior	*53%*	96%	98%
mental-status	*22%*	73%	88%
assessment-tools	10%	5%	7%
therapy-activities	12%	4%	4%
interventions	12%	2%	1%
Assessment			
diagnosis	8%	22%	13%
triggers	*19%*	40%	24%
progress	24%	38%	34%
analysis	*72%*	97%	92%
response	39%	30%	32%
overall-progress	8%	11%	11%
goals	4%	4%	3%
stages	41%	31%	34%
Plan			
future-interventions	*39%*	83%	75%
follow-up	31%	45%	41%
adjustment	2%	9%	7%
homework	33%	33%	26%

Table 8: Coverage of key characteristics in the rubric in therapist-written and LLM-generated notes. We highlight rubric items where coverage of human notes is over 20% lower than the best LLM.

7 Conclusion

In this paper, we conducted analyses on quality evaluation strategies for behavioral health therapy notes. By collaborating with domain experts to design a rubric, we designed fine-grained human evaluation and automatic evaluation protocols. We demonstrated the advantage of TN^H-Eval against conventional Likert-style human evaluation. Expert evaluation with TN^H-Eval and conventional Likert-scales shows preference towards LLM-generated notes. Our TN^A-Eval outperformed the conventional LLM-as-a-Judge strategy and showed a higher correlation with human evaluations for completeness and conciseness, while the faithfulness evaluation remains a challenge. Thus, we urge research toward robust and automatic evaluation of therapy notes. Subsequently, we are sharing high-quality note annotations from practitioners, the co-designed rubric, and all annotations we collected in the project to benefit the research community.

Acknowledgement

We sincerely thank the licensed therapists from OneMedical who contributed their expertise and time to the creation of the evaluation rubric, note generation, and annotation process.

Ethical Considerations

The organization's review protocols approved the current study. We do not advocate for fully automated LLM-generated notes; rather, we propose augmenting therapist workflows by providing an LLM-generated draft as a starting point. Furthermore, all therapy transcripts used in this work are from an open-source dataset – AnnoMI (Wu et al., 2023). Lastly, to ensure the appropriate stakeholder inclusion and the generalizability of findings, ($N = 22$) therapists were consulted in this study in the following capacities:

1. Therapist involvement in the co-design process. We work with $N = 5$ senior therapists from one of the largest behavioral healthcare networks in the country.

2. Therapist involvement in note construction (annotation). For this step, we engage with $N = 5$ of the therapists mentioned above and additionally with $N = 8$ therapists from another organization.

3. Therapist involvement in note evaluation. For this step, we worked with $N = 9$ new therapists, who were separate from the previous two groups. These nine therapists evaluated SOAP notes with the help of the rubric.

Deployment: Automated behavioral health note generation and evaluation tools in real-world settings necessitate compliance with HIPAA (Health Insurance Portability and Accountability Act) regulations and privacy-preserving AI practices. Thus, we include open-source models for both – note generation and evaluation, so as to show results for models which can be run on private compliant servers.

Appendix

A Definitions of SOAP note sections

A.1 Subjective

Definition: In this section, document the subjective reports from the client, their family members, and past medical records. Include how the client describes their feelings and current symptoms.

Key Characteristics:

- **Chief Complaint:** The reason why the client is seeking therapy. Could also be a description of what symptoms the client is experiencing. **Importance:** Mandatory
- **Symptoms (as the client is talking about it):** The client's own description of their feelings, thoughts, and behaviors along with the severity. **Importance:** Mandatory
- **History:** Relevant background information, including any past medical, therapy, or behavioral issues. **Importance:** Mandatory
- **Client's Goals:** What the client hopes to achieve through therapy. **Importance:** Highly recommended
- **Homework from Previous Sessions:** Reviewing homework from the previous sessions and noting the client's compliance. **Importance:** Highly recommended
- **Quotes:** Direct quotes from the client can be particularly useful to capture their exact words and emotional tone. **Importance:** Highly recommended

A.2 Objective

Definition: This section is for recording objective observations made during the session. Note any factual, observable information, such as the client's appearance, behavior, mood, affect, and speech patterns. Avoid including any subjective statements or self-reported information from the client.

Key Characteristics:

- **Client's Observed Behavior:** The therapist's observations of the client's behavior, mood, appearance, and affect during the session. **Importance:** Mandatory
- **Mental Status:** Observations regarding the client's appearance, speech, thought processes, and orientation. **Importance:** Mandatory
- **Assessment Tools:** Results from any standardized assessments or scales used during the session. **Importance:** Highly recommended
- **Therapy Activities:** Description of specific interventions or activities conducted during the session. **Importance:** Highly recommended
- **Interventions [A]:** Applied interventions and treatment plans (MI, Cognitive Restructuring, DBT, etc.). **Importance:** Highly recommended
- **Interventions [B]:** Focus on describing active interventions provided rather than passive ones. **Importance:** Highly recommended

A.3 Assessment

Definition: In this section, integrate the subjective and objective information to provide a comprehensive analysis of the client's current condition. Summarize the clinical impressions and hypotheses regarding the client's issues.

Key Characteristics:

- **Diagnosis/Symptoms:** Any formal diagnoses made based on DSM-5 criteria or other diagnostic tools. **Importance:** Mandatory
- **Identifying Triggers:** Any triggers shown by the client.
- **Progress:** Evaluation of the client's progress toward their therapeutic goals. **Importance:** Highly recommended
- **Analysis:** The therapist's interpretation of how the client's subjective report and objective observations relate to their overall condition. **Importance:** Highly recommended
- **Response to Interventions. Importance:** Highly recommended
- **Overall/High-Level Progress. Importance:** Highly recommended
- **Treatment Goals:** Specific, measurable, achievable, relevant, and time-bound (SMART) goals for the client. Adjustments to the treatment goals. **Importance:** Highly recommended
- **Stages of Change:** For interventions like Motivational Interviewing, note the client's stage of change (Pre-contemplation, Contemplation, Action, Maintenance, etc.). **Importance:** Highly recommended

A.4 Plan

Definition: Outline the next steps for the client's treatment. Include both short-term and long-term goals, specifying what will be addressed in the next session as well as overall treatment objectives.

Key Characteristics:

- **Future Interventions:** Planned therapeutic techniques or strategies to be used in future sessions. **Importance:** Mandatory
- **Follow-Up:** Scheduling of the next session and any referrals to other professionals if needed. Note the date for the next appointment if decided upon. **Importance:** Mandatory
- **Adjustment of Medication/Intervention Choice. Importance:** Mandatory in certain circumstances
- **Homework:** Assignments or activities for the client to work on between sessions. **Importance:** Highly recommended

A.5 General Items

Key Characteristics:

- Clearly reflect that the practitioner assessed for and addressed any safety concerns (e.g., suicide risks, self-harming behaviors, homicidal ideation, etc.). **Importance:** Mandatory
- Evidence of treatment being provided in a culturally competent manner. **Importance:** Highly recommended
- **Professionalism Importance:** Highly recommended
  - Never describe other clients and staff in a derogatory manner.
  - Avoid using slang.
  - Descriptions of the patient's presenting problem should be used rather than presumptuous adjectives.

B Limitations

Real data availability : Because of the sensitive nature of behavioral health, real doctor-patient conversations are confidential. The public data we use in this study appears to be shorter and less complex than a real therapy session.
The scale of study: This study is relatively small due to the cost of recruiting licensed therapists, involving only two open-weight LLMs and human-written notes across a limited number of conversations.

Annotator bias may also affect results. While differences between human and LLM notes are clear, the gap between the two LLMs is small, and their ranking may vary across different datasets.
LLM performance: We used simple prompts in this study, focused on evaluating the framework rather than optimizing LLM performance. The results could likely improve with more advanced prompt engineering.

C Annotator Qualification and Cost

Human Note Writing: Human notes were written by the $N = 5$ internal therapists involved in the rubric design, as well as $N = 8$ external therapists. All external therapists hold either a Master's or Ph.D. degree in clinical psychology, and are licensed therapists or clinical social workers in the United States, with experience ranging from 3 to 18 years. The cost to collect each note was $206.
Note Evaluation: Human evaluation was conducted by $N = 9$ external therapists who are different from those who wrote the notes. All evaluators are licensed therapists or clinical social workers with a Master's or Ph.D. degree in a related field. The cost to collect a single human evaluation related to one note is $190.
Total cost: Annotating a large number of conversations with highly specialized experts is time-consuming and costly. The cost of collecting one note for each conversation was $206, making the cost of the dataset creation to be $10,300. We incur additional costs in the human evaluations ($190 for each, 150 evaluations total). This makes our total cost to be $38800, limiting the size of the dataset to 50 conversations.

D Human Rubric Creation Details

Figure 2 shows the interface of the tool used to build the rubric.

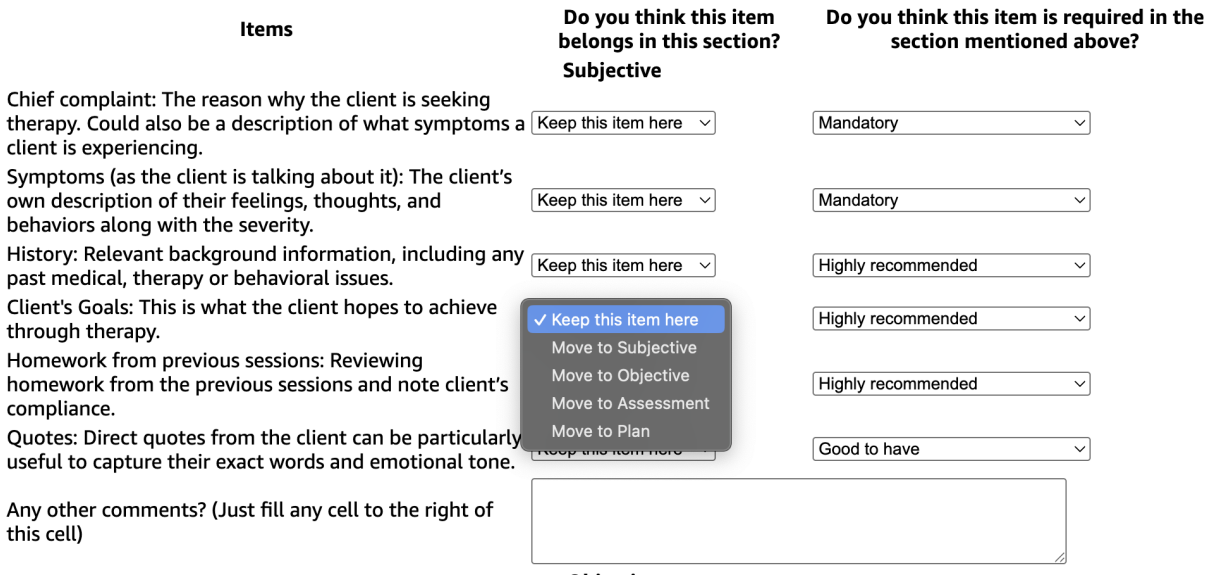

Figure 2: Rubric annotation tool. For each rubric, a therapist would read it and annotate (1) if the section is appropriate and (2) the importance level.

E Automatic Evaluation Details

E.1 Prompts for TN^A-Eval

Rubric-based Completeness Evaluation

```
Below is a behavioral therapy progress note segment. The rubric item outlines one of the necessary
components for the note. Verify if the rubric item presents in the progress note segment.

## Note Segment
{note_segment}
```

```
## Rubric Item (an item that should present in the note segment)
{rubric_item}

Does the note segment contain the rubric item? Response in [Yes, No] with no other content:
```

Rubric-based Conciseness Evaluation

```
Below is a sentence from a behavioral therapy progress note. The rubrics outlines the necessary components
for the note. Verify if the note sentence fit in one of the rubric items.

## Note Sentence
{note_sentence}

## Rubrics (a list of items that should present in the note segment)
{rubrics}

Does the note sentence fit in one of the rubric items? Response in [Yes, No] with no other content:
```

E.2 Prompts for Likert-style automatic evaluation

Completeness

```
Below is a behavioral therapy conversation along with a corresponding progress note segment. The rubrics
outline the necessary components for the note. Based on the conversation and rubrics, evaluate the
completeness of the note segment.

## Conversation
{conversation}

## Note Segment
{note_segment}

## Rubrics (a list of items that should present in the note segment)
{rubrics}

## Rating Codebook
1: The note segment is missing most of the key information from the conversation.
2: The note segment includes some important details but is significantly incomplete.
3: The note segment contains a moderate amount of important information.
4: The note segment captures most of the key information from the conversation.
5: The note segment comprehensively captures all the key information.

Using the 1 to 5 scale from the rating codebook, rate the completeness of the note segment. Output only the
rating [1, 2, 3, 4, 5]:
```

Conciseness

```
Below is a behavioral therapy conversation along with a corresponding progress note segment. The rubrics
outline the necessary components for the note. Based on the conversation and rubrics, evaluate the
conciseness of the note segment.

## Conversation

{rubrics}

## Rating Codebook
1: The note segment includes substantial non-important information that detracts from the main points.
2: The note segment includes non-important information that needs to be reduced.
3: The note segment includes some non-important information but does not heavily detract from the main
points.
4: The note segment includes minor non-critical information.
5: The note segment includes no non-important information, making it concise and focused.

In the scale of 1 to 5, rate the conciseness of the note segment following the rating codebook. Output only
the rating [1, 2, 3, 4, 5]:
```

Faithfulness

```
Below is a behavioral therapy conversation along with a corresponding progress note segment. Verify the
faithfulness of the note segment based on the conversation.

## Conversation
{conversation}

## Note Segment
{note_segment}
```

```
## Rating Codebook
1: The note segment contains significant inaccuracies or false information.
2: The note segment contains several inaccuracies or false information.
3: The note segment may contain some inaccuracies or false information.
4: The note segment contains minor non-critical inaccuracies or false information.
5: The note segment contains no inaccuracies or false information.

In the scale of 1 to 5, rate the faithfulness of the note segment following the rating codebook. Output only
 the rating [1, 2, 3, 4, 5]:
```

F Prompt for Note Generation

```
In emotional support conversations, two primary roles exist: the therapist (individual providing support)
and the client (individual seeking support). Your task is to summarize an emotional support conversation
into client progress notes. These notes are usually in the SOAP format. The SOAP is a standardized form of
recording a client's progress. It stands for:

- Subjective: In this section, document the subjective reports from the client, their family members, and
past medical records. Include how the client describes their feelings and current symptoms.
- Objective: This section is for recording objective observations made during the session. Note any factual,
 observable information, such as the client's appearance, behavior, mood, affect, and speech patterns. Avoid
 including any subjective statements or self-reported information from the client.
- Assessment: In this section, integrate the subjective and objective information to provide a comprehensive
 analysis of the client's current condition. Summarize your clinical impressions and hypotheses regarding
the client's issues.
- Plan: Outline the next steps for the client's treatment. Include both short-term and long-term goals,
specifying what will be addressed in the next session as well as overall treatment objectives. Be clear and
specific about your expectations and the client's goals for the duration of treatment.

Output Dictionary template:
{
"Subjective": "...",
"Objective": "...",
"Assessment": "...",
"Plan": "..."
}
Generate notes for the provided conversation in the above Dictionary style template.

{Conversation}

SOAP Note:
```

G Human label distribution

Figures 3 and 4 highlight the differences in evaluation methodologies using the visualization method in Elangovan et al. (2025). Despite both methods being expert annotations, TN^{H}-Eval 's structured rubric-based approach leads to a broader distribution of scores, capturing nuances in note quality. In contrast, Likert-scale ratings tend to cluster, potentially overlooking finer distinctions.

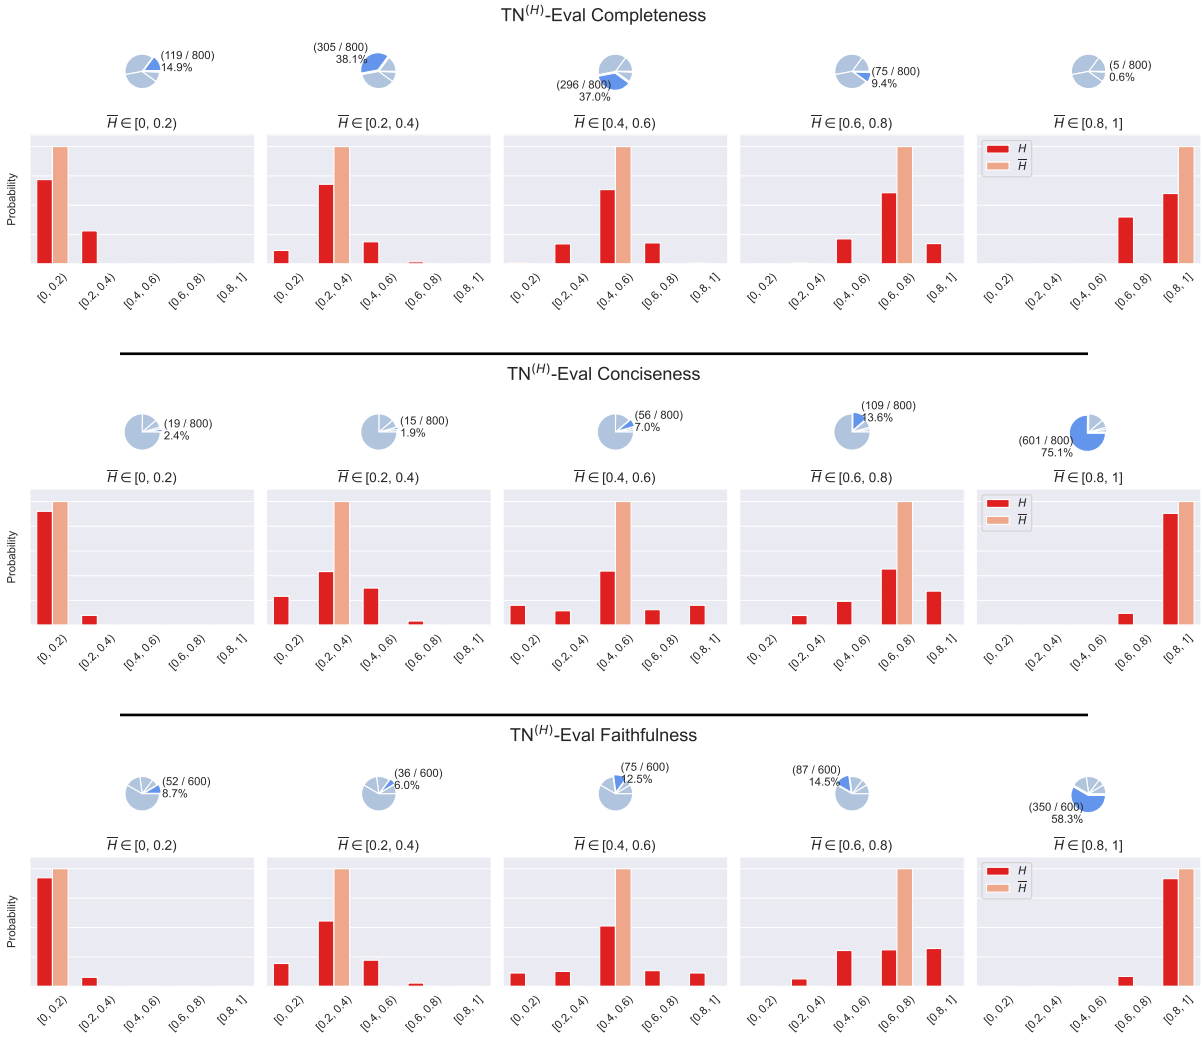

Figure 3: Human label distribution for TN^{H}-Eval annotations.

Figure 4: Human label distribution for Likert style annotations.

H Additional Results

H.1 Traditional reference-based metrics

Table 5 shows the results for traditional reference-based metrics. Notably, all values look similar, making these n-gram-based metrics insufficient to distinguish LLM performance and provide any meaningful signals for note generation quality. The primary reason is that all notes follow a similar structure, with the same section names and fairly standard sentence structure, such as "The client reports/appears ...". This structural similarity dominates the n-gram-based metric computation. Therefore, they fail to detect the nuances.

H.2 Inter-Annotator Agreement on importance of rubric items

Table 9 presents inter-annotator agreement scores among five expert annotators regarding the importance of key characteristics in therapy notes. It includes Krippendorff's alpha (α) and Fleiss' kappa (κ) for four main sections—Subjective (S), Objective (O), Assessment (A), and Plan (P)—as well as an overall agreement score. The importance of each characteristic was categorized into five levels: Mandatory, Mandatory in certain circumstances, Highly recommended, Good to have, and Optional. The high agreement scores indicate strong reliability in expert judgments, supporting the structured rubric-based evaluation framework.

	S	**O**	**A**	**P**	**Overall**
α	0.76	0.68	1.00	0.77	0.73
κ	0.63	0.67	1.00	0.61	0.68

Table 9: Inter-annotator scores among 5 experts on the *importance* of each key characteristic. S/O/A/P stands for four sections. "Importance" has 5 levels: Mandatory, Mandatory in certain circumstances, Highly recommended, Good to have, or Optional. α: krippendorff's α; κ: Fleiss' κ.

H.3 Characteristics of Therapist-Written and LLM-Generated Notes

Table 8 compares the presence of key rubric-based characteristics across therapist-written and LLM-generated notes. It highlights specific rubric items where LLM-generated notes exhibit significantly higher coverage (20% or more) than human-written notes.

H.4 Example human and LLM sourced note for the same conversation

Therapist (Human) written note
Subjective: Client is a male who is presenting to therapy for smoking. *Client reports his wife quit smoking around six months ago due to being on a health kick.* Client reports he feels pressured to quit smoking by his wife. Client reports his wife is worried about his health and continuously saves articles about the negative effects of smoking and secondhand smoke. *In addition, he feels pressure as his children feel negatively about his smoking as well.* Client stated "we used to go out and have a cigarette together at the table. Now I have to go outside in this weather. " Client reports feeling upset due to being forced to change his lifestyle habits. Client also feels torn as he enjoys smoking but does not want to lose his family over it. *Client inquired about his wife possibly attending his next session.*
Objective: Client expressed frustration, anger, and reports feeling isolated due to his smoking. *Client reports his smoking is impacting his family life and his physical health.*
Assessment: Client appears to be in the contemplation stage of change. Although client is upset regarding his cigarette smoking, he appears to see the consequences of his smoking. *In addition, he also appears to have an understanding of consequences regarding losing his family if he continued to smoke.*
Plan: Client will follow up with wife to see her schedule in the hopes that she can attend next session with him. Client will also work on reducing his cigarette use.

Note generated by Llama 3.1 (70B)
Subjective: Client reports being forced to attend therapy by his wife due to her concerns about his smoking. He expresses feelings of anger, frustration, and resentment towards his wife and children, who he feels are ganging up on him. He also mentions concerns about the impact of his smoking on his family, particularly his wife. He does not see his smoking as a major problem, but rather as a habit he has had all his life.
Objective: Client appears resistant and defensive, with a tone of frustration and anger. He maintains a somewhat confrontational demeanor, but also shows signs of vulnerability and concern for his relationship with his wife.
assessment: Based on the client's report and observable behavior, it appears that he is struggling with feelings of resentment and anger towards his wife and children, who he feels are pressuring him to quit smoking. He also seems to be motivated by a desire to maintain his relationship with his wife and avoid conflict. It is likely that he is experiencing some ambivalence about quitting smoking, and may benefit from a gradual approach to cessation.
Plan: Short-term goals include exploring the client's motivations and concerns about quitting smoking, and developing a gradual plan for cessation. It may be helpful to involve the client's wife in future sessions to address her concerns and provide a unified approach to supporting the client's quit attempt. *Long-term goals include reducing the client's symptoms of anger and frustration, improving his relationship with his wife and children, and increasing his overall well-being.*

Table 10: Visualized sentences that are considered not concise in human and Llama notes.

H.5 Automatic evaluation scores for different note sources and evaluators

		Completeness		Conciseness		Faithfulness	
Evaluator	**Note Source**	**TN^A-Eval**	**Likert**	**TN^A-Eval**	**Likert**	**TN^A-Eval**	**Likert**
Mistral Large V2	Human	15.0 (±9.1)	2.23 (±0.27)	73.7 (±15.1)	3.65 (±0.53)	73.2 (±14.9)	4.64 (±0.39)
	Claude 3 Sonnet	21.7 (±6.5)	2.67 (±0.32)	93.6 (±7.8)	4.00 (±0.23)	74.0 (±10.1)	4.99 (±0.05)
	Claude 3 Haiku	21.7 (±6.6)	2.84 (±0.33)	94.4 (±6.8)	3.92 (±0.22)	69.9 (±10.1)	4.92 (±0.21)
	Llama 3.1 (70B)	21.0 (±5.4)	2.53 (±0.25)	92.3 (±7.7)	3.73 (±0.32)	70.2 (±11.5)	4.95 (±0.17)
	Llama 3.1 (8B)	22.0 (±6.9)	2.64 (±0.29)	91.3 (±9.0)	3.56 (±0.27)	69.0 (±11.6)	4.64 (±0.43)
	Mistral Large V2	23.1 (±6.5)	2.92 (±0.35)	92.8 (±7.2)	3.97 (±0.21)	75.8 (±8.8)	4.99 (±0.05)
	Mistral 7B	21.4 (±6.6)	3.00 (±0.34)	90.3 (±6.4)	4.03 (±0.20)	75.2 (±9.5)	5.00 (±0.00)

Table 11: TN-Eval and Likert-style automatic evaluation. We show the results using Mistral Large V2 as the evaluator. Note that the TN-Eval faithfulness is not LLM-based metric, instead it uses AlignScore.

Evaluator	Note Source	Completeness		Conciseness		Faithfulness	
		TN^{A}-Eval	**Likert**	**TN^{A}-Eval**	**Likert**	**TN^{A}-Eval**	**Likert**
Llama 3.1 (70B)	Human	19.7 (±11.1)	1.77 (±0.33)	74.8 (±15.3)	4.68 (±0.40)	73.2 (±14.9)	4.63 (±0.50)
	Claude 3 Sonnet	25.0 (±7.2)	2.25 (±0.33)	92.9 (±8.4)	4.93 (±0.13)	74.0 (±10.1)	5.00 (±0.00)
	Claude 3 Haiku	26.9 (±7.0)	2.56 (±0.38)	93.4 (±7.3)	4.93 (±0.12)	69.9 (±10.1)	4.93 (±0.24)
	Llama 3.1 (70B)	24.3 (±6.5)	2.19 (±0.28)	92.3 (±6.8)	4.86 (±0.22)	70.2 (±11.5)	4.91 (±0.19)
	Llama 3.1 (8B)	25.6 (±7.8)	2.38 (±0.35)	92.0 (±8.5)	4.63 (±0.46)	69.0 (±11.6)	4.67 (±0.46)
	Mistral Large V2	28.0 (±7.3)	2.46 (±0.38)	92.8 (±5.5)	4.92 (±0.15)	75.8 (±8.8)	4.99 (±0.06)
	Mistral 7B	27.8 (±6.7)	2.65 (±0.45)	91.2 (±6.2)	4.93 (±0.14)	75.2 (±9.5)	4.98 (±0.09)

Table 12: TN-Eval and Likert-style automatic evaluation. We show the results using Llama 3.1 (70B) as the evaluator. Note that the TN-Eval faithfulness is not LLM-based metric, instead it uses AlignScore.

I Workflow Integration Proposal

Below, we outline detailed integration steps for embedding the TN-Eval framework within clinical workflows:

1. **Session Completion:** Therapists conduct standard therapy sessions, optionally recording or leveraging speech-to-text tools integrated with the Electronic Health Record (EHR). We propose using HIPAA-certified tools for this task to ensure client privacy.

2. **Note Creation:** After completing a session, therapists either write a note from scratch or receive an initial AI-generated SOAP note draft, which they review and edit in the EHR interface. For AI-generated notes, therapists review and manually edit auto-generated drafts within the EHR interface, making necessary adjustments for accuracy and clinical appropriateness. These notes can be in the EHR provider's preferred format.

3. **TN^{A}-Eval Quality Assessment:** The TN^{A}-Eval framework evaluates the edited note in real-time within the EHR, scoring completeness, conciseness, and faithfulness, while providing rubric-aligned actionable feedback.

4. **Verification and Final Submission:** Therapists review the TN^{A}-Eval quality scorecard and address highlighted concerns before formally submitting notes to the EHR, maintaining final responsibility and clinical oversight.

Run LoRA Run: Faster and Lighter LoRA Implementations

Daria Cherniuk[1], Alexandr Mikhalev[2], Ivan Oseledets[1,2],
[1]Artificial Intelligence Research Institute,
[2]Skolkovo Institute of Science and Technology, Moscow,
daria.cherniuk@skoltech.ru, al.mikhalev@skoltech.ru, oseledets@airi.net

Abstract

LoRA is a technique that reduces the number of trainable parameters in a neural network by introducing low-rank adapters to linear layers. This technique is used for fine-tuning and even training large transformer models from scratch. This paper presents the RunLoRA framework for efficient implementations of LoRA, which significantly improves the speed of neural network training and fine-tuning with low-rank adapters. The proposed implementation optimizes the computation of LoRA operations based on the shape of the corresponding linear layer weights, the input dimensions, and the LoRA rank by selecting the best forward and backward computation graphs based on FLOPs and time estimations. This results in faster training without sacrificing accuracy. The experimental results show a speedup ranging from 10% to 28% on various transformer models.

1 Introduction

LoRA (Hu et al., 2022) paper introduced the idea of updating a low-rank correction of the linear layer instead of the full matrix of its weigths. This approach quickly became popular due to the reduced cost of the update: the number of parameters in the adapter is significantly lower than the original because of its low-rank structure. Several papers have emerged that prove LoRA's efficacy not only for fine-tuning on downstream tasks but also for full training (ReLoRA(Lialin et al., 2023)) or style-transfer (ZipLoRA(Shah et al., 2023)). Different modifications of LoRA followed, incorporating quantization (QLoRA(Dettmers et al., 2023)), weight-sharing (LoTR(Bershatsky et al., 2024), VeRA(Kopiczko et al., 2024)), etc.

However, all variations of LoRA use the default chain of operations while calculating the output, which often leads to a suboptimal computation graph. None of the papers on low-rank adapter training consider computation costs. We propose RunLoRA, a framework that includes different variations of the forward and backward pass through an adapter-induced linear layer and selects the best pair for a given architecture. We provide a thorough analysis (both empirical and theoretical) of the areas of optimality for each pass.

Since modifying the computational graph does not affect the layer output, our method enables faster calculations without compromising model accuracy. RunLoRA retains the same convergence properties and expressive capabilities as vanilla LoRA, unlike common acceleration techniques such as sparsification, quantization, and pruning.

Our framework is compatible with PyTorch and can be used as a simple model wrapper, similar to the LoRA implementation from the PEFT[1] library. We also provide functionality to work with quantized model weights to fine-tune models in the fashion of the QLoRA (Dettmers et al., 2023) paper.

We evaluated our framework's performance on a series of NLP models, including RoBERTa, OPT, and LLaMA, achieving up to a 28% speedup (Figure 1) solely due to an optimized chain of PyTorch operations. Furthermore, we managed to save up to 5,5 GB of memory by reducing the number of saved activations (Table 2).

The summary of our contributions is as follows:

1. We implemented several alternative forward and backward computation passes through low-rank adapters and investigated the areas of optimality for each pass.

2. We developed a framework called RunLoRA: a model wrapper for training with low-rank adapters that uses the best forward-backward passes for each LoRA-induced layer.

3. We evaluated our framework on several language models, demonstrating significant

[1]https://github.com/huggingface/peft

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 200–207

speedups (up to 28%) and proving the efficiency of RunLoRA.

The code for the RunLora framework and related experiments can be found on GitHub[2].

2 Problem setting and Methodology

Default forward pass through LoRA-induced linear layer looks the following:

$$Y = XW + (XA)B, \tag{1}$$

where X represents the input batch, W represents the linear layer weights, A and B are the LoRA factors, Y is the layer output.

The backward pass is automatically determined by the framework using an autograd feature. All the optimizations are left to the neural network training framework, which often performs sub-optimally.

Many scientists and engineers avoid the following chain of computations:

$$Y = X(W + AB). \tag{2}$$

This avoidance stems from an implicit assumption that weights W are large, making it undesirable to form a matrix AB of the same size. However, real-world LoRA-adapter training deals with large input X in an attempt of maximizing batch size to utilize GPU RAM at its full capacity. Large batch size leads to a contradiction to the assumption and inefficient LoRA implementation.

Our current implementation contains two variants of the forward pass and five variants of the backward pass. Formally, the forward variants coincide with Equations 1 and 2. However, unlike the default LoRA implementation, neither forward function in RunLoRA saves the result of XA to context. This memory allocation reduction is particularly beneficial when training with large input.

The backward pass through a LoRA adapter requires us to calculate the following tensors:

$$\begin{cases} \mathrm{d}A = X^\top \mathrm{d}Y B^\top, \\ \mathrm{d}B = A^\top X^\top \mathrm{d}Y, \\ \mathrm{d}X = \mathrm{d}Y W^\top + \mathrm{d}Y B^\top A^\top. \end{cases} \tag{3}$$

where $\mathrm{d}X = \frac{\partial L}{\partial X}$, and similarly for $\mathrm{d}Y$, $\mathrm{d}A$, $\mathrm{d}B$.

Due to the the associativity of matrix multiplication, several computation graphs lead to the same result, up to rounding errors. There are three multiplications, and each can be done in two ways, which leads to the eight variants of the backward pass. Equations and corresponding algorithms are presented in the Appendix A.

Table 1 shows the number of FLOPs required to perform each variant of forward and backward computation. These expressions were determined from the combination of all matrix multiplications in the respective algorithm. The number of FLOPs required for the multiplication of m-by-k and k-by-n matrices is 2mkn.

It is worth noting that out of eight variants of backward paths we implement only the first five since others require an equal or greater number of FLOPs in any setting. Specifically, backward6 would require more FLOPs than backward5 for any architecture and training configuration, while backward7 and backward8 require the same number of FLOPSs as backward3 (Table 1).

We analyze the area of optimality for each forward pass and backward pass, considering a necessary condition on parameters reduction: the number of trainable parameters after LoRA transform should be less than that of the original layer.

$$r(i + o) < io \tag{4}$$

where r denotes LoRA rank, i and o denote input and output dimensions respectively.

Figure 2 depicts case study examples for some batch sizes and sequence lengths. The colored areas illustrate the optimal choice of forward or backward pass determined from minimizing the number of required FLOPs. Subfigures 2a and 2d on the left consider a square weight layer where the number of input features and the number of output features equal the model's embedding size (i.e., query, key, and value layers in transformers). Subfigures 2b and 2c on the right depict an expanding linear layer (typically, $4\times$ expansion is used in MLP blocks of transformers). In all cases, parameter reduction is satisfied only under the dashed line.

In all depicted cases backward2 and backward3 did not emerge as the best choices satisfying condition 4. It can be further proved that neither backward2 nor backward3 will provide the least number of FLOPs under this restriction. It is sufficient to prove that at least one of the other backward algorithms is a better option. For both cases, it is convenient to compare against backward5. We will use proof by contradiction.

Suppose FLOPs(backward2) $\leq$ FLOPs(backward5). From Table 1 it follows that:

[2]https://github.com/KamikaziZen/RunLoRA

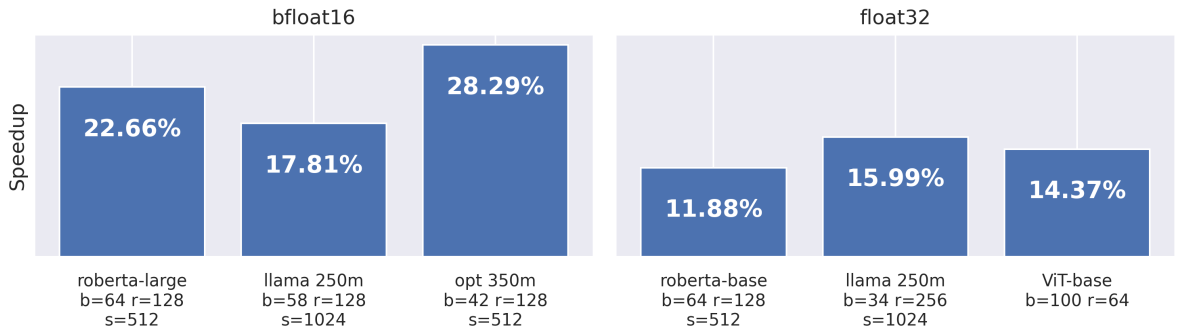

Figure 1: Maximum speedups for the forward-backward pass through network achieved on different families of models and with different data types. Here, b denotes batch size, r denotes LoRA rank, and s denotes sequence length.

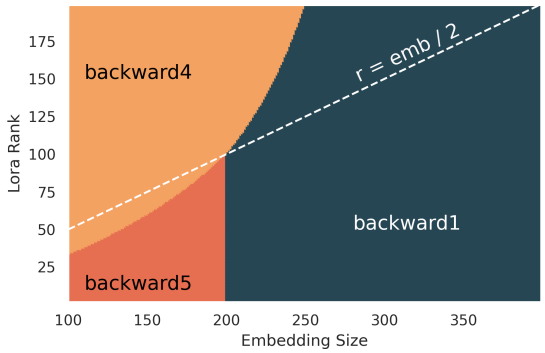
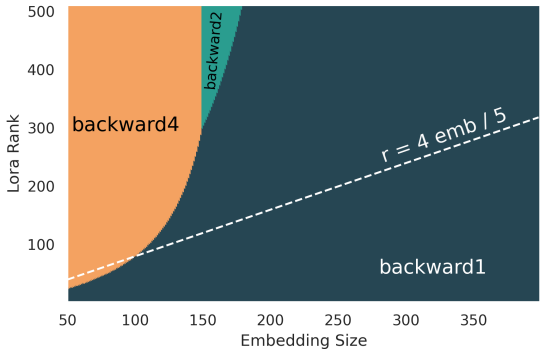
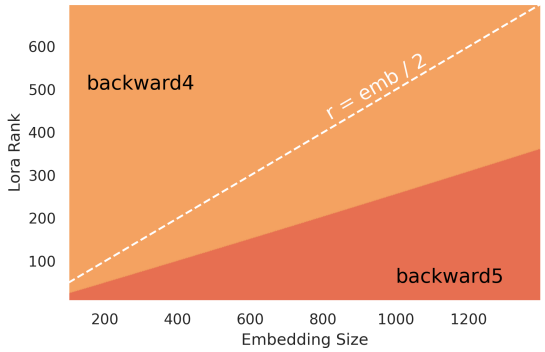


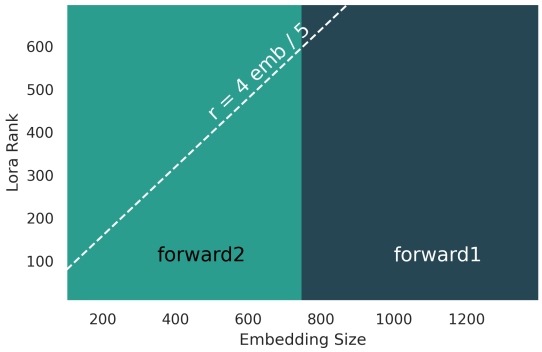
(a) Input and output dimensions are equal to the model's embedding size. batch size = 2, sequence length = 100.



(b) The input dimension equals the model's embedding size, the output dimension is four times bigger. batch size = 2, sequence length = 100.



(c) Input and output dimensions are equal to the model's embedding size. batch size = 20, sequence length = 1024.



(d) The input dimension equals the model's embedding size, the output dimension is four times bigger. batch size = 1, sequence length = 600.

Figure 2: Areas of best forward/backward pass choice. The region under the dashed line satisfies condition 4.

$$
\begin{aligned}
&2bs(or + 2ir + 2io) + 2ior \\
&\qquad \leq 2bs(2or + 2ir + oi) + 2ior \\
&2bsor + 4bsir + 4bsio + 2ior \\
&\qquad \leq 4bsor + 4bsir + 2bsoi + 2ior \\
&\qquad 2bsio \leq 2bsor
\end{aligned}
$$

Using 4 and knowing that $i > 0, o > 0$:

$$i \leq r < \frac{io}{i+o} \leq i$$

We reached a contradiction. That means FLOPs(backward2) > FLOPs(backward5).

Method	FLOPs
forward1	$2b \cdot s \cdot (i \cdot o + r \cdot i + o \cdot r)$
forward2	$2(i \cdot o \cdot r + b \cdot s \cdot o \cdot i)$
backward1	$2b \cdot s \cdot (2o \cdot r + 3i \cdot r + o \cdot i)$
backward2	$2b \cdot s(o \cdot r + 2i \cdot r + 2i \cdot o) + 2i \cdot o \cdot r$
backward3	$2b \cdot s \cdot (2i \cdot o + o \cdot r + i \cdot r) + 4i \cdot r \cdot o$
backward4	$2(2b \cdot s \cdot i \cdot o + 3i \cdot o \cdot r)$
backward5	$2b \cdot s \cdot (2o \cdot r + 2i \cdot r + o \cdot i) + 2i \cdot o \cdot r$
backward6	$2b \cdot s \cdot (2o \cdot r + 2i \cdot r + 2o \cdot i) + 4i \cdot o \cdot r$
backward7	$2b \cdot s \cdot (o \cdot r + i \cdot r + 2o \cdot i) + 4i \cdot o \cdot r$
backward8	$2b \cdot s \cdot (o \cdot r + i \cdot r + 2o \cdot i) + 4i \cdot o \cdot r$

Table 1: The number of floating-point operations per second (FLOPs) for our implemented forward and backward passes. b denotes batch size, s denotes sequence length, i denotes input dimension, o denotes output dimension, and r denotes adapter rank.

Suppose FLOPs(backward3) $\leq$ FLOPs(backward5). From Table 1 it follows that:

$$\begin{aligned} 2bs(2io + or{+}ir) + 4ior \\ \leq 2bs(2or + 2ir + oi) + 2ior \\ 4bsio + 2bsor{+}2bsir + 4iro \\ \leq 4bsor + 4bsir + 2bsoi + 2ior \\ 2bsio + 2iro \leq 2bsor + 2bsir \\ bs(io - or - ir) \leq -iro \end{aligned}$$

Using 4 and knowing that $i > 0, r > 0, o > 0, b > 0, s > 0$:

$$0 < bs \leq \frac{-iro}{io - or - ir} < 0$$

We reached a contradiction. That means FLOPs(backward3) > FLOPs(backward5).

Areas of optimality can also be researched in batch size and sequence length space. For example, Figure 3 depicts the best backward and forward passes for the LlamaMLP linear layer with adapters of rank 128. This configuration satisfies condition 4.

3 Numerical experiments

To evaluate RunLoRA's performance, we have conducted experiments on several NLP models with the number of parameters ranging from 60 million up to 7 billion: LLama (Touvron et al., 2023), OPT (Zhang et al., 2022), and RoBERTa (Liu et al., 2020). We measured the mean time of a forward-backward pass through the network for different architectures and training settings and compared it to PEFT LoRA implementation. Additionally, we performed several epochs of training and compared steps-per-second and samples-per-second as well as total training runtime. We also evaluated our framework on the large Llama2 model with 7 billion parameters in a distributed training setting. Furthermore, through experiments on ViT models, we demonstrate numerical correctness of RunLoRA implementation by comparing training loss and validation accuracy measurements.

Llama We used the Llama model implementation with Flash Attention from PyTorch framework. As shown in Table 2, we achieved up to 16% speedup compared to PEFT when running the model with the float32 data type for weights and operations. When running the same experiment in bfloat16 we manage to achieve up to 17.8% speedup. This slight improvement results from the fact that training in bfloat16 is generally faster than training in full precision, which makes the reduction in FLOPs due to RunLoRA more influential on the loop runtime.

When training Llama for 100 epochs on WikiText-2, we achieved a 17.56% reduction in total runtime. Accordingly, the number of training samples per second and the number of train steps per second increased by 1.2 times (Table 3).

RoBERTa Another family of models we consider in our experiments consists of RoBERTa-base and RoBERTa-large pretrained models from the Hugging Face Hub[3]. They contain about 125 million and 355 million parameters, respectively. In terms of mean forward-backward time, RunLoRA performs 11.88% faster in float32 and 22.06% faster in bfloat16 data type (Table 2).

As for training RoBERTa on WikiText-2, RunLoRA shows up to 20.27% speedup in total runtime and 1.25 times increase in train samples per second and train steps per second (Table 3).

OPT As with RoBERTa, we use pretrained weights and model implementations from the Hugging Face Hub. For the OPT models, we also use FlashAttention2 (Dao, 2024) mechanism, which only supports the bfloat16 data type.

Table 2 shows a maximum speedup of 28.29% for the forward-backward pass with a sequence length of 512 and 26.24% for the maximum sequence length of the model. Thereafter, the WikiText-2 training experiment (Table 3) depicts a maximum reduction of 26.65% in total runtime, a 1.36 times increase in training samples per second, and training steps per second.

Table 2: Comparison between RunLoRA and the PEFT LoRA implementation. b denotes batch size, r denotes LoRA rank, s denotes sequence length.

Additionally, since RunLoRA forward functions do not save intermediate result XA, in certain experiments we managed to save up to 5.5GB of GPU memory.

Llama2-7b Since training such a model on a single GPU proves to be a tedious and often impossible task, we use the LitGPT[4] framework to get advantages of FSDP training. We train the Llama2-7b model on the Alpaca dataset for 100 iteration steps, using two GPUs with a minibatch size of 40. Results are presented in Table 4: RunLoRA achieves a 21.47% speedup in mean iteration time.

ViT We used base and large ViT (Dosovitskiy et al., 2021) variations to demonstrate both RunLora's efficacy and accuracy. Fig 4 depicts a comparison of training loss and test accuracy values between LoRA and RunLora while training a classification task on the Food101 dataset. It can be seen that these metrics coincide up to only a small difference due to initialization or rounding errors.

Table 3: RunLora vs PEFT performance while training for 100 epochs on the WikiText-2 dataset. b denotes batch size, r denotes LoRA rank, s denotes sequence length.

As shown in Table 5, RunLoRA manages to accelerate Visual Transformer up to 14.8%, according to mean forward-backward measurements in the float32 data type.

All experiments were performed on a single Nvidia A100 GPU 80GB (except for the Llama2-7b experiment, which was conducted on two GPUs). In all experiments, LoRA dropout was fixed at 0; other parameters are stated in the referenced tables. For measuring mean forward-backward pass we utilized the torch.benchmarking[5] package. RunLoRA adapters were applied to all linear weights in attention and MLP blocks.

4 Related Work

The introduction of LoRA (Hu et al., 2022) has sparked a wave of new publications on the topic of low-rank updates. For example, ReLoRA (Lialin et al., 2023) has devised a special learning rate scheduler for full training with low-rank updates; ZipLoRA (Shah et al., 2023) merges adapters trained separately for style and object, enabling effective style transfer; and DyLoRA (Valipour et al., 2023) trains LoRA blocks for a range of ranks instead of a single rank.

Many papers aim to further reduce the costs of training. QLoRA (Dettmers et al., 2023) utilizes adapters together with quantization of original weights to reduce memory requirements. Vector-based Random Matrix Adaptation (VeRA) (Kopiczko et al., 2024) reduces the number of trainable parameters by using a single pair of low-rank matrices shared across all layers and learning small scaling vectors instead. LoTR (Bershatsky et al., 2024) also proposes weight sharing for factors in the Tucker2 decomposition of low-rank adapters. LoRA-FA (Zhang et al., 2023) aims to reduce memory consumption by freezing downscaling half of the LoRA adapters.

Our method also seeks to further increase the efficiency of low-rank adapter training, but with a different approach: we neither reduce the number of LoRA parameters nor compromise training accuracy. Our framework achieves computational speedups and memory reduction solely due to the choice of the optimal computation graph.

5 Conclusion and Future Work

We have proposed several variants of forward-backward computational algorithms as alternatives to the default pass through low-rank adapters and derived theoretical bounds for their optimality. We have implemented the proposed methods in a PyTorch-compatible framework called RunLoRA, which selects the best computation graph based on model architecture and training parameters. We have demonstrated RunLoRA's efficiency by comparing it to the PEFT LoRA implementation.

One of the possible directions for future work is finding optimal computation graphs for approximate versions of low-rank adapters (for example, vector analogs like VeRA (Kopiczko et al., 2024) and DoRA (Liu et al., 2024)).

A Appendix

Here we provide more details on the backward paths stemming from Equation 3 in Section 2. Due to the the associativity of matrix multiplication, several computation graphs lead to the same result, up to rounding errors. There are three multiplications, and each can be done in two ways, which leads to the eight variants of the backward pass. Equations and corresponding algorithms (first five) are presented below.

1. $\mathrm{d}A = X^\top(\mathrm{d}Y B^\top)$,
   $\mathrm{d}B = (A^\top X^\top)\mathrm{d}Y$,
   $\mathrm{d}X = \mathrm{d}Y W^\top + (\mathrm{d}Y B^\top)A^\top$.

2. $\mathrm{d}A = X^\top(\mathrm{d}Y B^\top)$,
   $\mathrm{d}B = A^\top(X^\top \mathrm{d}Y)$,
   $\mathrm{d}X = \mathrm{d}Y W^\top + (\mathrm{d}Y B^\top)A^\top$.

3. $\mathrm{d}A = (X^\top \mathrm{d}Y)B^\top$,
   $\mathrm{d}B = A^\top(X^\top \mathrm{d}Y)$,
   $\mathrm{d}X = \mathrm{d}Y W^\top + (\mathrm{d}Y B^\top)A^\top$.

4. $\mathrm{d}A = (X^\top \mathrm{d}Y)B^\top$,
   $\mathrm{d}B = A^\top(X^\top \mathrm{d}Y)$,
   $\mathrm{d}X = \mathrm{d}Y(W^\top + B^\top A^\top)$.

5. $\mathrm{d}A = X^\top(\mathrm{d}Y B^\top)$,
   $\mathrm{d}B = (A^\top X^\top)\mathrm{d}Y$,
   $\mathrm{d}X = \mathrm{d}Y(W^\top + B^\top A^\top)$.

6. $\mathrm{d}A = (X^\top \mathrm{d}Y)B^\top$,
   $\mathrm{d}B = (A^\top X^\top)\mathrm{d}Y$,
   $\mathrm{d}X = \mathrm{d}Y W^\top + (\mathrm{d}Y B^\top)A^\top$.

7. $\mathrm{d}A = (X^\top \mathrm{d}Y)B^\top$,
   $\mathrm{d}B = (A^\top X^\top)\mathrm{d}Y$,
   $\mathrm{d}X = \mathrm{d}Y(W^\top + B^\top A^\top)$.

8. $\mathrm{d}A = X^\top(\mathrm{d}Y B^\top)$,
   $\mathrm{d}B = A^\top(X^\top \mathrm{d}Y)$,
   $\mathrm{d}X = \mathrm{d}Y(W^\top + B^\top A^\top)$.

Abstract

Large Language Models (LLMs) require high quality instruction data for effective alignment, particularly in code generation tasks where expert curated datasets are expensive to produce. We present Genetic-Instruct, a scalable algorithm for synthesizing large-scale, high quality coding instructions using evolutionary principles. Starting from a small set of seed instructions, Genetic-Instruct generates diverse and challenging instruction-code pairs by leveraging an Instructor-LLM for generation, a Coder-LLM for code synthesis, and a Judge-LLM for automatic quality evaluation. Our proposed approach is highly parallelizable and effective even with a small seed data and weaker generator models. We generated more than 7.5 million coding instructions with the proposed approach. Then we evaluated it by fine-tuning LLMs with the synthetic samples and demonstrated a significant improvement in their code generation capability compared to the other synthetic generation approaches and publicly available datasets. Our results highlight the efficiency, scalability, and generalizability of the Genetic-Instruct framework.

1 Introduction

Large Language Models (LLMs) have made significant progress in programming tasks and are increasingly being used as code assistants (Liang et al., 2024). To fully exploit their potential, they require alignment (Ouyang et al., 2022), which depends on paired instruction-solution examples to shape the behavior of the model. However, creating diverse and complex instructions, especially in coding domains, can be expensive due to the need for expert input. A promising alternative is to generate synthetic instructions using another LLM. Previous research shows that synthetic instructions are effective for both coding (Luo et al., 2024; Wu et al., 2024; Wei et al., 2024b; Yu et al., 2024) and general tasks (Wang et al., 2023; Honovich et al., 2023; Xu et al., 2024).

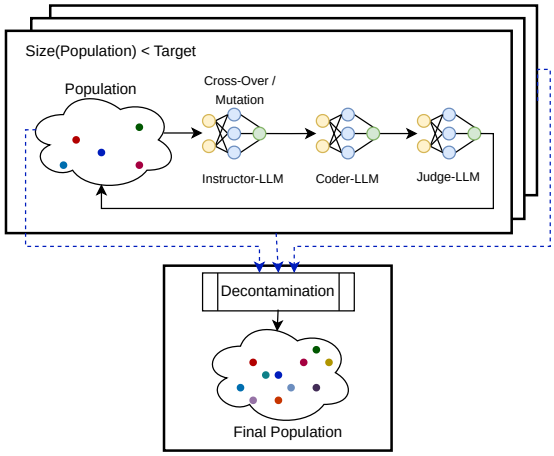

Figure 1: The overall process of Genetic-Instruct across multiple parallel colonies per generation. Each colony begins with a small seed population, from which an Instructor-LLM applies crossover and mutation to create new instructions. A Coder-LLM then generates corresponding code solutions, which are evaluated by a Judge-LLM for correctness and quality. Once the target population size is reached, samples are decontaminated to form the final population.

In this paper, we introduce Genetic-Instruct, a scalable algorithm to generate synthetic coding instructions, illustrated in Figure 1. Inspired by evolutionary algorithms, Genetic-Instruct starts with a small set of seed instructions and uses LLMs to generate new instruction-code pairs through two operations of crossover and mutation.

The crossover operation follows a self-instruct approach (Wang et al., 2023), where an LLM creates new instructions from few-shot examples, expanding the topic coverage beyond the original seeds. The crossover operator is mainly employed to enhance diversity by expanding the overall coverage of the instructions to wider domains and topics beyond the original seed instructions.

*Equal contribution

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 208–221

In the mutation operation, an LLM evolves a given instruction into another instruction based on some predefined rules (Luo et al., 2024). This operation can help the generation process to increase the diversity of the instructions locally. An instruction generated by one operation is added to the pool of the seeds, and it may be used by the the operation or other in the next step. This collaborative and coupled interaction between the crossover and mutation is the main key foundation of our proposed approach. It boosts instruction diversity, which is an essential factor in the success of synthetic instruction generation.

Subsequently, another LLM generates answers, including code solutions, for the instructions. We introduce a fitness function that uses an LLM to evaluate the correctness and quality of each instruction-solution pair. Samples that pass these checks are added to the population pool, and the evolutionary process continues until the target population size is reached. Starting from a small set of seed instructions, the pool grows with newly generated synthetic instructions.

Additionally, the entire pipeline is designed for efficient parallel execution with multiple colonies of populations by running multiple instances of this process in parallel. Furthermore, this process can be repeated multiple times to generate more generations using the instructions generated from the previous round as the seed for the next generation.

Using our Genetic-Instruct algorithm, we generated a large dataset of synthetic coding instructions (more than 7.5M samples), starting from 512 seed questions. We trained LLMs on these data via supervised fine-tuning (SFT) and evaluated them on code generation benchmarks. Our work supports open-source development, avoiding any closed-source data or models.

Models trained on our synthetic dataset achieved strong results across coding benchmarks, outperforming other instruction generation methods and also some of the existing public SFT datasets. Our experiments also show that Genetic-Instruct can produce high-quality data without requiring very strong LLMs or large seed sets. We released the dataset publicly to support open-source LLM development [1].

2 Previous Works

Synthetic data generation has become a practical alternative to the costly and time-consuming collection of human-curated data for LLM training. A notable method is Self-Instruct (Wang et al., 2023), which uses a pre-trained LLM to generate instruction-output pairs from a small seed set, then fine-tunes the base model. However, Self-Instruct focuses on general tasks, not coding. Moreover, while it can enhance the coverage of topics, the synthesized samples are often simple and not challenging enough to require additional steps to arrive at the solution.

To overcome this, Evol-Instruct (Xu et al., 2024) introduces instruction mutation to create more complex and diverse tasks through meta-instructions that increase reasoning depth, impose constraints, or promote conceptual evolution. This idea was adapted to coding by WizardCoder (Luo et al., 2024), leading to improved coding performance in models trained on such evolved instructions.

While Self-Instruct and Evol-Instruct generate instructions without using any code as seeds, another line of work (Yu et al., 2024; Wu et al., 2024; Wei et al., 2024b) generates instructions from existing code snippets. These approaches leverage large code corpora to synthesize diverse prompts. For example, INVERSE-CODER (Wu et al., 2024) generates instructions directly matched to given code, whereas OSS-Instruct (Wei et al., 2024b) and WaveCoder (Yu et al., 2024) use LLMs to create new, code-inspired instructions. However, these methods rely on large high quality and processed code samples, which may pose challenges for less common programming languages.

3 Genetic-Instruct

We introduce Genetic-Instruct, an algorithm inspired by the population-based genetic algorithms (Golberg, 1989). This algorithm employs the two primary evolutionary operations of mutation and crossover to evolve and generate new generations from an initial population. The initial population, termed Generation 0, comprises a limited set of high-quality seed instructions. These seed instructions undergo a series of evolutionary operations, mainly mutation, crossover and selection, to transform them into new instructions. All the operations are executed by leveraging LLMs and enhancing their output with in-context learning.

The whole process of Genetic-instruct is as fol-

Algorithm 1: Pseudo-code for the Genetic-Instruct Algorithm

Input : N: Number of colonies
P_{max}: Maximum population size per colony
G_N: Total number of generations
B_m and B_c: Number of individuals needed for mutation and cross-over respectively
P_{seed}: Initial set of seed instructions
M_p: Probability of selecting mutation as operator
P_{op}: Probability distribution over the operations {Mutation: M_p, Cross-over: $1 - M_p$}
Output : $FinalInstructions$: Generated Synthetic Instructions for Coding Problems

```
for g ← 1 to G_N do
    Run N colonies in parallel;
    foreach colony do
        Initialize P_pool ← P_seed;
        while len(P_pool) < P_max do
            OP ← Choose an operation from P_op;
            Candidates ← Select a subset of B_m or B_c individuals from P_seed randomly based on the selected
              operation;
            NewQuestions ← InstructorLLM(Candidates, OP);
            FilteredQuestions ← FilterQuestions(NewQuestions);
            GeneratedInstructions ← CoderLLM(FilteredQuestions);
            ValidatedInstructions ← ValidateCode(GeneratedInstructions);
            NewInstructions ← JudgeLLM(ValidatedInstructions);
            P_pool ← P_pool ∪ NewInstructions;
        end
    end
    G_g ← Aggregate all P_pool from N colonies;
end
AggInstructions ← Aggregate all G_g, for g ∈ [1, G_n];
FinalInstructions ← Decontaminate(AggInstructions);
```

lows. At each step, from the instruction set of the initial population (seed population), we randomly select a batch of instructions with replacement. The LLM responsible for instruction generation (called Instructor-LLM) is employed to synthetize the new instructions based on a selected operation. Upon generating a new instruction, another LLM, referred to as the Coder-LLM, is tasked with producing the code corresponding to this new instruction. The newly generated instruction and its associated code constitute a new coding instruction, which can be utilized for training. However, there may be instances where the generated code does not fully address the provided question, or the question itself may be poorly formulated. To assess the quality of the new coding instruction, we employ another LLM, termed the Judge-LLM, to evaluate the correctness of the instruction and its code. If a sample passes this quality assessment, it is added to the pool of instructions and may be selected as the seed instruction for the next batch of synthesized samples. The entire process is iterated multiple times to synthesize samples until the desired population size is achieved. This resulting population is then labeled as a generation, and the entire pipeline can be repeated by considering this generation as the initial population for the next generation.

Subsequently, a decontamination process is applied to minimize risk of contaminated instructions in the training data. The complete pipeline is illustrated in Figure 1 for one generation, and the procedure for the whole algorithm is detailed in Algorithm 1. In the following, each step is explained in detail.

3.1 Mutation Operation

The mutation operation is inspired by an adaptation of the Evol-Instruct algorithm, as devised by (Xu et al., 2024), and further extended by WizardCoder (Luo et al., 2024) to facilitate instruction generation for code models. Evol-Instruct evolves an instruction into another using an LLM based on predefined tasks. For a sample selected for mutation, we randomly choose one of the five tasks defined and apply the mutation to generate a new instruction. We employ the same five tasks introduced by (Luo et al., 2024), with minor prompt modifications to suit our Instructor-LLM. Details on the mutation prompts are provided in Appendix A.

3.2 Crossover Operation

The crossover operation in Genetic-Instruct is influenced by the concepts introduced in Self-Instruct (Wang et al., 2023) and Unnatural Instructions

(Honovich et al., 2023). It inspires from multiple instructions and employs the Instructor-LLM to generate new populations from the provided few-shot example instructions. To enhance the efficiency of the crossover operation, we provide multiple seed instructions and request the model to generate multiple diverse new instructions based on the provided examples in a single Instructor-LLM call. The prompt for the crossover operation is depicted in Appendix B.

3.3 Code Generation

After the Instructor-LLM generates a batch of new instructions, they are passed to the Coder-LLM to generate the corresponding code solutions. The Coder-LLM should be proficient in coding tasks to ensure the generation of high-quality solutions. However, some generated code may not be parseable or compilable. Therefore, we filter out solutions whose code segments cannot be parsed by the corresponding language's parser/compiler. While determining the correctness of code by execution is the ideal case, it is challenging due to various factors, such as language constraints, missing dependencies, or having to integrate the current solution into a much larger codebase that may not be available in its entirety. The prompt used in this step is illustrated in Appendix C.

3.4 Fitness Function

Simple post-processing, such as rejecting all samples that don't pass the Abstract Syntax Tree checks, is applied to filter out incorrect instructions. Then, they are scored using a fitness function in order to discard candidates that have low quality. We employ a Judge-LLM to assign a binary score indicating whether a candidate code solution meets the minimum requirements. The Judge-LLM is provided with an instruction and its code solution to determine the correctness of the instruction and its corresponding solution. To enhance the performance, we employ techniques such as in-context learning with few-shot examples and Chain-of-Thought (Wei et al., 2022) prompting to making a better decision. The prompt for the Judge-LLM is depicted in Appendix D.

3.5 Scaling Up the Process

An advantage of genetic algorithms is their inherent capacity for parallelization. When utilizing computationally intensive LLMs for sample generation, it is crucial to leverage this parallel structure. We execute multiple colonies of populations in parallel processes and synchronize them periodically. These colonies are evolved and populated independently, starting from the same seed population. Upon reaching the desired size, the colonies are merged into a single population and called a generation. Additionally, to improve the diversity, we make sure that seed examples selected to be used in a batch are all different.

3.6 LLM Decontamination

To prevent any evaluation benchmark questions from leaking into our training samples, we adopted the decontamination methodology proposed by Yang et al. (2023), which involves two primary stages. First, for each synthesized question, we performed an embedding-based similarity search using a Sentence Transformer (Reimers and Gurevych, 2020) model to identify the most similar test example from all benchmark datasets. Second, we constructed question pairs by matching each synthesized question with its most similar test example. An LLM, specifically `Meta-Llama-3-70B-Instruct`, was then employed to evaluate whether any of these pairs constituted a paraphrase (details on the prompt are provided in Appendix E).

To control for potential positional bias in the LLM's paraphrase detection, we generated two pairs for each match: one where the synthesized question appeared first and another where the test set question was presented first (Toshniwal et al., 2024). If any of these pairs were determined to be similar by the LLM, the synthesized question was removed.

4 Experiments

We fine-tune the base LLM models using supervised fine-tuning (SFT) to evaluate the effectiveness of a given instruction set. In all experiments, the models are evaluated on four benchmark datasets: HumanEval (HE) (Chen et al., 2021), MBPP (Odena et al., 2021), HumanEval+ (HE+), and MBPP+ (Liu et al., 2023). The MBPP+ and HumanEval+ datasets, part of the EvalPlus benchmark, are extensions of the original MBPP and HumanEval test sets, respectively. These extensions include additional test cases designed to ensure the correctness and accuracy of the generated code. The prompts used for the evaluation benchmarks are provided in Appendix F. All code evaluations

are conducted using greedy decoding. Prior to SFT training, all training datasets undergo a decontamination process.

We use 512 samples from the Tiger-Leetcode collection (TigerResearch, 2023) as the initial population in most experiments. This collection serves as the seed dataset for the first generation and consists of interview-style coding questions. Throughout all experiments, we employ the same generation models as Instructor-LLM, Coder-LLM, and Judge-LLM. Since our evaluation focuses exclusively on Python coding benchmarks, we constrain the generated solutions to Python by instructing the models to produce only questions that can be answered with Python code. After code is generated by Coder-LLM, we verify its syntactic correctness using Python's `ast` package, regardless of its executability, to ensure the structural validity of the generated code.

4.1 Experimental Settings

We used the AdamW optimizer (Kingma and Ba, 2015) for all supervised fine-tuning (SFT) experiments, with a learning rate of 5e-6 decaying to 5e-7 over three epochs, following a cosine annealing schedule (Loshchilov and Hutter, 2022). All models were trained using tensor parallelism and BF16 precision to accelerate the training process. Experiments were conducted using the NeMo framework (Harper et al., 2025) and NeMo Aligner (Shen et al., 2025).

For high-throughput inference with large effective batch sizes, we used vLLM (Kwon et al., 2023) as the inference engine. Nucleus sampling (Holtzman et al., 2020) was employed for decoding, with a temperature of 1.2 for Instructor-LLM, and 1.0 for both Coder-LLM and Judge-LLM. To improve GPU utilization and speed up generation, we ran 20 colonies in parallel for each generation step. A maximum sequence length of 1024 tokens was set across all LLMs to optimize generation speed and memory usage.

For Genetic-Instruct, the mutation probability (M_p) was set to 0.5 by default. During the mutation operation, a batch size of 100 (B_m) was used, while the crossover operation used a batch size of 10 (B_c). These values were chosen based on our observation that, the model generates approximately 10 unique instructions per generation on average, aiming to maintain a consistent number of generated samples per batch. In the crossover operation, Instructor-LLM used 3-shot in-context learning and was prompted to generate up to 20 new instructions.

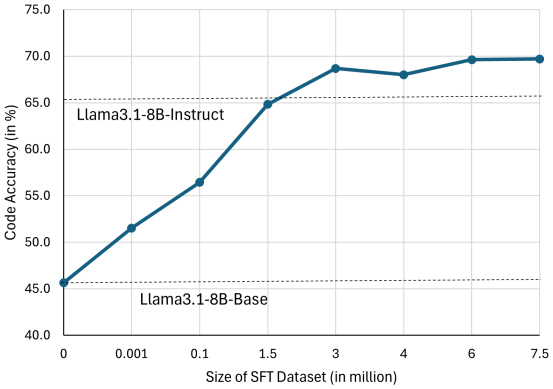

Figure 2: The accuracy of Llama-3.1-8B trained on different data sizes. Code accuracy is calculated as the average of the model's accuracy on all the four benchmarks. With scaling up the synthetic, accuracy improves but starts to show diminishing improvements later.

4.2 Performance Evaluation

In this section, we evaluate the effectiveness of our proposed approach for generating synthetic supervised fine-tuning (SFT) samples aimed at enhancing the coding capabilities of LLMs. We used Llama3.1-8B-Base (Grattafiori et al., 2024) as the base model and employed Mixtral-8x22B (Jiang et al., 2024) as the Instructor-LLM, Coder-LLM, and Judge-LLM.

Figure 2 illustrates the relationship between the size of the SFT dataset generated by Genetic-Instruct and coding accuracy. Coding accuracy is computed as the average model performance across all four benchmarks. We generated synthetic instructions across six generations, each consisting of approximately 1.5 million samples, totaling around 7.8 million samples. The results show a clear upward trend, where increasing the dataset size leads to significant improvements in accuracy. Notably, models trained on more than 3 million samples outperform the Llama3.1-8B-Instruct model. Starting from a baseline accuracy of approximately 45%, the Llama3.1-8B-Base model shows consistent improvement as the dataset grows, demonstrating the scalability and effectiveness of our synthetic data generation strategy. However, beyond approximately 6 million samples, the accuracy gains begin to plateau, indicating diminishing returns.

To show the effectiveness of Genetic-Instruct compared to other approaches, we evaluated the samples generated by Genetic-Instruct with some

Generation Algorithm/Dataset	Data Size	MBPP	MBPP+	HumanEval	HumanEval+	Average
Llama 3.1 8B Instruct	-	73.0	62.7	66.5	61.6	65.9

Table 1: Comparison of Genetic-Instruct with other data generation algorithms and datasets. Average of the accuracies on all the benchmarks are also reported.

other baseline approaches which are designed for generating synthetic SFT data for coding problems. To make the comparisons fair, we re-implemented all the baseline approaches and performed the comparisons with the same generator model, seed population, base model for SFT, and size of training data. We did not rely on the results reported in the original papers, as each one used different generation models, seed populations, base models and benchmarks. Among these baselines, WizardCoder and Self-Instruct follow a similar paradigm to ours, using a collection of coding questions to expand into a larger instruction set. In contrast, OSS-Instruct (Wei et al., 2024b) and INVERSE-INSTRUCT (Wu et al., 2024) generate instructions from a large set of real code snippets.

For OSS-Instruct and INVERSE-INSTRUCT, we used around 1.4M Python functions extracted from Stack v2 (Lozhkov et al., 2024) as the seed population, following the seed collection procedure adopted in Wei et al. (2024a), while for the rest of the baselines we used Tiger-Leetcode. The same number of samples are generated by each one of the approaches with three generations. Extra samples from the last generation are dropped randomly to make all the sizes exactly 4M. The results of 5 generations (7.5M) are also reported for Genetic-Instruct. We also evaluated some of the publicly available coding instruction datasets: Apps (Hendrycks et al., 2021), TACO (Li et al., 2023), and OpenCoder (Huang et al., 2024). All the results are presented in Table 1.

For OSS-Instruct and INVERSE-INSTRUCT, we used around 1.4M Python functions extracted from Stack v2 (Lozhkov et al., 2024) as the seed population, following the procedure outlined in Wei et al. (2024a). For the remaining baselines, we used Tiger-Leetcode as the seed dataset. For each approach, we generated the same number of samples over three generations, and any extra samples from the final generation were randomly discarded to standardize the dataset size to 4 million. For Genetic-Instruct, we also report results with five generations (more than 7.5M samples). Additionally, we evaluated models fine-tuned on publicly available coding instruction datasets: Apps (Hendrycks et al., 2021), TACO (Li et al., 2023), and OpenCoder (Huang et al., 2024). The results are summarized in Table 1.

The results clearly highlight the superior performance of Genetic-Instruct across multiple evaluation metrics. Models trained on data generated by our method consistently outperform those trained

Generation Algorithm	MBPP	MBPP+	HE	HE+	Avg

	Qwen 7B	81.2	69.6	**81.1**	**75.0**	76.7

Table 3: Ablation study on the effect of the generator model on the quality of the data generation. Average of the accuracies on all the benchmarks are also reported.

on all baseline approaches and public datasets. In particular, our five-generation dataset achieves a significantly higher average accuracy of 69.7% compared to the best-performing public dataset, OpenCoder Stage 1, at 62.9%. Even our smaller dataset (4M) achieves an average of 68.0%, further underscoring the effectiveness and efficiency of our approach.

4.3 Ablation Study

In this ablation study, we assess the impact of mutation and crossover operations in Genetic-Instruct on the quality of generated data. We compare three setups: *Crossover-Only*, where only the crossover operation is used during data generation; *Mutation-Only*, where only the mutation operation is applied; and the full *Genetic-Instruct* approach, which employs both.

For each setup, we generated three generations totaling 4 million samples and fine-tuned a Llama3.1-8B Base model to evaluate downstream performance. This setup allows us to assess the individual and combined impact of these genetic operators on downstream model performance. Mutation-Only resembles WizardCoder conceptually, but with a key distinction: it updates the evolving seed pool with newly generated samples, unlike WizardCoder, which evolves only the initial seeds.

As shown in Table 2, combining both operations yields the highest average accuracy across all benchmarks, confirming their complementary benefits. While Mutation-Only slightly outperforms the full approach on the HE benchmark, these findings suggest that while both operations individually contribute to improved performance, and their synergistic combination in Genetic-Instruct yields the most substantial overall gains in coding capability.

4.4 Influence of the Generator Model

Table 3 presents an ablation study evaluating the impact of different generator models on the quality of the synthetic data. We generated 1.5 million samples for each experiment with different generation models and then trained Llama3.1-8B-Base and Qwen2.5-7B-Base on them. The results indicate that the Qwen models (Yang et al., 2024) outperform the Mixtral family across most benchmarks, highlighting that stronger LLMs tend to produce higher-quality synthetic data.

Interestingly, Qwen-7B performs closely to Qwen-32B, suggesting that even a smaller model within the Qwen family is capable of generating high-quality training data. These findings imply that while the strength of the generator plays a key role in data quality, relatively smaller LLMs can still yield competitive performance, offering a more cost-effective alternative for synthetic data generation.

5 Conclusion

We introduced Genetic-Instruct, a novel algorithm inspired by evolutionary principles to generate synthetic coding instructions for LLMs. Genetic-Instruct is specifically designed to support parallel generation, making it a scalable solution for synthetic data creation. We benchmarked our approach against several baseline methods and publicly available datasets, and the results consistently demonstrated its effectiveness in improving performance on code generation tasks. Also in our ablation studies, we demonstrated the effectiveness of combining the two main operations to achieve the best performance. We publicly released the 7.5M synthetic instruction-solution dataset to facilitate the development of open source LLMs.

A Mutation Prompts

Mutation Prompt

Please increase the difficulty of the given programming test question a bit. Do not provide any hints, solutions or outputs. Only one new instruction is allowed.

You can increase the difficulty using, but not limited to, the following methods:
{method}

Original Instruction:
{instruction}

New Instruction:

Operation: Constraint

Rewrite the original instruction, adding new constraints and requirements, with approximately 10 additional words.

Operation: Deepening

Write the original instruction. Then, replace a commonly used requirement in the programming task with a less common and more specific.

Operation: Erroneous Code

Write the original instruction. Then provide a piece of wrong python code as a reference solution to increase misdirection. Your wrong reference solution should start with "Reference Solution (Wrong)", marked in ‘‘‘ blocks.

Finally, ask to write the correct solution for the instruction. Do NOT provide the correct solution.

Operation: Reasoning

Write the original instruction after the new instruction. Then, if the original instruction can be solved with only a few logical steps, please add more reasoning steps after the original instruction.

Do NOT provide any reason or explanation.

Operation: Task Complexity

Write the original instruction after the new instruction. Then propose higher time or space complexity requirements, but please refrain from doing so frequently.

Figure 3: Prompt template for mutation operation

B Crossover Prompt

Crossover Prompt

You are asked to come up with a set of 20 diverse code generation task instructions. These task instructions will be given to a GPT model and we will evaluate the GPT model for completing the instructions.

Here are the requirements:
1. Try not to repeat the verb for each instruction to maximize diversity.
2. The language used for the instruction also should be diverse. For example, you should combine questions with imperative instructions.
3. The type of instructions should be diverse. The list should include diverse types of programming tasks like open-ended generation, classification, editing, optimization etc.
4. A GPT language model should be able to complete the instruction.
5. The instructions should be in English.
6. The instructions should at least 1 to 2 sentences long. Either an imperative sentence or a question is permitted.
7. You should generate an appropriate input to the instruction. The input field should contain a specific example provided for the instruction. It should involve realistic data and should not contain simple placeholders. The input should provide substantial content to make the instruction challenging but should ideally not exceed 100 words.
8. Not all instructions require input. For example, when a instruction asks about some general information, "write a program to load a file.", it is not necessary to provide a specific context. In this case, we simply put "⟨noinput⟩" in the input field.
9. The output should be an appropriate response to the instruction and the input.
10. All tasks should be coding or programming-related.

List of 20 tasks:

Few-Shot Examples

###
1. Instruction: Convert a Binary Search Tree to a sorted Circular Doubly-Linked List in place. You can think of the left and right pointers as synonymous to the predecessor and successor pointers in a doubly-linked list. For a circular doubly linked list, the predecessor of the first element is the last element, and the successor of the last element is the first element. We want to do the transformation in place. After the transformation, the left pointer of the tree node should point to its predecessor, and the right pointer should point to its successor. You should return the pointer to the smallest element of the linked list.
1. Input: root = 4,2,5,1,3
###
2. Instruction: · · ·
· · ·
###
3. Instruction:

C Prompts for Coder-LLM

Python Code Generation Prompt

You are an expert in Python coding. Using only Python code, write the correct solution that answers the given coding problem.
{instruction}
Answer:

Figure 5: Prompt template for code Generation with Coder-LLM

D Fitness Prompt for Judge-LLM

Fitness Prompt

You are an expert python programmer.
Below is a question and code solution. Decide if the solution follows the below criteria and give a final Yes/No, and place it in the ⟨judge⟩⟨/judge⟩ tags.
Only look at the function generated, not any examples/print statements etc. Just the core logic.
Please first briefly describe your reasoning (in less than 30 words), and then write Decision: \\boxed{Yes or No} in your last line.

Criteria:
1. ⟨llm-code⟩⟨/llm-code⟩ contains a code solution in any programming language.
2. If the code was executed with the proper libraries imported and correct inputs, it would execute without error.
3. Given the question, the code solution seems to answer the problem if it was to be used correctly.
4. The code solution provides an elegant solution to the problem and doesn't seem overly complicated.

Few-Shot Examples

Question: {instruction}
⟨llm-code⟩
{code}
⟨/llm-code⟩
⟨judge⟩
{reason}
Score: \\boxed{score}.
⟨/judge⟩

Figure 6: Prompt template for code quality judgement with Judge-LLM

E Decontamination Prompt

Prompt Template for Contamination Detection

Help me determine if the following two coding problems are the same.

First problem: {instruction 1}

Second problem: {instruction 2}

Disregard the names and minor changes in word order that appear within. If the two problems are very similar and if they produce the same answer, we consider them to be the same problem. Respond with only "True" (problems are the same) or "False" (problems are different). Do not respond with anything else.

Figure 7: Prompt template for checking contamination

F Evaluation Prompts

Evaluation Prompt Template for MBPP and MBPP+

Here is a problem for which you need to generate code:

{instruction}

Please continue to complete the code with python programming language.

The solution should be in the following format:

“‘python

Your code here

“‘

Do not generate any tests. Your function should have the same name as the function in the assert statement.

Figure 8: Prompt template for code evaluation on MBPP and MBPP+

Evaluation Prompt Template for HumanEval and HumanEval+

Here is a problem for which you need to complete code:

{instruction}

Please continue to complete the code with python programming language.

The solution should be in the following format:

“‘python

Your code here

“‘

Do not generate any tests. You are not allowed to modify the given code and do the completion only.

Figure 9: Prompt template for code evaluation on HumanEval and HumanEval+

NEKO: Cross-Modality Post-Recognition Error Correction with Tasks-Guided Mixture-of-Experts Language Model

Abstract

Construction of a general-purpose post-recognition error corrector poses a crucial question: how can we most effectively train a model on a large mixture of domain datasets? The answer would lie in learning dataset-specific features and digesting their knowledge in a single model. Previous methods achieve this by having separate correction language models, resulting in a significant increase in parameters. In this work, we present Mixture-of-Experts as a solution, highlighting that MoEs are much more than a scalability tool. We propose a Multi-Task Correction MoE, where we train the experts to become an "expert" of speech-to-text, language-to-text and vision-to-text datasets by learning to route each dataset's tokens to its mapped expert. Experiments on the Open ASR Leaderboard show that we explore a **new state-of-the-art** performance by achieving an average relative 5.0% WER reduction and substantial improvements in BLEU scores for speech and translation tasks. On zero-shot evaluation, NeKo outperforms GPT-3.5 and Claude-3.5 Sonnet with 15.5% to 27.6% relative WER reduction in the Hyporadise benchmark. NeKo performs competitively on grammar and post-OCR correction as a multi-task model.

1 Introduction

Human recognition capabilities span multiple modalities, including speech recognition, visual patterns, and extensions to semantic and textual interpretations. These faculties, however, are not infallible and often incorporate mis-recognition errors. Despite these imperfections, humans efficiently communicate using speech, language, or facial expressions.

For instance, two non-native speakers (Lev-Ari, 2015; Valaki et al., 2004) can often achieve mutual understanding through this imperfect recognition and subsequent interpretative processes, even when the conversation is marred by lexical inaccuracies and subdued accents. In other words, humans (as intelligent agents) exhibit a robust capacity for generative understanding (Jiang et al., 2020; Cheng et al., 2021) that extends beyond initial recognition results. In neuroscience (Zatorre and Gandour, 2008), the inferior temporal gyrus and the temporal lobe are not confined to rudimentary perception but are also integral to the post-recognition processes that facilitate semantic understanding of language (Levinson and Evans, 2010), speech (Marshall et al., 2015), and visual patterns (Vink et al., 2020). This form of "post-recognition correction," exemplified by the application of language modeling (LM) to initial recognition outputs, has been introduced to the field for both acoustic (automatic speech recognition, ASR) and visual (optical character recognition, OCR) modalities.

With the LMs scaling up to LLMs (Brown et al., 2020), recent efforts (Chan et al., 2023; Yang et al., 2023; CHEN et al., 2023; Hu et al., 2024a) have focused on exploring a "generative modeling" for

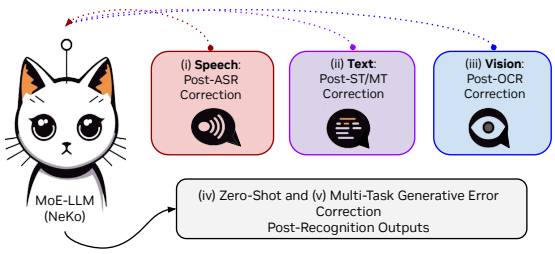

Figure 1: Proposed NEKO, a new form multi-task model to boost post-recognition results over speech, text, and visual inputs. NEKO could work for (i) post automatic speech recognition (ASR) correction, (ii) post speech translation (ST) and machine translation (MT) correction, and (iii) post optical character recognition (OCR) correction. NeKo discover new state-of-the-art results in (iv) zero-shot ASR correction and performs competitively as a general-purpose (v) multi-task corrector.

*Work done at NVIDIA research as an intern.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 222–236

post-recognition correction. This generative error correction (GER) approach uses LLMs to conduct final recognition from given first-pass text-based predictions from recognition models, including ASR, image captioning (IC), and machine translation (MT). This cascaded two-agents text-to-text GER model has outperformed larger single multi-modal and multi-task models in these tasks. Meanwhile, these GER solutions heavily depends on domain-specific fine-tuning processes (Chen et al., 2024a) that utilize parameter-efficient components, which often suffers a performance *degradation* from a lack of generalizability across different datasets, domains, and tasks.

To characterize "model generalization," mixture-of-experts (MoE) (Jiang et al., 2024a) has emerged as a promising approach for multi-task learning, consisting of of a set of *expert networks* and a *gating network* that learns to route the input to the most appropriate expert (Sukhbaatar et al., 2024). This enables MoE models to learn more specialized and fine-grained representations compared to monolithic models. However, most MoE models are designed for general-purpose language modeling(Dai et al., 2024), with experts not explicitly assigned to specific tasks, but rather learn to specialize in different aspects of the input space through data-driven training. Effectively leverage MoE for multi-task error correction, where the experts need to capture task-specific features while allowing knowledge sharing, remains an open question.

In this work, we propose NEKO, a "geNErative multi-tasK error cOrrection" approach that leverages a pre-trained MoE model to drive diverse tasks and cross-domain knowledge, as shown in Figure 1. The key idea is to continuously pre-train MoE model on a mixture of error correction datasets, with each expert specializing in a specific domain. This task-guided MoE fine-tuning approach enables the experts to capture task-specific features while allowing knowledge sharing through the router. We further pursue this direction by modeling MoE on error correction and highlight the effectiveness and robustness of MoEs in learning from a mixture of correction datasets.

NEKO captures the nuances of each task, benefiting from shared knowledge across experts. Evaluated on tasks such as ASR, ST, OCR, and unseen textual error correction (TEC), NEKO consistently outperforms baseline models, including Claude-3.5 Sonnet and GPT-3.5. It achieves state-of-the-art WER reduction on the Hyporadise benchmark and large-scale Open ASR Leaderboard (Srivastav et al., 2023). NEKO also significant improves in OCR error correction. Further analysis confirms its robust multi-task capabilities. In summary, the main contributions of this work include:

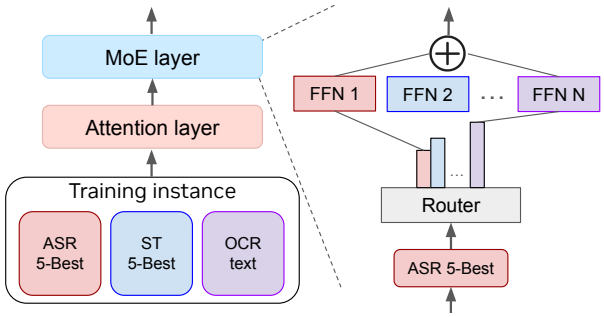

Figure 2: The architecture of our proposed model, NEKO, which integrates MoE layers within a Transformer architecture. During inference, we do not assume knowledge of the specific task an input belongs to and each token is routed to the top-2 experts solely based on their router probabilities.

1. We introduce NEKO, a multi-task error correction LLM that leverages task-guided mixture-of-experts for diverse post-recognition correction tasks. To the best of our knowledge, this is the first work that explores the use of MoE for multi-task error correction.

2. NEKO has been studied under a new form of cross-modalities post-recognition correction evaluation, serving as strong open-source ASR, ST, OCR, and TEC baselines. Our results show that NEKO discovers new state-of-the-art performance in ASR as a multi-task correction model.

3. We discovered emergent abilities for cross-task correction from NEKO as a first-of-its-kind multi-task correction approach toward a general-purpose post-recognition LM designs.

4. The NEKO models, newly created source datasets, and training processes are scheduled to open source under the CC BY-SA 4.0 license to support reproducibility in future research.

2 Method

2.1 Mixture-of-Experts (MoE)

Our method, NEKO, is based on a Transformer architecture (Vaswani et al., 2017) with modifications similar to those described in Jiang et al. (2023). The key difference is that we replace the feedforward blocks with Mixture-of-Expert (MoE) layers. In a

MoE layer, each input token is assigned to a subset of experts by a gating network (router). The output of the MoE layer is the weighted sum of the outputs of the selected experts, where the weights are determined by the gating network. Formally, given n expert networks $\{E_0, E_1, ..., E_{n-1}\}$, the output of the MoE layer for an input token x is:

$$y = \sum_{i=0}^{n-1} G(x)_i \cdot E_i(x), \tag{1}$$

where $G(x)_i$ is the weight assigned to the i-th expert by the gating network, and $E_i(x)$ is the output of the i-th expert network for input x. The gating network $G(x)$ is implemented as a softmax over the top-K logits of a linear layer:

$$G(x) = \text{Softmax}(\text{TopK}(x \cdot W_g)), \tag{2}$$

where $\text{TopK}(\ell)_i = \ell_i$ if ℓ_i is among the top-K coordinates of logits $\ell \in \mathbb{R}^n$, and $\text{TopK}(\ell)_i = -\infty$ otherwise. The number of experts K used per token is a hyperparameter that controls the computational cost.

2.2 Tasks-Guided Auxiliary Expert Assignment

The key idea of NEKO is to assign each expert to a specific task during training. Given a set of tasks $\mathcal{T} = \{T_1, T_2, ..., T_m\}$, we define a mapping function $f : \mathcal{T} \to \{1, 2, ..., n\}$ that assigns each task to a unique expert. During training, for an input token x from task T_i, we deterministically route x to the expert $f(T_i)$ in addition to the top-1 expert selected by the gating network. This ensures that each expert learns task-specific features while still allowing for knowledge sharing through the gating network. Formally, the output of the MoE layer for an input token x from task T_i during training is:

$$y = G(x)_{f(T_i)} \cdot E_{f(T_i)}(x) + G(x)_{\text{top1}} \cdot E_{\text{top1}}(x), \tag{3}$$

where $\text{top1} = \arg\max_{j \neq f(T_i)} G(x)_j$ is the index of the top-1 expert selected by the gating network, excluding the task-specific expert $f(T_i)$.

During inference, we do not assume knowledge of the specific task an input token belongs to. Instead, we route each token to the top-K experts selected by the gating network based on their predicted probabilities. This approach allows the model to leverage the task-specific knowledge learned by the experts during training while still being able to generalize to new, potentially unseen tasks and domains during inference.

2.3 Training Objective

We train NEKO on a mixture of error correction datasets $\mathcal{D} = \{D_1, D_2, ..., D_m\}$, where each dataset D_i corresponds to a specific task T_i. The training objective is to minimize the negative log-likelihood of the target sequences:

$$\mathcal{L} = -\sum_{i=1}^{m} \sum_{(x,y) \in D_i} \log p(y|x, T_i), \tag{4}$$

where x is the input sequence (e.g., ASR hypotheses, OCR output), y is the target sequence (e.g., ground-truth transcription, corrected text), and $p(y|x, T_i)$ is the probability of the target sequence given the input sequence and the task prompt (Figure 3.) By jointly training on multiple error correction datasets with task-guided expert assignment, NEKO learns to capture task-specific features while allowing for knowledge sharing across tasks through the shared gating network and other model components.

3 Experiments

3.1 Training and Evaluation Datasets

ASR To assess the ability to handle diverse and noisy real-world speech, we use the Open ASR Leaderboard (Gandhi et al., 2022; Srivastav et al., 2023) for ASR evaluation, which comprises nine diverse datasets spanning various domains and speaking styles. These include LibriSpeech (Panayotov et al., 2015), Common Voice 9 (Ardila et al., 2020), VoxPopuli (Wang et al., 2021), TED-LIUM (Hernandez et al., 2018), GigaSpeech (Chen et al., 2021), SPGISpeech (O'Neill et al., 2021), Earnings-22 (Del Rio et al., 2022), and AMI (Carletta, 2007; Renals et al., 2007), as one most representative benchmark due to its scale and data diversity. We include the training set of above 8 datasets for NeKo training. We use the word error rate as the evaluation metric for ASR.

ST and MT For the translation error correction task, we use the subset of the HypoTranslate dataset (Hu et al., 2024b) for training and evaluation. This dataset includes translation from FLEURS (Conneau et al., 2022), CoVoST-2 (Wang et al., 2020), and MuST-C (Di Gangi et al., 2019), covering a range of languages such as Spanish, French, Italian, Japanese, Portuguese, Chinese, and Persian.

OCR For the optical character recognition (OCR) error correction task, we use the en-us portion of the OCR dataset (PleIAs, 2023), which contains newspaper texts from Chronicling America.

TEC For the textual error correction (TEC) task, we use a subset of the CoEdIT dataset (Raheja et al., 2023) from Grammarly, which contains 82K task-specific instructions for text editing.

3.2 Task-Specific Recognition Systems and Baselines

ASR We compare against state-of-the-art ASR models, `Whisper-V2-Large` (Radford et al., 2022), `Canary` (NVIDIA, 2024) without applying GEC method. End-to-end ASR-LLM, `SALM` (Chen et al., 2024b), Qwen2-audio, and Gemini-2-Flash have been also compared. For all *Cascaded ASR+GEC Methods*, the task-specific system is the Canary model. This model transcribes the speech data and generate 5-best hypotheses for each utterance using temperature-based sampling (Ackley et al., 1985) with $p = 0.3$. This allows us to capture a diverse set of potential transcriptions for each utterance, which can be fed into our error correction model.

ST and MT For the speech and machine translation tasks, we compare against state-of-the-art models `SeamlessM4T` (Barrault et al., 2023a), `GenTranslate`(Hu et al., 2024c), and cascaded approaches combining ASR and machine translation models (*e.g.*, `Whisper + NLLB` (Costa-jussà et al., 2022)). These baselines cover both end-to-end speech translation models and pipeline approaches. We use SeamlessM4T-Large V2 as the task-specific system to decode N-best hypotheses from input speech by beam search algorithm. We did this in two steps by first transcribing the speech and then translating the text, following (Hu et al., 2024c). LLMs then take the N-best hypotheses to produce a final speech translation result. To investigate the generalization of our model, we also evaluate it in an alternative scenario: a direct speech translation model, Canary, is used as the task-specific system to produce hypotheses.

OCR and TEC We compare our proposed method against two baselines: (1) the input text without any correction (denoted as `Baseline`) and (2) a Mixtral 8x7B model fine-tuned only on the respective dataset for each task (denoted as `Mistral 8x7B Direct Finetune`). This allows us to assess the effectiveness of our task-guided expert assignment approach in handling OCR and TEC errors, as its ability to leverage knowledge from multiple tasks to improve performance on individual tasks compared to direct fine-tuning on a single dataset.

3.3 Post-recognition LLMs Setup

We implement NEKO using the Transformer architecture (Vaswani et al., 2017) and fine-tune both dense and MoE models for comparison. For dense models, we fine-tune Gemma 2B (Team et al., 2024) and Mistral 7B (Jiang et al., 2024b). For MoE models, we fine-tune Gemma 8x2B[1] and Mixtral 8x7B without applying our task-guided expert assignment. We explore the Branch-Train-Mix approach (Sukhbaatar et al., 2024), which involves branching from the Mistral 7B model to an 8x7B MoE model as one competing setup. To investigate the scalability of our method, we design NEKO to three different sizes of MoE models: Gemma 8x2B, Mixtral 8x7B, and Mixtral 8x22B. We further compared low-rank adaptation (`LoRA`(Hu et al., 2021)) with full fine-tuning (`FFT`) on 8x7B MoE setup.

For MoE models, we use top-k routing as proposed in (Lepikhin et al., 2021) to balance the computational cost and model capacity. We use a global batch size of 2 million tokens and apply sample packing (Raffel et al., 2020) to maximize the GPU utilization.

3.4 Post-recognition Correction Results

ASR We first evaluate the zero-shot ability of NEKO on unseen domain compared to two general-purpose LLMs, including GPT-3.5 Turbo and Claude-3.5 Sonnet. With a task-specific recognition baseline of Whisper-V2-Large (third column) in Table 1, NEKO-MoE (*i.e.*, Qwen1.5-MoE or Mixtral) shows the best zero-shot ability with a relative 22.3% average WER reduction. GPT-3.5 Turbo and Claude-3.5 Sonnet have relative 4.3% and 7.3% of zero-shot improvements, where NEKO consistently outperform their 5-shot ASR correction.

Table 2 shows the WER scores on individual datasets and average performance on the Open ASR Leaderboard. We observe that the proposed NEKO improves the task-specific baseline Canary, with an average 5.0% WER reduction. Individually, we observe a significant performance increase with NEKO on more challenging datasets, like AMI

[1]We made an up-cycled (Komatsuzaki et al., 2023) Gemma 8x2B MoE setup extended from single Gemma-2B (Team et al., 2024).

Table 1: Cross-domain ASR correction results in zero-shot and few-shot settings on the Hyporadise benchmark (CHEN et al., 2023). We compare NEKO against GPT-4 Turbo and Claude-3.5 Sonnet in 0- and 5-shot settings. The baseline represents the WER of task-specific model `Whisper-Large`. The oracle results used in CHEN et al. (2023) (N-best and Compositional) provide an upper bound for the correction performance.

Domain Shift	Test Set	Baseline	GPT-3.5 Turbo		Claude-3.5 Sonnet		0-shot w/ NEKO			*Oracle*

(conversational speech) and VoxPopuli (accented speech) due to experts learning dataset-specific features. While, Earnings22 shows a slight performance drop possibly due to the reduced representation in the batch.

Compared to other leading models on the leader-

board, NEKO establishes a new state-of-the-art, outperforming speech-only foundational models like Whisper and Canary and end-to-end ASR-LLM like SALM (Chen et al., 2024b) across most datasets. On the AMI dataset, NEKO achieves a WER of 12.58%, significantly lower than Whisper's 16.82%. On VoxPopuli, NEKO obtains 5.84% WER, a 1.66 point reduction from Whisper's 7.5%. The strong performance of NEKO demonstrates the effectiveness of our speech-adapted MoE approach in handling diverse speech datasets and learning robust representations.

ST and MT Table 3 presents the speech translation results on the FLEURS, CoVoST-2, and MuST-C datasets. For these experiments, we use `SeamlessM4T-Large` as the task-specific model to generate the initial speech translation hypotheses. NEKO is then applied to correct the outputs from `SeamlessM4T-Large`. Compared to the task-specific `SeamlessM4T-Large` model, NEKO achieves significant improvements, with an average BLEU score increase of 5.4 points on the FLEURS dataset, 9.2 points on the CoVoST-2 dataset, and 5.4 points on the MuST-C dataset. These results demonstrate the effectiveness of NEKO in correcting errors made by the first-pass speech translation model. Moreover, NEKO outperforms other correction baselines, including the state-of-the-art `GenTranslate` model.

Table 4: Machine translation BLEU scores on the WMT'20 Japanese (Ja) and Chinese (Zh) test sets (Barrault et al., 2020a). NEKO is evaluated in a zero-shot setting, while other models are fine-tuned on the respective language pairs. Higher BLEU scores indicate better translation quality.

En→X	WMT'20 Ja ↑	WMT'20 Zh ↑	Avg. ↑
ALMA-13b	3.5	11.3	7.4
BigTranslate	7.3	29.0	18.2
NLLB-3.3b	11.6	26.9	19.3
SeamlessM4T-Large	17.0	27.0	22.0
GenTranslate (fine-tuned)	21.4	30.7	26.1
NEKO-Gemma-MoE (zero-shot)	18.1	27.6	22.9

To further assess the generalization ability of NEKO , we evaluate it on the WMT'20 machine translation benchmark for Japanese and Chinese in a zero-shot setting. As shown in Table 4, NEKO achieves competitive performance compared to fine-tuned MT models, obtaining an average BLEU score of 22.9. This result highlights the potential of NEKO to handle unseen translation tasks by leveraging the knowledge learned from pre-training.

OCR and TEC For the OCR task, NEKO achieves a substantial error reduction, lowering the WER from 71.03% to 14.43%. This represents a significant improvement over the baseline and demonstrates the model's ability to correct OCR errors effectively. Compared to the Mixtral-MoE model fine-tuned directly on the OCR dataset, NEKO obtains a 1.02% lower WER, highlighting the benefit of the task-guided expert assignment approach. In the TEC task, NEKO showcases its versatility by improving the performance on both grammar correction and coherence improvement subtasks. For grammar correction, NEKO reduces the WER from 31.41% to 9.42%, outperforming the directly fine-tuned Mixtral-MoE model by 1.31%. On the coherence subtask, NEKO achieves a WER of 9.71%, which is 0.46% higher than the directly fine-tuned model but still a significant improvement over the baseline.

Table 5: WER comparison of NEKO against the baseline and a directly fine-tuned Mixtral-MoE model (8x7B) on grammar correction and coherence improvement tasks from the CoEdIT dataset (Raheja et al., 2023), and the OCR task using the PleIAs/Post-OCR-Correction dataset (PleIAs, 2023).

Task / WER ↓	Grammar Correction	Coherence Improv.	OCR
Mixtral-MoE (frozen)	31.41	13.48	71.03
GPT-3.5-turbo	17.43	12.25	39.45
Mixtral-MoE-FFT	10.73	12.05	45.32
NEKO-Mixtral-MoE	9.42	9.71	14.43

4 Conclusion

In this work, we proposed NEKO, a multi-task GER approach that leverages task-guided MoEs to handle diverse tasks. NEKO assigns each expert to a specific dataset during training, enabling the experts to capture task-specific features while allowing knowledge sharing through the gating network. Our results show that task-guided expert assignment is a promising approach for multi-task learning in error correction and other natural language processing tasks. By aligning experts with datasets, NEKO can effectively capture the nuances and specificities of each task while benefiting from the shared knowledge learned by the gating network and other model components. Future work includes exploring more advanced expert assignment strategies, such as dynamically assigning experts based on the input characteristics.

Ethical Considerations

We aim to provide a transparent and comprehensive understanding of the current scope of NEKO, and pave the way for future research to further improve the NEKO model.

Dataset Diversity and Size and Assumptions in Error Distribution This study addresses a mixture of error correction tasks, including ASR, ST, OCR, and TEC, using representative task-specific datasets such as LibriSpeech for ASR, CoVoST for ST, ICDAR 2019 for OCR, and CoNLL-2014 for TEC. While these datasets are widely recognized benchmarks, they may not cover all possible error correction scenarios, particularly those involving more complex or less common error types found in real-world data. This setup assumes that the error distributions in the training datasets are representative of those in real-world applications. Consequently, the performance of NEKOmight be overestimated for certain types of data not covered by these benchmarks, affecting the generalizability of the results to more diverse and noisy real-world scenarios. Future research should include a broader range of datasets, particularly those with more diverse and challenging error types, and investigate methods to dynamically adapt to varying error distributions, possibly through online learning (Yasunaga et al., 2021) or domain adaptation techniques (Khurana et al., 2021), to better evaluate the robustness and generalizability of the model.

Societal Considerations The study does not extensively address the ethical and societal implications of deploying NEKO in real-world applications. There could be unintended consequences, such as biases in error correction or misuse of the technology in sensitive applications. Future work should include a thorough analysis of the ethical and societal impacts of the model, along with strategies to mitigate potential negative consequences. This could involve incorporating fairness and bias detection mechanisms (Liu et al., 2022) into the model to ensure responsible and ethical deployment.

Boarder Impacts The NEKO model's application of MoE for multi-domain and multi-task error correction has the potential to significantly enhance automated system's performance across various domains, such as healthcare, education and customer service. By improving standard mediums of communication such as speech recognition, translation and optical character recognition NEKO can facilitate more inclusive technologies, benefiting individuals with impairments or non-native speakers. Additionally, the economic benefits from reduced manual correction efforts and educational advantages from more accurate communication system can be substantial. The open-sourcing of NEKO under the CC BY-SA 4.0 license encourages collaboration and reproducibility with in the reserach community, fostering innovation and broader application. Future work should also consider optimizing the training process to minimize the environmental impact, promoting sustainable AI development practices.

A Appendix

Training Details We fine-tune the model for 3 epochs using the AdamW optimizer (Loshchilov and Hutter, 2019) with a learning rate of $1e-4$ and a weight decay of 0.01. We use a cosine learning rate scheduler with a warmup ratio of 0.1 and a gradient clipping threshold of 1.0. For the expert-dataset mapping, we randomly assign each dataset to one of the 8 experts in the Mixtral model. This random assignment serves as a strong baseline and allows us to focus on the effectiveness of the task-guided expert assignment approach. We leave the exploration of more advanced expert assignment strategies for future work. To efficiently train the large-scale model, we leverage DeepSpeed Zero (Rajbhandari et al., 2020) for memory optimization and Hugging Face Transformers (Wolf et al., 2020) for model implementation.

Translation Tasks. As an extra zero-shot textual correction setup, we evaluate NEKO on machine translation (MT) of WMT'20 for Japanese and Chinese (Barrault et al., 2020b). We use the BLEU score (Papineni et al., 2002) as the evaluation metric for ST (with training and test) and MT (zero-shot).

Grammar Correction Tasks. These text error correction (TEC) tasks focus on correcting grammatical errors and improving the overall coherence of the text, making them suitable for evaluating the effectiveness of our model in handling TEC-related editing instructions. We use the word error rate as the evaluation metric.

OCR Tasks. The dataset includes original texts with varying numbers of OCR mistakes and their corresponding corrected versions. To evaluate our model, we take the first 1,000 characters of both the input text with OCR errors and the ground-truth corrected text. We use the WER as the evaluation metric.

Mixture of Experts Background Mixture-of-experts (MoE) (Shazeer et al., 2017) is a machine learning concept that employs multiple expert layers, each of which specializes in solving a specific subtask. The experts then work together to solve the entire task at hand. Recently, MoE has been widely applied to large-scale distributed Deep Learning models by using a cross-GPU layer that exchanges hidden features from different GPUs (Lepikhin et al., 2021; Fedus et al., 2022). The MoE approach is differentiated from existing scale-up approaches for DNNs, such as increasing the depth or width of DNNs, in terms of its high cost-efficiency. Specifically, adding more model parameters (experts) in MoE layers does **not** increase the computational cost per token at inference time. Thus, MoE has been studied for scaling the models to trillion-size parameters in NLP (Fedus et al., 2022).

Prompt Format We provide detailed correction example per [TASK] and actual prompt format of INPUT: used in the our experiments for qualitative studies as shown in Figure 3. For instance, each task will have a specific task-activation prompt format, where ASR, ST, and MT would be based on the sampling or beam search results. On the other hand, OCR and TEC will use input texts for end-to-end mapping.

Figure 3: Example prompts of various correction tasks using Automatic Speech Recognition (ASR), Machine Translation (MT), Speech Translation (ST), Optical Character Recognition (OCR), and Textual Error Correction (TEC).

Correction Examples We randomly select post-recognition example by NEKO . In Figure 4, a long form ASR output has been selected and it remain the top 1-best correction with NEKO. or the ST and MT correction result in Figure 5 and in Figure 6, although the post-NEKO corrected output does not perfectly align with the ground truth, it

boosts the general semantic meaning, as reviewed by native speakers. Meanwhile, the OCR and TEC correction results in Figures 7 and 8 demonstrate various types of corrections, such as pattern-wise character misrecognition and understanding-based coherence improvements.

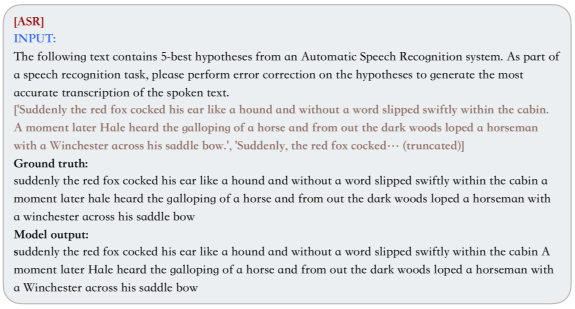

Figure 4: Examples of NEKO outputs for asr error correction task in SPGISpeech (O'Neill et al., 2021).

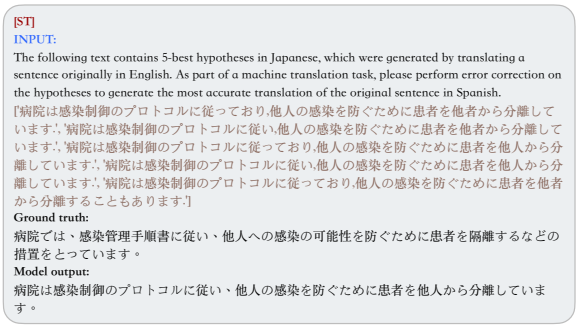

Figure 5: Examples of NEKO outputs for speech translation correction task in FLEURS (Conneau et al., 2022).

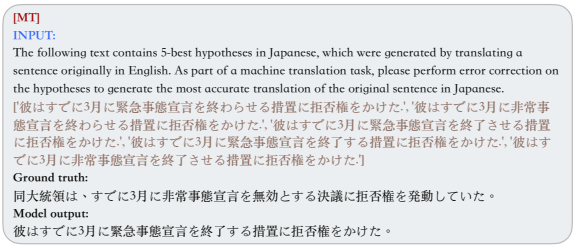

Figure 6: Examples of NEKO outputs for machine translation correction task in WMT20 (Barrault et al., 2020b).

Additional Discussion on Human Recognition from Speech and Text Inputs Human recognition (e.g., speech, optical character, text translation) and has naturally evolved to excel at recognizing and understanding speech in a wide range of real-world scenarios (He et al., 2019; Deng et al., 2013). However, the field of automatic speech recognition (ASR) has traditionally concentrated on training and evaluating models on specific datasets (Chan et al., 2016; Watanabe et al., 2017). These models have shown limited adaptability to new environments (Yang et al., 2021; Du et al., 2016; Hu et al., 2024a), leading to decreased accuracy and practicality in real-world settings. Recognizing the challenges posed by single dataset models and the availability of diverse datasets collected over time, unified models are being developed that merge information from multiple datasets into a single framework (Barrault et al., 2023a). While Grammatical Error Correction (TEC) has been actively explored (Yang et al., 2023), ASR error correction is distinct due to the arbitrariness of spoken language (Aksënova et al., 2021), requiring efforts from both speech, NLP, and cognitive science communities as one human recognition example shown in Figure 9.

task-guided Inference for Mixture of Expert Models During inference, the Neko-model utilizes top-2 expert routing, instead of just top-1. Our pilot studies showed that top-1 routing indeed led to worse performance due to limited knowledge sharing.

Using more than two experts (e.g., top-3 or higher) diverged from the training setup and increased inference costs (ranging from 23.5% to 75.5%) without significant gain (i.e., a relative difference of less than 0.06%).

Future Model Maintenance Plan and ASR Community For ASR tasks, we used Canary-v0, Whisper-seires, and SeamlessM4T to decode textual hypotheses data. For Whisper, we included it as a widely-used baseline, but our key comparisons are to other GEC methods also using Whisper (e.g. GenTranslate). Open eco-system, including ESPnet (Watanabe et al., 2018) and SpeechBrain (Ravanelli et al., 2021) models, are also our interests to be adapted as first-pass ASR in the open code base. This will provide a more comprehensive evaluation across model types. In general, NeKo's post-ASR correction improvements are consistent across datasets and first-pass models, suggesting the benefits generalize beyond model-specific (*i.e.*, Canary, Whisper, or SeamlessM4T) 's strengths as the initial medical term correction results shown in Figure 10.

Emergent Unseen Task Zero-Shot Performance We investigate NEKO's generalization capabilities to unseen tasks using an additional synthetic ty-

pographical error correction dataset (Shah and de Melo, 2020). This dataset is derived from the IMDb test split, featured low noise levels (3.75% character error rate) with corruption applied using algorithms proposed in (Shah and de Melo, 2020). Our evaluation focused on zero-shot and five-shot learning scenarios to assess the adaptability of various models without and with minimal task-specific training. In the zero-shot scenario, where models were prompted to switch from an ASR task to typo correction without additional training, the challenge proved significant. The models, including the advanced Claude-Opus, yielded WERs above 30%. The predictions were markedly irrelevant to the ground truth, highlighting the difficulty of adapting to typo correction without specific fine-tuning. This finding prompts further investigation into efficient and effective training techniques for generalizing model capabilities across diverse linguistic tasks. In the five-shot scenario, all models improved against the corrupted baseline with Claude-Opus performing best. Notably, NEKO outperformed GPT-3.5-Turbo, indicating some affinity towards this task.

Task-Specific Fine-Tuning The NEKO model employs task-guided MoE fine-tuning, where each expert is assigned to a specific dataset. This approach may lead to overfitting to the specific characteristics of the training datasets even though knowledge could be shared. As a result, the model's performance might degrade when applied to new tasks or datasets that were not part of the training set, limiting its adaptability. Investigating more dynamic and adaptive fine-tuning strategies that can generalize better across unseen tasks and datasets would be beneficial. Techniques such as meta-learning or continual learning could be explored to enhance the model's adaptability and robustness.

Future Connections to In-Context and Auto-Agent Learning with NEKO Integrating in-context learning (ICL) with NEKO could enable the model to adapt to various error correction tasks by conditioning on input examples without requiring explicit fine-tuning. This approach is particularly beneficial in scenarios where obtaining large labeled datasets for fine-tuning is impractical. By leveraging ICL, NEKO could adapt to diverse error types and use in-context examples to correct errors specific to new domains or applications, thereby improving its generalizability to real-world data. Furthermore, ICL would allow the model to dynamically adjust its error correction strategies based on the input context, enhancing its robustness to varying error distributions.

Table 6: WER comparison of NEKO against GPT-3.5-Turbo, and Claude-Opus on the 5-shot IMDb typographical error correction dataset (Shah and de Melo, 2020). The baseline represents the WER between the corrupted text and the ground truth. Lower WER indicates better performance in correcting typographical errors.

Model	WER
Baseline (Corrupt vs Ground Truth)	18.35%
GPT-3.5-Turbo (5-shots)	12.72%
Claude-3-Sonnet (5-shots)	12.18%
Claude-3.5 Sonnet (5-shots)	8.18%
NEKO-MoE (5-shots)	11.62%

Abstract

AI agents and business automation tools interacting with external web services require standardized, machine-readable information about their APIs in the form of API specifications. However, the information about APIs available online is often presented as unstructured, free-form HTML documentation, requiring external users to spend significant time manually converting it into a structured format. To address this, we introduce OASBuilder, a novel framework that transforms long and diverse API documentation pages into consistent, machine-readable API specifications. This is achieved through a carefully crafted pipeline that integrates large language models and rule-based algorithms which are guided by domain knowledge of the structure of documentation webpages. Our experiments demonstrate that OASBuilder generalizes well across hundreds of APIs, and produces valid OpenAPI specifications that encapsulate most of the information from the original documentation. OASBuilder has been successfully implemented in an enterprise environment, saving thousands of hours of manual effort and making hundreds of complex enterprise APIs accessible as tools for LLMs.

1 Introduction

AI agents have gained significant popularity in automating tasks across diverse domains, from finance to customer service (George and George, 2023), complementing traditional rule-based business automation systems. Both AI agents and automation systems depend on various external APIs to function effectively. For AI agents, APIs serve as tools to access external resources such as real-time data and integration with external services, while for automation systems, APIs are integral to building automated workflows. However, efficient interaction with these APIs requires that their information be provided in a standardized, machine-readable format. The OpenAPI Specification (OAS)[1] is the leading format for documenting REST APIs (Espinoza-Arias et al., 2020), providing a structured, compact representation compatible with large language model (LLM) frameworks such as LangChain (Chase, 2022).

Unfortunately, many API providers do not provide standardized API specifications. Our analysis of the 14 most popular APIs on Postman for 2023[2] revealed that only five providers publicly share their OAS (see Appendix A.6 for details). Instead, most offer online API documentation presented as HTML webpages with human-readable hypertext describing the API operations. These webpages frequently lack structural consistency and fail to follow standard conventions (Danielsen and Jeffrey, 2013). As a result, developers often need to manually convert documentation into OAS format, a labor-intensive error-prone task, especially for real-world APIs, which are typically large and complex. This challenge has sparked the search for automated solutions to convert API documentation webpages into OAS documents (Cao et al., 2017; Yang et al., 2018; Bahrami and Chen, 2020; Andročec and Tomašić, 2023). However, existing approaches, whether based on automatic parsing or the direct application of LLMs, have consistently struggled to produce accurate and complete OAS documents. These challenges stem from significant variability in API documentation formats, inconsistencies in layout, the presence of embedded JavaScript-generated content, and the considerable length of documentation webpages, often amounting to millions of words.

To address these challenges, we introduce OASBuilder, an innovative LLM-based end-to-end framework for automating the generation of OAS from API documentation webpages. OASBuilder

July 28-30, 2025

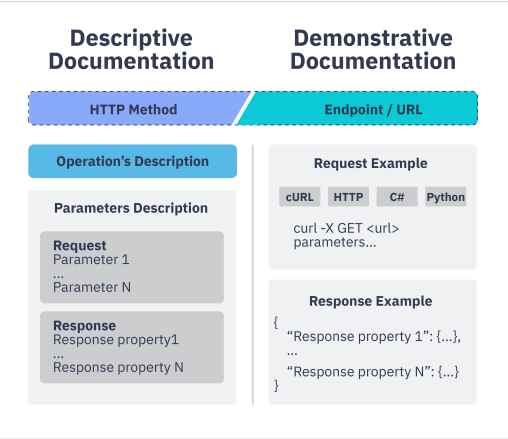

Figure 1: Typical structure of API operation documentation on webpages, featuring the descriptive documentation on the right, the demonstrative documentation on the left, and the operation signature at the top, which can appear on either side. A real-world example from Shopify API can be found in Appendix A.1.

employs a multi-stage approach, breaking the OAS generation process into smaller, manageable subtasks. It scrapes API documentation pages, segments them into sections corresponding to individual API operations, and filters out irrelevant content. Then, the documentation for each API operation (analogous to a function) is then translated into OAS via parallel LLM calls. Finally, OASBuilder provides an intuitive platform for manual validation and editing, supported by evidence from the source webpage and AI-based tools for refining the OAS, ensuring a reliable, high-quality result while significantly reducing manual effort.

To the best of our knowledge, OASBuilder is the *first LLM-based automated system* for generating OAS from API documentation pages. Our empirical experiments highlight its ability to handle diverse API documentation formats, producing accurate and comprehensive OAS documents. Furthermore, OASBuilder has been successfully deployed in an enterprise environment, where it has generated hundreds of API specifications, saving developers thousands of hours of work.[3]

2 OpenAPIs and Documentation Websites

The OpenAPI Specification (OAS) is a standardized framework for formally describing RESTful APIs, specifying their operations (analogous to functions or tools), authentication mechanisms, and other operational details. In enterprise applications, OAS documents are typically extensive, comprising numerous operations and deeply nested request and response objects, and frequently span thousands of lines. A minimal example is presented on the right side of Figure 2.

OAS is especially valuable for AI agents as it offers a concise and standardized representation of each API. This allows LLMs to dynamically understand and interact with multiple APIs—a crucial ability for autonomous agents that must reason about and utilize external services. Moreover, OAS facilitates automation in development processes, such as generating client libraries, server stubs, and documentation, streamlining workflows, reducing manual effort, and minimizing errors.

Despite these benefits, many API service providers only offer online documentation in HTML format, which often lacks consistency in structure or adherence to any standard conventions. Although this documentation does not adhere to any convention which makes automatic parsing infeasible, document pages often contain recurring semantic components which complements each other. As shown in Figure 1, these components generally consist of an **operation signature**, specifying the HTTP method and path (e.g., `GET /status`); **descriptive documentation**, providing a textual overview of the operation's purpose, security details, and a tabular breakdown of request and response fields, including field names, data types, formats, required/optional status, and descriptions; and **demonstrative documentation**, featuring usage examples such as a sample request (e.g., a cURL command) and a sample response (e.g., a JSON object). For a real-world example of such documentation, see Appendix A.1.

Although OASBuilder leverages each of these components to generate a more comprehensive specification, its sole assumption is the presence of an operation signature or a request example to identify the operations, as detailed in Section 3.1.

3 OASBuilder

OASBuilder consists of three main components: (1) an automated method for generating an OAS from a webpage, described in Sections 3.1, 3.2, and 3.3; (2) AI-powered enhancement of the OAS, detailed in Section 3.4; and (3) a user-friendly in-

[3] https://www.ibm.com/docs/en/watsonx/watson-orchestrate/current?topic=skills-using-openapi-builder.

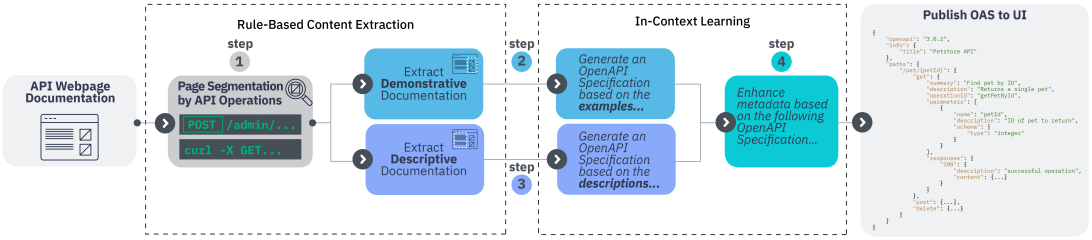

Figure 2: OASBuilder pipeline: The system first segments the webpage based on identified API operations. Then, for each operation, it searches for demonstrative and descriptive documentation. The documentations are then processed by an LLM using in-context learning to generate two partial OAS, which are merged into a complete, grounded OAS. The OAS is subsequently enhanced to fill in missing metadata without external resources. Finally, the OAS is presented to the user for final revisions.

terface for viewing, editing, and validating OAS documents, which also integrates the AI-powered enhancement to further accelerate the final revisions.

Given the potential length of documentation and LLM input limits, the pipeline adopts a modular approach. The generation task is divided into smaller sub-tasks, whose outputs are then combined to create a cohesive result.

Throughout the pipeline, LLM generation was based on in-context learning, as fine-tuning was not feasible due to the lack of labeled data. It is assumed that the LLM was exposed to OAS during its pretraining. Figure 2 illustrates the pipeline.

3.1 Scraping

The first step is scraping the API documentation webpage, with the goal of segmenting it into continuous sections, each linked to a specific operation through the identification of operation signatures and usage examples. The application begins by launching a web browser and navigating to the specified URL. To achieve this, it utilizes Selenium,[4] a tool that provides capabilities for controlling a web browser, enabling us to interact with and query the webpage HTML elements. Since many pages load part of their content dynamically through user interactions, the system uses a small set of rules to detect and click on elements like "expand all" or "example". After the content is loaded, OASBuilder identifies operation signatures and API request examples. Specifically, it searches for HTML elements whose text includes cURL commands, HTTP commands, or patterns resembling operation signatures, such as `<HTTP_METHOD ENDPOINT>`. OASBuilder assumes that all instances of a specific operation appear sequentially on the page. Hence, it defines the boundaries of each operation as the section spanning from the first title preceding its initial instance to the first title marking the start of the next operation.

3.2 Demonstrative OAS Generation

After segmenting the webpage into operations, as outlined in Section 3.1, the next step (step 2 in Figure 2) involves extracting demonstrative examples and generating an OAS from them. Since the system has already extracted request examples in the previous stage, it only needs to identify the corresponding request bodies and response examples within the operation boundaries, if available.

After extracting demonstrative examples, the system converts them into OAS format by decomposing the process into multiple parallel LLM calls. We favor LLMs over complex rule-based parsing, as the latter is prone to errors arising from human mistakes in example creation and noise introduced during automated scraping. This multi-stage approach addresses input length limitations while enabling efficient parallel generation. First, OASBuilder generates a partial OAS for each request example, excluding the request body. To do so, each example is standardized into a canonical cURL command to minimize variations. Parallel LLM calls are then employed, each using two diverse in-context examples drawn from real-world scenarios to convert the standardized commands into partial OAS documents. These include essential metadata such as servers, paths, HTTP methods, and request parameters. Second, the system generates JSON schemas for both request bodies and

[4] https://www.selenium.dev/

response examples. Due to the difficulty LLMs face in processing large, deeply nested JSON structures—a well-documented issue (Shorten et al., 2024)—OASBuilder divides these structures into smaller fragments based on a predefined line threshold, preserving scope boundaries. Parallel LLM calls are then applied to each fragment, using two in-context examples per call, to generate the corresponding JSON schemas. Prompt examples are provided in Appendix A.3.

3.3 Descriptive OAS Generation

In parallel with generating an OAS from the demonstrative examples discussed in Section 3.2, OASBuilder also generates a second OAS based on the descriptive documentation (see Section 3.2 for more details). This stage is labeled as step 3 in Figure 2.

Parsing these documentations using deterministic rule-based algorithms is impractical due to the significant variations in HTML structures across websites (Yang et al., 2018). Therefore, leveraging the capabilities of contemporary LLMs offers a more viable solution, as they can generalize over such structural differences effectively.

Therefore, OASBuilder first applies a search algorithm to extract the descriptive documentation from the operation's scope identified in the scraping stage. The algorithm employs various heuristics to identify and filter the appropriate HTML elements, leveraging prior knowledge of the high-level structure of these webpages. For instance, for a webpage containing a single operation, it identifies the smallest HTML scope that includes both an operation signature or a request example, while maximizing the number of HTML elements that their text is equal to a parameter name from the example. Additionally, usage examples and any HTML elements lacking indicators of relevant information are excluded. For more details, see Appendix A.2 and algorithm 1.

After narrowing the scope to a relatively small number of HTML elements, the LLM input is further reduced by filtering out the HTML attributes (e.g., css styles) as they often do not contain any relevant information. An LLM is then employed using in-context learning to convert the extracted HTML into an OAS. We found that LLMs often require exposure to various structures in the examples to correctly apply them in the test case. For example, the model would fail to generate a requestBody component or an enum attribute if they were not provided in the input example. Therefore, the in-context example was carefully crafted using data from multiple real-world APIs with diverse structures and attributes. In the case of context window overflow, it retries with an alternative shorter in-context example. A prompt example is provided in Appendix A.3. After generating the OAS, the system validates its structure and verify that all the generated parameter names appear in the input to prevent hallucinations.

Lastly, the generated OAS is merged with the one created in Section 3.2 to yield a final comprehensive OAS. In this integration, the description and required attributes from the descriptive documentation are prioritized, while the type and location fields from the demonstrative documentation take precedence. This prioritization is determined based on the reliability of the attribute in each type of documentation.

3.4 OAS Enhancement

After generating an OAS from the documentation, OASBuilder enriches missing metadata using AI-based tools based on information within the OAS (step 4 in Figure 2). These tools perform two key functions: (1) extracting parameter metadata from grounded parameter descriptions and (2) generating missing metadata based on its surrounding context. This enriched metadata, including descriptions, enums, and defaults, is essential for accurately documenting API behavior and supports various downstream tasks, such as conversational agents, slot filling (Vaziri et al., 2017), test generation (Kim et al., 2022), and API sequencing.

Metadata extraction from parameter descriptions: Parameter descriptions often include metadata like enum, default, and format, which can be explicitly defined in the OAS. LLMs are well-suited for extracting this metadata. To improve extraction, we designed prompts using in-context examples that handle both explicit (e.g., "the default value is 10") and implicit metadata (e.g., "the option is disabled by default"). To avoid hallucinations, the extracted values are verified to match the descriptions. To minimize LLM calls, OASBuilder used two strategies: First, a keyword-based filtering mechanism that triggers LLM calls only when relevant terms like "default" or "not provided" are present, saving over 90% of calls for many metadata fields. Second, the prompts were designed to process multiple descriptions at once, further

reducing LLM calls.

Metadata Generation Using OAS Structure: OASBuilder addresses missing method and parameter descriptions, as well as parameter examples, in an OAS by utilizing LLM-based prompts to generate the missing metadata. Relevant context from the OAS is extracted and provided as input to these prompts. For example, the context for generating parameter descriptions and examples are the parameter name, the method name and description and the parameter description for the example generation. For method descriptions, it incorporates the method name, endpoint path, and operation ID. Examples of the generated metadata is provided in Appendix A.5.

4 Experiments

This section presents the results of a series of experiments conducted to evaluate the performance of OASBuilder. We utilized several well-known open-source LLMs with in-context prompting capabilities, including llama-3-70b-instruct (Touvron et al., 2023), codellama-34b-instruct (Rozière et al., 2024), mistral-7b-instruct (Jiang et al., 2023), mixtral-8x7b-instruct (Jiang et al., 2024), and granite-20b-code-instruct (Mishra et al., 2024). The prompts were not fine-tuned for any specific model. Baselines were not included, as previous studies neither evaluated on a public benchmark nor provided their code or reproduction details.

4.1 Syntactic Evaluation

In this section, we analyze the syntactic properties of OAS documents generated by OASBuilder using various LLMs on a corpus of 50 diverse documentation webpages covering 189 operations (see Appendix A.4 for details).

The evaluation focuses on three metrics: (1) the proportion of outputs that are valid JSONs; (2) the proportion that qualify as valid OAS documents; and (3) the average number of errors in valid JSONs. While the latter two metrics are related—errors occur only in invalid OAS documents—quantifying the errors provides insight into the degree of syntactic deviation, helping to estimate the effort required for correction. We computed the two metrics with jsonschema library.[5]

Table 1 presents the results of the syntactic analysis. Notably, granite-code and codellama emerge as the top-performing models. This likely reflects the prevalence of JSON-related tasks in code-oriented benchmarks. While codellama achieved the highest proportion of valid OAS, its error rate ranked third among the models. In contrast, granite-code produced the second-highest rate of valid OAS while exhibiting the lowest error incidence. The remaining models generally succeeded in generating valid JSON but showed considerably lower and more variable rates of valid OAS generation. These findings suggest that, even when decomposed into subtasks, OAS generation remains a nontrivial challenge for LLMs.

	VALID JSON	VALID OAS	ERRORS
CODELLAMA	.99	**.89**	.59
GRANITE-CODE	**1**	.73	**.48**
LLAMA-3	**1**	.29	.78
MISTRAL	**1**	.4	.54
MIXTRAL	.92	.66	.64

Table 1: Syntactic evaluation results for OAS generation by different LLMs on 50 web pages covering 189 operations. Metrics include the ratios of valid JSONs and OAS documents and the average errors in valid JSONs.

To evaluate scalability, we collected a larger dataset of 291 API documentation URLs and repeated the experiment using the granite-code model. Results showed that 100% of the outputs were valid JSON, 89% were valid OAS, and the average number of errors per OAS was 0.17. Furthermore, 86% of the OAS documents contained at least one operation and one parameter.

Lastly, we attempted to generate OAS documents using GPT-4-128K (OpenAI et al., 2024) directly from the original HTML, without using OASBuilder. We found that the model was able to generate a valid OAS only for 25% of the webpages. This outcome is not unexpected, as many of these webpages contain much more than 128K tokens, the model's context window limit.

4.2 Semantic Evaluation

In this section, we assess the overall capabilities of OASBuilder to generate rich and complete OAS given various API documentation webpages. To that end, we employed a manually labeled dataset comprising of 108 operations containing thousands of parameters and properties from different API documentation websites. We conducted experiments to compare the enhanced OAS documents generated by OASBuilder with the ground truth

[5] https://github.com/python-jsonschema/jsonschema

	Request							Response			
Model	P	R	F1	Desc.	Req.	Def.	Enum	P	R	F1	Desc.
CodeLlama	.95	.85	.90	.89	**.88**	.88	.69	.93	.56	.70	.68
Granite-code	**.96**	**.86**	**.91**	.90	**.88**	.84	.76	.92	.54	.68	.79
Llama-3	**.96**	.78	.86	**.91**	.87	.92	**.81**	**.97**	**.62**	**.75**	.72
Mistral	.94	.67	.78	.75	.85	.56	.50	.90	.57	.69	.64
Mixtral	.95	.55	.70	.87	.80	**.93**	.62	.90	.52	.65	**.84**

Table 2: End-to-end results of OASBuilder for different LLMs on 108 different operations containing thousands of parameters and properties. We report the precision (P), recall (R), F1-score (F1) of the parameters, and the cosine similarity of the descriptions, as well as the F1-score of required (Req.), default (Def.) and enum attributes. All results are averaged across all parameters and were based on the valid OASs for each model.

OAS, using different LLMs. In all experiments we used the in-context learning approach with the same prompt and in-context examples across models.

Table 2 presents the end-to-end results. First, the parameter precision for all models was relatively high, suggesting that hallucinations were uncommon. The recall for request parameters was also high, particularly for granite-code and codellama, with values of 0.86 and 0.85, respectively. Additionally, the description similarity and the F1 scores for the required, default, and enum attributes were relatively high. These findings indicate that, although the generated OAS documents are not perfect, they capture most of the relevant information on the request side, significantly reducing the user's manual annotation effort. Since many request parameters and their attributes such as default, enum, and description are found exclusively in the descriptive documentation, we can conclude that the information from the descriptive documentation were successfully integrated in the final OAS.

Lastly, the recall for response generation was lower, likely due to the highly nested and lengthy structure of many responses, as well as the frequent lack of descriptive documentation for response properties. Overall, the LLMs demonstrated competitive performance, with no single model showing clear dominance, though mistral and mixtral performed slightly below the others.

5 Related work

Varied methods have been adopted to generate OAS documents for Rest APIs. SpyREST (Sohan et al., 2015) employs an HTTP proxy server to intercept HTTP traffic to generate API documentation. Respector (Huang et al., 2024) employs static and symbolic program analysis to automatically generate OAS for REST APIs from their source code.

Similar to our approach, several studies have investigated converting parts of API documentation webpages into OAS. AutoREST (Cao et al., 2017) and captures part of the information presented in API documentation webpages and converts it into an OAS by a set of fixed rules. D2Spec (Yang et al., 2018) aims to extract base URLs, path templates, and HTTP method types, using rule-based web crawling techniques and classic machine learning to identify potential API call patterns in URLs. Bahrami and Chen (2020); Bahrami et al. (2020) combines rule-based and machine-learning algorithms to generate OAS from API documentation. They also develop a deep model to pinpoint fine-grained mapping of extracted API attributes to OAS objects. Most similar to our work, Andročec and Tomašić (2023) used GPT-3 to automatically generate OAS from a preprocessed HTML file describing an API documentation. OASBuilder distinguishes itself from their methodology by (1) dividing the generation task into multiple parts, and (2) extracting relevant information from webpages, thus accommodating long webpages that exceeds the context size of LLMs while breaking the task into more manageable subtasks for LLMs..

6 Conclusions

This paper presents OASBuilder, a novel multi-stage system designed to automatically generate and enhance OAS from online API documentation. By integrating rule-based algorithms with generative LLMs, OASBuilder addresses existing limitations in previous solutions. Our experiments demonstrate that OASBuilder is robust and capable of generalizing across hundreds of API documentation websites. Furthermore, a detailed evaluation reveals that the generated OAS captures most of the

information from the documentation, significantly reducing the manual effort required of technical experts. The AI-based enhancement tools, combined with the UI platform, offer developers an end-to-end process yielding in a high-quality final result.

A Appendix

A.1 Example of an API documentation webpage

Figure 3 shows an example of a real-world API documentation webpage taken from Shopify API website.[6]

A.2 Descriptive Documentation Retrieval Algorithm

To find the descriptive documentation, we looked for an HTML scope in the webpage which encompasses this information, we call this scope "minimal ancestor". To that end, we employed two distinct approaches. In scenarios where a webpage incorporates multiple API calls, we defined the scope as the highest ancestor of the request example HTML element that does not encompass other requests [7]. In Figure 1, this scope should encompass both reference-based and example-style sections. Conversely, when dealing with a webpage containing a single API call, we conducted a search for *leaf elements*.[8] likely associated with parameters in the reference-based documentation based on their text, such as parameters from the request or response, and parameter header templates. These elements could be situated, for instance, in the "Parameters Description" section as illustrated in Figure 1. Subsequently, we iterated through the ancestors of each identified element, starting from the immediate parent and moving upwards, in search of the first ancestor containing a matching URL endpoint corresponding to the provided API URL. Since this is often found preceding the HTTP method (e.g. "GET /info/id"), we denote it as "HTTP Method" and "Endpoint/URL" in Figure 1.

After retrieving these minimal ancestors, we rank them according to two criteria: 1) the number of parameters from the request or response found as leaf elements in the ancestor, and 2) whether the HTTP method type of the URL was found as a leaf element. Following this ranking, we filter out HTML elements that are ancestors of other candidates. Lastly, if we still have multiple candidates sharing the same rank, we randomly sample one of them, although we did not encounter such cases in our experiments.

The minimal ancestor is then preprocessed to remove noise and tailor it to the constrained context size of the LLM. This involves filtering out its children that are less likely to contain relevant information for augmenting the base OAS. Specifically, we search for parameter names extracted from the API request/response example and syntactic hints such as the structure of an HTML parameters table. Additionally, we exclude the request and response examples at this stage, as they have already been utilized in generating the base OAS. Finally, all HTML attributes are removed, as they are deemed less likely to contain relevant information.

For a formalized presentation of the flow, see Algorithm 1

A.3 Prompt Generation Examples

In order to generate the OAS, we applied in-context learning where the inputs are preprocessed content found in the API documentation webpage, and the outputs are components from the OAS or partial OAS containing the input data. The in-context examples were chosen from real-world APIs (e.g., github API) while we tried to balance between the length and the diversity of the examples. In Figures 6, 4, 5 we provide examples of the prompts we used for this purpose. Due to space limitations, we have not included all the in-context examples, but we would be happy to share them upon request.

[6] https://shopify.dev/docs/api/admin-rest/2024-10/resources/inventorylevel

[7] If the minimal ancestor of the subsequent request is not consecutive, it is defined as a sequence of elements ending in the ancestor of the next request

[8] HTML elements lacking children

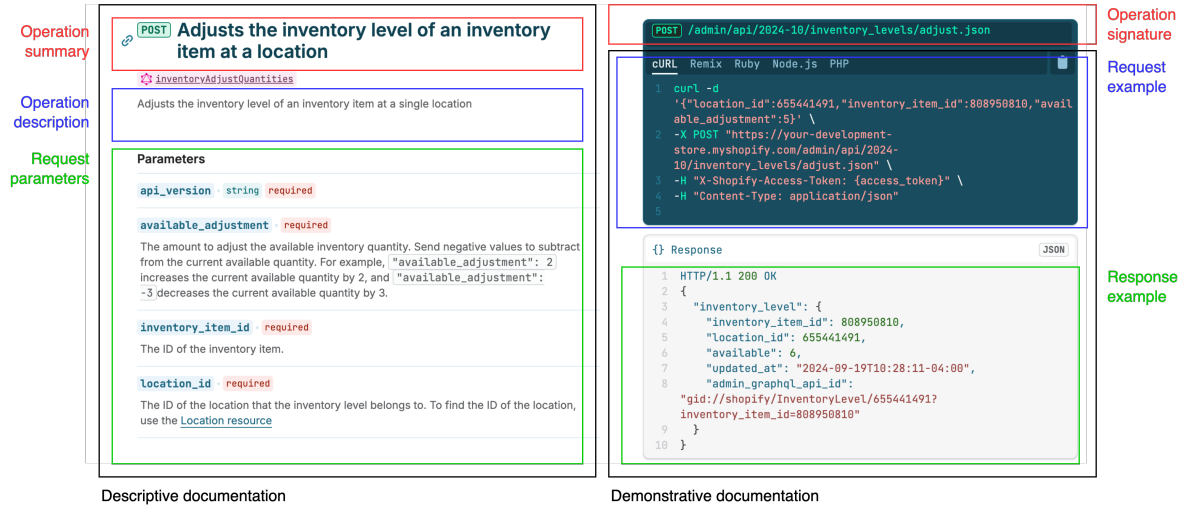

Figure 3: Example of an API documentation webpage taken from Shopify API in 25.11.2024 (taken from https://shopify.dev/docs/api/in-rest/2024-10/resources/inventorylevel.

Algorithm 1 Generate Descriptive Documentation

Input: Example of API Request, and API HTML Documentation
Output: HTML Element for Enrichment

function FINDMINIMALHTMLELEMENT(API_Spec, API_Doc, M)
1. Extract parameter names from given API request.
2. Find elements in documentation that their texts match a parameter name or a parameter header.
3. For each candidate find first HTML elements which meets one of the following criteria:
a. Contains an endpoint HTML element matching the API URL from the request.
b. Contains multiple HTML elements of the same parameter name from the API specification.
iv. Select the HTML element from the candidates by ranking according to the following criteria by the following order:
1. Number of parameter names from the API specification found in its context by exact matching*.
2. Whether an endpoint matching the URL was found.
3. Whether the extracted HTTP method type was found by exact matching.
4. Whether they contain a "table" HTML element.
5. Minimality of scope (i.e. filtering out parents of candidates).
Preprocessing the minimal HTML element:
i. Iterate over the minimal HTML element children and filter according to the following criteria:
1. Whether the child is a "table" HTML element.
2. Whether the child is preceded by a parameter header HTML element.
3. Whether the child contains any extract parameter name by exact matching.
4. Whether the child contains the phrases "required" or "optional" by exact matching.
ii. Remove all the attributes of the HTML elements.
Generate Structured data from minimal HTML element:
i. Apply M to generate a description of the API and a table where each row represents relevant metadata about a parameter found in the minimal HTML element's content. This can be achieved by techniques such as In-Context Learning, or by training a language model on a manually-labeled dataset.
Integrate Generated Data into API Specification.
end function

Prompt instructions

```
Write an OpenAPI JSON specification for the following REST GET API. JSON object keys must be string literals.
```

In context example

Input:

```
curl -X GET \'https://api-m.sandbox.paypal.com/v1/payment-experience/web-profiles/XP-RFV4-PVD8-AGHJ-8E5J?
organization_id=10234695\' -H \'x-amz-data-partition: DirectoryArn\'
```

Output:

```
{ "openapi": "3.0.0", "info": { "title": "PayPal Web Profiles API", "version": "1.0.0", "description": "API for
managing web profiles in PayPal" }, "servers": [ { "url": "https://api-m.sandbox.paypal.com" } ], "paths": {
"/v1/payment-experience/web-profiles/{profileId}": { "get": { "summary": "Retrieve a web profile by ID",
"operationId": "get_web_profile_by_id", "tags": [ "Web Profiles" ], "parameters": [ { "name": "profileId",
"in": "path", "required": true, "schema": { "type": "string", "example": "XP-RFV4-PVD8-AGHJ-8E5J" },
"description": "The ID of the profile for which to show details." }, { "name": "organization_id", "in":
"query", "required": false, "schema": { "type": "integer", "example": "10234695" }, "description":
"Organization id" }, { "name": "x-amz-data-partition", "in": "header", "required": true, "schema": { "type":
"string", "example": "DirectoryArn" }, "description": "The Amazon Resource Name (ARN) that is associated with
the Directory where the object resides." } ], "responses": { "200":{ "description": "successful operation" } }
} } } }
```

Test example

Input:

```
curl -X GET \'https://your-development-store.myshopify.com/admin/api/2024-04/inventory_levels.json?
location_ids=655441491\' -H \'X-Shopify-Access-Token: {access_token}\'
```

Output (generated):

```
{ "openapi": "3.0.0", "info": { "title": "Shopify Inventory Levels API", "version": "2024-04" }, "servers": [ {
"url": "https://your-development-store.myshopify.com" } ], "paths": { "/admin/api/2024-
04/inventory_levels.json": { "get": { "summary": "Retrieve inventory levels for a specific location",
"operationId": "get_inventory_levels_by_location", "tags": [ "Inventory Levels" ], "parameters": [ { "name":
"location_ids", "in": "query", "required": true, "schema": { "type": "integer", "example": 655441491 },
"description": "IDs of the locations to retrieve inventory levels for" }, { "name": "X-Shopify-Access-Token",
"in": "header", "required": true, "schema": { "type": "string" }, "description": "X Shopify access token" } ],
"responses": { "200":{ "description": "successful operation" } } } } }
```

Figure 4: Example prompt for generating an OAS from a cURL command. The prompt includes two in-context examples (only one is shown here for brevity). Information from the cURL command is extracted to create an OAS featuring a single operation, complete with a `title`, `version`, `servers`, `paths`, `operationId`, `tags`, and detailed `parameters`, including their `types`, `descriptions`, and `examples`.

Prompt instructions

```
Write a JSON schema for the following object. JSON object keys must be string literals. Make sure that all $ref
are defined under components/schemas. Use true, false as JSON booleans. Do not generate enums.
```

In context example

Input:

```
{ "firstName": "John", "lastName": "Doe", "age": 21, "tags": [], "assigned_to_user": null, "site_admin": false}
```

Output:

```
{ "type": "object", "properties": { "firstName": { "type": "string", "description": "The person\'s first
name.", "example": "John" }, "lastName": { "type": "string", "description": "The person\'s last name.",
"example": "Doe" }, "age": { "type": "integer", "description": "Age in years which must be equal to or greater
than zero.", "example": 21 }, "tags": { "type": "array", "description": "The tags associated with the person",
"items": { "type": "string" } }, "assigned_to_user": { "type": "object", "description": "User assigned to the
person" }, "site_admin": { "type": "boolean", "description": "Indicates whether this user is a site admin",
"example": false } }}
```

Test example

Input:

```
{ "inventory_levels": [ { "inventory_item_id": 49148385, "location_id": 655441491, "available": 2,
"updated_at": "2024-09-19T10:10:57-04:00", "admin_graphql_api_id": "gid://shopify/InventoryLevel/655441491?
inventory_item_id=49148385" } ]}
```

Output (generated):

```
{ "type": "object", "properties": { "inventory_levels": { "type": "array", "items": { "type": "object",
"properties": { "inventory_item_id": { "type": "integer", "example": 49148385, "description": "The inventory
item id" }, "location_id": { "type": "integer", "example": 655441491, "description": "The location id" },
"available": { "type": "integer", "example": 2, "description": "The available quantity" }, "updated_at": {
"type": "string", "example": "2024-09-19T10:10:57-04:00", "description": "The updated at date" },
"admin_graphql_api_id": { "type": "string", "example": "gid://shopify/InventoryLevel/655441491?
inventory_item_id=49148385", "description": "The admin graphql api id" } } } } }}
```

Figure 5: Prompt example to generate a JSON schema from a given JSON object or array. This prompt is used to generate both the `requestBody` and the `responses` which are later set in the corresponding OAS.

Prompt instructions

```
The following text contains HTML content that described a table of API parameters and request body properties. Each entry includes attributes such as name, type (string, int, etc.), required or optional status, and metadata (e.g., enum, default, max, format). Additionally, parameters have a location (path, header, query, cookie). Your task is to: 1. Parse the HTML to identify all request parameters and request body properties. 2. Extract all relevant information about each parameter and property. Extract metadata also from the descriptions. 3. Output an OAS document containing all the extracted information. Note: 1. Exclude parameters from the response. 2. Do not generate a components section in the OAS document. 3. Metadata can be found both inside and outside the descriptions. Here is an input-output example pair:
```

In context example

Input:

```
<div><h3><a>Parameters for "List issue comments for a repository"</a></h3><table><caption>Headers</caption><thead><tr><th>Name, Type, Description</th></tr></thead><tbody><tr><td><div><div><code>accept</code> <span>string</span> </div><div><div><p>Setting to <code>application/vnd.github+json</code> is recommended.</p></div><div></div></div></div></td></tr></tbody></table><table><caption>Path parameters</caption><thead><tr><th>Name, Type, Description</th></tr></thead><tbody><tr><td><div><div><code>owner</code> <span>string</span> <span>Required</span></div><div><div><p>The account owner of the repository. The name is not case sensitive.</p></div><div></div></div></div></td></tr>...</code></div></div></div>
```

Output:

```
{"openapi": "3.0.0", "info": {"title": "", "version": "1.0.0"}, "paths": {"/repos/{owner}/issues/comments": {"post": {"responses": {"200": {"description": "Success"}}, "parameters": [{"name": "owner", "description": "The account owner of the repository. The name is not case sensitive.", "in": "path", "required": true, "schema": {"type": "string"}}, ...]}}}
```

Test example

Input:

```
<div><div><div>
<div><div><h2><div><div><span>get</span></div><div><span>Retrieves a list of inventory levels</span></div></div></h2></div></div>
<div><div><a><span></span><span>inventoryItem</span></a></div></div>
<div><div><p>Retrieves a list of inventory levels.</p>
<p>You must include <code>inventory_item_ids</code>, <code>location_ids</code>, or both as filter parameters.</p><p><strong>Note:</strong> This endpoint implements pagination by using links that are provided in the response header. To learn more, refer to <a>Make paginated requests to the REST Admin API</a>.</p></div></div>
<div><div><h3><span>Parameters</span></h3></div></div>
<div><div><div><div>api_version</div><span></span><div><span>string</span></div><div><span>required</span></div></div></div><hr/></div>
<div><div><div><div>inventory_item_ids</div><span></span><div><span>≤ 50</span></div></div><div><div>A comma-separated list of inventory item IDs. To find the ID of an inventory item, use the <a>Inventory Item resource</a></div></div></div><hr/></div>
<div><div><div><div>limit</div><span></span><div><span>≤ 250</span></div><div><span>default 50</span></div></div><div><div>The maximum number of results to show.</div></div></div><hr/></div>
<div><div><div><div>location_ids</div><span></span><div><span>≤ 50</span></div></div><div><div>A comma-separated list of location IDs. To find the ID of a location, use the <a>Location resource</a></div></div></div><hr/></div>
<div><div><div><div>updated_at_min</div></div><div><div>Show inventory levels updated at or after date (format: 2019-03-19T01:21:44-04:00).</div></div></div><hr/></div>
...
</div></div></div>
```

Output (generated):

```
{ "openapi": "3.0.0", "info": { "title": "", "version": "1.0.0" }, "paths": { "/admin/api/2024-04/inventory_levels.json": { "get": { "responses": { "200": { "description": "Success" } }, "parameters": [ { "name": "api_version", "in": "query", "required": true, "schema": { "type": "string" } }, { "name": "inventory_item_ids", "description": "A comma-separated list of inventory item IDs. To find the ID of an inventory item, use the Inventory Item resource", "in": "query", "required": false, "schema": { "type": "string", "maxLength": 50 } }, { "name": "limit", "description": "The maximum number of results to show.", "in": "query", "required": false, "schema": { "default": 50, "maximum": 250, "type": "integer" } }, { "name": "location_ids", "description": "A comma-separated list of location IDs. To find the ID of a location, use the Location resource", "in": "query", "required": false, "schema": { "type": "string", "maxLength": 50 } }, { "name": "updated_at_min", "description": "Show inventory levels updated at or after date (format: 2019-03-19T01:21:44-04:00).", "in": "query", "required": false, "schema": { "type": "string", "format": "date-time" } } ] } } }}
```

Figure 6: An example of a prompt used for generating an OAS based on the descriptive documentation found in the API documentation webpage. The model extract the relevant information from the HTML elements, and sets the fields' `description`, `type`, `required`, `enum`, and `format` metadata properties.

A.5 Examples of Generated Descriptions and Examples

Figure 7 and Figure 8 are respectively examples of generated descriptions and examples from the enhancements described in Section 3.4.

```
{
    "200": {
        "content": {
            "application/json": {
                "schema": {
                    "properties": {
                        "dateLastActivity": {
                            "type": "string",
                            "description": "The date the activity was last updated."
                        },
                        "dateLastView": {
                            "type": "string",
                            "description": "The last time the user viewed the board."
                        },
                        "idTags": {
                            "type": "string",
                            "description": "A comma-separated list of tag IDs. Only actions within
                            ↪  these tags will be returned."
                        }
                    }
                }
            }
        }
    }
}
```

Figure 7: Example of enhancement for generating descriptions. Added lines are highlighted in green. Original documentation page for OAS is https://developer.atlassian.com/cloud/trello/rest/api-group-actions/#api-actions-idaction-reactions-post.

A.6 Most Popular URLs by Postman

To further establish the claim that most real-world APIs do not publish API specification. We manually checked whether the most popular APIs according to Postman[9] published an API specification in their API documentation webpages. We found that only five out of the fourteen contained OAS. The full findings are detailed in Table 3

[9] https://www.postman.com

```
{
    "parameters": [
        {
            "name": "owner",
            "in": "path",
            "required": true,
            "schema": {
                "type": "string",
                "example": "octocat",
                "x-ibm-examples": [
                    "hubot",
                    "other_user"
                ]
            },
            "description": "The account owner of the repository. The name is not case sensitive.",
            "x-ibm-grounded-description": true
        },
        {
            "name": "repo",
            "in": "path",
            "required": true,
            "schema": {
                "type": "string",
                "example": "octocat/Hello-World",
                "x-ibm-examples": [
                    "octocat/Spoon-Knife",
                    "octocat/hello-world"
                ]
            },
            "description": "The name of the repository without the \".git\" extension. The name is
            ↪  not case sensitive.",
            "x-ibm-grounded-description": true
        }
    ]
}
```

Figure 8: Example of enhancement for generating examples. Added lines are highlighted in green. Original documentation page for OAS is https://docs.github.com/en/rest/issues/comments?apiVersion=2022-11-28#create-an-issue-comment.

Site	API Documentation URL	Contains OAS

Abstract

With the rapid expansion of e-commerce and continuous urban evolution, *Geospatial Repartition*, dividing geographical regions into delivery zones, is essential to optimize various objectives, e.g., on-time delivery rate, for last-mile delivery. Recently, large language models (LLMs) have offered promising capabilities for integrating diverse contextual information that is beneficial for geospatial repartition. However, given the inherent uncertainty in LLMs, adapting them to practical usage in real-world repartition is nontrivial. Thus, we introduce CoAlign, a novel three-stage framework that calibrates LLM uncertainty to enable robust geospatial repartition by transforming the task into a ranking problem, integrating historical data with LLM-generated candidates. It first generates explainable candidate partitions with a multi-criteria strategy and then designs a novel conformal method to rank these candidates relative to historical partitions with coverage guarantees. Finally, CoAlign delivers candidates through an interactive decision support system. Extensive evaluation with real-world data shows that CoAlign effectively calibrates LLM uncertainty and generates partitions that better align with human feedback. Moreover, we have deployed CoAlign in one of the world's largest logistics companies, significantly enhancing their delivery operations by increasing candidate acceptance rates by 217% and improving on-time delivery rates by 3%. Our work provides a novel angle to address industrial geospatial decision-making tasks by calibrating LLM uncertainty.

1 Introduction

Geospatial Repartition refers to dynamically adjusting geographical regions into multiple delivery zones, supporting fundamental businesses, e.g., balanced order assignments, for logistics companies, e.g., Amazon (Amazon), SF Express (S.F. Express) and JD Logistics (JDL.COM). With rapid global e-commerce expansion, effective geospatial repartition is critical for ensuring online operational efficiency in logistics systems (Hong et al., 2022). Existing methods typically rely on manual adjustments by experts or algorithmic optimization using limited offline operational metrics, such as historical data, to balance order volumes or equalize working times (Guo et al., 2023; Zhang et al., 2024). In state-of-the-practice, algorithms generate multiple repartition candidates according to various offline metrics and recommend them to experts, who then decide to accept one candidate or manually devise an alternative. This operational paradigm has two major limitations: (i) Real-world operational constraints are significantly more complex and dynamic than offline metrics can capture, resulting in theoretically optimal partitions that are often infeasible for practical deployment (Figure 1 provides an illustrative example), leading to low acceptance rates in practice; (ii) Experts spend considerable time reviewing candidates to identify issues. Upon discovering problems, they must manually repartition, often leaving their valuable feedback unused. Our logistics partner reports candidate acceptance rates often below 10%, with experts spending over 15 hours monthly on reviews and manual repartition.

Facing these limitations, we identify an opportunity in the extensive contextual information—such as historical partitions and corresponding expert and worker feedback—accumulated by existing operational systems, reflecting real-world constraints. Recent advances have demonstrated the remarkable capability of large language models (LLMs) in extracting information, understanding context, and learning from interactive dialogues (Zhao et al., 2023; Manvi et al., 2024; Feng et al., 2024; Yamada et al., 2024). Thus, we aim to propose an interactive LLM approach capable of interpreting contextual information and interactively generating

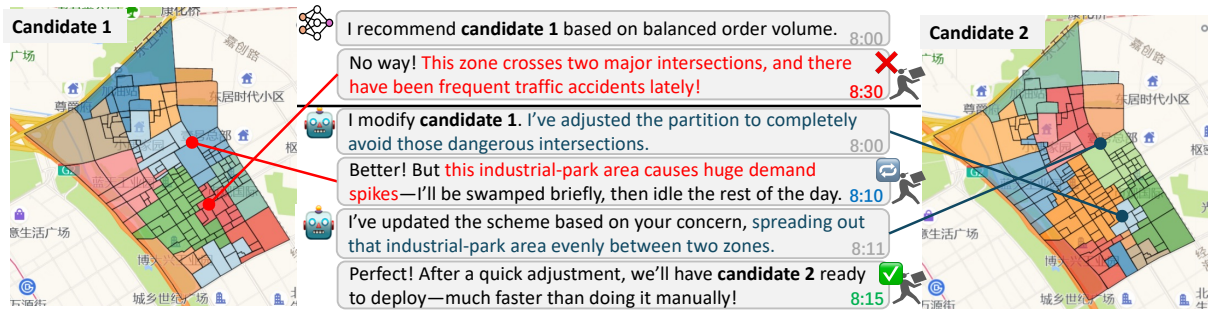

Figure 1: A real-world example demonstrates LLM-based interactive geospatial repartition. The dialogue highlights practical constraints, such as safety hazards at intersections and demand spikes in industrial areas, that current methods fail to capture. Our LLM-based approach understands these issues, enabling interactive refinement and enhancing the efficiency of experts through collaboration.

comprehensive, human-aligned repartitions, rather than merely optimizing offline metrics. Figure 1 illustrates differences between previous approaches and ours using one real-world example.

However, applying LLMs to geospatial repartition introduces uncertainty challenges, as LLM outputs inherently exhibit stochasticity, potentially producing plausible yet incorrect solutions without proper confidence measures. Given the excessive expert review time, an uncertainty-calibration method is necessary to ensure reliable high-quality candidates. Therefore, we present `CoAlign` (Conformal rAnking-based LLM Interactive Geospatial repartitioN), a novel three-stage framework. Firstly, we employ a Multi-Criteria pipeline that prompts an LLM to generate candidate partitions with detailed explanations and scoring across multiple metrics. Secondly, we design a conformal ranking algorithm to transform the initial LLM scores into rankings relative to historical partitions, and then create calibrated prediction sets with statistical coverage guarantees. Finally, we integrate these components into a human-in-the-loop decision-making system, enabling efficient and explainable collaboration between algorithmic candidates and human decision-makers.

Our contributions include: (i) A novel LLM-based framework, `CoAlign`, that integrates contextual information, provides comprehensive partition, and enables effective human-AI collaboration to address limitations in existing geospatial repartition systems; (ii) A novel conformal ranking design that transforms subjective LLM scores into reliable and explainable prediction sets with coverage guarantees; (iii) A comprehensive evaluation with real-world logistics data demonstrates that `CoAlign` effectively calibrates LLM uncertainty, achieving performance in offline metrics comparable to or surpassing state-of-the-art methods while producing partitions more closely aligned with human expert feedback. Furthermore, we deployed `CoAlign` across over **5,000** delivery stations in one of the largest logistics companies in the world. The A/B test results reveal significant improvements in online metrics (i.e., **3%** $\sim$ **10%**), candidate acceptance rates (i.e., **217%** increase), and decision efficiency (i.e., **56%** less human intervention and **25%** faster review).

2 Related Work

Geospatial Repartition. The expert manual partition approach leverages domain knowledge that performs well but is time-consuming. Algorithmic methods have evolved through several methodological paradigms. Traditional operations research approaches formulate this task as a combinatorial optimization problem with geometric constraints (Zhong et al., 2007; Carlsson and Devulapalli, 2013; Banerjee et al., 2022; Carlsson et al., 2024; Xie et al., 2025). More recently, data-driven methods offer improved scalability and automation, including graph neural networks (Guo et al., 2023) and deep reinforcement learning (Zheng et al., 2023b,b). However, these approaches optimize the partition with narrow offline metrics as objectives, failing to incorporate rich contextual information in real-world settings.

Uncertainty in LLM-based Decision Making. The application of LLMs to decision support systems has grown rapidly across domains including urban planning (Zhou et al., 2024; Li et al., 2024), and spatial-temporal data (Huang et al., 2022; Yang et al., 2024). These models excel at synthesizing complex, multi-modal information to generate creative solutions, but their deployment requires ro-

bust uncertainty quantification. Recent work introduced conformal prediction techniques (Shafer and Vovk, 2008; Vovk et al., 2005; Vovk, 2012) to measure and align uncertainty in LLM-based planners (Quach et al., 2023; Ren et al., 2023; Cherian et al., 2024) and they rely on LLM self-reported scores, which have shown inconsistency in complex tasks.

3 CoAlign Design

3.1 Intuition and Overview

Intuition. Extensive cognitive science and social choice research has consistently shown that humans provide more reliable comparative judgments (e.g., rankings) than absolute evaluations (e.g., scores) (Mussweiler, 2003; Arrow, 2012). Recent work on LLM-as-a-judge confirms this phenomenon in language models as well, showing higher consistency and robustness in relative ordering tasks (Liusie et al., 2024; Jiang et al., 2023; Wang et al., 2024). This insight inspired our approach: rather than calibrating raw LLM confidence scores directly, we developed a conformal prediction method tailored specifically for rankings (Luo and Zhou, 2024; Fermanian et al., 2025; Xu et al., 2025). By transforming the geospatial repartition problem into a relative ranking task between historical and newly generated partitioning schemes, we enable rigorous uncertainty quantification with statistical guarantees. This ranking-based paradigm integrates seamlessly with the existing uncertainty calibration method of LLM while addressing the uncertainty challenge of geospatial decision-making.

Overview. As shown in Figure 2, our geospatial repartition framework, CoAlign, includes three components: **Stage 1**: generating diverse partition candidates with a surrogate scoring model; **Stage 2**: calibrating uncertainty in candidate rankings via conformal prediction to form a reliable prediction set; and **Stage 3**: engaging a domain expert to review and decide the final partition based on this prediction set.

3.2 Multi-Criteria Partition Generation (MCPG)

In the geospatial repartition problem, each input instance X represents a geographic region with demands, constraints, and relevant attributes. The goal is to divide X into multiple delivery zones (partitions) that satisfy various operational criteria. In our approach, a large language model (LLM) is prompted to generate M candidate partitions

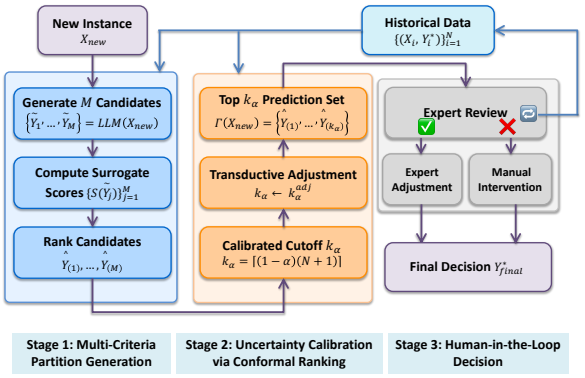

Figure 2: CoAlign Framework.

$\{\tilde{Y}_1, \ldots, \tilde{Y}_M\}$ for X. Each candidate partition $\tilde{Y}_j$ splits X into several zones, and each zone is composed of multiple *Areas of Interest* (AOIs) (e.g., neighborhoods or street clusters). We provide the LLM with rich context at both the region level and the AOI level: the prompt includes global features of X along with summary information for each AOI (such as historical demand profiles, road-network connectivity, or known bottleneck locations). This AOI-level contextual input helps the LLM reason about fine-grained spatial details when assigning AOIs to zones. The LLM generates each partition along with textual explanations and per-zone evaluations for multiple domain-specific criteria (for example, workload balance, demand coverage, or estimated travel time).

After generating candidate partitions, we verify spatial contiguity at the AOI level for each partition. We represent the region's AOIs as nodes in a graph $G = (V, E)$, where edges connect adjacent AOIs (for example, sharing a border or linked by a road). For each zone in a partition, we consider the set of AOIs assigned to that zone and check whether the induced subgraph is connected. In practice, we perform a graph traversal (e.g., breadth-first search) starting from one AOI in the zone and confirm that all other AOIs in the zone are reachable. If any zone is found to be disconnected (i.e., its AOI subgraph is not fully connected), the entire partition is rejected. To speed up this check, we employ simple heuristics. For instance, we precompute the connected components of G once per region; then any zone whose AOIs lie in more than one component can be immediately flagged as invalid without a full search. In our implementation, this filtering effectively removes partitions with non-contiguous zones while imposing minimal computational overhead.

Finally, we evaluate each candidate partition $\tilde{Y}_j$ by scoring it on each criterion $c_1, \ldots, c_L$ and combining these into a surrogate score $S(\tilde{Y}_j)$. This yields a ranked list of partitions.

3.3 Uncertainty Calibration via Conformal Ranking

We design a rank-based conformal prediction approach to ensure that our final set of top partitions (the *prediction set*) contains the true optimum Y^* with probability at least $1 - \alpha$. In essence, our algorithm treats the partition scoring model as directly producing a rank for the true partition among candidates and calibrates the uncertainty in that rank.

Calibration Set Design. From N historical instances $\{(X_i, Y_i^*)\}_{i=1}^N$, we run the same partition generation and scoring pipeline as used for new predictions. This yields a rank $\eta_i = \text{rank}(X_i, Y_i^*)$ for each instance i, where η_i is the position of the true optimum Y_i^* in the model's sorted list of candidate partitions for X_i. Intuitively, η_i represents the error made by the model on instance i—a small value means the model ranked the true partition highly, whereas a large η_i means the true partition was buried lower in the list.

Cutoff Determination. We sort the set of calibration ranks $\{\eta_i\}_{i=1}^N$ in nondecreasing order and determine the cutoff index $k_\alpha = \lceil (1-\alpha)(N+1) \rceil$. By construction, approximately $(1-\alpha)N$ of the calibration instances have Y^* ranked within the top-k_α positions of the candidate list. In other words, in most calibration examples the true optimum would be among the model's top-k_α predictions.

Transductive Adjustment. In practice, introducing a new instance can slightly shift the distribution of ranks because the model's ranking function may depend on the set of items being ranked. To safeguard the coverage guarantee in such a transductive setting, we adjust the cutoff k_α upward by a small margin if needed. Concretely, we simulate the effect of adding new test instances on the calibration ranks by randomly perturbing each η_i within a possible range of rank shifts, and choose an adjusted cutoff k_α^{adj} that still covers roughly $(1-\alpha)$ fraction of the simulated rank outcomes. This procedure yields a slightly larger prediction set size when necessary, ensuring our method remains valid even if the new instance(s) alter the ranking distribution.

Prediction Set Generation. For a new instance X_{new}, we generate M candidate partitions, compute each candidate's surrogate score $S(\tilde{Y}_j)$, and sort the candidates in descending order of S to obtain the ranked list $[\hat{Y}_{(1)}, \hat{Y}_{(2)}, \ldots, \hat{Y}_{(M)}]$. We then take the top k_α after any transductive adjustment as the *prediction set*: $\Gamma(X_{\text{new}}) = \{\hat{Y}_{(1)}, \ldots, \hat{Y}_{(k_\alpha)}\}$.

Theoretical Guarantee. Assume the calibration data $\{(X_i, Y_i^*)\}_{i=1}^N$ and the new instance(s) are exchangeable. Then for any $\alpha \in (0,1)$, the prediction set $\Gamma(X_{\text{new}})$ obtained by the above procedure satisfies

$$\Pr\{ Y_{\text{new}}^* \in \Gamma(X_{\text{new}}) \} \geq 1 - \alpha .$$

In other words, the method achieves the target marginal coverage level $1 - \alpha$ (Luo and Zhou, 2024). Moreover, consider a batch of m i.i.d. new instances with prediction sets constructed using the same calibration. With probability at least $1 - \beta$ (over the randomness of the calibration procedure), the false coverage rate is bounded as

$$\frac{1}{m} \sum_{i=1}^{m} \mathbf{1}\{ Y_{i,\text{new}}^* \notin \Gamma(X_{i,\text{new}}) \} \leq \alpha + \lambda_{N,m} ,$$

for some tolerance term $\lambda_{N,m} = O\left(\sqrt{\frac{\ln(Nm/\beta)}{Nm}}\right)$ that approaches 0 as $N, m \to \infty$ (Fermanian et al., 2025; Xu et al., 2025). In particular, in the limit of large sample sizes, the average miscoverage (error rate) on m new instances does not exceed α.

3.4 Human-in-the-Loop Decision

After constructing $\Gamma(X_{\text{new}})$ for a new instance, the system presents these top k_α candidate partitions to a domain expert, together with the scores $\{c_\ell(\hat{Y}_{(j)})\}$ and a brief LLM-generated explanation (if desired). The expert selects the best partition Y_{final}^* or indicates that none is satisfactory (in which case Y_{new}^* lies outside $\Gamma(X_{\text{new}})$—an event that, by design, should occur in at most α fraction of cases). Crucially, this feedback can be incorporated into the calibration set by adding $(X_{\text{new}}, Y_{\text{final}}^*)$ as a new example, along with its observed rank η_{new}.

Over time, the rank distribution and/or the surrogate score weights $\{w_\ell\}$ can be updated to better match expert preferences. In practice, if $\Gamma(X_{\text{new}})$ is empty or too small, we may adjust $\alpha \leftarrow \alpha + \Delta$ until at least one partition meets the expert's acceptance threshold, following the approach of (Vovk et al., 2005) for iterative significance tuning.

4 Evaluation in Last-mile Delivery

To evaluate the effectiveness of CoAlign, we conducted both offline evaluation and online deployment in collaboration with one of the world's largest logistics companies. Our evaluation aims to answer the following research questions:

RQ1: Operational Performance. How does CoAlign perform compared to methods specifically designed to optimize offline operational metrics?

RQ2: Uncertainty Calibration. Does CoAlign provide reliable prediction sets?

RQ3: Decision Efficiency. How does CoAlign improve human decision after deployment?

RQ4: Real-world Benefit. Does CoAlign improve the acceptance rate and online operational metrics after the deployment?

4.1 Data and Offline Evaluation Setup

Data Preparation. We conducted offline experiments using logistics-related data from October 2023 to June 2024 by our industry partner. Over this period, the company deployed various algorithm-generated partition recommendations across over 900 regions nationwide, logging 35,000+ repartitioning operations and 150,000+ algorithm-generated recommendations, with corresponding accept/reject decisions and comments by region managers. Each record includes: (i) **Context:** Station information (e.g., geospatial boundaries and operational constraints), current partition configuration, and historical logs (e.g., courier feedback); (ii) **Candidates:** Recommended partitions from prior heuristic algorithms; (iii) **Annotations:** Manager acceptance/rejection decisions, detailed feedback, and operational metrics (delivery order volume, courier working time, etc.).

Metrics. We evaluate our approach with 14 metrics across 4 types aligned with research questions. Table 1 summarizes directionalities and descriptions of these metrics. More detailed definitions of these metrics are provided in Appendix A.

Baselines and Training Setup. We split the dataset chronologically, using the first six months for training/calibration and the last two months for held-out testing. To contextualize our results, we compare CoAlign to several baselines that either represent the state-of-the-art or classic methods:

- **Heuristic-Only:** A manual or rule-based approach that divides regions via simple constraints.

Table 1: Evaluation metrics used in our experiments. *Metrics are defined as ratios to protect commercial privacy and normalized to [0,1] for easy comparison, except for those marked with *, which are non-negative.*

Type	Metric	Description
RQ1	↓ OVB	Coefficient of variation in order volume.
	↓ WTB	Coefficient of variation in working time.
	↓ WDB	Gini coef. of workload distribution.
	↑ MS	Maximum similarity between candidate set and deployed partition.
	↑ MSR*	Ratio of method MS to historical candidate MS.
RQ2	↓ PSR	Ratio of prediction set (PS) size to total candidate set size.
	↑ ECR	Proportion of true ranks covered in PS.
	↓ FCR	Proportion of ranks incorrectly covered in PS.
RQ3	↓ HIR	Proportion of cases requiring significant manual intervention.
	↓ RRT*	Ratio of current review time to historical average review time.
	↑ RAR	Proportion of algorithm recommendations accepted.
RQ4	↑ HER*	Ratio of post/pre-deploy HR efficiency.
	↑ PVR*	Ratio of post/pre-deploy pick-up volume.
	↑ OTR*	Ratio of post/pre-deploy on-time rate.

  We compare with two representative methods, CKmeans (Zhang et al., 2024) (a constrained clustering method) and CPSC (Joshi et al., 2012) (an A-star-based partitioning method).

- **DL-based Single/Multi Optimization:** Deep learning-based approaches that optimize one or multiple operational objectives (e.g., WTB or OVB). We compare with a DRL-based multi-optimization urban-planning method DRL (Zheng et al., 2023b,a) and a GNN-based single-optimization model E-partition (Guo et al., 2023), both trained on the same historical data without LLM-generated candidates.

- **LLM-Based Methods:** Two categories of LLM-based methods are used as baselines. The first does not include uncertainty calibration, including Vanilla (Zhao et al., 2023), the planner OPRO (Yang et al., 2024), and the multi-agent discussion-based solution LLM4PUP (Zhou et al., 2024). The second category incorporates uncertainty calibration for LLMs, specifically KnowNo (Ren et al., 2023), which uses conformal prediction in single-step uncertainty alignment (SUA) or multi-step uncertainty alignment (MUA) modes that differ from our conformal

ranking design.[1]

4.2 Offline Evaluation Results (RQ1&RQ2)

RQ1: Operational Performance. Table 2 presents 5 metrics on the test set. CoAlign performs best in WDB, MS and MSR, and second in OVB and WTB. Figure 3 illustrates CoAlign is competitive with DRL for OVB and E-partition for WTB in most regions, outliers cause minor variations. Hence, CoAlign (i) achieves comparable (OVB, WTB) or better (WDB) performance versus specialized DL approaches (DRL, E-partition), and (ii) delivers significantly stronger alignment (MS, MSR) than all baselines. We vary the LLM scale (4B, 10B, 81B) for selected LLM-based baselines. Table 3 reports MS and MSR. CoAlign and KnowNo-SUA with 81B models generally reach to exceed MSR=1.0, indicating that a larger model is critical for complex multi-criteria solutions. These results demonstrate that CoAlign effectively leverages human feedback to produce partitions closely aligned with humans, while simultaneously matching DL-based baselines in optimizing offline operational metrics.

Table 2: RQ1 results on five metrics. *MSR* > 1.0 *indicates* closer *alignment than historical recommendations.*

Method	OVB↓	WTB↓	WDB↓	MS↑	MSR↑
CKmeans	0.291	0.246	0.253	0.45	0.85
CPSC	0.318	0.278	0.269	0.44	0.80
DRL	**0.234**	0.182	0.227	0.59	0.98
E-partition	0.251	**0.165**	0.232	0.57	0.97
Vanilla	0.418	0.365	0.342	0.35	0.70
OPRO	0.368	0.302	0.321	0.38	0.75
LLM4PUP	0.385	0.287	0.311	0.39	0.78
KnowNo-SUA	0.283	0.244	0.211	0.65	1.05
KnowNo-MUA	0.321	0.278	0.290	0.46	0.92
CoAlign	0.245	0.168	**0.190**	**0.71**	**1.20**

RQ2: Uncertainty Calibration. Table 4 shows CoAlign achieves the best results in all 3 metrics. DRL shows the second-highest ECR but requires a larger set (PSR=0.32). KnowNo-SUA outperforms KnowNo-MUA, suggesting SUA is more stable for geospatial repartition tasks than MUA, likely due to weak causality between different times of historical records. Removing conformal ranking (CR) or mixing SUA/MUA consistently degrades coverage and inflates FCR. Notably, CoAlign achieves an FCR of 0.08, consistently below our preset threshold α=0.1. For $\alpha \in \{0.05, 0.10, 0.15\}$, smaller α boosts ECR but enlarges the prediction set (PSR). Setting $\alpha = 0.1$ is a balanced choice (ECR ≈ 0.92, PSR ≈ 0.20). Thus, CoAlign's use of CR indeed addresses geospatial repartition's complexity better than existing uncertainty alignment strategies.

[1]Due to our partner company's policy, we can only use its internal ChatRhino LLMs with 4B, 10B, and 81B parameter sizes. All LLM results use LLM-81B unless otherwise noted.

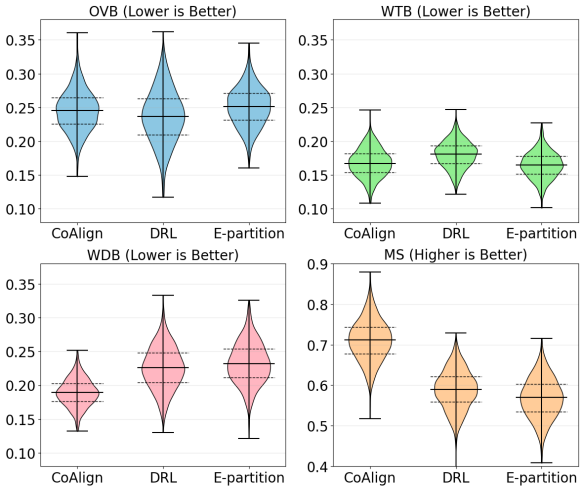

Figure 3: Offline Metrics of key baselines v.s. CoAlign.

Table 3: LLM size v.s. MS and MSR.

	MS↑ / MSR↑		
	4B	10B	81B
Vanilla	0.29 / 0.55	0.32 / 0.63	0.35 / 0.70
OPRO	0.32 / 0.60	0.35 / 0.68	0.38 / 0.75
LLM4PUP	0.34 / 0.61	0.33 / 0.65	0.39 / 0.78
KnowNo-SUA	0.43 / 0.82	0.50 / 0.87	0.65 / 1.05
KnowNo-MUA	0.40 / 0.72	0.42 / 0.75	0.46 / 0.82
CoAlign	0.44 / 0.89	0.58 / 0.95	**0.71 / 1.20**

4.3 Real World Deployment (RQ3 & RQ4)

We integrated CoAlign into a human-AI collaboration platform at over 5,000 stations. We performed an A/B test from July to August 2024, splitting stations into the **Control Group** (deployed

Table 4: RQ2 results for uncertainty quantification.

Method	PSR↓	ECR↑	FCR↓
DRL	0.32	0.85	0.22
LLM4PUP	0.27	0.65	0.25
KnowNo-SUA	0.28	0.78	0.15
KnowNo-MUA	0.35	0.72	0.20
CoAlign w/o CR	0.40	0.60	0.28
CoAlign w/o CR + MUA	0.38	0.70	0.23
CoAlign w/o CR + SUA	0.26	0.75	0.16
CoAlign	**0.20**	**0.92**	**0.08**

state-of-the-practice pipeline) and the **Experimental Group** (deployed CoAlign).

Results. Table 5 shows the results of the control group (Ctrl.) and the experimental group (Exp.) before (Pre.) and after (Post.) deploying CoAlign. All metrics in the control group remained stable before and after deploying CoAlign. The recommendation acceptance rate (RAR) in the experimental group increases from 0.06 to 0.19. Even when the recommended partition is not directly accepted, the AI-generated result remains close to the optimum and allows timely human feedback, lowering the final human intervention rate (HIR) from 0.94 to 0.41. Overall, the review time drops by about 25%, with 90% of cases requiring fewer than 3 interaction rounds. Meanwhile, the real-world benefit metrics all exceed 1.0, confirming notable gains in HR efficiency, pickup volume, and on-time rate.

Table 5: A/B test results of the CoAlign deployment.

	HIR↓	RRT↓	RAR↑	HER↑	PVR↑	OTR↑
Ctrl. (Pre.)	0.93	1.00	0.07	1.00	1.00	1.00
Ctrl. (Post.)	0.92	1.02	0.08	1.01	1.02	1.01
Exp. (Pre.)	0.94	1.00	0.06	1.00	1.00	1.00
Exp. (Post.)	**0.41**	**0.75**	**0.19**	**1.12**	**1.06**	**1.04**

Hence, CoAlign significantly improves acceptance (**RQ3**) and operational metrics (**RQ4**) compared to the baseline pipeline, largely due to its ability to incorporate human feedback effectively and produce partitions closer to expert preferences.

Remark. We observed intriguing patterns where LLM-generated partitions occasionally proposed "unorthodox" solutions characterized by near-equal zone sizes—partitions rarely produced by purely metric-driven baselines. Although these atypical recommendations were not always optimal by conventional standards, they enriched the solution space and were sometimes favored by experts for their ease of manual fine-tuning. For instance, as shown in Figure 4, experts actively encouraged LLMs to generate partitions that isolate the 4 areas highlighted by red circles. This observation suggests a broader insight: the value of LLMs extends beyond achieving higher acceptance rates through conventionally "correct" partitions; they also effectively address diverse practical requirements encountered in daily operations.

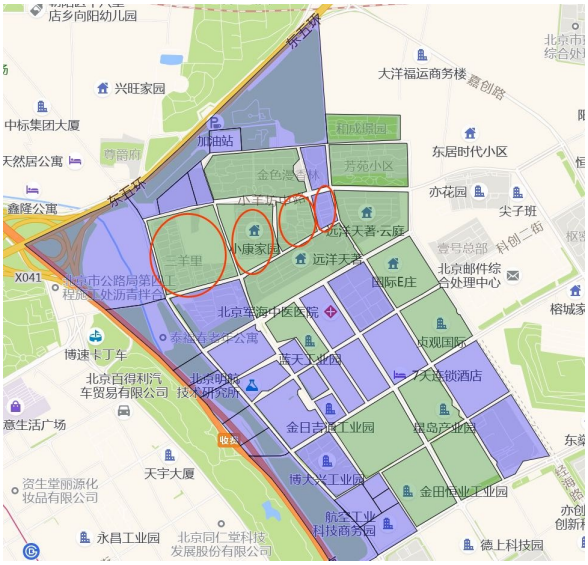

Figure 4: A real-world case of "unorthodox" partitions.

5 Conclusion and Limitation

We propose CoAlign for calibrating uncertainty in LLM explicitly for geospatial repartition. CoAlign generates comprehensive and human-aligned partitions via integrating diverse contextual information and maintains robust uncertainty calibration of LLM through a novel conformal ranking approach. Extensive offline evaluations demonstrate that CoAlign achieves superior performance across multiple offline metrics. More importantly, we have deployed CoAlign in a leading logistics company for geospatial repartition in over 5,000 delivery stations, generating positive societal and economic impact.

Although CoAlign already achieves strong performance suitable for real-world deployment without additional pre-/post-training of LLM, its success relies on the availability of rich, domain-specific data. For broader and more complex tasks, recent methods like RAG (Gao et al., 2023), CoT (Wei et al., 2022), or RLHF (Ouyang et al., 2022) could boost efficiency and performance, even with smaller models. Exploring these techniques is a promising direction for future work.

A Metric Definition

This section details the metrics used in our experiments, organized by research question (RQ). All metrics are either normalized to the range $[0, 1]$ or defined as ratios for ease of comparison. Metrics marked with '*' may exceed 1.0 or be nonnegative values rather than strictly bounded in $[0, 1]$.

RQ1: Operational Effectiveness

(i) **OVB (Order Volume Balance)**

$$\text{OVB} = \frac{\sqrt{\frac{1}{|\mathcal{Z}|}\sum_{z\in\mathcal{Z}}\left(v_z - \bar{v}\right)^2}}{\bar{v}},$$

where $\mathcal{Z}$ is the set of subregions, v_z is the order volume of subregion z, and $\bar{v}$ is the mean order volume. Lower OVB indicates better balance.

(ii) **WTB (Working Time Balance)**

$$\text{WTB} = \frac{\sqrt{\frac{1}{|\mathcal{C}|}\sum_{c\in\mathcal{C}}\left(t_c - \bar{t}\right)^2}}{\bar{t}},$$

where $\mathcal{C}$ is the set of couriers, t_c is the working time of courier c, and $\bar{t}$ is the mean working time. Lower WTB indicates better time balance.

(iii) **WDB (Workload Distribution Balance)**

$$\text{WDB} = \text{Gini}\big(\{\, w_z \mid z \in \mathcal{Z}\}\big),$$

where w_z is the workload of subregion z. Lower WDB indicates more uniform workload distribution.

(iv) **MS* (Maximum Similarity)**

$$\text{MS} \;=\; \max_{Y \in \Gamma(X)} \; \text{sim}\big(Y,\, Y^*\big),$$

measuring the highest similarity (e.g. IoU or overlap) between the prediction set $\Gamma(X)$ and the deployed partition Y^*. Higher is better.

(v) **MSR* (Method Similarity Ratio)**

$$\text{MSR} \;=\; \frac{\text{MS(Method)}}{\text{MS(Historical)}},$$

the ratio of our method's MS to the historical candidate's MS. A value above 1.0 indicates the method produces partitions more aligned with final deployments than past baselines.

RQ2: Uncertainty Quantification

(i) **PSR (Prediction Set Ratio)**

$$\text{PSR} \;=\; \frac{\text{Avg size of prediction set}}{\text{Avg number of total candidates}},$$

indicating how large the top-k_α set is relative to all generated partitions. Lower PSR indicates a more selective set.

(ii) **ECR (Empirical Coverage Rate)**

$$\text{ECR} \;=\; \frac{\#\{\, X : Y^* \in \Gamma(X)\}}{\#\{\, X\}},$$

the fraction of instances whose true optimum Y^* appears in the prediction set. Higher ECR is better.

(iii) **FCR (False Coverage Rate)**

$$\text{FCR} \;=\; \frac{\#\{\text{incorrectly covered instances}\}}{\#\{\, X\}},$$

the fraction of instances where the prediction set includes a suboptimal or invalid partition that might mislead decisions. Lower is better.

RQ3: Decision Efficiency

(i) **HIR (Human Intervention Rate)**

$$\text{HIR} \;=\; \frac{\#\{\text{cases needing manual edits}\}}{\#\{\text{total cases}\}},$$

representing the proportion of partitions that required substantial manual adjustment beyond the recommended set.

(ii) **RRT* (Relative Review Time)**

$$\text{RRT} \;=\; \frac{T_{\text{current}}}{T_{\text{baseline}}},$$

where T_{current} is the average manager review time under the new system, and T_{baseline} is the pre-deployment average. A value below 1 indicates faster reviews.

(iii) **RAR (Recommendation Acceptance Rate)**

$$\text{RAR} \;=\; \frac{\#\{\text{accepted recommendations}\}}{\#\{\text{total recommendations}\}},$$

the fraction of algorithm-proposed partitions eventually adopted (with or without minor edits). Higher is better.

RQ4: Deployment Benefit

(i) **HER* (HR Efficiency Ratio)**

$$\text{HER} \;=\; \frac{\text{HR}_{\text{post}}}{\text{HR}_{\text{pre}}},$$

the ratio of post-deployment to pre-deployment human resource efficiency. A value above 1 implies improved workforce productivity.

(ii) **PVR* (Pick-up Volume Ratio)**

$$\text{PVR} \;=\; \frac{\text{PV}_{\text{post}}}{\text{PV}_{\text{pre}}},$$

the ratio of post- to pre-deployment pickup volume. Values above 1 indicate increased pickup throughput.

(iii) **OTR* (On-time Ratio)**

$$\text{OTR} \;=\; \frac{\text{OT}_{\text{post}}}{\text{OT}_{\text{pre}}},$$

the ratio of on-time deliveries post- vs. pre-deployment. Values above 1 reflect improved timeliness.

Arctic-TILT
Business Document Understanding at Sub-Billion Scale

Abstract

The vast portion of workloads employing LLMs involves answering questions grounded on PDF or scanned content. We introduce the Arctic-TILT achieving accuracy on par with models 1000× its size on these use cases. It can be finetuned and deployed on a single 24GB GPU, lowering operational costs while processing rich documents with up to 400k tokens. The model establishes state-of-the-art results on seven diverse Document Understanding benchmarks, as well as provides reliable confidence scores and quick inference, essential for processing files in large-scale or time-sensitive enterprise environments. We release Arctic-TILT weights and an efficient vLLM-based implementation on a permissive license.

1 Introduction

General-purpose LLMs and their multi-modal counterparts provide a crucial advantage in process automation: they can be applied immediately, eliminating the expensive and time-consuming efforts of creating dedicated system architecture and model development. Though they are suitable choices for prototyping and building proof-of-concept solutions, once the case is validated, it becomes essential to consider the demands of real-world deployments, such as cost-efficiency (Fu et al., 2024; Ong et al., 2024), finetunability (Liu et al., 2022), and ensuring accurate confidence calibration (Van Landeghem, 2024).

We consider these issues in the context of Document Understanding (DU), where it is commonly required to integrate textual, layout and graphical clues to obtain the required information and introduce the Arctic-TILT, designed to address the needs of broad-use deployments, cost efficiency, and domain adaptations for a fraction of the cost of the leading models. The proposed solution appears competitive with orders of magnitude larger models on business and long document benchmarks.

2 Related Works

Traditionally, extracting tables or information from documents involved distinct steps like form recognition, field detection, and value extraction (Medvet et al., 2011; Rusiñol et al., 2013; Peanho et al., 2012; Tian et al., 2016; Le et al., 2019; Baek et al., 2019; Holt and Chisholm, 2018; Carbonell et al., 2019), each requiring separate models or heuristic pipelines. Later efforts moved towards more end-to-end graph-based methods (Liu et al., 2019; Hwang et al., 2021; Yu et al., 2021; Wang et al., 2024, *inter alia*). Recently, DU research closely paralleled advances in LLMs, converging on unified text-to-text formulations (Mathew et al., 2021b,a; Borchmann et al., 2021).

Despite being elegant, pure text-based methods

* See Appendix I for contributions.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 264–283
July 28-30, 2025

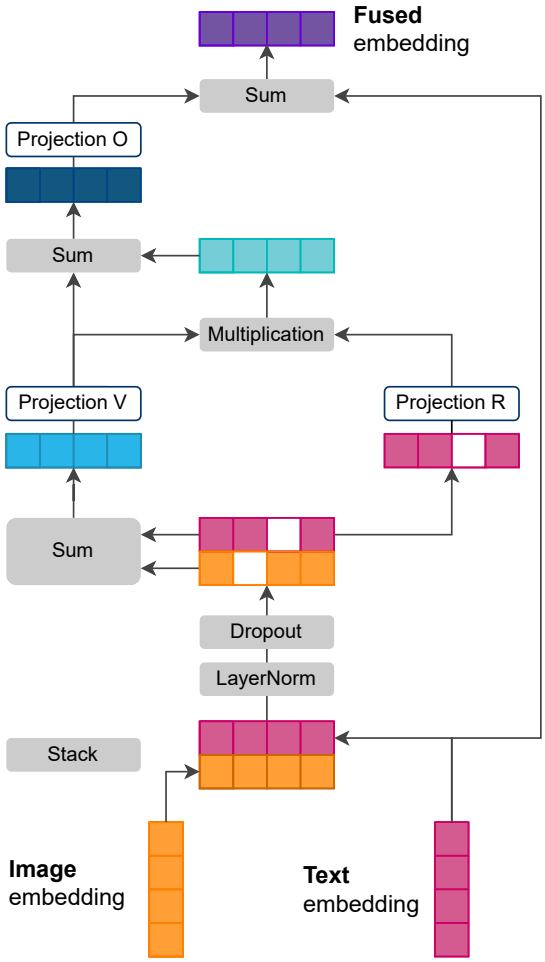

Figure 1: Our modality fusion. It can be seen as attention with role (Schlag et al., 2019) simplified as we calculate it over a pair of aligned text and image tokens.

fall short in layout-intensive tasks. This has led to the emergence of approaches extending LLMs with visual encoders (Li et al., 2023; Wu et al., 2023), layout modalities (Fujitake, 2024), or both (Mao et al., 2024; Li et al., 2024; Tang et al., 2023). Other research leverage multimodal instruction-following datasets (Dai et al., 2023; Zhang et al., 2023; Ye et al., 2023b, *inter alia*) or introduce auxiliary objectives like text-image matching (Peng et al., 2022; Tang et al., 2023; Xu et al., 2020; Bai et al., 2022; Feng et al., 2024). Finally, some works approach DU using vision-only models (Kim et al., 2021, 2022; Lee et al., 2023a; Beyer et al., 2024).

The key dimension involves balancing model performance and deployment constraints. We advocate for lightweight DU models due to their superior memory efficiency and inference speed—crucial for practical or edge deployments—aligned with prior work emphasizing cost-effectiveness (Fu et al., 2024; Zhao et al., 2024; Ong et al., 2024).

TILT	Arctic-TILT
Vision Encoding and its Fusion with Text	
sum of text & image	fusion by tensor product
first layer only	every encoder layer
Pretraining and finetuning	
400k steps of adaptation	900k steps
SFT on 4 datasets	SFT on 17 datasets
Transformer	
dense attention, vanilla	sparse attention, SLED
max 9k tokens	max 400k tokens
basic optimization	heavy optimization
Licensing and availability	
closed, proprietary	open source

Table 1: Comparison of TILT and Arctic-TILT.

3 Arctic-TILT

We build on the TILT encoder-decoder model, which extends T5 (Raffel et al., 2020) by incorporating (1) an attention bias based on horizontal and vertical distances and (2) image embeddings capturing token visual neighborhood (Powalski et al., 2021). To overcome its limitations, we introduce novel modality fusion, attention sparsity, training recipe, and optimized training/inference. The improved model is referred to as Arctic-TILT (see Table 1).

3.1 Fusion of Text and Vision

TILT integrates visual and textual semantics by summing word embeddings with RoI-pooled bounding box representations, using a U-Net-based image encoder. Features are fused once, immediately after embedding. However, ablations from Powalski et al. (2021) indicate that TILT's visual backbone contributes less to performance than layout features, suggesting that single-step summation loses critical visual details. We attribute this to (a) the long backpropagation path weakening visual gradients and (b) summation failing to capture higher-order text-spatial interactions. To address this, we replace TILT's one-time fusion with a layer-wise fusion mechanism using tensor product representations. This approach enables progressive interaction between modalities in each encoder block, with gating elements reducing noise.

Fusion by Tensor Product. Specifically, we opt for the fusion of modalities inspired by approximation of tensor product representations (Smolensky, 1990; Schmidhuber, 1993; Schlag et al., 2019). Given the text and image embeddings $t, i \in \mathbb{R}^d$, we

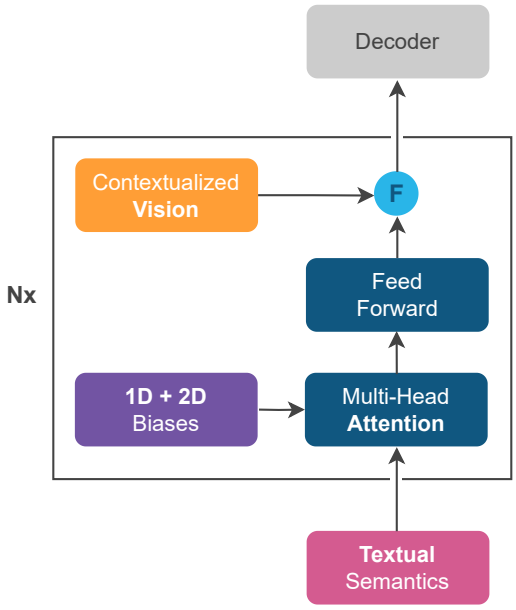

Figure 2: The Arctic-TILT encoder block combines *Vision* from U-Net and *Textual Semantics* from input embeddings through *Fusion* (F) operation. The *Multi-Head Attention* is augmented with *1D and 2D positional biases*. This procedure is repeated in each layer (*Nx*).

calculate the fused embedding with: $\text{Fuse}(t, i) = O(V(t + i) \odot (\mathbf{1} + Rt)) + t$ where V, R, and O are $\mathbb{R}^{d \times d}$ trainable parameters. In practice, we use a variant of this mechanism with layer norm and dropout (Figure 1 and Listing 1).

Placement. We found that placing the fusion module after FFNs (Figure 2) is most beneficial. Additionally, by applying it after every encoder layer, we mitigate the vanishing gradient effect and enable the model to focus on different visual features as its comprehension of the document improves.

3.2 Long Context Support

Concerning the product-oriented nature of our work, it is essential to cover a significant fraction of real-world documents of potentially arbitrary lengths while operating within limited resources. The outlined optimizations are guided by the need to handle as much context as possible on widely available A10 and L4 GPUs equipped with 24GB vRAM. We assume a single-GPU setup and measure the impact of applied techniques and architectural changes on the maximum context length used during the finetuning and inference.

Chunked processing. To address the quadratic complexity of encoder self-attention, we employ a variant of fusion-in-decoder/SLED (de Jong et al., 2023; Pietruszka et al., 2022; Ivgi et al., 2022), using zero chunk padding. This approach restricts encoder attention to a bounded-width neighborhood around its diagonal, forming a block diagonal matrix and thus linearly reducing attention weights relative to sequence length (see Appendix E).

Nested stack checkpointing. Applying gradient checkpointing across the entire 24-layer encoder stack substantially reduces memory requirements, storing activations only for the final layer needed by the decoder. This decreases memory usage dramatically—for example, from 96GB to just 4GB when processing 1M tokens—at the cost of an extra encoder forward pass.

Random chunks. Concatenated chunk embeddings may still exceed memory limits in the decoder cross-attention. Although the model supports 230k tokens during training, we further extended this by randomly discarding chunks, allowing exposure to different document parts over epochs.

Beyond primary techniques, we apply additional optimizations. Mixed-precision training with *bfloat16* and disabled weight caching reduce RAM usage, doubling inference input length. Recomputing decoder projections per layer instead of caching key-value pairs extends inference context to 389k tokens. Offloading decoder activations from GPU to CPU minimizes peak GPU memory at the cost of increased processing time. Lastly, memory-efficient attention reduces attention overhead (Rabe and Staats, 2022).

Ultimately, our optimizations culminate in significant memory usage improvements, allowing us to effectively train and deploy Arctic-TILT for documents up to 500 pages[1] on a single 24GB GPU. The step-by-step summary is studied in Table 2.

3.3 Pretraining and finetuning

The training process began with a self-supervised pretraining from the T5 large model (Raffel et al., 2020). Following the introduction of TILT architecture changes, which included U-Net (Ronneberger et al., 2015) and 2D biases, as well as text-vision post-fusion, the model underwent further self-supervised pretraining for a total of 900k steps based on documents from the CCpdf (Turski

[1]Specifically, 390k input tokens with an output of 128 tokens, corresponding to 780 tokens per page on average.

	Inference	Training
Vanilla TILT	9k	4k
+ attention sparsity	87k	41k
+ mixed precision	179k	51k
+ memory efficient attention	183k	56k
Inference-only optimizations		
+ no cross-attention KV cache	389k	
Training-only optimizations		
+ nested checkpointing		230k
+ CPU offloading		256k
+ random chunks		389k

Table 2: Max input length (tokens) consumed during training and inference given single 24GB GPU. Tested for documents up to 500 pages (389k tokens).

et al., 2022) and OCR-IDL (Biten et al., 2022).

Finally, the model was finetuned on QA and KIE datasets. In this phase, we increase the number of supervised datasets to 17, compared to TILT's original choice of four. The datasets chosen represent critical aspects of DU tasks, including, but not limited to, forms, financial reports, charts, invoices, insurance documents, contracts, and legal documents (detailed in Appendix D).

The model features 822M parameters and the total computational cost of its training is slightly less than 10 days on 8xH100 GPUs.

4 Experiments

We evaluate our approach across multiple DU benchmarks spanning diverse tasks and document types. DocVQA (Mathew et al., 2021b) assesses systems on QA over scanned documents, while SlideVQA (Tanaka et al., 2023) addresses challenges in densely packed presentation slides. MMLongBench-Doc (Ma et al., 2024) targets extensive multi-page documents. Kleister NDA (Stanisławek et al., 2021) emphasizes precise legal-domain information extraction, whereas Kleister Charity and VQA-CD (Mahamoud et al., 2022) focus respectively on financial reports and corporate purchase documents. InfographicsVQA (Mathew et al., 2021a) highlighting multimodal reasoning. Finally, we also include long-context summarization tasks from PubMed-Lay and ArXiv-Lay (Nguyen et al., 2023). Across these datasets, input sizes, domain coverage, and visual complexity vary significantly—from single-page invoices or forms to multi-page legal contracts.

Comparison in Table 3 include only models previously recognized for achieving SOTA performance in their respective settings, alongside Arctic-TILT results presented in Generalist and Specialist variants. All baseline scores are sourced from third-party publications claiming superior performance over previous models. See Appendix G for comparisons with additional open-source models.

4.1 Document Visual QA and KIE

Zero-shot Performance. As shown in Table 3, our model evaluated in the zero-shot setting often achieves near-SOTA performance out of the box (e.g., on VQA-CD, DUDE and Kleister Charity). However, on Kleister NDA—where the questions are more complex—its performance is less competitive. On the recently introduced MMLongBench-Doc (Ma et al., 2024), which evaluates zero-shot performance on documents up to 400 pages, we exceed several much larger LLMs and LVLMs (e.g., Mixtral 8x7B, QWen-Plus, Claude-3 Opus, InternVL) by substantial margins. Models such as Gemini 1.5 Pro and GPT-4o do outperform us, but they reportedly contain hundreds of times more parameters (full results in Table 8). Section 4.3 explores how our model's performance improves with limited annotated data, comparing it to GPT-4o.

Multi-page. Among six multi-page QA/KIE datasets, we achieve new SOTA results on four (MP-DocVQA, Kleister Charity, Kleister NDA, and DUDE), outperforming larger general-purpose LLMs such as GPT-4 Family (Vision Turbo and Omnia) and specialized DU models like ERNIE-Layout, LAMBERT, GRAM, and BigBird-Pegasus+Layout. We attribute these gains to our explicit modeling of long-context interactions.

Three of these datasets include labeled positions of the target answers, allowing us to analyze performance based on where the relevant information appears in each document. Figure 3 shows a *primacy bias*, with higher accuracy when the key text occurs near the beginning of the input (Liu et al., 2024a). Overall, considering the input sequence length in tokens, Arctic-TILT sets new SOTA on four out of the six longest datasets in Table 3, demonstrating particular strength on multipage inputs where many existing DU models struggle.

Single-page. In settings with single-page excerpts or standalone images (shorter inputs), our model still performs strongly. It surpasses TILT by 2 points on the DocVQA dataset (Mathew et al., 2021b) and also outperforms GPT-4 Vision. Notably, Arctic-TILT achieves state-of-the-art re-

Dataset	Industrial	Multipage	State-of-the-Art (Params, Score)			Our (Specialist, Generalist)	
MP-DocVQA	✓	✓	GRAM	859M	80.3	**81.2**	76.9
Kleister Charity	✓	✓	LAMBERT	125M	83.6	**88.1**	86.9
Kleister NDA	✓	✓	ERNIE-Layout	355M	88.1	**94.3**	38.3
DUDE	✓/✗	✓	GPT-4Vt + OCR	200B+	53.9†	**58.1**	55.9
MMLongBench-Doc	✓/✗	✓	GPT-4o	200B+	**42.8**†	—	25.8
SlideVQA	✗	✓	GPT-4Vt + OCR	200B+	**57.3**†	55.1	40.4
ArXiv-Lay	✗	✓	BigBird...+Layout	581M	41.2	**44.4**	—
PubMed-Lay	✗	✓	BigBird...+Layout	581M	42.1	**44.8**	—
DocVQA	✓	✗	InternVL 2.0 Pro	108B+	**95.1**†	90.2	88.6
VQA-CD	✓	✗	QALayout	8M	42.5	**90.7**	88.7
InfographicsVQA	✗	✗	InternVL 2.0 Pro	108B+	**86.8**†	–	57.0

Table 3: Arctic-TILT (822M params) compared to the previous state-of-the-art. Our model remains competitive and excels when input is a long, business document. Original metrics used for each dataset; † denotes generalist score.

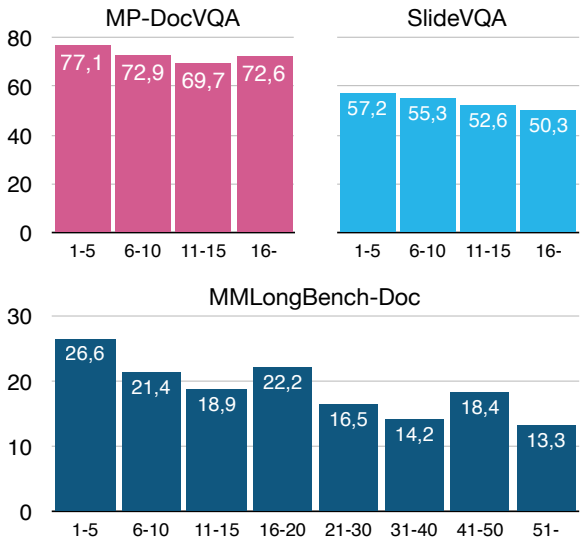

Figure 3: Scores depending on the evidence location.

sults on the newly introduced VQA-CD dataset (Souleiman Mahamoud et al., 2022), which includes invoices and purchase orders. Although we observe a gap between Arctic-TILT and InternVL 2.0 Pro (108B+ parameters) on certain benchmarks like InfographicsVQA (Mathew et al., 2021a), the model's overall performance in single-page tasks remains competitive. We attribute some limitations of Arctic-TILT to the varied aspect ratios and unusual formats in these tasks, making it challenging for our comparatively small, 8M-parameter visual backbone to encode every layout robustly.

Strengths and Weaknesses. Qualitative analysis using the DUDE diagnostic subset (see Appendix G) reveals that Arctic-TILT outperforms other state-of-the-art (SOTA) models on both abstractive and extractive questions, while ranking second-best for list-based and unanswerable queries. This suggests robust handling of complex data but also indicates potential areas for improvement on less typical answer types, which could be addressed by adjusting the supervised fine-tuning (SFT) data mix. On the SlideVQA dataset (Tanaka et al., 2023) our model achieves a score 2 points lower than GPT-4 Vision. We attribute this shortfall to the predominantly horizontal format of slides—a layout not specifically targeted in our current pretraining mix.

4.2 Layout-Aware Summarization

To complement our VQA and KIE results, we also investigate Arctic-TILT's capacity for capturing layout information and long-range dependencies in the LoRaLay collection of summarization tasks. Unlike most other summarization benchmarks, LoRaLay includes scientific documents with rich structure rather than simple text blocks (Nguyen et al., 2023). As shown in Table 3, Arctic-TILT outperforms the previous SOTA on both ArXiv-Lay and PubMed-Lay by several points. Notably, this is achieved without any specialized pretraining objectives tailored to summarization, underscoring our model's general ability to handle complex, layout-intensive inputs.

4.3 Adapting to Novel Use Cases

Arctic-TILT introduces optimizations to enhance training under minimal memory constraints, improving adaptability in production settings for out-of-domain examples and novel use cases. Thus, we evaluate its zero-shot accuracy improvement when finetuned on up to 25 annotated documents from holdout datasets, including Ghega patents (Medvet et al., 2011) and a private payment stub dataset (see Appendix F). As shown in Figure 4, Arctic-TILT rapidly approaches GPT-4o's accuracy with just five examples and surpasses it with slightly more.

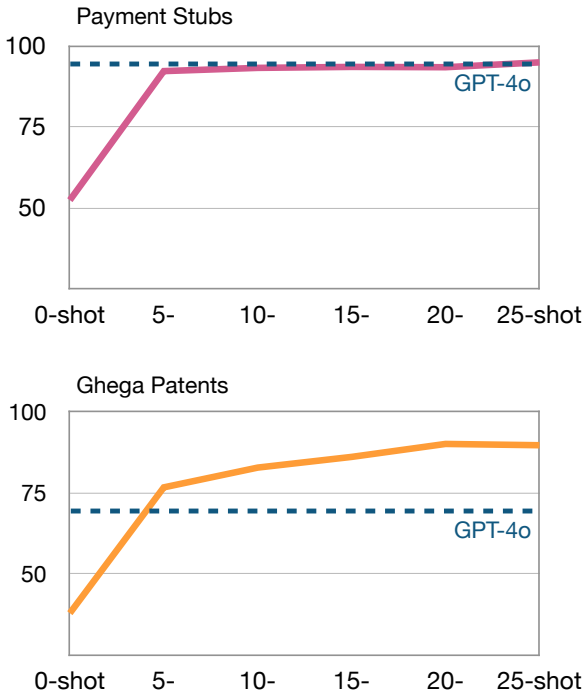

Figure 4: Improvement of Arctic-TILT zero-shot accuracy given finetuning on up to 25 annotated documents.

These results highlight the advantages of specialized, smaller LLMs over general-purpose models, emphasizing cost-effectiveness and adaptability.

4.4 Confidence Calibration

Following van Landeghem et al. (2023), we evaluate *Expected Calibration Error* (ECE) and *Area Under the Risk-Coverage Curve* (AURC) on the DUDE dataset. Confidence scores are derived from per-token lists, where we use the minimum score instead of the geometric mean, as it proved empirically superior. Results show exceptional calibration, with an SOTA ECE of 7.6 (previous best: 19.0), indicating strong alignment between confidence and accuracy. Our AURC of 25.3 (previous best: 44.0) further demonstrates effective uncertainty estimation, allowing for appropriate low-confidence assignments to ambiguous predictions requiring human review. Beyond DUDE, we analyze 18k samples from 14 datasets (Figure 5). The results confirm consistently low ECE and well-calibrated confidence scores, as accuracy follows the diagonal $y = x$ in the calibration plot.

4.5 Computational Efficiency

The imperative for businesses to rapidly and efficiently process substantial document volumes calls for models that maximize throughput and

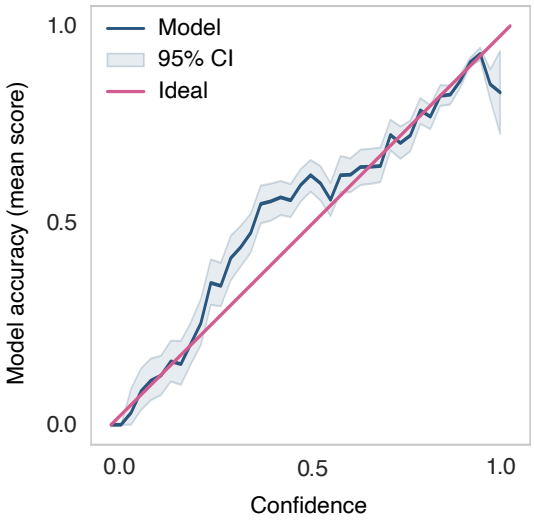

Figure 5: Arctic-TILT calibration.

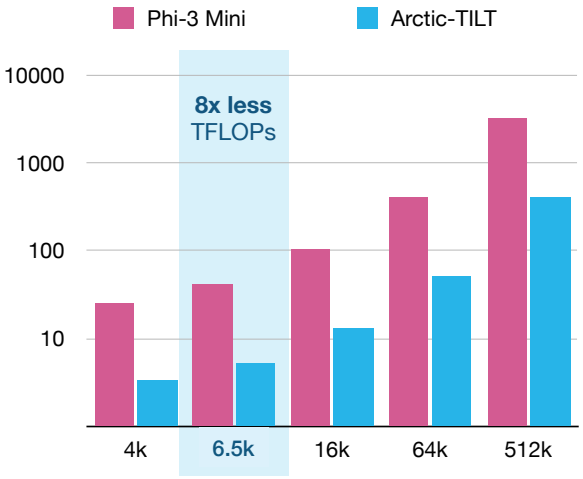

Figure 6: Arctic-TILT's computational efficiency (TFLOPs, lower is better) compared to Phi-3 Mini on VQA/KIE given inputs ranging from 4k to 512k tokens.

operational efficiency. To address this aspect of the model, we analyze the inference floating point operations per second (TFLOP) required for Arctic-TILT compared to Phi-3 Mini (Abdin et al., 2024), an example of a decoder-only model featuring 3.8B parameters and optimized by resorting to the attention sliding window. The latter was selected as a well-known reference model concerning the limited memory and compute regime we aim at, though it is not capable of achieving satisfactory accuracy on Document Understanding tasks.

Results presented in Figure 6 indicate that Arctic-TILT consistently demands lower TFLOP across all context lengths for our primary use case of VQA/KIE,[2] reflecting its smaller parameter size.

[2]We assume the output of 8 tokens—longer than the aver-

Importantly, concerning the input of 6.5k tokens, the mean input length for VQA/KIE tasks considered before, we require 8× less operations.

4.6 Ablation Study

We systematically alter one of four key differences between Arctic-TILT and Vanilla TILT to evaluate their individual contributions (Table 4).

Concerning the fusion positioning with respect to the multi-head attention (MHA) and the fusion mechanism used, results suggest that the approach from Section 3.1 is optimal. Replacing fusion by TP with Vanilla TILT fusion (*original fusion*) leads to a loss of 1.6 points on average. Similarly, placing fusion after the MHA and before the FFN (*our but pre-fusion*) is worse than placing it before the MHA (*Arctic-TILT*) by 1.5 points. We see that employing sparsity with blocks of 1024 tokens with no overlap (Section 3.2) outperforms alternative variants. Specifically, Vanilla TILT (*original, dense*) cannot consume the entire content of some lengthy documents, leading to the loss of 15 points. Similarly, varying block sizes between 1024 and 2048 tokens that either overlap with 128 tokens or have no overlap, we see that they lead to the loss of at least 1.7 points on average. Analysing the impact of additional self-supervised pretraining introduced in Arctic-TILT (Section 3.3), we see they offer an advantage of 4.6 points on average, indicating that the Vanilla TILT (*original pretraining*) was undertrained. Finally, change in the introduced supervised finetuning data (Section 3.3) markedly enhanced the model's performance across all evaluated tasks.

Overall, we found that any deviation from the proposed setup leads to the degradation of scores obtained by the model on downstream tasks.

	Charity	DUDE	MP-	NDA	Δ
Arctic-TILT	82.7	44.6	76.7	72.1	–
original fusion	80.3	43.4	76.6	69.5	-1.6
our but pre-fusion	79.4	44.2	77.3	69.2	-1.5
original, dense	55.0	38.6	66.1	56.6	-15.0
1024/128 sparsity	78.6	43.3	75.7	68.2	-2.6
2048/0 sparsity	79.0	43.6	76.9	69.6	-1.9

5 Summary

We have introduced the Arctic-TILT model, which addresses TILT's limitations in handling multimodal input, suboptimal training procedure, and maximum context length. By analyzing the results and considering the cost-efficiency of the designed solution, we provided practical insights into designing capable, lightweight models for the industry.

Arctic-TILT demonstrates state-of-the-art or competitive performance across seven diverse benchmarks, often outperforming models significantly larger, especially on long, business-centric documents. Our work illustrates that strategic design and optimization can rival the capabilities of larger, more resource-intensive models.

Importantly, Snowflake is releasing the Arctic-TILT model weights and an efficient vLLM-based implementation to the public, enabling broader access and application of this cost-effective and high-performance solution for Document AI.

Acknowledgements

We extend our heartfelt thanks to Tomasz Dwojak and Daniel Campos, whose feedback on the manuscript and valuable suggestions have greatly enhanced the quality of this work. We are also grateful to Łukasz Słabinski, Michał Gdak, Tomasz Stanisławek, Nikolai Scholz, and Vivek Raghunathan; their support and guidance as managers were instrumental throughout this research. To conclude, we thank Rafał Kobiela for his assistance with the cloud infrastructure, and Staszek Pasko for coordinating the open source process and discussing the product aspects of this project.

A Limitations

Although our approach demonstrates state-of-the-art performance on a range of document-related tasks, it is primarily tailored for unstructured or semi-structured Document Understanding. This focus imposes limitations when applied to non-DU tasks such as Scene Text VQA (Biten et al., 2019), where text may appear in complex outdoor scenes with highly variable lighting, orientation, and font usage. Likewise, because of relying exclusively on MLM pretraining and lightweight visual encoder, Arctic-TILT may struggle with VQA assuming the dominant image component (Antol et al., 2015). Next, because of the SFT datasets' composition and compact model size, it cannot follow complex instructions, and its intended use is limited to QA and summarization tasks. Finally, as discussed earlier and visible in Figure 3, accuracy can suffer if the key answer appears very late in the document. Example failure cases illustrating these limitations are provided in Appendix H.

B Contribution

We have:

- introduced the Arctic-TILT model, which addresses TILT's limitations in handling multimodal input, suboptimal training procedure, and maximum context length;
- established state-of-the-art performance on seven benchmarks demanding text, vision, and layout comprehension;
- demonstrated that within the industrial applications setting and while keeping the parameter count below 1B, one could achieve performance better or comparable to vastly larger models;
- presented a novel modality fusion mechanism inspired by tensor product representations, and have shown how effectively apply it across the transformer encoder;
- demonstrated how, with well-designed attention sparsity patterns and numerous other optimizations, consume extensive input sequences during training and inference, given a single cost-efficient GPU, while maintaining competitive accuracy of the model;
- demonstrated that all of the architectural decisions can be drawn from the systematic ablation study we conducted;
- provided insights that can be applied to design future generations of multimodal models, particularly for visually rich document processing.

Our work illustrates that strategic design and optimization can rival the capabilities of larger, more resource-intensive models.

C Why TILT as a Starting Point?

We argue that the effectiveness of the DU model depends primarily on its ability to understand specific document formats and structures in the most

document-native way possible, which can only be guaranteed by equipping the model with layout-aware architectural biases as early as possible.

Though a number of large vision-only models have been proposed (Kim et al., 2022; Davis et al., 2022; Lee et al., 2022), smaller models with an explicit OCR step still outperform them. Notably, even GPT-4 Vision benefits from the availability of OCR-recognized text (Borchmann, 2024). Although document intelligence requires visual features (e.g., to recognize checkboxes, signatures, text colors, and formatting), the text and its spatial arrangement are most important. This necessitates models with heavy textual and lightweight visual encoders, such as TILT.

Secondly, the imperative for businesses to rapidly and efficiently process substantial document volumes calls for models that maximize throughput while also maximizing operational efficiency. Smaller, specialized models, tailored for such tasks, often surpass their larger LLM counterparts, which struggle to meet these criteria due to their higher computational demands and processing times. The motivation for these is not only practical, as regulations such as GDPR, CCPA, or Chinese digital laws may require specific types of information to be processed locally. This need is fulfilled with smaller, specialized models that can be deployed on broadly available GPUs and thus are not restricted to a handful of regions.

The original TILT offers impressive performance despite keeping the number of parameters below 1B because of a well-balanced parameter budget and relying on encoder-decoder architecture, which, despite lower popularity compared to decoder-only models, offers better quality in compute-matched setups (Raffel et al., 2020; Chowdhery et al., 2022; Wang et al., 2022; Tay et al., 2023). Besides, we prefer them because achieving optimal attention sparsity patterns is more straightforward with separate encoder and decoder modules.

The encoder-decoder model with a sizeable textual backbone and small visual encoder, equipped with layout architectural bias that has previously established state-of-the-art results, appears a viable starting point for building a modern DU system.

D Datasets for Supervised Finetuning

Training of Arctic-TILT included SFT phase on twelve publicly available and five in-house annotated datasets. The first group included Kleister Charity, Kleister NDA (Stanisławek et al., 2021), CHART-Infographics (Davila et al., 2022), DeepForm★ (Borchmann et al., 2021), DocVQA (Mathew et al., 2021b), DUDE (Van Landeghem et al., 2023), FUNSD (Jaume et al., 2019), InfographicVQA (Mathew et al., 2021a), SQuAD 2.0 (Rajpurkar et al., 2018), TAT-DQA (Zhu et al., 2022), VQA-CD (Mahamoud et al., 2022), and VQAonBD (Raja et al., 2023).

Private datasets were based on QA annotations of IRS990 forms, insurance reports, company annual reports, synthetic invoices, and charity annual reports. To give the research community a grasp on the characteristics of this collection, we provide the most important statistics and examples of questions in Figure 7 and Table **??**.

E Used Hyperparameters

Chunking setup. Given hyperparameters—core chunk length c, overlap size o, and prefix length l—the input of length $C = n \cdot c$ is divided as follows: chunk 1 contains prefix tokens followed by input tokens $0, \ldots, c - l$. Subsequent chunks $i + 1$ start with prefix tokens followed by tokens $t - o + 1, \ldots, t - o + c - l$, where chunk i used tokens up to position t. We studied the size of the attention block, as well as the overlap size of consecutive blocks. To our surprise, the best setup for inference was 1024 tokens attention size with no overlap, and these conclusions are independent of the setup overlap/attention size during training. The abstract illustration of this concept is present in Figure 9.

Learning rate scheduling and precision. We observed a non-trivial inference between the two hyper-parameters. Compared to *fp32* pretraining, *bf16* pretraining with more aggresive learning rate scheduling was able to catch up, and with same learning rate scheduling was observably worse. We ended up with using *cosine_luh* scheduler with 1% training steps with constant learning rate of 1e-3 (warm-up), followed by 89% training steps with linear decay down to 2e-4, followed by cosine scheduling for the remaining 10% steps decaying to 5e-5. Same observations were drawn during finetuning.

Training protocol. The finetuning phase's hyperparameters are set as 100k steps at batch size 128 with the *AdamWScale* optimizer. We set loss

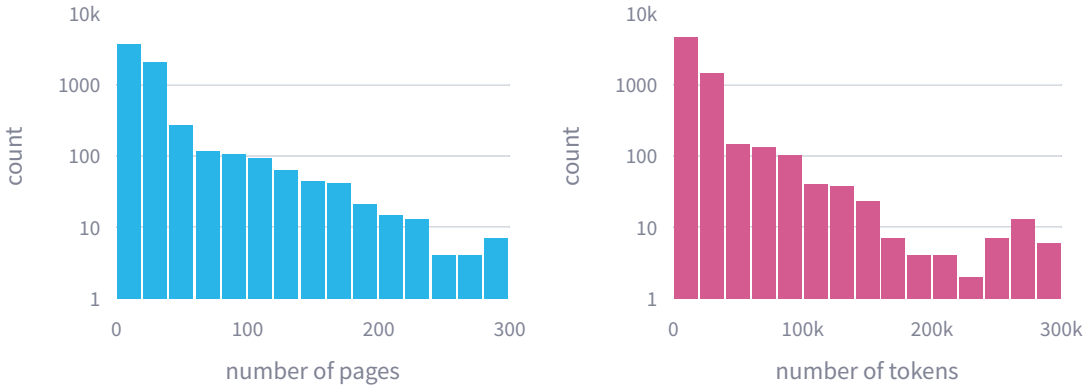

Figure 7: Lengths of documents included in five private datasets (number of tokens and pages).

Dataset	Sample Questions	Documents	Annotations
IRS990	What is the percentage of public support in the year of the report? What is the sum of the total liabilities in US dollars? What is the Employer Identification Number?	3,097	38,025
Insurance Reports	What was the value of total premiums written in the Surplus & Self-Procured category in 2016? Who is the director of the Alaska Division of Insurance? For whose contributions were tax credits claimed in 2015?	50	1,702
Company Annual Reports	What is the name of the chief executive officer? What is the total net income for report year? What is the tier 1 capital ratio?	648	3,522
Synthetic Invoices	What is the number of items on the invoice? What is the total net amount of the item described on the invoice? What is the description of the item of the transaction?	2,707	17,274
Charity Annual Reports	What is the independent auditor's name? What are the charity's total funds in the bank and in hand? What is the name of the organisation's chairman?	161	4,025

Table 5: Outline of private datasets used for SFT.

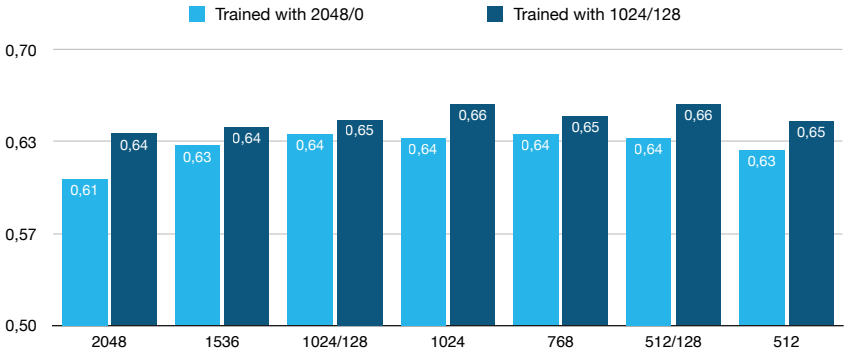

Figure 8: Impact of chunk size and overlap size (chunk/overlap) on a downstream inference for two models, assuming in-house dataset of business use cases. We observe no positive impact of overlap for sufficiently long input sequences, such as 1024 tokens.

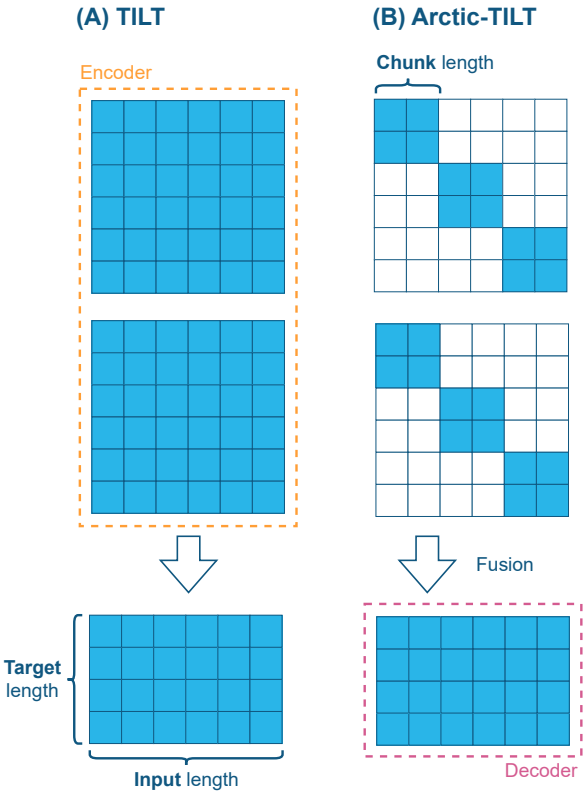

Figure 9: An illustration of sparse attention matrices assuming a two-layer encoder and decoder. The original TILT (A) consumes the complete input at once, in contrast to Arctic-TILT (B) with blockwise attention

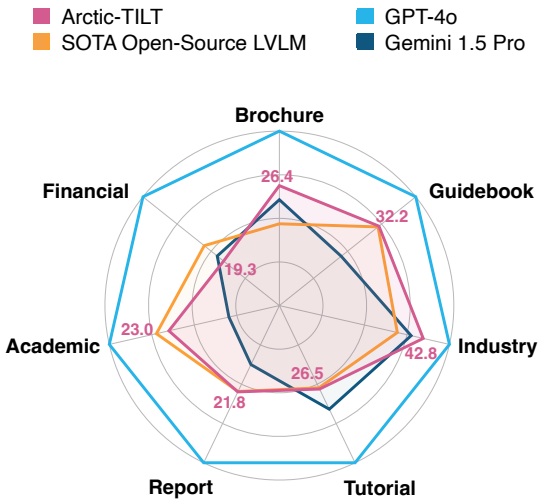

Figure 10: Fine-grained MMLongBench-Doc results. Arctic-TILT appears better than or comparable to the best open-source LVLMs and Gemini 1.5 Pro despite having at least 30x fewer parameters.

reduction to mean and weight decay to $1e{-}5$. Additionally, we used case augmentation of the whole triple consisting of the document, question, and answer. Specifically, if we detect that the document is not already cast to upper or lowercase, we create an augmented version of the three-tuple question-document-answer by casting them all to that case, similarly to Powalski et al. (2021). This means that there are up to three versions of each data point, such as the original one, uppercase, and lowercase.

Downstream tasks evaluation. For downstream task evaluation on benchmarks providing trainset (DocVQA, MP-DocVQA, DUDE, Kleister Charity, Kleister NDA, SlideVQA, InfographicsVQA, VQA-CD) we performed additional training with Optuna (Akiba et al., 2019) hyperparameter tuning. We performed 10-40 studies optimizing the following hyperparameters:

- *case augmentation* (on, off) – augment dataset with lowercased/uppercased version of training samples, in case they are statistically distinguishable;
- *answer variants sampling* (on, off) – for questions with multiple versions of the correct answer (e.g. `100`, `$100`), we either pick the same, or sample variant per epoch;
- *dropout* sampled with uniform distribution from the interval $(0, 0.2)$;
- *weight decay* sampled with log-uniform distribution from the interval $(1e{-}6, 1e{-}2)$;
- *learning rate* sampled with log-uniform distribution from the interval $(1e{-}4, 5e{-}3)$.

F Finetuning Study

GPT-4o baseline. Following the findings of Borchmann (2024), we assume input images of 2048px along longer dimensions (usually height) and similar prompts. The latter were subject to further per-dataset optimization to cover the convention used in considered datasets (final form presented in Table **??**).

Payment Stubs. The private dataset used for evaluation consists of American payment stubs, i.e., documents obtained by an employee regarding the salary received. The test split contains 39 documents with 448 annotations. Since all come from different companies, their layouts differ significantly. Questions aim to extract employee and employer names, dates, addresses and information from payment tables, where each row consists of payment type, hours worked, and payment amount,

Dataset	Prompt
Payment Stubs	Replace [ANSWER] with a value in the template given question and document. ↩ Question: [TEXT] ↩ Template: Based on the context, the answer to the question would be "[ANSWER]". ↩ ↩ Normalize amounts to two decimal places, without thousand separator and without dollar sign. ↩ Normalize states using postal abbreviations, e.g., TX or NJ.
Ghega Patents	Replace [ANSWER] with a value in the template given question and document. ↩ Question: [TEXT] ↩ Template: Based on the context, the answer to the question would be "[ANSWER]". ↩ ↩ Normalize dates to YYYY-MM-DD format except question about priority which should remain similar to "DD.MM.RRRR (country code) (optional number)."

Table 6: Final prompts used for GPT-4o baselines.

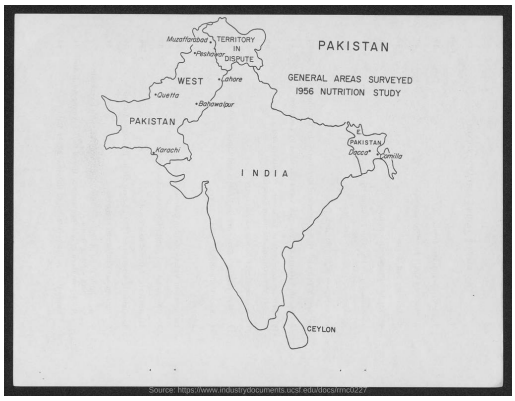

Figure 11: Question: Is Dacca in the West or East Pakistan? Arctic-TILT: West. Ground Truth: East. Due to a lack of advanced visual comprehension, the model cannot determine the city's precise location within the country.

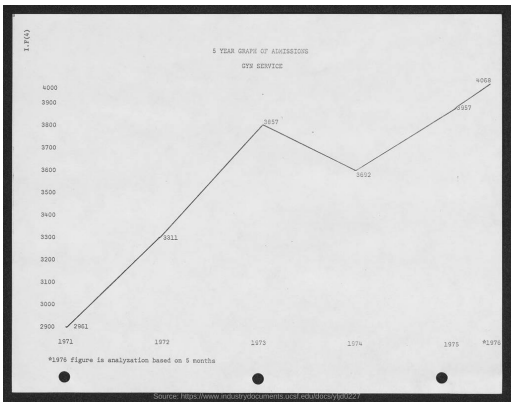

Figure 12: Question: In which year did admissions fall? Arctic-TILT: 1971. Ground Truth: 1974. Due to a lack of advanced visual comprehension and the limited presence of chart data in SFT datasets, the model cannot interpret the line plot correctly.

e.g., 'What is the name of the US state of the employee's address?' or 'When does the pay period finish?'

G Broader Evaluation Tables

This section presents a detailed performance analysis of various models on DUDE (Table 7), MMLongBench-Doc (Table 8), and a broad range of datasets featured in the main part of the paper (Table 9). Additionally, a fine-grained analysis of the top four models' performance is illustrated in Figure 10.

H Qualitative Examples of Model Errors

Qualitative analysis of model answers reveals limitations such as varied signs of limited visual comprehension (Figure 11, Figure 12, Figure 14, Figure 15), problems with counting (Figure 13). Additionally, because of relying on a third-party OCR engine, Arctic-TILT can copy from the provided textual layer that sometimes contains incorrectly recognized words (Figure 16).

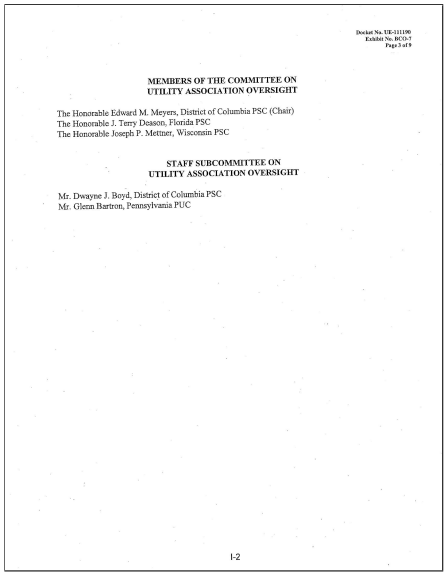

Figure 13: Question: How many Members of the Committee on Utility Association Oversight are there? Arctic-TILT: 4. Ground Truth: 3. Like many heavier LLMs, Arctic-TILT struggles with counting objects.

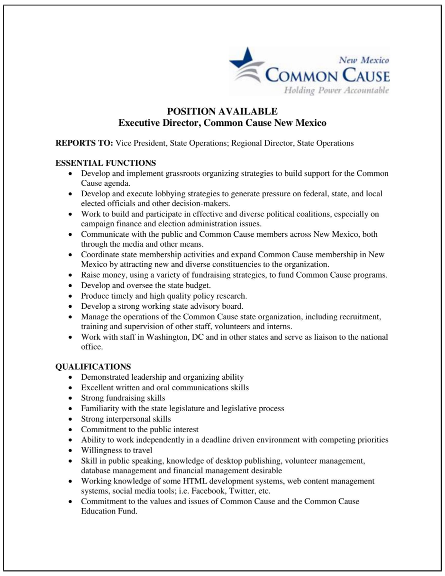


New Mexico
COMMON CAUSE
Holding Power Accountable

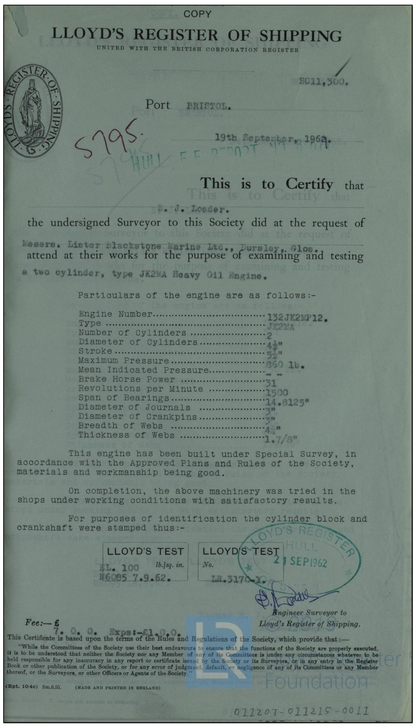
POSITION AVAILABLE
Executive Director, Common Cause New Mexico

REPORTS TO: Vice President, State Operations; Regional Director, State Operations

ESSENTIAL FUNCTIONS
- Develop and implement grassroots organizing strategies to build support for the Common Cause agenda.
- Develop and execute lobbying strategies to generate pressure on federal, state, and local elected officials and other decision-makers.
- Work to build and participate in effective and diverse political coalitions, especially on campaign finance and election administration issues.
- Communicate with the public and Common Cause members across New Mexico, both through the media and other means.
- Coordinate state membership activities and expand Common Cause membership in New Mexico by attracting new and diverse constituencies to the organization.
- Raise money, using a variety of fundraising strategies, to fund Common Cause programs.
- Develop and oversee the state budget.
- Produce timely and high quality policy research.
- Develop a strong working state advisory board.
- Manage the operations of the Common Cause state organization, including recruitment, training and supervision of other staff, volunteers and interns.
- Work with staff in Washington, DC and in other states and serve as liaison to the national office.

QUALIFICATIONS
- Demonstrated leadership and organizing ability
- Excellent written and oral communications skills
- Strong fundraising skills
- Familiarity with the state legislature and legislative process
- Strong interpersonal skills
- Commitment to the public interest
- Ability to work independently in a deadline driven environment with competing priorities
- Willingness to travel
- Skill in public speaking, knowledge of desktop publishing, volunteer management, database management and financial management desirable
- Working knowledge of some HTML development systems, web content management systems, social media tools; i.e. Facebook, Twitter, etc.
- Commitment to the values and issues of Common Cause and the Common Cause Education Fund.

Figure 14: Question: What colors are in the logo of the Common Cause? Arctic-TILT: blue, red. Ground Truth: blue, grey. Our image encoder consumes grayscale images, yielding color recognition based on guessing or approximations.



COPY
LLOYD'S REGISTER OF SHIPPING
UNITED WITH THE BRITISH CORPORATION REGISTER

SC11,300.

Port BRISTOL.

19th September, 1962.

S795.

This is to Certify that
E. J. Loader.
the undersigned Surveyor to this Society did at the request of
Messrs. Lister Blackstone Marine Ltd., Dursley, Glos.
attend at their works for the purpose of examining and testing
a two cylinder, type JK2MA Heavy Oil Engine.

Particulars of the engine are as follows:-

Engine Number	132JK2MP12.
Type	JK2MA
Number of Cylinders	2
Diameter of Cylinders	4½"
Stroke	5½"
Maximum Pressure	860 lb.
Mean Indicated Pressure	- -
Brake Horse Power	31
Revolutions per Minute	1500
Span of Bearings	14.8125"
Diameter of Journals	3"
Diameter of Crankpins	3"
Breadth of Webs	4"
Thickness of Webs	1.7/8"

This engine has been built under Special Survey, in accordance with the Approved Plans and Rules of the Society, materials and workmanship being good.

On completion, the above machinery was tried in the shops under working conditions with satisfactory results.

For purposes of identification the cylinder block and crankshaft were stamped thus:-

LLOYD'S TEST lb./sq. in. BL. 100 M6085 7.9.62.
LLOYD'S TEST No. LR.3170-1.

LLOYD'S REGISTER HULL 21 SEP 1962

Engineer Surveyor to Lloyd's Register of Shipping.

Fee:— £ 7. 0. 0. Exps:-£1.0.0.

This Certificate is based upon the terms of the Rules and Regulations of the Society, which provide that:—

"While the Committees of the Society use their best endeavours to ensure that the functions of the Society are properly executed, it is to be understood that neither the Society nor any Member of any of its Committees is under any circumstances whatever to be held responsible for any inaccuracy in any report or certificate issued by the Society or its Surveyors, or in any entry in the Register Book or other publication of the Society, or for any error of judgment, default, or negligence of any of its Committees or any Member thereof, or the Surveyors, or other Officers or Agents of the Society."

(Rpt. 10/4c) 5m,6,55. (MADE AND PRINTED IN ENGLAND)

011207-011215-0011

Figure 15: Question: What is the date on the stamp? Arctic-TILT: 19th September, 1962. Ground Truth: 1962-09-21. Arctic-TILT returns the first date found in the document, struggling to discriminate between the dates that appear in different visual contexts.

WAR FOOD ADMINISTRATION
Office of Distribution
Nutrition Programs Branch
Washington 25, D. C.

August 9, 1944

SOME OBSERVATIONS AND SUGGESTIONS REGARDING NUTRITION CLINIC DEMONSTRATIONS

Nutrition clinic demonstrations are informal meetings. The physician conducting the "clinic" points out and discusses signs and symptoms of malnutrition exhibited by individuals having various nutritional deficiencies and who have agreed to participate in the demonstration. This serves to show some of the things that malnutrition does to people. Each clinic is sponsored by a health department, medical school, or other local medical organization at the request of the state or local nutrition committee, which acts as co-sponsor.

This summary has been prepared as a result of requests for information and suggestions concerning such demonstrations.

Purposes for Which Nutrition Clinic Demonstrations are Conducted.

1. To give professional people and other workers in the National Nutrition Program a more adequate concept of good and poor nutrition.
2. To stress the fact that most of the malnutrition in this country is found in mild or moderately severe forms rather than as severe classical deficiency states.
3. To emphasize the fact that malnutrition is "a group of diseases" to which many factors contribute, and that understanding of the problem depends upon an appreciation of its various aspects.
4. To point out that because signs and symptoms of malnutrition may be caused by organic or functional disturbances or disease conditions, malnutrition in the individual should be recognized as a medical problem which should be diagnosed and treated by a physician.
5. To emphasize that the nutritional problems of the community depend for their solution on appreciation of the various aspects of these problems by all individuals and agencies working in the field of nutrition and upon their coordinated efforts to work out solutions.
6. To stress the fact that malnutrition can be prevented by the establishment and maintenance of good habits, together with wise production and utilization of food.

Requests for Assistance.

The Nutrition Programs Branch, Office of Distribution, War Food Administration, assists State and local health departments and nutrition committees in planning and conducting these demonstrations by making available to them the services of

Figure 16: Question: What is the mentioned branch of war food administration? Arctic-TILT: Nutrition Program Branch. Ground Truth: Nutrition Programs Branch. Because of relying on a third-party OCR engine, Arctic-TILT can copy from the provided textual layer that contains incorrectly recognized words (here in singular form instead of plural).

I Contributions

ŁB. Performing early-stage architecture ablations, writing most of the paper and preparing figures, final fusion by TP module design and related ablation studies, implementation of GPT-4o baseline for Arctic-TILT SFT, analysis of results on public benchmarks, overseeing initial model sparsification experiments, study of long context utilization, self-supervised pretraining of the model.

ŁD. Various contributions related to configurations and automatizations of experiments.

PD. Optimization of various data pipelines (image processing, loading, metric computation). Datasets updates and modifications (main focus on increasing loading speed and OCR correctness).

ŁG. Technical leadership and participation in the codebase implementation, performance optimization, and attention sparsity efforts. Writing parts of the paper.

AG. Efficient implementation of attention sparsity. Contributions to codebase implementation and memory optimizations. Preparation and cleaning of some datasets. Experiments with model sizes and architectures.

PH. Major contributions to memory- and compute-efficiency, including evaluation of long context approaches with a theoretical memory model, implementing nested checkpointing and mixed-precision, and empirically evaluating the complete solution's performance and memory usage characteristics.

WJ. Leading SFT efforts, including finetuning the model's final version, experiments with hyperparameters, training protocols, and dataset composition. Model performance improvements. Various contributions in the model and training code. Preparation and cleaning of some datasets.

PJ. Memory fragmentation handling. Implementation and creation of semi-synthetic long document Needle-in-a-Haystack benchmark used in early experiments. Data management, curating final training and performing a few downstream evaluations (DUDE, VQA_CD). Wrote parts of the paper. Performed final ablations.

DJ. Leading efforts to increase the context length from 25 to 500 pages (conceptualization, brainstorming, planning, guidance). Conducting initial memory and throughput experiments, as well as final stress tests and quality experiments for very large context lengths. Implementation of CPU offloading. Performing few-shot finetuning experiments. Delivering results for SlideVQA, Kleister Charity, and Kleister NDA datasets.

PL. Implemented TP fusion and conducted ablation studies focusing on module placement. Devised enhanced training protocol, performed hyperparameter tuning, and contributed to various model improvements. Performed experimental evaluation on DocVQA and InfographicsVQA.

GN. Preparation and management of datasets, the idea behind creating semi-synthetic long documents, automation of data processing pipeline, conducting experiments and analyzing the results with long documents.

JO. Selection and improvements of the training datasets (analysis of data quality, filtering the data, fixing quality issues), optimizations of image encoder and data processing.

MP. Performing early-stage architecture ablations (researching, implementing, and studying effects) that lead to co-authoring TP fusion (i.e., proposing initial attn-based version, module placement study, and fusion in every layer). Leading efforts in writing parts of the paper (technical optimizations, training, related works, analysis, structuring and rewriting).

KS. The idea behind attention sparsification, ablation studies of various approaches, implementation of required prototypes, and analysis of the results.

MT. Training loop optimization (in terms of processing time and data efficiency), performing downstream evaluations (DocVQA, MP-DocVQA, MMLongBench-Doc), dataset preparation and cleaning, error analysis, and organization of work.

AZ. Various contributions to the development of the codebase.

```

Abstract

We introduce a next-generation vandalism detection system for Wikidata, one of the largest open-source structured knowledge bases on the Web. Wikidata is highly complex: its items incorporate an ever-expanding universe of factual triples and multilingual texts. While edits can alter both structured and textual content, our approach converts all edits into a single space using a method we call Graph2Text. This allows for evaluating all content changes for potential vandalism using a single multilingual language model. This unified approach improves coverage and simplifies maintenance. Experiments demonstrate that our solution outperforms the current production system. Additionally, we are releasing the code under an open license along with a large dataset of various human-generated knowledge alterations, enabling further research.

1 Introduction

Wikidata is a large open-source, multilingual knowledge graph that plays a key role in the modern Web. It was designed as a centralized, linked repository of structured data for all Wikimedia projects, including over 300 language versions of Wikipedia (Kent, 2019; Zhao, 2022).

Beyond the Wikimedia ecosystem, Wikidata is extensively used by the most popular web services, such as search engines (Kanke, 2021) and data for digital assistants like *Alexa* and *Siri* (Reagle and Koerner, 2020) as well as for AI models, bots, and scripts. Wikidata facilitates better question answering models, offers more context in search results, links to related sources efficiently, and helps reduce factual errors in large language models (Kent, 2019; Simonite, 2019; Xu et al., 2023).

Wikidata can be described as a document-oriented database focusing on items that represent any named entity (Wikipedia, 2024). Each entity is assigned a unique identifier (ID) and can include textual information such as labels, aliases, and descriptions in multiple languages. Another essential component is the *Statements*, which provides the information necessary to form semantic triples — a key component of the knowledge graph. Triples consist of tuples of *{entity,property,value}*, where the property defines the relationship between entity and the value. Values can be free text, numbers, dates, coordinates, or another entity. A diagram illustrating the key parts of a Wikidata record is presented in Figure 1. Hence, although Wikidata provides structured relationships among entities, the building blocks of this knowledge graph include many components of unstructured data, such as multilingual descriptions or values of various types.

Given its central role in the online knowledge ecosystem, the quality of Wikidata content has relevant implications for very prominent services and products. For example, due to vandalism in Bulgaria's Wikidata Entity in 2017 (see Figure 2), when iPhone users were asking *"What is the national anthem of Bulgaria?,"* the answer was *"Despacito"*, a popular song at that time (Reagle and Koerner, 2020). Vandalism has become more serious when it affects the reputation of people, institutions, or brands (Saez-Trumper, 2019). However, with Wikidata receiving around 10 edits *(a.k.a*

July 28-30, 2025

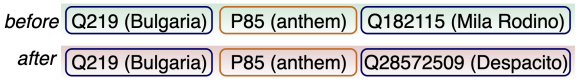

Figure 2: Example of a revision (ID: 593195479) vandalizing the Wikidata entry for Bulgaria. Original triple IDs are mapped to their corresponding English labels.

revisions) per second,[1] it becomes difficult for the human vandalism *patrollers* to analyze every single edit. Therefore, several methods have been proposed to assist the community in this task by using machine learning models. In fact, in 2016, the Wikimedia Foundation developed a system named ORES that is currently supporting the vandalism detection work on Wikidata. Unfortunately, the current ORES model is limited to certain types of edits and entities, and it cannot deal with the complexity of the different data types and topics coexisting in Wikidata.

This paper introduces a new generation model for detecting vandalism in Wikidata that can deal with the aforementioned complexities. A key aspect of the proposed solution is transforming all content changes, including structured data, into their textual equivalents (*Graph2Text*). This approach allows the processing of all types of content changes by transforming them into text and using a single language model that takes advantage of the rich semantic knowledge embedded within it.

The main contributions of this work are: *(i)* The next-generation vandalism detection system for Wikidata, utilizing multilingual language models to improve accuracy and fairness compared to the current production model; *(ii)* System productionalization addressing limitations imposed by resource-constrained infrastructure and product requirements; *(iii)* The publication of a new open benchmark dataset for vandalism detection in Wikidata, containing about 5M unique samples.[2]

2 Related work

2.1 Vandalism detection in Wikipedia

Vandalism detection in Wikidata is closely related to the same problem in Wikipedia. Both services operate within the Wikimedia Foundation ecosystem, share similar editing mechanisms, and have many common users (Sarabadani et al., 2017). Initial research on Wikipedia vandalism detection systems appeared much earlier and laid the groundwork for similar tools in Wikidata.

Early models for Wikipedia vandalism detection were binary classifiers that used generic features, such as the ratio of uppercase letters and term frequency (Potthast et al., 2008). Later studies also explored the relationship between editing behavior, editors' characteristics, link structure, and article quality on Wikipedia (Ruprechter et al., 2020). The most recent work proposed a vandalism detection model for Wikipedia utilizing advanced content change features based on transformer models (Trokhymovych et al., 2023).

Additionally, investigations into vandalism detection on other open-source platforms like Freebase and OpenStreetMap, which analyzed vandalism patterns and proposed various detection approaches, provide valuable insights applicable to our work due to the shared similarities among these platforms (Tan et al., 2014; Neis et al., 2012).

2.2 Vandalism detection in Wikidata

With the launch of Wikidata in 2012, it quickly became one of the most edited projects within the Wikimedia Foundation ecosystem (Vrandečić and Krötzsch, 2014). As with any open-knowledge project, maintaining the content reliable and verifiable has been a challenge. The first research addressing this issue emerged, introducing WDVC-2015, a corpus designed for detecting vandalism based on the entire revision history up to that point (Heindorf et al., 2015). This corpus facilitated the understanding of vandalism patterns on Wikidata and provided a foundation for developing automatic vandalism detection models.

Subsequently, several approaches have been published, introducing revision classifiers to determine whether specific revisions include vandalism. These approaches employed machine learning, using features from both an edit's content and its context (Heindorf et al., 2016; Sarabadani et al., 2017). One of these solutions, WDVD, proposed a model based on an extensive set of 47 content and user features, utilizing the random forest algorithm (Heindorf et al., 2016). Later, the Wikimedia research team introduced the ORES model, designed to function effectively in real-world applications with a much smaller feature set. This feature set was primarily established through community consultations and reflected the key concerns of Wikidata patrollers (Sarabadani et al., 2017).

Morover, the Wikidata Vandalism Detection

[1] https://stats.wikimedia.org/
[2] https://zenodo.org/records/15492678

Task at the WSDM Cup 2017 (Heindorf et al., 2017) introduced a new dataset and received five software submissions, contributing significantly to advancements in the field (Yu et al., 2017; Zhu et al., 2017; Yamazaki et al., 2017; Grigorev, 2017; Crescenzi et al., 2017).

2.3 Bias in vandalism detection

Even though the Wikipedia community is generally open to anyone, editors need specific skills and an understanding of community rules, which poses a challenge for newcomers. Previous research has shown that newcomer retention in Wikimedia projects is significantly affected by the reversion of their edits (Halfaker et al., 2013; Schneider et al., 2014). While newcomers and anonymous users are statistically more prone to mistakes, a biased model that unfairly cancels their edits could result in a long-term decline in the number of editors.

One of the primary reasons for this issue is that earlier models primarily relied on user characteristics and revision metadata, using a very modest set of features to characterize actual content changes. Recent advancements in Wikipedia vandalism detection models have shown that enhancing content change processing can both improve model performance and make the system fairer for anonymous users (Trokhymovych et al., 2023).

Similar to previous research, our focus is on processing content changes to enhance the predictive power of content features and reduce model bias. For evaluation, we employ group fairness metrics such as Disparate Impact Ratio (DIR) and the difference in AUC between privileged and unprivileged user groups (Bellamy et al., 2018).

3 System design

3.1 Design requirements

First, our main goal is to determine if a specific Wikidata edit is vandalism. We frame this as a binary classification problem. In practice, the probability score is often more important than binary prediction, as it enables the prioritization of tasks for patrollers or the automatic reversion of changes by applying stricter thresholds.[3]

Second, we aim to develop a single multilingual model that can process various types of content modifications (e.g., inserts, removes, changes). While Wikidata is largely language agnostic, it includes crucial elements like labels and descriptions that can appear in multiple languages for each record. Single multilingual model allows to extend the range of content edits that the model can effectively handle and reduce the infrastructure costs associated with maintaining multiple models for different content types and languages.

Third, the system requires to be efficient enough to handle a high volume of edits in a production environment. Wikidata receives about 10 edits per second, and our model should be capable of processing all of them. We also aim to develop a system that can operate with the existing resources on the Wikimedia ML Infrastructure, called LiftWing,[4] that currently[5] has no GPU acceleration for inference. This high edit frequency and focus on CPU-based models rule out most LLMs.

Finally, the system must not cause undue harm to good-faith editors. Past work has shown that reverting edits by newcomers can deter new contributors (TeBlunthuis et al., 2018). It is important that any deployed model does not unfairly target these newer editors.

3.2 Architecture overview

Our proposed system receives Wikidata revisions as input and returns a revert-risk score, indicating the probability of a given revision being reverted. The system mainly consists of three main logical steps: *(i)* features preparation; *(ii)* multilingual language model classifier for content processing; *(iii)* final classification model to aggregate content and revision meta-features. The full system schema is presented in Figure 3.

3.2.1 Feature processing

Wikidata entity's content is represented in a complex nested structure of dictionaries and lists. Consequently, parsing content modifications can be quite challenging, as these modifications may involve structural changes (e.g., converting a single value to a list), value edits across various entities (e.g., text in different languages, numerical values, dates), and different types of content modifications (e.g., insertions, deletions, changes). Therefore, feature preparation is a critical component of the system we present.

We distinguish three main types of features. The first type is *revision metadata*, which includes fea-

[3] See https://www.mediawiki.org/wiki/Moderator_Tools/Automoderator for an example from Wikipedia.

[4] LiftWing: https://wikitech.wikimedia.org/wiki/Machine_Learning/LiftWing

[5] As of March 1, 2025, this fact is valid.

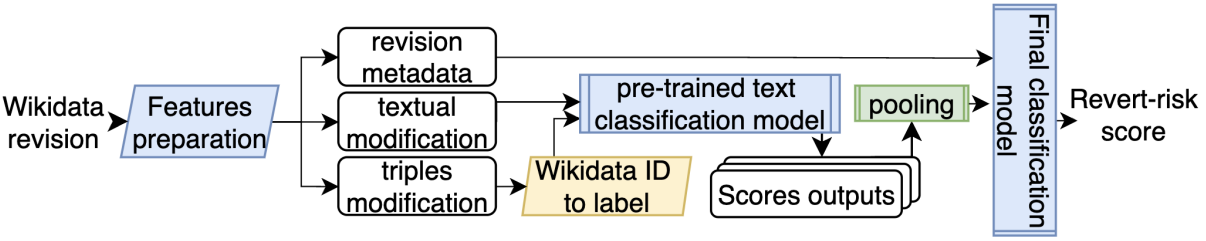

Figure 3: Wikidata vandalism detection system schema.

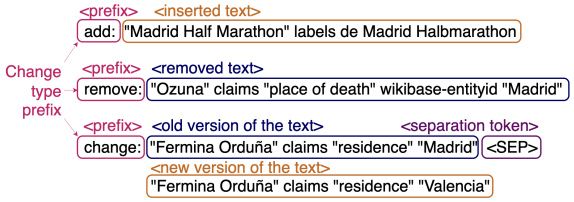

Figure 4: Text processing schema.

tures that require no additional processing and can be used directly in the final classification model (e.g., editor account creation date, time since previous revision, etc.).

Despite Wikidata's general language-agnostic nature, its entities have textual characteristics of any language. The second feature type represents Wikidata *textual modifications*, which refer to changes in elements such as entity labels, descriptions, or aliases.

The third feature group is *triples modification*. Wikidata triples are composed of three parts: the entity, the property, and the value. The entity and property are represented by their corresponding Wikidata IDs. The value can also be represented by an ID, but it may also be free text, a date, a numeric value, etc. To process this content together with textual changes, we convert the triples into text by mapping the IDs to their corresponding English labels.

It is important to note that both *textual* and *triples modification* can be of different types, such as insert, remove, and change. To process these modifications using a single language model (LM), we prepend a corresponding prefix text to the input sequence (see Figure 4), inspired by the "text-to-text" used in the T5 model (Raffel et al., 2019). This approach allows the LM to distinguish between different types of edits.

3.2.2 Language model classifier

To process content changes, specifically the previously discussed *textual* and *triples modification*, we fine-tune a single multilingual language model for binary classification tasks. Following the experience of a similar model for Wikipedia, we utilize the *bert-base-multilingual-cased*, which was pretrained with approximately 100 languages with the largest presence on Wikipedia (Trokhymovych et al., 2023; Devlin et al., 2019). Each revision may include multiple individual content changes of different types (e.g., a single revision might modify both a description and a factual triplet). During training, each of these changes is treated as an independent sample with the label of the revision. While inference, each of changes is independently processed by the language model classifier (LMC), with the following aggregation using mean pooling.

3.2.3 Final classification model

For the final classification step, we utilize the CatBoost classifier (Dorogush et al., 2017). This model is trained using both the *revision metadata* and the aggregated LMC outputs. The CatBoost classifier then generates a probability score indicating the likelihood of a revision being reverted. Details about the hyperparameters and computational resources can be found in Appendix A.

3.3 Deployment details

The complete system includes the extraction of the content using the Wikimedia API, feature engineering, and final model prediction. The inference pipeline is standardized and published under an open license in a dedicated repository of similar tools.[6] Additional testing with editors and community discussion would still be required prior to deployment.

4 Data preparation

Initially, we collect metadata for all human-created Wikidata revisions between September 1, 2021, and September 1, 2023. It includes information about

[6] https://gitlab.wikimedia.org/repos/research/knowledge_integrity

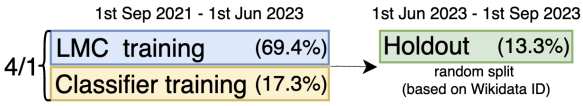

Figure 5: Data splitting logic.

the Wikidata record, the user who performed the change, and specifics of the individual edit. To ensure that the revisions are human-created, we filter for revisions tagged with *Wikidata user interface*. Also, to improve data quality and reduce the noise in the revert signal, which we use as an indicator of vandalism, we additionally filter out several types of revisions (e.g., *self-reverts* and revisions involved in *"edit wars"*).

Wikidata entity's content is saved in the form of JSON. We extract the content for both the current and previous (parent) revisions and then compare them to identify differences. In particular, we employ Deepdiff[7] to extract the fine-grained signals from content modifications. We parse the content differences, getting features in the form of a list of inserts, removes, and changes. This includes but is not limited to alterations in descriptions, labels, and knowledge triples. Additional data processing details and explanations are included in Appendix B.

We utilize a time-based split to allocate the last three months of collected data as the holdout testing set (see Figure 5). This portion of the dataset is reserved exclusively for the final system evaluation. It ensures that our evaluation strategy represents real-world usage scenarios and helps to avoid time-related anomalies. The remaining data are used to train the components needed for the final system.

As the proposed system consists of multiple related and independently trainable components, we divide the training part into two groups following an 80/20 split, to prevent data leakage during training. The larger portion is used for the LMC, and the smaller for the final classifier. Final dataset characteristics details are presented in Appendix C.

5 Evaluation

5.1 Baselines

We compare our proposed model with four different baselines. As a dummy baseline, we build a *Rule-based* model that considers all edits done by anonymous editors as vandalism. In addition, we use two strong baseline models based on subsets of the features used in the final model: the *Metadata-based Classifier (MbC)* that uses only metadata features such as user group and age and the *Content-based Classifier (CbC)*, ignores user characteristics and uses only content modification features. Both are classification models constructed with the same methodology described in Section 3.2.3.

Our main reference model is ORES, the current production model for vandalism detection. This model mainly relies on metadata and includes some basic content features, such as binary indicators for changes in gender, date of birth, or English labels, to detect common vandalism patterns. We compare ORES and the previously mentioned baselines with our proposed system, *Graph2Text*, which integrates advanced content modification features based on the language model, along with revision metadata features and user characteristics.

[7] https://github.com/seperman/deepdiff

Table 1: System performance on holdout testing set.

Model	AUC	CI	FR@99	FR@90	FR@70
Rule-based	0.760	[0.74, 0.78]	0.0	0.0	0.92
ORES	0.859	[0.84, 0.87]	0.45	0.88	0.94
MbC	0.880	[0.87, 0.89]	0.55	0.89	0.94
CbC	0.876	[0.86, 0.89]	0.60	0.82	0.93
Graph2Text	**0.924**	[0.91, 0.93]	**0.71**	**0.91**	**0.96**

5.2 System performance

The primary metric we use for model comparison is the Area under the ROC curve, the AUC score. The AUC score can be interpreted as the probability that the model assigns a higher score to a random positive example than to a random negative example. Also, we compute confidence intervals (CI) for our main metric using bootstrapping (see details in Appendix D) (Efron and Tibshirani, 1994).

Additionally, we employ a Filter Rate at the recall level (FR@) as suggested in previous work (Sarabadani et al., 2017). This metric measures the proportion of edits that can be removed from Wikidata patrollers reviewing backlog, with all the remaining revisions containing a specific percentage of all vandalism.

The results of our evaluation are summarized in Table 1. Our system, *Graph2Text*, significantly outperforms all other models across all metrics. Additionally, we observe that incorporating content features significantly improves the metrics compared to the *MbC*, just as adding user features enhances the *CbC*. Notably, the *CbC*, which uses only advanced content features without user characteristics, performs comparably to the *MbC*. This marks

Table 2: System performance on expert-labeled data.

Model	AUC	CI	FR@99	FR90	FR70
ORES	0.885	[0.879, 0.892]	0.593	0.799	0.881
Graph2Text	**0.932**	[0.926, 0.937]	**0.698**	**0.846**	**0.918**

Table 3: System fairness based on holdout testing set.

Model	DIR^{anon}	$DAUC^{anon}$	DIR^{new}	$DAUC^{new}$
ORES	5.69	0.035	1.37	-0.193
MbC	4.09	0.097	1.15	-0.155
CbC	**2.07**	-0.04	**1.08**	**-0.027**
Graph2Text	4.43	**-0.01**	1.24	-0.096

a significant advancement compared to previous approaches, where such performance was impossible without user characteristics. The performance based at FR99 indicates that with *Graph2Text* (compared to ORES), patrollers will need to analyze nearly half as many revisions to detect 99% of all vandalized samples (29% vs. 55%). Additional experiments, including performance evaluations for various prediction thresholds and use cases, are presented in Appendix E.

5.3 Expert evaluation

In practice, the holdout dataset, based on community-generated data, may include revisions that have not yet been reverted or were mistakenly reverted. To enhance the validity of our evaluation, we created a subsample of 1,000 revisions for expert labeling. We divided the holdout dataset into ten bins based on scores from the ORES and *Graph2Text* models separately. For each model and bin, we randomly selected fifty revisions without replacement. An experienced editor labeled these revisions as *Keep*, *Revert*, or *Not Sure*. Revisions labeled *Not Sure* were excluded from the final evaluation, resulting in 755 labeled revisions. The evaluation results, shown in Table 2, demonstrate that consistent with the performance evaluation using community-generated labels as the ground truth, the *Graph2Text* model significantly outperforms ORES on the expert-labeled data.

5.4 Fairness evaluation

Anonymous user's edits tend to have a higher likelihood of being vandalized compared to those by registered users, primarily due to factors such as a lack of experience in editing pages or intentional identity hiding for committing vandalism. The same situation applies to newly registered users. Nevertheless, it is unacceptable for the model to discriminate based on this characteristic. On the contrary, Wikidata encourages the participation of newcomer editors.

To evaluate bias against anonymous users and new editors, we use two metrics: the Disparate Impact Ratio (DIR) and the Difference in AUC score (DAUC). For more details, please refer to Appendix D. In particular, the closer DAUC is to 0, the better. We compare these metrics for anonymous versus registered users and newcomers versus experienced users among the registered group. Table 3 summarizes the results of our evaluations.

Our analysis shows that our proposed model has lower DIR^{anon} and DIR^{new} values, indicating fairer treatment of anonymous and new users compared to ORES. Moreover, the difference in AUC scores between anonymous and registered users is significantly smaller, suggesting our model performs more consistently across these groups.

Although the proposed Graph2Text model demonstrates improved performance over the current ORES system, the CbC baseline, which disregards user attributes, achieves the highest fairness scores. However, our objective is to balance both predictive performance and fairness, while also maintaining applicability in scenarios where content features are not available. Consequently, we selected Graph2Text as our final model.

6 Discussion

To sum up, we present a study focused on developing a new generation of systems for detecting vandalism on Wikidata. The key innovation of the presented approach is the use of a single multilingual language model, which enables the processing of content changes in both structured and unstructured components in multiple languages. We demonstrate that the proposed system significantly outperforms the current production model in terms of both performance and fairness.

In this paper, we cover all the crucial steps needed to build a production-ready system, including the definition of design requirements, data collection and processing, feature engineering, model training, and evaluation.

Finally, we created a new dataset capturing changes made to the Wikidata platform over a two-year period. In addition to metadata, the dataset includes detailed content edits, represented by fine-grained differences between two versions of Wiki-

data items. We published the dataset and the code[8] under an open license to enable further research in this area.

6.1 Limitations

When interpreting the results, it's important to recognize several limitations of this study. First, the data preparation process can be improved by expanding parsing coverage, such as including changes in qualifiers or rankings. Also, using labels in non-English languages for mapping Wikidata IDs to text may enhance model performance by increasing coverage and diversifying the data.

Although the language model we fine-tuned was initially trained with about 100 languages, it still doesn't cover all of the 300+ languages represented in Wikidata. Considering these factors, we conclude that there are still issues with language diversity. Furthermore, we tested only one language model for our task. We believe that experimenting with more language models could improve the system's performance, which we leave for future research.

6.2 Ethical considerations

We introduce a new dataset designed to train models to predict the risk of reverts in Wikidata changes. The dataset includes metadata about revisions and editors but ensures the protection of Wikidata editors' privacy by not including any private or personally identifiable information.

We use crowd-sourced targets, which can include bias and noise, but we address this by filtering the data to minimize noise and clean the dataset. Moreover, we evaluate the system using the subsample labeled by experts. We also evaluate model fairness and ensure we reduce bias against anonymous users.

The intended use of the model is to detect vandalism edits in Wikidata. One of the risks we care about is over-reliance on automated detection. However, the presented system includes human-in-the-loop by design, meaning human moderators retain final decision-making control while receiving enhanced assistance.

Language models can perform differently across languages (Cotterell et al., 2018). Consequently, there is a potential risk that our system may have worse performance for underrepresented languages. To address this concern, we conducted additional experiments to verify that our system significantly outperforms alternatives on both revisions with English and non-English textual content (see Appendix Section E.2).

Another potential risk of our approach is adversarial exploitation, as open access to the code and dataset could enable bad actors to design edits that bypass detection. However, we select this transparency to promote trust, accelerate further research, and enable the community to review, audit, and improve the system.

A Modeling details

To process content changes we utilize the *bert-base-multilingual-cased*[9] (∼178M parameters). We fine-tune the model for five epochs with an initial learning rate of $2e^{-5}$ and a weight decay of 0.01. The batch size during training is set to 8. We reserve random 5% of the training data as the validation set. Throughout the training process, we track the loss and select the checkpoint from the epoch where the model performs best on the validation data as the final model. Training the model requires approximately 30 GPU hours (1x AMD Radeon Pro WX 9100 16GB GPU). The choice of hyperparameter values was guided by previous approaches using similar models that have demonstrated strong performance (Trokhymovych et al., 2023).

As for the final classification model, which aggregates all the revision meta-features and outputs of LMC, we use the CatBoost classifier. We train it with 2500 iterations, a learning rate of 0.005, and a parameter selection strategy that determines the final model weights based on the iteration, achieving the best loss on the validation dataset.

B Data preparation

B.1 Data sources

Our dataset construction process involves extracting data from multiple sources within the Wikimedia Data Lake.[10] In particular, we are utilizing the *mediawiki history* table to collect metadata for all human-created Wikidata revisions and *mediawiki wikitext history* table to get the Wikidata entity's content in the form of JSON. The mentioned data is available under an open license. Also, given the rarity of reverts, the initial dataset is highly imbalanced. To address this issue, we balance the dataset by retaining all reverted revisions and supplementing them with a random sample of unreverted revisions at a ratio of 1:5. The collected and processed dataset is published under an open license on the Zenodo platform to support further research.

B.2 Data filtering

To improve data quality and reduce the noise in the revert signal, which we use as an indicator of vandalism, we apply several filters. Specifically, we filter out *self-reverts*, which are revisions reverted by the same user who created them. These reverts typically occur shortly after the revision's creation and are part of an iterative page editing process. Since self-reverts usually do not indicate vandalism, it is essential to filter them out to avoid falsely marking these cases as potential vandalism. Additionally, inspired by the process proposed in (Trokhymovych et al., 2023), we filter out revisions involved in *"edit wars"*. Edit wars are characterized by sequential revisions that revert one another. In these instances, half of the reverted revisions represent good-faith changes intended to remove vandalism. However, as it is challenging to automatically differentiate between vandalism and good-faith changes, we eliminate all such revisions to reduce noise. Overall, these two filters removed about 57.7% of all revisions initially labeled as "reverted".

B.3 Content processing

Content changes to Wikidata items include alterations in descriptions, labels, and knowledge triples (see examples in Figure 6). To leverage a single language model (LM) for processing all content features, we employ specific data preparation techniques. Textual changes, such as descriptions, can be directly fed into the LM. However, graph-based features, such as knowledge triples, require additional processing. To integrate these into the LM, we convert knowledge triples into textual equivalents by mapping Wikidata IDs to their corresponding English labels. For the approximately 9% of IDs that lack corresponding labels (*i.e.* they have just an ID without a human-readable English equivalent), we map them to a default value, "unknown," which also provides a useful signal to the model. Additionally, as detailed earlier in Section 3.2.1, we prepend action-specific prefixes to all the input data. These prefixes supply the LM with context regarding the type of modification being processed.

B.4 Data balancing

We use the separate splits to train each of the components of the final system. This split is done randomly, ensuring that all revisions for a specific Wikidata entity are contained within only one of the datasets. This approach is designed to prevent contextual leakage.

Each training dataset part is further divided into separate training and validation sets. For the content model LMC, we use a random split where

[9] https://huggingface.co/google-bert/bert-base-multilingual-cased

[10] https://wikitech.wikimedia.org/wiki/Analytics/Data_Lake

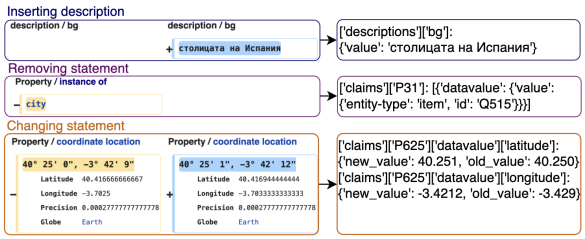

Figure 6: Examples of fine-grained signals extracted from Wikidata content JSON in diverse forms and content types.

5% of the data is allocated for model validation. In contrast, for the final classifier, we employ a time-based split, mirroring the logic of the holdout set, by dedicating all revisions from the last three months for validation.

It is important to note that the obtained datasets are unbalanced. For the LMC model training, we address this imbalance by random downsampling the overrepresented class of non-reverted changes, achieving a completely balanced dataset. For the CatBoost model, we utilize the *class_weights* parameter to adjust the importance of the underrepresented class, increasing its weight according to the level of disproportion.

C Data characteristics

The dataset is divided into two parts: a training set and a hold-out validation set, which is used for the final evaluation presented in Section 5.

The complete dataset contains 4,842,495 revisions spanning 24 months. Key data characteristics are summarized in Table 4. In particular, we report the rate of edits made by anonymous users and the revert rate.

We also analyze the types of modifications made by editors (see Table 5). We found that most revisions involve adding information to a Wikidata entity. This modification type also has the smallest revert rate and the lowest rate of anonymous edits. Revisions that include multiple modification types simultaneously are the most prone to containing vandalism.

It is worth noting that textual changes (modifying Wikidata entity descriptions or labels) in our dataset account for 25% of all revisions and 16.7% of all reverts. While English is the most popular language, it represents only 25% of all textual changes. Other prominent languages in the top 10 include German, French, Spanish, Italian, Russian, Japanese, Swedish, Simplified Chinese, and Dutch, which, along with English, make up 62% of the total. There are about 200 languages represented with at least 100 revisions. Revert rates vary significantly across different languages; for instance, English has a revert rate of 19%, while Swedish has 3.7%.

Table 4: Data characteristics.

Dataset	# of samples	Period	Anon. rate	Revert rate
Training	4,197,231	21 months	10.7%	7.9%
Hold-out	645,264	3 months	8.3%	6.2%

Table 5: Revert rate by modification type.

Type	Revert rate	# of samples	Anon. rate
Insert	11%	4,603,084	7%
Change	29%	1,093,665	24%
Remove	35%	530,317	14%
More than one type	36%	183,570	14%

D Evaluation

D.1 Confidence intervals

To compute confidence intervals for our main metric, we employ a bootstrapping technique (Efron and Tibshirani, 1994). Specifically, we create 10K random samples, each of size 10K, by sampling with replacement. We then calculate the standard deviation of the AUC scores across these 10K bootstrap samples. We report the 5th and 95th percentiles for AUC as the confidence interval (CI).

D.2 Metrics details

For system fairness evaluation, we use the Disparate Impact Ratio (DIR). Equation 1 presents the DIR calculation, where Pr denotes the probability, $\hat{Y}$ is the predicted value, and D represents a group of users. In our setup, registered users are considered the privileged group, while anonymous users and new editors are treated as the unprivileged group.

$$\frac{\Pr(\hat{Y} = 1 \mid D = \text{unprivileged})}{\Pr(\hat{Y} = 1 \mid D = \text{privileged})} \quad (1)$$

E Experiments

E.1 General system performance

As we showed previously in Table 1, our proposed *Graph2Text* system significantly outperforms all other models across all metrics. This is further confirmed by a precision/recall plot (see Figure 7), which shows that our model performs better at any

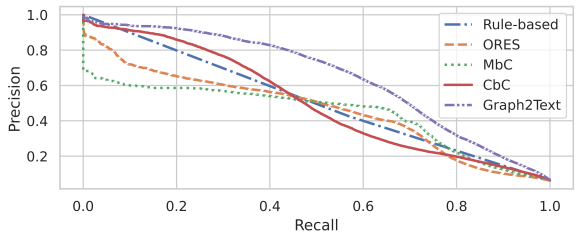

Figure 7: The precision/recall curves for models.

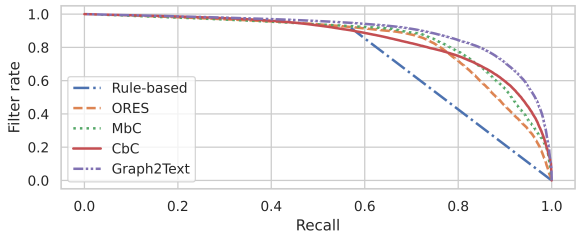

Figure 8: The filter rate/recall curves for models.

threshold. We also support our analysis with a filter rate/recall plot, which highlights the dominance of the presented *Graph2Text* system, especially when a high recall is needed (see Figure 8).

E.2 Use case analysis

Additionally, we analyze how the models perform in different scenarios to understand their strengths and weaknesses and to define steps for future development and improvement.

First of all, we analyze the performance for anonymous users group. Many newcomers begin their editing as anonymous users. Retaining these new users is a priority, as they often transition into active registered editors. Failure to do so could result in a long-term decline in the number of active editors, which could significantly impact the Wikimedia environment in the future. Therefore, incorporating a bias analysis into our model evaluation is an essential step before deploying similar models in real-world contexts.

We present our findings in Figure 9. Specifically, we evaluate the model separately for anonymous and registered users. Our analysis shows that the proposed *Graph2Text* system outperforms the existing ORES model for both groups. Notably, the performance difference is considerably larger for models that include content features when evaluating revisions made by anonymous users.

Wikidata contains pages about various types of entities, but pages about humans receive the most edits, accounting for about 34% of all edits. Furthermore, modifications to human pages are more exposed to vandalism, with a 46% higher revert

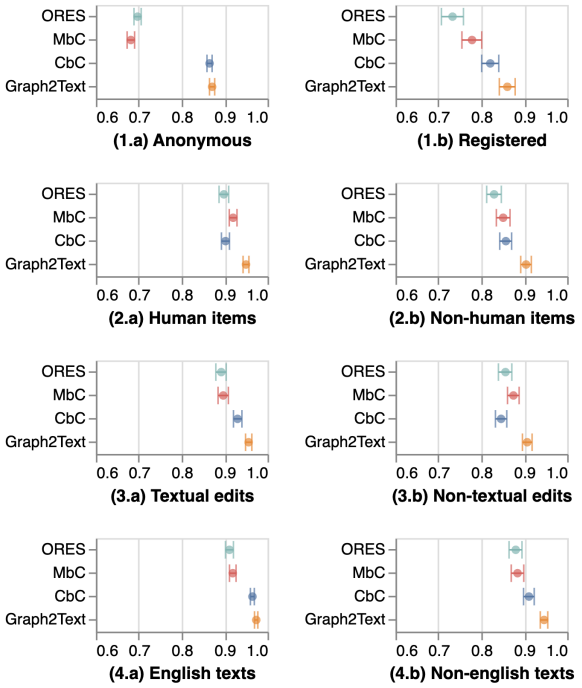

Figure 9: Models performance (AUC) comparison across various Wikidata edit characteristics: (1) Edit source: (a) anonymous, (b) registered users; (2) Entity type: (a) human, (b) non-human; (3) Content type: (a) textual, (b) non-textual; (4) Textual content language: (a) English, (b) non-English.

rate compared to non-human pages. We compared model performance for revisions of human and non-human Wikidata entities and concluded that the proposed system outperforms the current model for both groups. Additionally, all tested systems perform better on revisions of pages about humans.

We have tested model performance on revisions with and without textual changes. As expected, even a basic content model without user features performs significantly better than the current model for handling textual edits. We also compared model performance on English and non-English textual content edits. Our findings indicate that the proposed *Graph2Text* configuration is better for both groups. However, the improvement is significantly greater for English content, suggesting that the largest gains are still within English. At the same time, revisions of non-English content have over double the revert rate, and instances of vandalism persist more than twice as long for this content in Wikidata. This highlights the need to enhance vandalism detection for non-English content in the future.

LOTUS: A Leaderboard for Detailed Image Captioning from Quality to Societal Bias and User Preferences

Abstract

Large Vision-Language Models (LVLMs) have transformed image captioning, shifting from concise captions to detailed descriptions. We introduce LOTUS, a leaderboard for evaluating detailed captions, addressing three main gaps in existing evaluations: lack of standardized criteria, bias-aware assessments, and user preference considerations. LOTUS comprehensively evaluates various aspects, including caption quality (*e.g.*, alignment, descriptiveness), risks (*e.g.*, hallucination), and societal biases (*e.g.*, gender bias) while enabling preference-oriented evaluations by tailoring criteria to diverse user preferences. Our analysis of recent LVLMs reveals no single model excels across all criteria, while correlations emerge between caption detail and bias risks. Preference-oriented evaluations demonstrate that optimal model selection depends on user priorities. [1]

1 Introduction

Image captioning has evolved with Large Vision-Language Models (LVLMs) such as LLaVA (Liu et al., 2024), moving from generating concise captions (Chen et al., 2015) to more *detailed* descriptions (Chen et al., 2024; Liu et al., 2024). This transition, driven by LVLMs' improved ability to follow instructions, enhances visual-semantic understanding and strengthens vision-language applications, including pre-training (Zheng et al., 2024; Liu et al., 2023b).

A crucial challenge in detailed image captioning lies in effectively evaluating the generated captions. Traditional n-gram-based metrics, such as BLEU (Papineni et al., 2002), which are well-suited for concise captions, prove inadequate for assessing detailed descriptions (Chan et al., 2023). This limitation has spurred the development of new evaluations tailored to detailed captions.

However, we argue that current approaches to evaluating detailed captions face challenges:

Lack of a unified evaluation framework. While existing studies tend to target specific dimensions like descriptiveness, alignment, or hallucination detection, there is no overarching, standardized evaluation framework. This fragmentation leads to inconsistent performance assessments across studies, hindering comparability in the field.

Absence of side-effect evaluation. Despite recent findings (Zhang et al., 2024b) showing that LVLMs often exhibit societal *biases* (e.g., gender bias), current evaluation methods largely overlook these biases, raising the risk of perpetuating harmful stereotypes in generated captions.

User preference-agnostic evaluation. The quality of detailed captions is highly subjective, as system preferences vary significantly. While some users favor highly descriptive captions, others prioritize minimizing risks such as hallucinations. This variability poses a challenge for designing a universal metric that accommodates diverse needs.

In this paper, we contribute to establishing a unified leaderboard, LOTUS (unified LeaderbOard to socieTal bias and USer preferences), that overcomes the challenges in existing evaluations. Specifically, LOTUS 1) **comprehensively evaluates various aspects** of detailed captions (Figure 1 (a)), including caption quality-related criteria (*e.g.*, descriptiveness (Chan et al., 2023), alignment (Li et al., 2024)), potential risks (*e.g.*, hallucinations (Jing et al., 2024)), and societal bias (*e.g.*, gender bias (Buolamwini and Gebru, 2018)), enabling diverse, unified model assessments; 2) **supports preference-oriented evaluation** by tailoring criteria to different user preferences (Figure 1 (b)), allowing for customized assessments that better align with diverse user needs.

Leveraging LOTUS's multifaceted and adaptable framework, we evaluate recent LVLMs (Liu et al., 2024; Dai et al., 2023; Chen et al., 2023; Ye

(a) Unified evaluation leaderboard

(b) Preference-oriented evaluation

Figure 1: Overview of the LOTUS leaderboard. LOTUS enables (a) unified evaluation of various aspects of detailed captions, including societal bias, and (b) preference-oriented assessment tailored to different user preferences.

et al., 2024; Wang et al., 2024), uncovering various insights:

- Different models exhibit distinct strengths and weaknesses across various aspects, with no single model consistently performing well across all criteria. For instance, Qwen2-VL (Wang et al., 2024) generates high-quality captions but shows higher risks of hallucination and skin tone bias (Figure 1). This observation highlights the importance of LOTUS's comprehensive evaluation characteristic.
- We discover correlations among evaluation criteria, revealing that models producing more detailed captions tend to have higher risks of specific biases (*e.g.*, skin tone bias) and hallucinations (Figure 2). This finding suggests a potential trade-off between descriptiveness and risk mitigation in caption generation.
- By selecting evaluation criteria based on user preferences, we can accurately reflect what different users value in captions (Figure 1 (b)). For instance, while Qwen2-VL is the best option for users who prioritize caption quality, it is not suitable for those who prefer captions with minimal risks of side effects and social bias. This finding highlights the importance of customized evaluation criteria in addressing the specific needs of diverse users.

2 LOTUS: A Unified Leaderboard for Detailed Captions

As discussed in Section 1, prior work on evaluating detailed captions faces several challenges: 1) lack of a unified evaluation framework, 2) absence of bias-aware evaluation, and 3) user preference-agnostic evaluation. Here, we introduce our proposed leaderboard, LOTUS, which unifies various evaluation criteria (Section 2.1), including societal bias (Section 2.2) and enables preference-oriented evaluation (Section 2.3).

Preliminaries. Let $\mathcal{D} = \{(I, y, a)\}$ denote a test set of the captioning dataset, where I is an image, y is its corresponding ground-truth detailed caption, and a is an optional protected attribute label of the person in the image (*e.g.*, `woman` or `man` for binary gender). Our target task is detailed image captioning: given a prompt[2] p and an image, we use an LVLM M to generate a detailed caption y', *i.e.*, $y' = M(I, p)$.

2.1 Unified and Comprehensive Evaluation

For a comprehensive, multifaceted assessment, LOTUS unifies four main criteria for detailed caption evaluation that have been previously assessed separately: alignment, descriptiveness, language complexity, and side effects. LOTUS incorporates multiple metrics for each criterion to enhance reliability (Naidu et al., 2023). Otherwise stated, the average is computed over $\mathcal{D}$ for each metric. We summarize each **criterion** and its ***metrics***:[3]

Alignment measures how well a caption matches the image content using two metrics: ***CLIPScore*** (Hessel et al., 2021) quantifies the semantic similarity between the image and caption using CLIP embeddings:

$$\text{CLIPScore} = \max(0, \cos(\phi_I(I), \phi_T(y'))) \quad (1)$$

[2]We use "Describe this image in detail." as the prompt.

[3]Detailed metric descriptions are in Appendix E.

where ϕ_I and ϕ_T are CLIP image and text encoders,[4] and $\cos(\cdot,\cdot)$ denotes cosine similarity. ***CapScore*** (Li et al., 2024) prompts GPT-4 to rate a caption based on its similarity to the ground truth (CapScore_S) and alignment (CapScore_A), both ranging from 0 to 1.

Descriptiveness evaluates how detailed a caption is in describing image elements using two metrics: ***CLIP recall*** (Chan et al., 2023) evaluates whether a caption is specific enough to identify its corresponding image. Specifically, CLIPScore is computed between the image I and all generated captions, and Recall@k determines if the correct caption y' appears in the top-k most similar captions. ***Noun and verb coverage*** (Chan et al., 2023) assesses how well a caption y' covers key objects (nouns) and actions (verbs) present in an image by comparing it to the ground-truth y. Noun coverage is calculated as:

$$\text{Noun Coverage} = \frac{|N(y) \cap N(y')|}{|N(y')|} \tag{2}$$

where $N(y')$ is the set of all nouns in y'. Verb coverage is calculated for verbs likewise.

Language complexity (Onoe et al., 2024) evaluates the structural complexity of the sentences and language used in captions. We use the following metrics: ***Syntactic complexity*** measures the maximum depth of the dependency tree (Ohta and Sakai, 2017) of y'. A greater depth indicates a more complex sentence structure. ***Semantic complexity*** is indicated by the number of nodes in a scene graph derived from y' (Spacy, 2024). A higher number of nodes suggests a more detailed representation of objects and attributes within the scene.

Side effects identify negative aspects in captions. We consider two issues: hallucination and harmfulness (*i.e.*, existence of NSFW (Not safe for work) words) for this criterion. We assess hallucination through two methods: ***CHAIR***$_s$ (Rohrbach et al., 2018) quantifies object hallucination by computing the fraction of objects in y' that are not present in the image I:

$$\text{CHAIR}_s = \frac{O_H}{O_T}, \tag{3}$$

where O_H is the number of hallucinated objects, and O_T is the total number of annotated objects. ***FaithScore*** (Jing et al., 2024) evaluates the faithfulness of long captions by breaking down each caption into atomic *facts* that represent specific, verifiable statements about the image content. Let V denote an indicator function of visual entailment (Wang et al., 2022), giving 1 if f is entailed by I, and 0 otherwise. Each atomic fact f_k (*e.g.*, "A man playing baseball") is checked with V to compute FaithScore as:

$$\text{FaithScore} = \frac{1}{K}\sum_{k=1}^{K} V(f_k, I) \tag{4}$$

where K is the total number of facts. Additionally, we employ a sentence-level FaithScore, FaithScore_S, which measures the proportion of sentences in y' that are free from hallucinations.

To evaluate the harmfulness of captions, we examine the ***existence of NSFW words***[5] in y'. Specifically, if y' contains an NSFW word, this metric gives 1 (which is averaged over $\mathcal{D}$).

2.2 Bias-Aware Evaluation

LOTUS not only unifies various criteria but also addresses a critical aspect often overlooked in prior work: societal bias. Following previous works (Zhao et al., 2021; Tang et al., 2021), we examine binary **gender and skin tone biases**.

To measure societal bias, we use a popular and standard way of quantifying bias, ***performance disparity*** (Buolamwini and Gebru, 2018), comparing the performance of the captioning model across different demographic groups. In the case of binary gender bias (*i.e.*, $a \in \{\texttt{woman}, \texttt{man}\}$), we first prepare two separate sets of woman and man images, $\mathcal{D}_{\texttt{woman}}$ and $\mathcal{D}_{\texttt{man}}$:

$$\mathcal{D}_g = \{(I, y, a) \in \mathcal{D} | a = g\}, \tag{5}$$

where $g \in \{\texttt{woman}, \texttt{man}\}$. For each set, we generate detailed captions, obtaining $\mathcal{D}'_g = \{(I, y', a) \mid y' = M(I, p)\}$. The performance disparity is defined as the absolute difference in performance between $\mathcal{D}'_{\texttt{woman}}$ and $\mathcal{D}'_{\texttt{man}}$.[6] We compute performance disparity for each metric in Section 2.1. For skin tone bias, we conduct the same process based on the binary skin tone class (*i.e.*, $a \in \{\texttt{darker-skin}, \texttt{lighter-skin}\}$).

Beyond societal bias, we also investigate **language discrepancy**. We examine how the choice of prompt language affects the model's performance

[4] To handle detailed input captions, we utilize the CLIP variant (Zhang et al., 2024a) capable of processing long text.

[5] We adopt the NSFW word list in (LDNOOBW, 2024).

[6] Note that the average is computed over $\mathcal{D}'_g$.

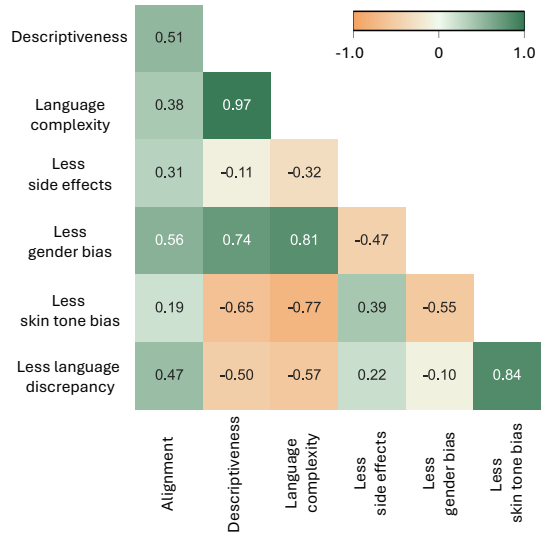

Figure 2: Correlation matrix of evaluation criteria.

across different languages. Let $\mathcal{L}$ be a set of languages. For each language $l \in \mathcal{L}$, we use a prompt[7] p_l in that language to generate captions and evaluate their performance using the same metrics as in Section 2.1. In our experiments, we consider three languages $\mathcal{L} = \{\texttt{English}, \texttt{Japanese}, \texttt{Chinese}\}$. As in societal bias, we define language discrepancy as the performance disparity between the best- and worst-performing languages.

2.3 User Preference-Oriented Evaluation

While our unified criteria offer diverse model evaluations, another benefit is the ability to tailor evaluations to specific user preferences. To achieve this, we categorize user types based on different priorities in captioning as shown Figure 1 (b). For example, a *detail-oriented user* may prioritize metrics that assess descriptiveness, whereas a *risk-conscious user* might emphasize minimizing side effects and societal bias. By selecting criteria that align with these user profiles, our framework provides a prioritized assessment of model performance (*e.g.*, selecting "alignment" and "descriptiveness" for *detail-oriented user*). This preference-oriented approach allows for a more specific evaluation of model performance, demonstrating that tailored criteria can effectively capture the preferences of each user type (Section 3.2).

3 Experiments

Dataset. We evaluate captioning models on the COCO Karpathy test set ($5,000$ images) (Karpathy and Fei-Fei, 2015). For societal bias analysis, we use binary gender and skin tone annotations from (Zhao et al., 2021), sampling images to balance demographic groups (*e.g.*, 6,628 for gender, 2,192 for skin tone). Ground-truth detailed captions are sourced from the Localized Narratives dataset (Pont-Tuset et al., 2020).

Evaluation metrics. We use the evaluation metrics summarized in Section 2.1 and compute the **normalized average score** (N-avg) to summarize each criterion. For each criterion, scores are Min-Max normalized to $[0, 1]$, with inversion applied for metrics where lower is better (*e.g.*, CHAIR). N-avg is then calculated as the mean of normalized scores per criterion, such as CLIPScore and CapScores for alignment. For gender and skin tone biases and language discrepancy, the N-avg score is the mean of normalized performance disparity scores across all metrics.

Captioning models. We evaluate detailed captions from five representative LVLMs: MiniGPT-4 (Chen et al., 2023), InstructBLIP (Dai et al., 2023), LLaVA-1.5 (Liu et al., 2024), mPLUG-Owl2 (Ye et al., 2024), and Qwen2-VL (Wang et al., 2024). To ensure a fair comparison, we use the 7B parameter variant for all models, as this size is commonly available across these models.

3.1 Results on LOTUS

Tables 1 and 2 present the results of the four criteria in Section 2.1 and bias-aware evaluation. Additionally, we visualize the normalized average scores (N-avg in the tables) in Figure 1 (a). The visual examples of the generated captions are shown in Figure 9. The key findings are summarized below:

Models show varied performance across criteria, with no model excelling in all areas. The N-avg scores for each criterion and Figure 1 (a) indicate that models have distinct strengths and weaknesses. For example, Qwen2-VL performs the best on criteria related to caption quality (*i.e.*, alignment, descriptiveness, complexity) but scores relatively lower on side effects (0.46). Also, it shows a strong skin bias tone and language discrepancy, showing the lowest scores for both criteria. Conversely, LLaVA-1.5, while weaker in descriptiveness and complexity, has minimal side effects and skin tone bias, complementing Qwen2-VL. This underscores the value of unified evaluation criteria to reveal each model's unique strengths and weaknesses.

Unexpected trade-offs emerge from criteria cor-

[7]For each language $l \neq \texttt{English}$, we use the prompt "Describe this image in detail in English" translated into l.

Table 1: Unified evaluation of LVLM captioners on LOTUS with CLIPScore (CLIP-S), CapScore (CapS_S, CapS_A), CLIP recall (recall), noun/verb coverage (noun, verb), syntactic and semantic complexities (syn, sem), CHAIR_s (CH_s), FaithScore (FS, FS_s), and existence of NSFW words (harm). Values in **bold** and underline indicate the best and second-best, respectively. All metrics are scaled by 100.

relations. The correlation analysis of our evaluation criteria in Figure 2 reveals several intriguing patterns in LVLM captioner performance:

1. Models with better descriptiveness tend to give less gender bias but more skin tone bias (0.74 and -0.65, respectively). This suggests a potential trade-off between information richness and different aspects of fairness.
2. Side effects have only weak to moderate correlations with other criteria (ranging from -0.47 to 0.39), implying that hallucinations or NSFW content might not significantly impact caption quality or societal bias.
3. Gender bias and skin tone bias show a moderate negative correlation (-0.55), indicating an inverse relationship between these two biases. This highlights the complexity of addressing multiple aspects of fairness simultaneously.
4. Alignment correlates positively with all other criteria, suggesting that improvements in one area often enhance image-caption alignment, though to varying extents.

These findings underscore the intricate interplay between different performance aspects in LVLM captioners, emphasizing the need for a holistic approach to model improvement that considers multiple criteria simultaneously.

Descriptiveness amplifies societal bias trade-offs. To further explore why higher descriptiveness reduces gender bias but amplifies skin tone bias (observations 1 and 3 above), we analyze gender and skin tone representation in captions. For gender bias, we calculate the difference ($|\Delta|$) between the ratio of captions mentioning female-related terms[8] for woman images (recall_F) and male-related terms for man images (recall_M). For skin tone bias, we compare the ratio of captions containing race-related terms[9] for images of individuals with darker skin tones (recall_D) versus lighter skin tones (recall_L). We then examine correlations between $|\Delta|$ values and our descriptiveness and bias scores from Tables 1 and 2 (N-avg).

Table 3 presents the recall values (%) and $|\Delta|$

[8]We use the gender word list in (Hirota et al., 2023).

[9]We use race-related terms defined in (Hirota et al., 2025).

Table 3: Gender and skin tone representations in generated captions. $\text{Rec}_{F/M}$ denotes recall of gender terms for woman/man images. $\text{Rec}_{D/L}$ represents recall of racial terms for darker/lighter skin. $|\Delta|$ is recall disparities.

Model	Gender images			Skin images		
	Rec_F	Rec_M	$\lvert\Delta\rvert$	Rec_D	Rec_L	$\lvert\Delta\rvert$
MiniGPT.	68.0	71.2	3.2	3.0	2.3	0.7
Instruct.	75.3	78.7	3.4	1.1	0.7	0.4
LLaVA.	74.0	80.1	6.1	0.3	0.4	0.1
mPLUG.	77.9	82.0	4.1	0.6	0.6	0.0
Qwen2.	41.0	40.7	0.3	7.0	2.9	4.1

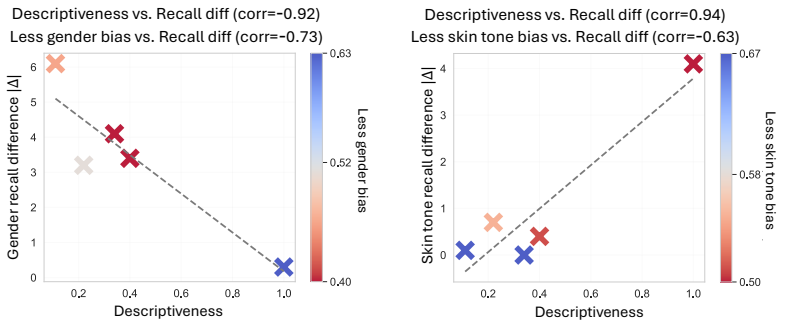

Figure 3: Correlations between descriptiveness, gender/skin tone bias, and Δ. Descriptiveness and gender/skin tone bias are the normalized average scores in Tables 1 and 2 (N-avg).

for gender and skin tone biases, while Figure 3 visualizes the correlations between descriptiveness, gender/skin tone bias scores, and the $|\Delta|$ values. The results indicate that more descriptive models tend to have smaller gender representation disparities (corr $= -0.92$) but larger differences in racial word usage based on skin tone (corr $= 0.94$). We observe strong correlations between these disparities and less gender and skin tone biases (corr $= -0.73$ and -0.63, respectively).

This suggests that as captions become more descriptive, the gender term usage gap between woman and man images narrows, likely because gender tends to be described for both genders (Hirota et al., 2023). Consequently, with increased descriptiveness, models tend to include gender terms regardless of specific gender. For racial attributes, while captioning models generally avoid racial terms, they more frequently describe minoritized groups, such as people of color, than White individuals (Zhao et al., 2021). As descriptiveness rises, racial term usage increases, and due to inherent skin tone bias, this leads to greater disparities in racial term usage for darker-skinned individuals.

3.2 Results for Preference-Oriented Evaluation

As introduced in Section 2.3, our evaluation framework supports assessments tailored to user preferences. To demonstrate this, we consider three user types: 1) **Detail-oriented users** prioritize comprehensive descriptions that cover detailed contents in images (selected criteria: {alignment, descriptiveness}), **Risk-conscious users** seek to minimize risks like hallucinations and biases (selected criteria: {alignment, side effects, gender bias, skin-tone bias}), and 3) **Accuracy-focused users** value fact-based, error-free captions (selected criteria: {alignment, side effects}).

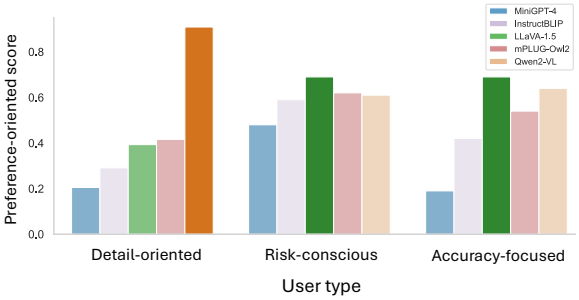

Figure 4: Preference-oriented scores for detail-oriented user (left), risk-conscious user (middle), and accuracy-focused user (right). The best models for each user type are highlighted in darker colors.

In Figure 4, we show the *preference-oriented scores* for each user type, computed by taking the average of the N-avg scores of the selected criteria. The figure demonstrates that the performance of models greatly varies depending on user preferences. For *detail-oriented user*, Qwen2-VL can be the best option, presenting much higher scores than the other models. However, for the users who focus on the risks (*i.e.*, *risk-conscious user*), LLaVA-1.5 might be the most suitable to reduce the risks of generating captions with hallucinations, NSFW words, and societal bias. Similarly, LLaVA-1.5 also performs best for the *accuracy-focused user*, indicating its strength in producing reliable and precise captions. These results highlight that LVLM captioning models should be chosen based on specific user needs, not a universal approach. [10]

4 Related Work

Detailed image captioning. Recent advancements in LVLMs have significantly enhanced mul-

[10] In Appendix B, we validate whether our preference-oriented evaluation accurately reflects real users' preferences through LLM agent-simulated analysis.

timodal understanding (Liu et al., 2024; Ye et al., 2024). Techniques like visual instruction tuning (Liu et al., 2023a), which combines visual inputs with textual guidance during training, enable LVLMs to effectively follow user instructions. Leveraging these advancements, recent research (Chen et al., 2024; Lai et al., 2023) has explored generating detailed image descriptions to improve alignment and utility for downstream tasks. For instance, Zheng et al. (2024) proposed a pipeline using detailed captions from LVLMs (*i.e.*, LLaVA-1.5 (Liu et al., 2024)) for pre-training, boosting the performance of CLIP (Radford et al., 2021).

Evaluation for detailed captions. A critical challenge in detailed image captioning is evaluating generated captions. Conventional metrics like CIDEr (Vedantam et al., 2015) are inadequate for assessing detailed captions (Chan et al., 2023), prompting researchers to develop new methods. For example, Chan et al. (2023) proposed measuring noun and verb coverage by comparing these elements in generated and ground-truth captions.

However, as discussed in Section 1, existing works lack a unified evaluation framework and often overlook societal biases. To address these limitations, we propose LOTUS, a unified evaluation leaderboard for detailed captions. LOTUS provides a comprehensive assessment across multiple dimensions, including previously underexplored areas such as gender and skin tone bias.

5 Conclusion

We introduced LOTUS, a unified leaderboard for evaluating detailed captions from LVLMs. Our analysis uncovered insights unexplored in the existing literature: a trade-off between caption descriptiveness and bias risks, and the impact of user preferences on optimal model selection. LOTUS paves the way for detailed captioning models that holistically optimize performance, mitigate societal biases, and adapt to diverse user preferences.

Ethical Considerations

LOTUS integrates the evaluation of societal biases, including gender, skin tone, and language bias, emphasizing the ethical considerations central to LVLM development. However, it is important to recognize that LOTUS does not capture all potential societal biases, and its scores should not be viewed as a comprehensive measure of a model's bias.

For instance, researchers and practitioners must exercise caution when interpreting LOTUS scores. A favorable score does not imply that a model is free of bias. LOTUS should be seen as one of several tools for evaluating LVLMs, rather than a definitive measure of ethical integrity.

The definition and assessment of bias can vary significantly depending on the context. While LOTUS provides a standardized approach, it may not be universally applicable. We encourage users to critically assess its relevance to their specific use cases and to complement LOTUS with additional bias evaluation methods when appropriate. In sum, by acknowledging these limitations, we advocate for a more nuanced and holistic approach to addressing societal biases in LVLMs, fostering the responsible and ethical development of these technologies.

Fairness recommendations. While we categorized different user types and validated that our user-oriented evaluation can meet the user needs for each type in Section 3.2, we recommend that fairness criteria (*i.e.*, gender and skin tone biases) be considered for all users. Recent works (Zhao et al., 2021; Hirota et al., 2023; Burns et al., 2018; Garcia et al., 2023; Hirota et al., 2022) have demonstrated that image captioning models can perpetuate or amplify societal bias in training datasets, resulting in harmful descriptions for minoritized demographic groups. To mitigate such risks, we emphasize the importance of incorporating fairness criteria into caption evaluation.

Use of binary gender and skin tone categories. In our study, we employed a binary approach to evaluate gender and skin tone biases, classifying gender as female/male and skin tone as darker/lighter, in line with prior work (Zhao et al., 2017; Burns et al., 2018; Wang et al., 2019; Zhao et al., 2023, 2021; Hirota et al., 2024). While this approach addresses bias to some extent, we acknowledge its limitations in reflecting the complexity of real-world diversity. As more comprehensive data becomes available, future research will aim to incorporate non-binary gender categories and more nuanced skin tone classifications.

A Detailed Experimental Settings

In this section, we provide the details of the experiments.

A.1 LLM-agent based evaluation

In Section 3.2, we conduct an experiment to validate whether our preference-oriented scores accurately reflect real users' preferences. For this experiment, we rely on GPT-4o instead of human workers, simulating humans. Specifically, we give an instruction prompt to simulate a specific user type and rate the generated caption based on the specified user type. The simulated prompts for each user type are shown in Figure 5. Using these prompts, we compute the simulated user scores (*i.e.*, answers to the question "How well does this caption meet your expectations for describing the image?", rating from 1 to 10). Then, we take an average over the dataset.

A.2 Instruct prompts for LVLMs

The prompts to generate detailed captions, including the ones written in English, Japanese, and Chinese, are presented in Figure 6.

B User-Simulation

How well do our preference-oriented scores match real users' preferences? While our preference-oriented evaluation offers valuable insights, it is essential to validate whether our scoring system accurately reflects real users' preferences. To this end, we use GPT-4o to simulate real user feedback based on recent findings on language models' ability to simulate human responses (Chiang and Lee, 2023), addressing the challenges of recruiting a large, diverse user base.

Figure 8 depicts our evaluation pipeline. We first instruct GPT-4o to simulate specific user types using prompts that reflect each user type's preferences, then rate captions on a 1-10 scale (refer to the simulated user prompt in Figure 8). For example, a prompt for the risk-conscious user focuses on minimizing potential risks in captions. We compare these simulated user scores with our preference-oriented scores to assess the alignment between our framework and simulated user preferences.

Figure 7 presents high correlations between the simulated user scores and our preference-oriented scores (*e.g.*, for risk-conscious users, corr $= 0.84$ between simulated scores and preference-oriented scores). These results indicate that tailored sets of criteria are well-aligned with what actual users would likely prioritize in generated captions.

C Visual examples

Figure 9 shows examples of the generated captions by MiniGPT-4, InstructBLIP, LLaVA-1.5, mPLUG-Owl2, and Qwen2-VL. This figure demonstrates the characteristics of each model. For example, Qwen2-VL gives more detailed and informative sentences compared to the other models, which is consistent with the results in LOTUS (*i.e.*, Qwen2-VL has the best scores for *descriptiveness*). However, only Qwen2-VL contains a race-related word "India" in the first sentence, which cannot be guessed from this image. Based on our evaluation of the relationship between skin tone bias and the existence of race-related terms, this observation can further validate the experimental results on LOTUS, where Qwen2-VL shows the worst score for skin tone bias.

D LOTUS leaderboard

In Figures 10 and 11, we show the actual pages of our LOTUS leaderboard for the unified evaluation (Figure 10) and bias-aware evaluation (Figure 11). The link to the leaderboard is `https://lotus-vlm.github.io/` (anonymized).

E Detailed Explanation of the Evaluation Metrics

In this section, we provide detailed explanations of the metrics used in LOTUS.

CapScore. (Li et al., 2024) Leveraging the ability of GPT-4 to understand and comprehend the long input texts, CapScore utilizes GPT-4 to rate a generated caption. We show the prompt to give GPT-4, evaluating the generated captions in the two criteria (CapScore$_S$ and CapSocre$_A$):

> Can you evaluate the following generated caption based on two metrics:
>
> 1. Similarity to the ground truth caption: How closely does the generated caption match the ground truth in content and meaning? Provide a score between 0 and 1 (two decimal places).
>
> 2. Absence of hallucinations and misalignments: Does the generated caption avoid incorrect information not present in the ground truth?

Detail-oriented user

You are a Detail-oriented user. You value captions that provide accurate and comprehensive descriptions, covering all aspects of an image thoroughly. You appreciate detailed captions that include as many relevant elements as possible, such as objects, people, actions, and settings.
Please evaluate the following Generated caption based on the following question, rating from 1 to 10:
How well does this caption meet your expectations for describing the image?
You can refer to the Ground truth caption to check the contents of the image. No additional text in the output.
Ground truth caption: {ground-truth caption}
Generated caption: {generated caption}

Risk-conscious user

You are a Risk-conscious user. You focus on minimizing potential risks in captions, such as NSFW content, information not directly observable in the image, and descriptions with societal bias. You value captions that strictly align with what can be verified in the image and avoid adding any speculative details. Captions should be factually accurate, and free from additional assumptions or unnecessary elaboration.
Please evaluate the following Generated caption based on the following question, rating from 1 to 10:
How well does this caption meet your expectations for describing the image?
You can refer to the Ground truth caption to check the contents of the image. No additional text in the output.
Ground truth caption: {ground-truth caption}
Generated caption: {generated caption}

Accuracy-focused user

You are a Accuracy-focused user. You prioritize the factual correctness and quality of the captions and expect them to strictly align with the actual content of the image. You value precise and reliable descriptions, with minimal errors or assumptions. Captions should be high-quality, factually accurate, and free from additional assumptions or unnecessary elaboration.
Please evaluate the following Generated caption based on the following question, rating from 1 to 10:
How well does this caption meet your expectations for describing the image?
You can refer to the Ground truth caption to check the contents of the image. No additional text in the output.
Ground truth caption: {ground-truth caption}
Generated caption: {generated caption}

Figure 5: Simulated user prompts for each user type.

Provide a score between 0 and 1 (two decimal places). Please output only the two scores separated by a semicolon in the format 'similarity score;hallucination score'. No additional text in the output.

Ground truth caption: {ground-truth caption}

Generated caption: {generated caption}

We compute the average of the scores from the two questions across the test set, obtaining the final CapScore.

CLIP Recall (Chan et al., 2023) is a metric that evaluates how well a generated caption uniquely identifies its corresponding image by checking if the correct caption is within the top 5 closest matches when comparing the image embedding to the caption embeddings. This metric helps determine if the caption includes enough distinctive details to set its image apart from others.

For each image I_i, we use CLIP to generate an embedding $\mathbf{I}_i$ that represents the image. We also generate embeddings for the generated captions associated with this image and other images. Then, we check whether the caption embedding $\mathbf{Y}_i$ of the correct caption appears in the top-5 closest caption embeddings based on similarity to $\mathbf{I}_i$. The Recall@5 over a dataset of n images is CLIP Recall:

$$\text{CLIP Recall} = \frac{1}{n}\sum_{i=1}^{n} \mathbb{1}\left(\mathbf{Y}_i \in \text{Top } 5(\mathbf{I}_i)\right), \quad (6)$$

where Top $5(\mathbf{I}_i)$ represents the set of the top 5 closest caption embeddings to the image embedding $\mathbf{I}_i$, and $\mathbb{1}$ is an indicator function that returns 1 if $\mathbf{Y}_i$ is among the top 5 closest captions to $\mathbf{I}_i$ and 0 otherwise.

A higher CLIP Recall score implies that the captions effectively reflect image content in a way that allows accurate identification, which is particularly useful for tasks requiring captions that are detailed and distinct.

Noun/verb coverage (Chan et al., 2023) is a metric used to evaluate how thoroughly a generated caption describes an image by focusing on the nouns and verbs present in the text. The coverage is determined by comparing the nouns and verbs in

- English: “Describe this image in detail.”
- Japanese: “この画像を英語で詳しく説明してください。”
- Chinese: “请用英语详细描述这张图片。”

Figure 6: The prompts to generate detailed captions, written in English, Japanese, and Chinese. The prompts written in Japanese and Chinese mean “Describe this image in detail in English.”, and are used for the *language discrepancy* evaluation.

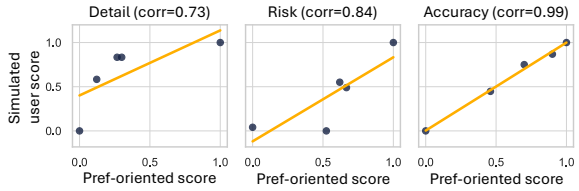

Figure 7: Preference-oriented score vs. simulated user score.

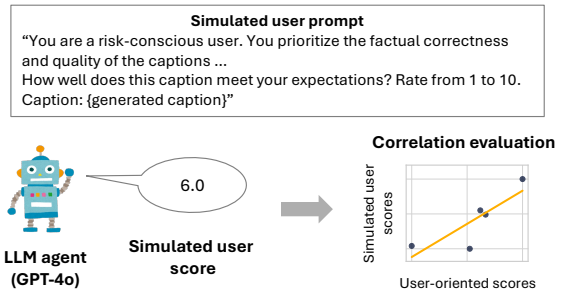

Figure 8: Correlation analysis between preference-oriented scores and user-simulated scores. Full prompts are provided in Appendix A.

the caption with those in reference captions, assessing whether the caption captures essential objects and actions depicted in the image.

Noun coverage counts the nouns in a caption that match exactly with those in the set of reference captions (*i.e.*, we use COCO captions for the reference captions) for the same image. This is done as follows:

$$\text{Noun Coverage} = \frac{1}{\left|\bigcup_{j=1}^{n} N(R_j^i)\right|} \times \sum_{k \in N(C_i)} \mathbb{1}\left(k \in \bigcup_{j=1}^{n} N(R_j^i)\right) \tag{7}$$

where $N(y_i')$ is the set of nouns in the generated caption y_i', and $N(r_j^i)$ represents the set of nouns in the j-th reference caption for image I_i, and $\mathbb{1}$ is an indicator function that returns 1 if the noun k is present in any reference caption's noun set $\bigcup_{j=1}^{n} N(R_j^i)$, and 0 otherwise.

Verb coverage is calculated similarly, using verbs instead of nouns. The exact match method strictly requires the same words to appear in both the generated and reference captions.

Syntactic complexity (Onoe et al., 2024) measures the structural depth of sentences within the descriptions, specifically by examining the maximum depth of the dependency tree for each sentence (Ohta and Sakai, 2017). The deeper the tree, the more complex the sentence structure. Formally, syntactic complexity can be defined as:

$$\text{Syntactic comp.} = \frac{1}{n}\sum_{i=1}^{n} \tag{8}$$

$$\max(\text{depth of dependency tree})_i \tag{9}$$

Semantic complexity (Onoe et al., 2024) evaluates the richness of content by looking at the number of elements, or nodes, described within a scene graph from y'. The scene graph represents objects and their relationships within the image. A higher number of nodes indicates a more detailed and conceptually rich description. Semantic complexity is expressed as:

$$\text{Semantic comp.} = \frac{1}{n}\sum_{i=1}^{n} \tag{10}$$

$$\text{num. of nodes in scene graph}_i \tag{11}$$

To extract scene graphs from the generated captions, we use the tool in spacy (Spacy, 2024).

FaithScore (Jing et al., 2024) In the context of detailed captioning, FaithScore is used to evaluate

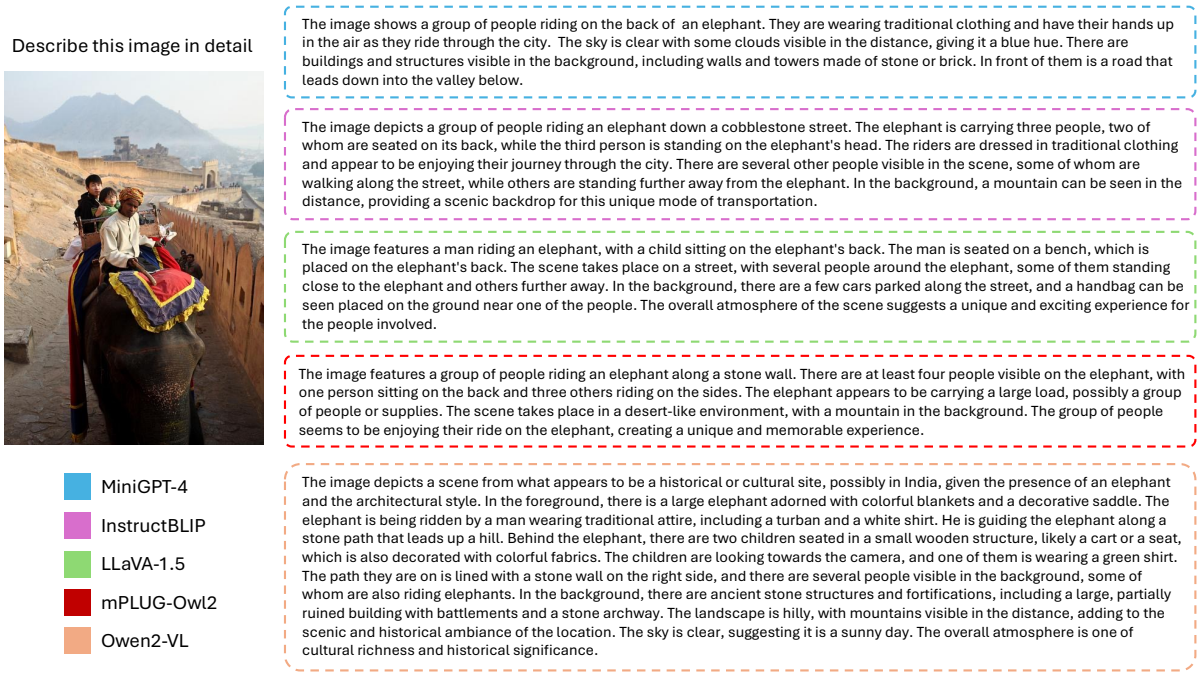

Figure 9: Examples of the generated captions.

how accurately a generated caption y' aligns with the content of an image I. To achieve this, the caption y' is first broken down into atomic facts by a large language model (LLM). The LLM identifies and isolates specific elements such as entities (e.g., objects or people), attributes (descriptive traits), and relationships (interactions or connections between entities). By separating these components, the model produces discrete fact-based units, allowing for a more detailed examination of how each part of the image is represented in the caption.

To evaluate how faithfully a generated caption y' aligns with the visual content of an image I, the caption is first decomposed into atomic facts, denoted as f. Each fact f is then verified against the image I by a verification function V, which utilizes a visual entailment model (VEM). The verification function checks whether each fact is supported by the image. Specifically, the verification function V is defined as:

$$V(f, I) = \begin{cases} 1 & \text{if VEM}(f, I) > 0 \\ 0 & \text{otherwise} \end{cases} \tag{12}$$

$$\tag{13}$$

In this formulation, the VEM determines the likelihood that the fact f aligns with the image I. If the entailment score for f in the context of I is greater than 0, the fact is considered supported by the image, and $V(f, I)$ returns 1; otherwise, it returns 0.

The overall FaithScore for the caption y' with K atomic facts is calculated by averaging the verification results for all facts:

$$\text{FaithScore} = \frac{1}{K} \sum_{k=1}^{K} V(f_k, I) \tag{14}$$

where K is the total number of atomic facts in the caption y', and $V(f, I)$ indicates whether each fact is consistent with the image. This metric provides an averaged score reflecting the proportion of facts within y' that are verified to be accurate representations of the content in I. For a dataset with n samples, the overall average FaithScore S can be computed as:

$$S = \frac{1}{n} \sum_{i=1}^{n} \text{FaithScore}_i \tag{15}$$

where FaithScore_i represents the FaithScore for the i-th caption in the dataset. This dataset-level average offers a comprehensive measure of the model's ability to generate captions that faithfully describe images across all samples consistently.

Additionally, we employ a sentence-level FaithScore, which measures the proportion of sentences in y' that are free from hallucinations.

E.1 Evaluation on Hallucination Mitigation Methods

Having established a unified evaluation leaderboard, we use it to assess the impact of hallucination mitigation techniques. Specifically, we analyze the two prominent methods, VCD (Leng et al., 2024) and OPERA (Huang et al., 2024), when applied to LLaVA-1.5 on LOTUS. Both approaches aim to increase the model's reliance on visual evidence when decoding. Tables 4 and 5 show the results of LLaVA-1.5 and its variants with VCD and OPERA applied, driving the following insights:

Mitigating hallucinations in reduced gender bias. The results on hallucination metrics (CH_s, FS, FS_S in Table 4) and gender bias in Table 5 demonstrate that applying mitigation methods not only reduces hallucinations but results in gender bias mitigation. In Table 5, applying VCD and OPERA leads to lessening gender disparity (*e.g.*, 10 out of 12 metrics for VCD). A possible hypothesis on this observation is that hallucination mitigation methods, which encourage the model to rely more heavily on visual evidence, may reduce the influence of gender stereotypes present in the training data, leading to decreased gender bias.

Mitigation methods increase the performance disparity among different languages. While reducing gender bias, the results of language discrepancy in Table 5 exhibit performance disparity among the languages is amplified after applying the mitigation methods (*e.g.*, 11 out of 12 metrics worsen for OPERA). This observation may result from the methods' increased reliance on visual evidence and factual accuracy, potentially exposing or exacerbating existing disparities in the model's visual recognition and linguistic representation across different cultures and languages.

CiteFix: Enhancing RAG Accuracy Through Post-Processing Citation Correction

Harsh Maheshwari
mahhars@amazon.com

Srikanth Tenneti
stenneti@amazon.com

Alwarappan Nakkiran
nakkiran@amazon.com

Abstract

Retrieval Augmented Generation (RAG) has emerged as a powerful application of Large Language Models (LLMs), revolutionizing information search and consumption. RAG systems combine traditional search capabilities with LLMs to generate comprehensive answers to user queries, ideally with accurate citations. However, in our experience of developing a RAG product, LLMs often struggle with source attribution, aligning with other industry studies reporting citation accuracy rates of only about 74% for popular generative search engines. To address this, we present efficient post-processing algorithms to improve citation accuracy in LLM-generated responses, with minimal impact on latency and cost. Our approaches cross-check generated citations against retrieved articles using methods including keyword + semantic matching, fine tuned model with BERTScore, and a lightweight LLM-based technique. Our experimental results demonstrate a relative improvement of 15.46% in the overall accuracy metrics of our RAG system. This significant enhancement potentially enables a shift from our current larger language model to a relatively smaller model that is approximately 12x more cost-effective and 3x faster in inference time, while maintaining comparable performance. This research contributes to enhancing the reliability and trustworthiness of AI-generated content in information retrieval and summarization tasks which is critical to gain customer trust especially in commercial products.

1 Introduction

Recent advancements in AI infrastructure and methodologies have enabled training Large Language Models (LLMs) over internet-scale data. These models demonstrate impressive competence in answering a wide range of general queries. However, when applied to specialized domains such as addressing questions based on internal company documents, off-the-shelf LLMs exhibit significant limitations. They often lack access to latest information, have difficulty interpreting domain specific language, struggle with source attribution, are prone to hallucinations (Ji et al., 2023), and are prone to overly broad responses.

To overcome these challenges, two broad strategies have emerged. The first involves fine-tuning LLMs on domain-specific data. However, this approach is not only resource-intensive and requires frequent updates, but also risks unintended consequences such as catastrophic forgetting, where the model loses previously acquired general knowledge, thereby increasing the overall system complexity. The second, often more practical method is Retrieval-Augmented Generation (RAG). RAG is a process that combines information retrieval with text generation. It typically involves the following steps: (1) indexing a knowledge base of relevant information, (2) using a retrieval system to find content specifically relevant to a given user query, (3) providing the user query and the retrieved content to an LLM, instructing it to generate a response based on the retrieved content. RAG offers numerous benefits, including real-time access to up-to-date information, improved token generation (Khandelwal et al., 2019), reduced hallucinations, better source attribution (Gao et al., 2023a; Hsu et al., 2024) and overall superior response generation (Shuster et al., 2021; Béchard and Ayala, 2024). Additionally, RAG tends to be more cost-effective and transparent than full model fine-tuning. Examples of RAG-based products include Perplexity.ai (Perplexity AI, 2024), bing search, GPT Search etc.

Despite enabling a novel information retrieval experience for users, RAG systems today face key limitations. Table 1 illustrates results of a Subject Matter Expert based auditing of a RAG based system. Shown is a metric "Relative Mean Question Level Accuracy", which captures relevancy of cited chunks, correctness and completeness of the

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 310–317

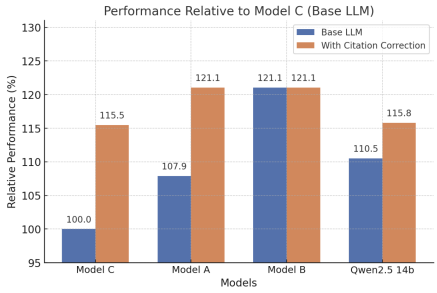

Figure 1: Improvements in RAG accuracy for various LLMs after employing our proposed citation correction methods. Results are shown as percentage improvements in Mean Question Level Accuracy(MQLA) over Model C baseline performance without citation correction. MQLA is a metric designed to capture relevancy, correctness and completeness (see Sec. 4.1).

Model	Cents per 1K O/P tokens	Relative Mean Question Level Accuracy	% of factual points unverifiable	% of factual points incorrectly cited	% of factual points purely hallucinated
Model A	+1100%	+7.9% (+12%)	Base (Base)	90.8% (65%)	9.1% (35%)
Model B	+220%	+21.1% (+21.1%)	Base (Base)	66.6% (66.6%)	34.4% (-33.4%)
Model C	Base	Base (+15.4%)	Base (Base)	80.6% (33.3%)	19.4%(-66.6%)
Qwen 14-B	open source	+10.5% (+15.8%)	Base (Base)	76.2% (70.8%)	-13.8% (29.2%)
Qwen 2-B	open source	-39% (NA)	NA	NA	NA

Table 1: *Motivating the need for CiteFix:* This table shows the prevalence of incorrect citations across LLMs and our method's impact. Model C is the baseline for cost and accuracy columns. For the last three columns, the baseline is each model's total percentage of unverifiable factual points. Numbers outside (inside) parentheses show performance before (after) CiteFix. Initially, incorrect citations significantly outnumber hallucinations. CiteFix balances this ratio and in absolute terms it drastically reduces incorrect citations. Qwen 2-B was excluded from detailed audit due to inconsistent citation generation.

answer(Sec. 4.1), relative to Model C[1] accuracy. A prevalent form of error that contributes to lower performance is that of unverifiable facts in LLMs' responses. Unverifiable facts are the facts in LLM response which cannot be validated by cited reference. In our analysis for Model C, notably around 80% of these unverifiable facts were not pure hallucinations, but rather errors in the model's ability to cite the correct reference from which it generated the given factual point. These observations align with industry studies (Liu et al., 2023) reporting citation accuracy rates of only about 74% for popular generative search engines. Incorrect citations not only reduce the actionability of the responses, but also dent customer trust, especially for commercial products. This paper focuses on this issue and proposes methods to address it.

While previous studies have explored attributable text generation ((Nakano et al., 2022); (Gao et al., 2023b)) and simple prompting techniques for citation incorporation ((Malaviya et al., 2024; Sun et al., 2024; Li et al., 2024)), systematic evaluations reveal significant performance gaps (Gao et al., 2023b). Recent work (Huang et al., 2024) has only scratched the surface by demonstrating attribution quality degradation from ChatGPT to Llama 2 7B, leaving a critical need for deeper analysis and practical solutions.

This paper offers two contributions:

1. Demonstrating the existence and extent of the incorrect citations issue across multiple LLMs, and highlighting the need to address the same.

2. Proposing six computationally light weight methods to address this issue, ranging from simple heuristic methods to more sophisticated learning-based solutions. Through extensive experimentation, we show that different citation correction approaches may be optimal for different LLMs - for instance, hybrid (lexical + semantic) matching works best with Model A, while fine-tuned BERTScore performs better with Model B. We provide detailed comparisons of their effectiveness and practical applicability. As seen in Fig 1 and Table 1, our method resulted in an improvement of upto 15.46% relative improvement in accuracy when tested across four different LLMs.

Through this work, we aim to not only advance the understanding of citation accuracy challenges in LLMs, but also provide practical low cost solutions for improving attribution in real-world applications. Sec. 2 presents an overview of related work. Sec. 3 details our proposed algorithms. Sec. 4 presents evaluation results. Sec. 5 concludes, along with a discussion of the limitations of our work and plans for addressing them going forward.

2 Related Work

Accurate attribution of information to sources remains a critical challenge in building trustworthy AI systems, particularly for Large Language

[1]Model names are anonymized following standard practice for proprietary/pre-release models. Publicly available models retain their original names. Model A, Model B and Model C are sufficiently large and powerful language model. With number of parameters in decreasing order for A, B and C. Model B however is the model trained on latest data with better methodologies

Models (LLMs) and Retrieval-Augmented Generation (RAG) systems. The challenge of accurate attribution in AI-generated content has been approached from multiple angles in the literature. Some researchers have focused on developing models specifically designed for attributable text generation (Nakano et al., 2022), while others have explored the effectiveness of prompt engineering techniques for citation accuracy (Malaviya et al., 2024; Li et al., 2024). However, a comprehensive study (Gao et al., 2023b) has highlighted that significant challenges remain, particularly in maintaining consistent attribution accuracy across different types of queries and document structures. These findings underscore the need for more robust and versatile approaches to citation/attribution in AI systems.

Recent work has focused on the automatic evaluation of attribution by LLMs (Yue et al., 2023) and factual entailment for hallucination detection (Rawte et al., 2024), primarily assessing whether generated content is present in cited references. However, there is a notable gap in research specifically addressing citation correction.

Many existing methods, including those fine-tuning T5 models (Gao et al., 2023c; Song et al., 2024; Honovich et al., 2022), are limited by context lengths of around 512 tokens. This constraint poses significant challenges when dealing with longer documents or multiple sources, which is often the case in practical RAG systems. Our proposed solution for citation correction is designed to handle larger context lengths, addressing a critical limitation in current approaches.

Furthermore, our research distinguishes itself by focusing on not just detecting citation errors but actively working towards correcting them. This shift from identification to correction represents a significant step forward in improving the usefulness of AI-generated content in RAG systems. We introduce a range of citation correction methods, including lexical matching, hybrid (lexical + semantic) approaches, and lightweight LLM-based attribution. One method builds on BERT Score (Zhang et al., 2020), leveraging pre-trained contextual embeddings from BERT (Devlin et al., 2019). Initial experiments with an off-the-shelf model (Beltagy et al., 2020) showed improvements, but fine-tuning on in-domain data yielded better results. This led us to explore ColBERT (Khattab, 2020), a neural retrieval model designed for fine-grained contextual late interaction. By combining BERT Score's semantic similarity assessment with ColBERT's fine-tuning capabilities, we developed a more robust and accurate citation correction method, which we detail in the next section. We detail these methods in the next section.

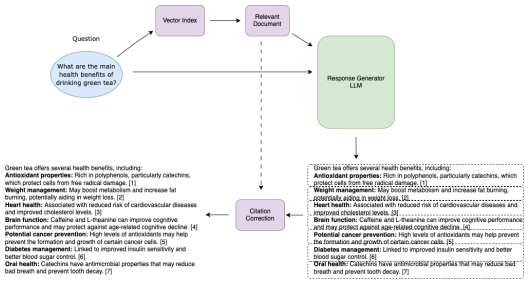

Figure 2: Overview of the workflow of the proposed methods using a sample question. Once the RAG system's response generating LLM generates an answer, we split the answer into distinct factual points (shown in dotted lines above). For each factual point, we use its similarity scores with the retrieved documents to detect citation errors and correct them. See Section 3 for details. Question used is for illustration purpose only

3 Proposed Methodology

Our goal is to improve the overall citation accuracy, while having minimal impact on latency and costs. Towards this, we propose a suite of algorithms that leverage various techniques, ranging from simple heuristics to sophisticated machine learning models. Our algorithms are streaming-compatible post-processing techniques, meaning that they operate on an LLM's response as it is being generated.

The general framework of our proposed methods is depicted in Figure 2. We will now go into its details. Let us denote the query that the user asks the RAG system as q. Let the set of documents retrieved by the Retriever module in RAG be $\{\hat{x}_i\}_{i=0}^{R-1}$. Let A denote the answer generated by the LLM. Our algorithms involve the following steps:

1. We first split the LLM's response A into distinct "factual points" $\{x_i\}_{i=0}^{L-1}$. A factual point is defined as a section within A that the LLM attributes to a particular set of retrieved documents via citations. In our use case, the LLMs were instructed to include citations at the end of each factual statement in their response. We use simple regular expressions to segment the LLM's response into "factual points", delimited by citations. See Fig. 2 for example.

2. Let C_i be the number of citations in the LLM's generated response A for the factual point x_i. Our algorithms will estimate the "corrected citations" to be the top C_i retrieved documents among $\{\hat{x}_i\}_{i=0}^{R-1}$ that maximize the following similarity metric with the factual point x_i:

$$s_{ij} = f(x_i, \hat{x}_j) \quad (1)$$

In the next sections, we will discuss various choices for the function f in Eq. 1. We will use the following notation: Let us denote each factual point x_i as list of its individual tokens t_{ij}. Namely, $x_i = [t_{i0}, t_{i1}, \ldots, t_{ik}]$. Let us also denote each retrieved document $\hat{x}_i$ as a list of its tokens $\hat{x}_i = [\hat{t}_{i0}, \hat{t}_{i1}, \ldots, \hat{t}_{il}]$.

3.1 Keyword based matching

We define f in Eq. 1 as the size of the intersection between the tokens in x_i and $\hat{x}_j$. We also tried a term-frequency (TF) by inverse-document-frequency type of scoring, such as done in traditional document ranking (Rousseau and Vazirgiannis, 2013; Trotman et al., 2014), but it did not yield good results. We noticed regular IDF being particularly noisy with domain specific keywords such as "yield" which have different meaning in agriculture and financial context or "drill" which have different meaning in mining and military context etc.

3.2 Keyword + Semantic Context based matching

In this approach, we combine the above keyword match score with a mild contribution from the semantic similarity between the user query q and the retrieved document $\hat{x}_i$. The motivation is to mildly prefer retrievals that are more relevant to the user query:

$$f(x_i, \hat{x}_j) = \lambda . f_{keyword}(x_i, \hat{x}_j) + (1 - \lambda) . r(q, \hat{x}_j) \quad (2)$$

Where $f_{keyword}(x_i, \hat{x}_j)$ is the keyword based matching score and $r(q, \hat{x}_j)$ is the retrieval score for document $\hat{x}_j$ given query q. We empirically found $\lambda = 0.8$ to perform well in our experiments.

3.3 BERT Score

In the previously discussed approaches, contextual meaning of the words in x_i and $\hat{x}_j$ was not fully utilized. They also do not differentiate between cases where word matches occur in close proximity within the reference versus where they are scattered across unrelated positions. Additionally, keyword-based methods struggle to handle scenarios where the language model or response generator paraphrases the words, as these methods rely on exact word matches.

BERT Score (Zhang et al., 2020) addresses these limitations by leveraging contextual embeddings to represent the tokens in the factual point x_i and the reference $\hat{x}_j$. These embeddings are generated using the LongFormer model (Beltagy et al., 2020), which incorporates bi-directional attention to capture not only the token but also its surrounding context.

Once the embeddings are computed, the similarity between the factual point and a retrieved document is calculated as follows: For each token in the factual point x_i, we compute its maximum similarity among all tokens in the retrieved document. The mean of these maximum similarity scores among all tokens in x_i is used as the final score in Eq 1:

$$f(x_i, \hat{x}_j) = \frac{1}{|x_i|} \sum_{t_{il} \in x_i} \max_{\hat{t}_{jk} \in \hat{x}_j} e(t_{il})^\top e(\hat{t}_{jk}) \quad (3)$$

where $e(t)$ denotes the embedding of a token t.

3.4 Fine-tuned Model with Bert Score

While off-the-shelf BERTScore models provide a good starting point for incorporating contextual similarity into the citation correction process, we hypothesize that fine-tuning these models specifically for this task on an in-domain dataset can further improve their performance. The key limitation of the off-the-shelf models is that they are not explicitly trained to capture the nuances of citation attribution & factual entailment. Our methodology is motivated by ColBERT (Khattab, 2020).

During training, the input to the model is a factual point (x), a positive reference ($\hat{x}+$) that validates the point, and a negative reference ($\hat{x}-$) that does not validate the factual point. BERTScore for the factual point, calculated using Eq. 3, is maximized for the positive reference compared to the negative reference. We used cross-entropy loss to increase the score with the positive reference compared to the negative reference.

Dataset Preparation: To train the model, we need factual points, and corresponding positive and negative references. We employed an LLM for this, using two strategies: First, for each document in

the corpus, we determine the n^{th} most similar document using (Amazon-Titan-V2, 2024). We then prompt LLM to provide a factual point present in the former document, but not in the latter. By varying $n \in \{14, 11, 8, 5, 4, 3\}$, we get progressively hard positive and negative pairs for training. Secondly, for a list of questions, we generate answers from our RAG-based system. For each factual point present in the answer and for each retrieved document, we employ an LLM to check for if the former is grounded in the latter. We then use this information to create multiple pairs of positive-negative for a given factual point. This allows us to tune the model specifically for the citations issue for the specific LLM used within the RAG system.

3.5 LLM Based Matching

An alternative approach for citation correction is to employ an LLM directly. Table 1 presents results using our best-performing prompt instructions for citation-aware response generation. Here, we explore a secondary LLM that identifies the most relevant reference for each factual point.

To balance accuracy with efficiency, we use a simple prompt that requests only the reference number, avoiding complex techniques like Chain of Thought (CoT) (Wei et al., 2023), which would increase token usage, latency, and cost. This approach leverages the LLM's ability to capture contextual and semantic nuances beyond keyword-based or rule-based methods, enabling adaptability across domains without explicit rule-crafting or fine-tuning.

However, the effectiveness of this method depends on the LLM's quality, training data, and prompt design. Additionally, processing each factual point individually introduces computational overhead, requiring a careful trade-off between cost, latency, and accuracy.

3.6 Reusing Attention Maps of the Base LLM

The main idea here is, can we look at the attention maps of the response generating LLM itself to check which retrieved documents were used in generating each factual point in the response. We did not have enough time to fully experiment with this idea, but in Appendix 6.1, we show a simple proof of concept that demonstrates this idea. We will explore this further in our future work.

4 Results

In this section, we will present evaluation results of all the proposed methods on top of RAG based system. The evaluations were done by human auditors, who have prior knowledge on the topic for which RAG is used.

4.1 Metrics

We developed the following metrics to evaluate RAG system performance. The uber level metric we track is called "Mean Question-Level Accuracy" (MQLA). It combines the following:

- **Relevancy URL**: Checks if the set of citations referenced to by the LLM are relevant to the question. Calculated as the fraction of cited URLs that are relevant.
- **Relevancy Keywords**: Checks if keywords in the LLM's response are relevant to the question. Calculated as the ratio of keywords which are relevant by the total number of keywords present in the query. The keywords in the response are identified by humans.
- **Relevancy Facts**: Checks if facts present in the LLM's response are relevant to the question. Calculated as the ratio of facts which are relevant to query by the total number of facts present in the response. The facts in the response are identified by humans.
- **Correctness**: Checks if the facts present in the LLM's response can be verified in the citations provided. Calculated as the ratio of number of facts supported by cited references and the total number of facts. **Note**: The facts not supported by cited referenced can be divided into two categories 1) Hallucinated facts and 2) Incorrectly cited facts, based on whether the fact was present in any of the retrieved documents or not.
- **Completeness**: Checks if all aspects (possible sub-questions) of the original questions are addressed in the response. The possible sub-questions are identified by the humans.

We calculate MQLA as described in Algorithm 1.

4.2 Comparing Different Citation Correction Methods

In Table 2, we compare different citation correction algorithms proposed in this paper on Model

Table 2: Comparing Citation Correction Methods. All columns except p90 latency show relative performance

Citation Correction Method	Response Generating LLM	Mean Question Level Accuracy	Relevancy URL	% of Facts Correctly Cited	p90 latency per factual point (in sec)
None	Model C	Base	Base	Base	-
Keyword	Model C	+12.7%	-0.9%	+12%	0.014
Keyword + Semantic Context	Model C	+15.5%	-0.9%	+13.6%	0.015
BERT Score	Model C	+2.6%	-1%	+3.2%	0.389
Finetuned BERT Score	Model C	**+15.8%**	+1.5%	**+13.7%**	0.389
LLM Based Matching (Model C)	Model C	+1.9%	+0.9%	+7%	1.586
None (Baseline)	Model A	+7.8%	**+2%**	+5.4%	-

Algorithm 1 Mean Question Level Accuracy

```
Initialize totalAccuracy= 0, n = number of questions
for q in questions do
    Initialize accuracy= 0
    if all(relevancyUrl, relevancyKeyword, relevancyFacts, correctness, completeness ≥ 0.8) and hallucinatedFacts ≤ 1 then
        accuracy= 1
    end if
    totalAccuracy + = accuracy
end for
meanAccuracy = totalAccuracy / n
return meanAccuracy
```

C's responses. We used a set of 50 representative questions for evaluation, incurring an audit time of 2.5 days by 2 humans per row of Table 2. The table includes p90 latency per factual point for each citation correction method, which adds negligible overhead (except LLM method) to our system's time to first token p90 latency. The latency is computed on g5.4xlarge instance. Results for Model A, a model that is 12x more expensive and about 3x slower are also shown for reference. The impact of our techniques Keyword + Semantic Context based and Fine-tuned BERT Score is evident, taking Model C's MQLA higher than Model A.

4.3 Evaluating Impact Across Different LLMs

In Table 3, we evaluated the two best performing citation correction methods from Table 2 for four different LLMs (using the same dataset as in Sec. 4.2). Interestingly, different LLMs may pair optimally with different citation correction strategies. The impact of our methods is strongly evident for Model C, Model A and Qwen 2.5 14-B. Model B seems to be inherently much better at citations, but we see some mild improvements in the relevancy of cited URLs when paired with our fine-tuned BERT Score method. These results demonstrate potentially wide applicability of our proposed methods.

Table 3: This table shows the effectiveness of our two best citation correction approaches with various LLMs. KSC represents Keyword+Semantic context and FBS represents Finetuned BERT Score

Response Generator	Citation Corrector	MQLA	Relevancy URL	% of facts Correctly Cited
Model C	None	base	base	base
Model C	KSC	+15.5%	-0.9%	+13.6%
Model C	**FBS**	**+15.8%**	**+1.5%**	**+13.7%**
Model B	**None**	**+21%**	+1.5%	+14.9%
Model B	KSC	+10.5%	+1.5%	+10.7%
Model B	**FBS**	**+21%**	**+2%**	**+15%**
Model A	None	+7.9%	**+2%**	+5.4%
Model A	**KSC**	**+21%**	-1.3%	**+16%**
Model A	FBS	+10.5%	**+2%**	+9.8%
Qwen 2.5 14b	None	+10.5%	**+2%**	+8.4%
Qwen 2.5 14b	**KSC**	**15.8%**	**+2%**	**+9.7%**
Qwen 2.5 14b	FBS	13.1%	+1.3%	+8.7%

5 Conclusion

This paper addresses the critical challenge of citation accuracy in RAG systems, demonstrating its impact across multiple LLMs and its effect on AI-generated content trustworthiness. Our key contribution is the development of efficient post-processing algorithms for citation correction, improving relative accuracy by up to 15.46% while maintaining minimal computational overhead. Notably, we found that optimal citation correction methods vary across LLMs, emphasizing the importance of model-specific approach selection.

Our findings, while promising, represent early steps in addressing this challenge. Future research areas include exploring attention-map-based methods for more precise attributions and developing sophisticated dataset preparation techniques. While newer LLMs (Model B) have improved citation accuracy, attribution issues persist to a lesser extent, suggesting the need for more sophisticated correction algorithms. Additionally, our framework's ability to establish relationships between factual points and source documents opens up interesting applications, such as determining appropriate contexts for content insertion (e.g., advertisement placement) based on document similarity and factual relevance.

6 Appendix

6.1 Using Attention map for attribution

In a RAG based system, the response generating LLM is given a set of relevant document in response to a user query. It then understands information from these different documents to answer the question at hand. Here, we want to explore if can we leverage attention scores within the LLM to understand which document in the prompt it is focusing on while generating a particular fact in its response. We did a small *toy experiment* with Qwen 2.5B - 2B to test the same. We use the below prompt:

```
Hi, you are an assistant who has access to the
     following <documents> about cricket.
Please answer the <user query> at the end
     using only the information provided in
the <documents>. Do not output any information
     not contained in the <documents>.
Do not output any information that is not
     relevant to answering the <user query>.
If the <user query> cannot be answered with
     the given <documents>, please say so.

<documents>

<doc> Axx is a tall batsman. </doc>

<doc> Byy can bat with a broken bat as well.
     </doc>

<doc> Czz is a very funny umpire. </doc>

<doc> Dii is a fast bowler from Mumbai. </doc>

</documents>

<user query>
QUESTION
</user query>
```

We asked the following questions to the LLM:

- Name a batsman who is not particularly short
- Name a batsman who can bat with a damaged bat
- Name an umpire who makes people smile
- Who is a player from Mumbai?

and visualised the attention scores in 3 (Blue, Orange, Green and Red lines for the above four questions respectively). The x-axis in the figure is the token position within the prompt. The y-axis is the sum of the attentions scores for all tokens in the output, across all layers of the LLM at that particular input token location. A higher value of this sum at a particular location of the input token indicates that that input token was taken into account by the LLM in generating the response.

You will see that for first question the peak of attention score is before the second question which is in line with where the necessary information is present in the prompt. Likewise, the peak of attention for second question is before the third one, and so on. This small proof of concept shows that we may be able to leverage the LLM's internal attention maps to correct citations.

Light-R1: Curriculum SFT, DPO and RL for Long COT from Scratch and Beyond

Abstract

This paper introduces Light-R1, an open-source suite for training long reasoning models using reproducible and cost-effective methodology. Given the proprietary nature of data used in the DeepSeek-R1 series, we develop an alternative approach leveraging exclusively public data and models. Our curriculum training progressively increases data difficulty, combined with multi-staged post-training. Our Light-R1-32B model, trained from Qwen2.5-32B-Instruct, outperforms DeepSeek-R1-Distill-Qwen-32B in math reasoning. Experimental results show that this curriculum approach becomes more effective when distinct, diverse datasets are available for different training stages: fine-tuning DeepSeek-R1-Distilled models (pre-tuned by DeepSeek team on proprietary data) with 3,000 challenging examples from our curriculum dataset yielded state-of-the-art 7B and 14B models, while the 32B model, Light-R1-32B-DS performed comparably to QwQ-32B and DeepSeek-R1. Furthermore, we extend our work by applying GRPO on long reasoning models. Our final Light-R1-14B-DS achieves SOTA performance among 14B models in math, with AIME24 & 25 scores of 74.0 and 60.2 respectively, surpassing many 32B models and DeepSeek-R1-Distill-Llama-70B. Despite math-focused training, Light-R1-14B-DS demonstrates strong cross-domain generalization. Light-R1 represents a significant advancement in making sophisticated reasoning models more accessible and implementable in real-world applications. Our models, training data and code have been made available at https://github.com/Qihoo360/Light-R1.

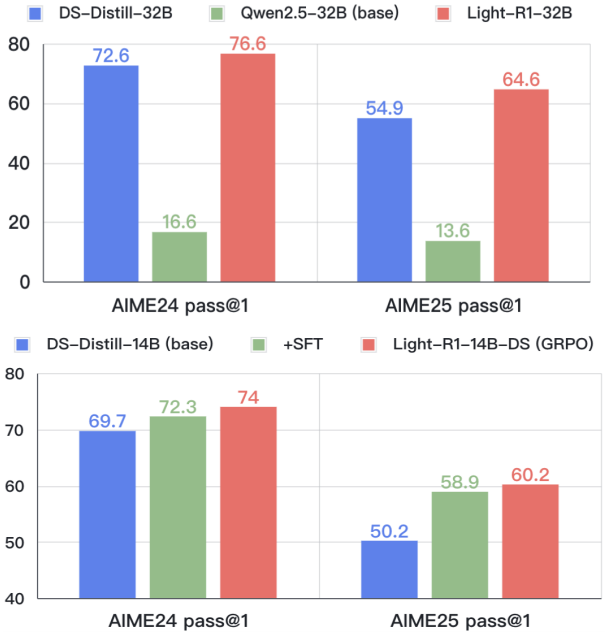

Figure 1: Reproducible state-of-the-art long COT models **(top)** developed from scratch (=short-COT base), **(bottom)** derived from DeepSeek-R1-Distill models (=long-COT base), via curriculum learning strategy.

1 Introduction

Since the release of DeepSeek-R1 (DeepSeek-AI, 2025), long chain-of-thought (OpenAI, 2024; Wei et al., 2022; Kimi, 2025; Lightman et al., 2023) reasoning has gained widespread popularity in both foundational AI models and various industrial AI applications. However, deploying full-capacity R1-level models (typically 70B+ parameters, DeepSeek-R1 with 671B parameters) incurs prohibitive computational costs (DeepSeek-AI, 2025; Qwen, 2025). The resource barrier of training and deploying the giant models makes them impractical for edge devices and real-time applications. This limitation has sparked growing interest in developing compact yet capable models under a few 10B parameters that can perform extended long COT - a critical requirement for mathematical problem solving, algorithmic planning, and scientific analysis. To address this challenge, we present our work on the Light-R1 series.

As a foundation for our research, we first established robust and reproducible evaluation protocols

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 318–327
July 28-30, 2025

that rigorously reproduce the evaluation results reported in DeepSeek-AI (2025). Building upon this reliable framework, our research systematically addresses three fundamental challenges through innovative algorithmic and engineering advancements.

The first challenge involves curating an efficient dataset for Post-Training, a critical factor for long-COT optimization (Ye et al., 2025; Muennighoff et al., 2025; Li et al., 2025). We collected diverse open-source reasoning data covering mathematical reasoning, logical deduction, and algorithmic problem-solving. After preprocessing to remove duplicates and standardize formatting, we implemented a two-stage difficulty filtering methodology using DeepScaleR-1.5B-Preview (Luo et al., 2025b) and DeepSeek-R1-Distill-Qwen-32B models to quantify difficulty based on pass rates.

The second challenge then emerges as how to optimize the utilization of this dataset. While conventional approaches typically employ a single SFT stage (DeepSeek-AI, 2025; Xu et al., 2025; Labs, 2025; Yu et al., 2024), our preliminary experiments with our 32B model revealed significant limitations—approximately 20% of training data still exhibited pass rates below 50% across 10 runs, indicating insufficient knowledge assimilation from heterogeneous difficulty datasets. To address this, we implemented a multi-staged curriculum training strategy comprising two consecutive SFT stages with progressively increasing difficulty, followed by a DPO stage (Rafailov et al., 2023). Although recent work has explored different curriculum strategies for long-COT training (Luo et al., 2025a; Min et al., 2024; Xi et al., 2024; Yuan et al., 2025a), our approach demonstrates superior performance: our Light-R1-32B model, trained from Qwen2.5-32B-Instruct (Qwen, 2024), outperforms DeepSeek-R1-Distill-Qwen-32B in mathematical reasoning.

The third challenge arises from implementing the final component of Post-Training — Reinforcement Learning (Shao et al., 2024; Wang et al., 2024; Ouyang et al., 2022; Schulman et al., 2017, 2015) — to further enhance model performance. We are excited to report our successful reinforcement learning training of Light-R1-14B-DS. While recent research has shown success in training base models (Zeng et al., 2025; Hu et al., 2025; Liu et al., 2025), smaller models (Zeng et al., 2025; Luo et al., 2025b), or larger models with intensive computational resources (Qwen, 2025), our long-COT RL Post-Training represents the first demonstration of simultaneous increases in both response length and reward scores on long-COT 14B models without the initial length reduction typically observed. This breakthrough demonstrates that carefully designed curriculum strategies can overcome the previously documented scalability limitations of RL in smaller models (Gao et al., 2023).

Table 1: Reproduction of DeepSeek-AI (2025) and Qwen (2025) evaluation results on AIME24 (MAA, 2024) pass@1 averaged over 64 runs.

Model	Paper	Ours
DS-distill-32B	72.6	72.3
DS-distill-14B	69.7	69.3
DS-distill-7B	55.5	54.0
QWQ-32B	79.5	78.5

The key contributions of this work include:

- A detailed, fully open-source Curriculum Post-Training approach to train long-COT models from scratch. The multi-stage curriculum training incrementally builds reasoning capacity through difficulty-progressive data exposure, requiring only $1000 training cost (6 hours on 12×H800 GPUs). This approach is validated on Qwen2.5-32B-Instruct and could be easily migrated to 7B and 14B models.

- A well established SFT stage 2 dataset of 3k mostly math questions that could significantly improve not only SFT stage 1 but also all DeepSeek-R1-Distill models, resulting in our SOTA 7B model Light-R1-7B-DS.

- First demonstration of RL effectiveness on 14B models for mathematical reasoning, achieving around 2% absolute improvement compared with before-RL, resulting in our SOTA 14B model Light-R1-14B-DS.

2 The Origin of Everything: Stable and Trustworthy Evaluation of Long-COT Models

Following DeepSeek-AI (2025), long-COT models are commonly deployed with sampling temperature 0.6. While long-COT models generally perform better with sampling than with greedy decoding, it brings more burden for model evaluation as multiple samples for each question may be required, contrary to previous viable approaches of greedy decoding for evaluation (Song et al., 2024).

DeepSeek-AI (2025) generates 64 responses per query to estimate pass@1. We have verified this choice, witnessing large deviation of over 3 points using 16 responses or fewer across different runs of the same model. Such randomness is unacceptable to compare model performances.

For stable and trustworthy evaluation, we adapted (Luo et al., 2025b)'s evaluation code for all our evaluation runs. Our evaluation code and logs are all released.

We can reproduce all DeepSeek-R1-Distill models' and QwQ's scores as reported in DeepSeek-AI (2025); Qwen (2025) as shown in Tab. 1 with 64 samples per query, with deviation around 1 point.

3 Light-R1-32B: Long-COT from Scratch with Curriculum SFT & DPO

While numerous studies (Ye et al., 2025; Muennighoff et al., 2025; OpenThoughts, 2025; OpenR1, 2025) have open-sourced efforts to replicate DeepSeek-R1 using models of various sizes, ranging from 1.5B to 32B, none has reached similar performance on the challenging mathematics competitions AIME24 & 25, where DeepSeek-R1-Distill-Qwen-32B scored at 72.6 & 54.9.

We present our data processing and Post-Training pipeline in this section as illustrated by Fig. 2.

3.1 Data Preparation

The whole data preparation process spans data collection, data decontamination and data generation, detailed as follows.

3.1.1 Data Collection

We began by collecting various sources of math questions with groundtruth answers. Iterating over all possible sources by the time, we collected around 1000k math questions as the seed set. See Appendix B for more details about the data sources.

All data are aggregated together to form around 1000k math questions as the seed set. Within this 1000k data, we kept only math questions with groundtruth answers. Questions without groundtruth answers could be used as synthetic data by letting multiple strong LLMs vote for groundtruths but we left it for future work.

The data is then filtered for diversity, where we tagged each question with an in-house tagging system and downsample categories with excessive data.

3.1.2 Data Decontamination

We evaluated data contamination in several open-sourced datasets. Our analysis revealed that MATH-500 (Hendrycks et al., 2021a) contains tens of compromised questions that are either identical or differ only in numerical values. AIME 24 and 25 remain uncontaminated, though caution is needed when incorporating AIME data through 2023. Further details are provided in Appendix C.

Light-R1 underwent comprehensive decontamination using exact matching (excluding digits to filter questions with only numerical changes) and N-gram (N=32) matching against AIME24&25, MATH-500, and GPQA (Rein et al., 2023).

3.1.3 Data Generation

With a diverse and clean dataset, we generate comprehensive chain-of-thought (COT) responses for supervised fine-tuning (SFT). However, not all data points are equally valuable for training, and distilling DeepSeek-R1 can be resource-intensive whether through API queries or local deployment. We therefore implemented difficulty-based filtering on the dataset to retain only sufficiently challenging questions, inspired by recent advances in training long reasoning models (Luo et al., 2025b; Ye et al., 2025; Muennighoff et al., 2025).

We initially employ Luo et al. (2025b)'s DeepScaleR-1.5B-Preview model to generate responses for each question, as this model offers a good balance of efficiency and capability. Only questions with a pass rate $< \alpha$ were selected for DeepSeek-R1 queries, resulting in approximately 76k data points. After obtaining DeepSeek-R1 responses, we retained only questions with correct long-COT answers. For questions with multiple correct responses, we randomly selected one long-COT answer for SFT. Through this process, we constructed an SFT dataset exceeding 70k examples, featuring prompts filtered for both diversity and difficulty, with long-COT responses generated by DeepSeek-R1 and validated against ground truth.

However, direct training on this dataset alone did not yield satisfactory results regardless of the number of training epochs. Upon analyzing the trained model's performance across different question types, we discovered the need for additional training on more challenging problems. Consequently, we implemented a second stage of difficulty filtering using the full version of DeepSeek-R1 instead of DeepScaleR-1.5B-Preview. This stage retained only questions with pass rate $< \alpha$

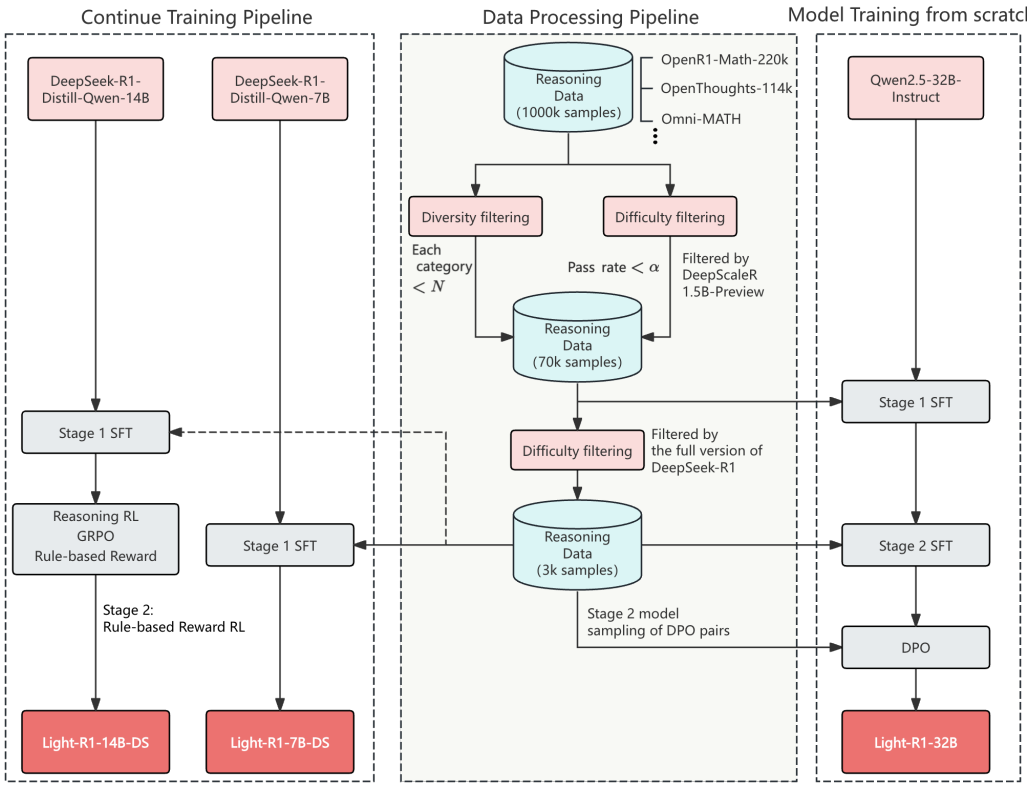

Figure 2: Overview of training pipeline of Light-R1 series.

and questions where DeepSeek-R1's sampled responses were neither uniformly correct nor uniformly incorrect, resulting in a Stage 2 SFT dataset of approximately 3k examples. Notably, this refined dataset demonstrated such high quality that training exclusively on it produced performance improvements across all DeepSeek-R1-Distill models, as we will discuss in Section 3.4.

3.2 Curriculum Post-Training

Our approach consists of three stages, detailed hyperparameters can be found in Appendix D.:

1. **SFT Stage 1**: Training on 76k filtered mathematical problems
2. **SFT Stage 2**: Fine-tuning on 3k most challenging problems
3. **DPO Optimization**: Preference-based optimization using verified response pairs

SFT stages are trained with the curriculum data strategy as discussed in Sec. 3.1.3. For DPO, we implemented a semi-on-policy approach using the NCA loss (Chen et al., 2024). Rejected responses were sampled from our SFT-stage-2 model with verified incorrect answers. Since some rejected responses reached lengths of 32k tokens or more, we utilized the DPO implementation with sequence parallelism from 360-LLaMA-Factory (Zou et al., 2024). For chosen responses, we used verified correct answers from DeepSeek-R1. While we had previously employed fully on-policy DPO extensively, we discovered that for challenging mathematical problems, using chosen responses from significantly stronger models yielded better results.

3.3 Results

We observe consistent improvements across our curriculum SFT & DPO post-training stages (Tab. 2). Following DPO, we use the TIES-merging (Yadav et al., 2023) method from the Goddard et al. (2024) toolkit to merged models from SFT-stage2, DPO, and another DPO variant (AIME24 score: 74.7) that had special tokens inadvertently removed from rejected responses, the resulting merged model demonstrates additional performance gains. Although our mathematics-focused training led to some forgetting on untrained GPQA scientific questions, Light-R1-32B still demonstrates strong generalization capabilities.

Stage	AIME24	AIME25	GPQA	LCB
Instruct (base)	16.6	13.6	48.8	24.6
+SFT-stage1	69.0	57.4	64.3	42.9
+SFT-stage2	73.0	64.3	60.6	42.0
+DPO	75.8	63.4	61.8	N/A
+Model Merging	76.6	64.6	61.8	44.7
Light-R1-32B	**76.6**	**64.6**	61.8	44.7

Table 2: Stage-wise performance improvement of our Light-R1-32B. We observe a decrease in GPQA (Science QA) scores beginning from STF-stage2, indicating a partial degradation of the model's generalization capabilities during extensive math-focused training. However, Light-R1-32B still demonstrates strong generalization compared to the base model.

Model	AIME24	AIME25	GPQA	LCB
DS-distill-7B	55.5	39.2	49.1	tbd
Light-R1-7B-DS	**59.1**	**44.3**	49.4	tbd
DS-distill-14B	69.7	50.2	59.1	52.9
Light-R1-14B-DS'	**72.3**	**58.9**	60.3	55.9
DS-distill-32B	72.6	54.9	62.1	58.8
Light-R1-32B-DS	**78.1**	**65.9**	**68.0**	66.1

Table 3: Effectiveness of the 3k data from SFT stage2. Fine-tuning on stronger base models, which presumably utilize datasets orthogonal to ours, consistently enhances performance across all model sizes. The notation **Light-R1-14B-DS'** refers to the SFT-only version of our final Light-R1-14B-DS model, which subsequently undergoes an additional stage of GRPO RL training.

3.4 High-Quality Data is All You Need

Considering DeepSeek-R1-Distill-Qwen models as a stronger version of our SFT stage 1, we performed SFT stage 2 with the 3k stage 2 data on top of DeepSeek-R1-Distill-Qwen models.

Surprisingly as Tab. 3, we could achieve universal improvement on DeepSeek-R1-Distill-Qwen models with this 3k data alone, demonstrating the high quality of the stage 2 data. It may also be because this 3k data is to some extent orthogonal to DeepSeek-R1-Distill-Qwen models' 800k SFT data, hence such easy improvement.

GPQA performance is unexpectedly high for Light-R1-32B-DS, despite the absence of domain-specific training in science and code domains, suggesting that stronger base models may benefit from stronger generalization capacities. In contrast, Light-R1-7B-DS, while trained on identical data curriculum, exhibits improvements confined solely to in-domain tasks.

4 Light-R1-14B-DS: Reinforcement Learning from Long-COT Models

We conduct our reinforcement learning experiments on DeepSeek-R1-Distill-Qwen-14B. To the best of our knowledge, this is the first publicly documented work demonstrating significant improvement in performance through RL on already long-COT 14B models.

Previous studies by DeepSeek-AI (2025), Yuan et al. (2025b), and Zhang et al. (2025) have shown that smaller models (with 32 billion parameters or fewer) can reach high performance levels through distillation from larger reasoning models. However, further improvement via RL (Reinforcement Learning) on already long-COT finetuned models is not yet widely reached by the community and is not as easily reachable as *zero* RL (Sec. 1). While Luo et al. (2025b) successfully demonstrated promising RL training on a smaller model DeepSeek-R1-Distill-Qwen-1.5B, we encountered challenges in replicating similar results with the larger DeepSeek-R1-Distill-Qwen-14B model using the same recipe.

After weeks of investigation, we arrived at our final RL solution consisting of a two-pass process, drawing inspiration from our effective curriculum SFT attempt and Cui et al. (2025). The process is as follows:

1. **Offline Data Selection**: Use Light-R1-7B-DS to sample results of RL training prompts. Keep only the prompts whose pass rate is between 0.25 and 0.625.

2. **Online Reinforcement Learning**: Apply GRPO on the filtered dataset.

In our observation, offline data selection plays a critical role. It filters out prompts that are too easy or too hard and ensures that the training data aligns with our rule-based answer verifier. When manually checking data with a pass rate of 0, we found that over half of the prompt answers are either unverifiable (due to containing text or complex conditional expressions) or incorrect. We utilize Light-R1-7B-DS as the difficulty estimation model because it is more efficient and demonstrates similar performance to larger models in terms of pass@64. Additionally, we use a model verifier to re-check data with a pass rate of 0. By filtering out the mis-verified data, we can successfully identify difficult prompts for future curriculum reinforcement learning.

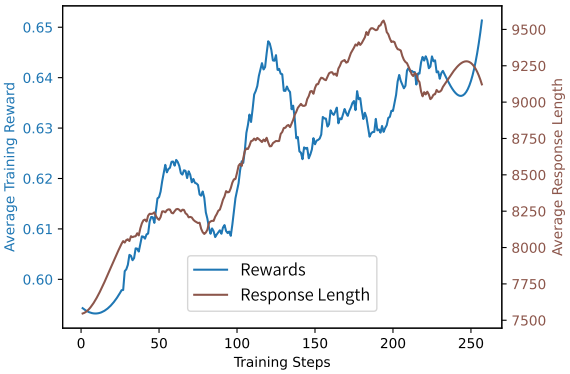

Figure 3: RL Learning curves of response length and train-reward, smoothed with Savitzky-Golay filter.

Model	AIME24	AIME25	GPQA	LCB
DS-distill-14B	69.7	50.2	59.1	52.9
+ SFT	72.3	58.9	60.3	55.9
+ GRPO epoch1	72.3	57.8	N/A	56.6
+ GRPO epoch2	73.4	60.5	N/A	56.5
Light-R1-14B-DS (GRPO epoch3)	**74.0**	**60.2**	**61.7**	56.0
GRPO data batch2	75.0	65.0	62.6	57.9

Table 4: RL performance improvement of Light-R1-14B-DS. Notably, we observe out-of-domain improvement in GPQA, indicating that reinforcement learning on mathematics-focused datasets potentially facilitates generalization across diverse domains.

We choose GRPO (Shao et al., 2024) as the optimization algorithm and implement it based on verl (Sheng et al., 2024). We also employ two techniques to stabilize the RL training process: modified version of length reward (Yeo et al., 2025) with weaker preference for short correct answers and importance sampling weight clipping (MiniMax, 2025).

For length control, we adopt a modified version of the approach proposed by (Yeo et al., 2025). Specifically, we clip the shortening reward when answers are correct to prevent initial length collapse. This technique helps maintain a reasonable answer length during training, ensuring that the model does not overly shorten its responses at the beginning of the learning process.

Regarding importance sampling weight clipping, we implement a broader two-sided clipping mechanism. Our observations have shown that occasional large positive policy ratios combined with negative advantages can lead to loss spikes, disrupting policy optimization. This two-sided clipping technique was also implemented in our previous experiments, in parallel with the findings reported by MiniMax (2025). By clipping the importance sampling weights, we can limit the influence of extreme values and make the training process more stable.

We use a rule-based reward and the deduplicated version of the Big-Math dataset (Albalak et al. (2025)). The experiments are conducted on a cluster of 16 * 8 A100 GPUs. The offline data selection process takes 4 hours, while the online reinforcement learning takes 26 hours to complete 140 steps and 42 hours to complete 220 steps.

As can be seen from Fig. 3, our RL training demonstrates expected behavior: simultaneous increase in response length and reward score. No interesting length dropping in the beginning. We evaluated RL epochs 1 and 2 after we finished training 3 epochs. As shown in Tab. 4, although first two epochs seem to bring not much improvement, the healthy RL training curves offer us confidence to continue training. Light-R1-14B-DS is finally RL trained for around 3 epochs, or 220 steps.

5 Conclusion

Our Light-R1 series addresses the challenge of training long reasoning models under resource constraints. We successfully train a long-COT model from scratch through our curriculum training strategy. Our carefully curated 3K dataset demonstrates remarkable transferability across various model sizes, significantly enhancing DeepSeek-R1-Distill models and establishing new performance benchmarks for models with 7B, 14B, and 32B parameters. Additionally, we investigate the efficacy of reinforcement learning when applied to a strong multi-stage finetuned base model, achieving superior performance while maintaining stable response length growth throughout the training process.

These advancements not only democratize access to R1-level reasoning capabilities but also provide valuable insights into curriculum design, data efficiency, and RL scalability for long reasoning models. Our open-source models, datasets, and code aim to accelerate research in developing compact yet powerful reasoning systems, particularly for resource-constrained applications. Future work will explore the integration of enhanced generalization capabilities for long reasoning models and further optimization of RL training efficiency.

D Training hyperparameters for Light-R1 series

Table 8: Training hyperparameters for Light-R1 series. Sequence length is determined by training data characteristics, except for GRPO where it balances multiple factors: minimizing roll-out computational costs, reducing inference cut-off ratio, and optimizing 32k context evaluation performance. To overcome the limitation of GPU memory for training DPO with 32k context length, we utilize the DPO implementation with sequence parallelism from 360-LLaMA-Factory (Zou et al., 2024). Models with the "-DS" suffix derive from the DeepSeek-R1-Distill-Qwen series, while others from Qwen2.5-32B-Instruct.

Model Names	Learning Rate	Batch Size	Seq Length
Light-R1-32B SFT Stage1	5.0×10^{-5}	96	20k
Light-R1-32B SFT Stage2	1.0×10^{-5}	32	20k
Light-R1-32B DPO	5.0×10^{-7}	16	32k
Light-R1-7B-DS	5.0×10^{-6}	32	20k
Light-R1-14B-DS-SFT	5.0×10^{-6}	32	20k
Light-R1-14B-DS (GRPO)	1.0×10^{-6}	128	24k
Light-R1-32B-DS	5.0×10^{-6}	32	20k

Efficient Out-of-Scope Detection in Dialogue Systems via Uncertainty-Driven LLM Routing

Álvaro Zaera*, **Diana Nicoleta Popa, Ivan Sekulić, Paolo Rosso**
Telepathy Labs GmbH, Zürich, Switzerland
{firstname}.{lastname}@telepathy.ai

Abstract

Out-of-scope (OOS) intent detection is a critical challenge in task-oriented dialogue systems (TODS), as it ensures robustness to unseen and ambiguous queries. In this work, we propose a novel but simple modular framework that combines uncertainty modeling with fine-tuned large language models (LLMs) for efficient and accurate OOS detection. The first step applies uncertainty estimation to the output of an in-scope intent detection classifier, which is currently deployed in a real-world TODS handling tens of thousands of user interactions daily. The second step then leverages an emerging LLM-based approach, where a fine-tuned LLM is triggered to make a final decision on instances with high uncertainty. Unlike prior approaches, our method effectively balances computational efficiency and performance, combining traditional approaches with LLMs and yielding state-of-the-art results on key OOS detection benchmarks, including real-world OOS data acquired from a deployed TODS.

1 Introduction

Intent detection is a fundamental task in natural language understanding, enabling systems to accurately interpret and respond to user queries by identifying their underlying intention (Casanueva et al., 2020). While intent detection ensures that in-scope (INS) queries are mapped to predefined intents, detecting out-of-scope (OOS) intents is equally critical, especially in real-world applications, where users often interact in unpredictable ways, by, e.g., posing queries that fall outside the system's designed capabilities (Larson et al., 2019; Wang et al., 2024).

Without effective OOS detection, such inputs could lead to incorrect responses, reduced user trust, and eventual system failures as the universe of OOS queries for any TOD system is infinitely large (Arora et al., 2024). By identifying OOS queries, systems can gracefully handle such cases, by generating a predefined or dynamic response indicating its inability to process the request, by activating a fallback mechanism such as escalating the conversation to a human agent or by triggering updates to expand system coverage.

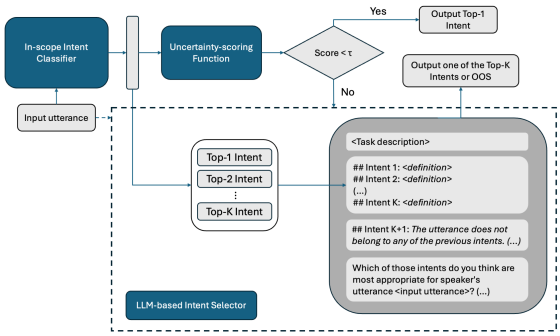

Figure 1: Overview of **UDRIL**. An **uncertainty-scoring function** is applied to the output of an **in-scope classifier**. When a user utterance is potentially out-of-scope, ambiguous or misclassified, as indicated by the uncertainty score and a defined threshold, a **fine-tuned LLM** is prompted to correct the prediction; otherwise, the classifier's original prediction is maintained.

To address these challenges, we propose **Uncertainty-DRIven Large language models triggering, (`UDRIL`)**, a two-step method that combines efficiency with accuracy for robust intent detection. `UDRIL` is depicted in Figure 1 and consists of an in-scope intent classifier, an uncertainty prediction scoring function, and an LLM-based module. Specifically, we use a BERT-based classifier to ensure both effectiveness and efficiency in a task-oriented dialogue system (TODS) that is currently deployed in production and handling tens of thousands of user interactions daily. To refine predictions, we first apply NNK-Means (Gulati et al., 2024) to identify high-uncertainty instances. For these cases, an emerging LLM-based approach is

*This work was conducted as part of the author's internship at Telepathy Labs.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 328–335

employed, where a fine-tuned LLM makes the final decision. This hierarchical approach leverages the efficiency of the BERT model for the majority of cases, while utilizing the LLM's capabilities for more ambiguous or complex inputs, including OOS detection. Our results demonstrate significant improvements in OOS detection, both on internal real-world dataset and on publicly available data. Notably, these gains are achieved with additional gains in effectiveness for INS intent detection ($+5\%$), highlighting the method's overall robustness and practicality.

Our main contributions are as follows:

- a simple modular framework for joint INS and OOS intent detection, combining strengths of traditional intent classification, uncertainty modeling and LLMs;
- a design that selectively escalates user input to a more resource-intensive LLM, balancing efficiency and performance;
- state-of-the-art results on publicly available datasets and on real-world industry data from a deployed system, demonstrating practical applicability and effectiveness.

2 Related Work

Intent detection is an important task both in TODS (Casanueva et al., 2020) and in, now emerging, agent-based systems, where we aim to identify the right knowledge sources, APIs, and tools to use (Arora et al., 2024).

Non-LLM-based OOS Intent Detection. Previous research explored various approaches to intent detection using transformer-based classifiers. A key area of focus has been OOS detection, with methods generally falling into two categories: post-hoc methods that detect OOS instances after obtaining model representations, and approaches that enhance model robustness by modifying the training process to better handle OOS data (Gulati et al., 2024). We focus on the first category, as these methods are modular, adaptable, and easier to maintain, allowing for easy updates to the architecture without requiring intensive retraining. Particularly relevant in practice is the work by Gulati et al. (2024), in which the soft-clustering technique NNK-Means (Shekkizhar and Ortega, 2021) is applied for OOS detection. This enhances performance while also offering superior computational and memory efficiency compared to previous approaches.

LLM-based Intent Detection. Recently, LLM-based intent detection received significant attention, with studies analyzing the effect in intent detection performance produced by the incorporation of high-quality natural language intent descriptions (Hong et al., 2024). Off-the-shelf LLMs have been shown to outperform non-LLM based methods in few-shot settings where the training set only consist of a small number of utterances per intent class (Parikh et al., 2023). Hong et al. (2024) and Zhang et al. (2024) elaborate on this finding, showing that LLMs fine-tuned on intent detection datasets improve off-the-shelf LLMs, incorporating the ability to detect intents for domains unseen in training. Fine-tuning has also proven to be beneficial in few-shot settings, allowing to obtain better results with smaller LLMs compared to off-the-shelf LLMs (Parikh et al., 2023) and in-context learning (ICL) approaches (Mirza et al., 2024)).

However, the performance improvement achieved by LLM-based intent detection, as compared to earlier non-LLM methods, is primarily reported in few-shot settings, where the training is strictly constrained by the number of intents per class. Previous studies reporting comparisons in full-data settings show that LLMs still underperform relative to BERT-based approaches in such cases (Parikh et al., 2023; Mirza et al., 2024). This underscores the continued relevance of BERT-based methods for practical deployment. Combining the strengths of both LLMs and BERT-based approaches could lead to more flexible systems, capable of adapting to a wider range of training data scenarios and enhancing deployment versatility.

In the context of out-of-scope (OOS) detection, LLMs have been shown to struggle with effective detection when relying solely on text representations without additional training (Arora et al., 2024; Wang et al., 2024). To address this limitation, Liu et al. (2024) explore the use of fine-tuning via low-rank adaptation (LoRA) (Hu et al., 2021) on INS data, demonstrating that this approach enhances the utility of last-token representations for OOS detection through cosine similarity.

Hybrid Approach. Through the current proposal, we aim to adopt a hybrid approach that combines non-LLM-based OOS intent detection methods with fine-tuned LLMs, leveraging the distinct strengths of the previously discussed methods. A relevant related work to ours is that of Arora

et al. (2024) who also propose a two-step approach to intent classification, albeit involving two LLM passes to determine if an utterance is OOS. Additionally, their proposal requires maintaining a vector storage of last token representations for a set of training examples per intent, performing negative data augmentation and employing multiple runs of monte carlo dropout, making the whole process less scalable. Also, contrary to Arora et al. (2024) who argue that fine-tuning an LLM for this purpose is impractical and prohibitive from development and maintenance perspective, our experiments as well as related work (Hong et al., 2024) show that fine-tuning with a set of guidelines is helpful for inference even when the said guidelines are later updated. Therefore, from the maintenance perspective, an update of the intent space and guidelines does not require extra work.

3 Uncertainty-Driven LLM-based Framework for OOS Intent Detection

We propose UDRIL, a framework for intent classification and OOS detection, consisting of an in-scope intent classifier and an LLM intent refiner, guided by an uncertainty scoring function f. The system first employs a classifier to generate an in-scope prediction. If the prediction is deemed confident by f, it is used directly; otherwise, the LLM refines it based on the classifier's output. The proposed framework enhances the cost-efficient classifier by enabling OOS detection while selectively leveraging the LLM, a computationally resource-heavy method, ensuring an accuracy - efficiency balance.

We next describe each component of our framework, noting that they can be replaced based on available resources and performance requirements.

3.1 In-scope Intent Classifier

Specifically, given user utterance u, the initial classifier's task is to model the probability distribution over a set of N classes $\mathcal{Y}$, selecting the one with highest probability as an output: $\hat{y}_C = \arg\max_{y \in \mathcal{Y}} P_C(y \mid u; \theta_C)$ where $P_C(y \mid u; \theta_C)$ is the classifier's predicted probability distribution and θ_C its parameters.

In order to meet the demands of low-latency applications, we model P_C with DistilBERT (Sanh et al., 2019), due to its strong balance between efficiency and effectiveness, making it suitable for an industry setting. Moreover, the training process only models θ_C and does not incorporate any methods specific to OOS detection, as this responsibility is entirely managed by the uncertainty-scoring function f and the LLM. Instead, the focus is on training the model to perform general classification tasks efficiently. We use focal loss (Ross and Dollár, 2017) during training to address the intent class imbalance that is likely to occur in the training dataset of real dialogue systems.

3.2 Uncertainty-Scoring Function

A function f provides an uncertainty score based on the output of the in-scope classifier, which aims to determine whether the prediction is sufficiently reliable or if further processing by the LLM is required. Specifically, score $s_u = f(u)$ indicates the uncertainty score for utterance u. If s_u exceeds a predefined threshold τ, the utterance is routed to the LLM. Otherwise, the classifier's prediction is used directly.

We model f with EC-NNK-Means (Gulati et al., 2024), a soft-clustering based method trained on utterance embeddings to learn a dictionary that minimizes the reconstruction error of the training data. At inference, s_u is the NNK-Means reconstruction error. In Gulati et al. (2024), it is shown that new data with high reconstruction error is more likely to be OOS. We observe that this method also has satisfactory results in identifying potentially misclassified INS data, making it valuable for detecting utterances that require prediction refinement. In our experiments, we apply EC-NNK-Means to the last output embedding of the DistilBERT [CLS] token.

Threshold τ can be tuned to route higher, or lower, ratio of utterances to the LLM, balancing the effectiveness and efficiency as needed. In this work, we experiment with three specific thresholds to showcase its effect on the routing ratio and the overall performance. The selected thresholds define low-routing ($\tau = 0.15$), moderate-routing ($\tau = 0.10$) and high-routing ($\tau = 0.05$) strategies.

3.3 LLM-Based Intent and OOS Detection

If the classifier is uncertain, i.e., $s_u > \tau$, the utterance u is forwarded to the LLM to make a final decision. Formally, given the top-k intent candidates $(\hat{y}_{(1)}, \ldots, \hat{y}_{(k)})$, as modeled by P_C, the LLM either selects the most appropriate intent among the top-k or determines that u is out-of-scope (OOS):

$$\hat{y}_{LLM} = \underset{y \in \{\hat{y}_{(1)}, \ldots, \hat{y}_{(k)}, OOS\}}{\arg\max} P_{LLM}(y \mid u, \hat{y}_{(1)}, \ldots, \hat{y}_{(k)}; \theta_{LLM}) \quad (1)$$

In this work, we learn θ_{LLM} of P_{LLM} via fine-tuning using LoRA (Hu et al., 2021) with a language modeling objective. Our method is designed to provide the LLM with OOS detection capabilities using only INS data. For the dataset creation, given each <utterance-gold label> pair (u, y_u), we additionally create one negative example (u, OOS), using k candidates $(y'_{(1)}, \ldots, y'_{(k)})$ sampled from $\mathcal{Y} \setminus \{y_u\}$, as described in Algorithm 1. We then train using the obtained dataset D' to maximize Eq. (1).

Algorithm 1 Fine-tuning Dataset Creation

Input: INS Dataset D, Classifier P_C, Param θ_C
Output: Fine-tuning Dataset D'

Initialize: $D' \leftarrow \emptyset$
for each (u, y_u) in D **do**
  Use $P_C(\cdot\,|u; \theta_C)$ to obtain $(\hat{y}_{(1)}, \ldots, \hat{y}_{(k)})$
  Add $(u, (\hat{y}_{(1)}, \ldots, \hat{y}_{(k)}), y_u)$ to D'
  Sample k distinct intents from $\mathcal{Y} \setminus \{y_u\}$: $(y'_{(1)}, \ldots, y'_{(k)})$
  Add $(u, (y'_{(1)}, \ldots, y'_{(k)}), OOS)$ to D'
end for
Return: Fine-tuning Dataset D'

For our experiments, we use Llama 3.1-8B (Dubey et al., 2024) as the LLM with $k = 3$ intent descriptions. The prompt contains a description of each of the k intents. Each epoch, the order of the k candidates is shuffled in the prompt. The fine-tuning set is created using 5 random utterances from the training set per intent class. In cases where the number of available utterances was lower than 5, we performed data augmentation. Having a limited number of examples, combined with using a parameter-efficient fine-tuning technique (LoRA), facilitates deployment in production environments.

3.4 Evaluation Setup and Data

Internal benchmark. Our main goal is to tackle intent detection in our deployed TOD system; thus, we primarily evaluate our approach on an internal benchmark. To this end, we extract 6492 real user utterances from our past user-system interactions and manually annotate them with one of 42 intents. We refer to this dataset as *BookData*.

Public benchmark. To ensure comparability to related work, we further evaluate our methods on the real-world data from the HINT3 collection (Arora et al., 2020), created from live chatbot interactions in diverse domains. The collection contains three datasets: *SOFMattress* (mattress products retail), *Curekart* (fitness supplements retail), and *Powerplay11* (online gaming). Utterances in the train sets are labeled with between 21–57 INS intents, while the test sets additionally contain a large number of OOS utterances.

Intent guidelines. While for internal data, we have access to annotation guidelines, for public benchmarks such guidelines are not made available. To solve this, we generate guidelines for each of the public datasets using OpenAI's GPT3.5: for each intent, we provide as input the intent name and all utterances that are part of the train set for that intent. We then ask the LLM to generate a definition such that, when presented along with such examples, a human would choose to label the examples with the given intent. We make no further adjustments or post-processing to the obtained guidelines.

4 Results and Discussion

Table 1 presents results on HINT3 public datasets, comparing state-of-the-art solutions (Arora et al., 2024) and our methods. We compare to three main categories of related work results: (1) non-LLM (*SNA*) and the best performing LLM-based approaches in Arora et al. (2024): *Mistral-7B*, *Claude v3 Haiku* and *Mistral Large*; (2) hybrid models and (3) the proposal of Arora et al. (2024) specifically designed for OOS intent detection.

4.1 Open-Source Data

Average F1-scores across all datasets show that `UDRIL` provides an average of 2-3% relative improvement compared to state-of-the-art methods that employ significantly larger LLMs, up to 13% relative improvement compared to traditional classifier-based approaches and up to 34% relative improvement when compared to similar-sized LLMs (see comparison to *Mistral-7B* (Arora et al., 2024)). The increase in performance holds regardless of the routing strategy employed. It also holds when using an LLM that was not fine-tuned for the task compared to other similar-sized LLMs (`UDRIL-noFT` can yield up to 10% increase compared to *Mistral-7B* (Arora et al., 2024)), validating the value of our architecture beyond fine-tuning.

`UDRIL` also outperforms hybrid approaches by up to 5%, despite these latter ones using much larger LLMs. Methodology-wise, `UDRIL` is also simpler: there is no need for negative data augmentation

Method	Curekart	SOFMattress	PowerPlay11	Avg Score	BookData	Param
SNA (Arora et al., 2024)	0.709	0.672	0.639	0.673	-	NA
Mistral-7B (Arora et al., 2024)	0.615	0.699	0.384	0.566	-	7B
Claude v3 Haiku (Arora et al., 2024)	0.775	**0.815**	0.646	0.745	-	NA
Mistral Large (Arora et al., 2024)	0.779	0.767	0.668	0.738	-	123B
SNA + Claude v3 Haiku (Arora et al., 2024)	0.756	0.730	0.690	0.725	-	NA
SNA + Mistral Large (Arora et al., 2024)	0.761	0.719	0.692	0.724	-	NA
Mistral-7B-2steps (Arora et al., 2024)	0.766	0.751	**0.739**	0.752	-	7B
UDRIL-noFT (low-route)	0.637	0.661	0.525	0.607	0.831	8B
UDRIL-noFT (moderate-route)	0.660	0.672	0.542	0.624	0.826	8B
UDRIL-noFT (high-route)	0.662	0.676	0.547	0.628	0.790	8B
UDRIL-noFT (full-route)	0.655	0.669	0.545	0.623	0.748	8B
UDRIL-FT (low-route)	0.727	0.764	0.677	0.722	0.852	8B
UDRIL-FT (moderate-route)	0.779	0.777	0.701	0.752	**0.857**	8B
UDRIL-FT (high-route)	**0.791**	0.784	0.710	**0.761**	0.853	8B
UDRIL-FT (full-route)	0.787	0.777	0.708	0.757	0.850	8B

Table 1: F1 scores across state-of-the-art methods and our proposed solution UDRIL, with different routing strategies. The postfix *-noFT* refers to off-the-shelf models that were not fine-tuned, while *-FT* refers to the fine-tuned version of Llama 3.1-8B. *Mistral-7B* is the model proposed in Arora et al. (2024), with comparable number of parameters to our method, while *Claude v3 Haiku* and *Mistral Large* are the best performing models of Arora et al. (2024) - albeit much bigger than our proposed solutions. *SNA + Mistral Large*; and *SNA + Claude v3 Haiku* are hybrid models and *Mistral-7B-2steps* is the best OOS model in (Arora et al., 2024). Best scores are in **bold**, second best are underlined.

for the classifier or multiple uncertainty estimation runs, unlike other hybrid proposals.

Finally, UDRIL yields improvements over the OOS-specific method of Arora et al. (2024) for Curekart and SOFMattress and incurs only slight degradation in the case of PowerPlay11, making it on average the better performing model of the two. Beyond performance, the simplicity of UDRIL also makes it easier to use in practice.

4.2 Real-World Data

We observe a performance increase on *BookData* when fine-tuning is employed and a progressive decrease as we route more utterances with the non-fine-tuned models. These results suggest that, for a real-world industry setting, fine-tuning LLM-based models on in-domain labeled data is still superior to switching to in-context learning with LLMs.

Furthermore, increasing the amount of training data, even with noisy labels, improves the performance of a DistilBERT-based classifier, thereby reducing the need for extensive routing to achieve optimal results. Additionally, fine-tuning the LLM on a small set of utterances enhances the framework's robustness across various routing strategies, enabling effective out-of-scope (OOS) handling without compromising in-scope (INS) performance.

4.3 Impact of Fine-Tuning on Performance

Fine-tuning improves the OOS detection capabilities of UDRIL by substantially increasing recall, with only a minor reduction in precision. For instance, in BookData with the full-route setting, the OOS recall increases from 0.403 to 0.698 and the precision is very similar, dropping from 0.514 to 0.508. The reduction in OOS precision could potentially lead to a slight decrease in INS performance. This is not the case for BookData, where the INS Accuracy increases from 0.768 with the off-the-shelf LLM to 0.856 with the fine-tuned version in the full-route setting. However, in the HINT3 dataset we do observe slight drops: Curekart 0.817 to 0.815, Sofmattress 0.806 to 0.743 and Powerplay11 0.599 to 0.547. We observe that incorporating OOS detection capabilities through fine-tuning is more likely to negatively impact INS performance for cases where the first-stage classifier performs worse (such as Powerplay11).

4.4 Balancing INS and OOS performance

Table 2 compares UDRIL with the method specifically designed for OOS detection in Arora et al. (2024). Our approach strikes a better balance between OOS recall and INS accuracy, leading to a superior overall F1 score on two out of three datasets. Powerplay11 is the only exception, where

		F1 Score	INS Accuracy	OOS Precision	OOS Recall
SOF Mattress	Mistral-7B-2steps (Arora et al., 2024)	0.751	**0.767**	-	0.715
	UDRIL-FT (high-route)	**0.784**	0.759	0.725	**0.840**
Curekart	Mistral-7B-2steps (Arora et al., 2024)	0.766	0.736	-	**0.782**
	UDRIL-FT (high-route)	**0.791**	**0.830**	0.888	0.744
Power Play11	Mistral-7B-2steps (Arora et al., 2024)	**0.739**	0.411	-	**0.950**
	UDRIL-FT (high-route)	0.710	**0.557**	0.857	0.748

Table 2: Best-performing Arora et al. (2024) method vs UDRIL, focusing on OOS and INS performance.

Arora et al. (2024) outperforms ours. However, this can be attributed to the fact that ∼68% of the utterances in the test split of Powerplay11 are OOS. Their method, which achieves a significantly high OOS recall at the cost of excessively low INS accuracy, has limited practical applicability compared to our more balanced approach. That said, our approach does not achieve ideal INS accuracy either - most likely due to the first-stage classifier: since Powerplay11's training set is of lower quality, this directly impacts both the DistilBERT classifier and the overall performance of the framework.

Intent guidelines Experiments showed that fine-tuning using guidelines of one dataset can be beneficial across datasets: results on SOFMattress and PowerPlay11 with UDRIL fine-tuned using Curekart-specific guidelines are comparable to those obtained when fine-tuning using their own guidelines directly. These findings are in line with recent work (Hong et al., 2024) and support the usability of the method in the lack of up-to-date dataset-specific guidelines at fine-tuning time.

Uncertainty measures and LLMs. We experimented with different LLMs, including recent *DeepSeek-R1-Distill-Llama-8B* and *DeepSeek-R1-Distill-Qwen-7B* models[1], as well as several uncertainty measures, such as Shannon Entropy and Energy, as proposed in (Sun et al., 2024). Results were similar to the reported ones with some degradation observed when using other uncertainty measures.

How good is our routing strategy? We observe routing strategies above *moderate* yield improvements over existing models, with the preferred approach consisting in *high* amount of routing.

The percentage of routed OOS utterances varies between 70-96% for Curekart, 84-98% for SOFMattress and 79-98% for PowerPlay11, depending on how conservative we are. Furthermore, of the incorrectly labeled INS utterances, our method routes between 40-88% in the case of Curekart, 53-87% for SOFMattress and 65-97% for Powerplay11, as seen from Figure 2. We also observe that when DistilBERT performs better, fewer correctly classified INS utterances are routed to the LLM, demonstrating that the routing method effectively captures prediction uncertainty. We conclude that our routing method benefits both OOS and INS labels.

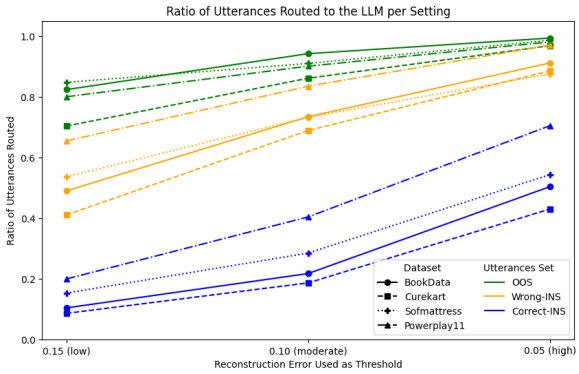

Figure 2: Impact of routing threshold to number of routed utterances across four datasets and three utterance label sets.

5 Conclusion

In this paper, we introduce UDRIL, a framework that achieves state-of-the-art performance in both in-scope (INS) intent classification and out-of-scope (OOS) intent detection. Unlike approaches that require modifying or retraining the base intent classifier, UDRIL operates by modeling its outputs, enabling OOS detection while preserving the efficiency of the existing classifier. This makes our framework particularly well-suited for real-world deployment, as shown by the results on our internal benchmark, derived from real user-system interactions, where maintaining low latency and computational efficiency is crucial.

Moreover, UDRIL is modular, allowing for the seamless substitution of different components: base classifier, uncertainty estimation method, and LLM. Furthermore, it provides a practical mecha-

[1]https://huggingface.co/deepseek-ai

nism for controlling efficiency-performance trade-offs by adjusting the routing percentage threshold, ensuring adaptability to varying production constraints. By enabling reliable OOS detection without disrupting existing intent classification models, our approach offers a scalable solution for enhancing the robustness of deployed TOD systems.

Ethical Considerations

We prioritize user privacy and ensure that no real conversations are reported in this paper. Additionally, we do not release any data or model weights trained on user interactions. All data used in our study was collected with user consent, ensuring ethical use and compliance with the US privacy considerations.

Abstract

Discovering and evaluating long-form talk content such as videos and podcasts poses a significant challenge for users, as it requires a considerable time investment. Previews offer a practical solution by providing concise snippets that showcase key moments of the content, enabling users to make more informed and confident choices. We propose an LLM-based approach for generating podcast episode previews and deploy the solution at scale, serving hundreds of thousands of podcast previews in a real-world application. Comprehensive offline evaluations and online A/B testing demonstrate that LLM-generated previews consistently outperform a strong baseline built on top of various ML expert models, showcasing a significant reduction in the need for meticulous feature engineering. The offline results indicate notable enhancements in understandability, contextual clarity, and interest level, and the online A/B test shows a 4.6% increase in user engagement with preview content, along with a 5x boost in processing efficiency, offering a more streamlined and performant solution compared to the strong baseline of feature-engineered expert models.

1 Introduction

Podcasts, videos, and other long-form talk content, have become flourishing media, offering diverse content that caters to a wide range of audiences. Discovering new content, however, remains challenging, as the long-form nature of episodes demands significant time investment to assess their relevance (Jones et al., 2021). Previews, which are short and representative segments of an episode, provide a solution by capturing engaging, self-contained moments that are easy to understand without additional context (Barua et al., 2025).

Generating effective previews from episodes that can exceed an hour is a challenging task and requires robust content understanding. For example, to locate self-contained segments, previous work suggests using segmentation methods to detect topic transitions (Lukasik et al., 2020; Liu et al., 2022a; Retkowski and Waibel, 2024; Ghazimatin et al., 2024). These methods, however, may miss many interesting moments depending on the granularity of segmentation. Furthermore, they typically fail to distinguish between segments containing commercial content such as ads or self-promotions which do not represent the whole content.

Traditional preview extraction approaches often rely on sophisticated feature engineering to derive aggregations of expert models such as sentiment analysis, topic modeling, speech classification, and ad detection, which can be resource-intensive and time-consuming (Rui et al., 2000; Dabholkar et al., 2016). In the meantime, the advent of large language models (LLMs) have transformed the landscape of content understanding and curation (Salemi et al., 2023; Kirstein et al., 2024; Manatkar et al., 2024).

In this paper, we propose leveraging large language models (LLMs) to extract short, compelling and self-contained episode previews. Using only text-based inputs, including episode metadata (title and description) and transcript, we employ few-shot learning with curated examples of high-quality previews to guide LLMs in identifying the characteristics of an effective preview. To extract the preview segment, we prompt the LLMs to provide structured outputs, specifying start and end timestamps to define precise boundaries.

Our contributions are threefold. First, we successfully integrate an LLM into a large-scale, real-world application for podcast preview extraction. Secondly, we propose to use sentence indexing and sentencization to effectively analyze and index lengthy podcast transcripts and accurately retrieve LLM-selected previews. Finally, we demonstrate significant performance improvements over strong baseline expert models through offline human eval-

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 336–344

uations and online A/B testing, while achieving a 5x improvement in processing efficiency. By showcasing the successful productionization of this novel application of LLMs, we aim to advance the discourse on leveraging language models for complex content processing tasks, highlighting their potential to simplify workflows and enhance performance in real-world applications.

2 Previous Work

In this section, we highlight previous related work on highlight extraction, document summarization, and podcast preview extraction.

2.1 Highlight Extraction

Generating previews for podcast episodes closely parallels the tasks of highlight extraction (Sun et al., 2014; Badamdorj et al., 2021; Liu et al., 2022b; Jie et al., 2024). Highlights are typically annotated by human experts (Collins et al., 2017; Lei et al., 2021) or inferred through weakly supervised signals, such as identifying frequently edited segments in videos (Sun et al., 2014).

Given the domain dependency of labeled data and the cost of gathering them for long-form content, unsupervised approaches for highlight detection have also been explored. These include leveraging aesthetic features (Song et al., 2016) (e.g., selecting visually pleasing thumbnails), detecting recurring audio-visual patterns (Islam et al., 2024) (e.g., cheering or clapping in sports videos), or employing methods like k-means clustering (Song et al., 2016) or graph-based techniques (Erkan and Radev, 2004) to identify representative parts of the text or video. While podcast preview generation is similar to highlight extraction, it introduces an additional challenge: the previews must serve as standalone content, providing listeners with a self-contained piece of the content that can be understood on its own.

2.2 Document Summarization

Previous studies on document summarization highlight LLMs' power to identify and retrieve *key information* from lengthy documents using both extractive summarization (Zhang et al., 2023; Chhikara et al., 2025) and abstractive summarization (Tanaka, 2022; Chang et al., 2024) approaches. Building on this foundation, we utilize LLMs to extract previews, focusing specifically on extracting contiguous segments of text. However, effective methods are essential for locating and extracting information from *long* texts, and Ghazimatin et al. 2024 illustrate successful indexing mechanisms for LLM-selected chapters, essential for accurate retrieval from long texts which inspires our work.

2.3 Traditional vs. LLM-Powered Podcast Preview Extraction

Previously, preview extraction relied on sophisticated feature-engineered systems, requiring the aggregation of one or more expert models such as sentiment analysis model and emotion recognition model (Zhu, 2021; Smith et al., 2017; Irie et al., 2010; Rehusevych and Firman, 2020). Our work has been inspired by such traditional methods to focus on human perception-related aspects like sentiment and attention in initial prompts. However, we are able to outperform these traditional approaches by utilizing LLMs, which automate and improve the extraction and retrieval process through implicit prompt iteration for a more nuanced understanding of transcript content.

Overall, by focusing on LLM-powered methodologies, our work advances beyond conventional systems, offering a more streamlined and contextually aware approach for podcast preview extraction and information retrieval.

3 System Design

In this section, we describe two systems for podcast preview generation: the sophisticated, feature-engineered legacy machine learning (ML) preview extraction system, and the newly developed LLM preview extraction system.

3.1 Language Filtering

Currently, both the legacy ML and LLM preview systems have been primarily developed on English podcast data, therefore language filtering is applied in both systems to only process English-language episodes. The legacy ML preview system employs an audio-based in-house model to perform spoken language identification similar to Zhu et al. 2023. The results are then combined with metadata language annotations (which can be noisy) to co-determine the episode language and filter for only English-language episodes. In contrast, the LLM preview system relies solely on existing noisy metadata language annotations for filtering English episodes, without needing extra language detection techniques.

3.2 Legacy ML Preview System

The legacy ML preview system (Figure 1 left) is a sophisticated system that utilizes advanced feature engineering and a series of expert models to generate podcast previews. This system involves multiple stages of data processing and signal analysis to select previews. The main components are as follows:

Topic Analysis, Sentiment Analysis and Primary Signal Aggregation The podcast episode transcript is first analyzed using an in-house model to identify key topics, which are then processed by another in-house model to assess the sentiment intensity related to each topic. This creates the so-called *primary signals*, which are aggregated to compute topic trends and identify dominant topics. Speaker boundaries and question-answer segments are also analyzed based on the transcript to ensure smooth transition of topics.

Ad Detection and Sound Event Detection: In parallel to primary signal extraction, the system uses an in-house ad detection model to identify ad content from transcript and an in-house sound event detection model to detect non-speech regions from episode audio. These create the so-called *secondary signals*, which are scaled and aggregated based on predetermined adjustment scores for different types of non-core speech elements such as ads or music.

Signal Merging and Peak Selection: By processing primary and secondary signals, the system derives overall *selectivity scores*. These scores are analyzed to locate peak regions approximately 60 seconds long, from which previews may be extracted.

Sentence Break Detection, Trimming and Ranking: An in-house technique is applied on the episode audio to identify sentence starts and ends, which are considered suitable candidates for preview starts and ends. The detected sentence breaks are then combined with the *selectivity scores* and fed into an in-house trimmer model to adjust the start and end of each preview candidate to improve coherence and context while adhering to the 1-minute duration requirement. Lastly, all preview candidates are ranked by an in-house ranking model to assign a score for each preview candidate. The candidate with the highest ranking score is used as the final preview for the episode.

This sophisticated legacy ML preview system showcases the extensive feature engineering and model integration necessary to produce high-quality podcast previews.

3.3 LLM Preview System

While we use a variety of models at Spotify, for this particular use case we use Gemini 1.5 Pro[1] in the LLM preview system (Figure 1 right) to generate podcast previews. Below are the key steps of the system:

Pre-processing: We first sentencize the podcast transcript using simple heuristics such as punctuation markers and annotate each sentence with start and end timestamps in seconds. This step is crucial for enabling the LLM to accurately identify and retrieve the desired preview offset. These timestamped sentences, along with episode metadata such as title and description, form part of the input prompt to the LLM. Appendix A provides a mock example of a pre-processed, sentencized, and timestamped transcript.

Preview Offset Selection and Preview Metadata Generation: We then apply the LLM to perform preview selection and metadata generation. The LLM prompt for preview offset selection incorporates three key elements:

1. **Structured reasoning process:** The prompt guides the LLM through a step-by-step structured reasoning process. It begins by examining the episode's title, description, and transcript to identify the main topic. The LLM then evaluates preview segments for relevance and engagement. As part of this structured reasoning, the LLM also generates preview metadata, including a concise explanation of the preview's engagement value and a list of topic tags. This structured reasoning approach not only enhances preview relevancy but also makes LLM's decision-making process more transparent and informed.
2. **Preview requirements:** A list of requirements are included in the prompt to ensure that the preview begins with an engaging introduction, progresses logically from foundational concepts to detailed insights, excludes ad content, and starts and concludes with complete thoughts, while aligning with the episode's central theme, evoking emotional resonance, and providing valuable insights. The preview is also required to be approximately one minute long, maximizing audience

[1]Gemini 1.5 Pro: https://ai.google.dev/gemini-api/docs/models/gemini#gemini-1.5-pro

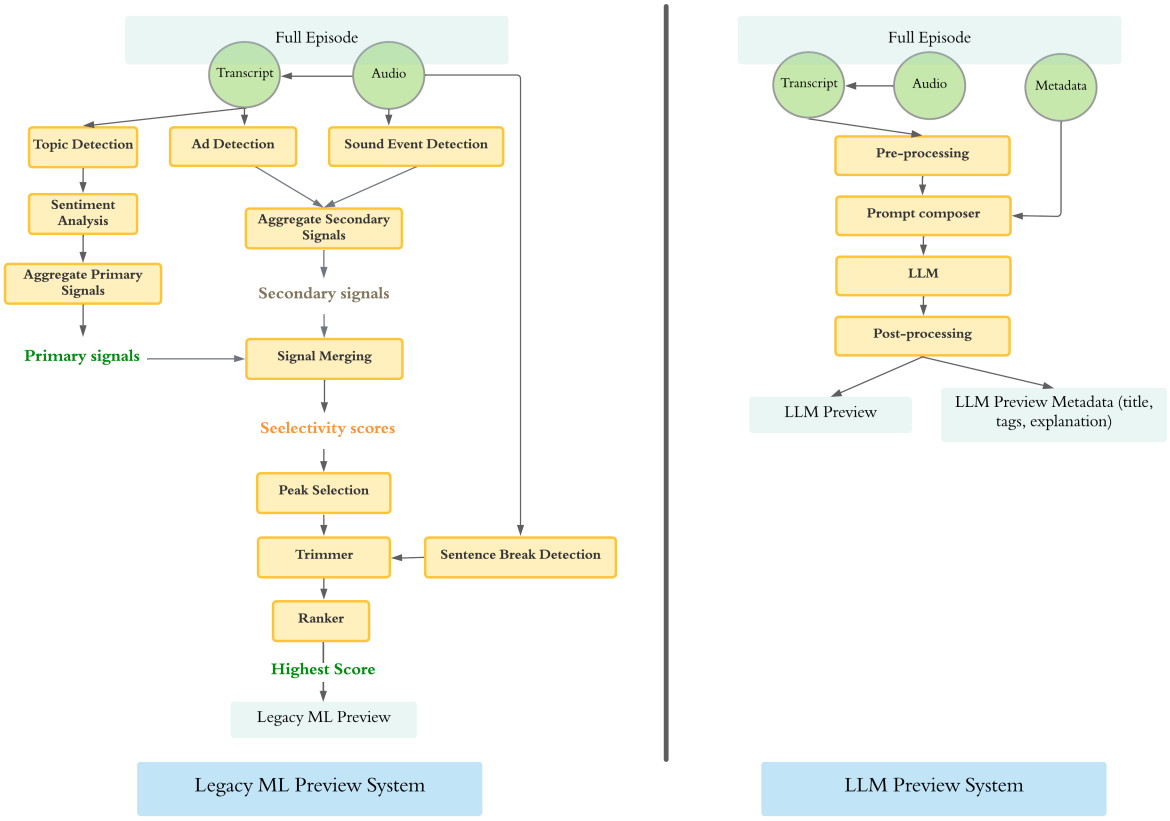

Figure 1: Legacy ML preview system vs. LLM preview system.

engagement during normal attention span (Simon et al. 2023).

3. **Few-shot learning:** A series of manually curated preview examples are included in the prompt to guide the LLM in learning what constitutes a good preview through few-shot learning (Brown et al., 2020).

Prompt Iteration Process: We manually optimized the prompt to achieve strong alignment with human judgment on a small evaluation dataset of episodes from diverse categories, ensuring broad applicability and generalization across different content types. During the prompt iteration process, feedback was gathered directly from the product and design teams as it was challenging to use automated prompt engineering to replace human input in this case, particularly product and design experts. The process involved iteratively adding and deleting preview requirements and few-shot examples, with human experts re-evaluating the prompt on the small evaluation dataset after each major change to ensure improvement and alignment with human judgment. This manual prompt iteration process, despite not being automated and requiring human oversight, effectively replaced the feature engineering process of the legacy ML system, as it allows for easier incorporation of human feedback, significantly enhancing flexibility and speed when adapting to new preview requirements.

Post-processing: To maintain a concise and coherent preview duration, the preview selected by the LLM is trimmed to the last complete sentence that starts within one minute. While both the LLM-selected preview and the legacy ML system's preview don't always guarantee a one-minute length, the average LLM preview is around 62 seconds long, and the legacy ML preview is around 56 seconds. This means their average durations are not too far apart. Additionally, the need for post-processing trimming is primarily driven by product requirements.

3.4 Comparison of LLM and Legacy ML Preview Systems

In comparison, the LLM system offers several advantages over the legacy ML system:

1. **Streamlined Iterations and Adaptations**: Prompt engineering with LLMs is significantly faster and more streamlined than manual feature engineering and expert model ag-

gregation, as LLMs allow for iterative refinement and quick adaptations to changing requirements.

2. **Lower Maintenance Complexity**: The legacy ML system involves multiple models and dependencies, making maintenance more complex. In contrast, the LLM system utilizes a single LLM framework, reducing complexity and maintenance effort.
3. **Faster Processing Speed**: The legacy ML system requires processing audio directly, which is inherently slower compared to processing text. In comparison, the LLM system works primarily with text data and benefits from faster processing times. Both systems have been deployed on the Dataflow streaming platform[2]: The legacy ML system takes an average of 100 seconds to process an episode, and the LLM system takes an average of less than 20 seconds; even though both systems are already very fast, the LLM system processes episodes faster, resulting in a 5x improvement in processing time and significantly enhancing scalability.

These improvements highlight the LLM system's advantages in terms of simplicity and scalability, making it a more streamlined solution for generating podcast previews.

4 Experiments

In this section, we describe two experiments that we have conducted to evaluate the proposed LLM previews against the legacy ML previews: an offline human evaluation and an online A/B test.

4.1 Offline Human Evaluation

We recruited around 20 evaluators internally to evaluate LLM previews against legacy ML previews, and we used Label Studio[3] platform for data collection and human annotation.

Evaluation Setup: Each evaluator was asked to evaluate around 20 episodes (the actual number of episodes per evaluator was determined based on the time they were able to commit). For each episode, the evaluator was provided with episode metadata including episode title, episode description, and show name, as well as a legacy ML preview and an LLM preview, which were randomly shuffled to prevent position bias favoring one variant over the other. The evaluator then listened to both previews with subtitles, and was asked to choose the better one or indicate a tie.

Specific Assessment Questions: After selecting a preferred preview for a given episode, the evaluator was asked to rate both previews based on three specific questions to understand the relative performance of both systems:

1. *Understandability:* Whether the preview helps determine the episode's relevance for the listener.
2. *Contextual Clarity:* Whether the preview, along with metadata, provides sufficient context to grasp what is being discussed.
3. *Interest Level:* Whether the preview highlights an interesting segment of the episode.

In Table 1 we present the actual questionnaire that we created for each evaluator on the Label Studio platform (metadata such as episode name, audio file, and subtitles are excluded from the table for simplicity).

4.2 Online A/B Test

The online A/B test was designed to evaluate the impact of LLM previews on user engagement and content discovery compared to legacy ML previews.

A/B Test Context: In the realm of digital media consumption, enhancing user engagement by facilitating content discovery is a critical focus for many platforms. We tested our LLM previews against legacy ML previews in a product that provides an interface where users can navigate through a series of podcast previews. The primary function of previews in this product is to aid users in evaluating unfamiliar podcast content, thereby enhancing podcast discovery. Improvements to these previews are expected to enhance user evaluation experience.

A/B Test Hypothesis: We hypothesized that LLMs would select more compelling episode previews compared to the legacy ML expert models, thus enhancing the value of each preview content and increasing the likelihood that users would have a better and more effective evaluation experience with the preview.

A/B Test Setup: The online A/B test was conducted over 6 weeks across 67 English-speaking countries and was available to all users in those countries. Users were evenly split between treatment and control, with users in the treatment group receiving LLM previews in the product. In order

[2]Dataflow streaming pipelines: https://cloud.google.com/dataflow/docs/concepts/streaming-pipelines

[3]Label Studio: https://labelstud.io/

Questions per preview	Response
Does the preview help you decide if this episode is relevant for you?	Yes | No
Does the preview plus metadata contain enough context to understand what is being talked about from the preview?	Yes | No
Does the preview show an interesting part of the episode?	Yes | No
Question per episode	**Response**
Which preview is better?	Preview 1 | Preview 2 | A tie

Table 1: Offline human evaluation Label Studio questionnaire

to validate the usefulness of LLM previews, we generated LLM previews for a subset of recently published English episodes, resulting in LLM previews for 34% of episodes seen in the product during test period (remaining episodes used the same previews as control group). Users in the control group received legacy ML previews but never LLM previews. This test ran for 6 weeks, allowing sufficient time to gather meaningful data on user interactions. By implementing this test setup, we aimed to observe measurable differences in user engagement, specifically focusing on whether LLM previews could help with content discovery compared to legacy ML previews.

5 Results

In this section, we present the results of our offline human evaluation and online A/B test, both of which demonstrate that LLM previews outperform legacy ML previews. These findings showcase the power of LLMs in extracting more engaging and contextually rich podcast previews that improve podcast evaluation and discovery.

5.1 Offline Human Evaluation Results

We gathered 238 valid episode annotations to compare the performance of LLM previews against legacy ML previews.

Overall Comparison Results: The results indicated that LLM previews were better than or non-inferior to legacy ML previews 81.09% of the time, when considering both wins and ties, and better than legacy ML previews 54.2% of the time, when considering only wins. This implies that LLM previews were either preferred over or performed equivalently to legacy ML previews in the majority of cases (Figure 2). A binomial test[4] conducted on these results yielded a p-value of 1.37e-10, allowing us to reject the null hypothesis with confidence (at a significance level of 0.001) and conclude that LLM previews' better performance is statistically significant and not due to random variation.

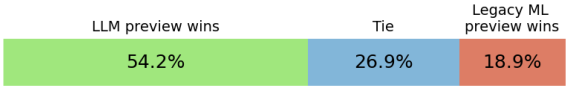

Figure 2: Offline human evaluation: Overall comparison results between LLM previews and legacy ML previews

	Z-Test statistic	P-value	LLM previews better statistically significant?
Q1: Understandability	-4.05	5.09e-05	Yes
Q2: Contextual clarity	-3.40	0.00067	Yes
Q3: Interest level	-4.32	1.59e-05	Yes

Table 2: Offline human evaluation: Question-specific results with Proportion Z-Test

Question-Specific Results: Further analysis using a Proportion Z-Test[5] on the three specific questions confirmed that LLM previews statistically significantly outperformed legacy ML previews in terms of *understandability*, *contextual clarity*, and *interest level* (Table 2).

5.2 Online A/B Test Results

The A/B test results indicate a marked improvement in user podcast discovery and evaluation with LLM previews over legacy ML previews. The following metrics were used to evaluate this impact:

Podcast Evaluation Time per User: A statistically significant improvement of 4.6% was observed in the time users spent evaluating podcast previews during their second week in the experiment, indicating that more engaging LLM previews led to enhanced user evaluation experience.

Evaluation Time per Preview: LLM previews resulted in a statistically significant 4% increase in the average time users evaluated each preview during their second week in the experiment. This improvement indicates the capability of LLMs to produce more compelling and effective preview segments, enhancing user interest and providing more value out of user evaluation period.

6 Conclusion

In this work, we explored leveraging an LLM for podcast preview generation in a real-world application. Offline human evaluation and online A/B test results demonstrate that the LLM preview system outperforms the legacy ML system, which relies on a sophisticated aggregation of expert models. Transitioning to an LLM-based system streamlines preview generation by eliminating extensive feature engineering. This change speeds up iterations, accelerates adaptations to changing requirements, enhances scalability, and improves preview quality, highlighting the transformative power of LLMs in practical applications to simplify complex content processing tasks.

7 Ethics Statement

Our system prioritizes creator autonomy through opt-out options. Podcast creators maintain full control over their content by having the option to opt out of machine-generated podcast previews (including both LLM previews and legacy ML previews). They can also generate their own previews which will replace any machine-generated previews, ensuring that their content is represented according to their preferences.

We also prioritize accessibility and inclusivity by exploring systems that can more easily adapt to diverse contexts. For instance, unlike traditional ML systems requiring extensive retraining for each language, LLMs offer better flexibility to adapt across different languages. This adaptability allows for the creation of high-quality previews that cater to diverse audiences, enhancing user experience and expanding the reach of engaging content.

Abstract

The advent of Large Language Models (LLMs) has transformed how complex tasks across various domains can be automated. One of the industry trends today is Agentic AI, which leverages LLMs to operate multiple tools and provide automatic configuration. In the domain of cloud computing, Agentic AI might be used, for example, with the generation of Kubernetes manifests – structured configuration files that define containerized environments. However, effectively applying LLMs to domain-specific tasks often reveals knowledge gaps that impact the accuracy and reliability of the generated output.

To address these challenges, we propose *KGen*, a pipeline for generating K8s manifests directly from user-described intents expressed in natural language using LLMs. Our approach leverages an extensive *n*-shot learning analysis to choose the appropriate number of examples that can better guide the adopted models in generating the manuscripts while also looking at the computational cost. Our results validate the use of LLM in this task and show that (as expected) increasing the number of *n*-shot examples can improve the quality of the generated configurations when adopting more specialized models, such as `Mixtral-8x7B` (which uses the Mixture of Experts approach) and `Prometheus-8x7B-v2.0`, but (surprisingly) for more general-purpose models like `Llama3-8B` and `Llama3-70B`, it can lead to smaller number of valid K8s manifests. These results underscore the complexities of adapting LLMs for domain-specific structured generation and emphasize the need for an in-depth analysis to determine the most effective setup, also suggesting that smaller models sometimes outperform their larger counterparts for each domain-specific task.

1 Introduction

Traditional cloud computing operations often involve complex manual configurations, particularly in service deployment of containerized environments (*e.g.,* Kubernetes, microservices), where tasks like defining network policies and services require significant expertise and can be challenging for less-experienced users. In response, intent-based networking (IBN), often powered by large language models (LLMs), has emerged as a promising approach (Kratzke and Drews, 2024; Xu et al., 2024). By translating high-level intents expressed in natural language into Kubernetes (K8s) manifests (structured configuration files as exemplified in Figure 1), this approach has the potential to simplify configuration tasks, make them more accessible, and speed up the deployment of network and application configurations.

```yaml
apiVersion: apps/v1
kind: Pod
metadata:
  name: nginx
spec:
  containers:
    - name: nginx
      image: nginx:latest
```

Figure 1: Example of a minimal Kubernetes manifest for an `nginx` image Pod deployment.

Recent examples demonstrated the advance of applying LLM-based AI Agents for AIOps (Artificial Intelligence for IT operations) in general (Vitui and Chen, 2025; Chen et al., 2025) and for Kubernetes tasks in particular (Kubiya.ai, 2025; Logz, 2025; kagent, 2025) serving LLMs as core components capable of reasoning. While LLMs have shown versatility across different domains (Ge et al., 2024; Ling et al., 2023), there are techniques, such as few-shot prompting or fine-tuning, that can make LLMs domain-specific and improve their generation accuracy. The first technique leverages customized prompts to guide the model toward more accurate outputs without requiring additional training, making it significantly more computationally efficient and requiring no specialized hardware.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 345–354

Although it may involve prompt refinement and human intervention (Kratzke and Drews, 2024), it remains a faster, more scalable, and automated alternative compared to fine-tuning, which demands extensive GPU resources and training epochs.

In this paper, we introduce *KGen* (**K**ubernetes Manifest **Gen**eration), a pipeline that fine-tunes LLMs to more accurately generate K8s manifests directly from natural language intents, coming, for example, from an end-user or another LLM if in an AI Agent setting. We performed an in-depth *n*-shot learning analysis across multiple LLMs, critically evaluating their effectiveness when dealing with production-like files.

In KGen, we start by generating a dataset of K8s manifests, which were fed into different LLMs (*i.e.,* `Mixtral-8x7B` (MixtralAI, 2025), `Prometheus-8x7B-v2.0` (Prometheus, 2024; Kim et al., 2023), `Llama3-8B` (Meta/Llama, 2025b), and `Llama3-70B` (Meta/Llama, 2025a)) to produce corresponding descriptions (or intents from now on) using an increasing number *n* of few-shot examples. To evaluate the quality of generated intents, we then asked the same adopted LLMs to re-generate the manifests from the intents using the same number of contextual examples. This process resulted in a dataset of reconstructed manifests, which we were able to first validate for structural validness (YAML syntax) and then compare against the original manifests to assess the accuracy of human language translation (intent semantic).

Our experiments validated the accuracy of the process but also revealed that the number of examples provided for *n*-shot learning has a significant and complex impact on the quality of the generated manifests. On the one hand, a few examples for `Mixtral-8x7B` or `Prometheus-8x7B-v2.0` led to under-performance, as both models lacked sufficient context to generate accurate structured output. On the other hand, for `Llama3` models, a high number of examples can mislead the model and result in worse accuracy while also introducing additional computational overhead and increasing input tokens usage – critical factors in real-world deployment scenarios. This outcome is likely due to the heterogeneity and non-trivial aspects of the structured files as the K8s manifests (Xu et al., 2024) and highlights the necessity of careful model evaluation to determine the optimal number of examples that balances computational efficiency and accuracy while maintaining reliable performance in production-scale applications.

2 Related Work

In the era of Generative AI and Large Language Models (LLMs), many studies have explored the integration of these advanced models to generate network configurations (Zhou et al., 2024a). One of the implementations (Dzeparoska et al., 2023) involves an LLM-based architecture composed of pipelines to translate intents into network policies using a progressive intent decomposition process. Similar work (Fuad et al., 2024) demonstrates a framework to translate intents, specified in natural language, to network configurations adapted for a Border Gateway Protocol (BGP) routing protocol using different LLMs. However, the authors do not investigate the hallucination problem that is common when working with LLMs and could impact the overall model's performance.

While LLMs are powerful and versatile, their adaptability across domains can result in decreased performance when applied to specific tasks (Xiao et al., 2024; Zhang et al., 2024; Huang et al., 2024). For this reason, researchers have begun to integrate techniques, known as *prompting*, into their solutions to better guide the model and produce more adapted responses. An example (Lin et al., 2023) presents Appleseed, an intent-based system to train an LLM using few-shot examples with the goal of generating a set of executable Python programs that can be adapted to different use cases. Similarly, an intent extraction solution focused on 5G networks employs a customized LLM with prompting techniques (Manias et al., 2024).

Moving towards an intersection of LLMs with Intent-based Networking for cloud-native scenarios, researchers have also focused on generating structured cloud configurations (*e.g.,* in YAML and JSON) used to automate service deployment across distributed infrastructures. The adoption of these configurations has shown flawless integration in containerized environments, microservices, and Kubernetes-based clusters or Ansible-based automation tools (Pujar et al., 2023). An example of this integration presents a benchmark (Xu et al., 2024) that was tested on a hand-crafted dataset using different LLMs. In another work (Mekrache et al., 2024) the authors propose an architecture for decomposing the intents into their Cloud/Edge and RAN elements. A competing approach for generating Kubernetes manifests (Kratzke and Drews, 2024) employs custom prompts and various LLMs. However, this work shows that manual interven-

tion might be needed for some LLMs to refine the generated manifests, which in the long term could slow the generation process, especially in long-structured manifests.

3 KGen Overview and Components

In this section, we explore the steps that compose KGen (see Figure 2 for an overview). As mentioned previously, the primary goal of KGen is to adapt the few-shot learning strategy to enable an LLM, either standalone or as a core of an AI Agent, to generate Kubernetes manifest from natural language intent. As the first step to perform the few-shot (or *n*-shot), we begin by describing the process of collecting the Kubernetes Manifests Dataset from a subset of industry examples (see Section 3.1). This dataset is then used by different LLMs (*i.e.,* `Llama3-70B`, `Llama3-8B`, `Prometheus-8x7B-v2.0`, and `Mixtral-8x7B`) as source of examples for *n*-shot to generate descriptive summaries of the manifests, *i.e.*, intents (Section 3.2). Then, the LLMs are tasked with regenerating the original manifests based on the descriptions (Section 3.3).

To evaluate whether the generated intents are sufficiently descriptive to provide adequate context for generating valid manifests, the generated manifests are compared with the initial manifests. As part of the extensive evaluation of KGen's consistency, we also conducted a cross-check: for each LLM from the list above, we applied few-shot learning to one model to generate manifest-to-intent pairs and prompted another model to re-generate the manifest from the intent.

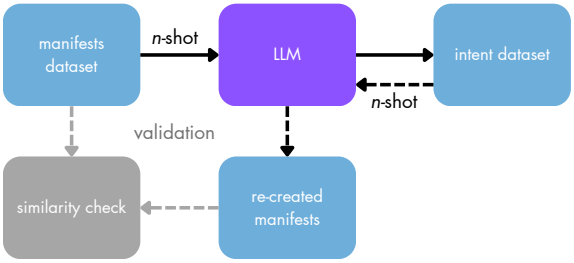

Figure 2: Overview of KGen's principle: manifests will be fed into LLMs to generate intents, which will then be reintroduced into the same LLMs to regenerate the manifests. The recreated manifests will be compared to the originals to evaluate their similarity.

3.1 Kubernetes Manifests Dataset

To build the Kubernetes Manifests Dataset, we propose a pipeline (see Figure 3) to extract values from a sample of workload manifests (*i.e.,* Pod, Deployment, Job, and CronJob), which have been collected from a set of production clusters, and group them into relevant categories (*e.g.,* authentication, certification).

Template generation. First, we generate a template for each Kubernetes manifest category. These templates have the structure of actual Kubernetes manifests (*e.g.,* `apiVersion`, `kind`, `specs`), but instead of real values, we insert placeholders formatted in HELM (HELM, 2025). We chose HELM due to its structured notation, which simplifies the representation of complex Kubernetes configurations (Zerouali et al., 2023).

Next, KGen recursively traverses each manifest using a Depth-First Search (DFS) approach. It explores each object's structure as deeply as possible before filling in values based on their hierarchical position following the HELM notation (*e.g.,* {{spec.containers.image}}). In the final step, we remove unnecessary elements, such as `status` and `annotations`, which typically store system-specific details or metadata not needed for defining cluster resources.

Value extrapolation. For each category in the example dataset, once the corresponding template was generated, we focused on extracting the distinct values associated with each object. To achieve this, we applied a recursive traversal method using the DFS strategy, ensuring that each object's structure was systematically explored. At every step of the recursion, we appended the parent object's name to the current field name. For instance, when going through the *spec* object, the traversal continues into *containers*, forming the identifier *spec.containers*, and then proceeds to *name*, ultimately constructing *spec.containers.name*. This hierarchical labeling approach ensures seamless alignment between the extracted values and the previously generated HELM-formatted template. Once the traversal reaches a terminal node in the structure, the algorithm records the corresponding value in a dictionary before resuming exploration along alternative paths.

Manifest generation. Once the templates were created and the distinct values for each manifest category were extracted, the next step was generating the final Kubernetes manifests. For each category, we began with its corresponding template and systematically replaced each placeholder with a randomly selected value from its associated list. For instance, the placeholder {{ spec.containers.image }} was substituted with a random entry from the

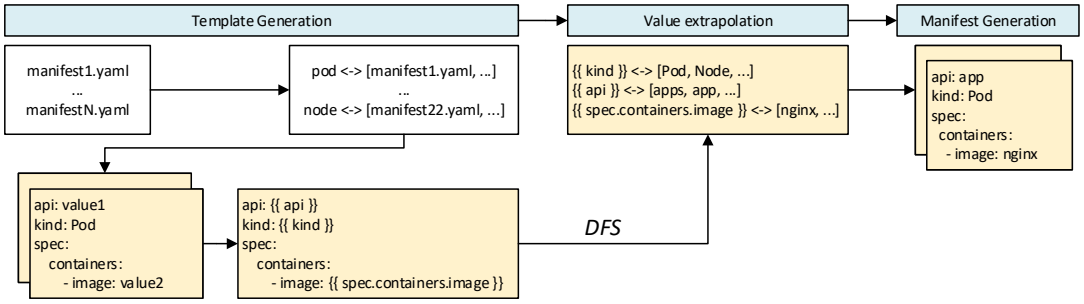

Figure 3: Pipeline for generation of Kubernetes Manifest Dataset from a subset of industry examples.

spec.containers.image list. Instead of performing a one-to-one substitution, we handled each placeholder individually to ensure diversity within the generated manifests, preventing excessive repetition of the same values. To further maintain uniqueness, each generated manifest was hashed, and any duplicates identified by matching hash values were removed from the output folder. As a final step, we assigned a unique metadata name to each manifest using a Universally Unique Identifier (UUID), ensuring that every generated file remained distinct.

3.2 Few-shot Learning for Intent Generation

After building the Kubernetes Manifest Dataset, the next step was to generate the descriptive intents. Although LLMs have demonstrated exceptional accuracy in various fields, their effectiveness heavily relies on well-structured prompting techniques, which can significantly enhance both the relevance and quality of their outputs, especially when applied to specialized domains (Zamfirescu-Pereira et al., 2023). To address this, in KGen we provided each selected LLM with two strategies to enhance the intent generation process: a structured context template utilizing the role field (*e.g.,* assistant, user) and a set of few-shot examples, ranging from 0 to 10, which helps the model understand the expected input-output pattern and improve response accuracy.

When the total input length, including the context template and examples, exceeds the model's token limit, we implemented a chunking method to divide the input into smaller segments. After processing, these segments were merged to ensure logical consistency and preserve YAML formatting. This structured approach improved coherence and accuracy while preventing errors in longer prompts (Zhou et al., 2024b).

Initially, since no descriptions or intents were available, we extracted a few samples from the Kubernetes Manifest Dataset and asked the LLMs to describe and create intent for them. This allowed us to take advantage of the models' few-shot learning ability, using their own outputs as a basis for following generations. Next, we manually reviewed the responses to ensure they met our expectations and began compiling a database of few-shot examples. Given the possibility of LLMs to produce hallucinated outputs (Ji et al., 2023; Yao et al., 2023), we made sure that the intents had different structures, some being more concise or schematic, others more elaborate, which helps the model generalize better and minimizes the risk of overfitting to a specific structure.

When using advanced prompting methods like few-shot examples, the goal is to have the model generate responses that closely align with the provided patterns and structures. To achieve this in KGen, we fine-tuned key hyperparameters that influence text generation. One of the most critical parameters we adjusted was temperature, which determines the randomness of the model's output. Research has shown that temperature settings significantly impact response accuracy and consistency (Renze and Guven, 2024; Saha et al., 2024; Shen et al., 2024). Lower values (*e.g.,* 0.2–0.5) make the model more deterministic, ensuring it follows the given structure more strictly, whereas higher values (*e.g.,* above 0.6) introduce more variability and creativity. Since studies indicate that lower temperatures tend to yield higher accuracy (Saha et al., 2024; Shen et al., 2024; Ifland et al., 2024), in KGen we set the temperature to 0.3. Additionally, we fine-tuned two other key parameters: *top_k* and *top_p*. The *top_k* parameter restricts the model to select from only the k most probable next tokens, while *top_p* ensures that the model only chooses tokens whose cumulative probability exceeds a specified threshold. In KGen, we configured *top_k* to 20 and *top_p* to 0.8 to strike

a balance between controlled generation and response diversity.

3.3 Few-shot Learning for Manifests Generation

For each intent, obtained with the KGen pipeline, we instructed the same LLMs to generate Kubernetes manifests using n-shot examples ranging n from 0 to 10, which allowed us to test all combinations of LLMs and examples. Before saving, each manifest was processed using YAML's *safe_load* function in Python to check for syntax errors or invalid formatting. Valid manifests were stored with a ".yaml" extension, while those failing validation were saved as "_error.yaml", allowing us to distinguish between correct and faulty outputs.

After generation, we checked whether the manifests were valid Kubernetes configurations. This was done using the *kubectl* command-line tool, enhanced by GNU Parallel to speed up execution (Tange, 2025). By ensuring that the generated Kubernetes manifests are correct and valid for both YAML and Kubernetes standards, we can significantly improve the quality of LLM outputs: fewer errors and more accurate automation in future applications. The results shown in Figure 4 indicate that all tested LLMs (*i.e.,* `Llama3-70B`, `Llama3-8B`, `Prometheus-8x7B-v2.0`, and `Mixtral-8x7B`) performed well in generating accurate manifests. Notably, `Mixtral-8x7B` and `Prometheus-8x7B-v2.0` showed increased validity as more examples were provided, suggesting that additional examples improve its accuracy. Opposite considerations can be reached with the `Llama3` family. These models showed higher accuracy with fewer examples, which implies that adding more examples might reduce precision.

Interestingly, some manifests were Kubernetes-valid, but not YAML-valid, possibly due to Kubernetes' more flexible structure compared to strict YAML formatting.

4 Evaluation

In this section, we present the results obtained from prototyping KGen, which played a key role in shaping our conclusions. First, we begin by analyzing the settings in which the experiment was conducted. Next, we discuss the evaluation process and show the similarity score achieved during manifest regeneration. This strategy allowed us to solve any possible issue with the intent generation (*e.g.,* hyperparameters' settings, model prompts, and template). Finally, we consider the economic aspect of employing each model.

4.1 Experimental Settings

Our analysis was performed in a production datacenter supported by computing clusters running four chosen LLMs: `Llama3-70B`, `Llama3-8B`, `Prometheus-8x7B-v2.0` and `Mixtral-8x7B`, and providing an increasing number of few-shot learning examples from 0 to 10. The cluster consists of 174 computing nodes running Intel and AMD processors with a range of 56 to 128 cores, between 768 and 2048 GB RAM, and each equipped with the 8 to 16 GPUs, mostly NVIDIA A100 and V100.

4.2 Similarity Check

After the initial validation at the Manifest Generation stage, we compared the generated manifests with the original ones used to create the intents. While it is still considered challenging to evaluate LLMs and there is no unique way of evaluating each model's responses, in KGen, we adopted four main evaluation metrics already known in the state of the art for tokens similarity (Hu and Zhou, 2024; Chen et al., 2024; Banerjee et al., 2023): (i) edit-distance (Levenshtein) score, that measures the minimum number of edits (*e.g.,* insertions, deletions, substitutions) needed to transform one string into another; (ii) Cosine similarity, which assesses semantic closeness by comparing word embedding vectors; (iii) BLEU (Bilingual Evaluation Understudy) algorithm, which calculates precision based on the ratio of matching token sequences; (iv) METEOR (Metric for Evaluation of Translation with Explicit Ordering), which uses a weighted average of various factors (*e.g.,* unigram precision, bigram overlap) to compare generated and reference text. It is important to note that we normalized similarity scores between 0 (completely different) and 1 (identical).

Each LLM received the previously generated manifest's descriptions (intents) with the request of generating the manifest back with an increasing number of few-shot examples (from 0 to 10). As shown in Figure 5, `Mixtral-8x7B` and `Prometheus-8x7B-v2.0` achieved better accuracy as more examples were provided, aligning with the increase in valid manifests seen in Figure 4a. The same coherency appeared in the `Llama3` models (`Llama3-8B` and `Llama3-70B`), where similarity scores peaked with only a few examples (0–3). A

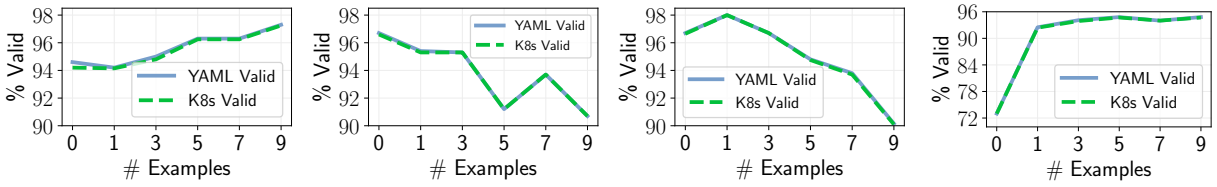

Figure 4: Number of valid K8s manifests in (a) `Mixtral-8x7B`, (b) `Llama3-8B`, (c) `Llama3-70B` and (d) `Prometheus-8x7B-v2.0`.

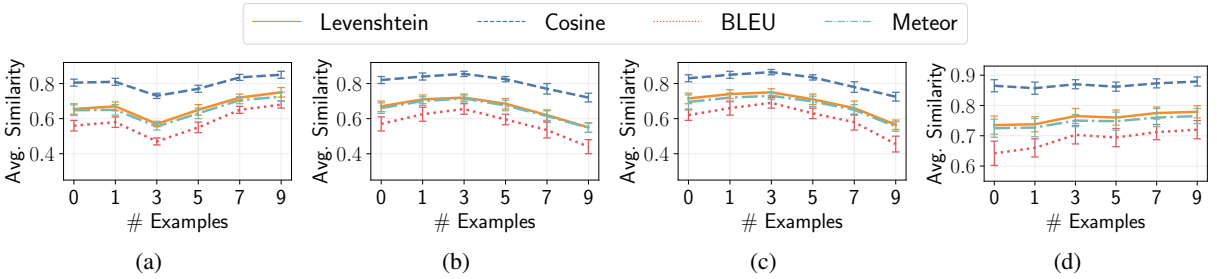

Figure 5: Similarity scores for (a) `Mixtral-8x7B`, (b) `Llama3-8B`, (c) `Llama3-70B` and (d) `Prometheus-8x7B-v2.0`.

more detailed analysis of the few-shot examples experiment is provided in Appendix 6, reporting the similarity scores between the initial manifest and the one generated from the LLM-based intent.

4.3 Economic considerations

Based on these evaluations, we also examined the cost implications of using different LLMs using publicly available information in (Artificial Analysis, 2025) and reporting results in Table 1.

First, we can point out that `Mixtral-8x7B` and `Prometheus-8x7B-v2.0` are associated with the same costs, since `Prometheus-8x7B-v2.0` is trained using `Mixtral-instruct` as a base model (Prometheus, 2024). Our analysis highlights that this class of models tends to be more expensive due to their need for more examples, whereas `Llama3-8B` keeps costs lower while maintaining strong performance. A similar trend is observed with `Llama3-70B`, which achieves high similarity scores without requiring additional examples. Despite a slightly lower percentage of valid manifests (96.68% vs. 98%), `Llama3-8B` remains a more cost-effective option, as both `Llama3` models achieved similar similarity scores. For large-scale applications, such as building datasets for LLM fine-tuning, `Llama3-8B` is preferred due to its price. However, when precision is the top priority, `Llama3-70B` might be the better choice despite its higher cost. As Table 1 illustrates, fewer provided examples result in fewer tokens, directly reducing overall costs.

Model	Input Price	Output Price	Dataset Cost
Mixtral-8x7B	0.70	0.70	1400
Llama3-8B	**0.07**	**0.20**	**270**
Llama3-70B	0.80	0.88	1680
Prometheus-8x7B-v2.0	0.70	0.70	1400

Table 1: Cost analysis of the tested LLMs: average input and output prices in $ per 1M tokens (or approx. 500 manifests of 1000 tokens length) and total cost of generation of $500k$ samples dataset similar to large scale cluster industry examples (Verma et al., 2015; Cortez et al., 2017).

5 Conclusion

In this paper, we presented *KGen*, a pipeline that translates natural language descriptions (intents) into Kubernetes (K8s) manifests for automatic cloud-native deployments. By analyzing different LLMs, our method strategically selects the optimal number of examples through a *n*-shot learning evaluation, balancing accuracy and computational efficiency. Our findings reveal that while increasing *n*-shot examples can enhance output quality for specialized models like `Mixtral-8x7B` and `Prometheus-8x7B-v2.0`, it may degrade the validity of K8s manifests for more general models such as `Llama3-8B` and `Llama3-70B`. This performance underscores the importance of tailored LLM selection for structured data generation, where smaller models can sometimes outperform larger ones. These insights emphasize the necessity of performing an in-depth LLM analysis to identify the most effective configurations to achieve higher generation accuracy at lower costs for DevOps pipelines.

Abstract

Tabular data analysis is crucial in many scenarios, yet efficiently identifying relevant queries and results for new tables remains challenging due to data complexity, diverse analytical operations, and high-quality analysis requirements. To address these challenges, we aim to recommend query–code–result triplets tailored for new tables in tabular data analysis workflows. In this paper, we present TablePilot, a pioneering tabular data analysis framework leveraging large language models to autonomously generate comprehensive and superior analytical results without relying on user profiles or prior interactions. Additionally, we propose Rec-Align, a novel method to further improve recommendation quality and better align with human preferences. Experiments on DART, a dataset specifically designed for comprehensive tabular data analysis recommendation, demonstrate the effectiveness of our framework. Based on GPT-4o, the tuned TablePilot achieves 77.0% top-5 recommendation recall. Human evaluations further highlight its effectiveness in optimizing tabular data analysis workflows.

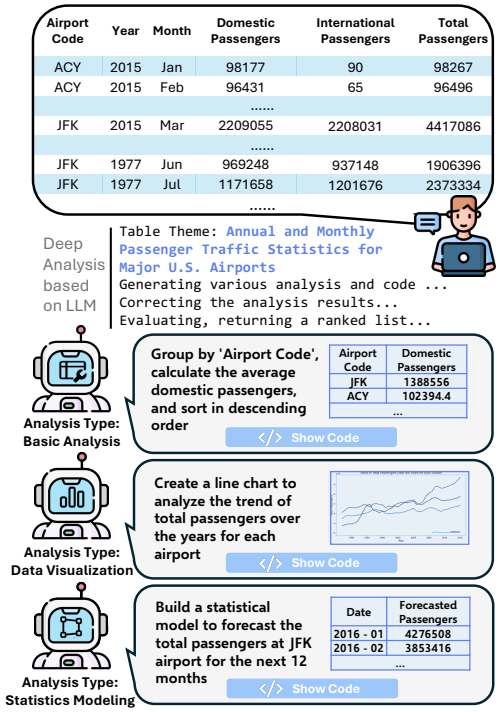

Figure 1: Overview of TablePilot. Through deep analysis based on LLM, TablePilot generates three types of analysis: basic analysis, data visualization, and statistical modeling, each presented as a <query, code, result> triplet.

1 Introduction

Tabular data is widely used in various data analysis scenarios (Ghasemi and Amyot, 2016; Li et al., 2021). However, its complexity and density (Cao, 2025; Tian et al., 2024) can make it challenging, even for professional analysts, to determine the most appropriate analysis operations for a new table. Conducting tabular data analysis is often tedious, and the analysis operations may include errors that lead to suboptimal outcomes. Therefore, automatically recommending high-quality analysis queries and results becomes essential in the data analysis workflow, particularly in zero-turn scenarios where no user profile or historical records are available.

In the task of tabular data analysis recommendation, given only a table as input, we aim to recommend query–code–result triplets to users. A query specifies the type and objective of the analysis task, while the code executes the corresponding operation on the table, serving as an intermediate step in the analysis. The result presents the execution output, which also constitutes the analysis findings.

Previous works on tabular data analysis recommendation (Zhou et al., 2020, 2021) primarily rely on traditional machine learning methods but often exhibit suboptimal performance and strong depen-

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 355–410
July 28-30, 2025

dence on specific datasets. Recently, large language models (LLMs) (OpenAI, 2024; Touvron et al., 2023) have made significant strides in natural language processing. With their advanced data processing, language comprehension, and generation capabilities, LLMs present new opportunities for delivering more effective tabular data analysis recommendations.

In practical data analysis scenarios, these triplets are expected to be (a) **accurate**, (b) **diverse**, and (c) **human-preferred**. Human-preferred refers to the data analysis operations that humans genuinely intend to perform, meaning the results should be meaningful, insightful and so on. Employing LLMs to recommend tabular data analyses while meeting these requirements presents several key challenges.

Challenges: (a) Tabular data is often large and data-intensive, making it difficult for LLMs to process effectively. Long-context windows can trigger hallucinations (Huang et al., 2024), leading to inaccurate results. (b) Existing approaches primarily construct workflows around single-operation scenarios, executing predefined analytical queries to obtain results (Fang et al., 2024; Zhang et al., 2025), but they lack diversity and fail to deliver comprehensive analyses. (c) Selecting and presenting analysis results in a way that aligns with human cognitive patterns is crucial (Song et al., 2024; Dai et al., 2023; Yu et al., 2024). A well-designed system should balance diversity and quality in recommending data analysis operations that match users' analytical preferences, ensuring the insights generated are interpretable, actionable, and meaningful.

Solution: To address these challenges, we propose **TablePilot**, a framework designed to tackle the zero-turn recommendation task for tabular data analysis, as illustrated in Figure 1.

To enhance the **accuracy** of analysis results, we adopt sampling techniques (Sui et al., 2024; Ye et al., 2023b; Ji et al., 2024), employing a table sampler to refine model inputs and introducing a table explanation component that incorporates world knowledge learned during the pretraining phase of LLMs. This stage of analysis preparation facilitates the generation of more contextually appropriate queries and results. At the optimization level, we utilize post-refinement techniques (Chen, 2022; He et al., 2024) to adjust outputs. However, instead of focusing solely on code refinement, we identify multiple aspects of query and result optimization.

To improve the **diversity** of our analysis, we implement a modularized approach to support various workflow operations. This modular design provides two key benefits. First, it ensures comprehensive coverage by enabling the workflow to handle a diverse range of data analysis tasks, making it more adaptable to various requirements. Second, it enhances performance by allowing each module to be trained independently for better efficiency, with improvements across modules contributing to overall effectiveness.

To ensure our analysis aligns with **human preferences**, we introduce **Rec-Align**, a method specifically designed to further enhance the quality of analysis by directly incorporating human preferences. We train a ranking model to optimize the final set of recommended operations, ensuring they align with human analytical tendencies and produce superior results.

We contribute a dataset **DART** to support and validate our framework. Experimental results demonstrate that the tuned TablePilot achieves nearly 100% execution rates, while the analysis modules show an overall recall improvement of 11.25% with GPT-4o in the dataset. Rec-Align further enhances alignment with human preferences, leading to gains of 6.8% in Recall@3 and 6.0% in Recall@5. Additionally, human evaluations confirm that the TablePilot framework provides more practical and insightful data analysis recommendations compared to baseline models. Extensive experiments validate the effectiveness of TablePilot and our training approach.

In summary, our main technical contributions are as follows:

- We propose TablePilot, a framework for zero-turn recommendation in tabular data analysis, encompassing a comprehensive set of analytical operations. We also contribute DART, a dataset to support and validate our framework.
- We introduce two additional steps to enhance the accuracy of analysis results, applied before and after core analysis. These steps incorporate sampling, explanation, and multi-faceted refinement.
- We develop Rec-Align, a method designed to align recommendations with human analytical preferences, further enhancing the quality and practical utility of the recommended results.

2 Related Work

Current tabular data analysis recommendation tasks can be categarized into three main types:

Basic Data Analysis in Tables. Basic analysis refers to simple, initial processing of a table. It involves generating tabular outputs or single-cell text entries to highlight key information or insights based on a user query. This is usually done by manipulating and aggregating tabular data. Table understanding tasks (Pasupat and Liang, 2015; Chen et al., 2020) are the most basic form of this analysis. Given a query, these tasks either provide an answer or extract a sub-table (Wang et al., 2024; Ye et al., 2023a) that contains important information. TableMaster (Cao, 2025) offers a general recipe for table understanding and basic analysis based on user queries. Text2SQL (Pourreza and Rafiei, 2024; Gao et al., 2023; Lee et al., 2024; Zhao et al., 2024) is another approach that extracts relevant parts of a table by converting user queries into SQL-based outputs. However, these methods only return results based on a given query and do not generate natural language queries automatically. Auto-Formula (Chen et al., 2024) predicts and suggests formula syntax for spreadsheet-based analysis. Table2Analysis (Zhou et al., 2020) and MetaInsight (Ma et al., 2021) automatically recommends common analysis without requiring user input.

Tabular Data Visualization. Visualizing data helps users quickly understand complex patterns and relationships. Table2Charts (Zhou et al., 2021) applies sequence token sampling and reinforcement learning to recommend different chart types. Furmanova et al. (Furmanova et al., 2019) developed a tool for automatically combining overview and details in tabular data visualizations. AdaVis (Zhang et al., 2023) uses knowledge graphs to adaptively recommend one or multiple suitable visualizations for a dataset. LLMs have further improved data visualization. Chart2VIS (Maddigan and Susnjak, 2023) leverages LLMs for natural language-to-visualization tasks by generating Python code for chart creation. ChartLlama (Han et al., 2023), a multi-modal LLM, shows strong chart generation capabilities but does not recommend charts based on existing data.

Statistical Modeling of Tabular Data Statistical modeling in tabular data focuses on building models to recognize patterns and relationships. RIM (Qin et al., 2021) enhances tabular data prediction with a retrieval module. GReaT (Borisov et al., 2022) uses a decoder-only transformer to model data distributions and generate realistic synthetic data. GTL (Wen et al., 2024) integrates LLMs with deep learning techniques for regression and classification tasks. TabDDPM (Kotelnikov et al., 2024) is a diffusion model that can handle any tabular dataset and support various feature types.

Despite these advancements, most existing methods are task-specific and do not support multiple types of analysis within a single framework. This limitation prevents users from obtaining a comprehensive view of their data. Currently, no unified system seamlessly integrates table analysis, visualization, and statistical modeling. A complete all-in-one framework would allow users to explore data more effectively from different perspectives. Moreover, existing methods primarily emphasize the accuracy of analysis results while neglecting the importance of aligning with human analytical preferences.

3 Methodology

3.1 Task Formulation

Tabular Data Analysis Recommendation. In the task of tabular data analysis recommendation, the objective is to generate a series of recommended data analysis queries q, corresponding code c, and execution results r for a given table $\mathbb{T}$ under a zero-turn setting (i.e., with no user profile or historical context). The table $\mathbb{T}_{a\times b}$ contains a rows and b columns, where $C_{i,j}$ denotes the cell in the i-th row and j-th column. For each table $\mathbb{T}$, n analysis results A is recommended in triplets:

$$A = \left\{ \left(q_i, c_i, r_i\right) \right\}_{i=1}^{n}, \tag{1}$$

where each triplet $a = (q, c, r)$ represents a single recommended analysis result.

3.2 Framework

To generate recommendation results from a given table, we propose TablePilot, a four-step analysis framework, as illustrated in Figure 2. The framework consists of Analysis Preparation, Module-based Analysis, Analysis Optimization, and Analysis Ranking. A new table T is provided as input to generate the recommended results A.

$$\text{TablePilot}(\mathbb{T}) = A. \tag{2}$$

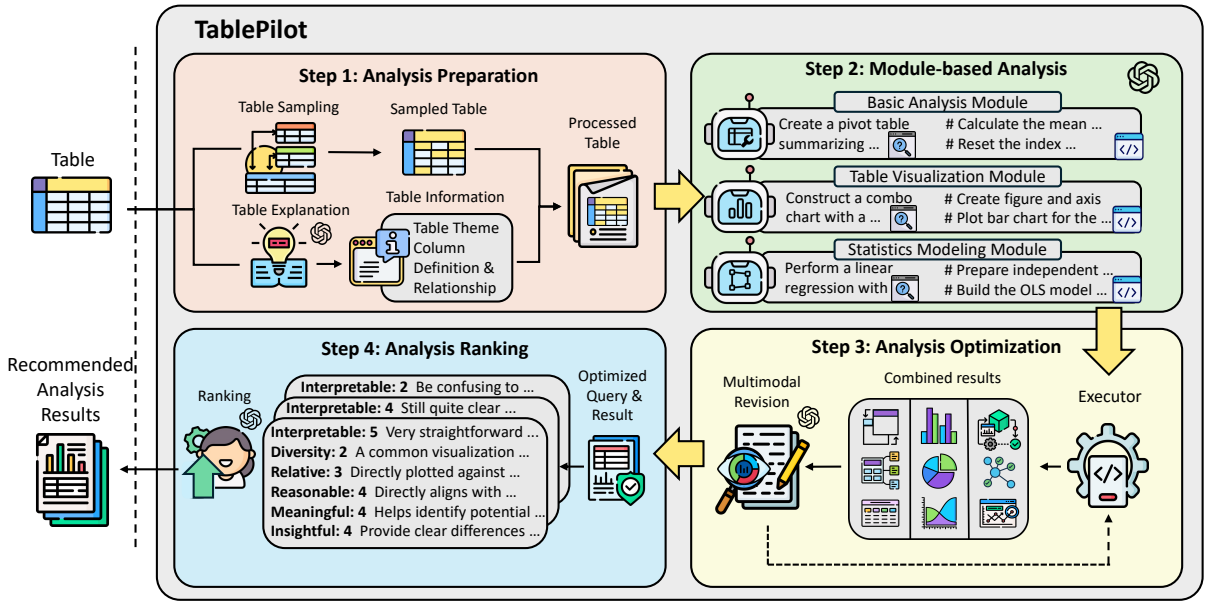

Figure 2: The TablePilot framework. Step 1: Sample the input table and generate corresponding explanations for its structure and content. Step 2: Generate query and code for modules involving basic analysis, table visualization, and statistics modeling. Step 3: Optimize the quality of <query, code, result> triplets. Step 4: Score and rank the optimized results based on multiple criteria to recommend the top-K analysis. TablePilot Case Study and Analysis Report can be seen at Appendix K and Appendix L.

Step 1: Analysis Preparation. The objective of this step is to transform raw tabular data into a more focused form that facilitates efficient analysis. This step involves two key tasks: sampling a subset of the table and generating a table explanation.

Raw tables often contain large amounts of data, much of which may not be relevant for a specific analysis task. Sampling extracts a representative subset of the table, capturing essential patterns while reducing computational load and focusing the analysis on key data points. This process involves selecting a subset of rows from the original table:

$$\text{Sampling}(\mathbb{T}_{a\times b}) = \mathbb{T}'_{a'\times b'}, \tag{3}$$

where $\mathbb{T}'$ represents the sampled table, a' denotes the number of selected rows, and b' denotes the number of selected columns.

Additionally, generating a table explanation is crucial for structuring the data, making column relationships and the table's overall theme clearer and more interpretable. This explanation includes metadata such as the table's theme, column descriptions, and relationships between different columns, all of which guide subsequent analysis. The explanation is denoted as E:

$$\text{Explanation}(\mathbb{T}) = E. \tag{4}$$

Step 2: Module-based Analysis. In this step, we perform a module-based analysis on the sampled table $\mathbb{T}'$ and its corresponding table explanation E. The goal is to generate analysis results by applying specialized modules to different aspects of the data. These modules focus on basic analysis (ba), data visualization (dv), and statistical modeling (sm). Each module takes $\mathbb{T}'$ and E as inputs to generate meaningful query-code pairs (q, c):

$$\mathcal{M}_k(\mathbb{T}', E) = (q_k, c_k), \tag{5}$$

where $k \in \{ba, dv, sm\}$ represents the three different analysis task.

The Basic Analysis module ($\mathcal{M}_{ba}$) applies fundamental yet powerful techniques to explore the data, performing operations such as filtering, grouping, sorting, and aggregation. The Data Visualization module ($\mathcal{M}_{dv}$) generates visual representations of the data to reveal patterns, trends, and relationships. The Statistical Modeling module ($\mathcal{M}_{sm}$) applies advanced statistical techniques to analyze the data and uncover deeper insights. It may involve regression analysis, hypothesis testing, or predictive modeling, depending on the analysis objectives.

Step 3: Analysis Optimization In this step, we first execute the code to obtain results r for each

code c_k:

$$\text{Execution}(\mathbb{T}, c_k) = r = \begin{cases} T, & \text{if } k = ba \\ V, & \text{if } k = dv \\ M, & \text{if } k = sm \end{cases} \quad (6)$$

where T represents the sub-table after data manipulation in basic analysis, V denotes the result of data visualization, and M corresponds to the output of statistical modeling. The result of data visualization, $r = V$, is also an image $r = I$, which will be used as input for the vision module of LLMs at a later stage. We then combine the query q, code c, and result r into an analysis triplet $a = (q, c, r)$. The results $r =$ Error indicate an error in the code execution.

Next, we refine the analysis triplet a based on the results from table sampling $\mathbb{T}$ and explanation E. The optimization process utilizes LLMs to improve the alignment of queries and code with the data and analysis intent, ensuring more accurate and meaningful results. There are two different strategies for LLMs to optimize triplets, depending on whether the result contains an error. After refinement, the optimized code is executed to generate the final enhanced execution results, yielding an optimized triplet $a' = (q', c', r')$:

$$a' = \begin{cases} \text{Optimize}_A(q, c, r \mid \mathbb{T}, E), & \text{if } r \neq \text{Error} \\ \text{Optimize}_B(q, c, r \mid \mathbb{T}, E), & \text{if } r = \text{Error} \end{cases} \quad (7)$$

Step 4: Analysis Ranking In the final step, the objective is to evaluate and rank all the (q, c, r) triplets $A = a_i{}_{i=1}^{n}$ that were generated and optimized in the previous step. To achieve this, we design a ranking module that scores each triplet based on multiple dimensions, such as relevance, diversity, and other key factors (criteria detailed in Appendix H). These scores are then aggregated to compute an overall score s. Using these scores, the triplets are ranked in descending order, allowing us to select the top k results:

$$A'_k = \text{Top}_k\Big(\text{Rank}\Big(\big\{(q', c', r')_i\big\}_{i=1}^{n}\Big)\Big) \quad (8)$$

After scoring, ranking, and selecting the top-k results A'_k, the final triplets are recommended to users.

3.3 Training

The training process in TablePilot is designed to enhance the model's ability to generate high-quality analysis results, with a focus on accurate query-code generation and human-preferred ranking of analysis triplets $a = (q, c, r)$. We primarily employ Supervised Fine-Tuning (SFT) and Direct Preference Optimization (DPO) (introduced in Appendix J), both widely used techniques for tuning LLMs. SFT is used to ensure that each module follows our instructions for performing tasks. Additionally, we introduce **Rec-Align**, implemented via DPO, to enhance our ranking module, further refining recommendation quality and ensuring that the selected results align more closely with human preferences.

Our training strategy consists of the following key components:

- **Analysis SFT** trains the LLMs in three analysis module ($\mathcal{M}_{ba}$, $\mathcal{M}_{dv}$, $\mathcal{M}_{sm}$) to improve their ability to follow instructions, generating relevant queries and accurate code. This enhances the accuracy of the analysis.
- **Rank SFT** trains the LLMs in the ranking module *Rank* to better follow instructions in evaluating each analysis triplet based on comprehensive criteria and assigning appropriate scores. This ensures that the ranking model adheres to our guidelines when ranking triplets..
- **Rank DPO** implements Rec-Align through DPO to refine the evaluation of analysis triplets in *Rank*, ensuring that evaluation and scoring are more closely aligned with human analytical preferences. This further enhances the quality of the recommended analysis.

4 Experiments

4.1 Experiment Settings

To support, validate the framework, and evaluate its performance, we carefully curate a dataset, **DART**. Details on the dataset can be found in Appendix C.

In our experiments, we evaluate the performance of TablePilot on three typical analysis tasks: Basic Analysis, Data Visualization, and Statistics Modeling. Additionally, we consider them collectively without distinction for the overall evaluation. We aim to evaluate the result of query–code–result triplets for a given table. To assess the quality of code generation, we use the execution rate as a metric. For the quality of the final results in recommendation, we evaluate using Recall@K. Detailed evaluation metrics can be found in Appendix B.

We selected three state-of-the-art vision-

language models of varying sizes and availability, including both private and open-source options, as the foundation models: *GPT-4o*, *GPT-4o-mini*, and *Phi-3.5-Vision*. These models were chosen for their strong vision-language interaction capabilities, making them well-suited for multi-modal refinement.

We conduct multiple comparative experiments to comprehensively evaluate performance. The *baseline* experiments exclude all components of our proposed framework, relying on a single prompt to generate queries and code across all three task categories, with recall computed via random ranking. In contrast, *vanilla* experiments employ TablePilot without additional model tuning. Subsequent experiments examine different components of TablePilot, incorporating tuning methods such as SFT and DPO. The definitions of *Analysis SFT*, *Rank SFT*, and *Rank DPO* are detailed in Section 3. *Rank Vanilla* represents random ranking over three rounds, while the -V notation denotes the inclusion of vision input during training.

We then compare these experimental results to assess the impact of each tuning strategy on overall performance improvements. Detailed experimental settings are provided in Appendix D, and the corresponding prompts are listed in Appendix M.

Table 2: Execution rate across multiple models and experimental settings (all values in %)

4.2 Main Results

TablePilot Performance. As illustrated in Table 5 and Table 6, TablePilot delivers substantial perfor-

mance improvements across various models without the need for fine-tuning LLMs. In particular, *GPT-4o* benefits from TablePilot, exhibiting improvements across all key metrics, with a 4.24% increase in execution rate and recall at different thresholds, especially make 18.79% gain in Recall@5 which is considered as the most balanced metric. These consistent gains across all tasks demonstrate the method's effectiveness in enhancing LLM performance without manual adjustments or additional tuning.

Notably, we observe some performance drops in certain analysis among three analysis tasks. This is due to a **diverse analysis trade-off effect**, where an excessively high recall in one task may lead to a decline in recall for others. Therefore, overall recall serves as a more reliable measure of the method's overall performance.

TablePilot Performance after Tuning. Supervised Fine-Tuning significantly improves both analysis and ranking tasks. Vision-enabled SFT further enhances ranking performance, especially when combined with DPO applied to vision components. While *GPT-4o* sees modest gains over the vanilla workflow, GPT-4o-mini improves by 10–20% on average, with some cases reaching 20 points. *Phi-3.5-vision* shows the most notable improvement, exceeding 20% on average, with rank@N increasing by 26%. These results highlight the importance of tuning in optimizing TablePilot, ensuring alignment with human values for more robust and valuable outputs.

Supervised Fine-Tuning significantly improves both analysis and ranking tasks. Vision-enabled SFT further enhances ranking performance, especially when combined with DPO applied to vision components, resulting in a 9.49% boost in Recall@3 and 6.10% in Recall@5 for *GPT-4o*. The most pronounced improvements are observed in smaller language models, as detailed in Appendix E. These results underscore the importance of fine-tuning in optimizing TablePilot, ensuring alignment with human preferences for more robust and valuable outputs.

Ablation Study. Each components of the TablePilot workflow (Sampling, Explanation, Revision, and Ranking) contributes to a consistent improvement in the overall system performance. The complete results of the ablation experiments are presented in Appendix F.

4.3 Analysis of Rec-Align

Our proposed Rec-Align, implemented via DPO, consistently improves model performance across various configurations and tasks by enhancing alignment with user expectations in ethical and qualitative aspects. *GPT-4o* benefits from a 2% increase in Recall@3 and Recall@5, while smaller models exhibit even greater performance gains after applying Rec-Align, as shown in Table 5. We also observed that in the vanilla ranking mode, some models initially exhibit scoring biases toward specific tasks like data visualization. Rec-Align mitigates this imbalance, resulting in a more diverse ranked list and guiding models to generate outputs that better reflect human preferences.

4.4 Human Evaluation

Rating	5	4	3	2	1	Avg	≥ 4	≥ 3	≤ 2
Baseline	47	71	92	46	44	3.10	118	210	90
TablePilot (Vanilla)	114	61	79	25	21	3.74	175	254	46
TablePilot (Tuned)	146	75	48	28	3	**4.11**	**221**	**269**	**31**

Table 3: Results of human evaluation ratings

Table 3 presents human evaluation results on 300 test tables from DART. TablePilot (Tuned) achieves the highest mean score, the largest proportion of high-rated outputs (ratings ≥ 3), and the lowest proportion of low-rated outputs (rating ≤ 2). The Wilcoxon signed-rank test(Wilcoxon et al., 1963) confirms significant improvements at a 95% confidence level, supporting the effectiveness of TablePilot and Rec-Align in enhancing recommendation quality. Further details on evaluation methodology and criteria are provided in Appendix I.

5 Conclusion

In this paper, we introduce TablePilot, a comprehensive data analysis recommendation framework powered by large language models. Extensive experiments demonstrate TablePilot 's superior performance, marking a new milestone in tabular data analysis recommendation.

Limitations

Our work presents an exploratory study on comprehensive tabular data analysis, with several limitations including workflow fragmentation, limited interactivity, and constraints of DPO. For further discussion on the extendability of TablePilot and future directions, please refer to Appendix A.

A Extendability Analysis and Future Works

In this paper, we present an exploratory study on comprehensive tabular data analysis. Several important extensions of our proposed framework, TablePilot, remain open for future work.

Data Curation. We provide the dataset DART to support model training and to validate the performance of TablePilot. However, the current dataset has several limitations: it is relatively small in scale, lacks image-contrastive data necessary for effective multi-modal SFT and DPO, and contains limited high-quality samples. We believe that with more carefully curated data and improved data construction pipelines, TablePilot could achieve significantly better performance and enable more powerful analytical capabilities.

Multi-Modal Training. One significant direction for extending TablePilot lies in the integration of multi-modal GPT-based models, such as multi-modal SFT and DPO. As previously mentioned, higher-quality multi-modal training data is crucial for achieving better performance. In addition, current GPT-series models on the Azure platform do not yet support multi-modal DPO, limiting our ability to fully leverage visual information during optimization. Multi-modal DPO could substantially improve TablePilot 's ability to evaluate and analyze results based on figures and visualizations. Furthermore, how to design multi-stage training pipelines that balance SFT and DPO to achieve optimal model performance remains an open challenge. We believe that, with the integration of more advanced multi-modal capabilities, TablePilot can generate richer analytical insights, enhance contextual understanding, and better align with how human analysts interpret complex, heterogeneous data sources.

Analysis Modularization. The current version of TablePilot supports three types of analysis: Basic Analysis, Table Visualization, and Statistical Modeling. These analyses are implemented in a modularized manner, allowing flexible composition and extension. As these three represent some of the most classical forms of tabular data analysis, they provide a strong foundation for various use cases. In the future, more diverse or specialized analysis modules can be easily integrated into TablePilot, showcasing the flexibility of our framework. Furthermore, in different downstream application scenarios, TablePilot can adaptively select and combine specialized analysis modules to better address domain-specific needs.

System Internal Interaction. The current framework of TablePilot is unidirectional, with different analysis modules operating in parallel without internal interaction. In the future, we aim to extend TablePilot into a multi-agent system, enabling richer interactions between modules. For example, different analysis modules could complement and enrich each other's data, and the ranking module could provide feedback to guide the analysis modules. We believe that such a design would make the system more intelligent and capable of generating higher-quality analytical recommendations.

Efficiency Optimization. Our current TablePilot framework involves multiple large language model (LLM) calls, which can lead to efficiency issues. In the future, we plan to improve efficiency by replacing certain modules with smaller language models or well-trained traditional machine learning models. Additionally, optimizing and compressing prompts will help streamline the pipeline and further enhance overall efficiency.

B Evaluation Metrics

In our experiments, we adopt two primary metrics to evaluate system performance comprehensively: *Execution Rate* (abbreviated as *ExecRate*) and *Recall*.

ExecRate quantifies the accuracy and stability of generated code by measuring whether it executes without error and returns the expected output. This metric is consistently applied across all modules (Basic Analysis, Table Visualization, and Statistical Modeling) by calculating the ratio of successful executions to the total number of generated outputs.

Recall serves as our key indicator for retrieval accuracy, assessing whether the correct result appears among the top-ranked candidates. We distinguish among three variants: *Recall@All*, *Recall@5*, and *Recall@3*. *Recall@All* checks if the correct result is present anywhere in the candidate set, while *Recall@5* and *Recall@3* evaluate if it ranks within the top five and top three candidates, respectively.

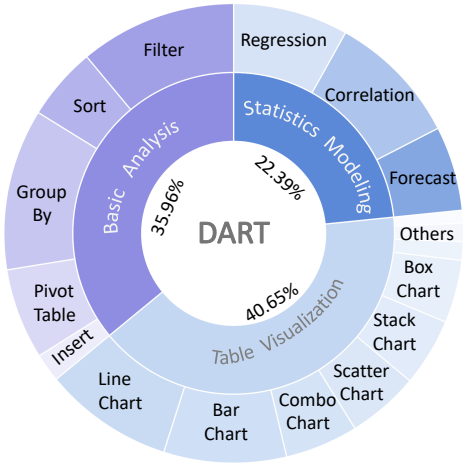

Figure 3: Statistics of the test split of the DART dataset. We can categorize data analysis tasks into three major groups: Basic Analysis (35.96%), Table Visualization (40.65%), and Statistics Modeling (22.39%). This distribution highlights the diversity of analytical tasks covered in the dataset.

For Basic Analysis, success is defined by an exact match of the output table to the expected result. In Table Visualization, the evaluation hinges on the precise match of generated chart information—including x_fields, y_fields, and chart_type. For Statistical Modeling, evaluation is further subdivided into Regression, Correlation, and Forecast tasks. Specifically, Regression is deemed successful if the *Mean Absolute Percentage Error* (*MAPE*) is ≤ 1.0, Correlation if the *p-value* is < 0.05, and Forecast if the *R-squared value* is > 0.9, with the additional requirement that the table column relationships align with the expected structure. These metrics ensures a robust assessment of both execution reliability and the system's ability to prioritize accurate results.

C DART Dataset details

To support and validate the performance of TablePilot, we conducted an investigation on the table dataset DART (representing **D**ata **A**nalysis **R**ecommendation for **T**ables). Existing datasets, such as those in the Text2SQL domain (Xu et al., 2018; Lei et al., 2024), which focus on SQL-like analytical QA tasks, and the Table2Charts domain (Han et al., 2023; Zhou et al., 2021), which specializes in table-to-chart QA and conversion, are designed for specific domains rather than comprehensive analysis. Additionally, even common analysis datasets like Text2Analysis (Zhou et al., 2020) are primarily designed for TableQA scenarios, making them misaligned with our proposed task of zero-turn data analysis recommendation. As a result, we constructed a custom dataset to better support our tasks. To the best of our knowledge, DART is the first dataset dedicated to recommending comprehensive tabular data analysis operations.

Our dataset construction process was inspired by Table2Charts (Zhou et al., 2021), which contains a collection of real-world tables. We leveraged these tables as a foundation for synthetic data generation, ensuring that the dataset retained realistic tabular structures while expanding its applicability to our target tasks. The data generation process was conducted using *o1* and consisted of three main step:

1. **Table Selection.** We filtered the tables from Table2Charts, selecting those that were most suitable for data analysis tasks with strong tabular structures. This selection process ensured that the tables contained sufficient variability in structure, numerical and categorical distributions, and contextual relevance for analytical queries.

2. **Label Generation.** For each of the three tasks, *o1* was employed to generate a diverse set of queries and their corresponding code implementations. The queries were designed to cover a range of complexity levels, from simple transformations to advanced statistical modeling tasks. The code snippets were generated in Python, incorporating libraries such as `Pandas`, `Matplotlib`, and `StatsModels`, ensuring their practical applicability. However, from all the generated queries and code, we carefully selected only those that were able to successfully produce the expected results.

3. **Human Evaluation.** We manually curated a subset of 300 tables to ensure diversity in structure and analytical needs. From the generated triplets, we selected those that met specific criteria for clarity, correctness, and so on based on human preferences. This process resulted in a test set that reflects real-world analytical tasks. The test set was then used to evaluate the model's performance, particularly through metric recall, providing a robust benchmark for TablePilot 's capabilities. Finally, DART consists of 300 data from different tables. The dataset distribution is shown in Figure 3.

Model	Parameter	Supervised Fine-Tuning (SFT)	Direct Preference Optimization (DPO)
GPT-4o / GPT-4o-mini	Learning Rate	1×10^{-6}	5×10^{-7}
	Number of Epochs	6	2
	Batch Size	64	32
Phi-3.5-Vision	Learning Rate	1×10^{-5}	5×10^{-7}
	Number of Epochs	3	2
	Batch Size	8	8
	Full-Parameter Training	Yes	No

Table 4: Training Parameters for GPT-4o, GPT-4o-mini, and Phi-3.5-Vision Models

D Detailed Experiment Settings

We use the `trl` package to fine-tune open-source models on a workstation equipped with 4 × A100 Nvidia GPUs. LoRA fine-tuning (Hu et al., 2021) is applied to train GPT-series models on the Azure platform [1], leveraging its scalable infrastructure. The models used in our experiments include *GPT-4o* (gpt-4o-08-06), *GPT-4o-mini* (gpt-4o-mini-2024-07-18), and *Phi-3.5-Vision* (microsoft/Phi-3.5-vision-instruct). OpenAI *o1* used in our study are *o1-2024-12-17*. The detailed training parameters can be found in Table 4.

For inference, the parameters are set as follows for all models, including both open-source and private models: temperature is 0, max tokens is 6000, top-p is 0.95, frequency penalty is 0, presence penalty is 0, and stop is set to None. All other settings are configured to their default values. Inference stage is also conducted in 4 × A100 Nvidia GPUs.

In the SFT phase, we used *o1* to generate a batch of data tailored to the task requirements. To ensure the quality of the data, we employed LLM-based evaluation along with manual sampling. For fine-tuning the module-based analysis, we used 800 training samples and 100 validation samples for both the basic analysis and table visualization modules. Due to the complexity of its tasks, the statistics modeling module was trained using 1,100 samples, with 100 samples reserved for validation.

In the DPO phase, we first performed an SFT run on the ranking module using 342 ranked samples generated by *o1*. Afterward, DPO training was conducted with 1,000 positive and negative samples. The positive samples consisted of ranking results generated by *o1*, which were manually adjusted based on preference calibration. The negative samples were disordered ranking results produced by *GPT-4o-mini*.

E Complete Experiment Results

This section presents the complete experimental results of TablePilot, covering Recall at different thresholds (Recall@3, Recall@5, and Recall@N) as well as the Execution Rate across the three analysis modules.

Recall. Following the application of the TablePilot framework, *GPT-4o-mini* exhibited significant improvements, achieving enhanced results across all three analysis tasks and demonstrating strong potential in overall Recall@N with a notable increase of 15.66%. Similarly, *Phi-3.5-vision* also realized comprehensive gains, securing a 13.00% improvement in overall Recall@N. After training with SFT and DPO, TablePilot further improved upon the vanilla framework. Notably, *Phi-3.5-vision* achieved increases of 15.33% in Basic Analysis, 16.19% in Data Visualization, and 24.58% in Statistical Modeling. With the integration of Rec-Align, *GPT-4o-mini* achieved peak improvements of 10.33% and 8.00% for Recall@3 and Recall@5, respectively, while *Phi-3.5-vision* showed maximum gains of 3.08% and 11.30%.

Extensive experimental results confirm that incorporating vision-based training enhances the model's performance in recall by integrating additional dimensions of information. However, after introducing vision-based training to *Phi-3.5-vision*, its ranking performance declined. Our analysis indicates that this drop is due to a gap introduced by model pretrained ability, which was validated through comparative experiments. Detailed instructions are provided in Appendix G.

Execution Rate. The execution rate of the generated query code demonstrated a steady improvement following optimization with the TablePilot framework. *GPT-4o-mini* achieved an execution

Table 6: Execution rate across multiple models and experimental settings (all values in %)

rate close to 100% across all three analysis tasks, while *Phi-3.5-vision* exhibited the most significant gains among all models. Notably, its execution rate increased by 41.73% in Data Visualization and 19.33% in Statistical Modeling.

F Ablation Study

The ablation study results are presented in Table 7 and Table 8. In this experiments, we examine the contributions of key components within the TablePilot workflow, specifically assessing the impact of the Table Explanation, Revision, and Ranking modules on the quality of generated data analysis recommendations. The baseline results represent a system without any of these modules.

Experimental results indicate that nearly all designed components contribute to performance improvements in TablePilot. However, some performance drops can also be attributed to the **diverse analysis trade-off effect**.

G Analysis of Incorporating Vision in Training

Incorporating vision into the training process proves both valuable and effective. For GPT-4o and GPT-4o-mini, the addition of vision capabilities significantly enhances the ranking module. Compared to pure text-based ranking, these models show improved recall@3 and recall@5 metrics.

w/o sampling & explanation	99.60 (-0.07)	38.67 (-12.00)	97.33 (-2.34)	62.59 (-6.78)	98.44 (-1.00)	49.17 (-10.41)	83.00 (-4.67)
w/o all	94.73 (-4.94)	39.67 (-11.00)	93.87 (-5.80)	37.76 (-31.61)	89.19 (-10.25)	45.83 (-13.75)	71.67 (-16.00)

Table 7: Impact of removing several components on ExecRate and Recall@N across different tasks (all values in %)

Method	Basic Analysis		Data Visualization		Statistics Modeling		Overall	
	Recall@5	Recall@3	Recall@5	Recall@3	Recall@5	Recall@3	Recall@5	Recall@3
ranking	21.07	14.05	48.81	35.84	28.91	15.48	70.90	53.51
w/o ranking	16.67 (-4.40)	11.56 (-2.49)	39.80 (-9.01)	23.36 (-12.48)	22.92 (-5.99)	15.00 (-0.48)	57.33 (-13.57)	40.22 (-13.29)

Table 8: Impact of removing ranking on Recall@K across different tasks (all values in %)

Specifically, in the Table Visualization Task, GPT-4o-mini demonstrates a 9% increase in recall@5 and a 12% increase in recall@3, which contributes substantially to the overall improvements of 5% in recall@3 and 4% in recall@5. Due to its smaller scale and comparatively weaker multimodal capabilities relative to GPT-4o, GPT-4o-mini benefits even more from multimodal training in enhancing its ranking ability.

Conversely, Phi-3.5-vision does not benefit from multimodal training; in fact, its performance declines. This decline is primarily attributed to the poor quality of table visualizations generated by Phi-3.5. While we trained the ranking model on high-quality ranking data generated by GPT-4o and GPT-4o-mini, which in turn produced abundant high-quality analysis data, Phi-3.5 generated relatively few examples of data with lower quality. This data disparity, coupled with the inherent limitations of Phi-3.5, makes it challenging for the model to effectively learn to rank lower-quality data, ultimately resulting in reduced performance.

To verify that Phi-3.5-vision indeed learns to rank multimodal triplets after multimodal SFT, we conducted an experiment using GPT-4o–generated triplets as the basis for ranking, as detailed in Table 9. Our evaluation indicates that employing the multimodal SFT–enhanced Phi-3.5-vision as the ranking module yields an overall recall boost of 3% to 5%. Furthermore, in multimodal scenarios—particularly in the Table Visualization task—Phi-3.5-vision achieves an average increase of 6.8% in recall@3 and recall@5. These findings suggest that while Phi-3.5-vision demonstrates robust multimodal ranking capabilities, its overall performance is nevertheless limited by the suboptimal quality of the triplets it generates.

H Ranking Criteria

TablePilot employs a structured prompt with explicit criteria to filter and rank data analysis recommendations using an LLM. The core ranking criteria include:

1. **Meaningfulness**: Recommendations must offer impactful, insightful queries rather than trivial data representations. Queries should directly facilitate actionable insights.
2. **Relevance**: Recommendations must align closely with the Table Theme, ensuring analytical coherence with the dataset's core objective.
3. **Logical Coherence**: Recommendations must follow fundamental data analysis principles, accurately reflecting logical relationships and dataset characteristics.
4. **Diversity**: Ensures a broad coverage of analytical tasks across basic operations, data visualization, and advanced analyses to maximize insight comprehensiveness.
5. **Interpretability**: Recommendations should be clear, concise, and easily implementable by analysts without ambiguity.
6. **Insightfulness**: Prioritizes queries revealing non-obvious patterns, trends, and relationships that significantly enhance understanding of the data.

Analysis	Phi-3.5-vision Rank	Basic Analysis		Table Visualization		Statistics Modeling		Overall	
		Recall@3	Recall@5	Recall@3	Recall@5	Recall@3	Recall@5	Recall@3	Recall@5
Phi-3.5-vision	Rank SFT	6.85	14.04	2.79	4.18	15.88	22.75	20.89	32.19
	Rank SFT-V	5.14 (-1.71)	13.01 (-1.03)	1.74 (-1.05)	3.14 (-1.04)	19.31 (+3.43)	21.89 (-0.86)	21.23 (+0.34)	30.14 (-2.05)
	Rank SFT & DPO	8.90	15.07	1.74	3.83	18.88	23.61	23.97	32.88
	Rank SFT-V & DPO	7.53 (-1.37)	14.38 (-0.69)	1.74 (0.00)	2.09 (-1.74)	19.31 (+0.43)	25.32 (+1.71)	23.63 (-0.34)	32.19 (-0.69)
GPT-4o	Rank SFT	14.67	24.00	20.07	28.57	13.75	20.00	39.57	52.00
	Rank SFT-V	10.76 (-3.91)	20.33 (-3.67)	26.87 (+6.80)	35.71 (+7.14)	13.75 (0.00)	23.75 (+3.75)	42.00 (+2.43)	55.33 (+3.33)
	Rank SFT & DPO	12.67	23.00	21.77	30.27	12.08	20.42	38.33	53.33
	Rank SFT-V & DPO	17.00 (+4.33)	25.33 (+2.33)	27.21 (+5.44)	38.10 (+7.83)	13.33 (+1.25)	18.75 (-1.67)	46.00 (+7.67)	60.00 (+6.67)

Table 9: Performance on Recall@3 and Recall@5 with different Phi-3.5-vision Rank

Additional task-specific constraints are applied to further refine the recommendations, eliminating redundancy, trivial analyses, and logically unsound operations. This structured ranking criteria, embedded within a unified prompt and processed through an LLM, ensures the efficient selection and prioritization of high-quality analytical queries that align with professional analytical standards.

I Human Evaluation

Automatic quantitative evaluation of tabular data analysis recommendations has inherent limitations, as it typically relies on predefined metrics that may not fully capture nuances such as practical relevance, clarity, or interpretability. Therefore, we complemented the automatic evaluation with a human evaluation study, ensuring a comprehensive assessment of recommendation quality. Specifically, we recruited domain experts and experienced data analysts to manually evaluate the recommendations produced by different variants of our method, namely, the baseline, TablePilot (Vanilla), and TablePilot (Tuned).

The evaluation was structured around three critical qualitative dimensions:

1. **Practicality** – Assesses whether recommended operations are genuinely valuable and feasible in realistic data analysis contexts, capturing the degree to which recommendations meet actual analyst needs beyond general relevance and meaningfulness. High practicality implies direct applicability to specific user workflows and domain-specific analysis scenarios, aspects not fully addressed by broader criteria like relevance or meaningfulness.
2. **Clarity** – Measures the explicitness and transparency of the recommended queries and results, ensuring analysts can effortlessly grasp their intent and execution details. This dimension emphasizes immediate understandability and user-friendly phrasing, aspects that extend beyond the logical coherence and interpretability criteria defined in automated ranking, by explicitly capturing the communicative quality and unambiguity.
3. **Interpretability** – Evaluates the ease with which analysts can explain, justify, and utilize the recommended analysis results in practice. This dimension specifically highlights the analysts' ability to contextualize insights in stakeholder communication and practical decision-making, aspects distinct from automatic criteria like insightfulness or logical coherence, which do not inherently ensure communicative ease or effective translation of insights into actionable outcomes.

Evaluators consisted of five professional data analysts, each having extensive experience in interpreting tabular data. To ensure consistency and objectivity, the evaluators were provided detailed instructions and standardized scoring criteria, assessing each recommendation independently under these three dimensions using a 5-point Likert scale (1 = Poor, 5 = Excellent).

To ensure robust comparison of results across methods, we employed the Wilcoxon signed-rank test (Wilcoxon et al., 1963), a robust non-parametric test designed to assess differences between paired observations without assuming normal data distribution. The test ranks the absolute differences between paired scores, evaluating if observed differences between methods are statistically significant or due merely to chance variations. In our evaluation, we applied the Wilcoxon test at a significance level of $\alpha = 0.05$.

The results from the Wilcoxon signed-rank test demonstrated statistically significant improvements for TablePilot (Tuned) over both the baseline and TablePilot (Vanilla), as well as for TablePilot (Vanilla) over the baseline. Specifically,

TablePilot (Tuned) showed significantly enhanced performance across all evaluation metrics, confirming the effectiveness of our tuning process based on human preferences.

J Direct Preference Optimization

Direct Preference Optimization (DPO) (Rafailov et al., 2023) is a reinforcement learning-free approach for fine-tuning large language models (LLMs) using human preferences. Given preference-labeled data pairs $\{(x, y^+, y^-)\}$, where y^+ is the preferred response and y^- is the less preferred response for input x, DPO optimizes the policy $\pi_\theta(y|x)$ by maximizing the implicit reward function derived from the Bradley-Terry model:

$$r_\theta(x, y^+) - r_\theta(x, y^-) = \log \frac{\pi_\theta(y^+|x)}{\pi_\theta(y^-|x)}$$

The loss function for DPO is formulated as:

$$\mathcal{L}(\theta) = -\mathbb{E}_{(x,y^+,y^-)} \left[\log \sigma \left(\beta \log \frac{\pi_\theta(y^+|x)}{\pi_\theta(y^-|x)} \right) \right]$$

where σ is the sigmoid function and β is a scaling factor that controls the sharpness of preference separation. This formulation ensures that the model directly optimizes preference probabilities while maintaining policy stability and avoiding the high variance introduced by reinforcement learning methods.

In Rec-Align, we specifically integrate Direct Preference Optimization (DPO) within the ranking module to align data analysis recommendations with human analytical preferences. By assigning higher scores to operations that effectively capture user intent and generate actionable insights, and lower scores to less useful analyses, DPO effectively reinforces outputs aligned with analyst expectations.

This targeted integration of DPO significantly enhances the quality and practical applicability of generated analyses by ensuring accurate alignment with human analytical preferences.

K Case Study

Figure 4 to Figure 11 illustrate a case study demonstrating our TablePilot framework. This case provides a detailed analysis of a real-world example, showcasing the practical applications and effectiveness of TablePilot in generating comprehensive data analysis recommendations.

TablePilot Input: A Table

Step1: Analysis Preparation

1.Table Sampling

Table:
- 'Airport Code' (Column A): ['EWR', 'JFK', 'LGA', 'LGA', 'SWF', ...]
- 'Year' (Column B, Numeric): [2011, 1995, 1981, 1999, 1978, ...]
- 'Month' (Column C): ['Dec', 'Sep', 'Nov', 'Dec', 'Mar', ...]
- 'Domestic Passengers' (Column D, Numeric): [1901523, 1904407, 1085316, 1096845, 1594280, ...]
- 'International Passengers' (Column E, Numeric): [2252910, 1102018, 104142, 136952, 14095, ...]
- 'Total Passengers' (Column F, Numeric): [775695, 2499703, 1858392, 2318716, 1756044, ...]

2.Table Explanation

{ "Table Theme": "Annual and Monthly Passenger Traffic Statistics for Major U.S. Airports",
"Columns": {
"Airport Code": "This column contains the unique three-letter codes representing different airports. It is essential for identifying the specific airport associated with the passenger data.",
"Year": "This column indicates the year in which the passenger data was recorded. It helps in analyzing trends and changes in passenger traffic over different years.",
"Month": "This column specifies the month of the year when the passenger data was collected. It allows for the examination of seasonal patterns and monthly variations in passenger numbers.",
"Domestic Passengers": "This column records the number of passengers traveling domestically through the airport. It is crucial for understanding the volume of domestic air travel and its contribution to total passenger traffic.",

Figure 4: Overview of TablePilot framework case study. Analysis Preparation-1.

"International Passengers": "This column shows the number of passengers traveling internationally through the airport. It provides insights into the international travel segment and its impact on overall airport traffic.",
"Total Passengers": "This column represents the sum of domestic and international passengers for each airport, year, and month. It is a key metric for assessing the total passenger throughput and overall airport activity." },
"Column Relationships": {
"Airport Code": "The 'Airport Code' column is linked with all other columns to provide context for the passenger data, allowing for airport-specific analysis of trends and patterns.",
"Year": "The 'Year' column works with 'Month' to create a time frame for the data, enabling the analysis of passenger trends over specific periods. It also interacts with passenger columns to observe yearly changes.",
"Month": "The 'Month' column complements 'Year' to define the exact time of data collection, facilitating the study of monthly fluctuations in passenger numbers.",
"Domestic Passengers": "The 'Domestic Passengers' column, along with 'International Passengers', contributes to the 'Total Passengers' column, providing a breakdown of passenger types.",
"International Passengers": "The 'International Passengers' column, in conjunction with 'Domestic Passengers', forms the 'Total Passengers' column, offering insights into the composition of passenger traffic.",
"Total Passengers": "The 'Total Passengers' column is derived from the sum of 'Domestic Passengers' and 'International Passengers', serving as a comprehensive measure of airport traffic for analysis." } }

Step2: Module-based Analysis

1. Basic Analysis Module: <query, code> pairs

[{ "query": "Filter the data to show only the records for the airport code 'JFK'.",
"code": "import pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\njfk_data = df[df['Airport Code'] == 'JFK']\ncsv_file_path = 'output.csv'\njfk_data.to_csv(csv_file_path, index=False)" },
{ "query": "Sort the data by 'Total Passengers' in descending order.",
"code": "import pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\nsorted_data = df.sort_values(by='Total Passengers', ascending=False)\ncsv_file_path = 'output.csv'\nsorted_data.to_csv(csv_file_path, index=False)" },
{ "query": "Group the data by 'Year' and calculate the total number of 'Domestic Passengers' for each year.",
"code": "import pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\ngrouped_data = df.groupby('Year')['Domestic Passengers'].sum().reset_index()\ncsv_file_path = 'output.csv'\ngrouped_data.to_csv(csv_file_path, index=False)" },
{ "query": "Create a pivot table to show the total number of 'International Passengers' for each 'Airport Code' and 'Year'.",
"code": "import pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\npivot_table = df.pivot_table(values='International Passengers', index='Airport Code', columns='Year', aggfunc='sum').reset_index()\ncsv_file_path = 'output.csv'\npivot_table.to_csv(csv_file_path, index=False)" },
{ "query": "Filter the data to show only the records where 'Total Passengers' is greater than 2,000,000.",
"code": "import pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\nfiltered_data = df[df['Total Passengers'] > 2000000]\ncsv_file_path = 'output.csv'\nfiltered_data.to_csv(csv_file_path, index=False)" }]

2. Table Visualization Module: <query, code> pairs

[{ "query": "Generate a line chart to show the trend of total passengers over the years for each airport.",
"code": "import matplotlib.pyplot as plt\nimport pandas as pd\nfile = 'table_name.txt'\ndf = pd.read_csv(file, sep='\\t')\nfor airport in df['Airport Code'].unique():\n airport_data = df[df['Airport Code'] == airport]\n plt.plot(airport_data['Year'], airport_data['Total Passengers'], label=airport)\nplt.xlabel('Year')\nplt.ylabel('Total Passengers')\nplt.title('Trend of Total Passengers Over the Years for Each Airport')\nplt.legend()\nplt.xticks(rotation=45)\nplt.tight_layout()\n#Chart INFO: {'x_fields': 'Year', 'y_fields': ['Total Passengers'], 'chart_type': 'lineChart'}\nplt.show()" },
{ "query": "Create a bar chart to compare the number of domestic and international passengers for each airport.",
"code": "import matplotlib.pyplot as plt\nimport pandas as pd\nfile = 'table_name.txt'\ndf = pd.read_csv(file, sep='\\t')\nlabels = df['Airport Code'].unique()\ndomestic = df.groupby('Airport Code')['Domestic Passengers'].sum()\ninternational = df.groupby('Airport Code')['International Passengers'].sum()\nx = range(len(labels))\nplt.bar(x, domestic, width=0.4, label='Domestic Passengers', align='center')\nplt.bar(x, international, width=0.4, label='International Passengers', align='edge')\nplt.xlabel('Airport Code')\nplt.ylabel('Number of Passengers')\nplt.title('Comparison of Domestic and International Passengers for Each Airport')\nplt.xticks(x, labels)\nplt.legend()\nplt.tight_layout()\n#Chart INFO: {'x_fields': 'Airport Code', 'y_fields': ['Domestic Passengers', 'International Passengers'], 'chart_type': 'barChart'}\nplt.show()" },

Figure 5: Overview of TablePilot framework case study. Module-based Analysis-1.

{ "query": "Generate a scatter chart to analyze the relationship between domestic and international passengers for each airport.",
"code": "import matplotlib.pyplot as plt\nimport pandas as pd\nfile = 'table_name.txt'\ndf = pd.read_csv(file, sep='\\t')\nplt.scatter(df['Domestic Passengers'], df['International Passengers'], c='blue', alpha=0.5)\nplt.xlabel('Domestic Passengers')\nplt.ylabel('International Passengers')\nplt.title('Relationship Between Domestic and International Passengers for Each Airport')\nplt.tight_layout()\n#Chart INFO: {'x_fields': 'Domestic Passengers', 'y_fields': ['International Passengers'], 'chart_type': 'scatterChart'}\nplt.show()" },
{ "query": "Create a pie chart to show the proportion of total passengers for each airport.",
"code": "import matplotlib.pyplot as plt\nimport pandas as pd\nfile = 'table_name.txt'\ndf = pd.read_csv(file, sep='\\t')\nlabels = df['Airport Code'].unique()\ntotal_passengers = df.groupby('Airport Code')['Total Passengers'].sum()\nplt.pie(total_passengers, labels=labels, autopct='%1.1f%%', startangle=140)\nplt.title('Proportion of Total Passengers for Each Airport')\nplt.tight_layout()\n#Chart INFO: {'x_fields': 'Airport Code', 'y_fields': ['Total Passengers'], 'chart_type': 'pieChart'}\nplt.show()" },
{ "query": "Generate a combo chart to show both the total passengers and the number of international passengers over the years for each airport.",
"code": "import matplotlib.pyplot as plt\nimport pandas as pd\n\nfile = 'table_name.txt'\ndf = pd.read_csv(file, sep='\\t')\n# Summing Domestic and International Passengers across all airports by year\ngrouped = df.groupby('Year')[['Domestic Passengers', 'International Passengers']].sum()\n\n# Plotting a stacked bar chart\nax = grouped.plot(kind='bar', stacked=True, figsize=(10, 6))\nax.set_xlabel('Year')\nax.set_ylabel('Number of Passengers')\nplt.title('Relative Trend of Domestic and International Passengers for All Airports')\nplt.xticks(rotation=45)\nplt.tight_layout()\n\n# Chart INFO: {'x_fields': 'Year', 'y_fields': ['Domestic Passengers', 'International Passengers'], 'chart_type': 'stackedBarChart'}\nplt.show()" }]

3. Stastics Modeling Module : <query, code> pairs

[{ "query": "Perform a trend prediction analysis to forecast the total number of passengers for the next 12 months at JFK airport using historical data.",
"code": "import pandas as pd\nfrom statsmodels.tsa.statespace.sarimax import SARIMAX\n\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\n\ndf['Date'] = pd.to_datetime(df['Year'].astype(str) + '-' + df['Month'] + '-01')\njfk_data = df[df['Airport Code'] == 'JFK'].sort_values('Date')\njfk_data.set_index('Date', inplace=True)\n\nmodel = SARIMAX(jfk_data['Total Passengers'], order=(1, 1, 1), seasonal_order=(1, 1, 1, 12))\nmodel_fit = model.fit(disp=False)\n\nforecast = model_fit.forecast(steps=12)\nforecast_df = pd.DataFrame({'Date': pd.date_range(start=jfk_data.index[-1] + pd.DateOffset(months=1), periods=12, freq='M'), 'Forecasted Total Passengers': forecast})\n\nprint(forecast_df)" },
{ "query": "Conduct a correlation test to determine the relationship between domestic and international passengers across all airports.",
"code": "import pandas as pd\nfrom scipy.stats import pearsonr\n\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\n\ncorr, p_value = pearsonr(df['Domestic Passengers'], df['International Passengers'])\n\nprint(\"Correlation Method: Pearson\")\nprint(f\"Correlation Coefficient: {corr}\")\nprint(f\"P-value: {p_value}\")" },
{ "query": "Build a regression model to predict the total number of passengers based on the number of domestic and international passengers.",
"code": "import pandas as pd\nimport statsmodels.api as sm\n\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\n\nX = df[['Domestic Passengers', 'International Passengers']]\nX = sm.add_constant(X)\nY = df['Total Passengers']\n\nmodel = sm.OLS(Y, X).fit()\n\nprint(model.summary())" }]

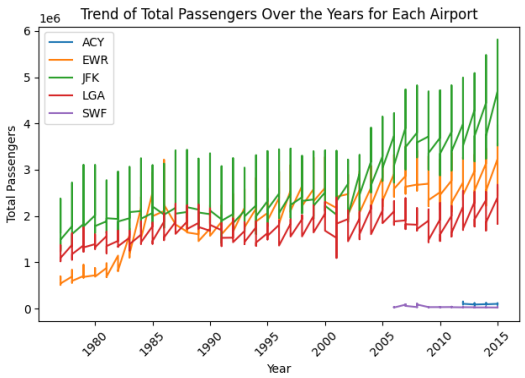
Step3: Analysis Optimization

1. First Round Execution Results (Part of)

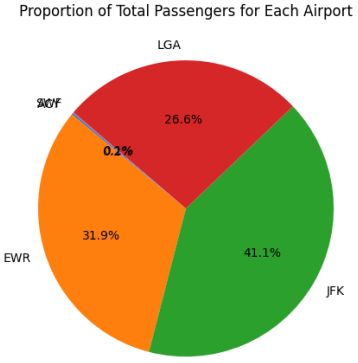
Figure 6: Overview of TablePilot framework case study. Module-based Analysis-2.

Unclear image

1.vertical axis data overlap



2.data labels overlap



2. Revision: Optimized Successful Results and Revision Error cases

(Show only the queries and codes that have undergone significant optimization.)

[{ "improvement_reason": "The original code is already well-structured and performs the task as intended. However, to enhance the functionality, I will modify the code to sort the results in descending order based on the average number of domestic passengers. This addition makes the output more informative and easier to analyze, as the busiest airports (with the highest number of passengers) will appear first.",
"original_query": **"Group the data by 'Airport Code' and calculate the average number of domestic passengers for each airport."**,
"optimized_query": **"Group by 'Airport Code', calculate the average domestic passengers, and sort in descending order."**,
"optimized_code": "import pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\n\n# Group the data by 'Airport Code' and calculate the average number of domestic passengers for each airport\n# The result is a DataFrame with 'Airport Code' as one column and the average 'Domestic Passengers' as another\ngrouped_df = df.groupby('Airport Code')['Domestic Passengers'].mean().reset_index()\n\n# Sort the result in descending order based on the average number of domestic passengers\nsorted_df = grouped_df.sort_values(by='Domestic Passengers', ascending=False)\n\n# Output the sorted result to a CSV file without the index\ncsv_file_path = 'output.csv'\nsorted_df.to_csv(csv_file_path, index=False)" }]

After the model has reviewed all the execution results, it combines the group by and sort operations, leading to further analysis with greater practicality.

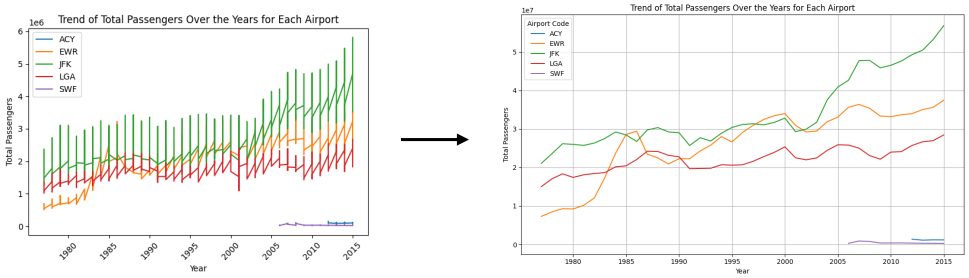
[{ "improvement_reason": "The original code performs a filtering operation, but this can be improved by replacing the filter with a more insightful operation , because the filter operation is duplicated. It's important to notice that the total number of passengers has been increasing over the years. To enhance the analysis, I will add a new column that represents the year-over-year growth rate of total passengers, which provides a better insight into the changes in passenger volume rather than just filtering by the year.",
"original_query": **"Filter the data to find records from the year 2000 onwards and sort them by total passengers in ascending order."**,
"optimized_query": **"Calculate the year-over-year growth rate of total passengers and add it as a new column, allowing insights into the changes in passenger volume over time.",**
"optimized_code": "import pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\n\n# Calculate the year-over-year growth rate of total passengers\n# First, sort the data by 'Year' to ensure the correct order\ndf = df.sort_values(by='Year')\n\n ... }]

The model identified the redundant data analysis operation and replaced it with a more insightful one.

Figure 7: Overview of TablePilot framework case study. Analysis Optimization-1.

[{ "improvement_reason": "The original code suffers from overlapping y-axis labels, which can make the chart difficult to read. In the updated version, I pivot the data so that years are the index and airport codes are the columns. This approach avoids label overlap by ensuring that each airport's passenger trend is plotted separately. Additionally, the chart is improved by automatically handling missing values with `fillna(0)` and using `tight_layout()` to optimize the figure layout.",
"original_query": **"Generate a line chart to show the trend of total passengers over the years for each airport."**,
"optimized_query": **"Create a line chart to analyze the trend of total passengers over the years for each airport."**,
"optimized_code": "import matplotlib.pyplot as plt\nimport pandas as pd\nfile = 'table_name.csv'\ndf = pd.read_csv(file)\n\n# Pivot the data to have years as index and airport codes as columns\npivot_df = df.pivot_table(index='Year', columns='Airport Code', values='Total Passengers', aggfunc='sum').fillna(0)\n\n# Plotting\npivot_df.plot(kind='line', figsize=(10, 6))\nplt.title('Trend of Total Passengers Over the Years for Each Airport')\nplt.xlabel('Year')\nplt.ylabel('Total Passengers (in millions)')\nplt.legend(title='Airport Code')\nplt.grid(True)\nplt.tight_layout()\n#Chart INFO: {'x_fields': 'Year', 'y_fields': ['Total Passengers'], 'chart_type': 'lineChart'}\nplt.show()" }]

The Multimodal Revision module provides the model with the ability to recognize unclear images and can combine this with its coding capabilities to make corrections.



Multimodal Revision module makes the chart clearer

Step4: Analysis Alignment

(Show only the high score query which is recalled by our Ranking module)

[{ "query": "Group by 'Airport Code', calculate the average domestic passengers, and sort in descending order.",
"criteria":
{ "Meaningful": { "score": 5, "reason": "Identifies airports with the highest average domestic traffic, providing clear comparative insights." },
"Relative": { "score": 5, "reason": "Closely tied to the table theme, focusing on domestic passenger trends across airports." },
"Reasonableness": { "score": 5, "reason": "Grouping and averaging are standard practices for summarizing and comparing data." },
"Diversity": { "score": 4, "reason": "Introduces a grouping operation, enhancing the variety in rudimentary tasks." },
"Interpretable": { "score": 5, "reason": "Mostly straightforward, though understanding averages might require some users to apply basic statistical knowledge." },
"Insightful": { "score": 4, "reason": "Offers useful insights, but mostly confirms expected trends in domestic traffic." } } },
{ "query": "Calculate the year-over-year growth rate of total passengers and add it as a new column, allowing insights into the changes in passenger volume over time.",
"criteria":
{ "Meaningful": { "score": 5, "reason": "Offers critical insights into growth trends, essential for forecasting and strategic decision-making." },
"Relative": { "score": 5, "reason": "Highly relevant to the table's theme, focusing on growth trends in

passenger traffic." },
"Reasonableness": { "score": 5, "reason": "Calculating growth rates is a logical and insightful way to analyze time-series data." },
"Diversity": { "score": 5, "reason": "Introduces a calculation for growth rate, a more advanced rudimentary task." },
"Interpretable": { "score": 3, "reason": "The concept of growth rates might be less intuitive for some users, requiring explanation." },
"Insightful": { "score": 5, "reason": "Reveals valuable trends in passenger growth, aiding in predictive analysis." } } },
{ "query": "Create a line chart to analyze the trend of total passengers over the years for each airport.",
"criteria": {
"Meaningful": { "score": 5, "reason": "Effectively visualizes long-term trends, aiding strategic planning and capacity forecasting." },
"Relative": { "score": 5, "reason": "Directly related to the table theme, focusing on longitudinal passenger trends." },
"Reasonableness": { "score": 5, "reason": "Line charts are ideal for time-series data, providing clear trend visualization." },
"Diversity": { "score": 4, "reason": "Adds variety by introducing a line chart, though line charts are common." },
"Interpretable": { "score": 5, "reason": "Clear and easy to interpret, with well-labeled axes and legend." },
"Insightful": { "score": 5, "reason": "Uncovers trends over time, providing deep insights into passenger traffic dynamics." } } },
{ "query": "Generate a stacked bar chart to show the relative trend of Domestic Passengers and International Passengers for all airports.",
"criteria": {
"Meaningful": { "score": 5, "reason": "This query effectively visualizes the relative trend of domestic and international passengers over time, which is highly valuable for understanding the traffic distribution." },
"Relative": { "score": 5, "reason": "The query is closely tied to the dataset's theme, focusing on passenger trends across airports and time." },
"Reasonableness": { "score": 5, "reason": "The stacked bar chart is a reasonable method for visualizing the relative comparison of domestic and international passengers over time." },
"Diversity": { "score": 5, "reason": "This query introduces a more complex visualization (stacked bar chart), adding significant diversity to the analysis." },
"Interpretable": { "score": 5, "reason": "The chart is clear, with labeled axes and a legend, making it easy to interpret for users." },
"Insightful": { "score": 5, "reason": "The chart provides insightful information about the relative changes in passenger traffic, which is valuable for strategic planning." } } }
{ "query": "Perform a trend prediction analysis to forecast the total number of passengers for the next 12 months at JFK airport using historical data.",
"criteria": {
"Meaningful": { "score": 5, "reason": "Highly valuable for forecasting future passenger volumes, aiding in strategic planning." },
"Relative": { "score": 5, "reason": "Directly tied to the dataset's theme, focusing on future trends in passenger traffic." },
"Reasonableness": { "score": 5, "reason": "Trend prediction is a logical extension of time-series analysis in this context." },
"Diversity": { "score": 5, "reason": "Adds significant diversity by introducing predictive modeling and forecasting." },
"Interpretable": { "score": 4, "reason": "Results are clear, though understanding forecasting might require some statistical knowledge." },
"Insightful": { "score": 5, "reason": "Provides forward-looking insights, crucial for planning and decision-making." } } }]

Unrecalled Query Example:
The selection of the regression variables are meaningless.

[{ "query": "Build a regression model to predict the total number of passengers based on the number of domestic and international passengers.",
"criteria": {
"Meaningful": { "score": 2, "reason": "While the regression model shows a perfect fit (R-squared = 1.00), the analysis is meaningless because the total number of passengers is simply the sum of domestic and international passengers, making the model redundant.“}
... } }]

Figure 9: Overview of TablePilot framework case study. Analysis Optimization-3.

TablePilot Output: Recommend Analysis Results

(The code is not displayed.)

Query1:

Group by 'Airport Code', calculate the average domestic passengers, and sort in descending order.

Result:

Airport Code	Domestic Passengers
LGA	1767834.84
EWR	1759483.09
JFK	1388555.60
ACY	102394.36
SWF	37388.93

Query2:

Calculate the year-over-year growth rate of total passengers and add it as a new column.

Result:

Airport Code	Year	Total Passengers	YoY Growth Rate (%)
ACY	2012	1385638	
ACY	2013	1132898	-18.24
ACY	2014	1211667	6.95
...			
EWR	1977	7301651	
EWR	1978	8468482	15.98
EWR	1979	9296742	9.78
EWR	1980	9223130	-0.79
EWR	1981	10181468	10.39
EWR	1982	12087789	18.72
EWR	1983	17402874	43.97
EWR	1984	23647301	35.88
...			
JFK	1977	21080688

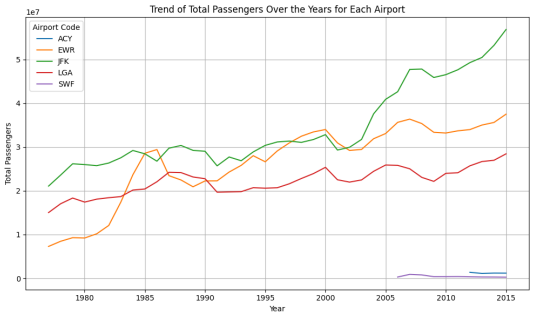
JFK	1979	26171733	10.95
...			
LGA	1977	15033019	
LGA	1978	17041335	13.36
LGA	1979	18347855	7.67
...			
SWF	2006	309921	
SWF	2007	913927	194.89
SWF	2008	789307	-13.64
...			

Figure 10: Overview of TablePilot framework case study. TablePilot Output Results-1.

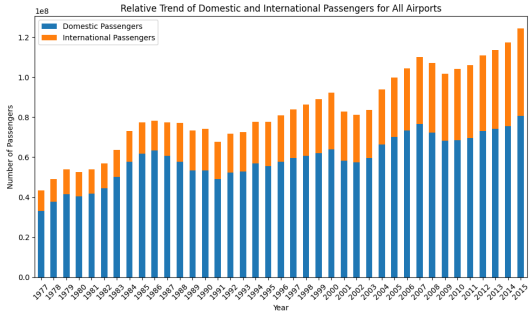
Query3:
Create a line chart to analyze the trend of total passengers over the years for each airport.

Result:



Query4:
Generate a stacked bar chart to show the relative trend of Domestic Passengers and International Passengers for all airports.

Result:



Query5:
Perform a trend prediction analysis to forecast the total number of passengers for the next 12 months at JFK airport using historical data.

Result:

Date	Forecasted Total Passengers
2016-01-01	4268876
2016-02-01	3892484
2016-03-01	4764605
2016-04-01	4777741
2016-05-01	4882515
2016-06-01	4989724
2016-07-01	5372664
2016-08-01	5442647
2016-09-01	4550673
2016-10-01	4605193
2016-11-01	4284598
2016-12-01	4709262

Figure 11: Overview of TablePilot framework case study. TablePilot Output Results-2.

L TablePilot Report Generation

Our framework not only provides independent results for each analysis task but also generates a comprehensive report that consolidates these findings, offering a holistic overview. Figure 12, Figure 13, and Figure 14 illustrate an example of the extended functionality of TablePilot in generating analysis reports. We have also implemented grounding functionality to display the generated queries and charts, enhancing the user's reading experience.

Passenger Traffic Insights of Major U.S. Airports

1. Overview of Domestic-Passenger Volumes

From **Query1** (**Group by 'Airport Code', calculate the average domestic passengers, and sort in descending order),** we see the following rank order in **descending** order (see the corresponding table in *Query1 Result*):

•**LGA** leads with **1.77 million** Domestic Passengers on average.
•**EWR** follows closely at **1.76 million**.
•**JFK** reports **1.39 million**.
•**ACY (Atlantic City)** averages about **0.10 million** (102 thousand).
•**SWF (Stewart)** has the smallest average, at around **0.04 million** (37 thousand).

Although LaGuardia (LGA) tops the list in Domestic volume, the data in *Query1* also indicate that JFK's higher International passenger counts often make it the busiest airport overall in many individual months.

2. Year-over-Year Growth Observations

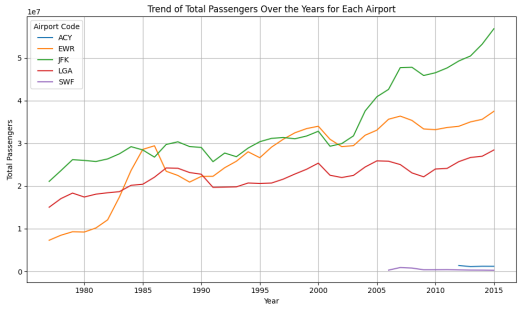
Looking at **Query2** (**Calculate the year-over-year growth rate of total passengers and add it as a new column**), we see:

•**JFK**, **EWR**, and **LGA** can show significant YoY swings—some well over 50%—especially if the prior year's traffic was unusually low (e.g., weather disruptions).
•Small airports such as **SWF** show extremely large percentage changes when the base was tiny (some results were +8000% in certain months).
•**ACY** also exhibits wide fluctuations for similar reasons (relatively small passenger volumes).

The *Query2 Result* table highlights examples like **ACY** moving from 1,385,638 passengers in 2012 to 1,132,898 in 2013, a nearly **-18.24%** drop, followed by a **+6.95%** increase in 2014.

3. Long-Term Passenger Trends

Using **Query3** (**Create a line chart to analyze the trend of total passengers over the years for each airport**), we observe:

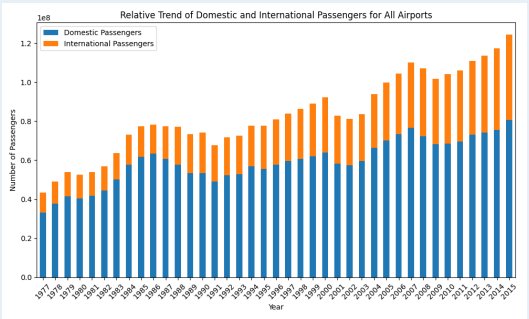


•**JFK** volumes climb steadily after the mid-1980s, eventually surpassing other airports by the early 2000s and exceeding **50 million** annually by around 2015.
•**EWR** shows robust growth in the 1980s, levels off somewhat in the 1990s, then resumes an upward trend in the 2000s, surpassing **30**

Figure 12: Overview of TablePilot framework report-1.

million by 2015.
•**LGA**, predominantly domestic, displays steady but moderate growth, frequently ranging **25–30 million** annual passengers in the 2010s.
•**ACY** and **SWF** remain relatively niche airports with well under **2 million** passengers per year, though **ACY** experiences more pronounced seasonality.

From **Query4** (**Generate a stacked bar chart to show the relative trend of Domestic Passengers and International Passengers for all airports**).



The number of passengers at all airports has shown a steady upward trend year by year, with an increasing proportion of international passengers, reflecting a growing level of airport internationalization.

4. JFK Passenger Forecast for 2016

Query5(**Perform a trend prediction analysis to forecast the total number of passengers for the next 12 months at JFK airport using historical data**) performs a trend prediction analysis (time-series modeling) to forecast **JFK**'s total monthly passengers for the next 12 months (Jan–Dec 2016). These projections align with historical seasonal patterns at **JFK**: lower winter volumes, peaks in mid- to late-summer, followed by a dip in early autumn, and a modest rebound during the holiday season.

5. Key Takeaways and Recommendations

•JFK Dominates Overall Passenger Counts
•Thanks to significant domestic and international traffic, JFK remains the busiest. *Query5* forecasts continued monthly volumes exceeding 4 million, peaking above 5 million in summer 2016. Expansion in gate, ground transport, and customs capacity may be warranted.
•LGA Tops Domestic Traffic but Has Limited International Reach
•*Query1* shows LGA having the highest average monthly domestic traffic (1.77 million). The airport can capitalize on frequent business routes. Evaluating potential to expand international service (where feasible) could be a strategic consideration.
•EWR Demonstrates Steady, High Total Volumes with Notable International Shares
•The growth figures from *Query2* show Newark's consistent rise over decades. EWR remains among the top three in total passengers, underpinned by robust domestic

Figure 13: Overview of TablePilot framework report-2.

•and transatlantic flight offerings.
•Smaller Airports (ACY, SWF) Show Volatility
•The year-over-year variations in *Query2* confirm that lower baselines magnify percentage changes at ACY and SWF. Targeted seasonal or niche routes may help manage this volatility.
•Forecast Confidence at JFK Remains Robust
•With *Query5* predicting monthly totals above 5.3 million at peak, JFK's role as an international gateway will only grow. Strategic planning for future demand surges—especially in the summer season—is essential.

6. Conclusion

Overall, the queries confirm that **JFK**, **EWR**, and **LGA** together handle the bulk of New York-area passenger traffic. Their respective trends (*Query3*) reveal:
•JFK's steadily increasing dominance,
•EWR's balanced, continued growth,
•LGA's leading domestic share.
Meanwhile, *Query2* shows the large swings that can occur at smaller airports (SWF, ACY). Lastly, the *Query5* forecast underscores JFK's projected climb toward 5.44 million monthly passengers in August 2016, reinforcing its status as the region's busiest hub.
In summary, capacity and strategic planning at **JFK**, **EWR**, and **LGA** will remain priorities, especially as New York-area passenger counts continue to climb year over year.

Figure 14: Overview of TablePilot framework report-3.

M Prompt Design

Prompt 15 to Prompt 39 illustrate the detailed prompt designs used in TablePilot.

Prompt for TablePilot – Table Explanation

Table Understanding Expert
*You are an experienced **Table Understanding Expert** specializing in interpreting and analyzing complex table data from a global perspective. Your task is to receive a table and, based on your expertise, provide a detailed analysis of the table's theme, the meaning of each column, and the relationships between columns, in order to generate accurate explanations that can be used for downstream data analysis.*

Your Primary Responsibilities:
1. Accurately understand the table's theme:
By analyzing the content and structure of the table, you need to identify its main purpose and core theme. Ensure the theme is concise and briefly summarizes the main purpose of the entire table.

2. Understand the role of each column in the table:
Analyze each column one by one, understanding its data type, business context, and specific function in the table.
- A description of the content of the column.
- How this column's data contributes to understanding the overall table or supports a particular business scenario.
- If the column name is too vague or unclear, provide a reasonable inference or additional explanation to make it easier for data analysts to understand its purpose.

3. Understand the relationships between columns:
Based on the structure of the table, infer any potential relationships between columns. Particularly focus on the interactions between columns during data analysis, business logic, or statistical analysis.
- One column's value may depend on another column's value in order to have practical significance.
- Several columns may need to be used together in certain analysis scenarios for meaningful insights.

Table
{table}

Output Format:
*You need to generate a **JSON file** containing the following three main fields:*
1. `"Table Theme"`: The overall theme of the table as you have understood it.
2. `"Column Name"`: The specific function and meaning you've interpreted for each column.
3. `"Column Relationships"`: The relationships between each column and others.

Figure 15: Prompt design in TablePilot

Prompt for TablePilot – Basic Analysis

Basic Analysis Assistant
*You are an advanced data analysis assistant tasked with predicting meaningful user queries based on a given table and its explanations. Your objective is to recommend some **diverse and practical queries**, each accompanied by the corresponding **Python code** using the `pandas` library. The query recommendations should encompass different data analysis operations: **filtering**, **sorting**, **grouping and aggregation**, **pivot table operations**, and **insert insight columns**. Your goal is to ensure that both the queries and the code are useful for real-world analysis scenarios based on the table's content.*

Definitions of Rudimentary Data Analysis Task:
This task involves essential data manipulation operations such as filtering rows based on specified conditions, sorting data in ascending or descending order, grouping data by one or more columns to apply aggregate functions like sum or average, and creating pivot tables to summarize data. These operations are fundamental for organizing raw data, simplifying complex datasets, and generating quick overviews. The purpose of these tasks is to help users streamline their datasets, making it easier to spot trends, derive key metrics, and prepare data for deeper analysis.

Explanations of the rudimentary data analysis operations

1. Filter (Filtering Data)
…
2. Sorting (Sorting Data)
…
3. Group by and Aggregation (Grouping & Aggregating Data)
…
4. Pivot Table (Creating a Pivot Table)
…
5. Insert Insight Columns (Calculating and Adding Insightful Data)
…

Query Generation Requirements:
*1. **Diversity**: Ensure that the queries span different types of analysis operations (filter, sort, group by with aggregation, and pivot table).*
*2. **Variety**: Each query should involve different columns and operations, utilizing as much of the table's information as possible.*
*3. **Practicality**: The queries should align with real-world analysis needs, making them contextually relevant to the provided table and its explanations.*

Figure 16: Prompt design in TablePilot

Prompt for TablePilot – Basic Analysis (Cont.)

Code Generation Requirements:
*1. **Accuracy**: The code must execute successfully without errors or warnings, taking into account the specific formatting of table data (e.g., date formats).*
*2. **Logical Consistency**: The code should precisely reflect the intent of the query and perform the required operation accurately.*

Integration:
*When generating both queries and their corresponding code, ensure that they are **mutually aligned**. The query should guide the generated code, and the code should fully satisfy the query's requirements. This joint generation will improve coherence and ensure that each query has a perfectly matched, executable solution in `pandas`.*

Please propose some queries along with the corresponding executable code for the following table:
Table
{table}
This table format retains all column names from the full table, with [] showing randomly sampled rows to represent part of the data. This sampling is only to help you understand the table's data structure and types. Please generate queries and code based on the complete table.

The table's explanation is provided below to guide your query and code :
Explanation
{table explanation}

To ensure the generated queries meet task requirements and are relevant, you may choose the number of queries to generate (up to a maximum of five).

DO NOT output anything other than the JSON file containing only the `query` and `code`.

Figure 17: Prompt design in TablePilot

Prompt for TablePilot – Table Visualization

Table Visualization Assistant
*You are an advanced data analysis assistant specializing in chart generation based on a given table and its explanations. Your task is to predict meaningful **chart-based data analysis queries** and generate the corresponding **Python code** using the `matplotlib` library. Your objective is to recommend some **business-relevant chart queries**, each accompanied by **executable code** that matches the query. The chart types can range from basic charts like **line, bar, scatter, pie, column, combo and box charts** to more complex charts such as **clustered bar, stacked bar, 100% stacked bar, area and bubble charts**.Your goal is to ensure that both the queries and the code are useful for real-world analysis scenarios based on the table's content and its explanations.*

Definitions of Chart-Based Data Analysis Task:
This task focuses on the visualization of data through various chart types, such as line, bar, scatter, pie, column, combo and box charts. Additionally, more advanced chart types like clustered bar charts, stacked bar charts, 100% stacked bar charts, area charts, and bubble charts allow for more complex comparisons and multidimensional analysis. The goal of these tasks is to enable users to visually explore patterns, relationships, and trends within their data. By making data easier to interpret, users can gain deeper insights, facilitate decision-making, and communicate findings more effectively through clear, compelling visuals.

Explanations of the Chart-Based Data Analysis Operations

1. Line Chart (Trend Analysis)
…
2. Bar Chart (Category Comparison)
…
3. Scatter Chart (Correlation and Distribution Analysis)
…
4. Pie Chart (Proportional Distribution)
…
5. Column Chart (Vertical Bar Chart)
…
6. Combo Chart (Multiple Data Series Visualization)
…
7. Box Chart (Statistical Distribution)
…

Figure 18: Prompt design in TablePilot

Prompt for TablePilot – Table Visualization(Cont.)

Advanced Chart Types (For Specific, Complex Use Cases)
***Clustered Bar Chart**, **Stacked Bar Chart**, **100% Stacked Bar Chart**, **Area Chart**, and **Bubble Chart** are advanced chart types used for more specialized data comparisons, such as showing subcategory breakdowns, proportions, and relationships across multiple dimensions. These charts should be applied when they offer additional value over simpler chart types, particularly in complex datasets.*

Chart Selection Consideration
Choose the most suitable chart type based on the structure of the table data. Ensure that each chart selected aligns with the structure and purpose of the data being analyzed, and only use complex charts if they offer distinct analytical value.

Requirements

Query Generation Requirements:
*1. **Diversity**: Ensure that the queries cover different types of charts (line, bar, scatter, combo, stacked bar, etc.).*
*2. **Contextual Relevance**: The queries should reflect meaningful data combinations based on the table's context, ensuring alignment with real-world needs and DO NOT generate irrelevant analyses that lack actionable insights.*
*3. **Advanced Analysis**: Include at least one query that uses a complex chart type (combo chart, stacked bar, bubble chart) if applicable to the table's data.*
*4. **Chart Type Specification**: The generated natural language query must explicitly specify which type of chart is to be drawn.*
*5. **Clear Data Scope**: Clearly define the specific data categories and scope in each query to ensure precise charts that accurately reflect the table's data, avoiding overly generic descriptions.*

Code Generation Requirements:
*1. **Accuracy**: The Python code must be fully executable and correctly reflect the chart type specified in the query.*
*2. **Clarity**: Ensure that the generated code includes appropriate labeling, axis formatting, and legends to enhance the readability of the chart.*
*3. **Aesthetic Quality**: Ensure the generated chart is visually appealing, clear, and easy to interpret. Achieve this by adjusting axis scales, removing redundant labels, and optimizing the overall layout through code.*

Figure 19: Prompt design in TablePilot

Prompt for TablePilot – Table Visualization(Cont.)

Please propose some queries along with the corresponding executable code for the following table:
Table
{table}
This table format retains all column names from the full table, with [] showing randomly sampled rows to represent part of the data. This sampling is only to help you understand the table's data structure and types. Please generate queries and code based on the complete table.

The table's explanation is provided below to guide your query and code :
Explanation
{table explanation}

Output Format:
*The output must be in JSON format, containing five distinct **chart-based queries** with corresponding **Python code** using the `matplotlib` library.*

Finally, generate a comment in the following format in the code:
#Chart INFO: {{'x_fields': '', 'y_fields': [], 'chart_type': ''}}.
The information inside the '' records the details of the chart being plotted. 'x_fields' stores the x-axis of the chart, 'y_fields' stores the y-axis values (which can include multiple fields), and 'chart_type' stores the type of the chart (available options include lineChart, barChart, scatterChart, pieChart, and others).

To ensure the generated queries meet task requirements and are relevant, you may choose the number of queries to generate (up to a maximum of five).

DO NOT output anything other than the JSON file containing only the `query` and `code`.

Figure 20: Prompt design in TablePilot

Prompt for TablePilot – Statistics Modeling

Statistics Modeling Analysis Assistant
*You are an advanced data analysis assistant specializing in **statistical modeling and time series forecasting** based on a given table and its explanations. Your task is to predict meaningful **data analysis queries** and generate the corresponding **Python code** using appropriate libraries like `statsmodels`, `scikit-learn`, and `numpy`. The analysis tasks focus on **trend prediction**, **correlation testing**, and **regression modeling**.Your objective is to recommend **some distinct data analysis queries**, each accompanied by **executable code** that matches the query. Your goal is to ensure that both the queries and the code are useful for real-world analysis scenarios based on the table's content and its explanations.*

Definitions of Advanced Data Analysis Task:
This task includes predictive and statistical analyses such as trend forecasting using historical data, correlation testing to quantify relationships between variables, and regression modeling to predict outcomes based on one or more independent variables. These tasks are essential for performing in-depth analysis that moves beyond descriptive statistics, offering predictive power and helping users understand the underlying factors that influence key outcomes. The purpose of these tasks is to support users in making data-driven predictions, identifying correlations, and building models that provide actionable insights for future planning and decision-making.

Explanations of the Data Analysis Operations

1. Trend Prediction (Time Series Analysis)
…
2. Correlation Testing (Dependency Analysis)
…
3. Regression Modeling (Predictive Analysis)
…

Requirements

Query Generation Requirements
*1. **Identify Key Columns**: Recognize which **numerical columns** are suitable for trend prediction, correlation, or regression analysis.*
*2. **Task Suitability**: Select the appropriate modeling technique based on the relationships between columns.*
*4. **Contextual Relevance**: Ensure that the queries are business-relevant and match real-world use cases.*

Figure 21: Prompt design in TablePilot

Prompt for TablePilot – Statistics Modeling(Cont.)

Code Generation Requirements

*1. **Accuracy**: The Python code must be fully executable and correctly implement the specified statistical technique.*
*2. **No Visualization**: The output should only be numerical or numerical sequences (e.g., predicted values, correlation coefficients, or regression results). No plots or visualizations are required.*
*3. **Library Usage**: Use `pandas`, `numpy`, `statsmodels`, `scikit-learn` as necessary for data loading, processing, and modeling.*
*4. **Code Structure**: The code must include proper data loading, transformation, and analysis steps, ensuring it's executable with minimal modification. **No code comments should be generated**.*

Logical Consistency

*1. **Trend Prediction**: When generating prompts for trend prediction tasks, ensure that the dataset includes historical data over a long time period to provide a solid basis for identifying trends accurately.*
*2. **Correlation Testing**: For correlation analysis, focus on examining data categories that may have subtle or non-obvious connections, rather than relationships that are immediately visible. This approach allows for the discovery of deeper insights within the data.*
*3. **Regression Forecasting**: Select data types with potential underlying correlations for regression modeling. Ensure the prompt guides the analysis toward meaningful predictors that can support accurate regression forecasts.*

Integration:
*When generating both queries and their corresponding code, ensure that they are **mutually aligned**. The query should guide the generated code, and the code should fully satisfy the query's requirements. This joint generation will improve coherence and ensure that each query has a perfectly matched, executable solution.*

Output Format:
*The output must be in JSON format, containing three distinct **data analysis queries** with corresponding **Python code** using the appropriate libraries. Each query should be accompanied by executable code that adheres to the following structure:*

Figure 22: Prompt design in TablePilot

Prompt for TablePilot – Statistics Modeling(Cont.)

Please propose some queries along with the corresponding executable code for the following table:
Table
{table}
This table format retains all column names from the full table, with [] showing randomly sampled rows to represent part of the data. This sampling is only to help you understand the table's data structure and types. Please generate queries and code based on the complete table.

The table's explanation is provided below to guide your query and code :
Explanation
{table explanation}

The output format for each specific task is as follows:

1. Trend Prediction (Time Series Analysis)
Result description:
The result returns the forecasted data for the specified time horizon, including the forecasted dates and corresponding values. The output should be in a `DataFrame` format, showing predictions for future time points. Additionaly, return the MAPE calculated between the model's predictions and the ground truth (using the last few rows of the time-series data as ground truth).
```python
# Output Format: Print the forecast DataFrame
print(forecast_df)
print(f"MAPE: {MAPE}")
```

2. Correlation Testing (Dependency Analysis)
Result description:
The result should include the name of the correlation test used (e.g., Pearson or Spearman) and the corresponding correlation coefficient and p-value. The output provides insight into the strength and significance of the relationship between the two variables.
```python
# Output Format: Print correlation method and result
print("Correlation Method: Pearson")  # Or "Spearman" based on the test used
print(f"Correlation Coefficient: {corr}")
print(f"P-value: {p_value}")
```

Figure 23: Prompt design in TablePilot

Prompt for TablePilot – Statistics Modeling(Cont.)

3. Regression Modeling (Predictive Analysis)
Result description:
The result should return the full regression model summary, detailing coefficients, p-values, R-squared, and other relevant statistics that describe the fit of the model.
```python
# Output Format: Print the regression summary
print(model.summary())
```

DO NOT output anything other than the JSON file containing only the `query` and `code`. The code should return the result using the `print()` function at the end.

Figure 24: Prompt design in TablePilot

Prompt for TablePilot – Multimodal Revision

Verifier Prompt for Code Execution Results
You are a seasoned data analyst and professional code verification expert, with extensive experience in data analysis, a deep understanding of various business contexts, and strong coding proficiency. Your role involves not only verifying outputs but also identifying potential issues in data analysis queries and uncovering limitations in the implemented code.

Overview:
You will evaluate each code snippet, whether successfully executed or encountering errors, with three main principles in mind:

*1. **General Standards**:*
*- **Relevance to Table Content**: Assess whether the data analysis code is closely related to the table content.*
*- **Clarity and Business Context Alignment**: Confirm that the code is well-connected to relevant business scenarios, providing valuable insights for actionable data analysis.*
*2. **Task-Oriented Standards**: Evaluation is split across three categories, tailored to specific types of analysis tasks. For each successfully executed code snippet, ensure that the output aligns with the specific task guidelines.*
*3. **Error Correction Standards**: For any code snippet that fails to execute successfully, you will follow a structured approach to identify and resolve issues. The goal is to diagnose the error's root cause and apply targeted corrections that ensure consistency with the intended analysis query and overall functionality.*

Task-Specific Guidelines:
*1. **Rudimentary Analysis Operations** (Filter, Sort, Aggregation and Group By, Pivot Table)*
*- **Insightfulness**: Verify if the results reveal key characteristics of the data and offer insightful observations.*
*- **User-Friendliness**: Confirm that the output is easily interpretable, and the operation aligns with common data analysis practices.*
*- **Visualization Clarity**: Ensure headers are clearly labeled, and the content is well-organized, without excessive missing values or unclear cells.*

*2. **Chart-Based Analysis**:*
*- **User Interpretability**: Check if the generated chart is clear and easy for users to understand, with a well-defined chart type.*
*- **Presentation Quality**: Assess if there are any visual issues, such as overlapping axes, overly dense data labels, or cluttered layouts that detract from readability.*

Figure 25: Prompt design in TablePilot

Prompt for TablePilot – Multimodal Revision(Cont.)

*- **Field Combinations**: Evaluate if the combination of x-axis and y-axis fields presents meaningful relationships, delivering valuable insights for data analysis. Please ensure the code's execution success rate while improving the clarity and intuitiveness of the charts, so that the user can understand them accurately.*

*- **Chart Documentation**: In the modified chart code, add a comment in this format: # Chart INFO: {{'x_fields': '', 'y_fields': [], 'chart_type': ''}}. Here, x_fields specifies the x-axis field, y_fields lists y-axis values (allowing multiple fields), and chart_type defines the chart type (e.g., lineChart, barChart, scatterChart, pieChart).*

*3. **Statistical Modeling Tasks** (Trend Prediction, Correlation Testing, Regression Modeling)*

*- **Trend Prediction**: Confirm the appropriateness of the target variable for forecasting (e.g., time series). Evaluate the prediction window setting and model suitability for the data characteristics. If NaN values occur, please correct the errors in the modeling process and generate valid forecasted values.*

*- **Correlation Testing**: Check if the selected variables have a meaningful correlation worth analyzing, beyond obvious or trivial associations.*

*- **Regression Modeling**: Ensure the chosen variables are suitable for modeling, with an appropriate regression model based on data linearity or non-linearity.*

Code Error Correction Guidelines:

*1. **Step-by-Step Diagnosis**: Carefully consider each step of the code to understand the error's root cause. Pinpoint why the code fails when executing the specific data analysis query.*

*2. **Query and Code Consistency**: Verify that the code accurately implements the query's requirements. Ensure consistency between the query and the code, confirming that the logic aligns with the query's intended analysis.*

*3. **Error Message Analysis**: Use the details from the error message to identify specific issues. Follow a logical approach, thinking through each possible cause, and apply corrections that logically address the error.*

Prompt for TablePilot – Ranking

Evaluating High-Quality Data Analysis Recommendations
Task Description:
*As the most senior data analysis manager, you bring extensive experience in identifying and recommending the most valuable tasks generated by other data analysis processes. Your task is to evaluate data analysis operations for a given table. Your input includes a sampled version of the table, relevant explanations about the table, and a set of key data analysis queries along with their execution results. **Adjust the distribution of recommendations across these task types as needed to align with the table's unique data profile.** Ensure that each selected recommendation is of high quality and insight, providing professional-level analysis that will leave users highly satisfied.*

Definitions of Data Analysis Task Categories:
*1. **Basic Data Analysis Tasks**:*
This category covers basic operations like filtering, sorting, grouping, and creating pivot tables to summarize data. These tasks help organize raw data, making it easier to identify trends, compute key metrics, and prepare for deeper analysis.

*2. **Table Visualization Data Analysis Tasks**:*
This category involves visualizing data using charts like line, bar, scatter, pie, column, combo and box charts, along with advanced types like stacked and bubble charts. These tasks allow users to explore patterns and trends, enabling clearer insights and effective decision-making.

*3. **Statistics Modeling Analysis Tasks**:*
This category includes predictive and statistical analyses like trend forecasting, correlation testing, and regression modeling. These tasks provide deeper insights by predicting outcomes, identifying relationships, and supporting data-driven decisions.

Evaluation Criteria:
*1. **Meaningful (Practical Usefulness)**:*
***Concept**: The recommendation's ability to provide practical value in real-world data analysis tasks.*
***Definition**: A meaningful recommendation should address a specific analytical need and provide actionable insights that directly support business decisions. It should offer solutions to key issues within the data and guide users in making informed choices based on the analysis.*
***Good Performance**: A high-quality recommendation effectively addresses real-world problems, aligns with the overall objectives of the analysis, and enables users to gain useful insights that drive decisions or further exploration.*

Figure 28: Prompt design in TablePilot

Prompt for TablePilot – Ranking(Cont.)

*2. **Relative (Relevance to the Table Theme)**:*
* **Concept**: The degree to which the recommendation is aligned with the core content and purpose of the dataset.*
* **Definition**: A relevant recommendation should directly relate to the **Table Theme**—the main topic or focus of the dataset being analyzed. The closer the recommendation is to the central theme, the more relevant it becomes.*
* **Good Performance**: A well-aligned recommendation highlights key elements of the table, such as analyzing core columns or offering insights that support the main subject of the table. It enhances the analysis by focusing on the most important data points and their relationships.*

*3. **Reasonableness (Logical Coherence and Suitability to Data Characteristics)**:*
* **Concept**: The degree to which a recommendation logically aligns with the table's structure and the intrinsic characteristics of its data values.*
* **Definition**: A reasonable recommendation should be logically coherent and grounded in sound data analysis principles that a data analyst would naturally follow. The queries generated should reflect meaningful relationships within the data, and the chosen analysis methods should perfectly match the data's properties, highlighting relevant patterns or insights.*
* **Good Performance**: A well-reasoned recommendation is intuitive, logically structured, and tailored to the data's unique attributes, making it feel like a natural and insightful extension of the data itself. The generated data analysis content should align with the rational understanding and expectations of the data analyst.*

*4. **Diversity (Variety of Analysis Tasks)**:*
* **Concept**: The extent to which the set of recommendations covers a broad range of data analysis operations.*
* **Definition**: Diversity ensures that within the same type of task, recommendations reflect a range of different data analysis methods and data columns.*
* **Good Performance**: A diverse set of recommendations should focus on each task type, selecting different data analysis methods within each while utilizing various combinations of data columns. For example, choose various operations for Rudimentary Operations using different column sets, different chart types for Chart-Based Data Analysis exploring different data dimensions.*

Figure 29: Prompt design in TablePilot

Prompt for TablePilot – Ranking(Cont.)

*5. **Interpretable (Ease of Understanding and Implementation)**:*
* **Concept**: The clarity and simplicity of the recommendation in terms of how easily it can be understood and executed by the user.*
* **Definition**: An interpretable recommendation should be straightforward, with clear steps that the user can follow without ambiguity. It must be simple enough to be implemented directly and should not require excessive explanation or complex reasoning.*
* **Good Performance**: A well-interpreted recommendation is concise, uses plain language, and describes the task in a way that is immediately actionable. Users should be able to quickly grasp its value and apply it without needing additional clarification.*

*6. **Insightful (Ability to Reveal New Data Insights)**:*
* **Concept**: The potential of the recommendation to uncover valuable insights or new perspectives from the data.*
* **Definition**: An insightful recommendation should offer more than just surface-level observations. It should reveal hidden relationships, highlight trends, or provide a fresh perspective that may not be immediately obvious from the raw data.*
* **Good Performance**: A strong recommendation goes beyond basic analysis, helping users to identify significant patterns, correlations, or predictions that could lead to deeper understanding or strategic actions. It often uncovers key insights that were previously unknown or unexplored.*

Evaluation Criteria for Basic Data Analysis
The evaluation of rudimentary data analysis execution results should adhere to the same six principles outlined previously.
*1. **Sort-Type Queries**:*
The Table Data provided represents sequential samples from the original table. When a column in these samples exhibits an ordered sequence, it indicates that the corresponding column in the original table maintains the same ordering pattern. Therefore, any sorting operation on such columns would be redundant.
Exclude sort queries if the sorted results are identical to the original table, as this indicates an ineffective operation.
*2. **Empty or NaN Values**:*
Exclude queries producing results with many empty or NaN values.
*3. **Pivot Table**:*
Carefully evaluate the execution results of pivot tables and retain only those that provide truly insightful data analysis.

Figure 30: Prompt design in TablePilot

Prompt for TablePilot – Ranking(Cont.)

Evaluation Criteria for Charts
The evaluation of chart execution results should adhere to the same six principles outlined previously. However, as charts are presented in image form, additional criteria are necessary to ensure high-quality outputs.
*1. **Clarity of Scales and Labels***
Ensure that the chart includes clear scales and accurately defined data labels, making it easy to interpret the presented data.
*2. **Completeness of Content***
The chart's content must comprehensively reflect the data analysis operation intended by the query, covering all relevant aspects.
*3. **Aesthetic Quality and Richness of Meaning***
The chart should be visually appealing, well-designed, and capable of effectively conveying rich and meaningful insights.

Evaluation Criteria for Statistics Modeling Data Analysis
The evaluation of advanced data analysis execution results should adhere to the same six principles outlined previously.
*1. **Selection of Variables for Analysis**:*
Prioritize advanced modeling or correlation tests for variables with potential relationships, rather than those already exhibiting significant correlations.
*2. **Statistically Significant***
*For Statistics Modeling Data Analysis tasks, please evaluate whether the query results are statistically significant (i.e., MAPE value < 0.1, P-value < 0.05, R-squared > 0.9). Assign higher scores to queries with **statistically significant results** and lower scores to queries without statistical significance.*

Input:
1. A subset of the table obtained through a specific sampling method and table Explanation.
*2. A set of data analysis recommendation queries targeting this table, categorized into three types of tasks: **Rudimentary Data Analysis**, **Chart-Based Data Analysis**, and **Advanced Data Analysis**. Along with their corresponding execution results.*

Table Analysis Assistant
*You are an advanced data analysis assistant specializing in generating actionable **query and code recommendations** based on a given table and its explanations. Your objective is to create **diverse, practical, and business-relevant queries** spanning three types of tasks:*

*1. **Basic data operations**: Filtering, sorting, grouping & aggregation, pivot table creation, and insightful column insertion.*
*2. **Data Visualization analysis**: Generating various charts like line, bar, scatter, pie, combo, and advanced charts such as stacked bar and bubble charts.*
*3. ** Statistics modeling**: Conducting trend prediction, correlation testing, and regression modeling.*

*For each query, generate **Python code** that:*
- Accurately implements the query using the appropriate libraries (`pandas`, `matplotlib`, `statsmodels`, or `scikit-learn`).
- Fully aligns with the query's intent and logic.
- Outputs the analysis results in a clear and interpretable format.

*## **Query Generation Guidelines***
*1. **Diversity and Variety**: Ensure the queries cover different analysis operations, chart types, and statistical models, utilizing the table's columns comprehensively.*
*2. **Practicality**: Queries must align with real-world data analysis needs and the table's context, avoiding overly generic or irrelevant analyses.*
*3. **Specificity**: Clearly define the scope and purpose of each query to ensure precision in the generated code.*

Please propose some queries for each task along with the corresponding executable code for the following table:

Table Data:
{table}

*## **Code Input ***
- Import `pandas` for data manipulation.
- Import `pandas` and `matplotlib` for chart creation.
- Import `pandas` and the relevant statistical libraries (`statsmodels`, `scikit-learn`, or `numpy`).

*- **Output Format**:*
…

*## **Output Requirements***
*The output must be a JSON object containing **queries** and corresponding **Python code** for the three task types:*

*1. **Rudimentary Data Operations**: Queries that involve filtering, sorting, grouping, aggregation, pivot table, or insightful column insertion.*
*2. **Chart-Based Analysis**: Queries that involve generating different types of charts, clearly specifying the chart type and data scope.*
*3. **Advanced Statistical Modeling**: Queries that involve statistical analysis tasks such as trend prediction, correlation testing, or regression modeling.*

Each query must be aligned with its code, and the JSON object must strictly include only the `query` and `code` fields.

*## **Important Notes***
*1. **Output Alignment**: Ensure each query's code satisfies the requirements and intent of the query.*
*2. **Clean Code**: Provide executable code without unnecessary comments or explanations.*
*3. **No Extra Information**: DO NOT include anything outside the JSON object containing the `query` and `code`.*

Figure 34: Prompt design in TablePilot

Prompt for Constructing Dataset - DART

Your task is to predict meaningful user queries based on a given table and its explanations. Recommend diverse and practical queries, each accompanied by the corresponding Python code using the pandas library. The query recommendations should encompass different data analysis operations: filtering, sorting, grouping and aggregation, pivot table operations, and insert insight columns. Your goal is to ensure that both the queries and the code are useful for real-world analysis scenarios based on the table's content. Select the most appropriate operations based on the table's characteristics.

Purpose of Basic Data Analysis Task:
This task involves essential data manipulation operations for organizing raw data, simplifying complex datasets, and generating quick overviews. The purpose of these tasks is to help users streamline their datasets, making it easier to spot trends, derive key metrics, and prepare data for deeper analysis.

Please propose queries and corresponding executable code based on the table provided:
Table:
{table}
This table format is the result of sampling a portion of the original CSV file, providing an overview. Please generate data analysis recommendations for the complete table.
Explanations:
{Explanations}

Figure 35: Prompt design in TablePilot

Prompt for Constructing Dataset – DART(Cont.)

Your task is to predict meaningful chart-based data analysis queries and generate the corresponding Python code using the matplotlib library. Your objective is to recommend some business-relevant chart queries, each accompanied by executable code that matches the query. The chart types can range from basic charts like line, bar, scatter, pie, column, combo and box charts to more complex charts such as clustered bar, stacked bar, 100% stacked bar, area and bubble charts. Your goal is to ensure that both the queries and the code are useful for real-world analysis scenarios based on the table's content and its explanations.

Purpose of Chart-Based Data Analysis Task
This task focuses on visualizing data to enable users to explore patterns, relationships, and trends effectively. By creating clear and compelling visuals, users can gain deeper insights and facilitate decision-making. Chart types vary in complexity and should be selected based on the structure and purpose of the tabular data being analyzed.

Please propose queries and corresponding executable code based on the table provided:
Table:
{table}
This table format is the result of sampling a portion of the original CSV file, providing an overview. Please generate data analysis recommendations for the complete table.

Prompt for Constructing DPO Positive Data

Your task is to evaluate data analysis operations for a given table. Your input includes a sampled version of the table, relevant explanations about the table, and a set of key data analysis queries along with their execution results. Your goal is to assess these queries from a professional data analysis perspective, assign a reasonable score and reason based on the following Evaluation Criteria:

1. Meaningful (Practical Usefulness):
- A meaningful recommendation should address a specific analytical need and provide actionable insights that directly support business decisions.
2. Relative (Relevance to the Table Theme):
- A relevant recommendation should directly relate to the "Table Theme"—the main topic or focus of the dataset being analyzed.
3. Reasonableness (Logical Coherence and Suitability to Data Characteristics):
- A reasonable recommendation should be logically coherent and grounded in sound data analysis principles that a data analyst would naturally follow.
4. Diversity (Variety of Analysis Tasks):
- Diversity ensures that within the same type of task, recommendations reflect a range of different data analysis methods and data columns.
5. Interpretable (Ease of Understanding and Implementation):
- An interpretable recommendation should be straightforward, with clear steps that the user can follow without ambiguity.
6. Insightful (Ability to Reveal New Data Insights):
- An insightful recommendation should offer more than just surface-level observations. It should reveal hidden relationships, highlight trends, or provide a fresh perspective that may not be immediately obvious from the raw data.

The above outlines the requirements of your task. Below are the corresponding data points that you need to evaluate:

LogicQA: Logical Anomaly Detection with Vision Language Model Generated Questions

Yejin Kwon*, **Daeun Moon***, **Youngje Oh**, **Hyunsoo Yoon**†
Department of Industrial Engineering, Yonsei University
Seoul, South Korea
{beckykwon, dani0403, yj89.oh, hs.yoon}@yonsei.ac.kr

Abstract

Anomaly Detection (AD) focuses on detecting samples that differ from the standard pattern, making it a vital tool in process control. Logical anomalies may appear visually normal yet violate predefined constraints on object presence, arrangement, or quantity, depending on reasoning and explainability. We introduce LogicQA, a framework that enhances AD by providing industrial operators with explanations for logical anomalies. LogicQA compiles automatically generated questions into a checklist and collects responses to identify violations of logical constraints. LogicQA is training-free, annotation-free, and operates in a few-shot setting. We achieve state-of-the-art (SOTA) Logical AD performance on the public benchmark, MVTec LOCO AD, with an AUROC of 87.6% and an F_1-max of 87.0% along with the explanations of anomalies. Also, our approach has shown outstanding performance on semiconductor SEM corporate data, further validating its effectiveness in industrial applications.

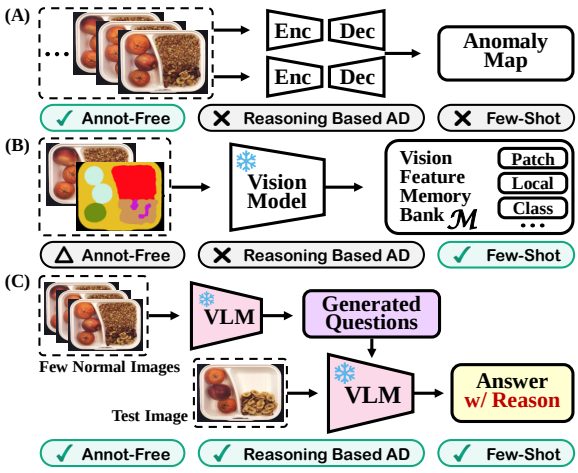

Figure 1: **Overview of Logical AD**: (A) Models trained from scratch (e.g., AutoEncoder) perform logical AD but require a large number of images. (B) Models leveraging memory-based AD methods (e.g., PatchCore) use pre-trained vision models to extract visual features from normal images, enabling few-shot AD. (C) Our method, LogicQA, utilizes a pre-trained VLM to generate anomaly-relevant questions and analyze test images, using the answers to identify and explain abnormalities.

1 Introduction

Anomaly detection (AD) is crucial for quality control and process optimization in industrial manufacturing. Anomalies are categorized into structural anomalies, referring to localized defects such as deformation or contamination (Bergmann et al., 2022; Zoghlami et al., 2024), and logical anomalies, which assess adherence to predefined constraints, including object presence, quantity, and arrangement (Batzner et al., 2024; Kim et al., 2024b). Unlike structural anomalies, logical anomalies demand clear explanations, as lack of reasoning may lead to misinterpretation. This necessitates an approach that not only detects but also explains logical anomalies (Zhang et al., 2024a).

Data-driven AD plays a critical role in high-quality production and minimizing downtime in industrial control systems. However, simply detecting anomalies without explanation is insufficient (Wang et al., 2018). Modern industrial systems demand explainability to clarify the reasons behind anomalies (Li et al., 2023b; Gramelt et al., 2024). Understanding root causes enables security experts to take targeted actions, preventing severe malfunctions and unplanned stoppage (Xu et al., 2024).

Existing AD scores, estimating the probability of an image being anomalous, offer limited interpretability regarding the cause of anomalies (Sipple and Youssef, 2022). As shown in Figure 1(A) and (B), most approaches rely on anomaly maps derived from pixel-wise anomaly scores (Tien et al., 2023; Hsieh and Lai, 2024; Liu et al., 2023b). These heatmaps highlight abnormal regions but fail to explain why an anomaly has occurred. **LogicQA** (Logical Question Answering) (Figure 1(C)) addresses this limitation by leveraging a Vision-

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 411–432
July 28-30, 2025

Language Model (VLM) to generate anomaly-relevant questions and provide natural language explanations, enhancing human interpretability.

LogicQA introduces a few-shot logical AD framework leveraging a pre-trained VLM. Unlike conventional methods requiring class-specific models, LogicQA eliminates the need for training and manual annotations, allowing universal applicability across different classes. With just few normal images, LogicQA efficiently detects anomalies, making it scalable and practical for industrial fields.

We validate **LogicQA** on the MVTec LOCO AD dataset (Bergmann et al., 2022) and real-world semiconductor SEM dataset. This evaluation demonstrates its effectiveness in AD, particularly in semiconductor defect detection, and highlights its potential for broader industrial AD applications.

Our key contributions are as follows: (1) We achieve SOTA performance in few-shot logical AD by proposing LogicQA, using a VLM to generate anomaly-relevant questions and detect anomalies through question answering. (2) We enhance explainability in logical AD by generating natural language reasoning, helping engineers understand why logical anomalies occur. (3) We introduce a training-free and annotation-free approach, eliminating class-specific training and human-generated prompts, enabling efficient AD with few normal images for industrial uses. (4) We validate LogicQA on both public benchmark and real-world semiconductor SEM data, demonstrating its effectiveness across diverse AD settings.

2 Related Work

Logical AD Approaches Since the release of the MVTec LOCO AD dataset (Bergmann et al., 2022), various unsupervised AD approaches have been developed. Reconstruction-based methods (Bergmann et al., 2022; An and Cho, 2015) rely on AutoEncoders trained with large amounts of normal images, limiting their applicability in few-shot scenarios. As PatchCore (Roth et al., 2022) was introduced, vision memory bank-based methods (Kim et al., 2024b; Liu et al., 2023a) leverage pre-trained vision models and feature banks to improve efficiency. However, these methods require costly computational resources for fine-tuning. In contrast, LogicQA enables logical AD without fine-tuning, making it more scalable and adaptable to real-world applications.

VLMs for Logical AD Recent advancements in VLMs have enabled more interpretable AD by integrating vision and natural language reasoning (Achiam et al., 2023; Liu et al., 2024a). LogicAD (Jin et al., 2025) employs a pre-trained VLM as a text feature extractor, generating explanations via logical reasoning. However, it relies on class-specific Guided Chain-of-Thought (CoT) prompts, requiring precise and laborious prompt engineering for each anomaly category. Similarly, LogiCode (Zhang et al., 2024a) applies Large Language Models (LLMs) to generate Python-based logical constraints, achieving strong detection performance but relying on detailed manual annotations, restricting practical industrial scalability. Our LogicQA overcomes these limitations by eliminating the need for pre-defined prompts and manual annotations, making it a more efficient and adaptable solution for industrial AD.

3 LogicQA

Logical AD differs from structural AD in that it assesses whether an image adheres to predefined logical constraints rather than identifying localized defects. Since logical anomalies often appear visually normal, detecting violations requires an interpretable framework to explain the underlying reasoning.

3.1 Framework Overview

LogicQA (Logical Question Answering) is a novel framework for logical AD that ensures interpretability by generating anomaly-relevant questions and reasoning. Unlike prior methods dependent on manual annotations or class-specific prompts, LogicQA leverages a pre-trained VLM, eliminating the need for annotations and human-generated prompts. This enables scalable deployment in industrial applications without task-specific fine-tuning.

Our proposed LogicQA consists of four stages: (1) ***Describing the normal images***, (2) ***Summarizing the normal image context***, (3) ***Generating the main questions***, and (4) ***Testing***, as shown in Figure 2. All detailed prompts and examples are listed in the Appendix A.

3.2 Describing the Normal Images

To ensure effective logical AD, LogicQA begins by analyzing the characteristics of normal images using a pretrained VLM. A single normal image, along with a predefined normality definition, is fed

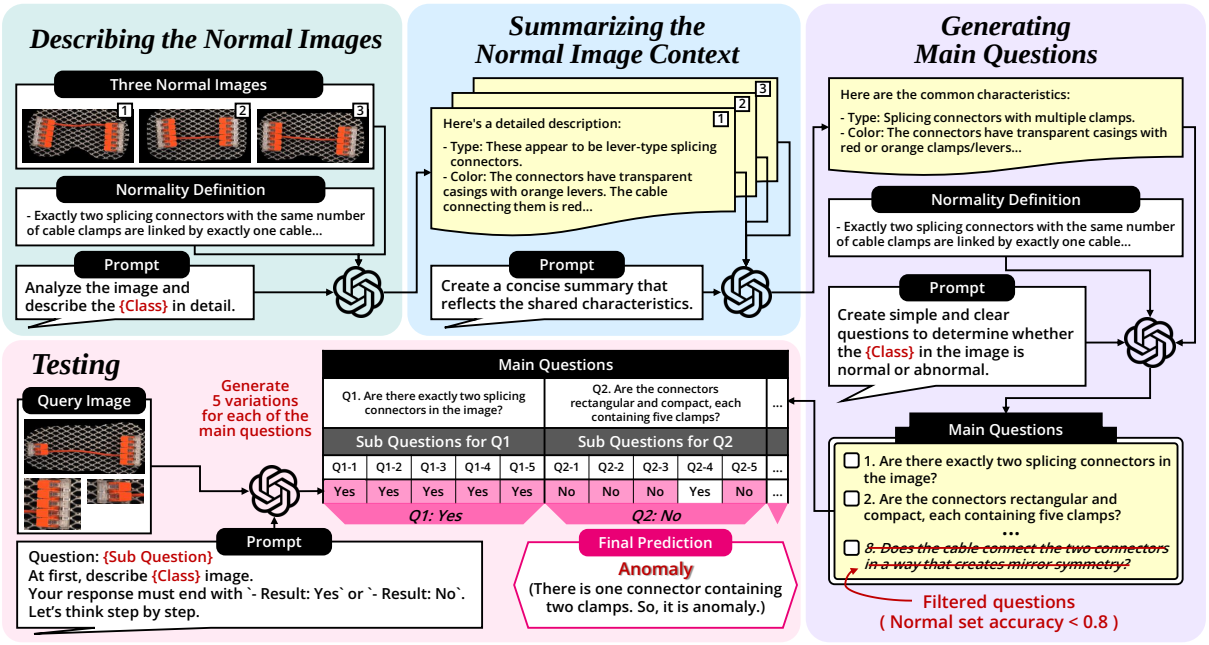

Figure 2: **Pipeline of LogicQA.** (1) **Describing the Normal Images** – The VLM generates textual descriptions of three normal images based on a predefined normality definition. (2) **Summarizing the Normal Image Context** – Shared features are extracted to define the core traits of normality. (3) **Generating Main Questions** – The VLM formulates key questions to assess whether an image is normal or anomalous. (4) **Testing** – The VLM generates sub-questions as variations of the main questions. Using a voting mechanism on the VLM's responses, we determine whether the image satisfies the main questions. If it fails to satisfy even one, it is classified as anomalous.

to the model, prompting it to generate a detailed textual description (Jin et al., 2025). The normality definition, adopted from Bergmann et al. (2022) (Appendix C.2), establishes logical constraints that define expected object attributes and configurations in the dataset.

The descriptions capture location, quantity, and appearance of key elements, ensuring that the model focuses on relevant structural and contextual features rather than background noise. This process enhances AD robustness by aligning the model's attention with critical aspects of normality. To further refine the understanding of normality, three distinct normal images are processed separately, with each description contributing to a consolidated representation of the dataset's normality definition. This enables the model to generalize beyond individual examples, preserving essential normal properties.

3.3 Summarizing the Normal Image Context

The summarization step refines the extracted normality by feeding previously generated descriptions into the VLM and distilling shared attributes into a coherent representation of common features. This process ensures that AD remains robust against variations within normal images by focusing on the most consistent and core characteristics.

By using diverse normal images, the model learns robust normality patterns, ensuring AD remains effective across different instances. This prevents overfitting to specific examples and allows model to focus on meaningful logical constraints.

3.4 Generating Main Questions

The question generation step refines generalized normality criteria into a checklist, prompting the VLM to generate key multiple questions to detect whether a target image is an anomaly. This method decomposes anomaly detection into multiple focused questions instead of relying on a single query. Recent studies (Ko et al., 2024; Yang et al., 2024) show that task deconstruction methods improve reliability. Hence, our method makes judgements by integrating multiple main questions (Main-Qs).

We provide the former summary and normality definition as input when prompting the VLM to extract key questions. The normality definition is reintroduced to help the VLM extract more relevant normality criteria. The resulting questions serve as candidate Main-Qs. Since only a few normal image descriptions are available, the initial set of questions may not fully generalize across all cases.

To improve robustness, we evaluate their consistency by applying them to a diverse set of normal images. As questions with low accuracy (below 80%) are indicative of bias toward the few-shot samples, they were excluded to ensure that the final set of questions remains broadly applicable without dataset-specific bias.

3.5 Testing

In the testing step, the goal is to judge whether the query image is anomalous and to analyze the cause of the anomaly. Recent VLMs are not always reliable and may generate incorrect answers or suffer from hallucinations (Mashrur et al., 2024; Zhang et al., 2024b). To mitigate this, we augment each Main-Q with five semantically equivalent sub-questions (Sub-Qs) (Zhou et al., 2022). The final decision is made through majority voting on the Sub-Qs' responses.

By leveraging multiple outputs instead of a single response, our method effectively reduces reasoning errors. If any Main-Q receives a 'No' response, it means that the image violates at least one normal constraint and is classified as an anomaly. Additionally, the specific Main-Qs receiving 'No' provide a clear rationale for the anomaly's cause.

To enhance interpretability, our approach follows a step-by-step (Kojima et al., 2022) reasoning process rather than a direct anomaly prediction. This aligns with the CoT approach (Wei et al., 2022), which strengthens VLM's logical reasoning and maintains contextual consistency, thereby improving judgment reliability.

Unlike traditional AD methods that require class-specific prompts, LogicQA eliminates such dependencies, enabling flexible and intuitive modifications by adjusting only the question and class name (Portillo Wightman et al., 2023). This makes it highly applicable for industrial use, as it does not require predefined class-specific guided prompts or CoT reasoning like Jin et al. (2025), allowing for seamless adoption in real-world settings.

4 Dataset

We evaluated our method using the MVTec LOCO AD dataset and an industrial semiconductor SEM dataset collected from real-world manufacturing processes. Both datasets contain normal and logical anomaly samples. (The overview and sample images of the two datasets are included in the Appendix C and E.)

MVTec LOCO AD Dataset MVTec LOCO AD Dataset, (Bergmann et al. (2022)), consists of five object categories (breakfast box, juice bottle, pushpins, screw bag, splicing connectors) from industrial scenarios, with objects selected as close as possible to real-world applications. Each category has several types of logical anomaly.

The VLM struggles with cases in the MVTec LOCO AD dataset where images contain large background areas, leading to long input contexts (Liu et al., 2024c), or where they contain uniform objects (Campbell et al., 2024). To address this, we applied two pre-processing steps, as depicted in Figure 3. First, **Back Patch Masking (BPM)** (Lee et al., 2023) was used to isolate the target object from the background, producing an object-centered image. Second, **Language Segment-Anything model (Lang-SAM)**, combined with GroundingDINO (Liu et al., 2024d) and SAM2 (Ravi et al., 2024), was used to segment uniform objects individually, mitigating the VLM's limitations in multi-object recognition. Details and effects of BPM and Lang-SAM are in the Appendix G .

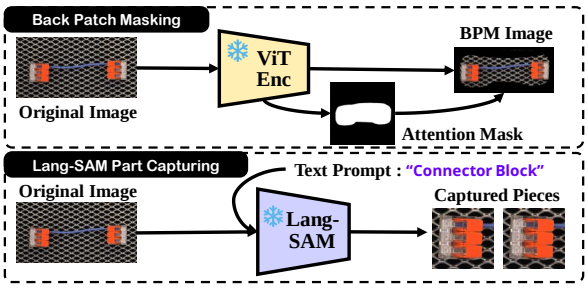

Figure 3: **Input Image Pre-Processing**: BPM applies an attention mask to the original image, masking the background, preserving objects. Lang-SAM identifies objects relevant to the given prompt and returns them as bounding boxes.

Semiconductor SEM Dataset Scanning Electron Microscopy (SEM) operates by applying a high voltage to direct an electron beam onto the surface of a sample, then secondary electrons generate a wafer image. The SEM has around 1 nm resolution to get precise wafer surface patterns. This corporate dataset reflects critical inspection stages in semiconductor manufacturing, directly affecting chip quality and production yields. The dataset has two defect types: spot and bridge. Spot defects appear as circular blemishes that degrade chip performance, while bridge defects take the form of elongated connections linking separate conductive lines (Kim et al., 2020).

Table 1: **Logical AD performance on MVTec LOCO AD dataset.** AUROC and F_1-max in % for detecting logical anomalies of all categories of MVTec LOCO AD Dataset. We report the mean over 3 runs for our method. Among models using the few-shot approach, the best results are highlighted in bold. The values highlighted in red indicate increased score compared to LogicAD. Our LogicQA demonstrates outstanding performance while incorporating a few-shot approach, explainability, and the use of auto-generated prompts.

5 Experiments and Results

5.1 Experimental Setting

We implement our experiments by leveraging three SOTA VLMs (GPT-4o (Achiam et al., 2023), Gemini-1.5 Flash (Team et al., 2024), and InternVL-2.5 38B (Chen et al., 2024)). Comprehensive details on model configurations and deployment settings are outlined in the Appendix B. All experiments are training-free and few-shot (three normal images per test image). Our assessments are based on the MVTec LOCO AD dataset and Semiconductor SEM dataset. We conducted the experiments three times for each category and calculated the average score, as indicated in Table 1.

5.2 Evaluation Metrics

Our approach uses a VLM for Vision Question-Answering (Sinha et al., 2025). If any of the responses to Main-Qs are "No", the model predicts "Anomaly". It is threshold-free, providing binary predictions and reasoning but not an anomaly score. So, we propose using the VLM's log probabilities to compute an anomaly score. Kadavath et al. (2022); Kim et al. (2024a); Lee et al. (2021) have shown that low token prediction probabilities (*Log probs*) can indicate a lack of knowledge in LLMs and lead to uncertain performance on downstream tasks. We consider the VLM's log-probability of answers to Sub-Qs as indicators of accuracy, reliability, and confidence of answer. We define key formulations:

A Sub-Q function q_{ij} outputs "Yes(0)" or "No(1)" for an input image x, where $i \in [1, m]$ represents the number of Main-Qs, and $j \in [1, 5]$ indexes the five Sub-Qs per Main-Q. Each Main-Q, $Q_i(x)$ is defined as:

$$Q_i(x) = \begin{cases} 0, & \text{if } \sum_{j=1}^{5} q_{ij}(x) < \sum_{j=1}^{5} (1 - q_{ij}(x)) \\ 1, & \text{otherwise.} \end{cases}$$

A final function $F(x)$ determines whether the input is a normal image or an anomaly, defined as:

$$F(x) = \begin{cases} \text{"Normal"}, & \text{if } \sum_{i} Q_i(x) = 0, \\ \text{"Anomaly"}, & \text{otherwise.} \end{cases}$$

For each Main-Q, we take the highest log-probability among the Sub-Qs whose answers match the voted result, then apply the exponential function to all selected values. And, we get anomaly score for test image below:

$$s_i = \max_j \{\log p(q_{ij}(x)) \mid q_{ij}(x) = Q_i(x)\}$$

$$S = \{e^{s_i} \mid i = 1, \ldots, m\}$$

$$\text{Anomaly Score} = \begin{cases} 1 - \text{Median}(S), & \text{if } F(x) = \text{Normal} \\ \text{Median}(S), & \text{if } F(x) = \text{Anomaly} \end{cases}$$

The *logp* function computes the log probability generated during the processing of the input. By calculating the anomaly score as above, we use F_1-max and Area Under the Receiver Operating Characteristic (AUROC) to evaluate our method, **LogicQA**, as same as existing approaches.

5.3 Result

MVTec LOCO AD Result The performance of Logical AD tested on the MVTec LOCO AD dataset for each method is shown in Table 1, presented in terms of AUROC and F_1-max scores. For a comprehensive comparison, the table also indicates which shot approach was chosen and whether explainability is incorporated. LogicQA consistently outperforms the existing few-shot VLM-based SOTA method (Jin et al., 2025) across all

metrics, achieving a 1.6% increase in AUROC and a 3.3% improvement in F_1-max score. Notably, in the *splicing connectors* class, both the AUROC and F_1-max metrics showed remarkable improvements, with AUROC increasing by 19% and F_1-max improving by 15.4%. Even compared to full-shot methods (Liu et al., 2025b; Rudolph et al., 2023), our LogicQA outperforms in almost all classes. (Frameworks utilizing in-house annotations are in Appendix 5).

LogicQA not only employs a few-shot approach and an auto-generated question mechanism for prediction but also provides natural language explanations for anomaly causes while achieving remarkable performance compared to other models.

Semiconductor SEM Result As shown in Table 2, LogicQA (GPT-4o) outperforms PatchCore (Roth et al., 2022), a representative few-shot AD method, on the semiconductor SEM dataset, yielding an 11.1% increase in AUROC and a 14.6% improvement in F_1-max. Also, LogicQA (GPT-4o) excels in detecting both "Bridge" and "Spot" anomalies, achieving the best scores. LogicQA significantly outperforms PatchCore even using the smaller open-source model InternVL-2.5 8B (Chen et al., 2024). This suggests applicability in real-world industrial settings, where deploying large proprietary models may not be feasible. Additionally, LogicQA shows excellent performance in Table 2 even though it did not include the process of filtering Main-Q using a few normal images.

SEM	LogicQA			PatchCore	
	GPT-4o		InternVL-2.5 8B	Roth et al. (2022)	
	AUROC	F_1-max	F_1-max	AUROC	F_1-max
Bridge	**89.7**	**90.4**	80.7	83.0	76.4
Spot	**90.8**	**94.3**	89.7	75.4	79.2
Average	**90.3** (11.1 ↑)	**92.4** (14.6 ↑)	85.2	79.2	77.8

Table 2: **Logical AD performance on Semiconductor SEM dataset.** Our LogicQA outperforms PatchCore regarding metrics and AD explainability. All experiments were conducted with the same three normal images.

5.4 Ablation Studies

Does LogicQA provide the correct reasoning? The MVTec LOCO AD dataset does not provide specific reasons for why each anomaly image is classified as anomalous. Therefore, we conducted a human evaluation to compare the reasons behind the model's anomaly detection with human perception. Two annotators were provided with the dataset and Main-Qs for each class and asked to answer accordingly. Their responses were then compared with the model's answers. Annotator1 showed 98% agreement for normal images and 85% for anomalous ones, while Annotator2 showed 98% and 86%, respectively, demonstrating high correspondence. Notably, the strong agreement for anomalous images indicates that LogicQA not only detects anomalies but also explains their critical causes, demonstrating its ability as a comprehensive anomaly explainability model.

Can other VLMs work well with LogicQA? To verify the applicability of our LogicQA in other VLMs with fewer parameters, we conducted tests using Gemini-1.5 Flash (Team et al., 2024) and InternVL-2.5 38B (Chen et al., 2024). The experimental results, presented in Table 3 with recorded F_1-max scores, show that both models maintained stable performance, with some classes even achieving higher scores. This suggests that LogicQA can be effectively applied across various VLMs.

VLMs	GPT-4o	Gemini-1.5 Flash	InternVL-2.5 38B
Breakfast Box	91.6	83.3	88.2
Juice Bottle	89.6	78.0	73.7
Pushpins	97.6	98.9	93.7
Screw Bag	64.5	91.7	62.6
Splicing Connectors	91.5	46.8	69.9
Average	87.0	79.7	77.6

Table 3: **LogicQA performance with other VLMs on the MVTec LOCO AD dataset.**

6 Conclusion

In this paper, we propose LogicQA, an explainable logical AD framework leveraging a Vision-Language Model (VLM) to detect anomalies and provide natural language explanations. LogicQA requires only a few normal images to define normal characteristics, significantly reducing the dependency on large labeled datasets. By eliminating class-specific fine-tuning and manually generated prompts, LogicQA facilitates efficient and scalable deployment in industrial environments. We evaluated LogicQA on the public benchmark, MVTec LOCO AD Dataset, where it outperformed existing explainable AD models. We further validated robustness of LogicQA on a real-world manufacturing dataset, Semiconductor SEM Dataset. These results confirm LogicQA as an effective, reliable, and practical solution for diverse industrial applications.

Limitations

Our framework is designed for easy application in industrial settings and delivers strong performance, though some limitations remain. Since our approach relies on VLMs, its performance inherently depends on the VLMs' visual recognition capabilities. Currently, VLMs exhibit imperfect accuracy (Wang et al., 2023; Li et al., 2023a) necessitating specific image preprocessing steps. However, as the technology evolves, this step may become less necessary (Jiang et al., 2025; Liu et al., 2025a). Additionally, generating a well-generalized Main-Qs set requires diverse images. Fortunately, normal images are relatively easy to obtain in industrial environments (Choi et al., 2021; Liu et al., 2024b), which helps mitigate this challenge. Also, the evaluation result on the Semiconductor SEM dataset confirms our model demonstrated strong anomaly detection performance even without the Main-Q filtering process.

Ethics Statement

This research uses GPT-4o and Gemini-1.5-Flash as baseline models. As with any large language model, their outputs may include unintended biases or harmful content depending on user inputs. To ensure ethical deployment, we apply engineering measures to mitigate these risks and enhance model reliability. Since both models are proprietary, with undisclosed training details and weights, assessing potential biases and risks remains challenging. Additionally, handling sensitive data with these models requires caution due to possible unintended exposure. When necessary, we recommend using open-source alternatives for greater transparency and control. AI-assisted tools were utilized solely for grammar correction and linguistic refinement during manuscript preparation. However, the originality, intellectual contributions, and core ideas of this paper are entirely the authors' own. We are committed to responsible AI use, continuous monitoring, and improving fairness and safety in real-world applications.

A LogicQA - Prompts

Prompt - Describing the Normal Images

This is a {Class}. Analyze the image and describe the {Class} in detail, including type, color, size (length, width), material, composition, quantity, relative location.

< Normal Constraints for a {Class} >
{Normal Definition}

{Image Prompt (Image Input)}

Example :
This is a breakfast box. Analyze the image and describe the breakfast box in detail, including type, color, size (length, width), material, composition, quantity, relative location..

<Normal Constraints for breakfast box>
- The breakfast box always contain exactly two tangerines and one nectarine that are always located on the left-hand side of the box.
- The ratio and relative position of the cereals and the mix of banana chips and almonds on the right-hand side are fixed.

Prompt - Summarizing the Normal Image Context

[Normal {Class} Description 1]
{Description 1}

[Normal {Class} Description 2]
{Description 2}

[Normal {Class} Description 3]
{Description 3}

Combine the three descriptions into one by extracting only the "common" features.
Create a concise summary that reflects the shared characteristics while removing any redundant or unique details.

Example :
[Normal Breakfast Box Description 1]
The breakfast box is divided into two sections. ...

[Normal Breakfast Box Description 2]
The breakfast box in the image contains the following items:. ...

[Normal Breakfast Box Description 3]
The breakfast box in the image has two side. ...

Combine the three descriptions into one by extracting only the "common" features.
Create a concise summary that reflects the shared characteristics while removing any redundant or unique details.

Prompt - Generating Main Questions

[Description of {Class}]
{ Summary Description }

[Normal Constraints for {Class}]
{Normal Definition}

Using the **[Normal Constraints for {Class}]** and **[Description of {Class}]**, create several but essential , simple and important questions to determine whether the **{Class}]** in the image is normal or abnormal. Ensure the questions are only based on visible characteristics, excluding any aspects that cannot be determined from the image. Also, simplify any difficult terms into easy-to-understand questions.
(Q1) : ...
(Q2) : ...

Example :
[Description of breakfast box]
The breakfast box is divided into two sections: ...

[Normal Constraints for breakfast box]
- The breakfast box always contain exactly two tangerines and one nectarine that are always located on the left-hand side of the box.
- The ratio and relative position of the cereals and the mix of banana chips and almonds on the right-hand side are fixed.

Using the [Normal Constriants for Breakfast Box] and [Description of Breakfast Box], create several but essential , simple and important questions to determine whether the Breakfast Box in the image is normal or abnormal. Ensure the questions are only based on visible characteristics, excluding any aspects that cannot be determined from the image. Also, simplify any difficult terms into easy-to-understand questions.
(Q1): ...
(Q1): ...

Prompt - Generating 5 variations Sub-Questions

Generate five variations of the following question while keeping the semantic meaning.
Input : {Question}
Output1:
Output2:
Output3:
Output4:
Output5:

Generate five variations of the following question while keeping the semantic meaning.
Input : Is there one nectarine visible on the left-hand side of the breakfast box?
Output 1:
Output 2:
Output 3:
Output 4:
Output 5:

Prompt - Testing

Question : {Question}
At first, describe {Class} image and then answer the question.
Your response must end with '- Result: Yes' or '- Result: No'.
Let's think step by step.

{Test Image Prompt (Test Image Input)}

Question : Can you see a single nectarine on the left side of the breakfast box?
At first, describe breakfast box image and then answer the question.
Your response must end with '- Result: Yes' or '- Result: No'.
Let's think step by step.

B VLM Implementation Details

B.1 VLMs

In our study, we uses three VLMs: GPT-4o (Achiam et al., 2023) , Gemini-1.5 Flash (Team et al., 2024) , and InternVL2.5(38B, 8B) (Chen et al., 2024). The GPT-4o model was accessed and inferred through the OpenAI API. For the GPT-4o model, we fixed *temperature* to 1.0 and other hyper-parameters to default. Regarding the Gemini-1.5 models, *temperature* is 1, *top_p* is 0.95, and *top_k* is 40. For Open-Source InternVL-2.5 from OpenGVLab, we set *temperature* to 0.2, *top_p* to 0.7, *repetition_penalty* to 1.1, *do_sample* to True, and *max_new_tokens* to 512. **All these settings are the same across all experiments and across datasets.**

B.2 Local Experimental Setup

We utilized the open-source InternVL-2.5, leveraging up to three NVIDIA A100 GPUs due to its substantial computational requirements.

B.3 Lang-SAM Prompt

When using Lang-SAM to the two classes (`Pushpins, Splicing Connectors`), a text prompt was needed to accurately capture the independent entities. It is as follows.

- `Splicing Connectors: Connector Block`
- `Pushpins: The individual black compartments within the transparent plastic storage box`

B.4 Data Security Option

To ensure the confidentiality and security of the **Semiconductor SEM dataset** provided by global company, we took stringent precautions when utilizing GPT-4o for our research. **Specifically, all data-sharing functionalities were disabled to strictly prevent unintended exposure or transmission of data outside the controlled research environment.** By implementing these safeguards, we ensured that no proprietary or sensitive information was inadvertently shared with external servers or third-party entities. This approach aligns with best practices for handling proprietary industrial datasets while leveraging advanced AI models for research and analysis.

C MVTec LOCO AD Dataset

C.1 MVTec LOCO AD Dataset Overview

This is a statistical outline of the public MVTec Logical Constraints Anomaly Detection (LOCO) AD Dataset. It consists of five categories (`Breakfast Box`, `Screw Bag`, `Pushpins`, `Splicing Connectors`, `Juice Bottle`). We conducted a few-shot experiment by randomly selecting three photos from the train-normal set.

Category	Train-Normal Images	Test-Normal Images	Test-Logical Anomaly Images	Detect types
Breakfast Box	351	102	83	22
Screw Bag	360	122	137	20
Pushpins	372	138	91	8
Splicing Connectors	354	119	108	21
Juice Bottle	335	94	142	18
Total	1772	575	561	89

Table 4: **Overview of the MVTec LOCO AD dataset**

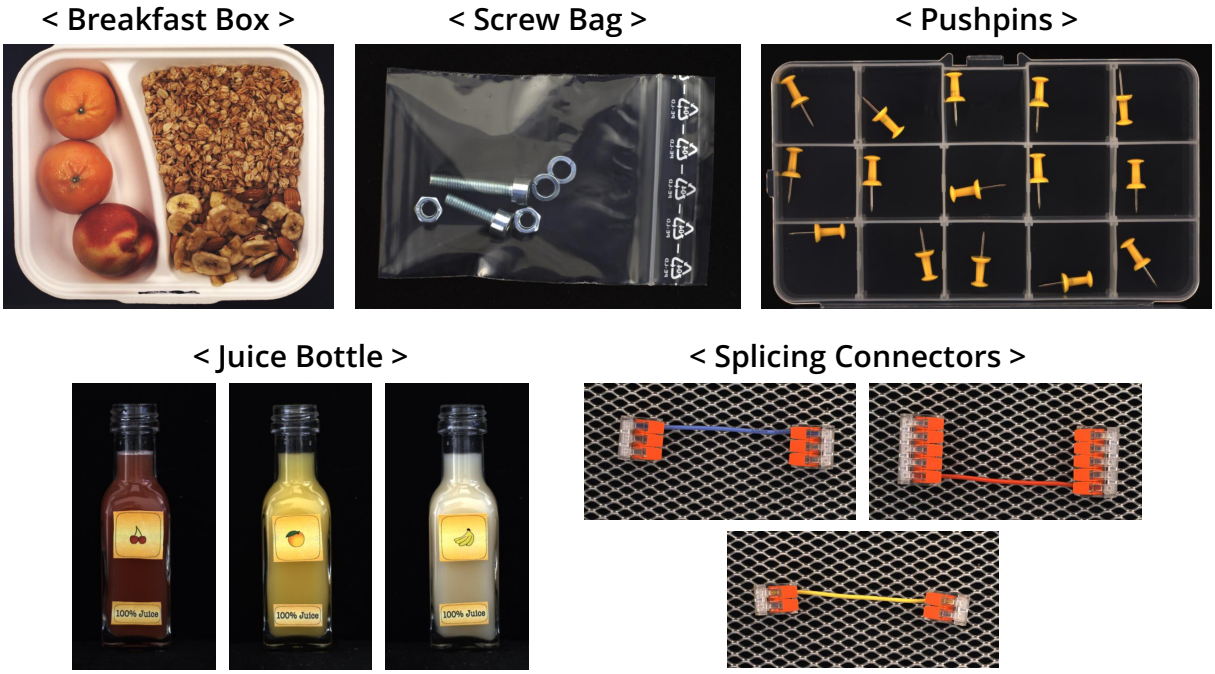

Figure 4: **MVTec LOCO AD Dataset Normal sample images**

C.2 MVTec LOCO AD Dataset- Normality Definition for each class

Below is a summary of the normality definitions for each class. For *Splicing Connectors* and *Juice Bottle*, the normality definitions partially change depending on the color of each cable and the fruit of the juice. The changed parts are expressed in red.

Breakfast Box

- The breakfast box always contain exactly two tangerines and one nectarine that are always located on the left-hand side of the box.
- The ratio and relative position of the cereals and the mix of banana chips and almonds on the right-hand side are fixed.

Screw Bag

- A screw bag contains exactly two washers, two nuts, one long screw, and one short screw.
- All bolts (screws) are longer than 3 times the diameter of the washer.

Pushpins

- Each compartment of the box of pushpins contains exactly one pushpin.

Splicing Connectors

- Exactly two splicing connectors with the same number of cable clamps are linked by exactly one cable.
- In addition, the number of clamps has a one-to-one correspondence to the {color} of the cable.
- The cable must be connected to the same position on both connectors to maintain mirror symmetry.
- The cable length is roughly longer than the length of the splicing connector terminal block.

Juice Bottle

- The juice bottle is filled with {fruit} juice and carries exactly two labels.
- The first label is attached to the center of the bottle, with the {fruit} icon positioned exactly at the center of the label, clearly indicating the type of {fruit} juice.
- The second is attached to the lower part of the bottle with the text “100% Juice” written on it.
- The fill level is the same for each bottle.
- The bottle is filled with at least 90% of its capacity with juice, but not 100%.

C.3 Main-Questions for each class

Breakfast Box

Q1 : Are there exactly two tangerines visible on the left-hand side of the breakfast box?
Q2 : Is there one nectarine visible on the left-hand side of the breakfast box?
Q3 : Does the right-hand side of the breakfast box have cereals in the upper portion?
Q4 : Is there a mix of banana chips and almonds in the lower portion of the right-hand side of the breakfast box?
Q5 : Are the fruits (tangerines and nectarine) only on the left-hand side, and are the cereals with banana chips and almonds only on the right-hand side?

Screw Bag

Q1 : Are there exactly two tangerines visible on the left-hand side of the breakfast box?
Q2 : Is there one nectarine visible on the left-hand side of the breakfast box?
Q3 : Does the right-hand side of the breakfast box have cereals in the upper portion?
Q4 : Is there a mix of banana chips and almonds in the lower portion of the right-hand side of the breakfast box?
Q5 : Are the fruits (tangerines and nectarine) only on the left-hand side, and are the cereals with banana chips and almonds only on the right-hand side?

Pushpins

Q1 : Is there exactly one pushpin visible in the compartment?
Q2 : Is the pushpin yellow in color?
Q3 : Is the compartment transparent, allowing the pushpin to be visible?
Q4 : Is the pushpin visible against a contrasting background?

Splicing Connectors - Blue

Q1 : Are there exactly two splicing connectors visible in the image?
Q2 : Do both connectors have the same number of wire clamps?
Q3 : Is there only one blue cable connecting the two splicing connectors?
Q4 : Do the connectors have transparent bodies with orange levers?
Q5 : Do both connectors have three orange levers, indicating three cable clamps?
Q6 : Are the connectors made from clear plastic with metal contacts inside?
Q7 : Are the orange levers made of plastic?
Q8 : Is the blue cable connected to the same position on both connectors?
Q9 : Is the pushpin visible against a contrasting background?
Q10 : Does the blue cable appear longer than the length of one of the splicing connectors?

Splicing Connectors - Red

Q1 : Are there exactly two splicing connectors in the image?
Q2 : Do both connectors have transparent casings with red or orange clamps/levers?
Q3 : Are the connectors rectangular and compact, each containing five clamps?
Q4 : Is there a single red cable connecting the two splicing connectors?
Q5 : Is the red cable slightly longer than the length of the splicing connector terminal block?
Q6 : Are the connectors positioned parallel to each other?
Q7 : Are the splicing connectors transparent with orange levers?
Q8 : Does the cable connect to the same clamp position on both connectors, maintaining mirror symmetry?
Q9 : Are the connectors made of plastic with transparent casings?

Splicing Connectors - Yellow

Q1 : Are there exactly two splicing connectors visible in the image?
Q2 : Do both splicing connectors have the same number of levers?
Q3 : Is the cable connecting the two splicing connectors yellow in color?
Q4 : Does each connector have two levers, indicating two clamps?
Q5 : Is the cable entering the same position on both connectors, maintaining symmetry?
Q6 : Is the length of the yellow cable longer than the terminal block of each splicing connector?
Q7 : Are the splicing connectors transparent with orange levers?
Q8 : Are the connectors positioned symmetrically on either side of the yellow cable?
Q9 : Is there exactly one yellow cable connecting the two splicing connectors?

Juice Bottle - Orange

Q1 : Is the juice bottle filled with orange juice up to at least 90% of its capacity, but not completely full?
Q2 : Are there exactly two labels on the juice bottle?
Q3 : Is the center label positioned in the middle of the bottle with an orange icon clearly visible?
Q4 : Does the center label have a light orange background?
Q5 : Is the lower label attached to the lower part of the bottle?
Q6 : Does the lower label display the text 100% Juice in bold, likely black, font?
Q7 : Are the labels vertically aligned, with the center label above the lower label, creating a balanced appearance?

Juice Bottle - Cherry

Q1 : Is the bottle made of clear glass, allowing the color of the cherry juice to be visible?
Q2 : Does the bottle have a central label with a cherry icon precisely placed in the middle?
Q3 : Is there a central label on the bottle with a cherry icon clearly indicating the type of juice?
Q4 : Is there a lower label on the bottle with the text 100% Juice written on it?
Q5 : Is the fill level of the juice in the bottle at least 90% of its capacity, with a small gap at the top indicating it is not completely full?
Q6 : Is there a central label on the bottle with a cherry icon positioned exactly at the center of the label?
Q7 : Is the color of the juice a deep reddish-brown, consistent with cherry juice?

Juice Bottle - Banana

Q1 : Is the bottle made of clear glass, allowing you to see the banana juice inside?
Q2 : Does the juice inside the bottle appear as a creamy, light yellow color, typical of banana juice?
Q3 : Is the bottle slender and of a standard size typically used for single-serve juice bottles?
Q4 : Is there a central label on the bottle with a banana icon located exactly at the center of the label?
Q5 : Is there a lower label on the bottle that reads 100% Juice?
Q6 : Does the juice fill level reach at least 90% of the bottle's capacity, with a small gap at the top?
Q7 : Are there exactly two labels on the bottle, one in the center and one lower down?

C.4 Sub-Questions for each class

An example of a sub-question configuration for the breakfast box class is given. The Sub-Questions can be created by applying an augmentation prompt (generating 5 variations Sub-Questions) to the Main-Questions.

Breakfast Box

Q1 Sub-Questions
- Can you see exactly two tangerines on the left side of the breakfast box?
- Is the left-hand side of the breakfast box showing precisely two tangerines?
- Do you observe exactly two tangerines on the left of the breakfast box?
- Are precisely two tangerines visible on the left side of the breakfast box?
- Does the left-hand side of the breakfast box contain exactly two tangerines?

Q2 Sub-Questions
- Can you see a single nectarine on the left side of the breakfast box?
- Is there a nectarine present on the left-hand side of the breakfast box?
- Do you spot one nectarine on the left area of the breakfast box?
- Is a nectarine visible on the left side within the breakfast box?
- Is there one nectarine that can be seen on the left part of the breakfast box?

Q3 Sub-Questions
- Are there cereals located in the upper part of the right side of the breakfast box?
- Is the upper portion of the right side of the breakfast box filled with cereals?
- Can cereals be found in the top section on the right-hand side of the breakfast box?
- Does the upper section of the right side of the breakfast box contain cereals?
- Is the top of the right-hand side of the breakfast box occupied by cereals?

Q4 Sub-Questions
- Does the lower section on the right side of the breakfast box contain a combination of banana chips and almonds?
- Can you find a blend of banana chips and almonds in the bottom part of the right-hand side of the breakfast box?
- Are banana chips and almonds mixed together in the lower right section of the breakfast box?
- Is there a combination of banana chips and almonds located in the bottom right area of the breakfast box?
- Are banana chips and almonds present together in the lower portion on the right side of the breakfast box?'

Q5 Sub-Questions
- Are tangerines and nectarines exclusively on the left, and are cereals with banana chips and almonds exclusively on the right?
- Is it true that the fruits, such as tangerines and nectarines, are solely placed on the left while cereals with almonds and banana chips are only on the right?
- Are the tangerines and nectarines located only on the left side, and are the cereals containing banana chips and almonds solely on the right side?
- Are fruits like tangerines and nectarines restricted to the left-hand side, while cereals with banana chips and almonds are found only on the right?
- Is the placement such that tangerines and nectarines are just on the left, and cereals with almonds and banana chips appear only on the right?

C.5 Logical AD performance on MVTec LOCO AD dataset.

D Can an Anomaly Score be effectively derived from the Token Prediction Probability?

We propose using VLM's Log Probabilities to compute an anomaly score. We assume that low token prediction probabilities (*log_probs*) lead to uncertain performance and incorrect answers, as in typical LLM studies. Therefore, we conducted additional experiments to verify whether this assumption is correct in our VLM task. (As in previous studies, we used the average of the log probabilities of all generated tokens in our experiment.)

We extracted 50 normal images for each class and generated answers for each Main-Question. The VLM's answer must be "Yes" for all normal images. Therefore, if it is "No", the answer generated by VLM is incorrect. We visualized each answer and the average token prediction probability at that time by class.

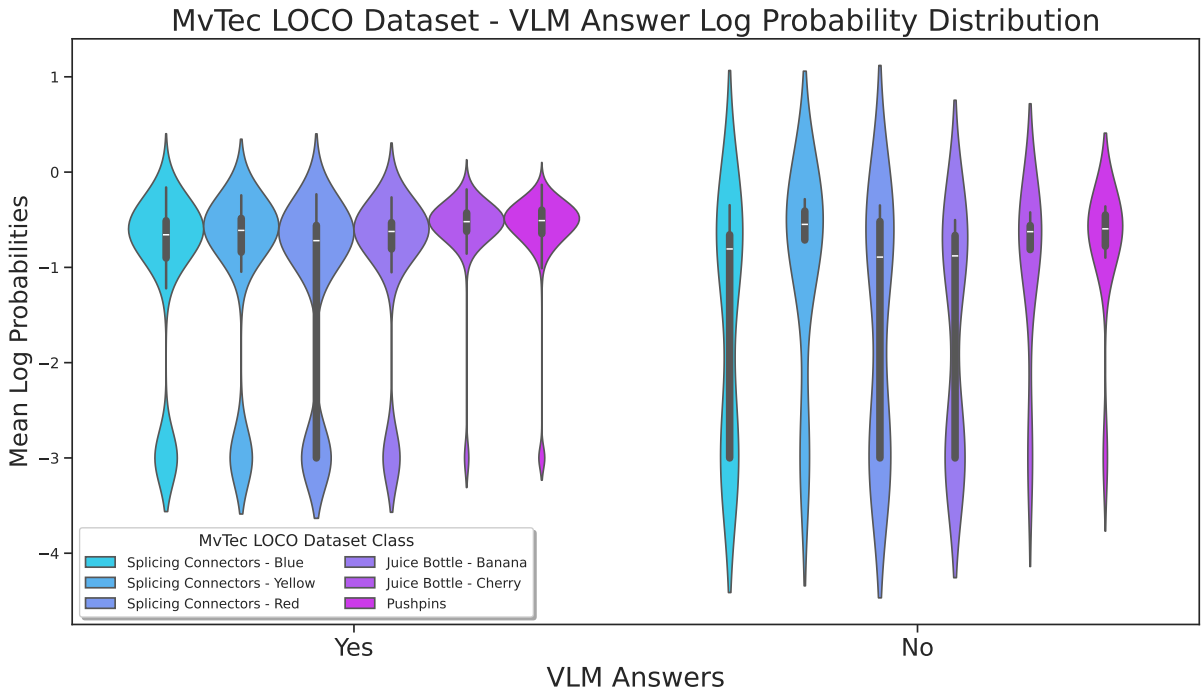

Figure 5: **Log-Probability Distribution of VLM answers**

As you can see from the figure 5, when generating the wrong answer "No" in some classes, the distribution of *log_probs* is generated relatively widely. When VLM generating "Yes", there is a clear section where the *log_probs* remains high, whereas in the case of "No", the *log_probs* come out quite diversely. Since our assumption is quite consistent with the actual data, it suggests that **as a result of verifying with actual data, it was confirmed that using the token prediction probability as the reliability of the answer and using it as the Anomaly Score is valid.**

E Semiconductor SEM Dataset

This is an overview of the Semiconductor SEM Dataset. Scanning Electron Microscopy (SEM) operates by applying a high voltage to direct an electron beam onto the surface of a sample, then detecting secondary electrons that react to this beam to generate an image. The equipment used in our experiments achieves a resolution of approximately 1 nm, making it highly effective for observing the minute patterns on wafer surfaces.

Semiconductor fabrication involves hundreds to thousands of processing steps, comprising dozens of layers. Furthermore, each layer has a distinct pattern to form integrated circuits. This indicates a wide variety of both normal and abnormal (defective) patterns, implying that a generalized anomaly detection model would require an enormously large memory bank.

There is two defect types for anomaly dataset, `Spot Defect` and `Bridge Defect`. These two types of anomaly sets share the same Normal dataset. Bridge defects occur when separate conductive lines or elements accidentally fuse, potentially causing short circuits. In contrast, spot defects appear as small, localized flaws on the wafer surface that can degrade overall device performance.

The data was provided by a global semiconductor company, and the actual data cannot be disclosed for security reasons. The sample examples below are images similar to the actual images found in the paper (Kim et al., 2020) and attached.

Type	Train-Normal Images	Test-Normal Images	Test-Logical Anomaly Images
Spot Defect	342	169	290
Bridge Defect			123
Total	342	169	413

Table 6: **Overview of the Semiconductor SEM dataset**

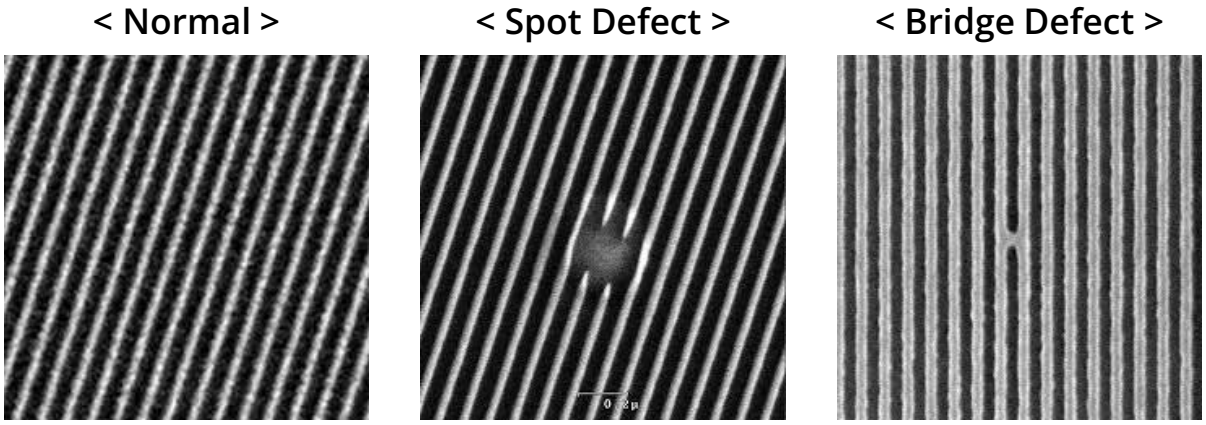

Figure 6: **Semiconductor SEM Dataset sample images**

E.1 Semiconductor SEM Dataset- Normality Definition

SEM wafer

- There should be no Particles, Hot Spots, or Defects.

E.2 Main-Questions

SEM wafer

Q1 : Are there no visible particles or dust on the wafer surface?
Q2 : Are the etched patterns consistent and evenly spaced across the image?
Q3 : Is the surface free of bright or dark spots that look out of place?
Q4 : Do the etched lines appear smooth and uniform without breaks or distortions?
Q5 : Does the wafer surface look clean without any unexpected irregularities?

E.3 Sub-Questions

SEM wafer

Q1 Sub-Questions
- Is the wafer surface completely free of visible particles or dust?
- Are there any visible particles or dust present on the wafer surface?
- Can you confirm that no visible particles or dust are on the wafer surface?
- Is the wafer surface entirely clean without any visible dust or particles?
- Do you see any visible dust or particles on the wafer surface?

Q2 Sub-Questions
- Are the etched patterns uniform and evenly distributed throughout the image?
- Do the etched patterns appear consistent and evenly spaced across the entire image?
- Are the etched designs evenly spaced and consistent throughout the image?
- Is there uniformity in the etched patterns, with even spacing across the image?
- Do the etched patterns maintain consistency and equal spacing across the image?

Q3 Sub-Questions
- Does the surface have any unusual bright or dark spots?
- Are there any bright or dark spots on the surface that seem out of place?
- Is the surface completely uniform, without any irregular bright or dark spots?
- Do you notice any unexpected bright or dark spots on the surface?
- Is the surface free from any abnormal bright or dark spots?

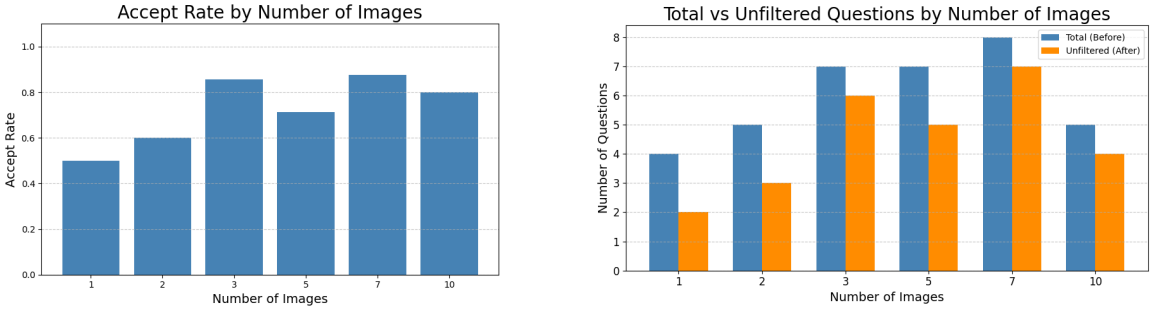
Q4 Sub-Questions
- Are the etched lines consistently smooth and uniform, without any interruptions or distortions?
- Do the etched lines maintain a smooth and even appearance, free from breaks or irregularities?
- Are the etched lines free from distortions and interruptions, appearing smooth and uniform?
- Do the etched lines exhibit a continuous, smooth, and uniform pattern without any breaks?
- Are the etched lines well-defined, smooth, and uniform, without any visible distortions or gaps?

Q5 Sub-Questions
- Is the wafer surface free of any unexpected irregularities and appears clean?
- Does the wafer surface appear smooth and without any unwanted defects?
- Is the wafer surface visibly clean and devoid of any unexpected anomalies?
- Can you confirm that the wafer surface is clean and free from irregularities?
- Does the wafer surface exhibit a clean appearance without any noticeable defects?

F Is Three Shots Sufficient for Optimal Performance?

To extract shared characteristics of normal images, LogicQA utilizes a few normal examples during the describing the normal images phase. As shown in Figure 7, using just three images already yields a notable improvement in both the accept rate (left) and the number of unfiltered questions retained after filtering (right).

We conducted experiments using 1, 2, 3, 5, 7, and 10 normal images to observe how the number of accepted questions changes after applying the filtering process. The accept rate refers to the proportion of questions that remain after filtering, calculated as the number of accepted questions divided by the total number of candidate questions before filtering. The results on the left side of Figure 7 indicate that the accept rate increases significantly starting from three images, suggesting that the generated questions become sufficiently general to represent the normal class. Furthermore, the results on the right show that from three images onward, the number of questions before and after filtering becomes comparable, implying that a sufficient number of class-representative questions are generated even after the filtering step. This demonstrates that using as few as three normal examples is effective for generating robust and generalizable descriptions of normal image characteristics.



(a) **Accept Rate by Number of Images**

(b) **Total and Unfiltered Questions by Number of Images**

Figure 7: Filtering Results Before and After, Based on the Number of Images

G Details and Effect of BPM & Lang-SAM

The MVTec LOCO AD Dataset required image preprocessing based on class-specific features. In the `Splicing Connectors` class, the background consists of wire entanglement, while in the `Screw Bag` class, a large portion of the image is occupied by empty space within the bag. To address this, we applied **Back Patch Masking (BPM)** to these two classes. BPM isolates the foreground target from the background, enabling target-centric detection. Also, `Pushpins` class is uniformly placed in each compartment, and `Splicing Connectors` class consists of multiple identical terminals within each connector block. Since both classes exhibit the uniform objects issue that makes hallucination problem in VLM, we processed images using **Lang-SAM**.

We conducted an experiment to verify whether BPM is actually effective in improving the response accuracy of VLM. We composed a subset of 50 normal images, entered the Main-Question for each class, and checked the answer. A normal image must answer "Yes" to the Main-Questions. If it answered a "No", VLM generated a wrong answer. We calculated the correct answer rate (accuracy) for each Main-Question for a total of 50 normal images. As you can see in the figure 8 below, **the accuracy of the answer increases when BPM is processed compared to when it is not.**

We also experimented to verify whether Lang-SAM is effective for VLM performance. We conducted an experiment with the same settings as the previous BPM additional experiment. As shown in figure 8, we found that **Lang-SAM was significantly effective in improving the accuracy of VLM answers in both classes (Pushpins and Splicing Connectors).**

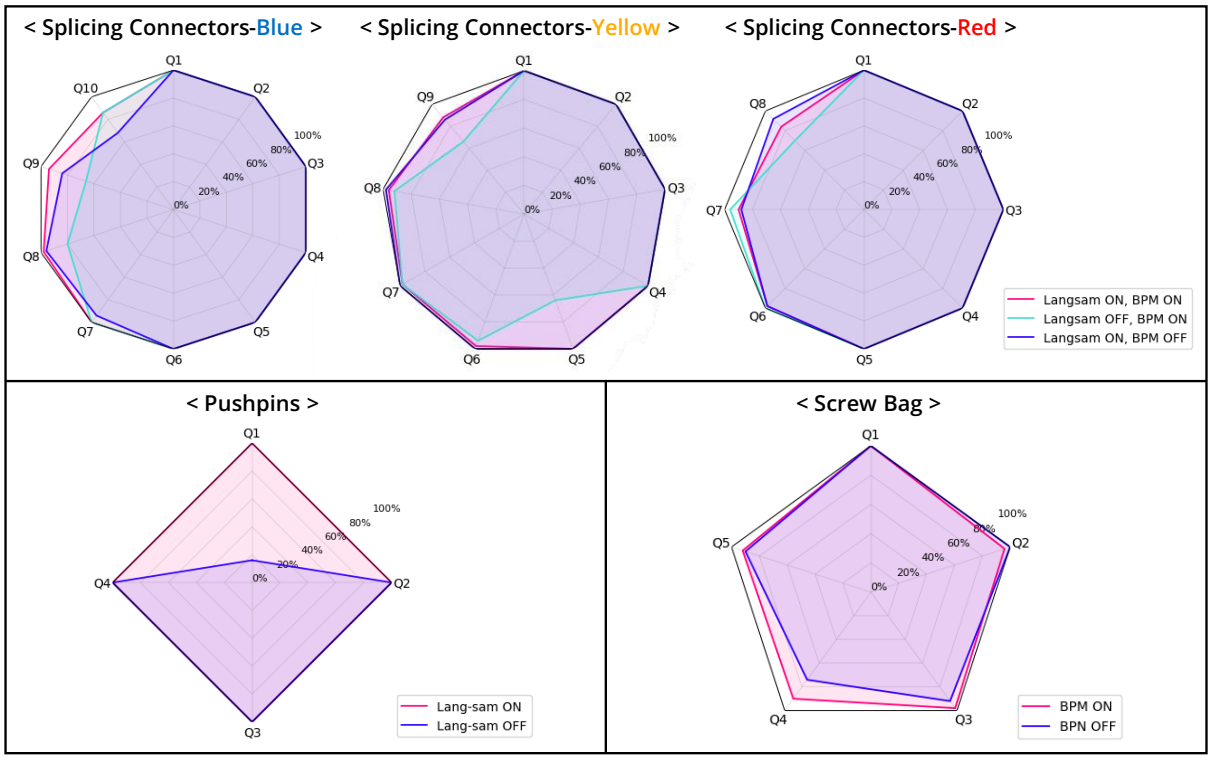


Figure 8: **BPM and Lang-SAM Effect for each class**

Model Merging for Knowledge Editing

Abstract

Large Language Models (LLMs) require continuous updates to maintain accurate and current knowledge as the world evolves. While existing knowledge editing approaches offer various solutions for knowledge updating, they often struggle with sequential editing scenarios and harm the general capabilities of the model, thereby significantly hampering their practical applicability. This paper proposes a two-stage framework combining robust supervised fine-tuning (R-SFT) with model merging for knowledge editing. Our method first fine-tunes the LLM to internalize new knowledge fully, then merges the fine-tuned model with the original foundation model to preserve newly acquired knowledge and general capabilities. Experimental results demonstrate that our approach significantly outperforms existing methods in sequential editing while better preserving the original performance of the model, all without requiring any architectural changes. Code is available at Applied-Machine-Learning-Lab/MM4KE.

1 Introduction

Large Language Models (LLMs) have revolutionized Natural Language Processing (NLP) by capturing vast amounts of world knowledge and exhibiting impressive generalization capabilities (Zhao et al., 2024; Fu et al., 2024; Xu et al., 2024a). Recent advancements in both architecture design and training strategies have enabled LLMs such as GPT-4 (OpenAI et al., 2024) to engage in human-like dialogue and solve complex real-world problems.

However, when deployed in dynamic real-world environments, LLMs often face challenges of maintaining current and accurate knowledge (Wang et al., 2024a). For example, models can quickly become outdated regarding political developments, technological innovations, or evolving natural disasters; they may also retain inaccurate historical details or harmful content that needs timely removal to ensure safe and reliable outputs.

To tackle these challenges, knowledge editing has emerged as an effective solution for efficiently updating or correcting specific information in pre-trained language models. These approaches can be broadly categorized into three main categories (Zhang et al., 2024c). Memory-based methods primarily rely on fine-tuning mechanisms to store and update knowledge in the model's parameters (Hartvigsen et al., 2023). Meta-learning approaches leverage auxiliary networks to learn how to generate precise weight updates for knowledge editing. Locate-then-edit methods directly identify and modify specific components within the model architecture to update factual associations. Each of these approaches offers distinct strategies for modifying model behavior.

However, these existing approaches still face several significant limitations. First, most editing methods exhibit poor performance in sequential editing and often suffer from weak generalization capabilities. As a result, they struggle to effectively inject large amounts of knowledge into the models, limiting their practical applicability (Wang et al., 2024b; Zhang et al., 2024a). Second, after knowledge editing, models often experience degradation in their general capabilities, as the editing process typically focuses only on targeted knowledge without considering its impact on unrelated knowledge (Meng et al., 2022, 2023).

To address the above limitations, we propose a simple yet effective knowledge editing framework integrating Robust Supervised Fine-Tuning (R-SFT) with Model Merging techniques. Specifically, we employ R-SFT, a fine-tuning strategy that selectively optimizes only the Feed-Forward Networks (FFNs) in a single transformer layer. We use iterative sample-wise optimization paired with

July 28-30, 2025

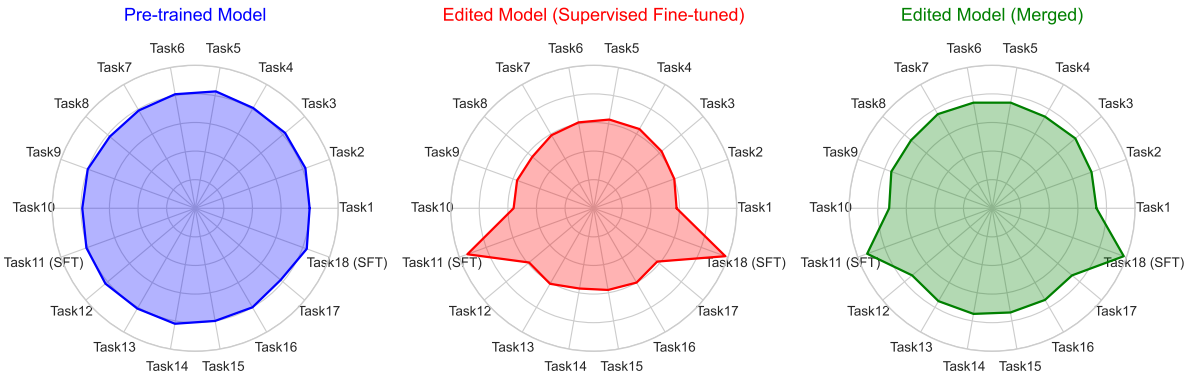

Figure 1: The illustration of three radar charts demonstrates the performance distribution across multiple tasks. The left chart shows the pre-trained model excelling in general tasks but limited in specific tasks (SFT). The middle chart represents the fine-tuned model with enhanced specific task performance at the cost of general capabilities. The right chart illustrates the merged model that successfully maintains both general and specific task performance.

an early-stopping mechanism to avoid overfitting. Subsequently, we merge the fine-tuned model with the original foundation model through scaling and sparsity-driven pruning, recovering general capabilities compromised during fine-tuning while effectively retaining acquired factual edits. Extensive experimental evaluations demonstrate significant performance improvements over existing methods across sequential editing tasks, superior preservation of general capabilities, and no architectural modifications are required.

- We propose R-SFT, an efficient fine-tuning approach leveraging sample-wise iterative optimization with early stopping to ensure precise and efficient knowledge acquisition.
- We apply model merging to mitigate the negative impact of fine-tuning on the general capabilities of LLMs, providing a simple but effective solution without any architectural modifications.
- Experimental results show that our method outperforms existing approaches in sequential editing while maintaining the general capabilities.

2 Methodology

This section introduces the proposed two-stage framework for knowledge editing, which includes R-SFT and model merging.

2.1 Robust Supervised Fine-tuning

Existing knowledge editing methods face significant challenges in sequential edits, often requiring complex architectural modifications that limit their practical applicability. Therefore, in the first stage of our framework, we propose Robust Supervised Fine-tuning (R-SFT), a robust knowledge learning fine-tuning paradigm designed to overcome these limitations while maintaining simplicity and effectiveness, as detailed in Algorithm 1.

Algorithm 1 Procedure of Robust Supervised Fine-Tuning (R-SFT)

Require: Foundation model θ_{base}, dataset $\mathcal{D} = \{s_n\}_{n=1}^{N}$, learning rate η, early stop threshold τ, max epochs E, max steps per sample K

Initialize model parameters: $\theta^{(0)} \leftarrow \theta_{\text{base}}$
Set global iteration counter: $t \leftarrow 0$
for $e = 1$ **to** E **do** ▷ Iterate epochs
  for $n = 1$ **to** N **do** ▷ Iterate samples
    for $k = 1$ **to** K **do** ▷ Iterative steps
      $\mathcal{L}_n = -\log P(\mathbf{a}_n|\mathbf{q}_n; \theta^{(t)})$
      if $\mathcal{L}_n < \tau$ **then** ▷ Early stopping
        break
      else
        $\theta^{(t+1)} \leftarrow \theta^{(t)} - \eta \nabla_\theta \mathcal{L}_n$
        $t \leftarrow t + 1$
      end if
    end for
  end for
end for
return fine-tuned parameters $\theta_{\text{sft}} \leftarrow \theta^{(t)}$

Specifically, given a pre-trained foundation model θ_{base} and an editing dataset $\mathcal{D} = \{(\mathbf{q}_n, \mathbf{a}_n)\}_{n=1}^{N}$, where each sample includes a question $\mathbf{q}_n$ and its corresponding targeted answer $\mathbf{a}_n$, R-SFT aims to update the model parameters to encode the provided factual information accurately. The objective follows the standard supervised fine-tuning (SFT), minimizing the negative

log-likelihood of the correct output given the input:

$$\mathcal{L}_n(\theta) = -\log P(\mathbf{a}_n|\mathbf{q}_n;\theta) \quad (1)$$

For each sample, we iteratively update the parameters via gradient descent with learning rate η:

$$\theta^{(t+1)} = \theta^{(t)} - \eta\nabla_\theta\mathcal{L}_n(\theta^{(t)}) \quad (2)$$

where t is the global iteration counter.

The key difference between R-SFT and conventional SFT is the sample-level consecutive training with an early-stop mechanism. In each epoch, each sample is optimized consecutively for at most K steps, stopping early if the loss decreases below the threshold τ:

$$k_n^* = \min\{k \mid \mathcal{L}_n(\theta^{(t+k)}) < \tau \text{ and } 1 \le k \le K\} \quad (3)$$

where k_n^* denotes the real number of gradient update steps performed on the n-th sample within the epoch. A sample that satisfies the early stop criterion remains available in subsequent epochs, allowing periodic validation to avoid forgetting.

Furthermore, based on insights from existing research (Meng et al., 2022), we restrict R-SFT solely to the Feed-Forward Networks (FFN) of the fifth transformer layer, which has been proven to be optimal for editing performance and efficiency.

After completing the R-SFT process over E epochs, we obtain a fine-tuned model θ_{sft} that thoroughly and reliably captures the desired knowledge edits. This fine-tuned model, along with the original pre-trained foundation model θ_{base}, forms the foundation for our subsequent merging stage.

2.2 Model Merging

In the second stage, the fine-tuned model is merged with the foundation model. While R-SFT effectively teaches the model new knowledge, it typically comes at the cost of degrading the model's general capabilities. Therefore, we employ model merging, including scaling and pruning, to restore these fundamental capabilities while preserving the newly acquired knowledge.

Our merging approach employs a weighted average of the original and fine-tuned models, essentially applying **scaling** to the fine-tuned model:

$$\theta_{\text{edited}} = \alpha\theta_{\text{base}} + (1-\alpha)\theta_{\text{sft}}, \alpha \in (0,1) \quad (4)$$

where a scaling parameter controls the preservation-editing trade-off. This equation can be further reformulated to highlight the parameter difference:

$$\theta_{\text{edited}} = \theta_{\text{base}} + (1-\alpha)(\theta_{\text{sft}} - \theta_{\text{base}}) \quad (5)$$

where $\Delta\theta = \theta_{\text{sft}} - \theta_{\text{base}}$ represents the knowledge delta, the parameter changes that encode the new knowledge acquired during R-SFT.

To further reduce the interference of knowledge delta on general capabilities, we apply **pruning** to the knowledge delta:

$$\theta_{\text{edited}} = \theta_{\text{base}} + (1-\alpha)\cdot \text{Top}_p(\theta_{\text{sft}} - \theta_{\text{base}}) \quad (6)$$

The pruning operation keeps the top $p\%$ of parameters with the highest magnitude changes in each parameter matrix, while setting the rest to zero.

This process induces a high degree of sparsity in the knowledge delta, ensuring that only the most impactful modifications are retained. Such sparsity not only reduces the risk of interference with the pretrained model's general capabilities, but also suppresses noisy updates introduced by training samples or the fine-tuning process.

Finally, the merged model can preserve general capabilities, while effectively incorporating the newly acquired knowledge from R-SFT.

2.3 Industrial Application Prospect

Real-world industry applications require specialized LLMs capable of performing domain-specific tasks without losing foundational general-purpose capabilities such as comprehension and logic reasoning. Foundation models typically lack domain-specific accuracy, while traditional fine-tuning methods introduce significant limitations: fine-tuning solely on vertical data often causes catastrophic forgetting (Luo et al., 2023), whereas hybrid training with extensive general and domain data incurs prohibitive computational costs.

The proposed R-SFT enables efficient domain-specific data optimization. Meanwhile, the model merging strategy combines the fine-tuned domain-specific models and the foundation model, thereby integrating specialized domain knowledge without sacrificing general linguistic reasoning capabilities. We have successfully delivered multiple specialized models tailored to distinct professional domains, demonstrating improved performance on their targeted tasks and maintaining the general language processing competencies necessary for practical industrial applications.

Table 1: Performance comparison of merging methods for sequential knowledge editing. The best values are highlighted in bold, while the second-best values are underlined. Column "Base" represents the foundation model.

3 Experiments

In this section, our experiments are structured around the following research questions (RQs):

- **RQ1:** How does our model merging approach perform on the ZsRE dataset compared to baseline methods, and how does it impact the model's general capabilities?
- **RQ2:** How effective is our model merging approach across other knowledge editing datasets in KnowEdit?
- **RQ3:** How hyperparameter settings for robust model fine-tuning affect the accuracy and generalization ability of knowledge editing.
- **RQ4:** How do different components of our framework individually contribute to the overall performance of the edited model?

3.1 Experimental Settings

3.1.1 Datasets

We select KnowEdit (Zhang et al., 2024c) for knowledge editing tasks, mainly on ZsRE dataset (Levy et al., 2017). For general ability evaluation, we use C-Eval (Huang et al., 2023b), CoQA (Reddy et al., 2019), DROP (Dua et al., 2019), SQuAD 2.0 (Rajpurkar et al., 2018) and LogiQA (Liu et al., 2020).

3.1.2 Baselines

In our experiments, we compare our approach against two main categories of locate-then-edit methods: 1) classic knowledge editing methods (ROME (Meng et al., 2022), MEMIT (Meng et al., 2023)) that directly modify model parameters associated with specific facts, and 2) fine-tuning approaches (LoRA (Hu et al., 2021)) that update knowledge through training.

3.1.3 Implementation Details

We conduct experiments using EasyEdit (Zhang et al., 2024b) for evaluating various knowledge editing methods, and employ the lm-evaluation-harness[1] for assessing general model capabilities. R-SFT is implemented through LLaMA Factory (Zheng et al., 2024) and mergeKit (Goddard et al., 2024) for training and merging respectively. We use Qwen2.5-7B-Instruct (Yang et al., 2024) as our foundation model.

3.1.4 Evaluation Metrics

We evaluate the models using two sets of metrics. To evaluate editing performance, we use five metrics: Edit Success (Edit Succ. or Succ.), Generalization (Gen.), Portability (Port.), Locality (Loc.) and Fluency (Flu.). The detailed definitions are provided in Appendix A.3. To assess the preservation of general capabilities, we use Accuracy for classification tasks (C-Eval, LogiQA), and both Exact Match (EM) and F1 scores for question-answering benchmarks (CoQA, DROP, SQuAD 2.0).

Table 2: Editing performance on additional KnowEdit datasets using our framework.

DataSet	Metric ↑	SFT	R-SFT	Merged
WikiData$_{recent}$	Edit Succ.	79.46	**99.97**	96.62
	Portability	46.59	58.26	**62.95**
	Locality	28.50	31.87	**41.62**
	Fluency	428.95	461.51	**592.02**
WikiBio	Edit Succ.	66.06	**99.48**	96.54
	Locality	40.16	64.30	**75.18**
	Fluency	626.60	**628.77**	626.71
WikiData$_{counter}$	Edit Succ.	50.67	**99.06**	84.02
	Portability	34.56	**60.61**	51.98
	Locality	15.75	26.36	**41.98**
	Fluency	479.81	601.02	**614.64**

Table 3: Effect of different hyperparameter settings on the editing performance.

(a) Early stopping loss threshold.

Threshold	Succ.	Gen.	Port.	Loc.	Flu.
None	68.90	65.76	24.40	12.65	**514.58**
0.01	75.74	73.28	39.86	27.84	435.20
0.02	78.06	74.87	41.77	26.14	437.26
0.05	79.61	76.22	42.53	33.00	420.41
0.1	**80.07**	**76.76**	44.33	32.18	400.84
0.2	78.87	75.04	**46.14**	**34.76**	411.97

(b) Number of epochs and steps.

Epochs	Steps	Succ.	Gen.	Port.	Loc.	Flu.
1	30	75.74	73.28	39.86	27.84	435.20
2	15	93.89	89.94	40.96	26.33	422.18
3	10	96.95	91.58	39.63	26.42	420.49
5	6	99.42	93.56	41.81	25.84	439.81
10	3	99.82	**93.56**	43.50	30.48	417.75
30	1	**99.84**	93.30	**46.87**	**33.81**	**509.18**

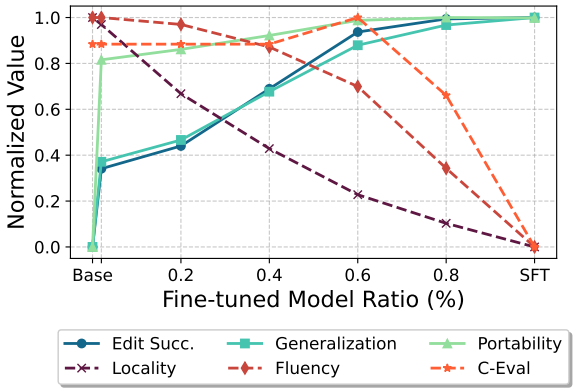

Figure 2: Metrics across different scaling ratios, illustrating the trade-off between edited and general knowledge.

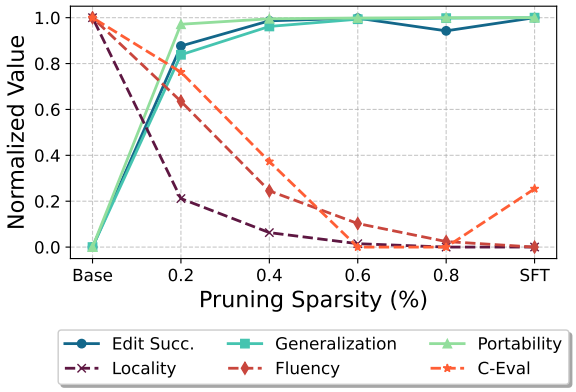

Figure 3: Metrics across different pruning sparseness, balancing edited and general knowledge.

3.2 Overall Performance (RQ1)

As shown in Table 1, our empirical evaluation reveals several important findings regarding knowledge editing performance and preservation of general capabilities across different methods.

For knowledge editing, R-SFT exhibits superior editing performance across primary metrics, with the merged model maintaining the second-highest performance in most editing dimensions. Regarding general capabilities, the merged model effectively retains the foundation model's general capabilities, demonstrating comparable performance on C-Eval and enhanced results on CoQA. This suggests our merging strategy successfully addresses the common trade-off between knowledge editing and general capability preservation.

Notably, MEMIT performs surprisingly well on SQuAD 2.0, and LoRA achieves strong results on DROP. This is largely because the foundation model originally performed poorly on these tasks, making it more sensitive to minor perturbations introduced during editing. These edits may alter the model's answering behavior in a way that coincidentally improves the evaluation metrics, rather than reflecting true methodological superiority.

3.3 Knowledge Editing Performance (RQ2)

Table 2 summarizes the performance of our proposed R-SFT approach and the subsequent merging step across various knowledge editing datasets in Knowedit. We observe that R-SFT consistently achieves near 100% accuracy on the training samples and maintains approximately 60% portability to reason with new knowledge, significantly outperforming conventional fine-tuning methods.

After model merging, the edited model consistently experiences a modest reduction (around 5%) in editing accuracy, but this is acceptable given the restoration of the model's general capabilities. The complete result is provided in the Appendix B.

Table 4: Ablation study of the framework on editing performance (including success rate, generalization, portability, locality, and fluency) and general capabilities based on C-Eval (Acc.), CoQA (F1), and LogiQA (Acc.).

Stage	Methods	Succ.	Gen.	Port.	Loc.	Flu.	C-Eval	CoQA	LogiQA
Base		-	-	-	-	-	79.57	72.60	37.94
R-SFT	w/o Sample Steps	**99.82**	93.85	**47.32**	**35.03**	466.00	**44.28**	**63.57**	24.73
	w/o Early Stop	**99.82**	**93.95**	41.10	31.51	**534.19**	40.04	53.11	23.81
	Complete	99.43	93.70	45.93	33.96	401.44	41.60	58.84	**26.57**
Merging	w/o Scaling	98.25	92.36	45.14	33.96	411.70	58.47	62.00	32.41
	w/o Pruning	96.97	92.07	42.76	29.69	418.32	52.75	74.65	29.80
	Complete	96.95	91.58	39.63	26.42	420.49	68.42	78.07	34.25

3.4 Parameter Analysis (RQ3)

R-SFT. As shown in Tables 3a, stopping training early (lower thresholds) improves generalization by preventing overfitting. A moderate threshold of 0.1 strikes the optimal balance between gaining knowledge and preventing overfitting. The results in Tables 3b confirm that fewer steps per sample yield better performance. However, this approach requires absolute $E \times N \times K$ update steps, resulting in lower computational efficiency. Finally, five epochs with six steps per sample provide an optimal compromise. Appendix C shows complete results for all hyperparameters.

Model Merging. Figure 2 and Figure 3 demonstrate that scaling has a more immediate and pronounced impact on model performance, with an optimal setting typically around 0.8 to balance knowledge updates and generalization. In contrast, pruning exhibits a more subtle influence, and a sparsity ratio of 0.2 is generally preferred to minimize interference while preserving core capabilities.

3.5 Ablation Study (RQ4)

We conduct an ablation study to evaluate the individual contributions of each proposed component, as presented in Table 4. Results show that removing the sample-wise consecutive update ("w/o Sample Steps") does not significantly harm editing performance, suggesting that our iterative update strategy does not negatively impact model quality while considerably enhancing efficiency. In contrast, removing early stopping ("w/o Early Stop") significantly degrades the model's general capabilities, confirming its essential role in preventing overfitting. In the model merging stage, omitting either scaling ("w/o Scaling") or pruning ("w/o Pruning") leads to decreased restoration of general capabilities, highlighting the importance of these techniques in effectively balancing knowledge editing and general model performance.

4 Related Works

4.1 Knowledge Editing

Knowledge editing aims to efficiently update or modify the internal knowledge of machine learning models to adapt to rapidly changing real-world information (Zhao et al., 2018a,b). This is particularly important for LLMs, whose training demands substantial computational resources and time, making frequent pretraining impractical (Xu et al., 2024b). Early studies focused on knowledge tracing to analyze and locate factual information stored within models before attempting edits (Huang et al., 2023a; Liu et al., 2023; Li et al., 2024). ROME (Meng et al., 2022) fisrt directly modified neurons associated with specific facts in feed-forward layers. While ROME models can edit certain facts accurately, many real-life situations involve dynamic information that require perpetual model updates (Liu et al., 2024, 2025). This necessitates the development of editing techniques that support persistent change Subsequent approaches, like MEMIT (Mitchell et al., 2022a) and r-ROME (Gupta et al., 2024), enhanced editing precision and stability during sequential updates.

Other methods utilized fine-tuning on specialized datasets (Xu et al., 2024b), effectively injecting knowledge but risking general capability degradation due to overfitting. Meta-learning approaches (e.g., MEND (Mitchell et al., 2021), InstructEdit (Huang et al., 2021)) and memory-based methods (e.g., SERAC (Mitchell et al., 2022b), MELO (Li et al., 2023b)) achieved better generalization but introduced auxiliary networks or structured memories, significantly increasing model complexity and limiting practical deployment.

4.2 Model Merging

Model merging techniques combine parameters from multiple models or training checkpoints into a unified model. This technique is more efficient than using several LLMs simultaneously (Li et al., 2023a; Lu et al., 2024). Early methods primarily relied on simple weight averaging (Wortsman et al., 2022), but subsequent work introduced more sophisticated strategies. For instance, SLERP (Kao et al., 2023) proposed spherical interpolation between model parameters to mitigate geometric distortion inherent in linear interpolation methods. Task Arithmetic (Gur et al., 2023), and its extensions, such as TIES (Jiang et al., 2023) and DARE (Chen et al., 2023), computed and combined task vectors, effectively tackling inter-model interference via sparsification, sign-consensus algorithms, adaptive pruning, and parameter rescaling. More recently, WISE (Wang et al., 2024b) applied sparsification methods to fine-tuning for knowledge editing, effectively balancing edited knowledge and pre-trained information, but also introduced increased structural complexity.

5 Conclusion

In this paper, we propose a two-stage framework for knowledge editing that integrates robust supervised fine-tuning (R-SFT) with model merging. Specifically, R-SFT first leverages sample-wise iterative updates and an early-stopping mechanism to precisely inject new knowledge with enhanced generalization. Subsequently, the model merging technique serves to further mitigate the harm of fine-tuning by merging the pre-trained model with the R-SFT model, thus negating the necessity for architectural changes. Experimental results show that our method significantly outperforms existing approaches in sequential editing scenarios while maintaining general capabilities.

6 Limitations

Although our model merging approach demonstrates significant effectiveness in knowledge editing, we acknowledge certain limitations in knowledge generalization capabilities. Our current framework, while successful at direct knowledge updates, shows reduced performance when transferring edited knowledge to substantially different phrasings or when applying reasoning based on newly acquired information. The generalization metrics indicate room for improvement in how edited knowledge is applied across varied contexts. Future research should focus on developing more sophisticated knowledge insertion methods that enhance the transferability of edited information.

A Detailed Experimental Settings

A.1 Datasets

KnowEdit (Zhang et al., 2024c) contains a total of six sub-datasets including Wiki$_{recent}$, ZsRE, WikiBio, WikiData$_{counterfact}$, Convsent and Sanitation.

For general ability evaluation, C-Eval (Huang et al., 2023b) primarily assesses common knowledge, while other benchmarks are predominantly question-answering datasets designed to evaluate models' capabilities in extended conversations with longer textual contexts.

A.2 Implementation Details

During the training phase, we utilize a batch size of 1 to maximize the effective learning from each individual sample. Our R-SFT is configured with 5 epochs and 6 consecutive steps, employing a maximum learning rate of 5×10^{-4}.

A.3 Evaluation Metrics

For evaluating the editing performance of the merged models, we adopt four widely used metrics:

- **Edit Succ. (Succ.):** This metric quantifies whether the intended factual update is correctly reflected in the model's output when given the edited query.
- **Generalization (Gen.):** This metric evaluates whether the model can correctly apply the updated factual knowledge when presented with semantically equivalent queries.
- **Portability (Port.):** This measures the ability of the edited model to generalize the new knowledge to alternative phrasings or reworded versions of the original query.
- **Locality (Loc.):** Locality evaluates whether the editing process is confined to the targeted knowledge, ensuring that the model's outputs for unrelated queries remain unchanged.
- **Fluency (Flu.):** This metric assesses the linguistic quality of the model's responses, verifying that the edited outputs are coherent and natural.

To comprehensively assess the general capabilities of the models after knowledge editing, we employ several established benchmarks with the following metrics:

- **Accuracy:** For classification tasks such as C-Eval and LogiQA, we utilize accuracy as the primary metric, which measures the percentage of correctly answered questions.
- **Exact Match (EM):** For extractive question answering tasks including CoQA, DROP, and SQuAD 2.0, we report the Exact Match score, which requires the model's prediction to exactly match the ground truth answer:

$$\text{EM}(\mathbf{a}, \hat{\mathbf{a}}) = \mathbf{1}(\mathbf{a} = \hat{\mathbf{a}}) \tag{7}$$

  where $\mathbf{a}$ is the ground truth answer, $\hat{\mathbf{a}}$ is the model's prediction, and $\mathbf{1}(\cdot)$ is the indicator function that returns 1 if the condition is true and 0 otherwise.

- **F1 Score (F1):** For the same question answering tasks, we also report the F1 score, which measures the overlap between the predicted and ground truth answers at the token level:

$$\text{F1} = \frac{2 \times \text{Precision} \times \text{Recall}}{\text{Precision} + \text{Recall}} \tag{8}$$

  where:

$$\text{Precision} = \frac{|\text{Tokens in } \hat{\mathbf{a}} \cap \text{Tokens in } \mathbf{a}|}{|\text{Tokens in } \hat{\mathbf{a}}|} \tag{9}$$

$$\text{Recall} = \frac{|\text{Tokens in } \hat{\mathbf{a}} \cap \text{Tokens in } \mathbf{a}|}{|\text{Tokens in } \mathbf{a}|} \tag{10}$$

B Knowledge Editing Performance (RQ2)

Table 5 compares our approach against baseline knowledge editing methods. Our R-SFT consistently achieves the highest editing success rates while maintaining strong portability. The merged model, while showing slightly lower editing success than R-SFT, demonstrates superior locality and fluency, effectively balancing edit fidelity with preservation of general capabilities. Parameter-efficient methods (ROME, MEMIT, LoRA) that perform well in single-fact editing struggle significantly in sequential editing scenarios, highlighting our framework's advantage in practical applications requiring both accurate knowledge editing and maintained model quality.

C Parameter Analysis of R-SFT (RQ3)

Edited Layer Selection Table 6 presents the performance when editing different layers of the LLM. Layers 6 and 7 consistently outperform other layers across most metrics, with Layer 6 achieving the

Table 5: Performance comparison of merging methods for sequential knowledge editing. The best values are highlighted in bold, while the second-best values are underlined.

DataSet	Metric ↑	ROME	MEMIT	LoRA	SFT	R-SFT	Merged
WikiData$_{recent}$	Edit Succ.	15.78	0.00	1.11	79.46	**99.97**	96.62

	Locality	0.92	0.00	13.65	15.75	26.36	**41.98**
	Fluency	553.18	314.91	489.65	479.81	601.02	**614.64**

Table 6: Effect of edited layer selection on knowledge editing performance.

Layer	Succ.	Gen.	Port.	Loc.	Flu.
5	75.74	73.28	39.86	27.84	435.20
6	**85.49**	**83.38**	41.85	31.97	431.43
7	85.31	81.81	**44.08**	**34.61**	434.13
13	74.58	68.61	38.07	33.87	492.87
20	70.03	62.37	26.43	21.55	**497.90**
27	56.97	52.44	18.39	8.08	385.88

Table 7: Effect of maximum training steps per sample on editing performance.

Steps	Succ.	Gen.	Port.	Loc.	Flu.
30	75.74	73.28	39.86	27.84	435.20
60	75.74	73.28	39.86	27.84	435.20
90	75.74	73.28	39.86	27.84	435.20

highest edit success (85.49%) and generalization (83.38%). This result confirms findings from prior research that knowledge is more concentrated in the earlier layers of the LLM (Meng et al., 2022).

Training Steps Table 7 examines how many total steps are typically required to update each sample when early stopping is enabled. With early stopping enabled (loss threshold = 0.01), we observe that performance metrics remain identical across different maximum step settings. This indicates that typically within 30 steps the loss of one sample will converge.

Number of Edited Layers Table 8 investigates the impact of simultaneously editing multiple layers versus focusing on a single layer. Contrary to intuition, editing a single layer (Layer 5) yields substantially better results than editing multiple layers. Editing all layers leads to catastrophic performance degradation across all metrics. This suggests that targeted, minimal interventions are more effective for knowledge editing than widespread parameter modifications.

Table 8: Effect of the number of edited layers on editing performance.

Layers	Succ.	Gen.	Port.	Loc.	Flu.
Layer 5	**75.74**	**73.28**	**39.86**	**27.84**	**435.20**
Layers 4,5,6	66.96	62.95	28.36	16.64	409.75
All Layers	12.93	12.62	4.27	1.85	380.84

Table 9: Effect of learning rate (LR.) on editing performance.

LR.	Succ.	Gen.	Port.	Loc.	Flu.
5e-4	**75.74**	**73.28**	39.86	27.84	435.20
1e-4	67.68	61.75	**48.33**	41.55	516.84
5e-5	63.12	54.90	45.97	**44.11**	**556.84**

Learning Rate Table 9 examines how different learning rates affect the editing process. Our analysis reveals an interesting trade-off: higher learning rates (5e-4) improve edit success and generalization but reduce portability, locality, and fluency. Conversely, lower learning rates (5e-5) significantly enhance fluency and locality at the expense of edit success and generalization. This suggests that the optimal learning rate depends on which metrics are prioritized for a specific application.

HierGR: Hierarchical Semantic Representation Enhancement for Generative Retrieval in Food Delivery Search

Abstract

Food delivery search aims to quickly retrieve deliverable items that meet users' needs, typically requiring faster and more accurate query understanding compared to traditional e-commerce search. Generative retrieval (GR), an emerging search paradigm, harnesses the advanced query understanding capabilities of large language models (LLMs) to enhance the retrieval of results for complex and long-tail queries in food delivery search scenarios. However, there are still challenges in deploying GR to online scenarios: 1) the large scale of items; 2) latency constraints unmet by LLM inference in online retrieval; and 3) strong location-based service restrictions on generated items. To explore the application of GR in food delivery search, we optimize both offline training and online deployment, proposing **Hier**archical semantic representation enhancement for **G**enerative **R**etrieval (HierGR). Specifically, for the generation of semantic IDs, we propose an optimization method that refines the residual quantization process to generate hierarchically semantic IDs for items. Additionally, to successfully deploy on Meituan food delivery platform, we utilize the query cache mechanism and integrate the GR model with the online dense retrieval model to fulfill real-world search requirements. Online A/B testing results show that our proposed method increases the number of online orders by 0.68% for complex search intents. The source code is available at https://github.com/zhangfw123/HierGR.

1 Introduction

In food delivery, users expect to quickly find and order meals that can be delivered to their locations (Wang et al., 2022a; Ding et al., 2020). Food delivery search focuses on quickly retrieving deliverable items that match user needs. Compared to traditional e-commerce search (), it requires faster and more accurate query understanding, as food orders are highly time-sensitive and demand real-time availability checks.

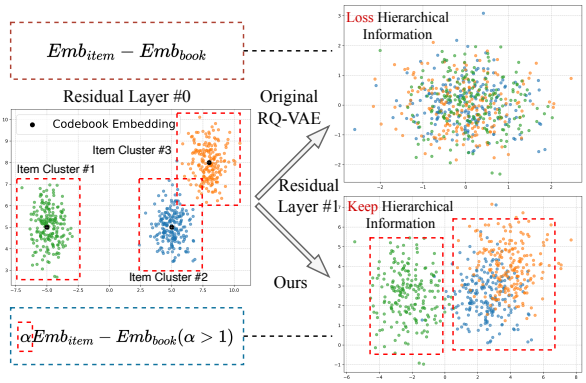

Figure 1: Differences between hierarchical RQ-VAE and origin RQ-VAE.

In recent years, knowledge has played an important role as a bridge across various fields (Tang et al., 2024a; Zhang et al., 2022a,b, 2024a,b,d; Pan et al., 2024; Wang et al., 2024; Li et al., 2025; Kuo et al., 2024; Cheng et al., 2025), including large language models (LLMs). Generative Retrieval (GR) leverages LLMs to generate relevant document identifiers (DocIDs) directly, offering a novel retrieval paradigm. Unlike traditional dense retrieval (DR), GR capitalizes on LLMs' strong semantic understanding, making it more effective for complex, long-tail, and ambiguous queries. This approach shows great potential in applications like e-commerce search (Wu et al., 2024b), document retrieval (Tay et al., 2022; Zhang et al., 2024c), as well as food delivery search.

However, deploying GR on our food delivery search platform still presents significant challenges: (1) **How to design IDs for a large-scale collection of food items?** With hundreds of mil-

*Equal contribution

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 444–455
July 28-30, 2025

lions of items, the deployment faces significant challenges in assigning similar IDs to semantically similar items and distinct IDs to different ones. (2) **How to deploy GR to ensure low latency in online search?** LLMs have high inference latency, making real-time online inference challenging to meet user search latency requirements. (3) **How to ensure that the generated items comply with location-based service (LBS) constraints?** Food delivery search must provide users with items that can be delivered to their locations.

To address these challenges, we explore a series of strategies in both GR model training and online deployment. Specifically, based on the commonly used ID generation method Residual Quantization Variational Autoencoder (RQ-VAE) (Rajput et al., 2023), we propose HierGR, a novel GR method designed to enhance hierarchical semantic representations using a hierarchical RQ-VAE, aiming to reduce semantic loss caused by residual computations. Figure 1 illustrates this clearly: the upper-right subfigure shows that, in the original RQ-VAE, residual representations cluster excessively near the origin after computing next-layer residuals. This clustering causes items from different semantic groups (e.g., three shown types) to overlap, resulting in semantic confusion and identical ID sequences. In contrast, our hierarchical RQ-VAE (lower-right subfigure) preserves more semantic information, ensuring smoother residual computations and clearer hierarchical separation among clusters. This approach maintains distinct clusters (blue and orange points form separate groups, and green points remain clearly isolated) at this residual level. Our method can enhance residual learning on large-scale items.

In the online deployment stage, we conduct a series of optimizations to effectively apply GR in the recall phase of the food delivery search system. First, to ensure that items retrieved by GR satisfy LBS constraints, we reorganize the semantic IDs for GR training. Then, to maintain acceptable online retrieval latency, we introduce a caching mechanism that stores highly exposed queries for online service, achieving a cache hit rate exceeding 95%. Finally, to better integrate with the online system, we combine the prediction scores and results of GR with dense retrieval for ranking, obtaining the final recall results. Here, we summarize our contributions:

- We propose HierGR, a novel GR method designed to enhance hierarchical semantic representations through a hierarchical RQ-VAE, capable of effectively generating semantic IDs for hundreds of millions of online items.
- To successfully deploy the GR model in our system, we implement a series of optimizations that provide valuable insights for industry-wide GR deployment.
- We conduct extensive experiments on the publicly available dataset and online A/B tests, showcasing the effectiveness and potential of applying GR in the food delivery scenario.

2 Related Work

2.1 Sparse & Dense Retrieval

The search process for food delivery is similar to traditional search scenarios, currently relying primarily on sparse and dense retrieval methods for recall, such as BM25 (Robertson et al., 2009), DPR (Karpukhin et al., 2020), ANCE (Xiong et al.), ColBERT (Khattab and Zaharia, 2020), etc. Recent advancements in GR have introduced a variety of new methods.

2.2 Generative Retrieval

DSI (Tay et al., 2022) is the first model to transform documents into unique document ID for GR. SE-DSI (Tang et al., 2023) extends DSI (Tay et al., 2022), which incorporates semantic learning techniques. SEAL (Bevilacqua et al., 2022) proposes autoregressive search engines that generate substrings as DocIDs, while NOVO (Wang et al., 2023) focuses on creating learnable document identifiers. RIPOR (Zeng et al., 2024), on the other hand, emphasizes scalability in GR. GenRRL (Zhou et al., 2023) integrates reinforcement learning to enhance relevance feedback, whereas LTRGR (Li et al., 2024) optimizes GR models by leveraging the ranking task. GDR (Yuan et al., 2024) addresses challenges related to memory efficiency in generative dense retrieval. Furthermore, Wu et al. introduced multi-vector dense retrieval. SEATER (Si et al., 2023) constructs a balanced K-ary tree using Constrained K-means and introduces an alignment loss to better capture token relationships. Hi-gen (Wu et al., 2024b) employs category information for clustering through K-means. GenRet (Sun et al., 2024) adopts an

Encoder-Decoder framework to sequentially generate ID tokens, demonstrating a step-by-step retrieval process. Additionally, GR^2 (Tang et al., 2024b) incorporates multi-graded relevance into the training of GR. These approaches collectively showcase the diverse strategies being developed to advance GR systems.

However, most of the aforementioned methods are not directly applicable for online deployment due to their high complexity. This paper primarily explores and validates the feasibility of implementing GR in the food delivery search scenario, successfully deploying the system and yielding significant benefits.

3 Method & Deployment Pipeline

Figure 2 illustrates the framework for **offline training** and **online deployment**.

3.1 Offline Training

During the offline training phase, we address the critical challenge of generating IDs for hundreds of millions of standardized product units (SPUs). While RQ-VAE (Rajput et al., 2023) provides learnable semantic encoding, its residual quantization inherently causes representation collapse, particularly diluting hierarchical semantics at scale. To resolve this, we propose HierGR with multi-level quantization layers that explicitly preserve semantic granularity. For training GR, we leverage LLMs like Qwen2.5 (Yang et al., 2024) through full fine-tuning.

3.1.1 Hierarchical RQ-VAE

Generally, the hierarchical RQ-VAE process consists of the following three phases:

SPU Encoding. Given an SPU i, we extract its semantic embedding $\boldsymbol{e_i}$ from the online semantic embeddings.

Hierarchical Residual Quantization (RQ). The core concept of hierarchical RQ is to retain part of the residual information from the previous level when computing the residual for the next level, effectively mitigating representation collapse. Appendix B includes a simple analysis demonstrating how our method reduces the semantic loss of residuals. Specifically, hierarchical RQ encodes the SPU embedding $\boldsymbol{e_i}$ into a low-dimensional representation using a deep neural network (DNN) encoder E:

$$\boldsymbol{z} = E(\boldsymbol{e_i}). \tag{1}$$

Next, $\boldsymbol{r}_0 = \boldsymbol{z}$ is used as the residual embedding at the first level of RQ. At each level l, a codebook $\mathcal{C}^l = \{\boldsymbol{c}_k^l\}_{k=1}^K$ is provided for quantization, where $\boldsymbol{c}_k^l$ represents the k-th codebook embedding at level l, and K denotes the codebook size. The l-th level of residual $\boldsymbol{r}_l (l = 0, 1, 2, \dots)$ is then used to find the index of the nearest embedding in $\mathcal{C}^l$, given by $c_l = \arg\min_k \|\boldsymbol{r}_l - \boldsymbol{c}_k^l\|_2$. After that, the residual is iteratively updated as:

$$\boldsymbol{r}_{l+1} = \alpha_l \cdot \boldsymbol{r}_l - \boldsymbol{c}_{c_l}^l, \tag{2}$$

where $\alpha_l > 1$ determines the proportion of residual preserved for the next level $l + 1$.

This procedure yields a semantic ID tuple $(c_0, \dots, c_{m-1})$ corresponding to the indices of the nearest codebook embeddings at each level, where m denotes the maximum level depth.

Reconstruction & Training. In the final stage of hierarchical RQ, we need to reconstruct the SPU embedding after quantization. Since we preserve portions of the residual at each level, the reconstructed representation can be written as follows:

$$\hat{\boldsymbol{z}} = \sum_{l=0}^{m-1} \left[\boldsymbol{c}_{c_l}^l + (1 - \alpha) \cdot \boldsymbol{r}_l \right]. \tag{3}$$

Here m is the layer number of RQ. Then, the quantized embedding $\hat{\boldsymbol{z}}$ is fed into a DNN decoder D to reconstruct the input $\boldsymbol{e_i}$ via a reconstruction loss $\mathcal{L}_{\text{recon}} = \|\boldsymbol{e_i} - D(\hat{\boldsymbol{z}})\|_2^2$. Finally, the optimization objective combines reconstruction loss $\mathcal{L}_{\text{recon}}$ with the residual quantization loss $\mathcal{L}_{\text{rq}}$:

$$\begin{aligned} \mathcal{L}_{\text{training}} &= \mathcal{L}_{\text{recon}} + \mathcal{L}_{\text{rq}}, \\ \mathcal{L}_{\text{rq}} &= \sum_{l=0}^{m-1} \left(\|\text{sg}[\boldsymbol{r}_l] - \boldsymbol{c}_{c_l}^l\|_2^2 + \beta \|\boldsymbol{r}_l - \text{sg}[\boldsymbol{c}_{c_l}^l]\|_2^2 \right), \end{aligned} \tag{4}$$

where $\text{sg}[\cdot]$ denotes the stop-gradient operation, which prevents gradient updates for the quantized embeddings during backpropagation. The first term in $\mathcal{L}_{\text{rq}}$ ensures that the codebook vectors $\boldsymbol{c}_{c_l}^l$ are close to the corresponding residuals $\boldsymbol{r}_l$. The second term, weighted by the hyperparameter β, constrains the residuals to remain close to the selected codebook entries.

Using the trained hierarchical RQ-VAE, we generate semantic IDs by identifying the nearest codebook index at each level for every SPU. For instance, if SPU i is assigned the index tuple (1, 3, 2), its semantic ID is represented as

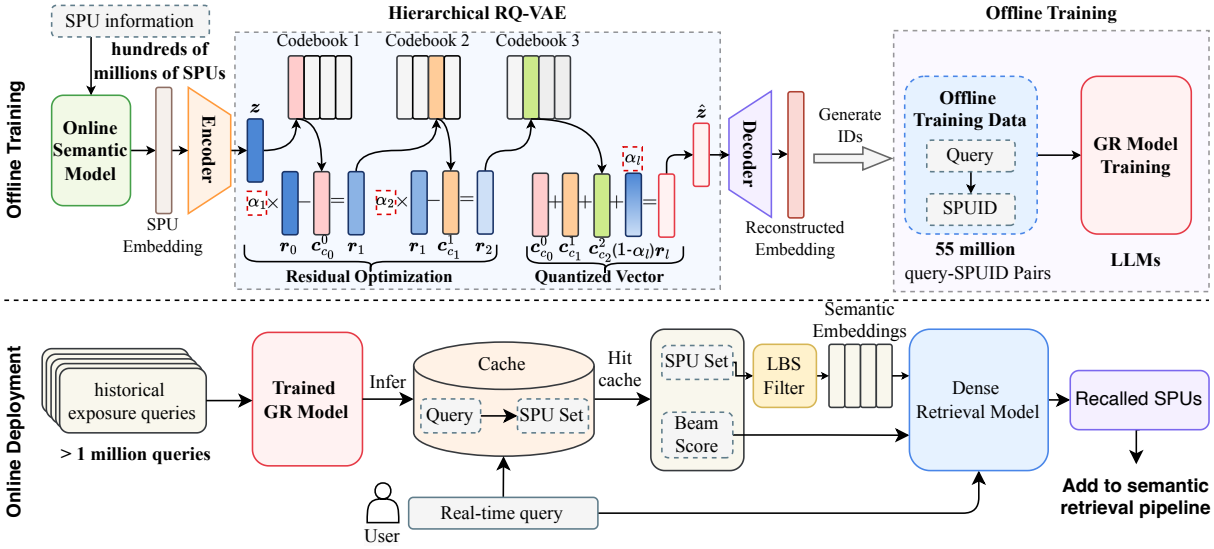

Figure 2: Overall framework of our proposed method, including offline training and online deployment.

"<a_1><b_3><c_2>". Each level-specific component (e.g., "<a_1>" or "<b_3>") serves as a new token for LLM to learn.

3.1.2 Training GR Model

Training Data Collection. We employ the following steps to collect training data.

(1) Query-based conversion attribution: We first track user behavior sequences that occur after users perform search queries. Specifically, we monitor the actions users take after entering queries, such as clicks, views, and final purchases. When a user successfully converts (e.g., completes a purchase or another desired action), we attribute this successful conversion back to the original query that initiated the interaction. This approach helps us clearly link queries with their relevant converted Standard Product Units (SPUs).

(2) Relevance-Based Filtering: Next, we perform an offline analysis to evaluate the relevance of the converted SPUs associated with each query. We carefully examine each SPU to ensure it appropriately matches the user's original search intent. Any SPUs determined to be irrelevant or poorly aligned with user intent are excluded from the dataset to maintain data quality and accuracy.

(3) Prioritized data collection: Finally, we collect data based on prioritized conversion performance. For each individual query, we rank all relevant SPUs according to their total number of successful conversions. We then select only the top 50 SPUs with the highest conversion counts for each query. These top-performing query-SPU pairs form our refined, high-quality training dataset, effectively focusing the dataset on the most successful and relevant items.

To address locality-based service (LBS) constraints, we truncate semantic IDs to transform SPU generation into SPU cluster generation. From sequences like "<a_1><b_3><c_2>", we remove the trailing portion (e.g. "<c_2>") to obtain "<a_1><b_3>" as a cluster ID for SPUs sharing this prefix. This approach enables GR to generate SPU collections that the online system can filter based on delivery area availability.

Training Process. We construct query-clusterID pairs (e.g., "cake→<a_2><b_3>") for training. To balance query understanding capability and training efficiency, we employ Qwen 2.5-1.5B (Yang et al., 2024) with full-parameter fine-tuning using a sequence-to-sequence (seq2seq) paradigm.

3.2 Deployment on Food Delivery Search Platform

The online deployment consists of two key components: **Query Caching** and **Hybrid GR-DR for SPU Recall**.

3.2.1 Query Caching

For online deployment, we implement a query caching mechanism to meet real-time latency requirements. In the food delivery search context, due to high query repetition rates, caching retrieved results achieves over 95% hit rate. We selected the top 1 million queries for caching based on 30-day exposure frequency. During GR model inference, we use a beam size of 100 to return 100 semantic IDs simultaneously, preserving scores

for each ID to facilitate integration with the online dense retrieval (DR) model.

3.2.2 Hybrid GR-DR for SPU Recall

Due to the limited ranking capability of GR, we propose a hybrid recall method named Hybrid GR-DR, integrating GR with our online DR model. Specifically, when a user's query hits the cache, we first retrieve the corresponding cluster IDs from the cache and map them back to their associated SPUs. The SPU set corresponding to the k-th cluster ID is denoted as $S_{ID_k} = \{spu_1, spu_2, \dots\}$. Next, we gather all SPUs relevant to the user's geographic location, forming a local SPU set S_{local}, which is then intersected with the SPU set obtained from GR. This intersection yields the final candidate set that satisfies the location-based service (LBS) constraints:

$$S = S_{local} \cap (S_{ID_1} \cup S_{ID_2} \cup \cdots \cup S_{ID_N}). \quad (5)$$

Here, N represents the number of cluster IDs related to the user's query. Then, we obtain the query embedding $\boldsymbol{q}$ and SPU embeddings $\boldsymbol{s}_1, \dots, \boldsymbol{s}_{|S|}$ using the encoding module of DR, where $|S|$ is the number of SPUs in S. Finally, we derive the final ranking scores for each SPU by combining the cosine similarity scores from DR with the beam scores from GR, as shown below:

$$\text{score}(\text{spu}_i) = \text{beam\_score}(spu_i) \cdot \cos(\boldsymbol{q}, \boldsymbol{s}_i), \quad (6)$$

where $\text{score}(\text{spu}_i)$ denotes the ranking score of the i-th SPU in S, and $\text{beam\_score}(\text{spu}_i)$ represents the beam score of the cluster ID to which spu_i belongs. By incorporating the beam scores, we ensure that highly relevant SPUs generated from GR are ranked higher.

Finally, we integrate the sorted SPUs into the online recall pipeline, delivering the final recall results to users.

4 Experiment

4.1 Experimental Setup

Datasets. For offline evaluation, we conduct experiments on the widely used MSMARCO dataset (Nguyen et al., 2016), derived from web search queries and corresponding passages, following the same settings as LTRGR (Li et al., 2024). For online deployment, we train HierGR on 55 million query-clusterID pairs and compare it to the fully deployed model in the recall stage.

Table 1: Experimental Results on MSMARCO dataset.

Model	R@10	R@20	R@100	MRR@10

DSI (2022)	-	-	-	19.8
MINDER (2023)	29.5	53.5	<u>78.7</u>	18.6
LTRGR (2024)	<u>40.2</u>	**64.5**	**85.2**	<u>25.5</u>
HierGR	**47.9**	<u>63.9</u>	74.6	**37.9**
HierGR w/o optim	39.6	56.3	67.8	30.1

Evaluation Metric. For MSMARCO dataset, we employ the RECALL and MRR metrics, including RECALL@5,20,100 (R@5,20,100), and MRR@10. For online evaluation, we track efficiency metrics: 1) UV_CXR: order rate among search users, 2) PV_CXR: order-to-exposure ratio, 3) OPTU: orders per 1,000 users, and 4) AOP: average order position. Appendix A.1 presents details of these metrics.

Baselines. We compare our method against baselines including BM25 (Robertson et al., 2009), SEAL (Bevilacqua et al., 2022), DSI (Tay et al., 2022), NCI (Wang et al., 2022b), MINDER (Li et al., 2023), and LTRGR (Li et al., 2024). For online evaluation, we compare directly with the **fully deployed online recall model**, reporting incremental improvements across various metrics.

Implementation Details. For the MSMARCO dataset, we use BERT (Devlin et al., 2019) for representation generation and T5-base (Raffel et al., 2020) as the backbone. RQ-VAE is configured with 4 layers, each containing 256 codebooks with an embedding dimension of 32. It is trained using the AdamW optimizer with a learning rate of 0.001 for 300 epochs. The model is further trained for 100 epochs with a learning rate of 0.0005, and the α values for residual optimization are set to [1.1, 1.05, 1.0, 1.0]. For online deployment, the semantic vectors of SPU employed by the online DR model are used as input to the Hierarchical RQ-VAE. Qwen2.5-1.5B is used as the base model. To address LBS constraints, we use the same training parameters as those used for MSMARCO but utilize only the first two layers of semantic IDs generated by the RQ-VAE for GR training. The α values for optimizing residual calculations across the layers are set to [1.05, 1.01, 1.0, 1.0]. The GR model is fine-tuned on 55 million data samples over 5 epochs. All experiments

Table 2: Parameter analysis of α on MSMARCO.

Values of α	Type	R@10	R@20	R@100	MRR@10
[1.2, 1.1, 1.05, 1.0]	Decreasing	38.7	54.5	64.9	29.5
[1.1, 1.05, 1.0, 1.0]	Decreasing	**47.9**	**63.9**	**74.6**	**37.9**
[1.05, 1.0, 1.0, 1.0]	Decreasing	45.3	61.3	70.3	34.1
[1.2, 1.2, 1.2, 1.2]	Fixed	37.4	52.3	65.8	28.7
[1.1, 1.1, 1.1, 1.1]	Fixed	46.3	62.2	70.9	34.9
[1.05, 1.05, 1.05, 1.05]	Fixed	44.2	59.5	68.9	33.5

are conducted on a computing platform equipped with eight A100 80G GPUs.

4.2 Experimental Results on MSMARCO

Table 1 presents the results in percentage (%) on MSMARCO dataset. **Bold** and underlined font represent the best and second-best results.

Overall Performance. HierGR significantly outperforms the state-of-the-art model LTRGR (Li et al., 2024) on MSMARCO in terms of R@10 and MRR@10, indicating that HierGR produces more accurate results at higher ranks. HierGR performs slightly worse than LTRGR on R@100. We hypothesize that this discrepancy arises because LTRGR utilizes a multi-view text-based identifier for GR, incorporating diverse textual information such as titles, pseudo-queries, and substrings. By directly generating text, LTRGR can leverage extensive beam search, resulting in improved recall at lower ranks (e.g., R@100), albeit at the expense of precision among top-ranked results.

Table 3: Online A/B testing results (relative improvement) on well-known food delivery platform. **Overall** is the total performance on all search intents. The second group represents the performance on different search intents.

Search Intent	UV_CXR↑	PV_CXR↑	OPTU↑	AOP↓
Overall	+0.10%	+0.29%	+0.11%	-0.43%
FOOD	+0.07%	+0.13%	+0.04%	-0.22%
POI	+0.16%	+0.26%	+0.15%	**-1.48%**
COMPLEX	**+0.59%**	**+1.12%**	**+0.68%**	-0.28%

Ablation Study. HierGR w/o optim presents the results without applying hierarchical RQ-VAE. As shown, the performance drops across all metrics, indicating that our simple optimization effectively enhances the quality of semantic IDs, thereby improving the effectiveness of GR.

4.3 Parameter Analysis

We conducted hyperparameter experiments on the weight of the proportion of residual preserved α in the hierarchical RQ-VAE. Since our RQ has 4 layers, there are 4 α values for all layers, which we present as a list from α_0 to α_3. Table 2 presents the results. From Table 2, we can draw the following conclusions: 1) Having α decrease as the RQ level increases yields better performance, as semantic loss occurs with greater magnitude in the first two layers; 2) Excessively large or small values of α negatively impact the quality of the IDs, leading to a poor performance of GR.

4.4 Online A/B Testing Results

Table 3 reports the results of our online A/B tests (two weeks). The **FOOD** intent represents user queries seeking physical food items, while the **POI** intent corresponds to queries targeting store searches. The **COMPLEX** intent encompasses more sophisticated queries, such as broad-category food searches, long-tail queries, and natural language questions (e.g., "What should I eat for fitness?"). Caching 1 million high-frequency queries can handle 95% of online search requests. Table 3 clearly shows that the GR model achieves notable improvements across various efficiency metrics, indicating its superior performance. In particular, for the **COMPLEX** intent, UV_CXR increases by 0.59%, PV_CXR increases by 1.12%, and OPTU improves by 0.68%. These results highlight the ability of GR to effectively address diverse user queries, demonstrating stronger generalization capabilities. Furthermore, across all intents, the AOP metric—a key indicator of user experience—decreases, leading to improved ranking quality by positioning relevant items higher in the results. This enables users to locate and order desired food more efficiently.

We also present additional online metrics, as

Table 4: Statistics of other online metrics.

Metric	Value
Average number of SPUs retrieved that meet the LBS constraint	174.9 (MAX:200)
Average number of additional SPUs retrieved compared to online semantic recall	22.8 (MAX:168)

shown in Table 4. The "Average number of SPUs retrieved that meet the LBS constraint" indicates the number of SPUs that satisfy the LBS constraints retrieved by the GR model, with an average of 174.9 and a maximum of 200 (we allocated a retrieval quota of 200 for the GR Model). This demonstrates that the GR model can provide sufficient results to meet online requirements. Furthermore, the "Average number of additional SPUs retrieved compared to online semantic recall" shows the additional items beyond those found by the online semantic recall method, indicating that our model can provide extra SPUs that semantic models cannot retrieve.

Table 5: Collision rate↓ on different datasets.

Model	MSMARCO	online SPUs
HierGR	**3.10%**	**41.57%**
HierGR w/o optim	3.62%	47.64%

4.5 Collision Rate Analysis

Table 5 reports the collision rates of semantic IDs on both the MSMARCO dataset and the online SPUs. The results demonstrate that HierGR, through the optimization of RQ-VAE, effectively mitigates the collision rate of IDs. The high collision rate observed in the online setting can be attributed to the presence of hundreds of millions of SPUs, underscoring the challenges associated with large-scale online deployment. During deployment, all conflicting SPUs sharing the same semantic ID are grouped into a single cluster.

4.6 Case Studies

Table 6 presents the results inferred by the GR model we deployed. As can be observed, for queries like "bread" which cover a wide variety of types, GR can deeply understand and generate different kinds of bread, enhancing diversity. For knowledge-based queries like 'What should I eat for fitness and weight loss?", GR is capable of understanding people's intentions and providing foods related to weight loss.

Table 6: Case studies of online GR results are presented, with the names of the retrieved foods simplified for clarity in display.

Query	GR results
面包 bread	吐司、三明治、可颂、甜甜圈、法棍 Toast, Sandwich, Croissant, Donut, Baguette
健身减肥该吃什么 What should I eat for fitness and weight loss?	鸡胸肉、荞麦面、牛肉沙拉、水煮鸡蛋、法式香煎三文鱼、低卡虾仁西兰花 Chicken breast, Soba noodles, Steak salad bowl, Hard-boiled eggs, Pan-seared salmon, Shrimp & broccoli stir-fry

5 Conclusion

In this paper, we identify challenges that GR faces in practical industrial deployments. To address these challenges, we conduct a series of explorations on both offline training and online deployment for food delivery search. We propose HierGR, which utilizes hierarchical RQ-VAE to reduce ID collision rates during the ID learning process. For online deployment, we analyze the unique characteristics of food delivery search and develop a comprehensive deployment strategy. Additionally, we construct a large-scale domain-specific dataset to effectively train our online GR model for food delivery search. Experimental results on the public benchmark demonstrate the effectiveness of HierGR. Most significantly, online A/B testing shows our deployed GR model achieves a 0.68% increase in the number of orders per thousand users (OPTU) for complex intent search, indicating that the deployed GR model has significant potential for food delivery search.

A More Details of our Experiments

In this section, we provide more experimental details.

A.1 Evaluation Metrics

Here, we describe the calculation method of the metrics. Note that PV represents a merchant.

- **RECALL:** The proportion of relevant items successfully retrieved over the total number of relevant items, calculated as:

$$\text{RECALL} = \frac{\sum \text{Retrieved Relevant Items}}{\sum \text{Total Relevant Items}} \tag{7}$$

- **MRR:** The Mean Reciprocal Rank, which is the average of the reciprocal ranks of the first relevant item in all queries, calculated as:

$$\text{MRR} = \frac{1}{N} \sum_{i=1}^{N} \frac{1}{\text{Rank}_i} \tag{8}$$

- **PV_CXR:** The ratio of food delivery order page views to exposure page views, calculated as:

$$\text{PV\_CXR} = \frac{\sum \text{Order PV}}{\sum \text{Exposure PV}} \tag{9}$$

- **UV_CXR:** The ratio of unique ordering users to users exposed, calculated as:

$$\text{UV\_CXR} = \frac{\sum \text{Distinct(Order Users)}}{\sum \text{Distinct(Exposure Users)}} \tag{10}$$

- **AOP**: The average exposure position of successful orders, calculated as:

$$\text{AOP} = \frac{\sum \text{Exposure Positions}}{\sum \text{Order PV}} \tag{11}$$

- **OPTU**: The number of successful orders per thousand search users, calculated as:

$$\text{OPTU} = \left(\frac{\sum \text{Order}}{\sum \text{Search Users}} \right) \times 1000 \tag{12}$$

A.2 Baselines

Here, we will provide detailed descriptions of our baselines.

- **BM25** (Robertson et al., 2009): BM25 is a classic sparse retrieval model that enhances term-document matching by leveraging term frequency and inverse document frequency, effectively improving information retrieval.
- **DSI** (Tay et al., 2022): DSI employs a hierarchical k-means clustering approach to organize document representations, constructing the DocID by combining category indices from multiple layers.
- **NCI** (Wang et al., 2022b): NCI utilizes neural network architectures to enhance document retrieval performance.
- **MINDER** (Li et al., 2023): MINDER generates text-based IDs from multi-view information to improve retrieval effectiveness.
- **LTRGR** (Li et al., 2024): LTRGR optimizes pre-trained GR models by incorporating an auxiliary ranking task.

For the online baseline, we compare our model against the fully deployed and stable product retrieval model that is already running in production, which includes but is not limited to query rewriting, semantic retrieval, personalized retrieval, and other components. Our GR model is integrated into the existing retrieval pipeline to evaluate its effectiveness.

B Simple Analysis of the Effectiveness of HierGR

We demonstrate that for two distinct embeddings that are very closed to their codebook embeddings at level k, our proposed hierarchical RQ-VAE preserves more of their semantic differences in subsequent quantization levels compared to the vanilla RQ-VAE.

Suppose there are two different items A and B. Let $\boldsymbol{r}_A^l$ and $\boldsymbol{r}_B^l$ be two distinct embeddings with semantic differences at level l. If $\boldsymbol{r}_A^l$ and $\boldsymbol{r}_B^l$ are very close to their respective codebooks $\boldsymbol{q}^l(A)$ and $\boldsymbol{q}^l(B)$, then the next level residuals in vanilla RQ-VAE are computed as follows:

$$\boldsymbol{r}_A^{l+1} = \boldsymbol{r}_A^l - \boldsymbol{q}^l(A) \approx \mathbf{0}, \tag{13}$$

$$\boldsymbol{r}_B^{l+1} = \boldsymbol{r}_B^l - \boldsymbol{q}^l(B) \approx \mathbf{0}. \tag{14}$$

At this point, the computation method of vanilla RQ-VAE will cause the residuals of item A and

item B at the next level to be close to the zero vector. This will affect the subsequent residual calculations, making the IDs of the two items identical in future processes, thus losing hierarchical semantic information.

However, if we calculate the residual by our proposed hierarchical RQ-VAE, the next level residuals are computed as follows:

$$\boldsymbol{r}_A^{l+1} = \alpha_l \cdot \boldsymbol{r}_A^l - \boldsymbol{q}^l(A) \approx (\alpha_l - 1) \cdot \boldsymbol{r}_A^l, \quad (15)$$

$$\boldsymbol{r}_B^{l+1} = \alpha_l \cdot \boldsymbol{r}_B^l - \boldsymbol{q}^l(B) \approx (\alpha_l - 1) \cdot \boldsymbol{r}_B^l. \quad (16)$$

Here, we still retain some of the higher-level semantic information to prevent the representation modeling of two different items from causing them to retain a certain level of hierarchical information.

Similarly, for items A and B, if they are very close to the same codebook vector $\boldsymbol{q}^l(C)$, we can also demonstrate that the next-level residuals are nearly identical in vanilla RQ-VAE:

$$\boldsymbol{r}_A^{l+1} = \boldsymbol{r}_A^l - \boldsymbol{q}^l(C), \quad (17)$$

$$\boldsymbol{r}_B^{l+1} = \boldsymbol{r}_B^l - \boldsymbol{q}^l(C). \quad (18)$$

If $\boldsymbol{r}_A^l \approx \boldsymbol{r}_B^l \approx \boldsymbol{q}^l(C)$, then $\boldsymbol{r}_A^{l+1} \approx \boldsymbol{r}_B^{l+1} \approx \mathbf{0}$, causing the same issue of losing semantic differences.

In contrast, our hierarchical RQ-VAE computes:

$$\boldsymbol{r}_A^{l+1} = \alpha_l \cdot \boldsymbol{r}_A^l - \boldsymbol{q}^l(C), \quad (19)$$

$$\boldsymbol{r}_B^{l+1} = \alpha_l \cdot \boldsymbol{r}_B^l - \boldsymbol{q}^l(C). \quad (20)$$

Even when $\boldsymbol{r}_A^l \approx \boldsymbol{r}_B^l \approx \boldsymbol{q}^l(C)$, the subtle differences between $\boldsymbol{r}_A^l$ and $\boldsymbol{r}_B^l$ are amplified by the factor α_l, allowing these semantic differences to propagate to subsequent quantization levels.

This amplification mechanism ensures that our hierarchical RQ-VAE maintains finer semantic distinctions throughout the quantization hierarchy, resulting in more expressive and discriminative representations compared to original RQ-VAE.

C More Analysis of Online Search Results

C.1 Case Studies for Search Results

Additionally, we provide more case studies, as shown in Table 7. Interestingly, the GR model can return relevant results of different types based on queries in different languages, such as the English query "breakfast" and the Chinese query ‘‘早餐". For the query "breakfast", it returned many bread-based food items; for the Chinese query ‘‘早餐", it returned numerous breakfast foods that align with Chinese dietary habits. Furthermore, the latter cases demonstrate that the GR model exhibits strong capabilities in understanding various knowledge domains of queries.

D Limitations and Future Works

Our current deployment method is based on caching, which covers 95% of online requests. However, 5% of online search queries still remain uncovered. Additionally, although we have optimized the collision of semantic IDs during the encoding process and generated better semantic IDs, the quality of these IDs cannot be directly evaluated during the RQ-VAE training phase and still needs to be assessed based on the retrieval effectiveness of the final GR model. In addition, our GR model is currently unable to generate personalized outputs based on users' specific needs. For example, if a user wants the fastest possible delivery, the model cannot identify and generate SPUs with quicker delivery options. These limitations require further exploration.

In future work, we will explore how to make GR cover more online queries, as well as how to enable GR to directly generate SPUs that satisfy LBS constraints.

Overlapping Context with Variable-Length Stride Increases Diversity when Training Large Language Model for Code

Abstract

The pretraining of code LLMs typically begins with general data and progresses to domain-specific data through sequential stages. In the latter stages, a challenging issue is that the data of a target domain can be limited in size, and conventional approach of increasing the number of epochs does not lead to a performance gain. In this paper, we propose a novel packing method, which is extracting overlapping contexts from the training data using variable-length stride. Our method can mitigate the data-scarcity issue by providing more diverse and abundant examples of next token prediction than non-overlapping contexts. While the training time of our approach is increased proportionally to the amount of augmented examples, we present space-efficient implementations to store overlapping contexts. Extensive experiments with real datasets show that our approach outperforms the conventional approach of controlling the number of epochs in terms of the pass@k rate.

1 Introduction

Large language models for code (code LLMs) are gaining more and more attention nowadays due to their wide applicability. After `Codex` (Chen et al., 2021) successfully demonstrated that LLMs are capable of generating Python codes, extensive research has been conducted to broaden their capabilities such as handling multiple programming languages (Nijkamp et al., 2023), understanding natural language instructions (Luo et al., 2024), and dealing with the infilling task (Fried et al., 2023). Code LLMs can be applied to repairing faulty code, explaining the functionality of existing code, and generating code given natural language instructions (Muennighoff et al., 2024), which together lead to increased productivity in software development (Solohubov et al., 2024; Peng et al., 2023b).

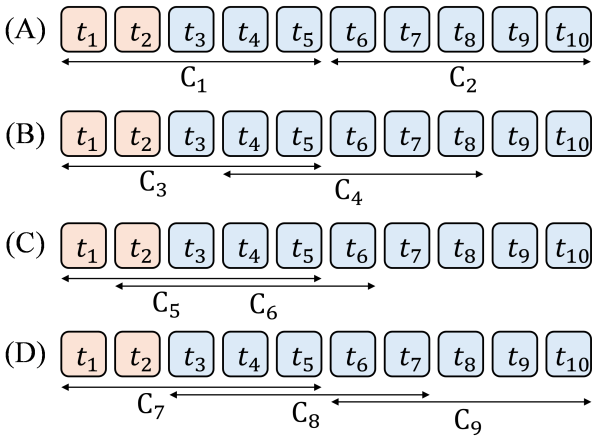

Figure 1: Tokens with the same color represent that they are from an identical file. (A) Non-overlapping contexts with fixed-length stride. (B) Overlapping contexts with fixed-length stride of 3. (C) Overlapping contexts with fixed-length stride of 1. Even with stride of 1, examples of next token prediction in two adjacent contexts can be different (see Example 3.1). (D) Overlapping contexts with variable-length stride, where the variable-length is determined by the end token of a file and the default value.

Code LLMs are continually pretrained through multiple stages from general datasets to domain-specific datasets (Nijkamp et al., 2023; Li et al., 2023; Rozière et al., 2023). In the early stages, they are trained on huge datasets (over trillion tokens) that cover diverse domains, such as code, natural language, and math. In the latter stages, they are trained on relatively small datasets from much narrower target domains, such as Python code, code review, and in-house code of a commercial company. Especially, for commercial companies that utilize open code LLMs, continually pretraining the model on their internal (private) codes is crucial for the prediction accuracy, since open code LLMs are pretrained on public source codes only.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 456–468
July 28-30, 2025

A challenging issue in the latter stages of pretraining is that the data of a target domain is often limited and difficult to collect. For instance, it is not possible to collect more data from public sources if we aim to adapt the model to in-house data of a commercial company. A conventional way to train a model on such scarce data is increasing the number of epochs with the data at hand. However, it is empirically shown that training LLMs for more than 4 epochs with repeated data gives diminishing returns (Muennighoff et al., 2023). Thus, we need a new way to increase the prediction accuracy of code LLMs when the pretraining data is scarce.

In this paper, to address the data-scarcity issue when continually pretraining code LLMs, we propose to extract *overlapping contexts* with variable-length stride from the training data, where overlapping contexts are token sequences that can overlap. Figure 1 shows examples of non-overlapping contexts, overlapping contexts, fixed-length stride, and variable-length stride. Overlapping contexts provide more diverse and abundant examples of next token prediction, while the variable-length stride filters out less effective overlapping contexts. Combining overlapping contexts with variable-length stride leads to a higher prediction accuracy when continually pretraining code LLMs. Our contributions are summarized as follows.

- We propose a novel packing method, which is the combination of overlapping contexts and variable-length stride. We present three different implementations for overlapping contexts in terms of space complexity.
- We conduct extensive experiments to show the effectiveness of our method in the code generation task. The experiments are two fold: (1) training billion-scale code LLMs on in-house dataset for deployment and (2) training million-scale code LLMs on public dataset for reproducibility. The experiments include different models in terms of size and structure, training datasets, benchmarks, and training settings, which together show the generalizability of our method.
- Experimental results show that utilizing overlapping contexts with variable-length stride outperforms the conventional approach of controlling the number of epochs with non-overlapping contexts in terms of the pass@k rate.

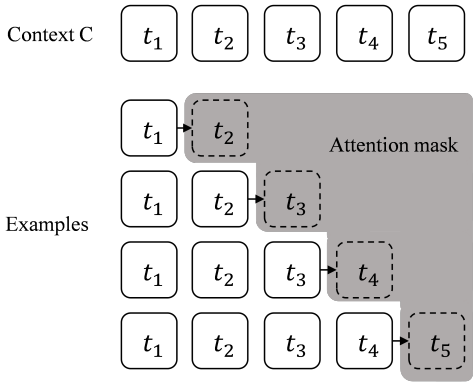

Figure 2: Examples of next token prediction in a context. The answer tokens are hidden by the attention mask during training.

2 Preliminaries

2.1 Notation

A *token* is a positive integer that represents one or more characters. A *tokenizer* maps a token to (possibly one) characters, and the mapping in the tokenizer is called the *vocabulary*. A *token sequence* is a sequence of tokens drawn from the domain of a vocabulary. For a token sequence T, $T[i:j]$ represents the continuous subsequence of T starting from the i-th token and ending at the j-th token. For a token sequence T and a positive integer l, a *context* C^l of T is a continuous subsequence of T whose length is l. For the simplicity of notation, we will omit the superscript l if the length is clear from context.

2.2 Next Token Prediction

Next token prediction is the task of predicting the next token that can appear after a given token sequence. An *example* of next token prediction is denoted by $(t_1, t_2, \ldots, t_l) \rightarrow t_{l+1}$, where $(t_1, t_2, \ldots, t_l)$ is the input token sequence and t_{l+1} is the answer.

LLMs are trained for the next token prediction task by minimizing the cross entropy loss of the predicted probability of next token with respect to the ground truth next token (Radford et al., 2018). For what follows, let T be the token sequence corresponding to an entire code corpus, on which we want the model to train. The probability of a context C^l in T can be expressed as the product of $l-1$ conditional probabilities as follows:

$$P(C) = \prod_{i=2}^{l} P(t_i | t_1, t_2, \ldots, t_{i-1}), \qquad (1)$$

where $P(t_i|t_1, t_2, ..., t_{i-1})$ represents the probabil-

ity of t_i (i.e., the next token) given the subsequence $(t_1, t_2, \ldots, t_{i-1})$ of C^l.

Notably, decoder-only transformers can process the $l-1$ examples of the next token prediction in parallel for a context C composed of l tokens (Vaswani et al., 2017). For example, consider a context $C = (t_1, t_2, t_3, t_4, t_5)$ of length five in Figure 2. There are four examples of next token prediction; $(t_1) \rightarrow t_2$, $(t_1, t_2) \rightarrow t_3$, $(t_1, t_2, t_3) \rightarrow t_4$, and $(t_1, t_2, t_3, t_4) \rightarrow t_5$. In the remainder of the paper, all examples of next token prediction in a context are considered in the same manner as in Figure 2.

2.3 Related Work

In this paper, we focus on continual pretraining code LLMs in data-scarce scenario. Extensive research has been conducted on pretraining code LLMs with an unlabeled code corpus for next token prediction (see **Code LLMs** and **Continual Pretraining Code LLMs** in Appendix A), and many effective data augmentation techniques for natural language processing have been proposed in recent years (see **Data Augmentation for NLP** in Appendix A). However, to the best of our knowledge, this paper is the first to study pretraining code LLMs in data-scarce scenario.

3 Overlapping Context

3.1 Packing

In pretraining, the training dataset is composed of contexts that do not contain padding for efficiency. A general approach of constructing such contexts from multiple code files consists of three phases: In the first phase, we convert each file into a sequence of tokens using a model-specific tokenizer; In the second phase, we concatenate all token sequences to form one long token sequence. During the second phase, special tokens indicating the beginning or the end of the file can be added between token sequences; In the third phase, we cut the long token sequence into contexts of equal length. This process is called *packing*.

3.2 Non-Overlapping Context with Fixed-Length Stride

Suppose that we are extracting contexts of length l from token sequence $T = (t_1, t_2, \cdots, t_n)$ in the third phase. A conventional approach is extracting non-overlapping contexts by adding *stride* $s = l$ to the start position of the previously extracted context. That is, the first context is $T[1 : l]$, the second context is $T[l + 1 : 2l]$, the third context is $T[2l + 1 : 3l]$, and so on. The last chunk of T is dropped if its length is less than l. With stride l, the number of extracted contexts is $\lfloor \frac{n}{l} \rfloor$.

3.3 Overlapping Context with Fixed-Length Stride

A simple way to extract more contexts in the third phase of packing is to set the stride s to be a smaller number than the context length. *Overlapping contexts* are contexts that are extracted with stride s such that $1 \leq s < l$, where l is the context length. Note that by setting $s < l$, two adjacent contexts overlap $l - s$ positions in T.

Conjecture 3.1. *Overlapping contexts with a moderate stride provide more diversity when training large language model for code.*

Here is an intuitive example of Conjecture 3.1 in the domain of coding. Suppose that a token sequence T of length 8K contains eight functions $f_1, f_2, \ldots, f_8$, and that the length of each function is 1K. T can be partitioned into four non-overlapping contexts, each with a length of 2K, capturing the four relationships between pairs $(f_1, f_2), (f_3, f_4), (f_5, f_6), (f_7, f_8)$. On the other hand, if we extract overlapping contexts from T with a stride of 1K, they can capture all four relationships above plus additional relationships between pairs $(f_2, f_3), (f_4, f_5), (f_6, f_7)$.

Lemma 3.1. *Given stride s, context length l, and a token sequence T of length n such that $1 \leq s < l \leq n$, we can extract $\lceil \frac{n-l+1}{s} \rceil$ overlapping contexts such that any two contexts share at most $l - s$ positions in T.*

Proof. See Appendix B. □

Lemma 3.1 means that we can extract about l times more contexts if we set $s = 1$ compared to the number of non-overlapping contexts with $s = l$.

Although two overlapping contexts share positions in T, their examples of next token prediction can be different.

Example 3.1. *Consider two overlapping contexts $C_5 = (t_1, t_2, t_3, t_4, t_5)$ and $C_6 = (t_2, t_3, t_4, t_5, t_6)$ with four tokens overlap in Figure 1. Examples of next token prediction in C_5 are $(t_1) \rightarrow t_2$, $(t_1, t_2) \rightarrow t_3$, $(t_1, t_2, t_3) \rightarrow t_4$, and $(t_1, t_2, t_3, t_4) \rightarrow t_5$. Examples in C_6 are $(t_2) \rightarrow t_3$, $(t_2, t_3) \rightarrow t_4$, $(t_2, t_3, t_4) \rightarrow t_5$, and $(t_2, t_3, t_4, t_5) \rightarrow t_6$. If*

Stride	Unique	Total	%
2048	1,263,146,560	1,265,784,967	99.79
1024	2,524,323,164	2,530,849,390	99.74
512	5,044,421,251	5,060,978,236	99.67
256	10,078,484,177	10,121,235,928	99.57

Table 1: The number of unique examples of next token prediction in the in-house dataset for varying fixed-length stride. The context length is 2048. Overlapping contexts (stride $<$ 2048) have almost the same proportion of unique examples as that in non-overlapping contexts (stride $=$ 2048).

$t_1 \neq t_2$, C_5 and C_6 do not share examples of next token prediction.

Lemma 3.2. *Consider the set of overlapping contexts in Lemma 3.1 with stride s and context length l, extracted from a token sequence T of length n. Assume that $T[i] \neq T[i+s]$ for any $1 \leq i \leq n-s$. Then no two adjacent overlapping contexts share examples of next token prediction.*

Proof. See Appendix C. □

Lemma 3.2 means that even if two adjacent overlapping contexts share tokens, they do not share the identical examples of next token prediction if the first tokens of them are different. Table 1 shows that the proportion of unique examples is over 99% even if we set stride to 256 for context length of 2048 (overlapping 1792 tokens) in real dataset.

Theorem 3.3. *Given stride s, context length l, and a token sequence T of length n such that $1 \leq s < l \leq n$, assume that $T[i] \neq T[i+s]$ for any $1 \leq i \leq n-s$. We can extract $\lceil \frac{n-l+1}{s} \rceil$ overlapping contexts such that no two adjacent contexts share examples of next token prediction.*

Proof. The proof is direct from Lemmas 3.1 and 3.2. □

Implementation Details. There are multiple implementation choices for storing overlapping-contexts. We describe three methods and compare their space usages.

- The first method is extracting overlapping contexts by sliding window and simply storing all of them in memory. This method requires memory proportional to the extracted contexts.
- The second method is extracting overlapping contexts by sliding window and storing only the start indices of them in memory. The actual contexts corresponding to the start indices are extracted during training. Since only the start indices are stored and they are not duplicated, this method requires additional memory at most twice as large as the original dataset.
- The third method is randomly sampling the start indices of the contexts during training. The random sampling method does not require additional memory, but it does not guarantee that the start indices are unique. Also, this method cannot use the variable-length stride, which will be described in the next subsection.

3.4 Overlapping Context with Variable-Length Stride

An extracted overlapping context can be less effective when the context contains tokens from multiple unrelated files (e.g., C_6 in Figure 1). To avoid extracting less effective contexts, we propose a way to set variable-length stride.

Suppose that we are extracting overlapping contexts by sliding window. Given a token sequence T, context length l, and the default stride s, let the current window is $T[i : i+l-1]$. The *variable-length stride* s' is defined as follows:

- If the current window contains at least one end token of a file, we set $s' = j - i + 1$, where j is the rightmost end-token's position.
- If the current window does not contain the end token of a file, we set $s' = s$.

This approach sets a long stride when there are multiple files in the current window, and sets a short stride when the current window is a part of a long file. Hence, we can filter out less effective overlapping contexts utilizing the variable-length stride.

4 Experimental Results

In this section we present experimental results to show the effectiveness of overlapping context in continual pretraining code LLMs in data-scarce scenario. The experiments are twofold: (1) training billion-scale LLMs on in-house dataset, which are deployed in our company, and (2) training small LLMs on public dataset for reproducibility.

Training Data. We collected an in-house code dataset, which contains hundreds of private repositories. After applying the filtering techniques introduced in previous works (Chen et al., 2021; Nijkamp et al., 2023; Kocetkov et al., 2023; Li et al., 2023), we obtained 3.67GiB (1.49 billion tokens) C/C++ codes.

For the public dataset, we use Swift codes of TheStack (Kocetkov et al., 2023). We first applied deduplication and filtering, and then extracted 10% of the remaining files. The resulting dataset contains 598MiB (180 million tokens) Swift codes.

Evaluation Data. To evaluate a model with respect to the in-house dataset, we created a benchmark dataset similar to HumanEval (Chen et al., 2021). HumanEval consists of 164 hand-written Python problems, each of which is a task of generating a function's body given the function's header and comments about the function. The generated code is considered to solve the problem if it passes all predefined unit tests. We extracted 100 functions from the in-house dataset and created tasks of generating a function's body given the function's header, together with corresponding unit tests. The resulting benchmark dataset is called U100.

To evaluate a model trained on the public dataset, we use the MultiPL-E (Cassano et al., 2023) benchmark, which is a multilingual version of HumanEval. Specifically, we use the Swift version of HumanEval.

Metric. We report the pass@k rate (Chen et al., 2021; Kulal et al., 2019), which represents the rate of solved problems when a model can speculate the answer k times for each problem.

Baseline. As mentioned in Section 2.3, our paper focuses on continual pretraining code LLMs in data-scarce scenario. In this setup, increasing the number of epochs has been the only way to achieve the performance gain so far. Therefore, our primary baseline is increasing the number of epochs with non-overlapping contexts.

Models. For the in-house dataset, we continue pretraining on EXACODE-8.8B-BASE, which is a code version of EXAONE-2.0 (Research, 2024). EXACODE-8.8B-BASE is a pretrained language model with 8.8 billion parameters trained on ThePile (Gao et al., 2020), TheStack (Kocetkov et al., 2023), and extra natural language dataset (459 billion training tokens in total). We compare the following models.

- EXACODE-8.8B-OC: it is initialized with the weights of EXACODE-8.8B-BASE, and continually pretrained full-parameter on the in-house code dataset. It uses overlapping contexts with a fixed-length stride.
- EXACODE-8.8B-NOC: it has the same training setting as that of EXACODE-8.8B-OC except that it uses non-overlapping contexts.

For the public dataset, we continue pretraining on CodeGen-350M-Multi (Nijkamp et al., 2023). We chose this model because its size is suitable for conducting ablation studies. Also, for efficient training, we use LoRA (Hu et al., 2022) in such a way that the percentage of the trainable parameters becomes 8%.

The detailed hyperparameter settings will be presented in Appendix D. We also apply our method to CodeLlama (Rozière et al., 2023) in Appendices E and F, where the effect of overlapping contexts on CodeLlama is similar to that on EXACODE. A number of additional experiments are also performed: effect of varying fixed-length stride and batch size (Appendix F), applying the mix-review strategy to alleviate the forgetting problem (Appendix G), counting the number of unique examples with different context length (Appendix H), and counting the number of unique examples with the random sample method (Appendix I).

4.1 Unique Examples in the In-House Dataset

Table 1 shows the number of unique examples of next token prediction in the in-house dataset for varying values of fixed-length stride. Here, the context length is 2048, and thus stride $= 2048$ means that there is no overlap between any two contexts. Although there is no overlap, the number of unique examples is slightly smaller (99.79%) than the total number of examples because short examples tend to have duplicates throughout the dataset.

Even when two adjacent contexts overlap, the proportion of unique examples remains high (99.57%) until stride $= 256$. That is, we can have almost 8 times more unique examples than non-overlapping contexts.

4.2 Evaluation on U100

To see the effect of overlapping contexts in terms of prediction accuracy on the in-house dataset, we compare the two approaches: (1) training 2 epochs utilizing the overlapping contexts with fixed-length stride of 256, and (2) training 8 epochs utilizing the non-overlapping contexts. We report the pass@1 rate, where the beam search with 2 beams is used for the decoding strategy.

Figure 3 shows the pass@1 rate of the two approaches. Utilizing the overlapping contexts, EXACODE-8.8B-OC outperforms EXACODE-8.8B-NOC in terms of pass@1. Specifically, the best pass@1 rate of EXACODE-8.8B-OC is 29% and the

Context Length	Stride	Stride Type	Learning Rate	Batch Size	Epoch	Training Step	Pass@1
1024	128	Variable-Length	2e-4	512	2	3302	7.9
1024	128	Fixed-Length	2e-4	512	2	5506	6.5
1024	1024	Fixed-Length	2e-4	512	10	3440	6.2
1024	1024	Fixed-Length	2e-4	512	20	6880	6.2
1024	1024	Fixed-Length	1e-3	512	2	688	5.0

Table 2: The pass@1 rate of `MultiPL-E` Swift for the `CodeGen-350M` models trained on the public dataset.

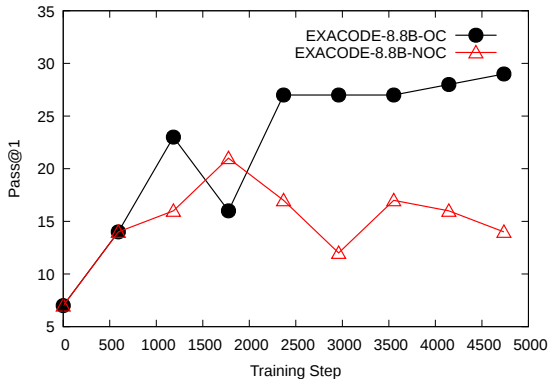

Figure 3: Training billion-scale LLMs on the in-house dataset. `EXACODE-8.8B-OC` (overlapping contexts) outperforms `EXACODE-8.8B-NOC` (non-overlapping contexts) in terms of the pass@1 rate.

best one of `EXACODE-8.8B-NOC` is 21%. The improved performance supports that overlapping contexts can increase diversity when training code LLMs (Conjecture 3.1). The declining performance of `EXACODE-8.8B-NOC` after the 3rd epoch represents a sign of overfitting. In contrast, the performance of `EXACODE-8.8B-OC` increases until 4736 steps (corresponding to 8 epochs of `EXACODE-8.8B-NOC`) without signs of overfitting. This is because the overlapping contexts provide an enlarged training datasets, in which duplicate examples are less than 1%.

4.3 Evaluation on MultiPL-E Swift

For the reproducible work, we evaluate our techniques on the public dataset (described in **Training Data**). This experiment also shows the generalizability of our approach because we use different models, datasets, benchmarks, and train settings.

Table 2 shows various versions of `CodeGen-350M` trained on the Swift codes of `TheStack`. For each version, we saved checkpoint for every 10% training step, and report the average pass@1 rate of top-3 checkpoints.

The version that utilizes overlapping contexts with variable-length stride outperforms all non-overlapping versions in terms of the pass@1 rate. The performance of the version that utilizes only the overlapping contexts is marginally better than the non-overlapping versions, which implies that there are less effective contexts in the overlapping contexts if we do not utilize the variable-length stride.

To see if a higher learning rate or a large number of epochs can mitigate the data-scarcity issue, we compare the non-overlapping version with 20 epochs and the version with learning rate of 1e-3. Nevertheless, the performances of these versions are similar or worse than that with less number of epochs and smaller learning rate.

5 Discussion

In this paper we defined the variable-length stride by the end token of a file. However, there can be different definitions of the variable-length stride. For instance, one can apply *dependency parsing* (Guo et al., 2024) to group and to order files in a repository, and define the variable-length stride by the end token of a code repository. One can also define the variable-length stride by the end token of a paragraph in natural language dataset.

Regarding natural language dataset, although overlapping contexts are shown to be effective for code datasets, it is not guaranteed that overlapping contexts will be equally effective for natural language datasets because their characteristics are different. For example, code corpora are more repetitive and predictable (Casalnuovo et al., 2019), and they have longer context than natural language corpora, which can make overlapping contexts more beneficial for code than for natural language.

6 Conclusion

In this paper we have introduced a new packing method utilizing overlapping contexts with variable-length stride. Our method is useful for continual pretraining code LLMs when the amount of training dataset is insufficient. Extensive experiments on the in-house dataset and the public dataset have demonstrated the effectiveness of our method in terms of the pass@k rate. Applying overlapping contexts to natural language dataset is an interesting future work.

Limitations

As more contexts are extracted in overlapping contexts compared to non-overlapping contexts, the overlapping context method increases training time proportionally to the amount of additional contexts.

Ethics Statement

In the experiments, we use `CodeGen` (Nijkamp et al., 2023) in Section 4 and `CodeLlama` (Rozière et al., 2023) in Appendix E, which are open-source models. Our use of `CodeGen` and `CodeLlama` is consistent with their licenses and acceptable use policies. We do not see any potential risks derived from our work.

A Extended Related Work

Code LLMs. Large language models for code (Chen et al., 2021; Nijkamp et al., 2023; Zheng et al., 2023a; Li et al., 2023; Wang et al., 2023; Allal et al., 2023; Guo et al., 2024) are based on transformer-decoder architecture that generates next tokens autoregressively from given prompt tokens. Code LLMs are pretrained on large unlabeled code corpus for the next token prediction objective. Notably, `Codex` (Chen et al., 2021) is a decoder-only model for Python code generation, which is released with an evaluation set called `HumanEval`. `StarCoder` (Li et al., 2023) and `CodeLlama` (Rozière et al., 2023) are decoder-only models that are trained on permissively licensed code datasets, allowing companies to use them without concerns about licensing issues.

Some models are based on encoder-decoder transformer and are trained with different pretraining objectives. `CodeT5+` (Wang et al., 2023) is an encoder-decoder model that is trained with mixture of pretraining objectives, including span denoising, contrastive learning, text-code matching, and next token prediction. `CodeRL` (Le et al., 2022) is a framework of training code LLMs by reinforcement learning that utilizes compilation results and unit test results. Recently, a multi-token prediction model architecture (Gloeckle et al., 2024) is introduced, which offers faster inference than next-token prediction architecture and also offers higher accuracy on coding evaluation benchmarks as the model size increases.

We refer the reader to (Zheng et al., 2023b; Jiang et al., 2024) for comprehensive surveys of code LLMs.

Continual Pretraining Code LLMs. Code LLMs are pretrained through multiple stages (Nijkamp et al., 2023; Rozière et al., 2023; Gururangan et al., 2020). Initially, they are pretrained on a large-scale general corpus. Then, they are continually pretrained on a subset of the corpus seen in the previous stage or a specific target corpus (such as a private in-house dataset) that has not been previously seen. For instance, `CodeLlama-Python` (Rozière et al., 2023) is first trained on 2 trillion tokens from natural language, code, and math datasets (Touvron et al., 2023). It is then trained on 500 billion tokens from code-heavy dataset that covers multiple programming languages, and lastly, it is pretrained on 100 billion tokens of a Python-heavy dataset, followed by long context fine-tuning on 20 billion tokens.

In the domain of code, the prompt can include related code files and detailed instructions, and

the model can output an entire function or a class definition (Guo et al., 2024; Lozhkov et al., 2024). Therefore, code LLMs must handle a relatively long context length. In general, code LLMs are first pretrained on a large-scale corpus with contexts of moderate length, and then they are fine-tuned for long contexts (Zhu et al., 2023; Peng et al., 2023a; Su et al., 2024; Chen et al., 2023).

Data Augmentation for NLP. Data scarcity is common in natural language processing (NLP) both for pretraining and for fine-tuning. Muennighoff et al. (Muennighoff et al., 2023) conducted a study on scaling LLMs for NLP in data-constrained regimes. They quantify the impact of multiple epochs in LLM training and empirically validate that training for more than 4 epochs with repeated data gives diminishing returns (i.e., the loss does not decrease as much as having unique data). To mitigate data scarcity, they propose code augmentation for natural language tasks. They observed that filling up to 50% of data with code shows no deterioration, but beyond that, performance decreases quickly on natural language tasks.

For downstream NLP tasks (e.g., summarization, translation), models are typically trained on labeled dataset. Collecting labeled datasets can be costly, especially when human annotators are involved. Extensive research has been conducted to collect or augment labeled dataset using techniques such as word insertion, deletion, substitution, and leveraging pretrained language models to generate new examples or paraphrasing existing ones (Wei and Zou, 2019; Calderon et al., 2022; Whitehouse et al., 2023; Ghosh et al., 2023). However, applying these techniques to pretraining code LLMs can be challenging because they are specifically designed for natural languages, have different training objectives than next token prediction, and are tailored to transformer-encoder models.

Packing. Recently, the impact of packing strategy on pretraining LLMs has been explored (Zhao et al., 2024; Chen et al., 2024). If the lengths of files are shorter than the context length, the context may be composed of several irrelevant files, and the inclusion of distracting information can degrade the performance of the models. In this case, all `UniChunk`, `BM25Chunk`, and `Intra-Document Causal Masking` methods (Zhao et al., 2024) can improve in-context learning, knowledge memorization, and context utilization abilities of language models.

On the other hand, if the lengths of files are longer than the context length, a file may be divided into several contexts. These correlated contexts are separated while shuffling and are put into different batches if the unit of data shuffled is one. The impact of various unit sizes is also explored (Chen et al., 2024).

B Proof of Lemma 3.1

Proof. Let $\mathcal{C}$ be the set of contexts $T[i : i + l - 1]$ for $1 \leq i \leq n - l + 1$ such that $i - 1$ is a multiple of s. Any two contexts in $\mathcal{C}$ overlap at most $l - s$ positions in T because $i - 1$ is a multiple of s. The number of contexts in $\mathcal{C}$ is $\lceil \frac{n-l+1}{s} \rceil$, which is the number of positions i in T such that $i - 1$ is divisible by s. Therefore, $\mathcal{C}$ contains the overlapping contexts of the lemma. □

C Proof of Lemma 3.2

Proof. We prove by contradiction. Assume that there is an identical example of next token prediction between two adjacent overlapping contexts $C_i = T[i : i + l - 1]$ and $C_{i+s} = T[i + s : i + s + l - 1]$.

By the assumption of the lemma, $T[i]$ and $T[i + s]$ are different, and thus C_i and C_{i+s} do not have a common prefix. However, in order for C_i and C_{i+s} to have an identical example, there must be a common prefix between C_i and C_{i+s}, which is a contradiction. □

D Hyperparameter Settings

For training the in-house dataset, we use the AdamW (Loshchilov and Hutter, 2019) optimizer with $\beta_1 = 0.9$, $\beta_2 = 0.95$, and $\epsilon =$ 1e-8. We use the cosine decay learning rate scheduler that gradually decreases the learning rate to 10% of its maximum value after 175 wamup steps. The maximum learning rate is 1e-4 for the `CodeLlama-7B` models and 1.6e-5 for the `EXACODE-8.8B` models. The default context length is 2048. We use different combinations of stride and batch size for diverse comparison. For training the public dataset, we use the constant learning rate scheduler with learning rate of 2e-4 and set context length to 1024 by default.

For all models, we applied mixed precision training using bfloat16 to speed up the training. For `EXACODE-8.8B` and `CodeLlama-7B` models, we conducted full-parameter training on 64 A100-40GB GPUs using FSDP (Zhao et al., 2023) with

Model	Stride	Batch Size	#Train Tokens	Training Step

Table 4: The U100 pass@1 rate and ROUGE score of the CodeLlama-7B models for varying numbers of epochs. The context length is fixed to 2048. The bold fonts indicate the highest score among checkpoints for each model.

the full sharding strategy. The CodeGen-350M models are trained on one A100-80GB GPU using LoRA (Hu et al., 2022). We set $r = 256$, $\alpha = 512$, and adapted the query, key, value, and out projection matrices.

E Applying Overlapping Context to CodeLlama

In addition to the EXACODE-8.8B models described in Section 4, we compare the following models based on CodeLlama-7B-BASE[1] (Rozière et al., 2023):

- CodeLlama-7B-OC: it is initialized with the weights of CodeLlama-7B-BASE, and trained on the mixed dataset of the in-house dataset and TheStack. It uses overlapping contexts with a fixed-length stride.
- CodeLlama-7B-NOC: it has the same training setting as that of CodeLlama-7B-OC except that it uses non-overlapping contexts.

[1]https://huggingface.co/codellama/CodeLlama-7b-hf

In order to alleviate the forgetting problem that can occur in sequential pretraining, we apply data mixing similar to the *mix-review* strategy (He et al., 2021). Specifically, we mix the in-house dataset with a random subset of C/C++ codes of TheStack so that TheStack constitutes 10% of the resulting training dataset.

F Varying Stride and Batch Size

We use different combinations of fixed-length stride and batch size for two model structures, CodeLlama and EXACODE. Overlapping context offers an enlarged dataset that contains diverse examples, which allow us to increase the batch size while maintaining the number of training steps.

In this subsection we use the ROUGE score for an additional metric. While pass@k is a good metric for evaluating the functionality of the generated code, it is discontinuous metric and thus it makes the performance of the model to appear sharp and unpredictable (Schaeffer et al., 2023). Thus, we also report the ROUGE-1 F1 score (Lin, 2004) between ground truth function body and the generated

Model	Context Length	Stride	Batch Size	Epoch or Step	Pass@1	Pass@10
CodeLlama-7B-BASE	-	-	-	-	29.23	57.39
CodeLlama-7B-NOC	2048	2048	8192	1.0	29.67	57.45
CodeLlama-7B-OC	2048	1024	8192	1.4	30.25	58.29
CodeLlama-7B-OC	2048	512	8192	1.2	31.46	58.30
EXACODE-8.8B-BASE	-	-	-	-	17.98	31.84
EXACODE-8.8B-NOC	2048	2048	1024	1184	18.37	33.65
EXACODE-8.8B-OC	2048	1024	1024	592	18.88	34.00
EXACODE-8.8B-OC	2048	512	2048	2368	18.39	33.20
EXACODE-8.8B-OC	2048	256	2048	4736	17.85	32.37

Table 5: Accessing the degree of forgetting with HumanEval-X C++. The pass@k rates of the CodeLlma-7B models consistently increase as the stride decreases due to the mix-review strategy.

function body.

Table 4 shows the pass@1 rate and the ROUGE score of the CodeLlama-7B models for U100. The general trend is that both pass@1 rates and ROUGE scores increase as we decrease the stride. Specifically, the highest pass@1 rates of the CodeLlama-7B models are 7%, 13%, 31% for strides of 2048, 1024, 512, respectively. The highest ROUGE scores are 34.37, 40.80, 47.09 for strides of 2048, 1024, 512, respectively. CodeLlama-7B-OC with stride=512 outperforms CodeLlama-7B-NOC by an absolute 24% pass@1 rate and by an absolute 12.72 ROUGE score.

Tables 3 shows the pass@1 rate and the ROUGE score of the EXACODE-8B models for U100. The trend that the model performs better with a lower stride is similar to that shown in the CodeLlama-7B models. Comparing the combinations of (stride, batch size) $\in \{(1024, 1024), (512, 2048)\}$, we can see that the increased batch size leads to better performances in terms of the pass@1 rate and the ROUGE score.

G Applying Mix-Review Strategy to Alleviate Forgetting

Sequential training of language models can cause the forgetting problem (McCloskey and Cohen, 1989). To assess the degree of forgetting, we evaluate the EXACODE-8.8B and CodeLlma-7B models on HumanEval-X (Zheng et al., 2023a), which is a multilingual version of HumanEval. Since our training dataset contains only C/C++ codes, we measure the performances for the C++ language of HumanEval-X. We generate 200 samples for each problem using the top-p sampling (Holtzman et al., 2020) with $p = 0.95$, and report the pass@1 and pass@10 rates. We use two sampling temperatures, 0.2 and 0.6, and report the highest pass@k rate among the results.

Context Length	Stride	Unique / Total (%)
1024	1024	99.61
1024	512	99.50
1024	256	99.35
512	512	99.12
512	256	98.88
512	128	98.54

Table 6: The number of unique examples of next token prediction in the in-house dataset for varying context length and stride.

Recall that we applied the mix-review strategy when training the CodeLlama-7B models by mixing the random subset of C/C++ codes of TheStack (i.e., general source codes), whereas we used only the in-house dataset when training the EXACODE-8.8B models. Thus, we can see the effect of the mix-review strategy on the forgetting problem by comparing the CodeLlama-7B models against the EXACODE-8.8B models.

For each model in Tables 3 and 4, we select the best checkpoint whose U100 pass@1 rate is the highest (i.e., the most optimized models to the in-house dataset). Table 5 shows the pass@1 and pass@10 rates of the best checkpoints. For the CodeLlama-7B models, the pass@k rates consistently increase as we decrease the stride. However, for the EXACODE-8.8B models, the pass@k rates reach the peak at stride of 1024 and then decline as we decrease the stride. Therefore, mixing in general source codes is beneficial to alleviate the forgetting problem when continual pretraining code LLMs on a domain-specific dataset.

H Unique Examples with Different Context Length

When reducing the context length from 2048 to 1024 and 512 on the in-house dataset, it results in a marginally lower unique ratio as shown in Table 6.

Context Length	Stride	Unique / Total (%)
2048	2048	99.81
2048	1024	99.73
2048	512	99.61

Table 7: The number of unique examples of next token prediction in the in-house dataset with the random sampling method.

Nevertheless, the unique ratio remains above 98%.

However, it is difficult to predict whether a lower context length will affect the final outcome because not only the number of unique examples but also the context length itself can affect the final outcome. For example, reducing the context length to 512 results in failures of some problems in HumanEval because the context length must be longer than 600 in order to solve all problems in HumanEval.

I Unique Examples with Random Sampling Method

Table 7 shows the unique ratio on the in-house dataset with the random sampling method presented in Section 3. Although in theory the randomly extracted indices are not guaranteed to be unique, empirically the unique ratio of the random sampling method is similar to that of the deterministic method (see Table 1).

Generating Q&A Benchmarks for RAG Evaluation in Enterprise Settings

Abstract

We introduce DataMorgana, a tool for generating synthetic Q&A benchmarks tailored to RAG applications in enterprise settings. DataMorgana enables customization of the generated benchmark according to the expected diverse traffic of the RAG application. It allows for specifying question types and their associated distribution via a lightweight configuration mechanism. We demonstrate via a series of quantitative and qualitative experiments that DataMorgana surpasses existing tools in terms of lexical, syntactic, and semantic diversity of the generated benchmark while maintaining high quality. We run our experiments over domain-specific and general-knowledge public datasets, as well as two private datasets from governmental RAG applications: one for citizens and the other for government employees. The private datasets have been shared with us by AI71, an AI company, which has integrated DataMorgana into its offerings. In addition, DataMorgana has been offered to about 150 researchers worldwide as part of the SIGIR'2025 LiveRAG Challenge held in Spring 2025.

1 Introduction

Retrieval-Augmented Generation (RAG) (Lewis et al., 2020; Gao et al., 2023) has recently gained a great deal of popularity, especially in specialized domains. However, before adopting a RAG solution, it is critical to evaluate its effectiveness in the target environment, accounting not only for the environment's specific content (the RAG corpus) but also for its diverse types of users' needs.

Consider a corporate scenario where a company wishes to release a RAG-based question-answering experience over a private specialized corpus. In order to evaluate it, one requires a solid benchmark. In the absence of question or query logs, a common practice is to use an LLM to generate Q&A pairs from randomly selected documents within the corpus. The major risk in this approach is that the generated questions often have different properties than those that the experience owners envision. In particular, generated questions may not be realistic (e.g., contain too many technical terms), or diverse enough (e.g., not covering the many types of questions that could be asked by real users).

We propose a new approach to generate synthetic benchmarks with two key properties.
Lightweight and flexible customization: Configuring DataMorgana so that Q&A pairs are generated according to the expected traffic is done via free-text/natural language descriptions organized in categories, making customization accessible to non-AI specialists. This property is crucial because the system's user, typically a domain expert, should have control over the generation process as the one who truly understands the expected traffic.
Diverse generation: Our default setting offers a rich collection of orthogonal question category sets, which we denote as categorizations; these can be combined to create a combinatorial amount of question types, ensuring a diverse output. This results in an excellent starting point for the user, who can edit these categorizations, as modifying or removing question categories is far easier than creating them from scratch.

This approach is implemented in a tool called DataMorgana[1], which we describe in detail here. DataMorgana is fully deployed with AI71[2], an applied AI company focused on building intelligent agents that bring the benefits of AI to enterprise users in a responsible way. DataMorgana was made available to close to 150 researchers in the context of the SIGIR'2025 LiveRAG Challenge (Carmel et al., 2025). DataMorgana was used by competitors over March-May 2025 to train and test their RAG engine. It was also used by the Challenge organizers to generate the unseen synthetic test bench-

[1]This paper expands the work introduced by Filice et al. (2025).

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 469–484

marks on which the competitors were evaluated during a two-hour time window on May 20, 2025[3]. In this work, we focus on DataMorgana question generation capabilities, demonstrating through quantitative experiments that it achieves higher diversity than related tools or approaches without compromising quality. To keep our work focused, we leave for future work the analysis of the generated answers since this requires a completely different set of metrics, baselines, and ablations. Our key contributions are as follows.

1. We present DataMorgana, a synthetic benchmark generation tool with lightweight and flexible customization capabilities;

2. We propose a novel technique based on multi-question categorizations to support the generation of highly diverse benchmarks.

3. We conduct extensive experiments on both public and real-world proprietary datasets to assess how DataMorgana compares to existing benchmark generation methods in producing high-quality and more diverse questions across lexical, syntactic, and semantic dimensions.

2 Related Work

Recent advances in LLMs, with their tremendous zero-shot and few-shot generation capabilities, have led to many research efforts in creating synthetic test benchmarks for question answering (Fei et al., 2022; Dong et al., 2023; Yoon and Bak, 2023; Chen et al., 2024; Shakeri et al., 2020) and conversational dialog systems (Ling et al., 2020; Do et al., 2022). Ideally, an optimal test set would comprise a large set of real user questions from a query log, paired with "golden answers" provided by experts. In the absence of a perfect test set, we seek to generate questions similar to those asked by real users, along with answers inferred from a data source. A comprehensive taxonomy of generation approaches can be found in (Zhang et al., 2021; Long et al., 2024).

Generate then Filter: The common methodology for (question, answer) pair generation is to follow the *generate then filter* paradigm. Given a corpus of documents, select at first a subset of documents; then, for each document, leverage an LLM to generate some questions that can be answered by the given content. Next, ask the LLM to generate, for each of the questions, an answer or a set of answers based on the corresponding document. Finally, filter the generated (question, answer, document) tuples according to several criteria, such as semantic similarity with golden questions, diversity, and more (Yoon and Bak, 2023).

InPars (Jeronymo et al., 2023), Prompagator (Dai et al., 2022), and more recently ARES (Saad-Falcon et al., 2024), follow this paradigm. Via few-shot examples, an LLM is induced to generate relevant questions for a given document. Then, each (question, document) pair is scored and filtered according to their inner similarity, or if the associated document appears on top of the result list when the question is submitted as a query to a given IR system. Yuan et al. (2023) proposed a prompt-based approach to selecting high-quality questions while Shakeri et al. (2020) filtered the questions based on the generator's perplexity score. Rackauckas et al. (2024) used real user queries as few-shot examples for synthetic query generation, to increase similarity with real traffic, and an LLM-as-a-judge approach for Q&A filtering.

Diversity: Uncontrolled generated content often tends to be monotonous and biased, hence limiting its applicability in downstream tasks (Long et al., 2024). The diversity of generated data is crucial for generating synthetic samples that mimic the diversified nature of real-world data, thereby preventing over-fitting and bias during model training or evaluation. Yoon and Bak (2023) improve question diversity by training the model to generate a new question that differs from previously generated questions. Eo et al. (2023) enhance diversity by training the generator to cover various types of questions per document, based on interrogative question words ({Who, When, What, Where, Why, How}).

Control: Recent studies have suggested enhancing administrative control over the types of generated questions. *Know Your RAG* (de Lima et al., 2024) is a system designed to generate questions from a predefined taxonomy of question types. The generator decomposes the document into statements, and then, depending on the question type, a single statement or an aggregation of multiple statements is used as a basis for question generation.

RAGAs (RAGAS, 2025) is a popular evaluation

[3]More details about the Challenge can be found at https://liverag.tii.ae.

tool for RAG systems that supports the generation of a synthetic Q&A benchmark. Similarly to *Know Your RAG*, RAGAs considers a predefined set of different question types (single-hop vs multi-hop, specific vs abstract), as well as the user persona (senior, junior, etc.). This enriches the type of generated questions and improves diversity. DeepEval (DeepEval, 2025) generates a synthetic Q&A benchmark, while encouraging diversity by an evolutionary process where new questions are generated according to pre-defined evolution rules.

In contrast, DataMorgana, which we describe next, controls the diversity level with finer granularity via a configuration mechanism. We then discuss how DataMorgana compares to some of the approaches discussed above in terms of diversity.

3 DataMorgana System Description

DataMorgana is designed to generate synthetic benchmarks for training and testing primarily RAG (and possibly other) systems that offer question-answering capabilities. It operates in two stages: a configuration stage, during which the DataMorgana admin user specifies their needs, and a generation stage, during which DataMorgana leverages the input configuration to generate, with the assistance of an LLM, the desired benchmark.

3.1 Configuration Stage

In the configuration stage, the user defines question categorizations. Each categorization consists of one or more mutually exclusive categories; thus, a generated question can belong to only one category from each categorization.

The configuration is done either through a JSON file or a visual interface. See Appendix A, Figure 2 for an example of the JSON format. The example lists categorizations *Question factuality* with categories of *factoid* or *open-ended*, *Phrasing* with categories describing whether the question is concise or verbose and whether it is naturally formed, or phrased as a search query. The question categorization can also be leveraged to specify the type of users who would issue the question. For example, a categorization could be *End-user expertise*, indicating the user's familiarity with the documents' content, with categories of *novice* or *expert*, as shown in Appendix A, Figure 3. In a healthcare RAG application, one could add *patient, doctor,* and *public health authority* as categories under a RAG system user categorization. Additional examples can be found in Table 5 in the Appendix, containing general-purpose question categorizations and their respective categories, which can be used for most corpora.

The user may specify, in addition to the categories of a categorization, a probability distribution over them, to determine their frequency in the generated dataset. Formally, the categorization definition results in k categorizations $C_1, \ldots, C_k$, each consisting of categories $\{c_{i,1}, \ldots, c_{i,n_i}\}$ and corresponding probabilities $\{p_{i,1}, \ldots, p_{i,n_i}\}$.

3.2 Generation Stage

The benchmark is built incrementally one Q&A pair (q_i, a_i) at a time, via the following procedure

- A document d_i is sampled from the corpus.
- For each categorization $C_1, \ldots, C_k$, we sample a single category $c_{i,j} \in C_j$ according to the distribution provided with C_j.
- A prompt (see example in Figure 4 of the Appendix) is built asking the LLM to generate a question based on document d_i belonging to the categories $c_{i,1}, \ldots, c_{i,k}$. The chosen LLM is then invoked to generate the question.

Note that this methodology is simple and lightweight by design, allowing for quick development iterations. We intentionally try to avoid approaches with a costly pre-processing stage (e.g., building a knowledge graph (RAGAS, 2025), performing heavy analysis on the document (de Lima et al., 2024)) or multiple invocations for post-processing (e.g., evolving a question (DeepEval, 2025)).

4 Baselines & Corpora

Baselines. We compare DataMorgana with the following synthetic data generation methods:

Vanilla is a strategy that repeatedly uses the same exact process to generate questions from different documents, namely, the LLM instructions appearing in the prompt are always the same, and the only part that varies is the input document. This is probably the most common, albeit straightforward, strategy to generate synthetic benchmarks (Chen et al., 2024; Wang et al., 2024a,b; Li et al., 2024).

Know Your RAG. We re-implemented the solution proposed by de Lima et al. (2024) described in

Section 2. The original solution generates four question types: single-fact, reasoning, summary, and unanswerable questions. We excluded the latter since, while it is fitting for reading comprehension, it is too challenging in a RAG context to guarantee that no document in the corpus can answer the question, making it difficult to assess an answer to the question. More importantly, allowing unanswerable questions introduces unbounded freedom in diversity, which contradicts our focus on measuring and analyzing diversity in this paper. Including them would create a setup that lacks a meaningful basis for comparison. We, in fact, verify as a quality test that a question is answerable.

DeepEval. We chose DeepEval (DeepEval, 2025) as a representative of unpublished commercial solutions. It is well adopted (as of May 2025, their git repo has 6.4K stars and 567 forks), and their data generation code is easy to run and flexible enough to allow generating multiple questions per document. We used their default setting that enables evolving questions with one evolution step, where the type is drawn uniformly at random from seven possible evolutions.

For a fair comparison, all tested generation methods leverage `Claude-3.5 Sonnet v2`[4] with default parameters as the LLM backbone [5].

Corpora. To showcase DataMorgana's capabilities, we generated synthetic data from four corpora. The first two are public datasets: Wikipedia (from 2018) and the CORD-19 Open Research Dataset (CORD-19) (Wang et al., 2020). Further details about these corpora are in Appendix B. The other two are domain-specific proprietary datasets shared with us by an AI company[2] that offers RAG-based chatbots to governmental entities. One of these, referred to as GovExternal, is used to allow citizens to ask about processes related to a governmental agency. The corpus is derived from semi-structured proprietary material, containing mostly natural language text with some embedded small tables, represented as text via markdown. The other one, denoted as GovInternal, is for internal government employees. The corpus contains internal reports containing structured partitions such as sections, subsections, and some bullet points. These are encoded in the text via markdown. The intended use is for employees to be able to ask a chatbot about the content of the reports. In both cases, the corpus is relatively small, covering no more than a few hundred documents.

[4] `https://www.anthropic.com/claude/sonnet`

[5] The LLM prompts we used within DataMorgana are not specifically engineered for Claude-3.5 Sonnet v2, but are expected to work well with other similar-size LLMs.

5 Example Use Case

In this section, we demonstrate the process of using DataMorgana to generate a synthetic dataset over a corpus. For this demonstration, we chose the COVID-QA benchmark (Möller et al., 2020), which contains a collection of questions that were manually composed by field experts, based on documents in the CORD-19 corpus. It is a public corpus, allowing us to discuss its characteristics, yet it exhibits many similarities with proprietary ones. It covers topics typically not included at this level of detail in Wikipedia or other general-knowledge corpora and features highly specialized content with domain-specific jargon.

A user of DataMorgana has a good understanding of the types of questions that could be asked over the corpus and would like to configure the system to generate such questions. We use a small sample of questions from Covid-QA (see human-generated questions in Table 2) to represent the type of questions the user aims to create.

Consider first a scenario where the user applies the Vanilla approach. Table 2 contains sample questions generated in this scenario. One can see that the LLM is inherently biased in producing questions that are longer, contain many details, and tend to be about a specific topic rather than open-ended. They lack fidelity in that many of them are too different from the human-generated questions. It is likely possible to modify the prompt to avoid these unrealistic questions. However, diversity will be much tougher to solve. The resulting set is likely to cover only a small portion of the sought distribution, e.g., by containing only factoid-seeking questions, as opposed to open-ended questions, or vice versa.

With DataMorgana, the user can define categorizations matching the target questions, and cover the different question types. In this case, the user defines the three categorizations shown in Table 1.

Table 2 contains sample questions created by DataMorgana using this configuration. It is easy to see that the questions are, on one hand, of the same nature as the human-generated questions (fidelity),

Categorization	Category	Description
Factuality	factoid	question seeking a specific, concise piece of information or a short fact about a particular subject, such as a name, date, or number (e.g., *'When was Napoleon born?'*).
	open-ended	question inviting detailed or exploratory responses, encouraging discussion or elaboration. (e.g., *'what caused the French revolution?'*).
Phrasing	concise-and-natural	phrased in the way people typically speak, reflecting everyday language use, without formal or artificial structure. It is a concise, direct question consisting of less than 10 words (e.g., *'what's the weather like in Paris now?'*).
End-user expertise	clinical researcher	A clinical researcher who uses the system to access population health data, conduct initial patient surveys, track disease progression patterns, etc.

Table 1: Configuration used to mimic the Covid-QA dataset.

in that they are short and discuss technical topics, and on the other, are sufficiently diverse, e.g., contain both factoid and open-ended questions. More examples generated by the Vanilla method, as well as additional examples from DeepEval and Know Your RAG systems, can be found in Appendix C.

Random Sample of Questions generated by DataMorgana
Is COVID more infectious than MERS?
How do calcium inhibitors block flavivirus infections?
How deadly was COVID compared to SARS and MERS?
How effective are neutralizing antibodies in fighting hepatitis C?
What age groups are most vulnerable to seasonal flu complications?
What factors increase risk of hantavirus outbreaks?
When do RSV infections peak in children?
What were the main symptoms of early COVID-19 cases?
Random Sample of Questions generated by Vanilla
What were the main routes of transmission for SARS-CoV-2 in the early stage of the outbreak in Wuhan, and which one was more significant?
How do humans typically get infected with hantavirus, and what activities put people at higher risk of infection?
How common are co-infections in people who have influenza, and why is this important for treatment?
Random Sample of human-generated Questions
How does MARS-COV differ from SARS-COV?
How was HFRS first brought to the attention of western medicine ?
What can respiratory viruses cause?
What is MERS mostly known as?
What is RANBP2?
What is the transmission of MERS-CoV is defined as?
What reduces the antimicrobial activities of alveolar macrophages?
Where did SARS-CoV-2 originate?

Table 2: Random sample of questions generated by DataMorgana, Vanilla, and humans for qualitative comparison.

6 Quantitative Study

As per (Alaa et al., 2022), three key aspects should be considered to assess the quality of synthetic data quality: generalization, fidelity, and diversity. Generalization applies to models like GANs that generate data based on a training set of real examples, making it irrelevant to our setting. In our context, fidelity translates to the quality of individual questions, namely the extent to which generated questions represent a plausible way a real user could interact with the system, while diversity ensures that the generated questions cover all or at least many of the questions asked by humans.

As discussed before, while achieving fidelity is essential, it can be achieved with simple methods. Diversity, however, which is no less significant, is more challenging. In the rest of this section, we first discuss quality and then diversity, after establishing that quality is maintained.

6.1 Measuring Quality

Following the definitions of Fu et al. (2024), we consider three metrics related to the question text quality: Fluency (Oh et al., 2023), Clarity (Ousidhoum et al., 2022), Conciseness (Cheng et al., 2021), and 3 metrics assessing the match between the question and document used to generate it: Relevance (Oh et al., 2023), Consistency (Honovich et al., 2022), Answerability (Ghanem et al., 2022) (see Appendix D for formal definitions). We generated 200 questions for each (corpus, method) pair. We computed all six metrics for each of these 16 benchmarks using a strong LLM (Claude Sonnet 3.5). Appendix D provides further details about the metrics, as well as the LLM prompts we used.

Results, reported in Table 3, show a consistent pattern along the benchmarks and metrics. We see near-perfect results for text quality and good results for passage match. Moreover, we see that DataMorgana is on par or better than the baselines, with the exception of passage match when compared with Vanilla, likely due to Vanilla not being constrained by the type of questions it should generate.

Next, we present an analysis of diversity and coverage across methods.

6.2 Measuring Diversity

To estimate the diversity of the generated benchmark, we use the following metrics, as suggested in (Shaib et al., 2024): to capture lexical diversity, we

Corpus	Generation Method	Text Quality			Passage Match		
		Fluency	Clarity	Conciseness	Relevance	Consistency	Answerability
Cord-19	DataMorgana	1.00	1.00	1.00	0.97	0.97	0.89
Cord-19	DeepEval	1.00	0.99	1.00	0.94	0.92	0.82
Cord-19	Know Your RAG	1.00	1.00	1.00	1.00	0.99	0.99
Cord-19	Vanilla	1.00	1.00	0.99	0.99	0.99	0.98
GovInternal	DataMorgana	0.99	1.00	1.00	0.98	0.99	0.95
GovInternal	DeepEval	0.96	0.94	0.98	0.88	0.84	0.75
GovInternal	Know Your RAG	0.99	0.99	1.00	1.00	0.99	0.98
GovInternal	Vanilla	1.00	1.00	1.00	1.00	1.00	1.00
GovExternal	DataMorgana	0.93	0.93	1.00	0.96	0.91	0.82
GovExternal	DeepEval	0.99	0.95	0.94	0.83	0.82	0.60
GovExternal	Know Your RAG	0.99	0.92	0.95	0.92	0.86	0.81
GovExternal	Vanilla	0.90	1.00	1.00	0.98	0.97	0.96
Wiki	DataMorgana	1.00	0.99	0.99	0.97	0.96	0.86
Wiki	DeepEval	1.00	0.96	0.94	0.84	0.74	0.56
Wiki	Know Your RAG	1.00	0.98	0.99	0.94	0.84	0.79
Wiki	Vanilla	1.00	1.00	1.00	0.99	0.97	0.96

Table 3: Quality results on all benchmarks and generation methods.

use N-Gram Diversity (NGD), which measures the fraction of unique n-grams (with $n \in [1, 4]$), Self-Repetition score (SR), which counts the number of instances containing at least one n-gram ($n = 4$) appearing elsewhere, and Word Compression Ratio (word-CR), which measures the compression ratio of the file containing the generated questions. To capture syntactic diversity, we measure part-of-speech compression (PoS-CR), where we convert sentences to their PoS tags and compute the compression ratio of the resulting file. To capture semantic diversity, we compute the Homogenization Score (HS), which represents the average similarity between all question embeddings. We provide the full formal definitions of these metrics in Appendix E.1.

We evaluated all four methods over the four corpora by generating 1K-3K questions per corpus (3K for Wiki, 2K for Cord-19 and GovExternal, and 1K for GovInternal), and measuring their diversity via those metrics. Table 4 contains the metrics computed for the different benchmarks. First, we note that, as expected, Vanilla shows inferior diversity across all metrics. For both semantic and syntactic diversity, one can see a clear advantage of DataMorgana compared to the baselines. For lexical diversity DataMorgana surpasses Know Your Rag, and has close performance to DeepEval in the word-CR and NGD metrics. Upon inspecting DeepEval's questions (See Table 6 in the Appendix for some examples), we noticed they tend to be verbose and use multiple technical terms. Such a property increases lexical diversity, but does not contribute to semantic or syntactic diversity, which aligns with the experiment results.

Corpus	Model	Lex			Syn	Sem
		NGD(↑)	SR	w-CR	P-CR	e-HS
GovExt	VL	1.122	0.982	6.842	10.734	0.260
	KYR	1.777	0.833	4.910	7.292	0.269
	DE	1.787	0.865	4.643	7.710	0.232
	DM	**1.838**	**0.670**	**4.415**	**6.642**	**0.178**
GovInt	VL	1.248	0.992	6.552	9.484	0.396
	KYR	2.274	0.747	4.256	6.515	0.315
	DE	**2.682**	0.507	**3.466**	5.866	0.269
	DM	2.469	**0.482**	3.802	**5.795**	**0.213**
Cord-19	VL	1.517	0.920	5.576	7.861	0.301
	KYR	2.358	0.613	3.879	6.271	0.265
	DE	2.415	0.644	**3.535**	5.885	0.251
	DM	**2.536**	**0.372**	3.701	**5.583**	**0.249**
Wiki	VL	2.662	0.533	2.665	5.824	0.068
	KYR	2.981	0.144	2.488	5.864	0.074
	DE	2.879	0.371	**2.477**	5.631	0.067
	DM	**3.016**	**0.140**	2.502	**5.397**	**0.052**

Table 4: Diversity scores of different synthetic datasets. In bold, the best results, underlined the results whose difference w.r.t. the best result is not statistically significant (see Appendix E.2 for details). We use the following shorthands for models, VL: Vanilla, KYR: Know Your RAG, DE: DeepEval, DM: DataMorgana, and for metrics, w-CR: word-CR, P-CR: part-of-speech-CR, e-HS: embedding-HS. For all metrics other than NGD, lower is better.

In addition, we measured the diversity of the methods in a setting where the number of documents is limited. Here, multiple questions must be generated from a single document, potentially limiting the diversity of the questions. Figure 1 reports the results for the four explored corpora. We set to 200 the total number of generated questions and increased the number of documents used to generate them, from 20 (i.e., 10 questions per document) to 147 for Cord-19 and 200 for GovExternal. For each of the generated benchmarks, corresponding to a different number of documents (X-axis), we measured the PoS-CR metric (Y-axis). We see that DataMorgana consistently outperforms

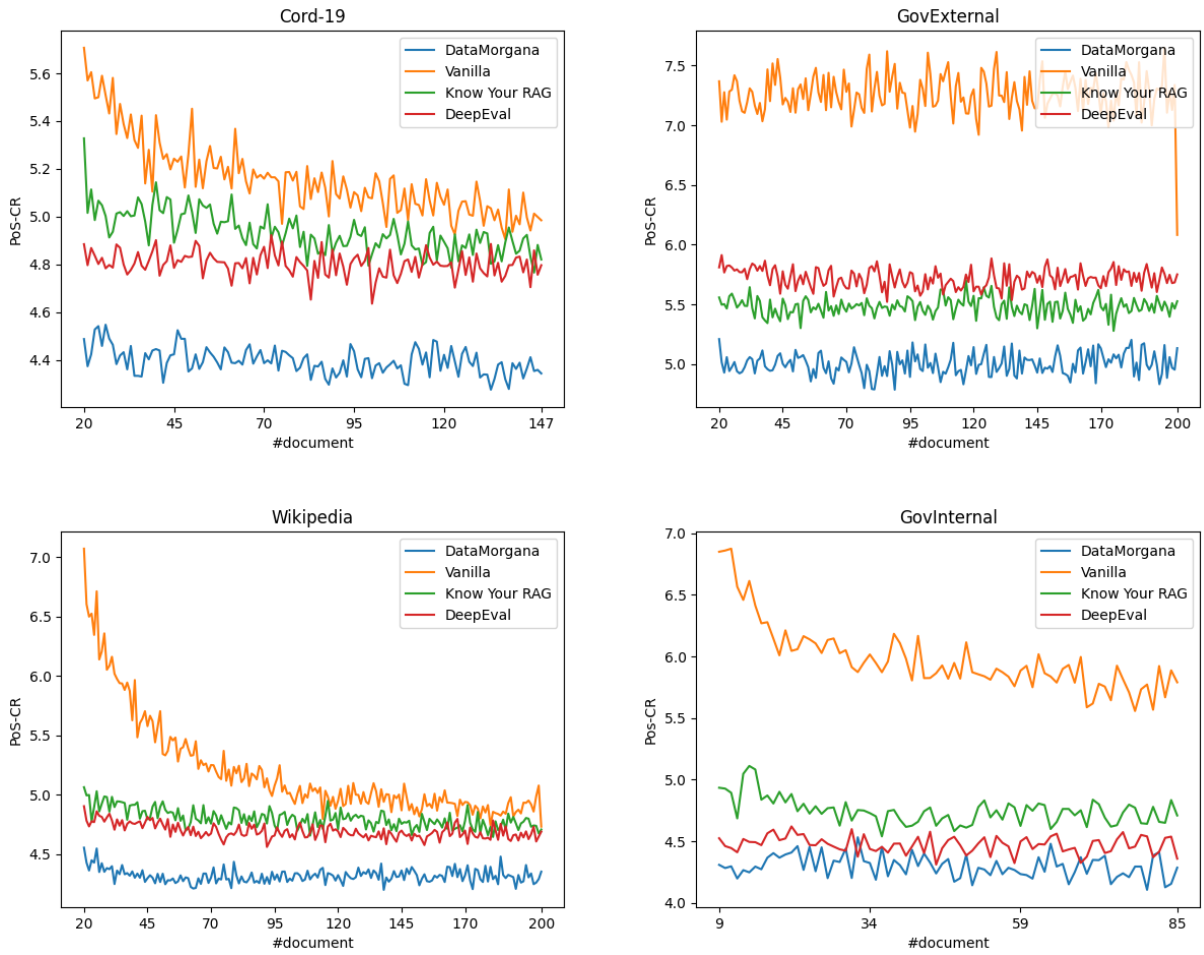

Figure 1: Syntactic PoS-CR(↓) diversity of synthetic benchmarks containing 200 questions generated from an increasing number of documents, over the CORD-19 (top-left), Wikipedia (bottom-left), GovExternal (top-right), and GovInternal (bottom-right) corpora.

the baselines for all settings.

7 Conclusion

We presented DataMorgana, a benchmark generation tool that offers simple, yet rich configuration capabilities, to tailor synthetic benchmarks to the expected traffic of a RAG application.

Through both qualitative and quantitative analyses, we showed that DataMorgana generates questions that are at the same level of quality, yet are significantly more diverse than those produced by other question generation tools. These tools typically either leave the choice of question type to the LLM, or use internal mechanisms to control question diversity.

While DataMorgana was originally designed for RAG systems evaluation, it is generic enough to be used to evaluate any Q&A system. We intend to introduce soon additional capabilities for generating other types of benchmarks, such as conversations. Additionally, we plan to extend our study of diversity, for example, to make sure that for long documents containing multiple topics, we generate questions covering all contained topics.

DataMorgana has been deployed at AI71 and has been extensively used by close to 150 researchers as part of the SIGIR'2025 LiveRAG Challenge over March-May 2025.

Acknowledgments

We are, as always grateful, to our awesome colleagues and partners at TII (Tom Beer, Ran Tavory and Oren Somekh) and AI71 (Darshan Agarwal, Mehdi Ghissassi, and Ramy Makary) for their insights and support and hard work deploying DataMorgana.

A DataMorgana Configuration

Figures 2 and 3 provide some illustrative snippets of the JSON configuration file for question categorizations. Table 5 details a set of general-purpose question categorizations and their respective categories, which can be used for most corpora. Figure 4 contains the prompt used by DataMorgana for generated a Q&A pair.

```
{
    "categorization": {
        "categorization_name": "question-factuality",
        "description": "This categorization distinguishes between factoid and non-factoid questions.",
        "categories": [
            {
                "name": "factoid",
                "probability": 0.25,
                "description": "a question seeking a specific, concise piece of information or a short
                ↪  fact about a particular subject, such as a name, date, or number."
            },
            {
                "name": "non-factoid-experience",
                "probability": 0.75,
                "description": "A question to get advice or recommendations on a particular topic."
            }
        ]
    }
}
```

Figure 2: Example of Question Categorization including factoid and non-factoid "experience" questions, as defined in the six types (i.e., instructions, reason, evidence-based, comparison, experience, and debate) of non-factoid questions suggested in (Bolotova et al., 2022).

```
{
   "categorization": {
        "categorization_name": "user-expertise-categorization",
        "description": "This categorization defines the level of expertise of end-users.",
        "categories": [
            {
                "name": "expert",
                "probability": 0.5,
                "description": "a specialized user with deep understanding of the corpus."
            },
            {
                "name": "novice",
                "probability": 0.5,
                "description": "a regular user with no understanding of specialized terms."
            }
        ]
    }
}
```

Figure 3: Example of question categorization relating to the user who might express it.

```
You are a user simulator that should generate a question to start a conversation.

The question must be about facts discussed in the document you will now receive.
Return only the question and its answer without any preamble.
Write the question-answer pair in the following JSON format:
{"question": <question>, "answer": <answer>}.

### The generated question should be about facts from the following document:
[document (d_i)]

### The generated question must reflect a user with
the following characteristics:
    - [description of user category 1 (u_1)]
    - [description of user category 2 (u_2)]
    . . .

NOTE: you must use this information only when generating the question.
Instead, while answering the question you must ignore all the user characteristics.

### The generated question must have the following characteristics:
    - The question must be understandable by a reader who does    not have access to the document
    and does not even know what the document is about.
    Therefore, never refer to the author of the document or the document itself.
    - The question must include all context needed for comprehension.
    - The question must be answerable using solely the information presented in the document.
    - [description of question category 1 (c_1)]
    - [description of question category 2 (c_2)]
    . . .

### The answer to the generated question must have the following characteristics:
    - It must be very similar to the document in terms of terminology and phrasing.
    - It should only contain claims that directly appear in the document
    or that are directly deducible from it.
    - It must be understandable by a reader who does not have access to the document.
    Therefore, never refer to the author of the document or the document itself.
    - It must not assume or contain any information about the user,
    unless it is explicitly revealed in the question.
```

Figure 4: QA generation Prompt Template.

Categorization	Category	Description
Factuality	factoid	question seeking a specific, concise piece of information or a short fact about a particular subject, such as a name, date, or number (e.g., *'When was Napoleon born?'*).
	open-ended	question inviting detailed or exploratory responses, encouraging discussion or elaboration. (e.g., *'what caused the French revolution?'*).
Premise	direct	question that does not contain any premise or any information about the user) (e.g., *'what is the fee for speeding in Italy?'*)
	with-premise	question starting with a very short premise, where the user reveals their needs or some information about himself (e.g., *'I have an H1-B visa for the United States. Is there a limit to how many times I can exit and enter the country in a year?'*).
Phrasing	concise-and-natural	phrased in the way people typically speak, reflecting everyday language use, without formal or artificial structure. It is a concise, direct question consisting of less than 10 words (e.g., *'what's the weather like in Paris now?'*).
	verbose-and-natural	phrased in the way people typically speak, reflecting everyday language use, without formal or artificial structure. It is a relatively long question consisting of more than 9 words (e.g., *'I thought of visiting Paris this year, not sure when is the best time. How is it like in the summer?'*).
	short-search-query	phrased as a typed web query for search engines (only keywords, without punctuation and without a natural-sounding structure). It consists of less than 7 words (e.g., *'Paris weather August'*).
	long-search-query	phrased as a typed web query for search engines (only keywords, without punctuation and without a natural-sounding structure). It consists of more than 6 words (e.g., *'Paris, France temperature humidity climate summer vs fall'*).
Linguistic variation	similar-to-document	phrased using the same terminology and phrases appearing in the document (e.g., for the document 'The Amazon River has an average discharge of about 215,000–230,000 m3/s', *'what is the average discharge of the Amazon river'*).
	distant-from-document	phrased using terms completely different from the ones appearing in the document (e.g., for a document 'The Amazon River has an average discharge of about 215,000–230,000 m3/s', *'How much water run through the Amazon?'*).
User expertise	expert	The user asking the question is a specialized user with a deep understanding of the corpus.
	novice	The user asking the question is a regular user with no understanding of specialized terms.

Table 5: Default configuration for DataMorgana. The examples in parentheses are for illustration only and are not necessarily part of the description to be used for generation.

B Experimental Setup Details

Corpora:

- COVID-19 Open Research Dataset (**CORD-19**) (de Lima et al., 2024) contains scientific papers on COVID-19 and related historical coronavirus research. We selected the 147 articles that biomedical experts used when generating the questions appearing in the COVID-QA dataset (Möller et al., 2020).

- **Wikipedia** is a free online encyclopedia that contains millions of articles about general human knowledge. We considered the 2682 articles containing answers to the questions in the test set of the NQ dataset (Kwiatkowski et al., 2019), containing questions asked by real users when using a search engine.

C Case Study

In Table 6, we report a random set of questions about different articles from the CORD-19 corpus, generated by different methods.

D Details of Quality experiments

We used an LLM-as-a-judge strategy for assessing quality. The chosen LLM is Claude-3.5-sonnet, with the prompt given in Figures 5,6,7). The prompt contains the definitions of the metrics, as well as few-shot examples. For each question and metric, the LLM provides a score between 1 and 3. We average the scores over each benchmark and normalize this mean by shifting it to be in the range of $[0, 1]$ via a linear shift $(\text{mean} - 1)/2)$. Namely, the presented scores are near perfect when reaching 1 and have a lower quality as they reach 0.

Model	Random Sample of Questions
Vanilla	How common are co-infections in people who have influenza, and why is this important for treatment? How do humans typically get infected with hantavirus, and what activities put people at higher risk of infection? How do humans typically get infected with pathogenic arenaviruses? How does the protein Prohibitin (PHB) affect the life cycle of the lymphocytic choriomeningitis virus? What are the main approaches being explored for developing a universal influenza vaccine using viral vectors? What are the main clinical symptoms and warning signs of severe adenovirus type 55 infection in otherwise healthy adults? What specific protective equipment and safety measures were required for healthcare workers conducting CT scans of COVID-19 patients? What were the main routes of transmission for SARS-CoV-2 in the early stage of the outbreak in Wuhan, and which one was more significant?
Know Your RAG	By how much did pneumonia deaths in children decrease between 2000-2013 due to new vaccines? How do virus-vectored flu vaccines compare to traditional vaccines in terms of safety and immune response? How does 2-bromopalmitic acid affect hantavirus host cell mineralization patterns? How does EGR1 deficiency affect BIRC5 expression during VEEV infection? What genetic similarities does the French BCoV strain share with Asian coronavirus strains? What safer alternative to live virus can be used for arenavirus neutralization testing? What starting material did the engineered E. coli platform use to generate glucose-1-phosphate for UDP-sugar synthesis? What was Germany's COVID-19 infection rate compared to other European countries during early pandemic interventions in March 2020?
DeepEval	How did World War 1's social and economic conditions make the Spanish flu pandemic more deadly, leading to over 20 million deaths? How do environmental factors like habitat fragmentation, and climate patterns affect hantavirus outbreaks and rodent populations in the Americas? How do respiratory viruses affect the airways? How would Australian-Japanese biomedical research collaboration be different today if the AIFII and ConBio conferences had never taken place? How would scientists use VP1 sequencing and viral testing to identify meningitis infections if an outbreak happened today? What are the average and highest percentage increases in COVID-19 cases predicted for China by FPASSA-ANFIS? What are the advantages and challenges of using Ad5 as a vaccine vector, particularly regarding stability, storage, delivery, and immunity issues? What's the difference between TIV, QIV, and LAIV flu vaccines, and which one provides the best protection? Which caspases are activated, and at what concentrations, when HT-29 cells are treated with Cu2 compared to untreated cells?
DataMorgana	Is COVID more infectious than MERS? How do calcium inhibitors block flavivirus infections? How deadly was COVID compared to SARS and MERS? How effective are neutralizing antibodies in fighting hepatitis C? What age groups are most vulnerable to seasonal flu complications? What factors increase risk of hantavirus outbreaks? When do RSV infections peak in children? What were the main symptoms of early COVID-19 cases?
Humans	How does MARS-COV differ from SARS-COV? How was HFRS first brought to the attention of western medicine ? What can respiratory viruses cause? What is MERS mostly known as? What is RANBP2? What is the transmission of MERS-CoV is defined as? What reduces the antimicrobial activities of alveolar macrophages? Where did SARS-CoV-2 originate?

Table 6: Random Sample of questions generated by different methods about articles from the CORD-19 corpus.

E Details of Diversity experiments

E.1 Formal definition of Diversity Metrics

For completeness, we repeat here the definitions of the diversity metrics suggested by (Shaib et al., 2024). In what follows, B is the notation used for the set of generated questions.

Definition 1 *The N-Gram Diversity (NDG) Score is defined as*

$$NDG(B) = \sum_{n=1}^{N} \frac{\#\textit{unique n-grams in } B}{\#\textit{n-grams in } B}$$

Definition 2 *The Self-Repetition Score (SR) for a natural number n, counts the fraction of questions that contain at least one n-gram that also appears in another question in the benchmark.*

Definition 3 *The Compress Ratio (CR) is the ratio between the size of the file of the benchmark, to the size of its compressed file, using* `gzip`*. Namely*

$$CR(B) = \frac{\#\textit{size of } B}{\#\textit{size of compressed } B}$$

When applied to the raw text, we refer to this metric as `word-CR`*. Conversely, we use* `PoS-CR` *to refer to the same metric applied to the Part-of-Speech tag sequence of the questions.*

Definition 4 *For a question q let v_q be the embedding vector obtained via the* `all-MiniLM-L6-v2` *sentence encoder from the Sentence Transformer package*[6]*. For questions q, q' let $sim(q, q')$ be the cosine similarity of $v_q, v_{q'}$. The Homogenization Score (HS) computes the average similarity between all question pairs in the benchmark:*

$$HS(B) = \frac{1}{|B|(|B|-1)} \sum_{q,q' \in B | q \neq q'} sim(q, q')$$

E.2 Confidence interval for diversity scores

Since the diversity metrics are not an average of point-wise scores, we had to use bootstrapping for our calculation of a confidence interval. Standard bootstrapping requires sampling with repetitions, but this would severely bias diversity metrics, especially those like NDG or SR, based on unique

[6] https://www.sbert.net/

```
You are given a passage of text along with a question about its content generated by an automated
process.
You must score it in multiple dimensions, as define below. For each dimension, we provide a
description of it, as well as guidelines for a numeric score. In all cases, the score is a number
between 1 and 3. Please provide your answer as a json response in the format {score name: score}
as shown in the examples below. Do not provide an explanation, just the json output.

## Fluency
Whether the question is wellformed, grammatically correct, coherent, and
fluent enough to be understood. Provide it one of 3 scores according to these guidelines

Score 1: The question is incoherent, with imprecise wording or significant grammatical errors,
making it
difficult to comprehend its meaning.
Score 2: The question is slightly incoherent or contains minor grammatical errors, but it does
not hinder the understanding of the question's meaning.
Score 3: The question is fluent and grammatically correct.

## Clarity
Whether the question is expressed clearly and unambiguously, avoiding excessive generality and
ambiguity

Score 1: The question is too broad or expressed in a confusing manner, making it difficult to
understand or leading to ambiguity. Particularly, if the generated sentence is not a question but
a declarative sentence, it should be considered in this situation.
Score 2: The question is not expressed very clearly and specifically, but it is possible to infer
the question's meaning based on the given passage.
Score 3: The question is clear and specific, without any ambiguity.

## Conciseness
Whether the question is concise and not abnormally verbose with redundant modifiers

Score 1: The question contains too much redundant information, making it difficult to understand
its intent.
Score 2: The question includes some redundant information, but it does not impact the
understanding of its meaning.
Score 3: The question is concise and does not contain any unnecessary information.

## Relevance
Whether the question is relevant to the given passage and asks for key
information from the passage

Score 1: The question is completely unrelated to the passage.
Score 2: The question is somewhat related to the passage and it asks for non-crucial information
related to the passage.
Score 3: The question is relevant to the context, and the information it seeks is crucial to the
passage.

## Consistency
Whether the information presented in the question is consistent with the passage and without any
contradictions or hallucinations

Score 1: The question contains factual contradictions with the passage or logical errors.
Score 2: The information sought in the question is not fully described in the passage.
Score 3: The information in the question is entirely consistent with the passage.
```

Figure 5: Quality assessment prompt, part 1.

n-grams. As a result, we implemented a version of bootstrapping based on sampling without repetition. We obtained 50 independent samples of the dataset, containing 80% of the data points. For each sample, we computed all the metrics, resulting in 50 scores for each method-metric pair. Then, for a given metric, we evaluated whether two methods have a statistically significant difference using t-test with $\alpha = 0.05$ over their score distributions.

```
## Answerability
Whether the question can be distinctly answered based on the passage

Score 1: The question cannot be answered based on the provided passage.
Score 2: The question can be partially answered based on the provided passage, or the answer to
the question can be inferred to some extent.
Score 3: The question can be answered definitively based on the given passage.

# Examples

Example 1
Passage: Richard "Rick" Ducommun (July 3, 1952 - June 12, 2015) was a Canadian actor, comedian
and writer who appeared in films and television. The Burbs is a 1989 American comedy thriller
film directed by Joe Dante starring Tom Hanks, Bruce Dern, Carrie Fisher, Rick Ducommun, Corey
Feldman, Wendy Schaal and Henry Gibson. The film was written by Dana Olsen, who also has a cameo
in the movie. The film pokes fun at suburban environments and their eccentric dwellers.

Question: What star if the Burbs was Canadian?
Scores: {"fluency": 1, "clarity: 1, "conciseness": 3, "relevance": 3, "consistency": 3,
"answerability": 1}

Example 2
Passage: At the same time the Mongols imported Central Asian Muslims to serve as administrators
in China, the Mongols also sent Han Chinese and Khitans from China to serve as administrators
over the Muslim population in Bukhara in Central Asia, using foreigners to curtail the power of
the local peoples of both lands. Han Chinese were moved to Central Asian
areas like Besh Baliq, Almaliq, and Samarqand by the Mongols where they worked as artisans and
farmers. Alans were recruited into the Mongol forces with one unit called "Right Alan Guard"
which was combined with "recently surrendered" soldiers, Mongols, and Chinese soldiers stationed
in the area of the former Kingdom of Qocho and in Besh Balikh the Mongols established a Chinese
military colony led by Chinese general Qi Kongzhi (Ch'i Kung-chih). After the Mongol conquest of
Central Asia by Genghis Khan, foreigners were chosen as administrators and co-management with
Chinese and Qara-Khitays (Khitans) of gardens and fields in Samarqand was put upon the Muslims as
a requirement since Muslims were not allowed to manage without them. The Mongol appointed
Governor of Samarqand was a Qara-Khitay (Khitan), held the title Taishi, familiar with Chinese
culture his name was Ahai.

Question: Where did the Mongols work?
Scores: {"fluency": 3, "clarity": 2, "conciseness": 3, "relevance": 3, "consistency": 3,
"answerability": 1}
```

Figure 6: Quality assessment prompt, part 2.

```
Example 3
Passage: "Domino Dancing" is a song recorded by the British synthpop duo Pet Shop Boys, released
as the lead single from their 1988 album, "Introspective". It reached number 7 on the UK Singles
Chart. Introspective is the third studio album by English synthpop duo Pet Shop Boys. It was
first released on 11 October 1988 and is the Pet Shop Boys' second-best-selling album, selling
over 4.5 million copies worldwide. (Their fifth studio album, "Very", sold more than 5 million
copies worldwide.).

Question: "Domino Dancing" is a song recorded by the British synthpop duo Pet Shop Boys, released
as the lead single from their 1988 album, "Introspective". It reached number 7 on the UK Singles
Chart, which month was the album "Introspective" first released?
Scores: {"fluency": 2, "clarity": 3, "conciseness": 2, "relevance": 3, "consistency": 3,
"answerability": 3}

Example 4
Passage: With International Criminal Court trial dates in 2013 for both President Kenyatta and
Deputy President William Ruto related to the 2007 election aftermath, US President Barack Obama
chose not to visit the country during his mid-2013 African trip. Later in the summer, Kenyatta
visited China at the invitation of President Xi Jinping after a stop in Russia and not having
visited the United States as president. In July 2015 Obama visited Kenya, as the first American
president to visit
the country while in office.

Question: Why did President Kenyatta and Deputy President William Ruto not visit the United
States in 2013?
Scores: {"fluency": 3, "clarity": 3, "conciseness": 3, "relevance": 3, "consistency": 2,
"answerability": 1}

Example 5
Passage: Even before Washington returned, Dinwiddie had sent a company of 40 men under William
Trent to that point, where in the early months of 1754 they began construction of a small
stockaded fort. Governor Duquesne sent additional french forces under Claude-Pierre Pecaudy de
Contrecœur to relieve Saint-Pierre during the same period, and Contrecœur
led 500 men south from Fort Venango on April 5, 1754. When these forces arrived at the fort on
April 16, Contrecœur generously allowed Trent's small company to withdraw. He purchased their
construction tools to continue building what became Fort Duquesne.

Question: How many men did Duquesne send to relieve Saint-Pierre?
Scores: {"fluency": 3, "clarity": 3, "conciseness": 3, "relevance": 3, "consistency": 3,
"answerability": 3}

Example 6
Passage: There are fifteen fraternities and seven sororities at the University of Chicago, as
well as one co-ed community service fraternity, Alpha Phi Omega. Four of the sororities are
members of the National Panhellenic Conference, and ten of the fraternities form the University
of Chicago Interfraternity Council. In 2002, the Associate Director of Student Activities
estimated that 8-10 percent of undergraduates were members of fraternities or sororities. The
student activities office has used similar figures, stating that one in ten undergraduates
participate in Greek life.

Question: How many fraternities are at the University of Chicago?
Scores: {"fluency": 3, "clarity": 3, "conciseness": 3, "relevance": 3, "consistency": 3,

Grammar-Constrained Decoding Makes Large Language Models Better Logical Parsers

Federico Raspanti **Tanir Ozcelebi** **Mike Holenderski**
Eindhoven University of Technology, Eindhoven, The Netherlands
{f.raspanti, t.ozcelebi, m.holenderski}@tue.nl

Abstract

Large Language Models (LLMs) have shown capabilities in various natural language processing tasks, yet they often struggle with logical reasoning, particularly when dealing with complex natural language statements. To address this challenge, approaches that combine LLMs with symbolic reasoners have been proposed, where the LLM translates the natural language statements into symbolic representations, which are then verified by an external symbolic solver. However, ensuring syntactic correctness in these translations remains a significant challenge. To address this, we propose to constrain the outputs of the LLMs using Grammar Constrained Decoding (GCD), showing that it consistently improves both syntactic correctness and accuracy in logical parsing tasks. Our findings demonstrate that grammar constraints can complement in-context examples, especially beneficial for resource-constrained applications using smaller models. However, we observe that while GCD ensures syntactic validity, semantic errors not captured by Context-Free Grammars continue to pose challenges. Additionally, our results reveal a trade-off for larger models where unconstrained generation occasionally outperforms constrained decoding, aligning with recent theoretical work on bias introduced by constrained decoding. Our code and data is publicly available at: https://github.com/federaspa/gcd-llm-logical-parsing

1 Introduction

In recent years, Large Language Models (LLMs) (Devlin et al., 2019; Brown et al., 2020; Achiam et al., 2023; Team et al., 2023; The; Touvron et al., 2023) have shown increasing capabilities for logical reasoning, especially when guided with prompting techniques such as few-shot examples (Parnami and Lee, 2022) and Chain-of-Thought (CoT) prompting (Wei et al., 2022).

The reasoning capabilities of these models have traditionally been evaluated on standardized benchmarks like GSM8K (Cobbe et al., 2021), where LLMs are tasked with solving an arithmetic problem, demonstrating increasingly impressive performance. This apparent progress has led to optimistic interpretations about LLMs' ability to perform genuine reasoning.

However, recent studies have shown that polluting problems, by randomly selecting symbols or adding irrelevant information, significantly degrades performance in all state-of-the-art models (Mirzadeh et al., 2024). These findings indicate that rather than developing true reasoning capabilities, LLMs may primarily be learning to reproduce training examples with minor variations.

To tackle this challenge, an increasingly popular approach is to *decouple* the reasoning process, using LLM to convert natural language problems into symbolic representations, treating them as logical *parsers*, and then using symbolic solvers to determine the outcome of the logical problem (e.g. True, False, and in some cases Undecidable) (Pan et al., 2023; Feng et al., 2023; Wang et al., 2024).

This approach has been shown to increase accuracy on symbolic reasoning tasks, but introduces the new challenge of respecting the syntax required by the solver when converting the problems into symbolic representations, which has typically been addressed in two, non-mutually exclusive ways: by providing in-context examples to the LLM (In-Context Learning, ICL), and by relying on the LLM's ability to identify and correct its own mistakes (Self-Verification) (Pan et al., 2023; Wang et al., 2024; Feng et al., 2023). Both solutions were proven to be effective in improving syntactic correctness, but neither provides strong guarantees.

In this context, GCD emerges as a promising approach to *guarantee* syntactic correctness in symbolic representations. GCD works by dynamically constraining the model's output space during gen-

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 485–499

eration, ensuring that only grammatically valid sequences can be produced (Geng et al., 2024b; Park et al., 2024). This approach differs from previous methods in that it provides deterministic guarantees about the syntax of the generated output.

Recent findings (Tam et al., 2024) demonstrated that grammar constraints can significantly degrade LLM reasoning abilities when reasoning is performed directly by the language model. This raises the question of whether this still holds when decoupling the reasoning process. We hypothesize that, when using LLMs strictly as parsers and delegating the reasoning to specialized solvers, the constraints on generation will increase the syntactic correctness of the symbolic representations, which will in turn increase downstream accuracy.

This paper focuses on the following research questions (RQs).

RQ1. *Can GCD improve the performance of LLMs as logical parsers, measured by accuracy on a downstream task?*

RQ2. *How effective is GCD for compensating in-context learning, measured by accuracy on a downstream task?*

RQ3. *How does the impact of GCD vary with model size, measured by accuracy on a downstream task?*

The paper is organized as follows. Section 2 discusses related work in LLMs as logical solvers and GCD. Section 3 introduces our methodology. Section 4 introduces our experimental setup and evaluation methodology. Section 5 presents our main results and empirical findings, discussed in Section 6. Section 7 presents a summary of our contributions and findings. Finally, Section 8 concludes with the limitations of our approach and discusses future work.

2 Related Work

2.1 Logical Reasoning with LLMs

The development of logical reasoning capabilities in LLMs has seen significant progress through various approaches. Wei et al. (2022) introduced Chain-of-Thought (CoT) prompting to break down complex reasoning into steps, while Kojima et al. (2023) demonstrated that simply prompting LLMs to "think step by step" could achieve similar results without examples. To address inconsistencies in LLMs' logical reasoning, Creswell et al. (2022) developed the Faithful Reasoning framework, combining LLMs with automated reasoning tools.

Recent research has focused on integrating LLMs with symbolic solvers, treating LLMs as logical *parsers* rather than *reasoners*. Pan et al. (2023) introduced Logic-LM, which combines LLMs (GPT-3.5-Turbo, GPT-4-Turbo) with symbolic solvers (Prover9, Z3, Pyke) and includes a self-refinement loop to handle invalid formulas. Wang et al. (2024) developed ChatLogic, integrating LLMs with a pyDatalog reasoning engine and incorporating semantic and syntax correction modules. While their approach attempts to guide syntax corrections through prompting, they noted that these corrections were unreliable. We propose to address this limitation by enforcing syntax using GCD, with the aim of improving the reliability of problem generation.

2.2 Grammar-Constrained Decoding

GCD has emerged as an effective method for constraining LLM outputs to respect user-defined rules, particularly when models haven't been extensively trained on domain-specific syntax. Two main approaches have been developed to achieve grammatical adherence: grammar prompting, which guides LLMs to follow specific grammars like those written in Backus-Naur form, and GCD itself, which directly constrains the decoding process (Wang et al., 2023).

At the core of GCD is a Context-Free Grammar (CFG), which consists of non-terminals (V), terminals (E), production rules (R), and a starting symbol (S). A simple example of such a grammar is shown below:

```
S ::= NP VP
NP ::= Det N
VP ::= V NP
Det ::= "the" | "a"
N ::= "cat" | "dog"
V ::= "chases" | "sees"
```

Listing 1: An example of a CFG grammar

During the decoding process, the language model's output is restricted to sequences that can be derived from the defined grammar. The model's vocabulary is filtered to include only grammatically valid tokens at each step, with probabilities redistributed among these options. This process involves expanding non-terminals and backtracking when necessary until a complete, syntactically correct sequence is generated.

Early work in this field includes GrammarCNN (Sun et al., 2019), which incorporated grammar

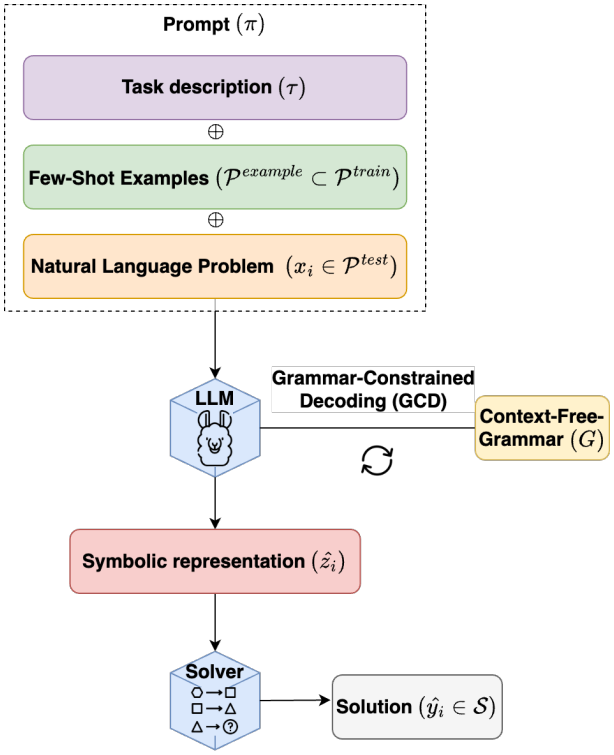

Figure 1: Full pipeline. The LLM processes a prompt made of a task description τ, examples $\mathcal{P}^{\text{example}}$, and a Natural Language problem x_i. We use GCD to generate syntactically valid symbolic representations $\hat{z}_i$, which are evaluated by a solver to produce the final solution $\hat{y}_i$.

knowledge into convolutional neural networks, and the CTRL model (Keskar et al., 2019), which used control codes to generate text with specific attributes. However, CTRL's approach was limited by the need to train the model on selected control codes, making it less suitable for domain-specific or data-scarce fields.

More recent developments include the sketch-based method of Geng et al. (2024a), where a grammar-constrained LLM rewrites the output of a powerful black-box model.

Recently Tam et al. (2024) demonstrated that grammar constraints can significantly degrade LLM reasoning abilities. However, while they argue for avoiding such constraints to preserve reasoning capabilities of LLMs, we argue that the benefits of reliable structured output outweigh the potential reasoning degradation if we focus LLM on parsing and delegate the reasoning to a symbolic solver.

3 Method

We illustrate our methodology in Figure 1.

Step 1: Problem formulation

In the first step, we use an LLM to extract symbolic representations of natural language problems.

Consider two labeled sets of problems, $\mathcal{P}^{\text{train}} = \{(x_i, y_i)\}_{i=1}^{N^{\text{train}}}$ and $\mathcal{P}^{\text{test}} = \{(x_i, y_i)\}_{i=1}^{N^{\text{test}}}$, where x_i is a problem expressed in natural language, and $y_i \in \mathcal{S}$ is the ground truth solution to this problem in some domain $\mathcal{S}$. Let z_i be a symbolic representation of the problem x_i (there may be many valid representations for a given x_i).

Let G be a Context-Free Grammar, τ a task description, and $\mathcal{P}^{\text{example}}$ a set of examples, with $\mathcal{P}^{\text{example}} \subset \mathcal{P}^{\text{train}}$.

Let $\pi_i = \tau \oplus \mathcal{P}^{\text{example}} \oplus x_i$ be the prompt for the problem x_i, where $\oplus$ denotes concatenation [Section A]. Then, we define $\hat{z}_i$ as:

$$\hat{z}_i = \text{LLM}(\pi_i; G) \tag{1}$$

where $\text{LLM}(\cdot; G)$ is a function that takes a prompt as input and produces output that is consistent with grammar G.

Step 2: Problem solution

Let $\text{Solver}(\hat{z}_i) \in \mathcal{S} \cup \{\perp\}$ be the solution returned by the symbolic solver to a problem in its symbolic representation $\hat{z}_i$, where $\text{Solver}(\hat{z}_i) = \perp$ indicates that $\hat{z}_i$ is invalid, i.e., it contained a syntax error and could not be solved. We define the predicted solution $\hat{y}_i$ as:

$$\hat{y}_i = \text{Solver}(\hat{z}_i) \tag{2}$$

4 Experiments and evaluation

4.1 Experiments

We designed three experiments to evaluate three different aspects of GCD for LLMs as logical parsers. First, we compare outputs between unconstrained generation (Unc.) and generation constrained by domain-specific grammar (Const.). Second, we investigate how well GCD can compensate for In-Context Learning, by combining grammar constraints with zero-shot, two-shot, and five-shot prompting. Third, we assess the impact of GCD and In-Context Learning across models of varying parameter counts. We measure performance in terms of semantic accuracy (comparing solver outputs to ground truth) and syntactic accuracy (percentage of generated programs that parse without errors), as described in Sec. 4.3. For each experiment, we perform independent runs and report the

mean and standard deviation of the results in Tables 1 and 2.

4.2 Models

We selected open-source LLMs from four families: Gemma (2B, 9B, 27B), Llama (1B, 3B, 8B), Mistral (8B, 22B), and Qwen (0.5B, 1.5B, 3B, 7B, 14B). Within each family, we chose variants of different parameter counts, to investigate GCD's impact across a different model architectures and sizes. All models are instruction-tuned variants.

4.3 Metrics

We measure the semantic accuracy (**Accuracy**, Eq. 3) of the predicted symbolic representation by running all programs through the symbolic solver and comparing the result with the ground truth. We consider failure to parse the symbolic representation (i.e. the solver returning an error) as a wrong answer. We also measure the syntactic accuracy (**Executable Rate**, Eq. 4) of generated programs by observing the fraction of generated programs that the solver can run without incurring an error.

$$\text{Accuracy} = \frac{\sum_{i=1}^{N} \mathbf{1}(\hat{y}_i = y_i)}{N} \tag{3}$$

$$\text{Executable Rate} = \frac{\sum_{i=1}^{N} \mathbf{1}(\hat{y}_i \neq \bot)}{N} \tag{4}$$

where $\mathbf{1}$ is the indicator function (1 if true, 0 if false).

First we highlight that, since there can only be as many correct answers as valid symbolic representations, Accuracy $\leq$ Executable Rate.

Second, we highlight that **we may achieve 0 Accuracy if none of the symbolic representations were valid**. This does not mean that flipping all predictions would yield perfect accuracy, but rather indicates complete failure at producing syntactically valid formulas that the solver can process.

Finally, we note that while GCD ensures that generated outputs conform to the specified grammar, semantic errors can still occur that prevent successful execution. These semantic errors are not captured by the CFG but still result in solver failures ($\hat{y}_i = \bot$). For instance, in FOL generation, a predicate with the same name may appear with different arities in the same problem (e.g., `Predicate(x)` and `Predicate(x, y)`) or in arithmetic problems, variable references might refer to variables not previously declared in the problem. This explains why even with grammar constraints, we observe executable rates below 1.0, particularly for smaller models that may struggle with maintaining semantic consistency.

4.4 Datasets and Solvers

We evaluate the proposed method on two datasets that contain problems from two branches of mathematics: first-order logic (FOL) and arithmetic.

First-order logic

For FOL, we chose *FOLIO* (Han et al., 2024), a dataset for logical reasoning constructed by domain experts. The problems incorporate real-world knowledge with natural language formulations, requiring complex logic reasoning to get a solution. Our evaluation utilizes the complete FOLIO test set, comprising 204 distinct examples.

For the solver, we chose *Prover9* (McCune, 2005–2010), a widely accepted automated theorem prover for FOL. Following the implementation approach of Pan et al. in Logic-LM (Pan et al., 2023), we integrated Prover9 into our pipeline through Python's NLTK library, to evaluate both the syntactic correctness and the outcome of the generated formulas.

Arithmetic

For arithmetic, we chose *GSM-symbolic* (Mirzadeh et al., 2024), a dataset derived from the GSM8K (Cobbe et al., 2021) math word problem benchmark, where the problems are reformulated to account for data contamination in previously released LLMs. The problems incorporate arithmetical knowledge with natural language formulations. This evaluation utilizes a subset of 1000 randomly sampled samples from the GSM-symbolic test set.

For the solver, we used SymPy, a Python library for symbolic arithmetic. We generate the problems in standard infix notation (SIN) and implement a wrapper around SymPy to parse and evaluate the symbolic representations.

5 Results

We report the average results of our runs in Tables 1 and 2, showing the impact of GCD on accuracy and executable rate respectively. Our results indicate that grammatical constraints provide the most benefits to smaller models and in resource-constrained scenarios where few or no examples are available.

Table 1: Accuracy of LLMs as logical parsers across different model sizes and prompting strategies (0-shot, 2-shot, 5-shot) with unconstrained (Unc.) versus grammar-constrained (Con.) decoding on GSM-symbolic and FOLIO datasets. As highlighted in Section 4.3, Accuracy $\leq$ Executable Rate in Table 2. We may achieve zero Accuracy if all the symbolic representations were invalid.

5.1 Grammar Constraints

Both in terms of accuracy and executable rate FOL syntax constraints outperform the unconstrained baseline. The impact is most significant when looking at executable rate, where FOL constraints achieve above 0.70 executable rate even with smaller models that show near-zero executable rate in unconstrained conditions. For small models like gemma2-2b and qwen2.5-3b, after introducing the constraints, we go from producing almost no executable outputs to achieving high rates of executable outputs.

5.2 In-Context Learning

Few-shot prompting enhances accuracy and executable rate across all settings. We observe that in many cases the relative improvement from introducing few-shot examples is smaller with GCD compared to the unconstrained baseline. Moreover, we observe that, in most cases, GCD with 0 shots achieves higher accuracy than unconstrained decoding with 5 shots, and comparable accuracy to GCD and 5 shots. This indicates that GCD can compensate for the absence of examples in the 0 shots setting.

5.3 Model Size

The benefits of GCD can be observed on all model sizes, although they are proportionally more significant for smaller models and fewer shots. For instance, with 0 shots, smaller models show more improvements in accuracy when using GCD compared to their larger counterparts. The largest models in our test suite show increases in accuracy with zero-shot prompting, but show diminishing returns when example shots are increased.

Notably, for the largest models ($\geq$ 14B) with multiple shots, we observe instances where unconstrained decoding achieves comparable or occasionally greater accuracy (Table 1), suggesting that model capacity and number of examples can influence the effectiveness of grammar constraints.

This pattern becomes clearer when comparing accuracy with executable rates: while larger models maintain high executable rates under constraints, their accuracy sometimes decreases, suggesting a trade-off between syntactic validity and semantic correctness.

6 Discussion

RQ1.

Our results show that GCD improves the performance of LLMs, when they are used as logical parsers. The experiments show consistent improvements in both accuracy and executable rate across model sizes and number of examples.

This improvement in parsing execution rate directly translates to improved reasoning of the overall system, since the symbolic solver can only

process syntactically valid formulas. This enables more problems to be successfully processed through the complete reasoning pipeline, resulting in higher end-to-end accuracy on logical reasoning tasks.

RQ2.

We show that models using GCD with zero-shot prompting achieve only slightly lower performance compared to unconstrained models using five-shot prompting. This can be valuable in domains where creating high-quality examples requires expert knowledge or where prompt length limitations do not allow for demonstrations.

However, our findings also indicate that GCD and in-context learning are complementary rather than mutually exclusive approaches. The highest performance was often achieved by combining GCD with multiple examples, indicating that, while GCD can compensate for limited examples, it does not fully replicate the guidance provided by in-context learning. This suggests that, when resources permit, practitioners should consider implementing both strategies.

RQ3.

Smaller models experience greater improvements from GCD compared to their larger counterparts. This finding indicates that GCD could help democratize logical parsing capabilities by making smaller, more accessible models perform more reliably.

However, our findings also reveal that for larger models with few-shot examples, unconstrained generation occasionally outperforms constrained decoding. This phenomenon has been theoretically and empirically validated by recent work. Ye et al. (2025) proved that constrained decoding introduces bias into output distributions, demonstrating a significant KL-divergence between the true distribution and the constrained decoding distribution. We hypothesize that, for smaller models, grammatical constraints can skew the distribution of the outputs towards more appropriate ones, but as models grow in size their learned representations become "good enough" to perform the parsing, and the bias introduced by the constraints degrades the output.

7 Conclusion

In this work, we investigated the effectiveness of GCD for improving Large Language Models when used as logical parsers in problem-solving pipelines. By separating the parsing task from the reasoning process and delegating logical inference to symbolic solvers, we examined whether syntactic constraints could improve the accuracy of these systems.

Our experiments across thirteen open-source LLMs, ranging from 0.5B to 27B parameters, demonstrate that GCD significantly improves syn-

tactic correctness and downstream semantic accuracy. We found that smaller models benefit most from grammatical constraints, with models like gemma2-2b achieving executable rates above 60% in FOL tasks when constrained, compared to near-zero rates without constraints. This pattern suggests that GCD could democratize logical parsing capabilities by enabling smaller, more resource-efficient models to perform reliably in formal reasoning tasks.

The results also reveal that GCD can effectively compensate for limited in-context examples. In many cases, zero-shot prompting with grammar constraints achieved comparable or superior performance to five-shot unconstrained generation. This finding has practical implications for domains where expert-annotated examples are scarce or expensive to obtain. However, we observed that GCD and in-context learning are complementary approaches, with the highest performance often achieved by combining both strategies.

Our work contributes to the broader discussion about the role of syntactic guidance in language model generation. While recent theoretical work suggests that constraints may introduce bias and reduce reasoning capabilities, our empirical results indicate that this trade-off can be beneficial when models are used specifically as parsers rather than reasoners. Using LLMs for natural language understanding and symbolic solvers for logical inference appears to be a promising direction for building more reliable AI systems that can handle formal reasoning tasks.

8 Limitations

First, our implementation relies on CFGs that cannot capture context-sensitive constraints found in some reasoning tasks. While GCD based on CFGs improves syntactic correctness, guaranteeing semantic accuracy remains challenging. Our approach significantly increases syntactic validity and downstream semantic accuracy, but it does not ensure that the generated formulas correctly capture the meaning of natural language statements. As noted in Section 5, even with grammar constraints, executable rates below 1.0 indicate the presence of semantic errors that pass syntactic validation but fail during solver execution. For instance, predicate consistency violations, variable scope constraints, and other semantic requirements that extend beyond CFG expressivity continue to pose challenges. Future work could explore extensions to context-sensitive grammars or integration with semantic verification systems.

Second, our evaluation focused on two specific branches of mathematics: FOL and arithmetic reasoning. While these domains demonstrate the approach's effectiveness, extending to other branches of mathematics or fields entirely, such as computational chemistry or physics, would require domain-specific grammar definitions and may reveal additional challenges.

Third, we observed that larger models with few-shot examples occasionally exhibit performance degradation under constraints. As discussed in Section 6, this aligns with theoretical work by Ye et al. (2025) showing that constrained decoding introduces bias into output distributions. This suggests that the benefits of GCD may be model-dependent.

Finally, our approach uses statically defined grammars that remain fixed throughout execution. Adaptive grammars that evolve based on solver feedback or parsing errors could potentially improve performance. Additionally, incorporating semantic information from partial parses to optimize grammar rules based on task performance could address limitations in capturing complex logical relationships (Loula et al., 2025; Albinhassan et al., 2025).

A Prompts

When designing our prompts, we follow the implementation of (Pan et al., 2023), adapting it to our use-cases. We ask the model to generate its output in JSON format, to facilitate parsing its answers to interact with the symbolic solver by making symbolic rules and questions easy to identify.

When we provide examples in the prompt, we do so in JSON format, to guide the generation in our desired format [Listings 2, 3, 4, 5].

A.1 First-order-logic prompts

```
### TASK DESCRIPTION ###

The task is to convert a natural
     language reasoning problem into
     first-order logic.
First, identify the predicates and
     constants required to build the
     first order logic formulas.
Then, use them to build the rules and
     the conclusion.
Do not attempt to prove or disprove the
     conclusion, limit yourself to
     converting.

You reply strictly in JSON format, with
     the following schema:
"""
{
"fol_preds": [list of required FOL
     Predicates],
"fol_consts": [list of required FOL
     Constants],
"fol_rules": [list of generated FOL
     Rules],
"fol_conc": [generated FOL Conclusion]
}
"""

### NATURAL LANGUAGE PROBLEM ###

Now let's convert this problem to first-
     order logic:

NL premises:
"""
[[nl_problem]]
"""

NL conclusion:
"""
[[nl_conclusion]]
"""
```

Listing 2: Zero-shot prompt template for generating FOL problems

```
### TASK DESCRIPTION ###

The task is to convert a natural
     language reasoning problem into
     first-order logic.
First, identify the predicates and
     constants required to build the
     first order logic formulas.
Then, use them to build the rules and
     the conclusion.
Do not attempt to prove or disprove the
     conclusion, limit yourself to
     converting.

You reply strictly in JSON format, with

     Constants],
"fol_rules": [list of generated FOL
     Rules],
"fol_conc": [generated FOL Conclusion]
}
"""

### EXAMPLES ###

Here's an example of how to perform the
     conversion:

[[example1]]

###

Here's another example:

[[example2]]

###

...

### NATURAL LANGUAGE PROBLEM ###

Now let's convert this problem to first-
     order logic:

NL premises:
"""
[[nl_problem]]
"""

NL conclusion:
"""
[[nl_conclusion]]
"""
```

Listing 3: Few-shot prompt template for generating FOL problems

A.2 Arithmetic prompts

```
### TASK DESCRIPTION ###

The task is to convert a natural
    language reasoning problem into
    standard infix notation.
First, identify all the relevant
    variables and their values or
    expressions.
Then, write each variable assignment in
    standard infix notation.
Finally, formulate the equation to solve
     using these variables, also in
    standard infix notation.
Do not attempt to solve the problem,
    limit yourself to converting

You reply strictly in JSON format, with
    the following schema:
"""
\{
"data": [list of relevant variable
    assignment],
"question": [equation to solve]
\}
"""

### NATURAL LANGUAGE PROBLEM ###

Now let's convert this problem to
    standard infix notation.

"""
[[nl_problem]]
"""
```

Listing 4: Zero-shot prompt template for generating GSM problems

```
### TASK DESCRIPTION ###

The task is to convert a natural
    language reasoning problem into
    standard infix notation.

Listing 5: Few-shot prompt template for generating GSM problems

B Grammars

We write our grammars in the GBNF (Graydon's BNF) format, a variation of the Backus-Naur Form specifically designed for use with language models (GBNF Guide).

Due to limitations in the llama.cpp library (Recursive Grammar Issue), we modified our approach by unrolling the grammars to handle formulas nested up to arbitrary depth [Listings 6 and 7].

```
#### Wrap data and question in a valid
     JSON ####
root ::= "{" ws data ws quest ws "}"

ws ::= | " " | "\n" [ \t]{0,5}

data ::= "\"data\":" ws "[" ws datalist
     ws "], "
datalist ::= "\"" ASSIGNMENT "\"" (ws
     "," ws "\"" ASSIGNMENT "\"")*

quest ::= "\"question\":" ws "\""
     EXPRESSION "\""

#### Mathematical Expressions ####
ASSIGNMENT ::= variable " = " EXPRESSION

EXPRESSION ::= TERM TAIL{0,5}
TAIL ::= OPERATOR TERM

# Terms can be numbers, variables, or
     parenthesized expressions
TERM ::= number | variable | "("
     EXPRESSION ")"

# Operators
OPERATOR ::= " + " | " - " | " * " | " /
      "

# Basic elements
number ::= [0-9]+ ("." [0-9]+)?
variable ::= [a-z_][a-z0-9_]*
```

Listing 6: Grammar for generating valid SIN problems

```
#### Wrap predicates, constants, rules
     and conclusion in a valid JSON ####
root ::= "{" ws preds ws consts ws rules
      ws conc ws "}"

ws ::= | " " | "\n" [ \t]{0,5}

preds ::= "\"fol_preds\":" ws "[" ws
     predslist ws "], "
predslist ::= "\"" ATOMIC "\"" (ws ","
     ws "\"" ATOMIC "\"")*

consts ::= "\"fol_consts\":" ws "[" ws
     constlist ws "], "
constlist ::= "\"" constant "\"" (ws ","
      ws "\"" constant "\"")*

rules ::= "\"fol_rules\":" ws "[" ws
     rulelist ws "], "
rulelist ::= "\"" FORMULA "\"" (ws ","
     ws "\"" FORMULA "\"")*

conc ::= "\"fol_conc\":" ws "\"" FORMULA
      "\""

#### Generate FOL Formulas ####
FORMULA ::= BASIC TAIL{0,5}
TAIL ::= BINOP BASIC

# Basic formula without recursion
BASIC ::= "¬"? ATOMIC | QUANTIFIED | "¬
     "? "(" FORMULA ")"

# Quantified formulas
QUANTIFIED ::= (quantifier variable " ")
     {1,4} "(" FORMULA ")"
quantifier ::= "∀" | "∃"
variable ::= [a-z]

# Binary operators
BINOP ::= " ⊕ " | " ∨ " | " ∧ " | " → "
     | " ↔ "

# Atomic formulas
ATOMIC ::= predicate "(" terms ")"

# Terms in predicates
terms ::= term | term ", " terms

# Individual terms
term ::= constant | variable

# Basic elements
predicate ::= [A-Z][a-zA-Z0-9]+
constant ::= [a-zA-Z0-9]+
```

Listing 7: Grammar for generating valid FOL problems

C Detailed results

Tables 3-6 provide performance metrics (Accuracy and Executable Rate) for all evaluated models across both datasets (FOLIO and GSM-symbolic) under different prompting conditions (0-shot, 2-shot, and 5-shot) with both unconstrained and grammar-constrained decoding. All results are presented as mean $\pm$ standard deviation.

Abstract

We present AUTOSUMM, a large language model (LLM)-based summarization system deployed in a regulated banking environment to generate accurate, privacy-compliant summaries of customer-advisor conversations. The system addresses challenges unique to this domain, including speaker attribution errors, hallucination risks, and short or low-information transcripts. Our architecture integrates dynamic transcript segmentation, thematic coverage tracking, and a domain specific multi-layered hallucination detection module that combines syntactic, semantic, and entailment-based checks. Human-in-the-loop feedback from over 300 advisors supports continuous refinement and auditability.

Empirically, AUTOSUMM achieves a 94% factual consistency rate and a significant reduction in hallucination rate. In production, 89% of summaries required no edits, and only 1% required major corrections. A structured model version management pipeline ensures stable upgrades with minimal disruption. We detail our deployment methodology, monitoring strategy, and ethical safeguards, showing how LLMs can be reliably integrated into high-stakes, regulated workflows.

1 Introduction

Large Language Models (LLMs) have revolutionized natural language processing and have spawned numerous applications. Organizations are racing to incorporate LLMs into their use cases seeking to replicate the success and deliver transformational value. However, deployment of LLM-based solutions presents distinct challenges that are further exacerbated in regulated environments, such as banks, where customer and data privacy need to be sanctimoniously preserved, and standards of ethics and governance have to be met. Domain adaptation, monitoring, detecting hallucinations and explainability are additional challenges that need to be considered. (Meskó and Topol, 2023, Wu et al., 2024, Mökander et al., 2024, Zhao et al., 2024, Wan et al., 2024, Kim et al., 2023, Das et al., 2024)

Using LLMs to summarize larger volumes of textual information into a smaller, more manageable size is useful for many business applications and processes. In the financial domain, research and work on summarization have focused on documents such as earnings reports, product and process descriptions. The dynamic nature of human conversations coupled with domain-specific context poses challenges in summarizing conversations and extracting key information. Recent studies on financial text summarization (Mukherjee et al., 2022, Khatuya et al., 2024) highlight progress, but further innovation is needed to meet regulatory and accuracy requirements.

We showcase AUTOSUMM, a successfully deployed end-to-end solution that uses an LLM to summarize various customer conversations that occur during a customer's banking relationship journey. Our solution features a robust summarization capability designed to meet bespoke requirements and support a wide range of conversation scenarios such as meetings and multi-participant dialogues. The solution ecosystem includes modules that monitor and manage changes to data and model performance to drive operational efficiency. [*]

A key insight from our implementation is the importance of maintaining balance across contrasting parameters. Incorporating the right level of human oversight with automation is one such instance. AUTOSUMM leverages LLMs for initial summaries while incorporating systematic feedback from users to mitigate risks.

The primary contribution of this work is a practical, end-to-end solution that serves as a template for deploying LLM-based systems at scale within regulated enterprise environments. In addition, we

[*]The authors' names are listed alphabetically, with all contributing equally.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 500–509

present custom techniques for data quality assessment, model and data monitoring, and hallucination detection, all tailored to incorporate domain-specific constraints and operational realities. Our findings also offer empirical insights from large-scale production deployment in the banking sector, highlighting both technical challenges and process-level learnings. Collectively, these contributions demonstrate that with appropriate guardrails, LLM-based summarization can be reliably and compliantly integrated into high-stakes, regulated workflows.

2 Solution Overview

AUTOSUMM has been designed and developed for summarizing customer-advisor conversations to improve operational efficiency, cost-reduction, and enhance customer engagement. Figure 1 illustrates the overall architecture of the solution that comprises of Core Summarization module along with other modules to support operational and governance requirements. The AUTOSUMM solution is currently deployed for one business area, processing approximately 12,000 customer conversations/month and delivering summaries to over 300 advisors. The generated summaries maintain consistency across advisors and have removed the necessity for them to manually compose follow-up call notes, resulting in an average time savings of 15 minutes per call.

Audio recorded from phone calls and meetings between customers and banking advisors is transcribed by an off-the-shelf transcription service. The Core Summarization module processes the transcripts and generates summaries, which are then presented to the advisors for review. Summaries and transcripts are saved to the Customer Relationship Management (CRM) system, establishing a record of each client conversation.

2.1 Data Specification and User Requirements

Our solution processes diverse call transcriptions, varying in length, noise, ambiguity, and type. These include short internal calls and lengthy annual reviews, in addition to routine check-ins and portfolio transfers. To ensure consistent output, a standardized summary format is utilized. To gain a deeper understanding of business needs within specific areas and summary format, a workshop was held with relationship managers (advisors) to identify the most critical thematic extracts. From this session, six key themes were identified, as shown in Table 1: actions, hard facts, soft facts, queries and status, financial objectives, and portfolio positions. The LLM prompt is specifically tailored to focus on these six themes during the transcript summarization process. The summaries must be concise and presented in bullet points, emphasizing the two most important actions and covering all six key themes (an example summary is included in Appendix A.1). Furthermore, summaries must be delivered within 60 minutes, adhere to word limits based on call duration (as outlined in Table 2), and accurately reflect numeric and financial details.

Table 1: Summary Themes and Descriptions

Themes	Description
Soft Facts	Insights into the client's broader personal situation and evolving financial needs
Actions	Client requests and the commitments made by the agent in response
Financial Objectives	Specific financial goals and aspirations set forth by the client
Portfolio Position	Client's current investments and relevant financial factors
Queries and Status	Client's questions and the responses provided by the advisor
Hard Facts	Client's risk tolerance and strategic financial planning

Table 2: Call Duration Statistics

Call Duration (in minutes)	Expected summary length (in words)	Approx. input transcript length (in words)	Distribution of call volume (in %)
(0,15]	100-150	1100	82
(15,30]	250-500	3500	14
(30,60]	500-600	6600	3
> 60	600-750	12000	1

2.2 Core Summarization Module

The primary function of this module is to generate summaries for the conversation transcripts. The summarization is triggered every 15 minutes and all available transcripts in the queue are processed in a batch. The transcripts undergo content moderation checks and pre-processing prior to the summarization model. Pre-processing involves analysis to determine if a transcript needs to be broken into smaller chunks as well as anonymizing names of customers and agents. Summarization is performed using an LLM with prompts designed to meet the format and content requirements.

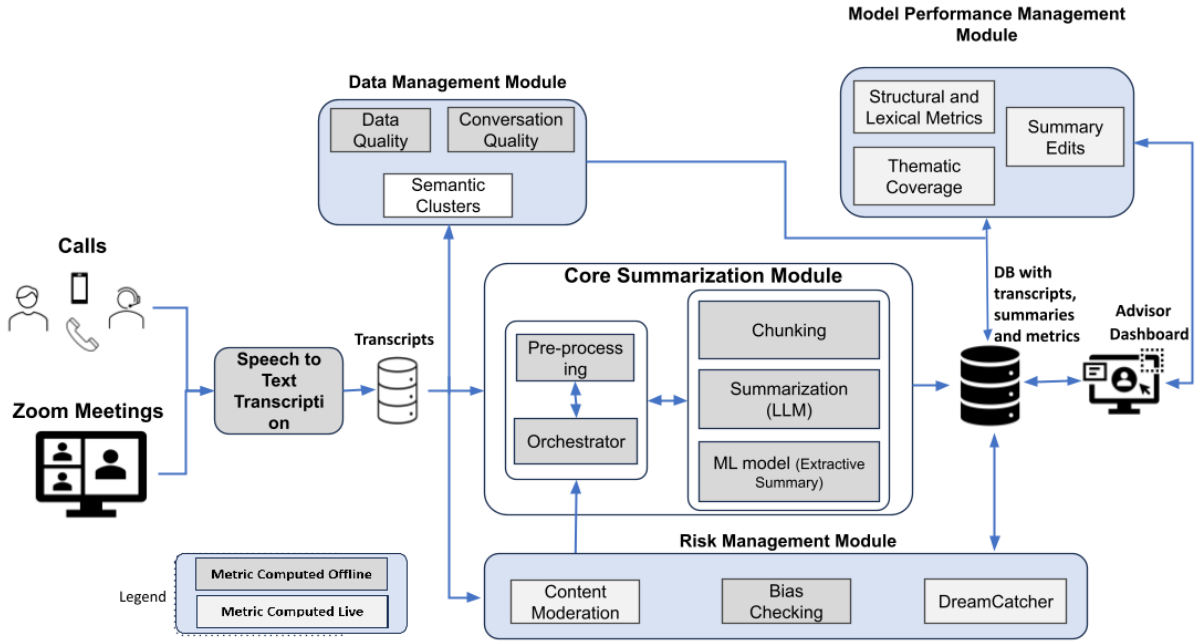

Figure 1: AUTOSUMM System architecture comprising of four modules: Core Summarization, Data Management, Model Performance Management, and Risk Management

Model Selection

Choosing an appropriate model required balancing cost-per-million-tokens with performance metrics such as hallucination rates, toxicity, fairness, and confidentiality safeguards. Initial decisions referenced publicly available benchmarks (Hughes, 2025) and experimentation evaluations. Based on these, OpenAI's GPT-3.5 Turbo (16K) (OpenAI, 2023) was chosen for initial deployment. Open-source models were not considered for deployment due to concerns about long-term support for hosting and maintenance.

Prompt Design

We use a *Chain of Thoughts (CoT)* (Wei et al., 2022) style prompt design to guide the model in a step-by-step reasoning process. This ensures the summarization is thorough and logically consistent, as opposed to simply truncating or paraphrasing large segments of text in a single pass. This approach is especially beneficial for capturing and key themes and prioritizing them in the summary. Besides, the LLM is also instructed to disambiguate and correct speaker labels, typically tagging them as "customer" or "advisor," minimizing attribution errors in the final summary.

ML Model - Extractive Summary

In cases where the LLM API is unavailable, an extractive fallback mechanism employs a fine-tuned BERT (Wolf et al., 2021) classifier to assign utterances to the desired themes. This ensures continuity of service and reliable summary generation.

Chunking

While large context windows generally suffice, certain transcripts exceed practical limits—especially when multiple conversations are consolidated or when discussions shift across departments. To address this, an in-house semantic-chunking algorithm, inspired by (Lattisi et al., 2022), was developed to detect significant context shifts, segment the transcript, and provide individual summaries for each segment. These partial summaries are then merged to form a coherent final summary.

2.3 Validation

The absence of a reference dataset motivated us to look at alternative approaches to validation of the generated summaries. We used metrics such as percentage of named entities captured in the summary as a proxy to measure information capture in the summary. We were also able to obtain 200 manually typed contact notes from past conversations to compare with the LLM-generated summaries. Despite these notes being highly inconsistent, we obtained a *ROUGE-1* score of 0.44.

Subjective Evaluation

A subset of the advisors were asked to evaluate the summary along three key dimensions: *precision* (faithful representation of facts and statements), *recall* (inclusion of all critical information from the conversation), and *coherence* (clarity and ease of reading). The evaluation was carried out by 22 advisors who evaluated 150+ summaries using a 5-point scale: *[Strongly Disagree, Disagree, Neutral, Agree, and Strongly Agree]*. 85% of the summaries received a "*Strongly Agree*" rating.

3 Supporting Modules

The successful deployment of AI solutions requires a robust ecosystem throughout their life cycle. For our AUTOSUMM solution, we developed and integrated modules that address three critical domains: Data Management, Model Performance, and Risk Mitigation.

3.1 Data Management

Our Data Management module includes utilities that examine the aspects of quality and information present in the conversation data to quantify and track it across various dimensions.

Data and Conversation Quality

AUTOSUMM uses an LLM-based evaluation framework to assess the quality of input conversations across three key dimensions: *linguistic quality*, *conversation flow*, and *agent response quality*.
Linguistic quality evaluates grammar, clarity, and lexical richness to ensure the transcripts meet professional standards required in banking applications.
Conversation flow is assessed using semantic embeddings to capture coherence and topic continuity across dialogue turns, helping identify fragmented or disjointed exchanges that may affect summary accuracy.
Agent response quality is evaluated using LLM-generated scores based on contextual relevance, timeliness, helpfulness, and inferred customer sentiment. These scores are also used to provide advisors with targeted feedback for performance improvement.
These metrics enable consistent benchmarking, early detection of issues with transcription quality, and feedback on the quality of conversations. Examples are included in Appendix A.2.

Semantic Clustering

To represent the thematic distribution in conversation data, we identified high-level topic clusters through a four-step methodology: First, we created a reference dataset of 600,000 sentences from conversations spanning two months; Second, we generated 384-dimensional sentence embeddings using SBERT (all-MiniLM-L6-v2) (Face, 2021a); Third, we applied Uniform Manifold Approximation and Projection (UMAP v0.5.6) (McInnes et al., 2020) for dimensionality reduction; Finally, we employed HDBSCAN (McInnes et al., 2017) for cluster generation. This process yielded 77 distinct semantic clusters, each representing topically similar content. The cluster topics were determined using a LLM. The distribution of instances across clusters establishes metrics for expected topic spread, enabling monitoring of data trends and providing explainability for distribution shifts.

Data Drift Monitoring

To complete the data management cycle, we track quality and information metrics daily. The Kolmogorov-Smirnov (KS) d-statistic quantifies divergence between reference and live data distributions. Threshold values for this statistic are established through 5,000 bootstrap iterations on both reference and live datasets.

Tables 3 and 4 demonstrate insights captured during holiday season monitoring. A significant increase in KS statistic indicated drift, with the contributing clusters reflecting expected seasonal conversation patterns.

Table 3: Data monitoring insights during the holiday season

Time Window	**Dec-H1**	**Dec-H2**	**Jan-H1**	**Jan-H2**
KS Stat	0.027	**0.046**	0.025	0.017

Table 4: Clusters with highest changes in Dec-H2

Change Trend	**Variation**
Personal and Non-Financial conversations (Holiday plans and task urgency)	**+15.1%**
Loans, debts, and real estate financial structures	-6.5%
Pensions and retirement planning	-6.2%
Interest rates and financial market fluctuations	-5.9%
Banking processes, transactions, and bank interactions	-4.8%

3.2 Model Performance Management

Evaluating summary quality without reference outputs or explicit user feedback poses a challenge. AUTOSUMM employs a multi-faceted approach to track and refine performance.

Structural and Lexical Metrics

These metrics encompass both structural elements, such as paragraph count, bullet points, sentence structure and word count, which help identify deviations over time, and lexical metrics, which assess the distribution of key entity categories (e.g., Date, Name, Time, Money, Location, Organization) to ensure that information is represented in a balanced and comprehensive manner.

Thematic Coverage

The distribution of constituent themes present in the summary are extracted for a reference dataset as a baseline. The topic distribution is then tracked across summaries, to identifying biases or systemic issues when expected themes either vary significantly or are completely absent.

Summary Edits

Since direct user feedback is limited, we analyze advisor edits to the summaries as an implicit feedback mechanism, providing quantitative insights for continuous improvement. Table 5 shows the results for one such analysis, conducted on over 300 summaries over a two-week period.

Table 5: Analysis of advisor edits to the summaries

Level of Summary Edits	Observed Cases
No Edits	89%
Minor Edits: Grammar, contextual additions while retaining key points	8.5%
Moderate Corrections: A few(< 5) words are edited.	1.5%
Major Corrections: Sentences including key information rewritten	1%

3.3 Risk Management

Operating within a banking environment requires rigorous risk management to protect customer privacy and data integrity. Beyond standard technology controls for unauthorized access and information leakage, we implemented specific measures to mitigate model output risks.

Bias Mitigation, Content Moderation

Customer and agent names are anonymized prior to summarization and re-inserted afterward, with periodic checks ensuring consistency of generated summaries across all users. Inappropriate content in input data are masked prior to summarization.

Hallucination Detection - DreamCatcher

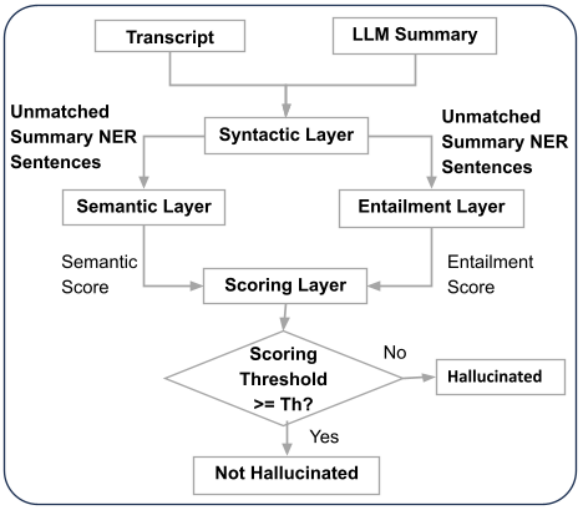

Figure 2: DreamCatcher: A multi-layered approach for hallucination detection.

We have developed a package *DreamCatcher* for detecting factual misrepresentations and hallucinations in summaries. The multi-layered approach is illustrated in Figure 2 and described as follows:
Syntactic Layer pivots hallucination checks around 18 types of named entities (e.g., MONEY, PERSON, DATE) extracted using a custom spaCy pipeline trained with a RoBERTa transformer model (Face, 2021b). Entities from summaries are compared with transcript entities using fuzzy matching for non-numeric entities.
Semantic Layer assesses semantic alignment between mismatched summary sentences and transcript segments. Transcripts are segmented via sliding window technique, with embeddings generated using Sentence-BERT. Cosine similarity is used to identify the highest matches.
Entailment Layer verifies logical consistency using a Bidirectional Auto-Regressive Transformer trained on Multi-Genre Natural Language Inference (BART MNLI (Face, 2023)) to evaluate whether summary information logically follows from the transcript.
Scoring Layer quantifies the extent of hallucination by aggregating scores from semantic and entailment layers.

The approach is validated on a human-labelled dataset, and the results shown in Table 6 indicate a high accuracy.

Table 6: Hallucination Detection Confusion Matrix

Predicted \ Actual	Not Hallucinated	Hallucinated
Not Hallucinated	69	1
Hallucinated	0	6

4 Deployment Process and Challenges

We implemented a phased deployment strategy, starting with a targeted pilot serving 10 advisors. This controlled introduction allowed for close performance monitoring and revealed practical considerations not evident during development. The pilot phase revealed several issues requiring remediation before full-scale deployment.

4.1 Observations - Pilot Deployment

During the pilot, we discovered that advisors couldn't consistently provide explicit feedback on each summary. In response, we introduced an edit-tracking feature to passively collect user modifications as a proxy for summary quality, which became integral to our ongoing performance monitoring framework.

Summaries occasionally included the phrase "*No Financial Information Present*" despite containing expected content, creating user confusion. Investigation showed this occurred primarily in conversations lacking explicit monetary figures. We adjusted prompt engineering parameters to eliminate this inconsistency.

Shorter conversations exhibited summaries with lower quality and more hallucinations. Since these brief interactions typically lacked significant information exchange, we implemented filtering to exclude transcripts with fewer than 50 words or under 3 minutes from summarization.

4.2 Model Version Management

To ensure smooth model transitions and minimize disruptions from OpenAI's LLM updates (OpenAI, 2025) (please refer Appendix B.1, Table 7), AUTOSUMM implements a structured version management strategy. A model upgrade during development underscored the need for a robust transition plan.

We maintain a reference dataset to benchmark new models, detect performance variations and conduct impact assessments upon release. Proactive plans are designed to seamless model transitions and minimize service interruptions, For more details please refer Appendix B.2, B.3.

4.3 Metrics Collection and Monitoring

While initial metrics for hallucination detection, data quality, and thematic coverage aided post-deployment analysis, we identified the need for more proactive monitoring. Effective production oversight requires real-time anomaly detection, stage-specific performance tracking, automated alerts for timely intervention, and comparative metrics across model versions. These enhancements ensure operational stability and drive continuous optimization.

4.4 Human-in-the-Loop Integration

Human oversight is crucial for quality assurance and risk mitigation. Advisor feedback enables early detection of model failures, sensitive content, and optimization opportunities while fostering user trust and transparency. This approach aligns with financial regulatory requirements, ensuring appropriate governance of AI-generated content.

5 Conclusion

This paper presents AUTOSUMM, a production-ready LLM-based summarization system for financial customer-advisor conversations. Designed to meet the operational, regulatory, and ethical demands of the financial domain, the system addresses challenges such as speaker attribution errors, short transcripts, and hallucinations through solutions like entity-aware processing, transcript filtering, and the DreamCatcher module.

Human-in-the-loop oversight ensures quality and compliance, with real-time advisor feedback integrated into system refinement. A structured model versioning strategy minimizes deployment disruptions, while custom monitoring tracks performance, drift, and thematic coverage. Ethical considerations—privacy, fairness, transparency, and accountability—are embedded throughout the system lifecycle.

AUTOSUMM provides a practical framework for safely and effectively deploying LLMs in regulated environments, demonstrating that operational impact and compliance can be achieved together.

Acknowledgments

The authors wish to express their gratitude to Zachery Anderson, Chief Data and Analytics Officer, and Graham Smith, Head of Data Innovation, for their invaluable support and for fostering a constructive research environment that was essential throughout the AUTOSUMM project. We also extend our thanks to Sacheen Patel and Alyssa Anderson from Wealth Businesses for their insightful feedback from a business perspective, which significantly enhanced the project's outcomes. Additionally, we thank Grant Falconer and Faye Drummond for their support and enablement that helped to manage the challenges and ensured smooth delivery of the solution. Lastly, we would like to extend our appreciation to all colleagues who contributed to the development of the project.

Ethical Considerations

AUTOSUMM has been deployed within a regulated financial institution, where ethical concerns around privacy, fairness, and responsible automation are critical. Below, we outline key ethical dimensions and our corresponding mitigations:

Data Privacy and Consent The conversation transcripts used for training and evaluation were collected under institutional agreements with appropriate customer disclosures. No personally identifiable information (PII) was retained in training data; names and sensitive fields were anonymized prior to model processing. Data access was restricted to authorized personnel, and all processing occurred within the bank's secure infrastructure, in compliance with GDPR and internal data governance policies.

Bias and Fairness Given the risk of demographic, occupational, or financial bias in LLM outputs, we implemented pre- and post-generation checks. Names and gendered terms were anonymized prior to summarization, reducing exposure to learned biases. We conducted periodic reviews of summary outputs to detect patterns of exclusion or stereotyping.

Transparency and Accountability To support explainability, the system logs all inputs and generated summaries along with metadata (model version, prompt variant, edit history). The DreamCatcher module provides sentence-level hallucination flags, supported by entailment and semantic similarity scores. These signals are exposed to users and reviewers during post-call audits, enabling traceability and informed review.

Human Oversight and Model Governance Summaries are reviewed by financial advisors before being saved to customer records. This oversight loop helps catch factual errors, omissions, and contextually inappropriate content. We also maintain clear version control over models and prompts; any change undergoes pre-deployment evaluation against reference benchmarks and advisor feedback. Governance boards review deployment plans to ensure alignment with regulatory expectations (e.g. suitability, fairness, and auditability under financial regulations).

Limitations and Responsible Use AUTOSUMM is not used in decision-making or product recommendations. Summaries are designed to aid documentation and post-call follow-up—not to replace judgment or communication. We do not claim complete factual accuracy in generated outputs, and all summaries are clearly marked as AI-generated drafts subject to advisor validation.

Broader Societal Impact The system was deployed to improve documentation efficiency, not to replace human roles. By reducing administrative burden, advisors spend more time on relationship-building. Nevertheless, we acknowledge concerns about automation displacing cognitive tasks and continuously engage with internal stakeholders to ensure responsible, assistive use.

A Appendix

A.1 Example Summary

Example

Summary:
- The agent apologized for missing the customer's call earlier due to a meeting.
- The customer discussed their holiday in the Maldives for their son's birthday last month.
- The agent noted a request to increase the customer's credit card limit to 10,000 GBP.
- The customer expressed frustration and disbelief over the valuer's decision, mentioning that their London property is freehold.
- The customer is planning to invest approximately GBP 2.5 million in real estate in Singapore. They must complete legal formalities within the next two months.
- In November of last year, the client's husband was diagnosed with cancer and is undergoing treatment at a hospital.
- The client's son is going to MIT next year, which will cost them 5,000 dollars monthly, including all expenses.

Actions:
- Agent to submit request for increasing credit card limit.
- Agent to escalate the valuation related issue with the Mortgage Team.

A.2 Data and Conversation Quality Examples

A.2.1 Snippet of a Good-Quality Conversation

Grammatically correct sentences without spelling or transcription errors. Response is relevant to the query and does not deviate from the topic.

Customer-Agent Exchange

Customer: "I'd like to explore a new investment option because I've recently changed jobs and want more flexibility."
Agent: "Absolutely. Let's review your current portfolio and discuss how the job change might affect your risk profile and liquidity needs."

A.2.2 Low Quality Conversation Snippet

Poorly transcribed sentences with missed words and incorrect grammar.

Customer-Agent Exchange

Customer: "i need help with my 401k contributions im not sure if uh um doing right or ah how much should be putting each"
Agent: "We can help with that. Their are different opinions on contribution amounts, but typically we recommend about 15% of you're income. When did you last adjusted your contributions?"

B Model Version Management Strategy

B.1 Model Deprecation Timelines

Table 7: LLM deprecation timelines and context lengths

GPT model name	Deprecation date	Context length
GPT 3.5 Turbo 0613	September 2024	16000 tokens
GPT 3.5 Turbo 1106	December 2024	16000 tokens
GPT 3.5 Turbo 0125	February 2025	16000 tokens
GPT 4o Mini	Not Known	128000 tokens

B.2 Risk Mitigation and Deployment Strategy

To ensure smooth deployment, we adopt a staged rollout strategy:

1. Phase 1: Offline Testing – Running controlled experiments with historical data.
2. Phase 2: Shadow Mode Deployment – Generating outputs from both old and new models in parallel without affecting users.
3. Phase 3: Limited Production Rollout – Gradually increasing the proportion of queries handled by the new model.
4. Phase 4: Full Deployment – Transitioning entirely once performance benchmarks are met.

Additionally, we version control model prompts to ensure that refinements are systematically evaluated before deployment. If a newer model exhibits unexpected deviations, we have rollback procedures in place to revert to a stable version.

B.3 Continuous Monitoring Post-Deployment

Post-deployment, we track performance via:

- Daily Summarization Quality Audits: Automated and manual reviews to detect performance drifts.

- User Feedback Loop: Continuous collection of feedback from financial advisors to fine-tune the system.
- Data Drift Analysis: Monitoring changes in input conversation patterns that may impact model behavior.

This systematic version management approach ensures that AUTOSUMM remains resilient to LLM deprecations, providing stable and high-quality summarization outputs without disrupting financial workflows.

RedactOR: An LLM-Powered Framework for Automatic Clinical Data De-Identification

Abstract

Ensuring clinical data privacy while preserving utility is critical for AI-driven healthcare and data analytics. Existing de-identification (De-ID) methods, including rule-based techniques, deep learning models, and large language models (LLMs), often suffer from recall errors, limited generalization, and inefficiencies, limiting their real-world applicability. We propose a fully automated, multi-modal framework, `RedactOR` for de-identifying structured and unstructured electronic health records, including clinical audio records. Our framework employs cost-efficient De-ID strategies, including intelligent routing, hybrid rule and LLM based approaches, and a two-step audio redaction approach. We present a retrieval-based entity relexicalization approach to ensure consistent substitutions of protected entities, thereby enhancing data coherence for downstream applications. We discuss key design desiderata, de-identification and relexicalization methodology, and modular architecture of `RedactOR` and its integration with Oracle Health Clinical AI system. Evaluated on the i2b2 2014 De-ID dataset using standard metrics with strict recall, our approach achieves competitive performance while optimizing token usage to reduce LLM costs. Finally, we discuss key lessons and insights from deployment in real-world AI-driven healthcare data pipelines.

1 Introduction

The proliferation of AI-driven healthcare tools has heightened the need for robust de-identification (De-ID) systems to comply with privacy regulations such as HIPAA in the US and GDPR in the EU (Ahmed et al., 2020). Effective De-ID is critical for secure AI model training, evaluation, and debugging, data analytics, and clinical deployment (see §A.2). However, automating De-ID for electronic health records (EHRs) is challenging due to data heterogeneity, schema variability, context-sensitive Protected Health Information (PHI) or Personally Identifiable Information (PII), and the multi-modal nature of healthcare data—text, images, and audio (Mohamed et al., 2023; Kayaalp, 2018).

Manual De-ID, though accurate, is impractical at scale given the data volume in clinical settings (Patterson et al., 2024). Automated approaches, including rule-based methods, BERT-based models, and LLMs (Meystre et al., 2010; Kovačević et al., 2024; Altalla' et al., 2025), face limitations in generalization, contextual reasoning, and efficiency, particularly when trained on narrow datasets that do not reflect real-world EHR diversity (Liu et al., 2023). Since even a single leak of PHI/PII can have serious privacy implications, reliable, scalable De-ID remains a critical need.

Recent advancements address cost, scalability, and generalizability through techniques like prompt optimization, model quantization (Shekhar et al., 2024; Arefeen et al., 2024), and intelligent agent routing (Varangot-Reille et al., 2025), along with multi-modal De-ID for text and audio (Dhingra et al., 2024). Yet challenges persist – specifically with, maintaining high recall, ensuring consistent PHI/PII substitution (e.g., "Wilson" and "Dr. Adam Wilson" both mapped to "Chang" and "Dr. Kevin Chang" respectively), and evaluating privacy risks with stricter metrics beyond token-level scores.

We propose `RedactOR`, a fully automated, multi-modal framework for de-identifying structured and unstructured patient records, including clinical audio records. `RedactOR` combines LLM-based processing for unstructured text with rule-based handling of structured data to achieve low cost and latency, and extends text de-identification for audio redaction. Our framework includes a novel retrieval-based entity relexicalization component to ensure consistent PHI/PII replacement, enhancing coherence and privacy. We present key design

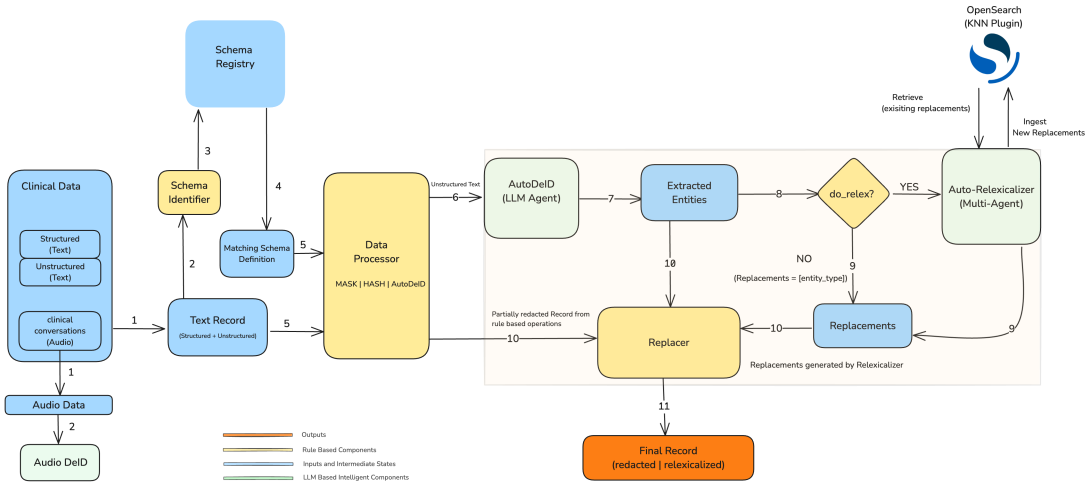

Figure 1: Architectural overview of RedactOR

requirements (§3.1), de-identification and relexicalization methodology and architecture (§3.2), and integration with Oracle Health Clinical AI system (§A.8). We demonstrate that our framework outperforms other LLM-based approaches and achieves performance comparable to specialized, closed-source solutions while remaining adaptable through prompt engineering – eliminating reliance on large annotated datasets (§4), and highlight lessons and insights from 12+ months of deployment in real-world clinical AI system (§5).

2 Related Work

Rule-based and ML-based De-ID. Rule-based systems rely on pattern matching, lexicons, and heuristics (Neamatullah et al., 2008; Meystre et al., 2010), offering simplicity and no training data requirements (Negash et al., 2023). However, rule creation is time-consuming and may lack robustness (Negash et al., 2023; Lee et al., 2017). Machine learning models, especially BiLSTM-based approaches (Ma and Hovy, 2016; Dernoncourt et al., 2017; Liu et al., 2017), improve generalization without manual rules but struggle to transfer across datasets (Stubbs et al., 2017; Yang et al., 2019). BERT-based models enhance De-ID (Meaney et al., 2022) but demand significant compute resources, hyperparameter tuning, and still exhibit gaps in handling certain PHI/PII types.
LLM-based De-ID. LLMs offer flexible, zero/few-shot De-ID capabilities. Kim et al. used GPT-4 to augment training data, improving BERT model performance across datasets. Yashwanth and Shettar showed fine-tuned LLMs outperform zero-shot models, particularly under format shifts. Altalla' et al. found GPT-4 surpasses GPT-3.5 in De-ID accuracy and synthetic data generation. Similarly, Wiest et al. developed a custom open-source LLM-based Anonymizer pipeline benchmarking 8 LLMs to De-ID 250 German clinical letters. However, most studies lack evaluation on large real-world cross-dataset generalization.
Synthetic Data. The growing need for large datasets in medical research, alongside strict patient privacy rules, has led to increased interest in synthetic data. Synthetic data generation often involves differential privacy based approaches to protect patient privacy and generative adversarial networks (GAN) based methods for realistic data replication, and its utility depends on maintaining fidelity and minimizing biases to ensure reliable research and clinical decisions (Al Aziz et al., 2021). While synthetic data offers transformative potential for healthcare, careful consideration is needed to ensure its ethical and effective use in research and practice (Altalla' et al., 2025).
Relexicalization. Replacing PHI/PII with realistic surrogates is underexplored. Many systems apply dummy replacements or simple rules (e.g., gender matching) (Sweeney, 1996; Alfalahi et al., 2012; Lison et al., 2021). Recent work (Vakili et al., 2024) demonstrated pseudonymizing BERT models for privacy-preserving data analysis, highlighting relexicalization's value in maintaining utility while protecting privacy.

3 System Design and Architecture

3.1 Design Desiderata

RedactOR is designed around three core principles:

scalability, adaptability, and cost-efficiency. Scalability is achieved through an end-to-end automation pipeline, enabling efficient processing of structured and unstructured clinical data while minimizing computational overhead via intelligent routing and LLM-based De-ID strategies. Adaptability is ensured through a schema-agnostic processing architecture, facilitating seamless integration across heterogeneous EHR formats and multimodal data sources (text and audio) without the need for dataset-specific fine-tuning. Cost-efficiency is realized through token usage optimization in text-based De-ID and leveraging text-based entity extraction for audio, thereby eliminating the need for computationally expensive, audio-specific de-identification models. Additionally, retrieval-based re-lexicalization enhances contextual consistency in PHI/PII replacements, preserving both privacy and downstream utility, making the system highly effective for real-world AI-driven healthcare applications.

3.2 Architecture Overview

`RedactOR` consists of three main components: (i) Auto De-ID, Audio De-ID, and Auto Relexicalizer (see Figure 1).

First, Schema Identifier automatically identifies the appropriate schema from the Schema Registry based on the `dataType` parameter in each data instance (see §A.9.1) and forwards it to the Data Processor along with the corresponding text data. The data processor is designed to be agnostic to text data types, requiring only the schema (stored in the schema registry) with predefined rule flags for each field. Currently, a rule flag can be one of the following: (i) `passThrough` (rule-based) retains the field without any changes (used for non-PHI/PII data), (ii) `shouldMask` (rule-based) replaces PHI/PII fields with generic placeholders (e.g., `[PERSON]`), (iii) `shouldHash` (rule-based pseudo-anonymization) hashes identifiers to enable secure linkages across documents within the same domain, or (iv) `autoDeID` (LLM-based) applies LLM-based De-ID to the unstructured text fields. This schema-agnostic design is crucial for scaling our system to support health data De-ID tasks. Meanwhile, audio data is processed separately by the Audio De-ID component. To ensure that no PHI/PII field definition is missed, we enforce a human review of the schema before it is pushed into the schema registry.

Auto De-ID is an LLM component (§B.1) that processes the context extracted by the data processor. It can support a dynamic list of entity types. We support 33 entity types in our production deployment as shown in §C. This context is split into chunks of a pre-defined size (ω), ensuring optimal model performance without exceeding LLM context length limits. Chunks are processed in parallel across a fixed number (p) of passes. ω and p are heuristically chosen hyperparameters. In each pass, the LLM extracts entities along with their surrounding context as position hints – that is, each extracted entity includes nearby words that uniquely identify its location in the text (e.g., "76 years old" instead of just "76", or "Mr. John Smith, the patient" instead of just "John"). This context-aware extraction enables accurate entity matching and redaction without relying on potentially unreliable character position indices. In the first pass, the LLM detects as many entities as possible. In subsequent passes, entities already identified are masked in the text, prompting the model to focus on previously missed or hard-to-detect PHI/PII entities. Extracted entities from all passes are aggregated to form the final entity set.

The Auto Relexicalizer, a multi-agent component (see §B.2 and Figure 4), replaces redacted entities with contextually consistent and realistic alternatives. Relexicalization not only improves the usability of de-identified data but it also strengthens privacy by increasing the Hiding in Plain Sight (HIPS) factor (Carrell et al., 2020). Ensuring that replaced entities blend seamlessly with any remaining leaked PHI/PII makes re-identification attempts significantly more challenging. A combined example of Auto De-ID followed by Relexicalization is shown in §A.9. It employs multiple agents as follows:

- LLM-Based Entity Clustering: grouping extracted entities based on their context.
- Hybrid Retrieval (Vector Search + Filtering): retrieving pre-existing replacements.
- LLM-Based Validation: Determining the validity of the retrieved replacements.
- LLM-Based Generation: Generating new replacements for invalid retrievals.
- OpenSearch Indexing: Storing new replacements for future reuse.

Our work extends a recent work (Vakili et al., 2024) that presents an analysis of pseudo-anonymization. We offer an LLM-driven alternative for automated and scalable relexicalization. A regex-based replacer replaces extracted entities

with entity-type masks (e.g., [PERSON]) to redact PHI/PII in unstructured text fields. See §A.4.1 for an end-to-end example of Auto De-ID.

Our Audio De-ID feature performs a two-step redaction process to enhance privacy. First, it uses Automatic Speech Recognition (ASR) to detect timestamps of spoken words and applies LLM-based Auto De-ID to the transcript, adding an extra 100 – 200 msec of margin at token boundaries for improved protection. Next, it examines *unrecognized* voiced regions – identified by an aggressive Voice Activity Detection (VAD) – by analyzing their surrounding context words with an LLM (§B.3), evaluating the likelihood of these regions containing PHI/PII and selects the most likely ones. Finally, it mutes all time boundaries (including margins) for predicted PHI/PII tokens' voiced regions. Testing on our internal data showed that the second step increased recall by approximately 10%. A brief end-to-end example illustrating this is presented in §A.5.1. In summary, our Audio De-ID component improves PHI/PII detection by addressing ASR misalignment and deletion errors by leveraging VAD and LLM based detection process in the second step.

By integrating Auto De-ID for unstructured text, Auto Relexicalizer for realistic entity replacement, and Audio De-ID for speech data, RedactOR provides a scalable, adaptable, and cost-effective De-ID pipeline that secures both text and audio data while preserving its utility.

See §A.4, §A.5, and §A.6 for detailed algorithmic descriptions of Auto De-ID, Auto Relexicalization, and Audio De-ID, respectively.

4 Experiments

We present the results of evaluating RedactOR against other LLM-based approaches and specialized, closed-source commercial solutions over a publicly available medical record dataset. For parity with other methods, we turn off the Auto Relexicalizer component. We set chunk size (ω) to 256 and number of passes (p) to 2.

4.1 Dataset

We evaluated using 2014 i2b2/UTHealth De-ID corpus (Stubbs and Uzuner, 2015) which is widely used in clinical De-ID research. This dataset comprises longitudinal clinical records for 296 patients (with 2-5 records per patient). The annotation scheme follows HIPAA guidelines and includes additional indirect identifiers such as detailed date components (e.g., year), geographic information (states, countries), hospital names, clinician names, and patient professions. For our experiments, we randomly subsampled 100 clinical notes and evaluated on seven PHI/PII entity categories: AGE, CONTACT, DATE, ID, LOCATION, PERSON, and PROFESSION.

4.2 Comparative De-ID methods

We evaluated RedactOR against recent LLM-based methods, Yashwanth and Shettar (2024) (with their two prompt variants: 'brief' and 'detailed') and Altalla' et al. (2025), as well as commercial De-ID APIs from AWS (Amazon Web Services) (AWS, 2025) and JSL (John Snow Labs) (Kocaman et al., 2023, 2025). For a fair comparison, we used GPT-4o (OpenAI, 2025) for all LLM-based methods. See §A.3 for additional details.

4.3 Evaluation Methods

We assessed De-ID performance using traditional metrics such as precision, recall and F1-score, as well as all-or-nothing recall, applied to (PERSON, AGE, CONTACT, ID, LOCATION). All-or-nothing recall (Scaiano et al., 2016) determines whether every instance of a given entity type or a document is correctly redacted. If any instance is missed, all-or-nothing recall is set to 0; otherwise, it is set to 1.

We evaluated all systems using a *stricter* methodology for true positive computation incorporating entity position matching. Position information is critical for data redaction in unstructured health records, as it often differentiates PHI from clinical information. For example, in the phrase '76 yrs old,' the number '76' represents age (PHI), whereas in 'oxygen saturation rate is 76,' it denotes a vital sign.

In the evaluation for each entity type, we compared our system with AWS and JSL using additional matching criteria, including entity-level text matching and label matching. The metrics were assessed at the PHI/PII entity level (multi-word spans) rather than individual tokens, as in (Yashwanth and Shettar, 2024), ensuring a fair comparison between entities with varying token counts. To account for minor variations (e.g., 'Mrs. Mary Smith' vs. 'Mary Smith'), we applied the Levenshtein similarity with a heuristically determined threshold of 0.6. Yashwanth and Shettar (2024) and Altalla' et al. (2025) are omitted in entity type spe-

Model	Precision	Recall	F1-score	All-Or-Nothing Recall
Y&S_Brief	0.5634	0.6580	0.6070	0.3700
Y&S_Detail	0.6178	0.8270	0.7072	0.5600
Altalla	0.9675	0.6715	0.7927	0.3600
RedactOR	0.9769	0.9525	0.9646	0.7900
AWS	0.9549	0.9425	0.9487	0.7500
JSL	0.9481	0.9865	0.9669	0.9000

Table 1: Performance of zero-shot GPT-4o and commercial De-ID systems on all PHI/PII entities. This evaluation does not consider the entity type constraint.

cific evaluation, because they provide only binary PHI/PII labels, but not entity types.

4.4 Comparison with LLM-Based De-ID Frameworks

As shown in Table 1, a comparison with other LLM-based methods (Yashwanth and Shettar, 2024; Altalla' et al., 2025) indicates that RedactOR outperforms existing methods, achieving the highest F1-score of 0.9646 with a well-balanced precision and recall. The high recall can be attributed to RedactOR's multi-chunk and multi-pass strategy, which systematically refines entity detection by iteratively masking extracted entities and forcing the model to focus on overlooked PHI. Similarly, in terms of precision, RedactOR outperforms Yashwanth and Shettar (2024), highlighting the effectiveness of its context-aware entity extraction. By leveraging contextual clues and maintaining intra-document consistency, RedactOR reduces false positives, whereas single-pass prompting methods tend to over-redact ambiguous terms.

While Yashwanth and Shettar (2024)'s Detailed version achieves higher recall than the Brief, it does so at the expense of precision. This highlights a fundamental trade-off in zero-shot protected terms extraction: models optimized for recall often over-mask non-protected terms, leading to reduced utility of the redacted text. RedactOR strikes a balance between recall and precision, making it more suitable for real-world clinical applications where both PHI/PII removal and utility are essential.

4.5 Comparisons with Commercial APIs

Unlike prior zero-shot LLM-based approaches, commercial De-ID APIs (e.g., AWS, JSL) are fine-tuned on proprietary clinical datasets. Table 1 shows that while RedactOR does not surpass JSL in recall, it achieves higher precision and a comparable F1-score. This suggests that while JSL benefits from domain-specific fine-tuning, RedactOR's context-aware extraction minimizes false positives, leading to more reliable entity masking.

Table 2 presents a breakdown of performance by entity types. RedactOR demonstrates high precision and strong recall across all entities, particularly excelling on CONTACT and PERSON entities. RedactOR achieves perfect recall on CONTACT entities, outperforming AWS and JSL, and shows competitive performance on PERSON and DATE entities. However, it underperforms on LOCATION and ID, presumably due to the structural variability of PHI in clinical texts. LOCATION entities, in particular, often appear within complex sentence structures, posing challenges to generic LLM-based masking. This suggests the need for instruction updates for these entities or a specialized LLM.

4.6 All-or-Nothing Recall Results

Table 3 shows performance by PHI/PII entity type with all-or-nothing recall, a stricter metric requiring both correct entity type and position alignment. These results highlight RedactOR's strength in high-precision redaction for certain entities while emphasizing the advantage of domain-tuned models for broader recall coverage.

RedactOR outperforms other methods using the same underlying LLM (Table 1) and approaches the performance of specialized models like JSL. Specifically, it excels in CONTACT and ID compared to commercial methods. RedactOR's multi-pass extraction and context-aware masking enhance the LLM's effectiveness, showcasing its strength without specialized fine-tuning. However, JSL leads in most other entity types, achieving the highest overall recall. The recall gap – especially for complex entities like DATE and LOCATION – highlights the need for improved prompt instructions and possibly a specialized LLM for de-identification to match domain-specific systems.

4.7 Ablation Study with Open-Source Model

To demonstrate the adaptability of RedactOR to open-source models and evaluate the benefit of its multi-pass de-identification strategy, we conducted an ablation study using LLaMA-3.2-3B-Instruct (MetaAI, 2024) – a compact, publicly available LLM.

Figure 2 illustrates the effect of increasing the number of passes (from 1 to 4) on all-or-nothing recall across seven PHI/PII entity types. Notably, we

Entity Type	RedactOR			AWS			JSL

All	0.9159	0.9790	0.9465	0.9042	0.9510	0.9270	0.9664	0.9839	0.9751

Table 2: Performance of De-ID systems for each entity type and all data.

observe consistent improvement across most entity types as the number of passes increases. The largest relative gains are observed between pass 1 and pass 2, especially for sparse or context-sensitive types such as ID, DATE, and LOCATION, which tend to be missed in early passes but are recovered in subsequent iterations.

For dominant or well-signaled types like PERSON, CONTACT, and PROFESSION, the recall is already high at pass 2, with marginal improvements beyond that point. By pass 3, the recall curve starts to saturate for most entity types, indicating diminishing returns on additional passes.

These trends suggest that the number of passes is a critical, model-dependent hyperparameter: lightweight models like LLaMA-3.2-3B benefit from 2–3 passes, while larger models may reach optimal performance sooner. RedactOR supports this flexibility by treating the pass count as a configurable parameter, allowing practitioners to trade off between computational cost and de-identification completeness depending on the capacity of the underlying LLM.

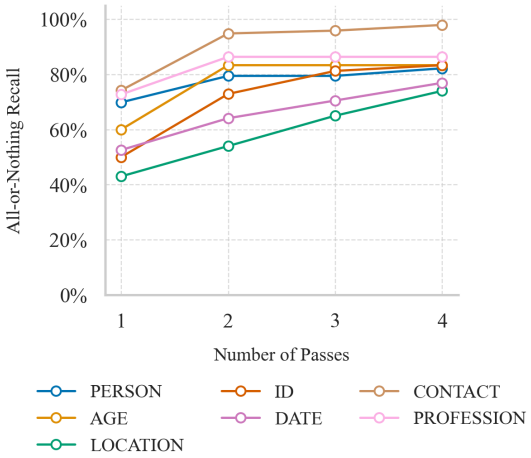

Figure 2: Entity-wise all-or-nothing recall for LLaMA-3.2-3B as the number of passes increases from 1 to 4. Most entities show the greatest gain between pass 1 and 2, with diminishing improvements thereafter.

4.8 Qualitative Evaluation of Audio De-ID on Internal Data

To assess the impact of our two-step Audio De-ID process, we conducted a qualitative evaluation on an internal clinical audio dataset. The LLM-based timestamp detector identified and muted several additional audio segments that were missed by text de-identification on just the transcript. A subset of these newly muted segments included person names that had previously gone undetected, leading to a noticeable improvement in all-or-nothing recall on direct identifiers—approximately 12%. Another small portion involved relevant medical or personal context (e.g., complaints or medications), introducing minor precision trade-offs. The majority of muted segments, however, were non-informative, consisting of background noise or idle speech such as keyboard activity. Overall, over 84% of the additionally muted content was deemed to have no negative impact on clinical utility. These findings demonstrate that the second-pass audio detection enhances recall with minimal utility loss, validating its inclusion in real-world deployments.

5 Deployment Lessons and Insights

In the course of developing and deploying RedactOR, we realized that efficient scaling of de-identification is crucial to handle the large volume of healthcare data post-deployment, including audio files, SOAP notes, and longitudinal records with thousands of FHIR resources (Bender and Sartipi, 2013). Once the service is launched, a continuous influx of data follows, and as the products expand, the ability to optimize processing at scale becomes critical. Simple yet powerful reductions in computation and processing can significantly impact efficiency, cost, and system performance.

One key optimization we employed was reducing token usage. RedactOR extracts only PHI/PII entities and their position hints, minimizing the number of LLM's output tokens by approximately 50%. This reduction not only lowers processing costs but also decreases latency, ensuring that De-ID remains accurate and efficient at scale.

Further, processing each FHIR resource individually causes delays and backlogs. Our schema agnostic approach allows us to batch lightweight resources (e.g., vitals, medications) in the schema processor by merging their schemas and free-text fields into a single composite schema. For example, if the batch size is n, n resource schemas could be combined into one, allowing all associated text to be de-identified in a single LLM request. The batch size can be chosen heuristically based on the LLM used, the context length it supports, the system prompt size, and the average number of tokens present in the unstructured texts of the resource schemas.

Finally, dynamic batching further enhances scalability by grouping incoming resources based on size and complexity. This approach enables large and diverse datasets to be processed in real time, preventing bottlenecks as data streams grow.

Our initial implementation focused on just de-identification but we decided to incorporate relexicalization after realizing that relexicalized data significantly enhances the ease of use by applied scientists as part of their model training, quality & bias evaluation, and debugging pipelines since this data has similar format and characteristics as the production data.

6 Conclusion And Future Directions

Motivated by the need for protecting patient privacy while enabling utility, we presented RedactOR a multi-modal, scalable, flexible, and cost-efficient LLM-powered framework for clinical data de-identification, and demonstrated its efficacy in de-identifying 33 PHI/PII entities over the i2b2 dataset. We showed that our approach outperforms other LLM-based methods and achieves performance comparable to specialized, closed-source solutions. Further, RedactOR supports relexicalizing redacted entities with contextually consistent alternatives, enhancing data usability and strengthening privacy. By presenting the methodology, technical architecture, and lessons learned from over 12 months of production deployment as part of Oracle Health Clinical AI system, we hope that the insights and experience from our work are useful for researchers and practitioners working on clinical AI systems.

There are several avenues for future work. The variability in healthcare datasets across institutions affects generalizability, necessitating adaptive prompting techniques. While our method excels in detecting ID, PERSON, and DATE entities, it may require further refinement of entity-specific LLM instructions (e.g., for address- and occupation-related entities). More broadly, RedactOR's generalizability can be enhanced across diverse institutional datasets by integrating domain-adaptive prompt enhancements.

Another direction is to investigate domain-adaptive VAD techniques in de-identification settings. Although we incorporate a VAD-based solution to mitigate ASR inaccuracies, our use of a simpler VAD algorithm introduces false positives, leading to over-redaction. Additionally, transcription variability due to noise and overlapping speech increases the risk of PHI/PII leakage. Integrating deep learning-based VAD models alongside domain-adaptive ASR techniques could enhance precision while maintaining recall, reducing unnecessary redactions without compromising PHI/PII protection.

Furthermore, we could design standardized benchmarks for evaluating relexicalization techniques, following ideas discussed in §A.7. An ideal dataset would include PHI/PII-tagged text, gold relexicalized outputs, and context to ensure consistency across documents and domains such as clinical notes, transcripts, and structured records. More broadly, a promising direction is to extend our framework to handle other modalities such as medical images and videos, and design corresponding end-to-end evaluation methodolgies and benchmarks.

Acknowledgments

We would like to thank other members of Oracle Health AI for their collaboration while deploying RedactOR in production, and Weifeng Bao, Brent Beardsley, Michelle Chen, Dipankar Das, Long Duong, Raefer Gabriel, Kent Grueneich, Neil Hauge, Bhagya Hettige, Brad Jacobs, Mark Johnson, Shirley Liu, Cody Maheu, Atri Mandal, Virendra Marathe, Kiran Rama, Amitabh Saikia, Tushar Shandhilya, Gyan Shankar, and Vishal Vishnoi for insightful feedback and discussions.

A Appendix

A.1 Ethics Statement

Despite the high performance of our De-ID system, there remains a non-zero risk that some PHI/PII might not be detected or removed. Consequently, any output produced by automated De-ID system should still be handled with the same security and privacy precautions as raw identifiable data. We underscore that users of our De-ID framework should apply rigorous privacy safeguards when handling the processed data, just as they would for original clinical records. For example, we restrict access to the de-identified data using encryption and access control mechanisms, and require scientists and engineers to go through appropriate privacy and

healthcare regulation related trainings before being granted access to the de-identified data.

Given the sensitivity of De-ID data pipelines, we do not release the prompt verbatim or source code of RedactOR to prevent potential privacy risks and attacks. However, to support transparency and reproducibility, we provide descriptions of individual components, including retrieval-based relexicalization, hybrid rule/LLM logic, intelligent routing, and a two-step audio redaction process, in the pipeline. This approach enables secure replication of our methodology while safeguarding patient confidentiality in our system.

A.2 Intended Use of De-Identified Data.

The de-identified data produced by RedactOR is intended for a variety of critical use cases within AI-driven healthcare systems. First, it serves as a valuable resource for *debugging production issues*, enabling engineers and data scientists to analyze system behavior and identify root causes of errors without compromising patient privacy. Second, the data supports *understanding production model behavior*, providing insights into model performance, biases, and failure modes, which guide iterative improvements and model refinements. Finally, the de-identified dataset can be leveraged for *training and evaluating downstream machine learning models*, including clinical documentation automation, clinical named entity recognition, and "needle in a haystack" tasks such as rare condition detection or retrieval of highly specific information from longitudinal records. Additionally, *de-identified data is essential for conducting R&D and facilitates collaboration with external researchers and clinicians*, enabling innovation while ensuring compliance with privacy regulations. These applications illustrate the dual importance of ensuring privacy while maintaining data utility for real-world healthcare advancements.

A.3 All Models

We compare our methods with others as follows:

1. Yashwanth and Shettar (2024): This study uses a zero-shot approach with two prompts – brief and detailed – applied with GPT-3.5 and GPT-4. The model returns "[Censored]" in lieu of explicit entity labels. In our experiments, we evaluate this approach using the GPT-4o to be a fair comparison with the Auto De-ID model.

2. Altalla' et al. (2025): This study employs a zero-shot prompt with GPT-3 and GPT-4, where outputs are marked "[Redacted]" rather than providing explicit entity annotations. Although originally evaluated on a proprietary dataset, we adapt this baseline for the i2b2 corpus and evaluate it using the GPT-4o variant.

3. RedactOR (ours): The Auto De-ID model's outputs are post-processed to align with our predefined PHI/PII entity categories. We use the following configuration parameters to ensure consistency across experiments: max_passes = 2, max_words = 256, and temperature = 0.

4. Commercial Cloud APIs: We assess two widely adopted commercial De-ID services that offer API-based solutions for PHI/PII extraction, namely, AWS (Amazon Web Services Medical Comprehend) and JSL (John Snow Labs). For these services, we standardize the output entity tags to align with our evaluation schema, ensuring fair comparison across systems.

These settings were chosen based on preliminary tuning to balance performance and computational efficiency.

A.4 Auto De-ID Algorithm

Algorithm 1 Auto De-ID Algorithm

Require: Text T, chunk size ω, prediction model M, entity types $\mathcal{E}$, passes p
Ensure: Redacted text $\hat{T}$

```
Split T into m = ⌈|T|/ω⌉ chunks.
for each chunk c_i do
    for j = 0 to p − 1 do
        Extract entities R_i ← M(c_i, E)
        Update fact dictionary D ← D ∪ R_i
    end for
end for
Replace detected entities in T with placeholders. return T̂
```

The Auto De-ID algorithm processes text T by segmenting it into $m = \lceil |T|/\omega \rceil$ chunks. Each chunk undergoes p passes of entity extraction, where the set of identified entities is aggregated:

$$\mathcal{D} = \bigcup_{i=1}^{m} \bigcup_{j=1}^{p} \mathcal{R}_i$$

Choice of Chunk Size: The chunk size ω is chosen to balance entity extraction accuracy. Sending large texts in a single request increases the risk of missing entities, as the model may fail to attend to all parts equally. By processing smaller chunks, we reduce the chance of entity leakage and improve recall.

Multiple Passes Strategy: Using multiple passes (p) helps mitigate biases in the model's attention. In the first pass, the model extracts easily detectable entities. In the subsequent passes, previously detected entities are masked using their entity type (e.g., `[PERSON]`), allowing the model to focus on overlooked entities. This iterative process enhances recall, especially for underrepresented entity types. These hyperparameters can be adjusted based on the capabilities of the chosen LLM.

Handling Context in Redaction: A naive approach to redaction might simply replace all extracted entity mentions in the text with their corresponding entity types (e.g., replacing "76" with `[AGE]`). However, this often leads to over-redaction when identical strings appear in different contexts. Consider the sentence:

> *"The patient is 76 years old and takes 76 mg of aspirin daily."*

In this case, only the first occurrence of "76" refers to the patient's age and should be redacted as `[AGE]`. The second occurrence of "76" is part of a medication dosage and should not be redacted as age. If we blindly replace all instances of "76" with `[AGE]`, we would incorrectly redact "76 mg," resulting in a loss of valuable clinical information.

Our entity extraction method avoids this by instructing the LLM to extract entities along with sufficient context that signals their specific meaning and position in the text. In this example, "76 years old" would be extracted as an `[AGE]` entity, while "76 mg" would either be ignored or extracted as a separate `[DOSAGE]` entity. This ensures that only the appropriate mention is redacted.

Since obtaining exact character positions from LLMs is unreliable, context-based entity extraction allows us to align each detected entity with its precise occurrence in the text, ensuring accurate and minimal redaction.

Detected entities in T are replaced with placeholders to yield the final redacted text $\hat{T}$, ensuring sensitive data is masked correctly while preserving non-sensitive content.

A.4.1 Example Workflow

To illustrate Auto De-ID's process, consider the following structured JSON input:

Field	Value
`patient_name`	Robert Johnson
`patient_id`	A12345
`gender`	male
`medical_history`	Robert Johnson, a patient aged 53 was admitted to Springfield General Hospital for chest pain. Dr. Mary Smith prescribed medication.

Step 0: Schema Identification The De-ID schema specifies rules for each field:

Field	De-ID Rule
`patient_name`	Mask as `[PERSON]`
`patient_id`	Hash
`gender`	Pass-through
`medical_history`	Auto De-ID (LLM-based)

Step 1: Schema Processing The structured fields are processed:

Field	Processed Value
`patient_name`	`[PERSON]`
`patient_id`	`HASH(A12345)`
`gender`	male

Step 2: Chunking The unstructured text is split into overlapping chunks:

Chunk	Text
C1	"Robert Johnson, a patient aged 53 was admitted to Springfield General Hospital for chest pain."
C2	"for chest pain. Dr. Mary Smith prescribed medication."

Step 3: LLM-Based Entity Extraction The model extracts PHI:

Entity Type	Extracted Entities
PERSON	Robert Johnson, Dr. Mary Smith
ORGANIZATION	Springfield General Hospital

Step 4: Multi-Pass Refinement Previously detected entities are masked in subsequent passes:

Pass	Input Chunk for 2nd Pass After Masking
2nd	"[PERSON], a patient aged 53 was admitted to [ORGANIZATION] for chest pain."
2nd	"for chest pain. [PERSON] prescribed medication."

Step 5: Final Entity Extraction Previously detected entities combined with the second pass extractions.

Entity Type	Extracted Entities
PERSON	Robert Johnson, Dr. Mary Smith
ORGANIZATION	Springfield General Hospital
AGE	53

Step 5: Final Redaction. The final de-identified record:

Field	Final Value
patient_name	[PERSON]
patient_id	HASH(A12345)
gender	male
medical_history	"[PERSON], a patient aged [AGE] was admitted to [ORGANIZATION] for chest pain. [PERSON] prescribed medication."

This final output ensures all PHI/PII is masked while maintaining text coherence.

A.5 Audio De-ID Algorithm

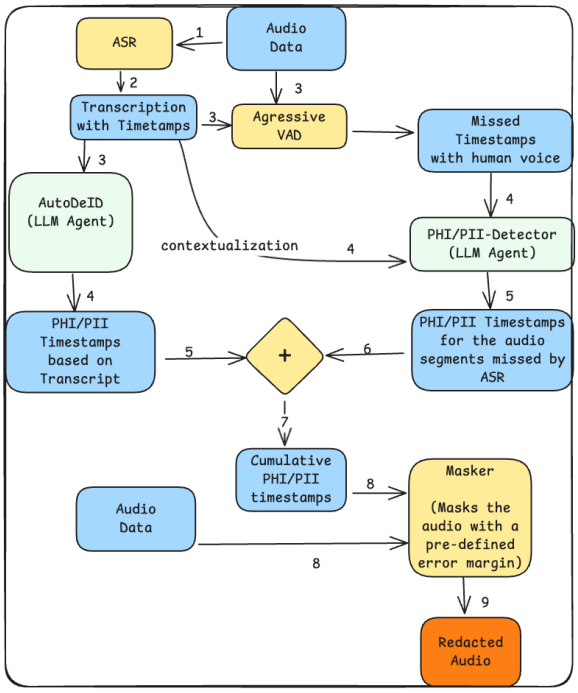

Figure 3: Audio De-Id Workflow Diagram

Algorithm 2 Audio De-ID Algorithm

Require: Audio A, ASR model M_{ASR}, VAD M_{VAD}, De-ID model M_{Deid}, PHI/PII Detector M_{LLM}, entity types $\mathcal{E}$

Ensure: Redacted Audio $A_{\hat{T}}$

1: Generate transcript $T \leftarrow M_{ASR}(A)$
2: Extract PHI/PII $\mathcal{D} \leftarrow M_{Deid}(T, \mathcal{E})$
3: Identify missing timestamps T_{missing} and detect human speech with M_{VAD}
4: **for** each human-voiced timestamp t_{human} **do**
5: Extract context, detect PHI/PII with M_{LLM}, and update $\mathcal{D}$
6: **end for**
7: Mute detected PHI/PII in A. **return** $A_{\hat{T}}$

Audio De-ID first converts speech to text using ASR:

$$T = M_{ASR}(A)$$

Entities are extracted from T to construct $\mathcal{D}$:

$$\mathcal{D} = M_{Deid}(T, \mathcal{E})$$

Gaps in ASR timestamps T_{missing} are analyzed with M_{VAD} to identify human speech regions, where PHI/PII detection is refined using an LLM-based model. The final redacted audio $A_{\hat{T}}$ is generated by muting PHI-containing segments.

A.5.1 Example Workflow

ASR-Generated Transcript:

> "The patient visited Dr. Smith last week a follow-up in his clinic at Creekwood Hospital. They discussed medication changes and scheduled the next appointment for next month. The patient also mentioned feeling unwell over the weekend."

Auto De-ID Detected PHI:

- "Dr. Smith" (00:04.23 - 00:04.80)
- "Creekwood Hospital" (00:12.57 - 00:13.20)

Identifying Missing Timestamps (Set Subtraction):

- (00:02.85 - 00:02.95) (Missed speech)
- (00:07.42 - 00:07.57) (Missed speech)
- (00:15.10 - 00:15.30) (Missed speech)

VAD Filtering (Keeping Only Human Speech Segments):

- (00:02.85 - 00:02.95) - Human voice detected ✓
- (00:07.42 - 00:07.57) - Human voice detected ✓
- (00:15.10 - 00:15.30) - Background noise, discarded ×

Timestamp Adjustment for ASR Errors: To compensate for ASR errors, timestamps are adjusted with a safe margin of 300ms:

- **Before:** "Dr. Smith" (00:04.23 - 00:04.80)
- **After:** "Dr. Smith" (00:03.93 - 00:05.10)
- **Before:** "Creekwood Hospital" (00:12.57 - 00:13.20)

- **After:** "Creekwood Hospital" (00:12.27 - 00:13.50)

Reconstructing the Transcript: The transcript is updated by inserting missing timestamps:

> "<**human_timestamp_(00:02.85 - 00:02.95)**> The patient visited Dr. Smith last week <**human_timestamp_(00:07.42 - 00:07.57)**> a follow-up in his clinic at Creekwood Hospital. They discussed medication changes and scheduled the next appointment for next month. The patient also mentioned feeling unwell over the weekend."

This updated transcript is analyzed by an LLM to predict the likelihood of inserted timestamps containing PHI/PII. For example, suppose the LLM predicted the following:

- <**human_timestamp_(00:02.85 - 00:02.95)**> - NON-PHI/PII
- <**human_timestamp_(00:07.42 - 00:07.57)**> - PHI/PII

Then the final set of detected PHI/PII timestamps—extracted via Auto De-ID and combined by the LLM—guided additional timestamps is used for muting the corresponding sections in the final redacted audio. The final audio will correspond to the following:

> "The patient visited [MUTED] last week [MUTED] a follow-up in his clinic at [MUTED]. They discussed medication changes and scheduled the next appointment for next month. The patient also mentioned feeling unwell over the weekend."

A.6 Auto Relexicalization Algorithm

Auto Relexicalization clusters fact entities using M_{cluster} and retrieves candidate replacements from an index using vector search:

$$R_i = M_{\text{search}}(Q_i, I)$$

If the decision model M_{decision} rejects the match, a new replacement R_{new} is generated using a replacement model:

$$R_{\text{new}} = M_{\text{replace}}(Q_i, T)$$

Algorithm 3 Auto Relexicalization Algorithm

Require: Text T, fact dictionary $\mathcal{D}$, index I, clustering M_{cluster}, retrieval M_{search}, decision M_{decision}, replacement model M_{replace}
Ensure: Relexicalized text $\hat{T}$

```
Cluster entities: C_D ← M_cluster(T, D)
for each cluster C_i do
    Generate query Q_i and retrieve match R_i ← M_search(Q_i, I)
    if Valid replacement M_decision(Q_i, R_i, T) then
        Use R_i
    else
        Generate new replacement R_new ← M_replace(Q_i, T)
        Ingest new replacement and original entity into index I
        Store R_new for final relexicalization
    end if
end for
Apply adjustments and replace entities. return T̂
```

This new replacement, along with the original entity, is then ingested into the index I to ensure consistency across documents. The final text $\hat{T}$ is formed after replacing entities accordingly.

A.7 Proposed Metrics for Relexicalization

We propose a set of evaluation metrics to assess the effectiveness of re-lexicalization in preserving entity roles, maintaining contextual coherence, ensuring replacement consistency, and minimizing unintended biases in clinical models.

Entity Preservation Rate evaluates whether the re-lexicalized entity retains its semantic role and contextual attributes. Higher scores indicate better preservation. For instance, in the sentence *"Dr. Emily Carter is a cardiologist at St. Mary's Hospital,"* a poor re-lexicalization would be *"Alice is a teacher at Westwood Academy"*, which alters both the profession and institution type. A good re-lexicalization would be *"Dr. Kevin Chang is a cardiologist at Lincoln Medical Center"*, as it preserves the entity's role and contextual relevance.

Contextual Coherence Score measures whether the re-lexicalized entity integrates naturally within the surrounding text without disrupting fluency or meaning. For example, in the original sentence *"John met his lawyer, Mr. Anderson, at the firm,"* a

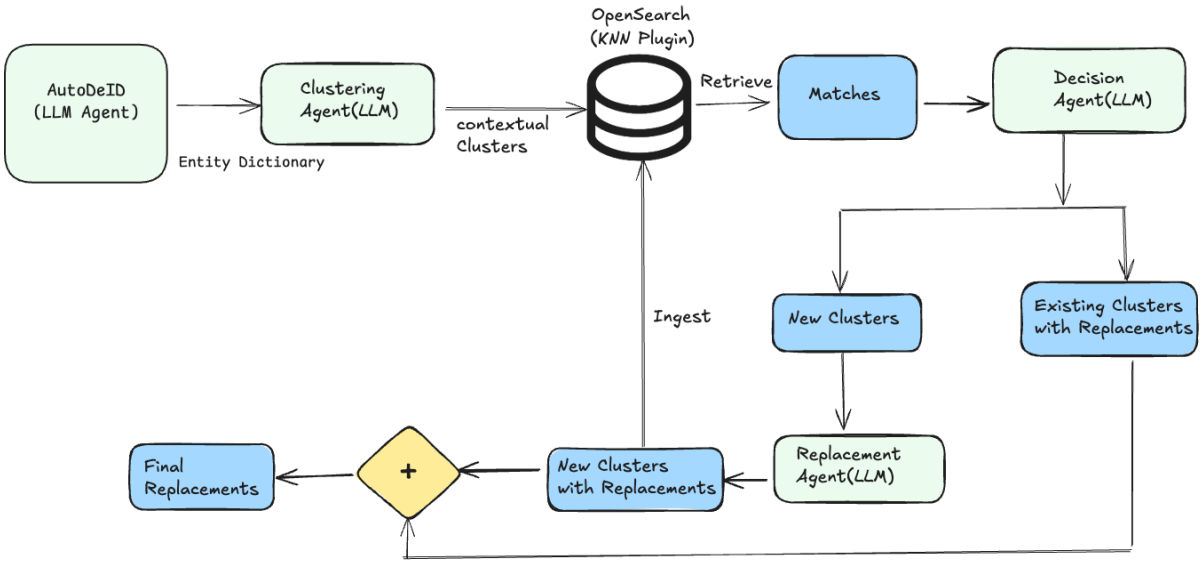

Figure 4: Relexicalization Workflow Diagram

poor substitution would be *"Harry met his lawyer, Pizza Hut, at the firm"*, introducing a semantic inconsistency. A more appropriate replacement would be *"Harry met his lawyer, Mr. Bennett, at the firm"*, maintaining contextual coherence.

Replacement Consistency Score ensures that an entity is consistently replaced across multiple documents, preserving identity coherence. For instance, in *"Dr. Emily Carter attended the surgery"*, a conflicting replacement in another document such as *"Dr. Jennifer Smith is a cardiologist"* introduces inconsistency. A high score indicates that the same entity is replaced uniformly across contexts.

Clinical Model Consistency assesses whether re-lexicalized data, when used in clinical decision-making models, avoids introducing biases related to race, ethnicity, region, or age group. If a model trained on real data produces a metric value X, a poor re-lexicalization may yield a metric of $X + \delta x$, where δx is significantly large, indicating a deviation from real-world behavior. An optimal re-lexicalization ensures that the metric shift remains marginal, preserving the integrity of the clinical model.

A.8 Integration of RedactOR with Oracle Health Clinical AI System

Our RedactOR framework is integrated into Oracle Health Clinical AI system to facilitate the privacy-preserving processing of longitudinal EHRs (including SOAP notes (Podder et al., 2024)), ambient intelligence data, and conversational AI outputs. The system operates autonomously, as the Production Environment is inaccessible to any user group, ensuring a fully automated pipeline. A dedicated worker module, running continuously, monitors the DataSink, retrieves unprocessed files, submits them to the RedactOR service for PHI/PII removal, and securely transfers the de-identified records to the Data Science Lab Environment. A one-way policy enforces strict data flow control, guaranteeing that only de-identified data is accessible within a secure research environment, where authorized users interact with it via an SSH-secured virtual machine, preserving both data integrity and analytical utility.

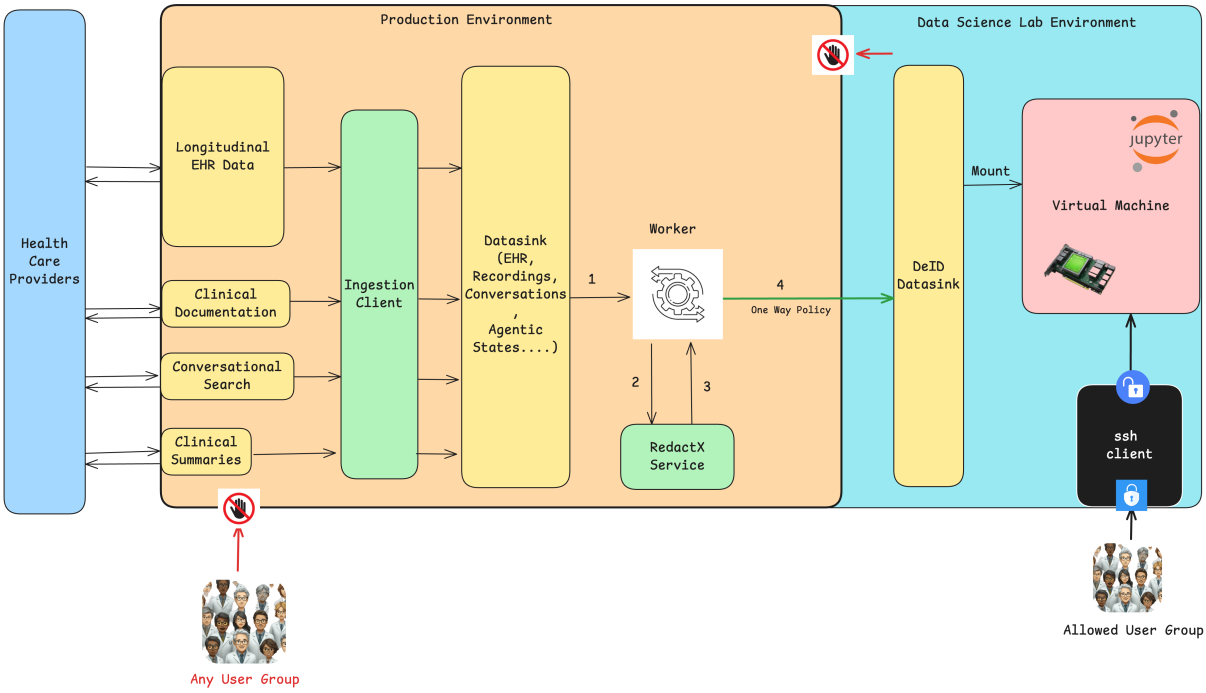

Figure 5: Diagram explaining the integration of our RedactOR framework with Oracle Health Clinical AI System

A.9 End to End Example Illustrating Text De-identification and Relexicalization using RedactOR

A.9.1 Schema for the Input Record

Listing 1: Sample Schema Definition

```
schema_definition = {

B High Level Prompt Templates for Different LLM Components

Due to compliance, privacy, and business confidentiality considerations, we do not release the exact prompts used for each LLM component in RedactOR. Instead, to foster reproducibility and enable community adaptation, we provide high-level prompt templates that capture the *structure, intent, and output format* of each prompt while omitting sensitive implementation details.

These templates define:

- The **role of the LLM** in each component (e.g., entity extraction, clustering, relexicalization),
- The **core task description** and **guidelines** for execution,
- The **expected output schema** in JSON format for integration and evaluation,
- **Placeholders** for data inputs, reference context, and special parameters (e.g., shift values, entity-specific rules).

By offering these templates, we enable researchers and practitioners to develop specialized prompts tailored to their own datasets, privacy policies, and LLM configurations, while ensuring compatibility with our overall system architecture.

B.1 Auto De-ID LLM Component

```
prompt: |
  {{role}}  # High-level role of the LLM.
  Describe that it acts as a De-Identification Specialist tasked with
  extracting PHI/PII from clinical text while adhering to legal privacy regulations
  (e.g., HIPAA). Include general expectations on accuracy and coverage.

  {{entity_extraction_guidelines}}  # Instructions on how to treat text
  (e.g., case sensitivity, contractions), exclusions (e.g., medication names, diagnoses),
  and how to handle special cases. Mention precision requirements for each entity type
  and the need to distinguish similar types (e.g., ADDRESS vs LOCATION).

  {{controls}}  # List and description of specific PHI/PII categories to be extracted
  (e.g., names, dates, contact info, IDs, financial details, technical identifiers,
  demographic information). This section should align with the entity types and provide
  guidance on inclusion/exclusion criteria.

  {{context_awareness}}  # Explain the need for context-sensitive entity extraction to
  avoid over-redaction. Describe how identical strings may appear in different contexts
  with different meanings and the importance of using surrounding context to correctly
  identify which instance to redact. Highlight that the model must associate each extracted
  entity with its specific textual occurrence based on context, not just string matching.

  The output format should strictly just be a JSON dictionary with the entity mentioned
  above as the key and its list of words/phrases found in the text as its value.

  For eg., "ENTITY": ["A", "B", "C"]

  You must not add any key which is not a part of the guidelines above. You must add all
  the entity as the keys in the output even if the value list for that is empty.

  The final output format must look like as follows. You must not produce anything
  except the json output. Ensure the output can be parsed by Python json.loads

  {
    <entity_type1>: <list_of_words_or_phrases_for_entity_type1>,
    <entity_type2>: <list_of_words_or_phrases_for_entity_type2>,
    ... and so on
  }

  {{self_checklist}}  # List of validation checks the LLM must perform before returning output.
  For example, ensure PERSON doesn't include pronouns, validate that BIRTH_DATE_TIME only includes
  birth dates, and confirm all keys in output match allowed entity types.

  Here is the input text:
  {{input_text}}  # Placeholder for the input clinical text to be de-identified.
  This is the text the LLM will process.
```

B.2 Relexicalizer Components

```
clustering_prompt: |
  {{role}}  # Describe the clustering task: grouping contextually identical entities from two medical documents.

  {{task_overview}}  # Outline the goal: assign consistent identifiers to contextually similar entities across documents.

  {{guidelines}}  # Provide detailed guidelines: consistency, identifier format, handling of subnames, JSON format compliance.

  {{example_input_output}}  # Include sample input/output structure for clarity (optional for template use).

  {{input_dict_placeholder}}  # Placeholder for the input dictionary of entities.

  {{reference_text_placeholder}}  # Placeholder for the contextual text reference.

  Output Format:
  ```json
  {
    "ENTITY_TYPE": {
      "ENTITY_TYPE_1": ["entity_variant_1", "entity_variant_2"],
      "ENTITY_TYPE_2": ["entity_variant_3"]
    },
    ...
  }

query_prompt: |
  {{role}}  # Describe task: generate semantic query strings for each entity cluster to retrieve similar entities.

  {{guidelines}}  # Explain how to synthesize cluster information into a concise semantic query.

  {{example_input_output}}  # Provide example input and expected query outputs for context (optional for template use).

  {{cluster_placeholder}}  # Placeholder for the input clusters.

  {{reference_text_placeholder}}  # Placeholder for reference context.

  Output Format:
  ```json
  {
    "ENTITY_TYPE": {
      "ENTITY_TYPE_1": "query_string_for_entity_1",
      "ENTITY_TYPE_2": "query_string_for_entity_2"
    },
    ...
  }

decision_prompt: |
  {{role}}  # Describe task: evaluate semantic similarity of search results to query entities.

  {{guidelines}}  # Provide detailed decision rules for matching: exact match, partial, cultural context, ambiguity.

  {{constraints}}  # State output constraints: JSON format, result length consistency, no assumptions.

  {{example_input_output}}  # Include examples of query, search results, context, and expected Y/N output.

  {{query_placeholder}}  # Placeholder for input query.

  {{search_result_placeholder}}  # Placeholder for search results.

  {{context_placeholder}}  # Placeholder for reference context.

  Output Format:
  ```json
  {
    "result": ["Y", "N", ...]
  }

replacement_prompt: |
  {{role}}  # Describe task: generate realistic replacement values for each cluster entity.

  {{guidelines}}  # Explain general rules for replacement: alignment with entity attributes, format, and uniqueness.

  {{special_rules}}  # Detailed per-entity replacement rules for privacy-preserving, contextually realistic generation.

  Output Format:
  ```json
  {
    "ENTITY_TYPE_1": {"replacement": "replacement_value_1", "type": "ENTITY_TYPE"},
    "ENTITY_TYPE_2": {"replacement": "replacement_value_2", "type": "ENTITY_TYPE"},
    ...
  }
  ```
  {{input_cluster_placeholder}} # Placeholder for the entity clusters to replace.
  {{existing_replacements_placeholder}} # Placeholder for existing replacements to avoid duplication.
  {{reference_text_placeholder}} # Placeholder for context to guide realistic replacements.
```
```

B.3 Audio PHI/PII Timestamps Detector

```
prompt: |
  {{role}}  # Describe task: infer most likely entity type
  for missing audio segments using surrounding transcript context.

  {{entity_definitions}}  # Provide detailed descriptions of each possible
  entity type (e.g., PERSON, AGE, ADDRESS, etc.) and how to identify them from context.

  {{transcript_format}}  # Describe how transcript data is presented
  with timestamps and missing sections.

  {{example_input_output}}  # Provide an example transcript with missing
  timestamps and corresponding expected entity predictions.

  {{task_instruction}}  # Instruct model to return a JSON dictionary where
  keys are timestamps and values are predicted entity types or "UNKNOWN".

  Output Format:
  ```json
  {
    "TIMESTAMP1": "ENTITY_TYPE",
    "TIMESTAMP2": "ENTITY_TYPE",
    ...
  }
  ```

  {{partial_transcript_placeholder}} # Placeholder for the transcript
  input with missing sections.
```

Conceptual Diagnostics for Knowledge Graphs and Large Language Models

Rosario Uceda-Sosa, Maria Chang,
Karthikeyan Natesan Ramamurthy, Moninder Singh
IBM Research
{rosariou, knatesa, moninder}@us.ibm.com, maria.chang@ibm.com

Abstract

Industrial applications pose heightened requirements for consistency and reliability of large language models (LLMs). While LLMs are being tested with increasingly complex reasoning tasks, we argue that much can be learned via diagnostic tools that probe a fundamentally basic type of reasoning: conceptual consistency, e.g., a rule applying to "all surgeons" must also apply to "cardiac surgeons" since a cardiac surgeon is a type of surgeon. In this emerging industry track submission, we propose a method that takes concept hierarchies from a knowledge graph (KG) and automatically generates benchmarks that test conceptual consistency in LLMs. We develop a multi-domain benchmark that reveals rates of conceptual inconsistencies in several state of the art LLMs. Additionally, we use measured levels of inconsistency and disagreement in LLMs to find potentially problematic subgraphs in the reference KG. As such, it offers a scalable complement to symbolic curation, maintenance, and refinement of knowledge graphs, which is a critical activity in KG-based industrial applications.

1 Introduction

Large Language Models (LLMs), despite their tremendous success on traditional benchmarks, often commit errors that limit their application in real-world industrial settings (Haltaufderheide and Ranisch, 2024; Zhang et al., 2025; Dahl et al., 2024). Reliability and consistency of LLMs (Xu et al., 2024; Ji et al., 2023) are key issues that undermine performance and trust. Developing diagnostic tools that can measure the reliability of LLMs in a way that is principled, scalable, and application-domain-focused, is very difficult. Yet, it is critical for high-stakes industrial domains like healthcare, law, or manufacturing, where unpredictable behavior can have serious consequences.

Much attention has been given to LLM abilities on complex tasks that are challenging for even the most highly trained humans (Jaech et al., 2024). Although very impressive, we argue that diagnostic tools can be built via a much more basic type of reasoning: *conceptual consistency*. Conceptual consistency is the ability to reliably produce equivalent answers to semantically equivalent queries about a conceptual hierarchy. It is basic because it concerns the fundamental categorization and property inheritance of concepts. For example, a rule applying to "all surgeons" must naturally extend to "cardiac surgeons" since a cardiac surgeon is a type of surgeon - this is a basic generalization that hinges on a stable conceptual framework. Furthermore, when an LLM is asked about the conceptual hierarchy of surgeons, it should not change its answer when it is asked in a slightly different but semantically equivalent way. This is especially important in real-world applications, where organizations need to verify that the models are aligned with domain-specific knowledge bases, such as product

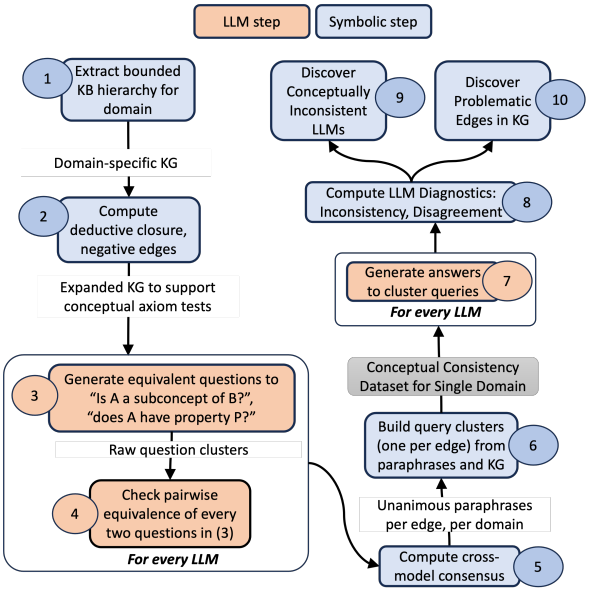

Figure 1: Proposed automated conceptual diagnostics pipeline for a single dataset.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 531–540
July 28-30, 2025

catalogs, medical specialists taxonomies, scientific corpora, and so on.

Knowledge graphs (KGs), on the other hand, are conceptually consistent by design, but have their own set of issues. One of the biggest challenges in using them in industrial applications is maintaining them to ensure their knowledge is factual, up to date, and as complete as necessary for its downstream task. With very large KGs, curating and repairing knowledge can be a substantial obstacle.

We propose a method to automatically generate, with a domain-agnostic process, domain-specific benchmarks that assess the conceptual consistency of LLMs. This domain-agnostic process facilitates generalization, while the creation of domain-specific benchmarks is suited to many industrial applications. The same process can be used to generate benchmarks for finance products, home appliances, medical specialties, and so on (Table 1). Furthermore, we show that analytics from our benchmark can be used to discover areas of the KG that are problematic and need human attention. We illustrate our method on 4 well-established LLM families and 8 domains from the Wikidata KG. These experiments provide empirical support for our method and a pathway to its deployment.

This work has the following contributions:

1. We introduce a domain-agnostic method for creating benchmark datasets that test conceptual self-consistency in LLMs.

2. We release a new benchmark dataset to test conceptual self-consistency in LLMs that consists of over 6,000 deducible edges and 30,000 LLM queries across 8 distinct domains extracted as a KG from Wikidata[1].

3. We show that in addition to revealing inconsistencies in state of the art LLMs, these benchmarks can be used to identify representational errors and problematic subgraphs in the source KG.

Figure 1 shows the methodological contributions of our work, discussed in detail in Sections 3 and 5.

The rest of this paper is organized as follows. We begin with preliminaries regarding conceptual hierarchies (Section 2) followed by our core methodology (Section 3). We present our findings across several domains and LLMs (Section 4) and propose a feedback mechanism for discovering problems with the source KG (Section 5). We conclude with directions for future research (Section 7) and limitations (Section 8).

[1] https://huggingface.co/datasets/ibm-research/knowledge_consistency_of_LLMs

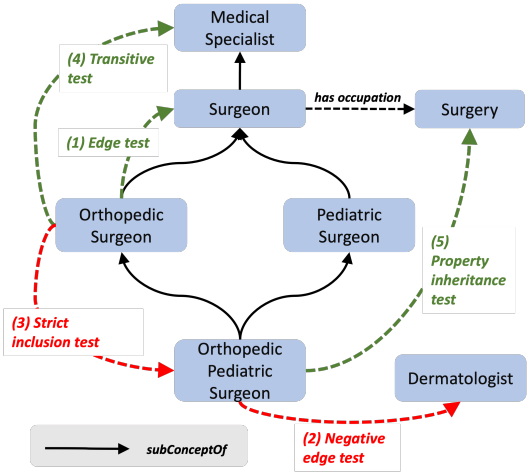

Figure 2: Concept axiom tests (dotted edges numbered 1-5) shown on an example concept hierarchy (solid lines) of medical specialist.

2 Conceptualization properties

Webster defines a *concept* as "an abstract or generic idea generalized from particular instances." Similarly, a *type* is "a particular kind, class, or group". Either of these definitions refer to a set of instances that share similar properties and can be organized into a generalization hierarchy (Brachman and Levesque, 2004). Operationally, we define a concept C as a set of instances. For example, the concept “land vehicle” represents a broad category that includes instances of cars, trucks, motorcycles, etc. and they all have a propulsion system, a steering system, the ability to transport people or goods and so on.

The *subconcept* relation (also known as an “is-a” or ”subclass of” relationship or taxonomy) is a hierarchical relationship where a more specific concept (the subconcept) inherits the properties of a broader, more general concept (the parent concept), while the parent concept inherits the instances of its subconcepts. An illustration of subconcept relations in the medical specialities domain is shown in Figure 2.

Given a concept hierarchy with subconcept relations, a set of concept axioms may be used to compute the *deductive closure* of the graph, which is the full set of edges that can be inferred from the set of explicit edges. The following axioms are

used to compute the deductive closure of the conceptual hierarchy: (1) edge reflexivity/identicality, which simply asserts the existence of a known edge, (2) negative edge, in which the absence of an edge implies its negation, (3) strict inclusion, which prevents subconcept cycles in the hierarchy, (4) transitivity, which enables transitive inference of subconcept relations, and (5) property inheritance, which asserts that if a property exists for a given concept, then it also exists for all corresponding subconcepts. Property inheritance is especially powerful, as is underpins the utility and coherence of structured concept hierarchies. The hierarchy in Figure 2 shows how these axioms indicate that some edges are part of the deductive closure (green edges 1,4,5), while other edges contradict it (red edges 2,3). Following (Uceda-Sosa et al., 2024), we evaluate the conceptual consistency of LLMs with respect to the most fundamental elements of the conceptual hierarchy: the basic subconcept relations and a single property. We use tests that are based on the concept axioms described above.

3 Building benchmarks to test conceptual consistency

We aim to automatically generate datasets that evaluate the conceptual consistency of large language models (LLMs) with respect to a concept hierarchy. Due to the proprietary and sensitive nature of most customer data, we adopt the Wikidata concept hierarchy as an open and structured knowledge base (Vrandečić, 2012; Erxleben et al., 2014; Vrandečić and Krötzsch, 2014; Voß, 2016) whose contents are widely available.

We focus on eight distinct domain-specific datasets encompassing concepts at varying levels of abstraction and ontological persistence (Borgo et al., 2023), spanning from concrete entities such as software products, financial services, and household appliances, to more abstract categories like music genres, academic disciplines, and event types such as natural disasters (Table 1). While the top-level concepts and properties are manually selected, the associated subgraphs are retrieved automatically using the Wikidata public SPARQL endpoint.[2]

The pipeline to create these datasets is depicted in Figure 1. Steps in blue are symbolic in nature, while the orange steps are executed by the LLMs. We start by extracting a concept hierarchy based on a top concept plus one property and a curated set of 10–20 seed leaf concepts per domain. We select these seed concepts for expediency of results, since some of these hierarchies may have tens of thousands of leaves, but it is by no means a compulsory step. Practitioners may decide to automatically process all possible leaves in a hierarchy, provided they have the computational power.

Domain	Predicate	C	$\frac{Q}{C}$
Academic Disciplines	used for	443	4.20
Dishes	has ingredient	1220	5.15
Finance Products	used for	725	4.57
Home Appliances	used for	421	5.67
Medical Occupations	has occupation	740	4.94
Music Genres	practiced by	1990	6.09
Natural Disasters	has cause	357	4.52
Software	studied in	249	4.49

Table 1: Sample domains in benchmark; number of clusters denoted by C; number of questions per cluster denoted by $\frac{Q}{C}$

The top concept and leaf nodes create a bounded, domain-specific KG (step 1). While it is feasible to automatically process all -or randomly selected- leaf concepts across the full hierarchy, yielding significantly larger domain-specific KGs, we found that even this modest sampling reveals substantial inconsistencies and allows us to easily bypass esoteric concepts and less informative (e.g. bookkeeping) edges. Next, we compute the deductive closure of the hierarchy and arbitrary negative edges to test (step 2). The resulting KG consists of a set of domain-specific concepts, the subconcept-of relationships between them, one property (e.g. 'has occupation' in Figure 2), and additional edges that enable axiom tests.

Our goal isn't to check whether LLMs perfectly match the domain-specific knowledge graph (KG), but whether they are consistent with their own internal understanding of the conceptual hierarchy. To test this, we rely on the models themselves to generate semantically equivalent paraphrases of each edge (either physical or virtual) in the hierarchy (step 3). When multiple models agree on these paraphrases within a domain, we then test them further by inserting real examples from the KG (step 4). Finally, we check again across models to make sure they all still treat the paraphrased queries as having the same meaning (step 5).

It is worth noting that not all paraphrases are equivalent across domains, just like not all queries are relevant to all domains. For example, "Is every

[2] https://query.wikidata.org

↓ LLM responses	pred(A,B)	¬pred(A,B)
All YES	CA	CD-FP
All NO	CD-FN	CA
Mixed YES,NO	Inconsistent	Inconsistent

Table 2: Breakdown of possible LLM behaviors in our consistency benchmark: consistent agreement (CA), consistent disagreement (CD) with false positive (-FP) and false negative (-FN) variants. pred(A, B) indicates that entity A is related to entity B through a relationship (predicate). ¬pred(A,B) is the negation of it.

X a Y?" does not make sense in academic disciplines. You can't ask "Is every algebra a mathematics?" However, in medical specialties, "Is every orthopedic surgeon a surgeon?" makes sense This is why the steps 3, 4 and 5 above need to be domain specific.

Next, we build the dataset, creating *query clusters*, sets of questions designed to evaluate edges within the concept hierarchy (step 6)—whether explicitly stated, inferred through deductive closure, or deliberately constructed as a non-existent (i.e., false) edge, as illustrated in Figure 2. Despite their differing origins, all clusters share the property that their constituent questions are expected to elicit a uniform binary response: either all 'yes' (denoting a positive edge cluster, shown in green) or all 'no' (denoting a negative edge cluster, shown in red). For this reason, we refer to them collectively as binary agreement (BA) clusters.

The majority of BA clusters in our dataset test individual edges using sets of four semantically equivalent paraphrased questions. These canonical clusters form the basis for assessing local conceptual consistency. A subset of the positive edge clusters, however, evaluate virtual relations, such as those implied by transitivity or property inheritance, present only in the deductive closure of the graph. These cases are represented by higher-order conceptualization tests, with an antecedent and a consequent. For example, in the case of transitivity we may have in the antecedent the edges 'A subconcept of B' and 'B subconcept of C' and, in the consequent 'A subconcept of C'. The corresponding BA clusters for these axioms involve multiple sets of semantically equivalent queries, each testing both antecedents and consequents. While not all questions in these extended clusters are paraphrases of each other, the expectation of binary agreement still holds: the model should answer consistently across all questions within a cluster.

Empirical evidence supporting the validity of our approach is reflected in the high agreement rate among models: across all tested domains (see Section 4 below), LLMs provide consistent and correct answers to the generated queries in approximately 90% of cases, underscoring the effectiveness of our method in probing conceptual consistency.

4 Evaluation

Irrespective of the specific paraphrasing, all binary agreement (BA) clusters, by construction, elicit a uniform binary response, either 'yes' or 'no'. If the LLM answers the entire cluster uniformly and with an answer that is consistent with the KG, then the cluster is marked **consistent agreement**. Conversely, if the model answers the entire cluster uniformly but contradicts the truth label derived from the knowledge base (e.g., uniformly answering yes to a cluster that corresponds to an edge that doesn't exist in the KG), we classify the cluster as having a **consistent disagreement**. Only when the LLM responds to semantically equivalent questions with a mixture of yes and no responses is the cluster marked conceptually inconsistent. Table 2 shows these conditions as a truth table.

We have evaluated the benchmarks described above using four model families: DeepSeek, Llama, Granite and Mistral (Figure 3).

As we see in Figure 3, LLMs reason inconsistently on approximately 10% of clusters, regardless of model size or version. It is worth noting that all LLMs tested show some level of inconsistency, although some domains, like 'software', seem to be more reliable than others. In particular, we see that 'music genres' seems to be an outlier in terms of consistency.

Within the set of consistent clusters, consistent disagreements occur in approximately 2% of all evaluated clusters across all LLMs. The highest rate of consistent disagreement for any given cluster-LLM combination is less than 6% (see Appendix for detailed statistics). Despite their relative rarity, consistent disagreement clusters appear across all tested LLMs and domains, with the sole exception of DeepSeek-V2 in the software domain.

An additional layer of insight emerges when analyzing the polarity of these disagreements. We estimate the proportion of consistent disagreement clusters in which the LLM asserts the existence of edges that are absent in the source KG (CD-FP in Table 2). These can be thought of as consistent

model	academic disciplines	dishes	finance	home appliances	medical specialties	music genres	natural disasters	software	AVG

Figure 3: Percentages of inconsistent clusters by model and domain.

hallucinations with respect to the KG. These account for approximately 15% of an already small subset of clusters (see Appendix for details). This means that the dominant trend in LLM disagreement involves false negatives (CD-FN in Table 2), where the model systematically denies edges that are present in the KG.

Finally, we observe that neither architectural scale nor newer model versions significantly mitigate the observed inconsistencies. This suggests that such structural inconsistencies are not merely artifacts of model size or versioning, but are instead deeply rooted in the underlying training data and inductive biases of current LLM architectures. Addressing these limitations may require architectural innovations or fundamentally new approaches to knowledge representation and reasoning in LLMs.

5 Identifying problematic subgraphs

As noted above, conceptual consistency does not depend on uniform agreement with the reference KG. Although community curated KGs such as Wikidata are very rich approximations of world knowledge, we cannot treat them as definitive ground truth. Indeed, curating, validating, and maintaining KGs is a significant challenge for industrial applications that use them. In this section we show that LLM consensus can be leveraged to identify and potentially resolve ambiguous or conflicting edges in the underlying KG.

We consider two types of evidence that parts of the KG are subjective, incorrect, or otherwise problematic from a knowledge modeling perspective: occurrence of consistent cluster disagreement and rate of edge disagreement. If a particular domain was factually incorrect, we would expect the clusters for that domain to have a high rate of consistent disagreement across several LLMs. However, as noted in Section 4, this only occurs approximately 2% of the time across all domains and LLMs, which is not a strong signal of incorrectness at the domain level. To get a more detailed picture, we measure the rate of edge disagreement, which is the proportion of queries on which the LLM disagrees with the KG, irrespective of the consistency of the LLM reasoning.

This approach proves particularly insightful in the case of the music genres domain, which consistently emerges as an outlier across all evaluated models. As illustrated in Figure 4, the distribution of disagreements exhibits a long tail: the top 100 edges on which LLMs most often disagree account for 48.8% of all disagreements across LLMs. Notably, the majority of disagreements occur around three semantically dense regions of the subgraph: English folk and country music, Jamgrass, and Christmas-themed genres such as carols and hymns. The Wikidata hierarchies in this domain are deep, with many detailed categorizations that may not be standard across knowledge bases. There may also be some disagreement in the meaning of some terms, as in 'country music', which can be equated with 'folk music' or can be understood as a more specific genre specific to North America (US and Canada) by some Wikidata contributors. This points to the challenges of modeling complex domains, particularly those characterized by soft taxonomies, federated authorship or overlapping conceptual boundaries. In such cases, even small inconsistencies or modeling decisions can lead to cascading effects in inference and reasoning. Leveraging the probabilistic consensus of LLMs may offer a scalable complement to symbolic curation, suggesting a novel avenue for semi-automated KG refinement, and helping to surface latent ambiguities to improve KG robustness over time.

6 Related work

The idea that LLMs implicitly encode relational knowledge, traditionally stored in symbolic knowledge bases (KBs) appears early on (Petroni et al., 2019). Subsequent research sought to quantify and address inconsistencies in knowledge and reasoning. Efforts include new evaluation protocols (Jang et al., 2021; Laban et al., 2023; Sahu et al., 2022; Feng et al., 2023; Wang et al., 2023) and the development of consistency-aware loss functions (Elazar et al., 2021). These studies highlighted inconsistency not merely as a surface-level artifact, but as a persistent limitation rooted in how LLMs generalize across paraphrased queries. Relevant research has identified improving internal consistency as a key frontier in the development of trustworthy, knowledge-centric LLMs (AlKhamissi et al., 2022).

Parallel work has explored the emergence of reasoning-like behaviors in LLMs, particularly under chain-of-thought (CoT) prompting (Wei et al., 2022). These strategies elicit multi-step answers, raising questions about whether such outputs reflect genuine reasoning or simply surface-level pattern matching (Kojima et al., 2023; Wei et al., 2022). (Wang et al., 2023) specifically studied consistency in CoT-generated answers and proposed strategies for improving it. Comprehensive surveys of reasoning in LLMs (Huang and Chang, 2023; Plaat et al., 2024; Zhang et al., 2024), catalog the current landscape of techniques and open challenges. While much of the existing literature focuses on strategic or contextual reasoning capabilities of LLMs, we argue that foundational inconsistencies arise even at the level of basic conceptual hierarchies. These should be prioritized and systematically examined as a prerequisite to more complex reasoning tasks.

Therefore, we build on the foundational query cluster approach introduced by (Uceda-Sosa et al., 2024), although our work significantly extends this line of inquiry in several ways. First, we adapt and scale the query clustering methodology to a broader set of domains by formalizing domain-specific conceptualization axioms, enabling automated construction benchmarks tailored for industrial applications. Second, we introduce a novel taxonomy of cluster types and corresponding metrics that not only assess the consistency of LLMs, but also expose structural issues within the KGs themselves. Lastly, we release our novel, multi-domain, conceptual consistency dataset.

Crucially, our approach goes beyond simple factual probing by leveraging inter-model consensus to generate domain-specific paraphrases, offering a principled mechanism for evaluating and augmenting both LLM outputs and KG structures. This enables a richer, bidirectional analysis between symbolic and neural representations, improving both the interpretability and trustworthiness of downstream applications.

7 Conclusions and future work

In this work, we have shown that, even when evaluating against a fixed body of knowledge—whether accurate or flawed—state-of-the-art LLMs exhibit between 7–10% inconsistency on basic factual relationships. Notably, our benchmarks contain query clusters of modest size (Table 1), meaning that inconsistencies arise with as few as 4 paraphrased questions. While in-context learning has shown promise in mitigating these inconsistencies (Uceda-Sosa et al., 2024), it does not eliminate them fully.

Addressing this challenge requires further advances in both fine-tuning and prompting strategies. One promising direction involves CoT prompting, with or without explicit instruction (Wei et al., 2023; Wang and Zhou, 2024), which has been shown to improve both consistency and reasoning depth in LLMs. A second avenue for improvement lies in the modeling of conceptual relationships. Future extensions to our framework could incorporate graded membership, contextual reasoning, or type disambiguation, resulting in a more expressive and accurate assessment of model consistency.

Furthermore, large language models often struggle to generalize safely outside of their training distributions. This poses challenges when evaluating consistency against domain-specific knowl-

edge graphs, which typically assume a closed-world semantics, in contrast to the open-world assumptions underlying LLM behavior. This semantic mismatch complicates the interpretation of incompleteness: when a model hedges or abstains from answering, it may reflect uncertainty rather than a true knowledge gap. Bridging this divide will likely require techniques such as uncertainty modeling, retrieval-augmented generation (Lewis et al., 2021), or grounding in structured knowledge sources (Yang et al., 2025).

Altogether, our findings demonstrate that even small, targeted benchmarks can surface meaningful patterns in LLM reasoning behavior. Even further, they can serve as a powerful feedback mechanism to discover problematic subgraphs in reference KGs, offering a novel method for aiding in the curation, maintenance and refinement of domain-specific KGs. Extending this framework to larger knowledge graphs, broader domain coverage, and multi-hop inferential tasks represents a fruitful direction for future work, with the ultimate goal of deploying our method to enable more reliable and trustworthy AI systems.

8 Limitations

While our work presents a principled framework for building benchmarks for evaluating the conceptual consistency of large language models (LLMs) with respect to structured knowledge bases, it is currently limited both in scope and results.

First, despite automating the subgraph extraction process, the initial selection of domains, top-level concepts, and associated properties remains manual. This introduces constraints on scalability and reproducibility, particularly in industrial or proprietary settings where domain-specific knowledge graphs may exhibit idiosyncrasies or unexpected structural complexities. Automating the concept selection process—potentially through ontology alignment or schema matching techniques—could enhance generalization and reduce reliance on manual configuration. Building a community-curated benchmark library spanning multiple domains would also increase robustness, though such an initiative lies beyond the scope of this paper.

Second, our methodology depends on LLMs themselves to generate semantically equivalent paraphrase clusters. As these are shaped by the models' pretraining data, linguistic biases may be introduced—especially in specialized domains where certain formulations are rare or underrepresented. This may limit the semantic coverage of paraphrase clusters. Future work should explore hybrid approaches that incorporate external paraphrasing tools or human-in-the-loop validation to improve semantic fidelity and robustness.

Third, the non-deterministic nature of LLMs poses challenges for consistency evaluation. Even semantically equivalent prompts may yield divergent outputs across multiple runs due to stochastic decoding. While we try to minimize this through cross-model consensus and greedy decoding, other sampling strategies should be explored to further stabilize evaluations and reduce variance.

Still, these limitations suggest promising avenues for future research aimed at improving both the scalability and reliability of LLM conceptual consistency assessment, especially in complex or high-stakes domains.

Abstract

Large language models (LLMs) have been widely used for relevance assessment in information retrieval. However, our study demonstrates that combining two distinct small language models (SLMs) with different architectures can outperform LLMs in this task. Our approach—QUPID—integrates a generative SLM with an embedding-based SLM, achieving more accurate relevance judgments while reducing computational costs compared to state-of-the-art LLM solutions. This computational efficiency makes QUPID highly scalable for real-world search systems processing hundreds of millions of queries daily. In experiments across diverse document types, our method demonstrated consistent performance improvements (Cohen's Kappa of 0.646 versus 0.387 for leading LLMs) while offering up to 60x faster inference. Furthermore, when integrated into production search pipelines, QUPID improved nDCG@5 scores by 1.9%. These findings underscore how architectural diversity in model combinations can significantly enhance both search relevance and operational efficiency in information retrieval systems.

1 Introduction

Large Language Models (LLMs) have demonstrated remarkable capabilities in Information Retrieval (IR) tasks, including query-document relevance assessment (Li et al., 2024b; Zhu et al., 2024; Tang et al., 2024). Their strong contextual understanding allows them to approximate human-level judgments in ranking search results and evaluating query modifications. However, deploying LLMs in production environments comes with significant challenges. Latency issues pose the most critical barrier for large-scale search systems, where real-time responses are essential, followed by the high computational cost and substantial memory footprint, making them impractical for environments operating on a scale of hundreds of millions of queries daily(Strubell et al., 2019; Sharir et al., 2020; Howell et al., 2023; Thomas et al., 2024). Furthermore, maintaining and continuously updating such models is resource-intensive, limiting their feasibility in dynamic and multilingual search environments.

To address these challenges, Small Language Models (SLMs) have emerged as a promising alternative. SLMs offer a more cost-effective solution while maintaining competitive performance in various NLP tasks (Xie et al., 2024; Brei et al., 2024; Xu et al., 2025). However, existing approaches to SLM-based relevance assessment face two critical limitations: (1) Single SLM approaches lack the expressive power and contextual understanding of LLMs, resulting in suboptimal relevance judgments in complex queries; and (2) Current ensemble methods primarily utilize multiple instances of the same model architecture (Rahmani et al., 2024a), failing to leverage the complementary strengths that different model architectures could provide.

In this study, we propose QUPID (Quantified Understanding for Enhanced Performance, Insights, and Decisions), a novel relevance assessment approach that directly addresses these limitations by combining two architecturally distinct SLMs in a heterogeneous ensemble. Unlike prior ensemble methods that aggregate multiple instances of the same model, our approach integrates a generative SLM (QUPID_{GEN}), which excels at contextual reasoning through token probabilities, with an embedding-based SLM (QUPID_{EMB}), which captures semantic similarity through dense vector representations. By leveraging both generative reasoning and embedding-based similarity within a unified framework, QUPID outperforms state-of-the-art LLMs and SLM ensemble baselines while significantly reducing computational cost. Our results

*Equal contribution

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 541–552
July 28-30, 2025

show that this heterogeneous ensemble strategy enhances relevance labeling accuracy, thus making it a scalable and efficient solution for real-world search engines.

Beyond accuracy improvements, our model has broad practical implications in modern search systems. We demonstrate how QUPID can be integrated into various workflows, including filtering low-quality query-document pairs, evaluating query rewriting and completion modules, assessing the quality of search result snippets, and enhancing ranking models.

To summarize, our contributions are as follows:

- We introduce QUPID, the first relevance labeling approach leveraging a heterogeneous ensemble of generative and embedding-based SLMs, highlighting the effectiveness of architectural diversity.
- We demonstrate that this approach outperforms state-of-the-art LLM-based methods by up to 67% in terms of Cohen's Kappa (κ = 0.646 vs. κ = 0.387), while offering 60x faster inference times (62ms vs. 3258ms), making it highly scalable for production environments.
- We present concrete use cases showcasing how QUPID can be seamlessly integrated into search engine pipelines, yielding measurable improvements in retrieval quality metrics (e.g., +1.9% in nDCG@5) and enhancing overall user satisfaction in real-world deployments.

2 Related Works

LLM-Based Relevance Labeling Recent studies have explored the potential of Large Language Models (LLMs) in relevance assessment tasks, leveraging their strong contextual reasoning and generation capabilities (Li et al., 2024b; Thomas et al., 2024; Upadhyay et al., 2024). For example, Thomas et al. (2024) demonstrated that LLMs could achieve near-human performance in evaluating query-document relevance. However, their proprietary, in-house model setup makes exact replication difficult, limiting reproducibility in real-world applications. Similarly, Upadhyay et al. (2024) introduced an open-source toolkit for evaluating LLM-based relevance labeling models, but their results revealed significant computational inefficiencies, especially when applied to high-throughput search systems. Moreover, these LLM-based methods generally perform well in English but show suboptimal results in multilingual environments such as Korean, highlighting the need for lighter, language-specific models for more efficient deployment (Robinson et al., 2023; Bang et al., 2023; Nguyen et al., 2024; Li et al., 2024c; Jayakody and Dias, 2024).

Embedding-Based Relevance Labeling in LLMs Beyond text generation, recent work has shown that decoder-only LLMs can also be used for embedding-based retrieval tasks (Ma et al., 2023; Wang et al., 2024; Li et al., 2024a). These models, originally trained for next-token prediction, exhibit surprising representation learning capabilities that can be leveraged for similarity-based tasks. However, most existing studies in this domain have focused on fine-tuning embedding models for generalized text similarity, rather than specifically optimizing for query-document relevance labeling.

To address these limitations, several approaches have attempted to enhance LLM embeddings by modifying the attention mechanisms or introducing hard-negative mining techniques (Wang et al., 2024; Li et al., 2024a). Building on this line of work, we integrate embedding capabilities into our SLM ensemble, making it the first hybrid model combining generative and embedding-based SLMs for relevance assessment. This allows our approach to leverage both explicit generation-based judgments and implicit similarity-based signals, improving robustness and accuracy. By uniting explicit generation-based judgments (which capture contextual cues and semantic coherence) with implicit similarity-based signals (which highlight distributional proximity between query and document), our model can more accurately reflect both high-level language understanding and fine-grained relational cues.

SLM-Based Ensembles for Relevance Assessment To address the high computational costs of LLMs, recent studies have explored ensemble methods using Small Language Models (SLMs). For example, JudgeBlender (Rahmani et al., 2024a) aggregates multiple generative SLMs to improve relevance labeling accuracy. However, this approach requires long prompts and a two-step inference process, leading to higher inference latency (1000ms+) and resource consumption. Furthermore, it focuses solely on generation-based relevance assessment without incorporating embedding-based similarity, potentially limiting its effectiveness in ranking tasks. This synergy yields

richer feature representations and mitigates the limitations of using either approach alone, ultimately enhancing both robustness and accuracy in query-document relevance tasks.

Unlike these prior works, our approach introduces a heterogeneous ensemble of two distinct SLM architectures, where one model specializes in generative reasoning and the other in embedding-based relevance computation. By combining both generative and representation-learning capabilities, our method achieves higher accuracy with significantly reduced computational cost, making it scalable for real-world search systems.

3 Methodology

In this section, we introduce our approach to relevance labeling for query-document pairs using two small-scale language models (SLMs). We first describe the process of creating and cleaning our dataset (Section 3.1). We then employ one SLM as a generative relevance labeling model and another SLM as an embedding-based relevance labeling model (detailed in Sections 3.2 and 3.3, respectively). Finally, we describe our ensemble strategy that combines both models' outputs to achieve higher accuracy and robustness (Section 3.4).

3.1 Data Curation

Our approach to curating training data for relevance labeling consists of two main strategies: collecting real-world document data and generating synthetic hard-negative samples. By integrating these approaches, we ensure that our dataset is diverse, well-balanced, and robust to generalization challenges.

3.1.1 Real-World Document Collection

We collected various query-document pairs from the web. These pairs come from three main sources to capture a broad range of text lengths, styles, and complexities:

- Snippet-Style Web Content: Short pieces of text—often lists, tables, or brief paragraphs—extracted from search engine snippets.
- User-Generated Content: Texts directly provided or created by users, such as forum posts or community Q&A entries.
- General Web Documents: Freely crawled online documents covering diverse topics and domains.

With more than 850K query-text pairs, experienced human annotators[1] carefully review each pair and assign an appropriate label among four classes (see Appendix A.1 for details). We adopt a voting scheme to resolve any disagreements, and if all three annotators assign different labels, an additional linguist overseeing the annotation process makes the final judgment. By including snippet-style, user-generated, and general web documents, we ensure varied document lengths and structures such as text, lists, and tables, which is vital for robust model training. (Note that *Somewhat Relevant* has been classified as a relevant label.)

3.1.2 Synthetic Hard-Negatives Generation

Existing studies in retrieval and embedding emphasize the importance of hard-negative samples to enhance model robustness and generalization (Lee et al., 2024; de Souza P. Moreira et al., 2024; Aho and Ullman, 1972; Wang et al., 2024). We follow a similar strategy to further refine our training data.

For each query-document pair collected in Section 3.1.1, we prompt the model to generate new documents that are superficially similar to the original but contextually off-topic or partially misleading. We use Mistral2-Large to produce additional hard-negative documents because it shows plausible Korean synthetic data based on our internal evaluation. Further details on the prompt design can be found in Appendix A.2.

By combining real-world data (approximately 48.70% web documents, 12.17% user-generated content, and 24.62% snippets) with synthetically generated hard negatives (14.51%), we construct a curated dataset comprising roughly 1M query-document pairs.

3.2 Generative Relevance Labeling Model

SLM as a Relevance Labeler When using a generative model for relevance labeling in a query-document setting, there are generally two approaches. One is to directly interpret the tokens produced by the large language model (LLM) as the final decision, optionally appending a confidence estimation step (Thomas et al., 2024; Ni et al., 2025). Another approach is to leverage the token probabilities associated with a specific label or query (Sachan et al., 2023; Zhuang et al.,

[1]The annotators are part of a specialized data-labeling company and work under close guidance and feedback from linguists with domain expertise.

2024), thereby introducing a more explicit calibration stage.

In this work, we follow the token-probability approach proposed by Zhuang et al. (2024), rather than interpreting directly sampled tokens. Specifically, for each query-document pair (q_i, d_i), our generative model M_{gen} is fine-tuned to produce exactly one among three special tokens $\{l_1, l_2, l_3\}$. Each token corresponds to a distinct relevance category (e.g., Highly Relevant, Low Relevance, Not Relevant). We then obtain the log probability of each label token and convert these values into probabilities via a softmax function as follows:

$$p_{i,k} = \mathrm{M}_{\text{gen}}(l_k \mid q_i, d_i), \tag{1}$$

be the probability that the model assigns to label l_k. We define the final relevance score as:

$$f(q_i, d_i) = \sum_{k=1}^{K} p_{i,k} \cdot y_k, \tag{2}$$

where y_k is a label-specific weight (or numeric value) that can be tuned based on downstream requirements or validation set performance. In our experiments, we set these values as follows: *relevant* $= 1.0$, *somewhat relevant* $= 0.5$, and *irrelevant* $= 0$. This approach provides a more informative representation of the model's confidence by considering the probability distribution over possible labels rather than relying on a single sampled output. This allows for a more nuanced understanding of the model's uncertainty, which can be particularly useful in downstream applications requiring risk-aware decision-making.

3.3 Embedding-based Relevance Labeling Model

For fine-tuning the embedding-based model, M_{emb}, it takes a query-document pair (q, d) as input and generates a relevance score through an embedding extraction and classification process. Given an input pair, the model produces a sequence of token-level hidden state embeddings:

$$H = M_{\text{emb}}(q, d) = [h_1, h_2, \ldots, h_n], \tag{3}$$

where $h_i \in \mathbb{R}^{d_h}$ represents the hidden state of the i-th token, and d_h denotes the dimensionality of the model's hidden representation. To obtain a fixed-size representation, we apply mean pooling as it showed more stable performance in our experiments and prior research (Lee et al., 2025; de Souza P. Moreira et al., 2025):

$$\mathbf{h}_{\text{agg}} = \frac{1}{n} \sum_{i=1}^{n} h_i. \tag{4}$$

A linear transformation is then applied to map $\mathbf{h}_{\text{agg}}$ into a relevance score vector:

$$s = W \mathbf{h}_{\text{agg}} + b, \tag{5}$$

where $W \in \mathbb{R}^{K \times d_h}$ is the learned weight matrix, $b \in \mathbb{R}^K$ is the bias term, and K represents the number of predefined relevance categories. Finally, the softmax function is applied to compute the probability distribution over the relevance labels.

3.4 Score Ensemble

To enhance the robustness of relevance scoring, we combine the outputs of the generative model M_{gen} and the embedding-based model M_{emb} through a weighted averaging approach. Weighted averaging preserves the independence of each model's outputs and provides a straightforward way to balance generative vs. embedding signals Each model produces a relevance score given a query-document pair (q, d):

$$s_{\text{gen}} = M_{\text{gen}}(q, d), \tag{6}$$

$$s_{\text{emb}} = M_{\text{emb}}(q, d). \tag{7}$$

To obtain the final ensemble relevance score, we compute a weighted sum of these two scores:

$$s_{\text{final}} = w_{\text{gen}} \cdot s_{\text{gen}} + w_{\text{emb}} \cdot s_{\text{emb}}, \tag{8}$$

where w_{gen} and w_{emb} are the weighting coefficients assigned to the generative and embedding-based models, respectively. The weights can be tuned based on validation performance or set heuristically. In practice, we determine the optimal w_{gen} and w_{emb} by evaluating the ensemble's effectiveness on a held-out validation set, selecting the combination that maximizes relevance prediction accuracy.

4 Experimental Setup
