Table 7: Statistics of synthetic data. Note that we adapt the self-reflection mechanism to enhance data quality, which also filters out some synthetic data.

F Statistics of Synthetic Data

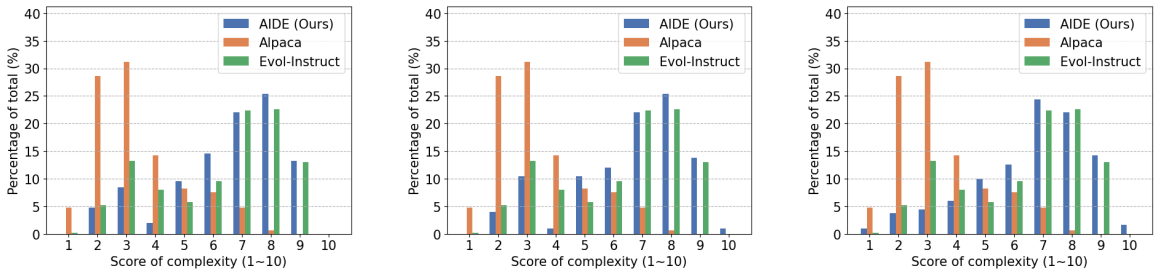
In Table 7, we demonstrate the amount of seed data used and the quantity of data synthesized in AIDE. Specifically, using $K = 2$ and 10 seed data points for each task, AIDE generates approximately 3K new data points in about 20 hours when adapting the self-reflection mechanism to improve the quality of new data.

G Detailed Analysis of Relevance, Diversity and Complexity (RQ3)

We conduct experiments to assess whether the synthetic data generated by AIDE preserves its complexity.

G.1 Analysis of Complexity

Similar to Evol-Instruct (Xu et al., 2024) using 5 predefined operations to expand the complexity of synthetic data, AIDE utilizes 3 predefined opera-



(a) Synthetic data for the Code task (b) Synthetic data for the C&E task (c) Synthetic data for the Impl. task

Figure 10: The complexity of randomly sampling 500 synthetic data from AIDE based on different domains, including code, cause and effect and implicatures. We also compare the complexity of randomly sampling 500 synthetic data from the state-of-the-art data synthesis methods including Alpaca and Evol-Instruct.

tions including reasoning, constraint and concrete following triplets from $\mathcal{A}$ to expand the complexity during data synthesis. For verifying the complexity of synthetic data from AIDE, we randomly sample 500 synthetic data from different synthetic methods including Alpaca, Evol-Instructs and our AIDE. Then we apply Claude Sonnet 3.5 to evaluate the complexity of synthetic data using the same prompt as that from Evol-Instruct. We plot the distribution of score of complexity ranging from 1 to 10, shown on Figure 10. We find that most of synthetic data from AIDE and Evol-Instruct obtain the score of complexity higher than 5, when comparing with that from Alpaca. It is worth mentioning that AIDE only uses 3 predefined operations less than the operations applied in Evol-Instruct while having the synthetic data with comparable complexity.

G.2 Visualization

We follow the approach in (Zhao et al., 2024b) and analyze the coverage of synthetic data from AIDE in the embedding space. Specifically, we use the jina-embeddings-v2-base-code (Günther et al., 2023) to embed data points about coding while employ jina-embeddings-v2-base-en to encode other text data. With the embeddings, we utilize t-SNE (van der Maaten and Hinton, 2008) to project embeddings into a two-dimensional space. We adopt the real data from the code line description task and the C&E task as baselines to demonstrate the coverage of synthetic data from AIDE.

In Figure 11a, we observe that the embedding clusters of synthetic data via AIDE and the embeddings of all real data from the Code task appear to be largely disjoint. Figure 11b demonstrates that the synthetic data has a larger range which covers all real data from the C&E task. This supports a conclusion that AIDE with few seed data related to specific tasks systematically cover different distributions of the target task space, and therefore fine-tuning Mistral-7B with synthetic data from AIDE leads to a positive effect on the improvement of performance of Mistral-7B in specific tasks.

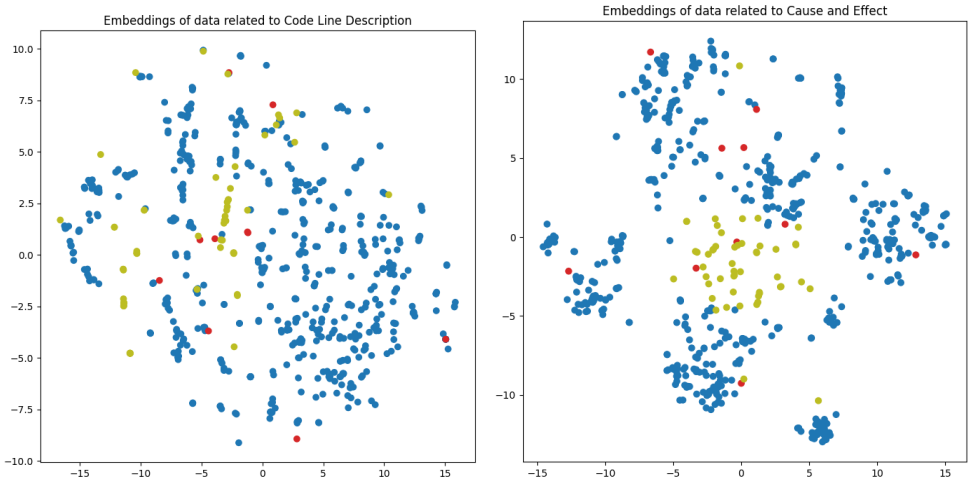
H Benchmark Statistics

The details of the benchmarks we employ in the paper are included below:

- **BIG-Bench** (bench authors, 2023) includes over 200 tasks that are currently challenging for language models, encompassing a wide range of categories. We selected the code line description task, cause and effect task, implicatures task, elementary math task and temporal sequence task, totally 5 tasks, which involve coding understanding, causal reasoning, logical reasoning. The selected tasks without training sets include 60, 153, 492, 7.688k and 1k data points in their test sets, respectively.

- **MMLU** (Hendrycks et al., 2021) is designed to evaluate the broad capabilities of language models across 57 tasks. We select 5 tasks from the benchmark, including high school biology, college computer science, philosophy, electrical engineering and marketing, which respectively contain 310, 100, 311, 145 and 234 data point in the test sets.

- **ARC** (Clark et al., 2018) is a set of grade-school science questions, which are designed to test a model's ability to perform complex reasoning. We select ARC-Challenge with the more difficult questions that are particularly challenging for AI models because they often require multiple steps of reasoning, inference,



(a) Synthetic data (Code task)

(b) Synthetic data (C&E task)

Figure 11: We observe that randomly sampling 600 synthetic data generated by AIDE using the seed data covers the all real test data from two tasks in the regions of embedding space, after projecting to two dimensions via t-SNE.

and external knowledge beyond the text provided in the question. We apply 1.17k testing data points in this task to test LLMs.

- **GSM8K** (Cobbe et al., 2021) is a dataset of 8.5K high quality linguistically diverse grade school math word problems. The dataset was created to support the task of question answering on basic mathematical problems that require multi-step reasoning. We select the main subset which has 7.47k training data points and 1.32k testing data points.
- **TruthfulQA** (Lin et al., 2022) is a benchmark to measure whether a language model is truthful in generating answers to questions. We select the multiple choice sets which contains 817 questions for testing.
- **MedQA** (Jin et al., 2020) is a comprehensive resource designed to enhance medical question-answering systems. It comprises 10,178 multiple-choice questions sourced from medical exams across the United States, Mainland China, and Taiwan. Each question is accompanied by several answer options, with the correct answer clearly indicated. We select 1,956 data points for the training set and 217 for the validation set. Additionally, we sample 10 seed data points to synthesize 2,173 data points through AIDE.
- **FinBen** (Xie et al., 2024) is part of the PIXIU project (Xie et al., 2023), an open-source initiative aimed at developing, fine-tuning, and evaluating large language models (LLMs) in the financial domain. PIXIU encompasses various components including FinBen, a financial language benchmark. The CFA task consists of 1.03k data points, which we divide as follows: 100 data points for the test set, 804 as gold training data, 89 for the validation set, and 10 as seed data points to synthesize 893 additional data points through AIDE.

Task Name	Abbreviation	# Test data
Code Line Descriptions	Code	60
Cause and Effect	C&E	153
Implicatures	Impl.	492
Elementary Math	Math	7,688
Temporal Sequence	Time	1,000
High School Biology	Bio.	300
College Computer Science	CS	100
Philosophy	Phi.	311
Electrical Engineering	EE	145
Marketing	Market.	234
Flare-cfa	CFA	100
ARC-Challenge	-	1,170
GSM8k	-	1,320
TruthfulQA	-	817
MedQA	-	100

Table 8: Data statistic of selected tasks from BIG-Bench, MMLU, ARC-Challenge, GSM8K and Truthful QA.

I Prompt for Extracting a Topic and Knowledge Attributes

We utilize Claude Sonnet 3.5 as the LLM extractor in AIDE, as shown in Figure 1. In Figure 12, we demonstrate a prompt used in the LLM extractor to extract a topic and knowledge attributes.

J Prompt for Synthesizing Data Points with a Triplet and an Operation

We apply Claude Sonnet 3.5 as the LLM synthesizer in AIDE, as illustrated in Figure 1. Figure 13 provides an example of a prompt used by the LLM synthesizer to generate a new data point, incorporating a triplet and a constraint operation.

K Prompt for Synthesizing Data Points with a Topic and Personas

We use Claude Sonnet 3.5 as the LLM synthesizer to generate new data points based on a persona and a constraint operation. Figure 14 demonstrates a prompt provided to the LLM synthesizer, incorporating both a persona and a constraint operation.

L An Example of 10-hop Synthesis without Residual Connection

Figure 15 presents an example of 10-hop synthesis without applying the residual connection. In multi-hop synthesis, when the hop depth K becomes large (e.g., $K = 10$), the synthetic data tends to include more irrelevant information.

M An Example of 10-hop Synthesis with Residual Connection

We introduce the residual connection mechanism in AIDE , as detailed in Section 3.3 and Figure 9. Figure 16 illustrates an example of 10-hop synthesis incorporating the residual connection.

N Prompt for Self-Reflection

During the self-reflection, when multi-hop synthesis synthesizes data through knowledge attributes for maintaining relevance, we apply a LLM as grader to check the relevance of the synthetic data and obtain a relevance score. Similarly, while we generate synthetic data through multi-hop synthesis using persona to expand diversity, a LLM grader checks the diversity of the synthetic data and return a diversity score. We show the prompt about checking relevance and diversity in Figure 17. With a self-reflection prompt in Figure 18, we collect the score of diversity and relevance as the feedback to process the synthetic data.

O Ethical Considerations

While AIDE is an effective framework for generating diverse, task-relevant data, it's important to consider the ethical implications. With only a few seed data points, AIDE leverages LLMs to extract, synthesize, grade, and annotate instruction-response pairs. However, like human annotators, LLMs can occasionally generate unethical, toxic, or misleading content. Although we use self-reflection techniques during synthesis, it's essential to adopt proven methods for detoxifying and reducing bias in LLM outputs. Stricter inspection and filtering rules should also be applied. Given AIDE's flexibility, future advances in bias mitigation and fairness can be integrated as additional modules.

P Limitations

We recognize AIDE 's limitations in the following two areas, which can serve as inspiration for future research opportunities in the field of data synthesis.

Ethical Consideration. Since our method AIDE relies on an LLM to serve as the extractor, synthesizer, grader, and annotator, it may inherit biases and fairness issues from the underlying LLM. However, AIDE stands to benefit from improved LLMs that incorporate advanced techniques for reducing bias and enhancing fairness.

Cognitive Process. While AIDE helps base models improve their performance in the Math task, the zero-shot performance of the fine-tuned base models remain around 20%. In the future, a potential future direction is to integrate Chain-of-Thought techniques into AIDE, such that AIDE can provide better synthetic data to enhance reasoning steps of the base models though fine-tuning.

Prompt for extracting a topic and knowledge attributes of a data point

I want you to act as an instruction analyzer.
Given an instruction, you should recognize its topic and knowledge attributes. You need to list at most 2 knowledge attributes while each knowledge attributes should be transferable and concise with one word or two words. Your should only output the topic within <Topic></Topic> XML tags and output knowledge attributes within <Attributes></Attributes> XML tags.
Follow the examples below to analyze <The Given Instruction>
<Example>
<The Given Instruction> As a sports commentator, describe the winning play in the final seconds of a championship game. </The Given Instruction>
<Topic> creative writing </Topic>
<Attributes> role-play, sports </Attributes>
</Example>
... Some examples ...
<The Given Instruction> {Here is instruction.} </The Given Instruction>

Figure 12: Prompt for extracting a topic and knowledge attributes.

Prompt for synthesis with a triplet and a constraint operation

I want you act as a Prompt Writer. Your objective is to rewrite a given prompt into a more complex instruction to make those famous AI systems (e.g., chatgpt and GPT4) a bit harder to handle. But the rewritten prompt must be reasonable and must be understood and responded by humans. You SHOULD generate the rewritten prompt within <Rewritten Prompt></Rewritten Prompt> XML tags through complicating <The Given Prompt>, such that <Rewritten Prompt> meets the following <EXPECTATIONS>
<EXPECTATION 1> The <Rewritten Prompt> SHOULD BE SIMILAR TO {a seed data point (a residual connection)}.
</EXPECTATION 1>
<EXPECTATION 2> The <Rewritten Prompt> can be obtained by adding simple constraints into content in <The Given Prompt>.
</EXPECTATION 2>
<EXPECTATION 3> The <Rewritten Prompt> is related to {topic} using {knowledge attribute}.
</EXPECTATION 3>
<EXPECTATION 4> Make the <Rewritten Prompt> become as SHORT as possible.
</EXPECTATION 4>
<EXPECTATION 5> <The Given Prompt>, <Rewritten Prompt>, 'given prompt' and 'rewritten prompt' are not allowed to appear in <Rewritten Prompt>.
</EXPECTATION 5>

Follow the below examples to generate <Rewritten Prompt> by {adding constraints} into <The Given Prompt>.

... Some examples ...

<The Given Prompt>{Here is instruction.}</The Given Prompt>

Figure 13: Prompt for synthesis with a triplet and an operation

Prompt for synthesis with a persona and a constraint operation

A persona is the aspect of someone's character. You can use the given character to generate a <Created Prompt>. Your goal is to use <The Given Persona> and an operation to create a <Created Prompt> different from <The Given Prompt>.You SHOULD generate the <Created Prompt> through the following actions:

<Action 1> <Created Prompt> should related to the topic {a topic}. </Action 1>
<Action 2> You need to use <The Given Prompt> and the character from <The Given Persona> to generate <Created Prompt>. </Action 2>
<Action 3> <Created Prompt> should be different from <The Given Prompt>. </Action 3>
<Action 4> The <Created Prompt> can be obtained by adding simple constraints into the generated content. </Action 4>
<Action 5> You should try your best not to make the <Created Prompt> become verbose. </Action 5>
Follow the examples below to generate <Created Prompt> and output the <Created Prompt> within <Created Prompt></Created Prompt> XML tags.

... Some examples ...

<The Given Prompt> {Here is instruction.} </The Given Prompt>
<The Given Persona> {Here is a persona.}</The Given Persona>

Figure 14: Prompt for synthesis with persona and a constraint operation

An example of 10-hop synthesis without the residual connection

Input: Create an example of an economic and a political issue.
1**-hop neighbor**: Design a scenario that incorporates both an economic and a political quandary, and introduce a critical factor that significantly influences the outcome.
.....
10**-hop neighbor**: Construct a multifaceted narrative that intricately weaves together various economic, political, and sociocultural elements, entwined with an unexpected turn of events that dramatically shifts the trajectory, demanding a methodical strategy to maneuver through the complex array of repercussions, emphasizing an in-depth exploration of ethical dilemmas, alongside an additional dimension probing into the subconscious drivers behind the choices made by each character, all while taking into account the impact of technological advancements and how they shape the development of the storyline.

Figure 15: An example of 10-hop synthesis without the residual connection. When the depth of hop K is large in multi-hop synthesis (i.e., $K = 10$), more irrelevant information can be introduced in the synthetic data.

An example of 10-hop synthesis with the residual connection

Input: Create an example of an economic and a political issue.
1**-hop neighbor**: Develop a multifaceted scenario encompassing interconnected economic and political challenges, each influencing the other in a complex and nuanced manner.
. . . . . .
10**-hop neighbor**: Craft an engaging narrative interlacing complex economic and political dilemmas, highlighting their symbiotic nature and profound impact on each other, necessitating a nuanced comprehension of their intricate interdependencies for adept navigation.

Figure 16: An example of 10-hop synthesis with the residual connection shown in Figure 9.

Prompt in self-reflection for evaluating the relevance/diversity score of the synthetic data

I want you to act as a domain expert to rate the relevance of <The Given Prompt> and <The Original Prompt>.

You should give an overall score on a scale of 1 to 10, where a higher score indicates the <The Given Prompt> is more relevant to/different from <The Original Prompt>.
You must just give <Score> without any other reasons within the <Score></Score> xml tags.
Follow the examples below to analyze and rate relevance of <The Given Instruction> and <The Original Prompt> in <Score>.

... N Examples ...

Your output should follow the format of examples, which means preserve the same format and show the score within <Score></Score> xml tags.
<The Original Prompt> {Here is the original instruction.} </The Original Prompt>
<The Given Prompt> {Here is the given prompt.} </The Given Prompt>

Figure 17: Prompt in the self-reflection can be used to evaluate the relevance score or diversity score of the synthetic data

Prompt for self-reflection to improve the synthetic data

I want you to act as a professional data generator.

The <Score> from grader shows that the <The Given Prompt> is not relevant to <Pre-prompt> (or the <The Given Prompt> is highly similar to <Pre-prompt>).
You are asked to rewrite <The Given Prompt> as the <Improved Prompt> using the <Pre-prompt>.
Generate <Improved Prompt> that improves the <Score> of relevance (or <Score> of diversity) by making <Improved Prompt> relevant to <Pre-prompt> (or by making <Improved Prompt> different from <Pre-prompt>).
Must only generate <Improved Prompt> within the <Improved Prompt></Improved Prompt> XML tags.

... N Examples ...

<Pre-prompt> {Here is the pre-prompt.} </Pre-prompt>
<The Given Prompt> {Here is the given prompt.} </The Given Prompt>
<Score> {Here is score.} </Score>

Figure 18: Prompt for self-reflection, which can be used to improve the relevance or diversity.

Prompt for a LLM judging the diversity of the synthetic data

You are a helpful AI assistant for evaluating and rating the difficulty and complexity of the following question.

Given an instruction, you should recognize its related knowledge without any explanation.
List several most related knowledge, the knowledge should be transferable, so that LLM can leverage them to answer similar questions.
Each knowledge should be concise with one word or two words.
Follow the examples below to analyze <The Given Instruction>.
<Example>
<The Given Instruction> As a sports commentator, describe the winning play in the final seconds of a championship game. </The Given Instruction>
<Knowledge> sports </Knowledge>
</Example>

... N Examples ...

You must just give the knowledge within the <Knowledge></Knowledge> XML tags without any other reasons.
<The Given Instruction> {Here is the given instruction} </The Given Instruction>

Figure 19: A LLM uses the prompt to judge the diversity of the synthetic data from the perspective of knowledge.

Prompt for a LLM judging the relevance of the synthetic data

You are a helpful AI assistant for evaluating and rating the difficulty and complexity of the following question.

We would like you to evaluate and rate the relevance of <Instruction1> and <Instruction2> .
You should give an overall score on a scale of 1 to 10, where a higher score indicates higher relevance between two instructions. You must just give a score without any other reasons.
Put the score within the <Score></Score> XML tags.

... N Examples ...

<Instruction1> {Here is the Instruction1} </Instruction1>
<Instruction2> {Here is the Instruction2} </Instruction2>

Figure 20: A LLM uses the prompt to judge the relevance of the synthetic data from the perspective of knowledge.

Synthesizing and Adapting Error Correction Data for Mobile Large Language Model Applications

Yanxiang Zhang*, **Zheng Xu***, **Shanshan Wu***, **Yuanbo Zhang**, **Daniel Ramage**
Google
{zhangyx, xuzheng, shanshanw, zyb, dramage}@google.com

Abstract

Error correction is an important capability when applying large language models (LLMs) to facilitate user typing on mobile devices. In this paper, we use LLMs to synthesize a high-quality dataset of error correction pairs to evaluate and improve LLMs for mobile applications. We first prompt LLMs with error correction domain knowledge to build a scalable and reliable addition to the existing data synthesis pipeline. We then adapt the synthetic data distribution to match the mobile application domain by reweighting the samples. The reweighting model is learnt by predicting (a handful of) live A/B test metrics when deploying LLMs in production, given the LLM performance on offline evaluation data and scores from a small privacy-preserving on-device language model. Finally, we present best practices for mixing our synthetic data with other data sources to improve model performance on error correction in both offline evaluation and production live A/B testing.

1 Introduction

Modern typing applications on mobile devices use many machine learning models, e.g., language models (LMs) (Ouyang et al., 2017; Liu et al., 2024b). The generative capacity of LMs can significantly improve user experience by (automatically) correcting various errors and predicting next words to facilitate typing. Recent advancement in large language models (LLMs) have achieved impressive performance on many language tasks (OpenAI, 2024; Google, 2024; Meta, 2024), opening new opportunities for rewriting in mobile applications (Gunter et al., 2024; Liu et al., 2024b). In practice, LLMs can be deployed on mobile devices or on servers in datacenters. However, mobile devices have limited resources that currently only support moderate-sized LLMs (often less than 10 billion parameters). Even for LLMs on servers, moderate-sized models are preferred for mobile applications because of the considerations of latency, privacy and serving cost.

Error correction (EC) is an important capacity of LLMs for mobile applications (see examples in Fig. 1). As LLMs' general capacity can decrease with the model size (Wei et al., 2022; Cho et al., 2024), it is important to evaluate and improve moderate-sized models for mobile applications. Moreover, the data distribution of mobile applications can differ from commonly collected public web data (Hard et al., 2018; Xu et al., 2023; Wu et al., 2024); typing on mobile touchscreens introduce more errors (Shi et al., 2025) in addition to common grammatical errors (Bryant et al., 2023; Stahlberg and Kumar, 2021). Such EC data for mobile applications differs from much of current LLMs' training data.

Post-training with high-quality data is commonly used to align LLMs with users (Wei et al., 2021; Chung et al., 2022; Ouyang et al., 2022) and bridge the domain shift (Cho et al., 2024). Low-Rank Adaptation (LoRA) method, which only trains a small subset of parameters, is efficient for fine-tuning models for mobile applications (Hu et al., 2022). LoRA additionally provides the flexibility to fine-tune a set of different adapters to customize for various downstream tasks, useful for deploying LLMs on mobile devices (Gunter et al., 2024). However, collecting high-quality data for post-training for mobile applications is challenging because of the domain shift and privacy considerations on user data.

Production LLM mobile applications have developed pipelines to synthesize error correction data. Liu et al. (2024b) collects public web data, and then uses trained task-specific models (Lichtarge et al., 2020) to detect grammatical errors. A typing simulator adds more mobile-specific errors to construct EC pairs based on the web data with detected

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1102–1112
July 28-30, 2025

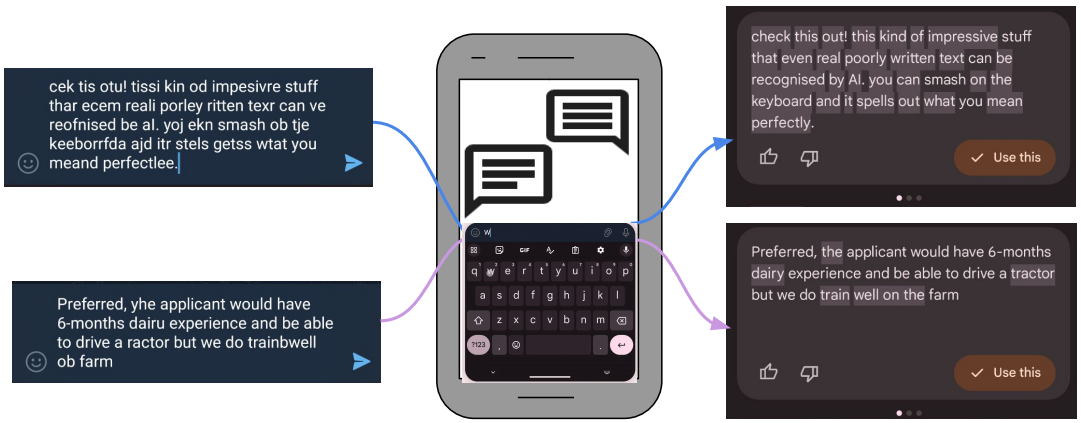

Figure 1: Examples of mobile LLM applications for error correction. User typing data has a domain shift compared to public web data. LLMs rewrite and correct highly corrupted text based on the context of the input itself.

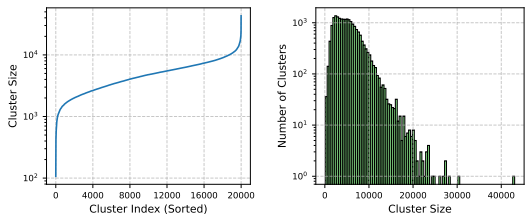
grammar errors. These EC data pairs are split into training and validation datasets. This data pipeline extracts only a small set of EC data from a large collection of web data due to the detection and selection process. Moreover, the data distribution of web data differs from the mobile user distribution, as discussed in (Wu et al., 2024). Indeed, we observe a discrepancy between offline evaluation on validation data and live A/B test metrics in production.

Privacy-preserving methods are required to access in-domain user data to improve the model performance. Federated learning (FL), where devices collaboratively learn a model without transferring user data, and differential privacy (DP), where model is mathematically guaranteed not to memorize training data, are combined to privately fine-tune LMs (Xu et al., 2023; Choquette-Choo et al., 2024; McMahan et al., 2024). However, production DP FL systems on mobile devices only reliably train models with 10 million parameters (Daly et al., 2024). Differentially private synthetic data is another promising approach to collect high-quality privacy-preserving data (Kurakin et al., 2023; Yue et al., 2023). However, DP synthetic data generation requires iterative interaction between LLMs and private data, such as fine-tuning LLMs as data generators. The quality of synthetic data also decreases with the generator model size. These methods are not yet applied to training moderate-sized LLMs with billions of parameters for production mobile applications.

In this paper, we synthesize error correction data to improve LLMs with billions of parameters for mobile applications. In a production data pipeline, we incorporate human knowledge of the mobile application domain and grammar errors to carefully design prompts, and use LLMs instead of grammar error detectors to scalably and reliably synthesize EC pairs (Sec. 2). To further overcome the discrepancy between offline evaluation on (synthetic) EC data and live A/B test metrics for model deployment in practice, we propose to adapt the data distribution to match the mobile application domain by reweighting the samples (Sec. 3). Small LMs with less than 100 million parameters are fine-tuned by federated learning with differential privacy on user data. These small LMs are used to generate initial scores for each offline evaluation sample. A reweighting model is parameterized to predict a final score for each sample based on the initial small LM scores. As the number of intial LM scores is small, the lightweight reweighting model is learnt by reweighting per-sample evaluation to predict only a handful of A/B test metrics collected during model deployment. We demonstrate that the reweighting model, together with privacy-preserving small LMs, effectively predicts live A/B test metrics. Finally, we present best practices for mixing our synthetic data with other data sources to improve the model performance (Sec. 4). LoRA method is used to further fine-tune an LLM with billions of parameters that is already post-trained for general purpose instruction following. A continue training strategy, where the model is first fine-tuned on our large-scale synthetic data, followed by fine-tuning on a mixture of existing smaller dataset and reweighted synthetic data, achieves superior performance on various offline evaluations, and 2.47% to 7.18% relative improvements on key metrics in production live A/B test.

2 Synthesizing Error Correction Data

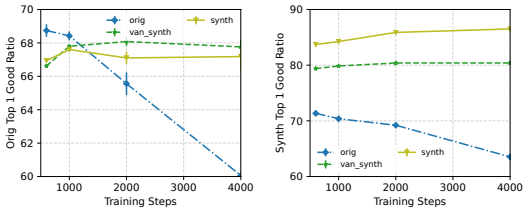
In this section, we discuss prompting LLMs as an addition to error correction data pipeline for efficiency and effectiveness, and show its advantage in scalability and domain adaptation. Following Wu et al. (2024), we synthesize an initial dataset in the domain of typing text on mobiles, by filtering and transforming public web data (i.e., C4 (Raffel et al., 2020) dataset), and collecting LLM generations with carefully crafted prompts of human knowledge. The initial dataset contains more than 100 million documents of conversation-like text, and even a small subset (about 0.2%) is much larger than the original EC dataset in production. We subsample the initial typing text dataset to reduce the subsequent processing costs from prompting LLM to add grammar and typing errors. To ensure good diversity and coverage during sampling, we first embed the documents using the Gecko (Lee et al., 2024) text embedding model, run k-means clustering to obtain 20k clusters. See Fig. 2 for statistics of clustering. We then sample 10 data points per cluster, resulting in a dataset contains about 200k documents, which has 2M examples where each example is either a sentence, or a user's utterance. Each example is relatively short similar to the examples in our target distribution, i.e., texts typed by users using their mobile keyboards in chatting or search applications. Majority of these texts are clean (i.e., error-free).



(a) (b)

Figure 2: The statistics of the 20k clusters for 100 million documents. The mean with standard deviation of cluster sizes is 5225 ± 2972.

To synthesize the EC text pairs, we add two types of errors to the clean texts: grammar error, and typing error. The grammar error is added by Gemini Ultra model (Google, 2024), and Table 3 shows the template of our prompt and an example. We experiment with different model sizes and find that Gemini Ultra performs best for analyzing and adding grammar errors. For high-quality data generation, the LLM is prompted to perform two more tasks in addition to generating the ungrammatical texts: (1) The first task is to describe the added grammar errors. This allows us to perform a global analysis of the added grammar errors, and confirm our data cover all the grammar error types from (Bryant et al., 2017). The top 4 error categories (and its percentage in our synthetic data) are related to verb (52%), missing words (15%), plural (10%), and capitalization (5%). In terms of the number of grammar error per example, 12% examples have 1 error, while more than 80% examples have 2 or 3 errors. (2) The second task is to correct the ungrammatical texts with LLM added grammar errors. We only keep examples when the corrected text and the original clean text are equal. This filtration process removes around 40% of the data. After adding the grammar errors, we next add typing errors that simulate the behavior of real users typing with mobile keyboard. This is done by heuristic rules that add various typing errors, such as transposition, omission, repetition, and spatial errors (Liu et al., 2024b).



(a) (b)

Figure 3: Good ratio for error correction on the (a) original validation data and (b) synthetic validation data. The models are trained with the original training data, synthetic training data, and vanilla sampling of synthetic data without clustering. LLMs are used to judge whether the EC output is acceptable to compute good ratio. Our large-scale LLM assisted synthetic data works well on both domains even if there is potential distribution shift from the original dataset collected by error detection on public web data.

2.1 Evaluation Setup and Preliminary Results

Our synthetic EC dataset has about 1.2M examples. Each example is a pair of (corrupted, clean) sentences. We random sample a small subset of our synthetic data for validation, and use the rest of data for LoRA fine-tuning a Gemini Nano model (Google, 2024). Both the training and validation dataset are much larger than the original dataset synthesized by the previous production data pipeline. Figs. 3, 6 and 7 shows the results of training and evaluation with the small original production dataset, and our large synthetic dataset, respectively. We provide an additional ablation curve

on our synthetic data with vanilla subsampling instead of clustering-based subsampling. Fig. 6 (in App. B) measures the error correction performance by sequence accuracy, i.e., the exact match between corrected sentence and the target clean sentences, and shows that fine-tuning help while too many steps on small dataset may quickly degrade utility. Our evaluation on error correction matches previous observation on dialogue generation and summarization tasks (Cho et al., 2024).

We further use Gemini Pro models as judges to measure whether the corrected sentence is a high-quality rewrite of the target sentence even if they do not exact match for each word, and report the good ratio for the top 1 output and the best of top 3 outputs from our fine-tuned LLMs, in Figs. 3 and 7. Good ratio mimics the user behavior on selecting rewritten text from mobile applications. We select a small number of models from training steps $\{600, 1000, 2000, 4000\}$ for evaluation to reduce the cost of LLM judges. Models from two different training runs are evaluated to compute standard deviation for error bars. The trend of the sequence accuracy and good ratios align well Figs. 3, 6 and 7. We observe performance discrepancy between the original production dataset and our synthetic dataset, which suggests a potential domain difference. Fine-tuning on our large-scale synthetic data is more robust compared to the small original dataset, and achieves competitive model performance even when evaluated on the original validation set. The clustering-based subsampling achieves comparable results on the original evaluation, and better results on the synthetic evaluation, compared to vanilla subsampling. In the rest of the paper, we will use the synthetic data subsampled with the clusters.

3 Privacy-Preserving Domain Adaptation by Reweighting

We have synthesized a large-scale error correction dataset in Sec. 2 by carefully prompting LLMs to simulate typing text and systematically add errors. However, Wu et al. (2024) suggests public LLMs and human prior knowledge in prompt may not be sufficient to bridge the potential domain shift. When deploying previously trained models, we observe misalignment in offline evaluation on the original validation set, and live A/B test metrics. We also observe the discrepancy between original validation set and our synthetic validation set in Fig. 3a. As our synthetic data explicitly guided LLMs with prior knowledge on mobile typing for synthesis, is it closer to the domain of mobile applications in practice? In this section, we developed a privacy-preserving approach for domain adaptation by reweighting samples in the dataset. The reweighting model is built upon a small LM trained with DP FL, and a handful of live A/B test metrics tracked in previous model deployment.

When evaluating an error correction model M on a dataset $\{(x_i, y_i)\}_{i=1}^N$ of N (corrupted, clean) samples, a measurement $\chi(M(x_i), y_i) \in \{0, 1\}$ is generated for each sample by comparing the model output $M(x_i)$ and corresponding target y_i. We have offline metric for evaluating the model by taking the average over all samples, i.e., $\sum_{i=1}^N \chi(M(x_i), y_i)/N$, which becomes sequence accuracy in Fig. 6 when $\chi(\cdot, \cdot)$ is exact match, and good ratio in Figs. 3 and 7 when $\chi(\cdot, \cdot)$ is judged by LLMs. To reweight samples for domain adaptation, we first train two small LMs S_p, S_f of about 8 million parameters for scoring samples. Model S_p is trained on public C4 dataset, and model S_f is further fine-tuned from S_p on user data in a production FL system (Xu et al., 2023; Wu et al., 2024). Model S_f is a privacy-preserving model with formal DP guarantee $\epsilon < 10$, and captures the domain information from mobile application. We define a reweighting model parameterized by $\theta = (\theta_f, \theta_p, \theta_b)$ as

$$w(\theta, y_i) = C_{\min} + (C_{\max} - C_{\min}) \, \sigma(\theta_f S_f(y_i) + \theta_p S_p(y_i) + \theta_b), \quad (1)$$

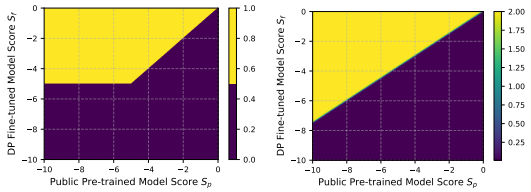
where $C_{\min}, C_{\max}$ are constants determining the minimum and maximum value of the reweighting scores, $\sigma(\cdot)$ is the sigmoid function, and $S_f(\cdot), S_p(\cdot)$ represent the average log likelihood on predicting words in the target sentence y_i.

When deploying K models $\{M_j(\cdot)\}_{j=1}^K$ in practice, we collect corresponding live A/B test metrics $\{v_j\}_{j=1}^K$. We consider key metrics like click through rate and accept rate for error correction in mobile applications, and hence each $v_j \in \mathbb{R}^d$ is a vector representing multiple metrics. We optimize the objective below to learn the reweighting model,

$$\min_{\theta, \alpha} R(\theta, \alpha) + \lambda \| \frac{1}{N} \sum_{i=1}^N w(\theta, y_i) - 1 \|^2, \quad (2)$$

$$R(\theta, \alpha) = \sum_{j=1}^K \| \frac{\alpha_1}{N} \sum_{i=1}^N w(\theta, y_i) \chi(M(x_i), y_i) + \alpha_0 - v_j \|^2$$

where $\alpha = (\alpha_1, \alpha_0)$ is regression parameter to predict live metrics from offline evaluation; per-sample reweighting score $w(\theta, y_i)$ is defined in Eq. (1) to adapt offline data to mobile application domain to achieve small regression residual $R(\theta, \alpha)$; λ is a hyperparameter on the regularizer of the reweighting scores.

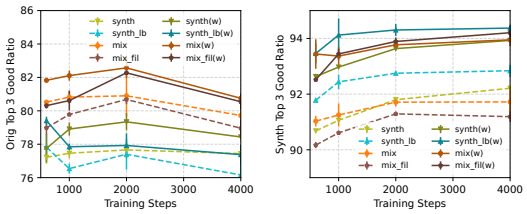


(a) (b)

Figure 4: Comparing the (a) heuristic $\{0, 1\}$ reweighting in (Wu et al., 2024) and (b) our reweighting model $w(\theta, \cdot) = 0.01 + 1.99\sigma(40.64S_f - 30.44S_p - 1.59)$. Both methods use public pre-trained small LM S_p and the same model further fine-tuned with DP FL S_f. The learnt scores in (b) have large overlap with manual selection in (a) from (Wu et al., 2024).

We use auto differentiation and L-BFGS optimizer in JAX (Bradbury et al., 2018) to optimize Eq. (2) to learn regression parameters $\alpha \in \mathbb{R}^{2d}$ and reweighting parameters $\theta \in \mathbb{R}^3$. The dimensionality of θ, α is relatively small, and they can be learnt from a handful of live metrics $\{v_j\}_{j=1}^K$ collected during launching different error correction models. We collected two sets of live metrics, the training set evaluated 10 models with live A/B test, and the validation set evaluated 5 models. We use top-3 good ratio as in Fig. 7 for offline evaluation on the original dataset. Due to production test configuration, the two sets of live metrics have different scales and hence we cannot use the same regression parameter. We set the range of reweighting scores as $C_{\max} = 2, C_{\min} = 0.01$, and regularizer strength $\lambda = 0.01$. Tab. 1 summarizes residuals for training, cross-validation and validation, and reweighting achieves smaller residual when predicting live metrics across different settings. The absolute value of cross-validation and validation residuals are smaller than training ressiduals as training is the summation over all live metric samples in Eq. (2).

After training, our reweighting model parameters are $(\theta_f, \theta_p, \theta_b) = (40.64, -30.44, -1.59)$, which suggests the reweighting score is positively correlated with the fine-tuned model output $S_f(\cdot)$ calibrated by pre-trained model output $S_p(\cdot)$. The difference of the two model outputs represent the likelihood discrepancy, which has also been used for inference time domain adaption (Liu et al., 2024a) and training data detection (Kandpal et al., 2024). Wu et al. (2024) discusses a heuristic filtering strategy for domain adaptation that is effective for selecting data to train small LMs for mobile applications. The heuristic filtering is equivalent to setting $w(y_i) = 1$ when $S_f(y_i) > S_p(y_i)$ and $S_f(y_i) > -5$, and $w(y_i) = 0$ otherwise. This heuristic approach often helps predicting live A/B test metrics compared to uniform weighting, but fails sometimes, and generally achieves higher residual than our reweighting score. Fig. 4 shows the difference between our reweighting model and (Wu et al., 2024) for different pre-trained and fine-tuned model scores.



(a) (b)

Figure 5: Good ratio for the best of top 3 candidates for error correction on the (a) original validation data and (b) synthetic validation data. Solid lines reweight the samples by the $w(\theta, \cdot)$ model learnt to fit live A/B test metrics in Sec. 3. The models are trained with synthetic training data with the same setting as in Fig. 7; $\times 4$ increased batch size (synth_lb); mixture of original and synthetic data; and mixture of original and filtered by $w(\theta, \cdot)$ (mix_fil). LLMs are used to judge whether the error correction output is acceptable to compute good ratio.

Finally, we further apply a defense in depth strategy when using our reweighting models for privacy-preserving domain adaptation. We use a standard production PII detection pipeline to remove any possible sensitive information in the synthetic data, even if they are hallucinated by LLMs. And our fine-tuned LLMs are equipped with another layer of safety and privacy safeguarding when deploying in practice.

4 Mixing Data for Fine-tuning

Based on our synthetic dataset in Sec. 2 and domain-adaptive reweighting model in Sec. 3, we improve Gemini Nano (Google, 2024) for error correction by LoRA fine-tuning (Hu et al., 2022). By combining the original dataset and the large-scale (reweighted) synthetic dataset in a continue training strategy, the model performance is improved in both offline evaluation and live A/B test in production. Unless otherwise specified, our experiments use the same configuration for training previous production models with the original data, as

$R(\theta, \alpha)$	$w = 1$	$w(y_i) \in \{0, 1\}$ (Wu et al., 2024)	Our $w(\theta, y_i)$
Train	1.51×10^{-4}	1.41×10^{-4}	1.19×10^{-4}
CrossVal	$(5.26 \pm 2.76) \times 10^{-5}$	$(4.23 \pm 2.42) \times 10^{-5}$	$(3.99 \pm 3.15) \times 10^{-5}$
Val	$(3.51 \pm 4.15) \times 10^{-6}$	$(5.44 \pm 7.10) \times 10^{-5}$	$(2.07 \pm 2.56) \times 10^{-6}$

Table 1: Regression residual R for different reweighting strategies. Smaller residual suggests reweighting helps predicting live metrics. We report mean and standard deviation for predicting each live metrics v_j in held-one out cross validation. We also use held-one out for validation set to fit only regression parameters with fixed reweighting.

described in Sec. 2. As Gemini Nano is already post-trained with general purpose instructions, our fine-tuning is a continuous post-training. During inference after model deployment, our model is only effective for mobile applications when our fine-tuned LoRA module is applied to the base Gemini Nano model.

We discuss our model training practices and observations. (1) **Increasing batch size.** Our synthetic dataset is much larger than the original dataset. As shown in Figs. 3, 6 and 7, at 4000 steps, the model performance trained on synthetic data still increases on synthetic validation data, while only starts to saturate on original validation data. In fact, 4000 steps do not complete a single epoch on our synthetic training data. We increase the batch size to $\times 4$, which is the largest batch size without requesting more resources. We found our LoRA fine-tuning is relatively robust for learning rate between $\times 1$ and $\times 4$ of the original learning rate, and hence fixed the learning rate to be $\times 1$. As shown in Figs. 5, 8 and 9, large batch training achieves comparable performance on original validation data, while improves the performance on synthetic validation data. We use large batch training in following experiments. (2) **Simple mixing** the small original dataset and the large scale synthetic data improves the performance on original validation data, but slightly degrades the performance on synthetic validation data. There is a trade-off on the ratio of the mixture: while it is relatively robust when we have original and synthetic ratio in the range of $1:1$ and $1:8$, ratio $1:4$ achieves good balance and is used in the following mixing experiments. (3) **Reweighting for training and evaluation.** Reweighting model in Sec. 3 is used to adapt the offline data distribution to the mobile application distribution. The trend in reweighted metrics in Figs. 5 and 9 generally align with the uniform weighted counterparty. In addition to reweighting to bring offline evaluation closer to live A/B test metrics, we further explore reweighting for domain adaptation in training. We filter the synthetic data set and only keep samples with reweighting scores $w(\theta, y_i) \geq w_t$. We choose the threshold $w_t = 1$ as $w(\theta, y_i)$ is in the range of $C_{\min} = 0.01$ and $C_{\max} = 2$, and about half of the samples in the synthetic dataset have reweighting scores passed the threshold. We only filter our synthetic dataset as the original dataset is already very small. Mixing the filtered synthetic data with the original dataset for training achieves good reweighted metrics even if the uniform weighted metrics slightly degrades compared to mixing with the full synthetic data. (4) **Continue training.** As our synthetic data is large, we propose a continue training strategy: first fine-tune on the full synthetic dataset for 1000 steps (about one epoch), and then continue training on the original data (ContOrig), the mixture of original and synthetic dataset (ContMix), and the mixture of the original and filtered synthetic data (ContMixFil), see Tab. 2. For each training method, we select the best model from steps $\{600, 1000, 2000, 4000\}$, and run training at least twice to compute the standard deviation.

In Tab. 2, ContMix and ContMixFil achieve best or close to best results on both original validation data and synthetic validation data. They achieve higher good ratio on the original validation data than model trained on the original data only, or the mixture of original and synthetic data. They are comparable to the best performance on synthetic validation data achieved by training on synthetic data only with large batches. As ContMixFil achieves better performance on the reweighted metrics that better reflects the mobile application domain, we further compare the model trained by Original and ContMixFil in production live A/B test. Compared to Original, ContMixFil achieves 2.47% to 7.18% relative improvement on key production metrics like click through rate and accept rate.

5 Conclusion

This paper presents a method to enhance error correction in mobile LLMs by creating a high-quality synthetic dataset using LLM prompts enriched with domain knowledge. We further adapt the public (synthetic) data to better match the domain of production mobile applications by developing

Training Method	Original Data Eval (%)				Synthetic Data Eval (%)			
	Top-1	Top-1 (w)	Top-3	Top-3 (w)	Top-1	Top-1 (w)	Top-3	Top-3 (w)

Table 2: Good ratio for error correction on the original validation data and synthetic validation data. Top-3 evaluates the best of three model outputs. Columns with "(w)" reweight the samples by the $w(\theta, \cdot)$ model learnt to fit live A/B test metrics in Sec. 3. The models are trained by the original dataset as in Fig. 3; the synthetic data with large batches, mixture of original and synthetic data as in Fig. 5; and three continue training strategies. Continue training gets the best, or close to best performance on offline evaluation of both original and synthetic validation data.

a privacy-preserving reweighting model, using a small LM trained with federated learning and differential privacy, alongside a few live A/B test metrics. Our experiments show that fine-tuning a billion-size LLM with a mixture of the original dataset and the reweighted synthetic data, especially via continue training, significantly improves performance in offline evaluations and live A/B tests.

A Prompt in Sec. 2

LLM prompt template

Imagine that you are an English school teacher. Your goal is to teach high school student English grammar. Here are some common grammartical errors: [...]

Given the following sentence(s):
[...original sentence...]
What grammartical errors are the students likely to make?

Now apply these grammatical errors to the original sentence(s), and generate the ungrammatical sentence(s). Do not modify the original sentence(s) except applying the grammatical errors.

The output should be in the following format: [...]

Finally, correct the grammatical errors in the generated ungrammatical sentence(s). Do not modify the sentence(s) except correcting the grammatical errors. The output should be in the following format: [...]

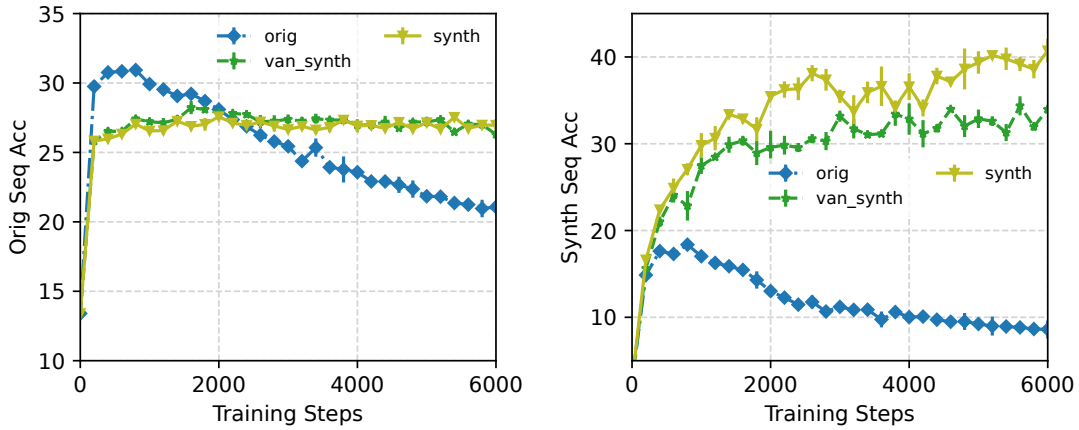
Example

Original sentence : Yesterday I went to a store that has nice furniture.

LLM output :
Ungrammatical sentences: Yesterday I went to a store that have nice furnitures.
Error 1: Subject-verb agreement error: “have” should be “has” to agree with the singular subject “store”.
Error 2: Plurization error: “furnitures” should be “furniture” as it is an uncountable noun.
Corrected sentences: Yesterday I went to a store that has nice furniture.

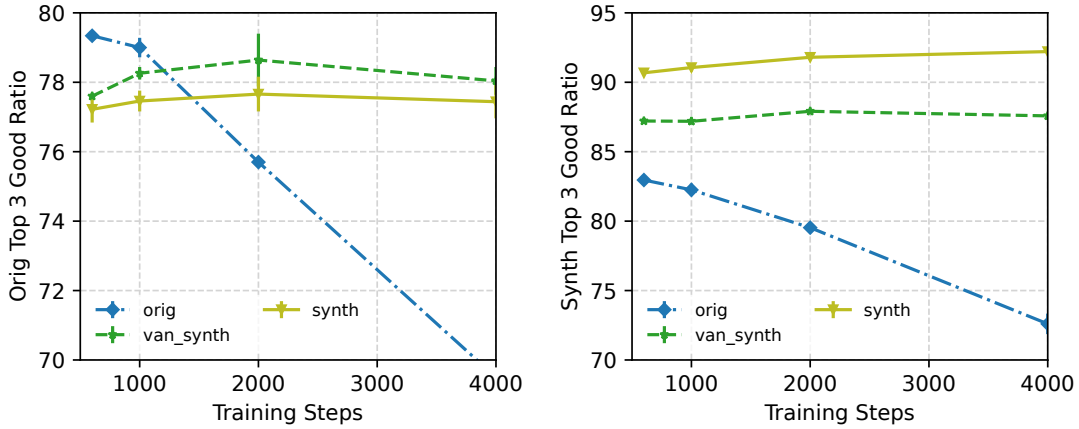
Table 3: Our LLM prompt for adding grammar errors and an example output. The prompt starts with a role (i.e., school teacher), analyzes the original sentence, and adds potential grammar errors, followed by correcting all errors. The [...] parts are omitted for simplicity.

B Additional results in Sec. 2



(a) (b)

Figure 6: Sequence accuracy of error correction on the (a) original validation data and (b) synthetic validation data. The models are trained with the original training data, synthetic training data, and vanilla sampling of synthetic data without clustering.



(a) (b)

Figure 7: Good ratio for the best of top 3 candidates for error correction on the (a) original validation data and (b) synthetic validation data. The models are trained with the original training data, synthetic training data, and vanilla sampling of synthetic data without clustering. LLMs are used to judge whether the error correction output is acceptable to compute good ratio.

C Additional results in Sec. 4

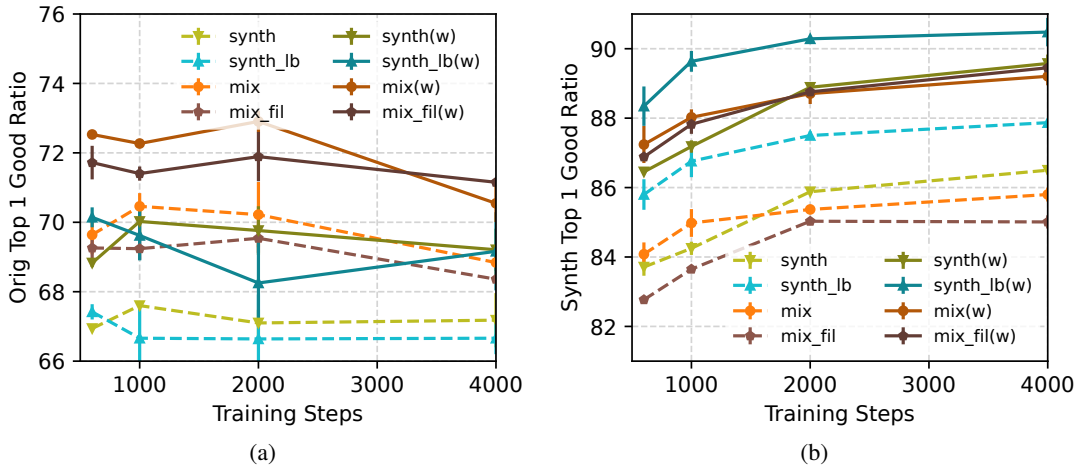
Figure 8: Sequence accuracy of error correction on the (a) original validation data and (b) synthetic validation data. The models are trained with synthetic training data with the same setting as in Fig. 7; $\times 4$ increased batch size (synth_lb); mixture of original and synthetic data; and mixture of original and filtered by $w(\theta, \cdot)$ (mix_fil).



(a) (b)

Figure 9: Good ratio for error correction on the (a) original validation data and (b) synthetic validation data. Solid lines reweight the samples by the $w(\theta, \cdot)$ model learnt to fit live A/B test metrics in Sec. 3. The models are trained with synthetic training data with the same setting as in Fig. 7; $\times 4$ increased batch size (synth_lb); mixture of original and synthetic data; and mixture of original and filtered by $w(\theta, \cdot)$ (mix_fil). LLMs are used to judge whether the error correction output is acceptable to compute good ratio.

D Limitation and Future Work

Our preliminary exploration on reweighting suggests combining live data from production applications and LLMs in a privacy-preserving manner is promising, and there are a lot of possibilities with the limited accessible information. Our usage of reweighting scores in training by filtering samples considers the trade-off of effectiveness, easy-to-implement, and future maintenance in production. There are many other potential domain adaptation methods for future experiments. Finally, We leverage a small privacy-preserving LM to capture domain information from mobile applications, while other forms of information such as histogram (Xie et al., 2024; Hou et al., 2024; Yu et al., 2024; Tan et al., 2025) are worth considering, especially given the flexibility of the next generation FL systems in trusted execution environments (Daly et al., 2024). With more data generated from the interaction of LLMs and users in production deployment, our approach can become more powerful for not only domain adaptation but also other improvement such as personalization and agency, enabled by privacy-preserving methods.

Abstract

Multilingual automatic speech recognition (ASR) in the medical domain serves as a foundational task for various downstream applications such as speech translation, spoken language understanding, and voice-activated assistants. This technology improves patient care by enabling efficient communication across language barriers, alleviating specialized workforce shortages, and facilitating improved diagnosis and treatment, particularly during pandemics. In this work, we introduce *MultiMed*, the first multilingual medical ASR dataset, along with the first collection of small-to-large end-to-end medical ASR models, spanning five languages: Vietnamese, English, German, French, and Mandarin Chinese. To our best knowledge, *MultiMed* stands as the world's largest medical ASR dataset across all major benchmarks: total duration, number of recording conditions, number of accents, and number of speaking roles. Furthermore, we present the first multilinguality study for medical ASR, which includes reproducible empirical baselines, a monolinguality-multilinguality analysis, Attention Encoder Decoder (AED) vs Hybrid comparative study and a linguistic analysis. We present practical ASR end-to-end training schemes optimized for a fixed number of trainable parameters that are common in industry settings. All code, data, and models are available online.

1 Introduction

Automatic speech recognition (ASR) in the medical domain is a critical foundational task, serving a wide range of downstream tasks and applications, including speech translation (Mutal et al., 2020), electronic health record (Kumah-Crystal et al., 2018), information extraction (Selvaraj and Konam, 2020), speech summarization (Le-Duc et al., 2024a). This technology improves patient care by automating clinical documentation (Hodgson and Coiera, 2016), mitigating shortages of specialized healthcare personnel (Latif et al., 2020), and contributing to more accurate diagnosis and treatment (Luo et al., 2024), particularly under the increased demands observed during pandemic scenarios. Furthermore, the size of the ASR market is projected to reach USD 7.14 billion in 2024, with an anticipated compound annual growth rate (CAGR) of 14.24% from 2024 to 2030, resulting in a market volume of USD 15.87 billion by 2030 (Insights, 2024).

Recent research on ASR in the medical domain has been hindered by the lack of publicly available datasets, mainly due to privacy concerns. Existing datasets (see Table 9), such as the English medical ASR dataset by Fareez et al. (2022), are limited to simulated data on respiratory diseases, restricting research to this category and reducing applicability to diverse accents. The *PriMock57* dataset, containing 57 simulated primary care consultations (9 hours of recordings), also lacks generalizability (Korfiatis et al., 2022). The *AfriSpeech-200* dataset (Olatunji et al., 2023) mixes general and medical-domain speech, while the *myMediCon* dataset (Htun et al., 2024) includes Burmese read speech, both of which lack real-world applicability. The *VietMed* dataset (Le-Duc, 2024) is a real-world dataset focused on the Vietnamese language.

Furthermore, commercial medical ASR APIs, such as Google Cloud Healthcare, IBM Watson, Microsoft Azure Speech Service, Deepgram, and Nuance Dragon Medical One, are not free and do not provide publicly available models for fine-tuning or deployment, nor do they disclose training

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1113–1150
July 28-30, 2025

details.

This work aims to democratize medical ASR, making it freely accessible to everyone. Our key contributions are as follows.

- We present the *MultiMed* dataset - the first multilingual medical ASR dataset - which includes human-annotated high-quality real-world medical domain speech in 5 languages. To our best knowledge, *MultiMed* is the world's largest medical ASR dataset on all major diversity benchmarks: total duration (150 hours), number of recording conditions (10), number of accents (16) and number of speaking roles (6).
- We release the first publicly available multilingual medical ASR models, spanning small to large end-to-end configurations.
- We present the first multilinguality study for medical ASR, which includes: reproducible empirical baselines, a monolinguality-multilinguality analysis, Attention Encoder Decoder (AED) vs Hybrid study and a linguistic analysis
- We present practical ASR end-to-end training schemes optimized for a fixed number of trainable parameters that are common in industry settings

All code, data, and models are published online.

2 Data

2.1 Data Collection

Speech data with human-annotated transcripts were initially collected from real-world medical conversations published by professional medical channels on YouTube. In contrast to simulated datasets in the literature where doctors and patients play roles, our real-world dataset encompasses natural conversations of 10 distinct recording conditions (Documentary, Interview, Lecture, News, Podcast, Webinar, Speech, Talk, Vlog, Workshop) and 6 speaker roles (Lecturer, Doctor, Host, Patient, Podcaster, Broadcaster). Details of data collection for each language to ensure diversity are described in the Appendix C.1.

Our adherence to the Fair Use Policy and regulations regarding data consent, privacy, and anonymization of speaker identities in medical research is detailed in the Appendix B.

2.2 Data Quality Control

Quality control of the initial human-annotated transcripts from professional YouTube channels was carried out through manual review by our annotators, involving the correction of small inaccuracies or the exclusion of too erroneous transcripts. All transcripts were reviewed by medical experts with a certified linguistic level, which ensured, to the best of our knowledge, the final high-quality transcripts. Details of our annotators are described in the Appendix C.2. Data processing was also performed to further enhance the quality of the transcripts, as described in the Appendix C.3.

2.3 Data Statistics

Table 1 shows the dataset statistics of our *MultiMed* dataset in comparison with all existing publicly available medical ASR datasets, to the best of our knowledge. As shown in the table, our *MultiMed* dataset is the world's largest medical ASR dataset across all major diversity benchmarks: total duration (150 hours of recordings), number of recording conditions (10), number of accents (16) and number of speaking roles (6).

The statistics for the dataset split for each language are also shown in Table 2.

3 Problem Definition

An ASR model transcribes an audio signal into text by mapping an audio signal $x_1^T := x_1, x_2, ..., x_T$ of length T to the most likely word sequence w_1^N of length N. The relation w^* between the acoustic and word sequence is defined as the probability p:

$$w^* = \arg\max_{w_1^N} p(w_1^N | x_1^T) \tag{1}$$

In beam search process, the auxilary quantity Q for each unknown partial string (tree of partial hypotheses) w_1^n is described as:

$$\begin{aligned} Q(n; w_1^n) :&= \prod_{n'=1}^{n} p(w_{n'} | w_0^{n'-1}, x_1^T) \\ &= p(w_n | w_0^{n-1}, x_1^T) \cdot Q(n-1, w_1^{n-1}). \end{aligned} \tag{2}$$

After eliminating the less likely hypotheses in the beam search process, the word sequence probability is determined by the most optimal hypothesis:

$$p(w_1^N | x_1^T) = Q(N; w_1^N). \tag{3}$$

The complete mathematical formulation of AED is shown in Appendix D, while the formulation for the hybrid model is presented in Appendix F.1.

4 Experimental Setups

4.1 Model Selection and Training

We opted to evaluate the performance of four pre-trained Whisper models (Radford et al., 2023) with varying sizes: Tiny, Base, Small, and Medium. These models, pre-trained on 680,000h of labeled multilingual data, offered a trade-off between accuracy and computational cost, allowing us to explore the impact of model size on performance. Details of hyperparameter tuning are shown in the Appendix E.1.

To investigate the impact of different fine-tuning strategies, we explored two main fine-tuning approaches for each model size: **Decoder-only fine-tuning** (encoder freezing) and **Fully encoder-decoder fine-tuning**. In the first approach, we focused on fine-tuning only the decoder of the pre-trained Whisper model. The encoder, responsible for aligning audio features, remained frozen during fine-tuning. This strategy aimed to leverage the previously learned representations of the pre-trained encoder for efficient time-frame alignment while adapting learnable parameters in the decoder for vocabulary generation. Otherwise, in the second approach, all parameters in both the encoder and decoder components of the pre-trained Whisper models were learnable. This approach allowed the model to proactively align time-frames in our dataset, potentially leading to better overall performance. The number of parameters for two fine-tuning settings is shown in Table 3.

Model	Fully encoder-decoder ft.	Decoder-only ft.
Tiny	37.76M	29.55M
Base	72.59M	52.00M
Small	241.73M	153.58M
Medium	763.86M	456.64M

Table 3: Statistics of total trainable parameters in the Whisper models for 2 settings: Fully encoder-decoder fine-tuning and decoder-only fine-tuning.

4.2 Evaluation Metrics

To assess the performance of the ASR models, we employed two standard evaluation metrics: Word Error Rate (WER) and Character Error Rate (CER). The description of the two metrics is shown in the Appendix E.2.

5 Experimental Results

5.1 Monolingual Fine-tuning

We fine-tuned various variants of the Whisper model in each language separately (known as monolingual fine-tuning) and analyzed the impact of model size and transfer learning (decoder-only vs. full encoder-decoder fine-tuning) on recognition accuracy, as shown in Table 4 and 5.

A clear correlation was observed between the size and performance of the model. As the model size increased from Tiny to Medium, WER and CER generally decreased across all languages, indicating that larger models better capture complex audio-text representations, improving accuracy.

The best results for most languages were obtained by fine-tuning only the decoder of the Medium model: Vietnamese achieved 20.05% and

Table 5: Main baselines - WERs and CERs of **fully encoder-decoder fine-tuning** using different Whisper models on each separate language (**monolingual fine-tuning**)

25.43% WERs on the dev and test sets, respectively; English reached 19.01% and 19.41% WERs; and French yielded 34.89% and 31.05% WERs.

An exception was Chinese, where fine-tuning the Small model's decoder produced the best results: 23.95% and 34.28% CERs on the dev and test sets. Since Chinese uses characters as fundamental units of meaning, CER is a more accurate measure of recognition than WER (Wang et al., 2016; Gao et al., 2006), unlike alphabetic languages.

5.2 Multilingual Fine-tuning

In addition to fine-tuning each language separately, we also combined all languages for experimentation, known as multilingual fine-tuning, as shown in Table 6. In multilingual fine-tuning, we achieved superior performance in most languages, though there was a slight performance degradation for Chinese, compared to monolingual fine-tuning in Table 5. Both high-resource languages, such as English, and lower-resource languages, including Vietnamese, French, and German, showed improvement under the multilingual fine-tuning regime. This outcome is noteworthy, as previous studies on multilingual fine-tuning observed that shared discrete latent speech representations across languages such as Vietnamese, English, Chinese, French, and German tend to cluster at large distances, and therefore usually affect accuracy in the multilingual setting (Baevski et al., 2020a; Conneau et al., 2021a; Vieting et al., 2023; Tüske et al., 2014; Chuangsuwanich, 2016).

Language	WER		CER	
	dev	test	dev	test

5.3 AED vs Hybrid

End-to-end ASR, with the AED approach, and Hybrid ASR models (Hidden Markov Models) are two key paradigms in ASR research. This section compares AED and Hybrid ASR models. For a fair comparison, we use wav2vec 2.0 (Baevski et al., 2020a) as the acoustic model for Hybrid ASR, as it is a Transformer-based encoder, similar to the Transformer-based encoder-decoder of Whisper.

Table 7 presents a comparison between the AED and Hybrid models. The AED models were pre-trained on 680,000 hours of labeled multilingual data, including 691 hours of Vietnamese, while the Hybrid models were pre-trained on unlabeled data. Despite having fewer parameters and less labeled data, Hybrid models achieve comparable WERs on the Vietnamese test set. AED models only outperform Hybrid models significantly when

		AED		Hybrid	
		Small	**Medium**	**w2v2-Viet**	**XLSR-53-Viet**
WER	**dev**	21.8	20.1	25.9	25.7
	test	28.8	25.4	29.0	28.8
#Data		680,000h labeled multiling. (691h labeled Viet.)		1200h unlabeled Viet.	56,000h unlabeled multiling. +1200h unlabeled Viet.
#Params		153M	456M	123M	123M
#Layers		12	24	8	8
Width		768	1024	768	768
#Att. Heads		12	16	16	16
Features		MFCC		Raw waveform	
LM fusion		Deep fusion		Shallow fusion	

Table 7: Comparison between AED and Hybrid experiments. WERs are reported on our Vietnamese dev and test set. All models were fine-tuned on the same Vietnamese set. Hybrid models employ wav2vec 2.0 as acoustic model (Baevski et al., 2020a). Full details of experiments are shown in Appendix F and the breakdown per speaker is shown in Table 11 in the Appendix.

scaled three times. This finding supports prior research on the data and computational efficiency of Hybrid models in general-domain ASR (Lüscher et al., 2019a; Zeyer et al., 2018b,c, 2019), and is the first confirmation of this trend in the medical domain.

6 Ablation Study: Freezing Schemes

This section presents the results of our ablation study. The Small Whisper models fit within a 24GB GPU without out-of-memory issues. We evaluated the impact of freezing various layers on performance, focusing on test set WERs for most languages and CERs for Chinese. The tested freezing configurations are shown in Table 8.

In both the *0-8 encoder* and *3-11 encoder* settings, model performance on test sets is worse than when the entire encoder is frozen in Table 5. This suggests that, within a fixed budget, freezing the entire encoder, which aligns time frame features with language representations, is crucial to achieve high accuracy and computational efficiency, as seen in the general domain AED ASR (Ueno et al., 2018).

We also explored the effect of freezing Whisper's decoder, focusing on fine-tuning only the last three layers of both the encoder and decoder (*0-8 encoder & 0-8 decoder*). As shown in Table 8, this setup resulted in worse performance compared to fine-tuning only the decoder while freezing layers 0-8 of the encoder (*0-8 encoder*). Performance degradation likely results from a significant reduction in trainable parameters in the decoder, which is responsible for generating subword units. Given the fixed vocabulary, out-of-vocabulary (OOV) words, and context length in Whisper's Byte-Pair Encoding (BPE) tokenizer (Gage, 1994), the decrease in trainable autoregressive parameters likely hinders the decoder's ability to effectively separate subword tokens, leading to reduced decoding accuracy (Ho et al., 2024; Bapna et al., 2020).

We fine-tuned the first three decoder layers and the last three encoder layers (*0-8 encoder & 3-11 decoder*), which generally resulted in higher test set accuracy for most languages compared to *0-8 encoder & 0-8 decoder*. This suggests that freezing a contiguous set of layers is the key to achieving high accuracy with an equivalent number of trainable parameters in the decoder.

Fine-tuning the last three decoder layers (*0-11 encoder & 0-8 decoder*) also outperformed *0-8 encoder & 0-8 decoder* in test accuracy and was competitive with *0-8 encoder & 3-11 decoder*, despite fewer trainable parameters. Likewise, the *3-11 encoder & 3-11 decoder* configuration yielded the worst performance in all languages. These findings support the hypothesis that consistent freezing of contiguous layer groups is critical for high accuracy within a fixed parameter budget.

7 Error Analysis

To our best knowledge, there has been no error analysis based on the linguistic perspective for languages other than English. Therefore, we used the English literature to compare with our findings.

We manually analyzed the errors in 50 randomly collected samples from each language. Generally, the errors observed in medical ASR systems are

Language	0-8 encoder				3-11 encoder				0-8 encoder & 0-8 decoder

Table 8: Ablation study - WERs and CERs of various freezing schemes using Small Whisper model on each separate language (**monolingual fine-tuning**). Small Whisper model has 12 layers in the encoder and 12 layers in the decoder. For example, *0-8 encoder* means freezing all layers from layer 0 to layer 8 in the encoder, the rest layers are fine-tuned.

diverse and cover a wide range of issues. For all 5 languages, these typically include misrecognition of drug names and dosages, incorrect medical institutions, anatomical discrepancies (e.g., left-right confusion), medical terms' inconsistencies, mismatches in patient age and gender, incorrect identification of physician names, and inaccuracies in dates. These findings are consistent with the study by Hodgson and Coiera (2016) in the English medical ASR dataset. Additionally, the misrecognition is exacerbated by the generation of non-existent terms, which is also known as hallucination in the Large Language Models (LLMs) era, as well as omissions (e.g. deletion errors) and duplications (e.g., insertion errors) within the ASR output (see Figure 12 in the Appendix). These findings are also confirmed by McGurk et al. (2008) in English ASR for radiology reports.

Furthermore, ASR errors typically arise from the proximity of vowels in the phonological space for Vietnamese, English, German, and French, while for Chinese, confusion predominantly stems from minimal pairs with distinct tones and homophones. Detailed error analysis based on the linguistic perspective for each language is in Appendix G.

8 Conclusion

In this work, we present *MultiMed*, a real-world dataset for ASR in the medical domain, accompanied by a collection of small-to-large end-to-end ASR models, covering five languages: Vietnamese, English, German, French, and Mandarin Chinese. To our best knowledge, *MultiMed* stands as the world's largest medical ASR dataset across all major benchmarks.

As the first study of multilingual ASR in the medical domain, our findings demonstrate that **(1):** multilingual fine-tuning produces superior accuracy compared to monolingual fine-tuning, although shared discrete latent speech representations across languages, such as Vietnamese, English, Chinese, French and German, exhibit clustering at large distances, which could potentially reduce accuracy in a multilingual fine-tuning setting. Furthermore, in the AED vs Hybrid study, we showed that **(2):** Hybrid models remain more efficient in terms of data utilization and computational performance compared to AED models. In the layer-wise ablation study of AED models, we found that **(3):** on a fixed budget, freezing the entire encoder is important for achieving both high accuracy and computational efficiency. Additionally, **(4):** maintaining the consistent freezing of a contiguous group of layers is important for achieving high accuracy. Finally, as shown in the linguistic analysis for multilingual medical ASR, we observed that **(5):** medical ASR errors often involve misrecognitions of drug names, dosages, institutions, anatomical details, demographics of patients, physician names, etc., along with hallucinated terms, omissions, and duplications. **(6):** Errors also often arise from the proximity of vowels in the phonological space for Vietnamese, English, German and French, while for Chinese, confusion predominantly stems from minimal pairs with dis-

tinct tones and homophones.

9 Limitations

Open research questions: Several research questions about the impact of multilinguality on medical ASR remain unaddressed and fall outside the scope of this study.

- Cross-language transfer learning: How can transfer learning be optimized to leverage data from high-resource languages to improve medical ASR performance in low-resource languages? Can shared acoustic and linguistic representations (e.g., from hospitals' recording conditions and shared medical terms across languages) effectively bridge the gap between typologically different languages?

- Zero-shot and few-shot medical ASR: What are the best methods for enabling general-domain ASR models to understand unseen medical-domain test set (zero-shot learning) or to adapt with minimal medical-domain data (few-shot learning)? How can medical-domain models be trained to generalize effectively across languages without overfitting to dominant languages (e.g., English) in the dataset?

- Code-Switching Challenges: How does each ASR module handle code-switching, where speakers switch between two or more languages within the same sentence, especially for medical terms?

- Bias and Fairness in Multilingual Medical ASR: How can we address biases in multilingual medical ASR models that disproportionately affect minority languages or speakers with diverse accents, especially when patients and doctors are not of major ethnicity? What metrics and evaluation protocols should be established to assess fairness and inclusivity in multilingual medical ASR systems?

Clinical impact: The primary objective of our study is to establish baselines rather than introduce novel techniques to minimize WER in medical ASR systems. Given the critical nature of medical transcription, inaccuracies in ASR output can have serious implications, potentially affecting patient diagnoses and treatment decisions (Adane et al., 2019). Thus, real-world deployment of our systems should be preceded by pilot testing in clinical environments to ensure reliability prior to full-scale implementation.

Contents

A Related Works

Among the limited existing studies below, to the best of our knowledge, none of them have made their datasets or pre-trained models publicly available, nor have they been conducted on publicly accessible datasets due to privacy concerns, which poses a significant challenge for the reproducibility and deployment of medical ASR research[1].

Multilingual medical ASR: The research carried out by Lüscher et al. (2023) has focused on the development of Hybrid ASR systems (Lüscher et al., 2019b) in the RETURNN framework (Zeyer et al., 2018a; Doetsch et al., 2017) to transcribing multilingual telephone conversations between patients and physicians, using Gammatone features (Schluter et al., 2007) as input in a supervised only approach. Vieting et al. (2023) examine the efficient utilization of the large multilingual acoustic pre-trained model XLSR-53 (Conneau et al., 2021b) for medical ASR in three languages, focusing on resolving the issue of sampling rate mismatch using wav2vec 2.0 (Baevski et al., 2020b) as encoder and RASR (Rybach et al., 2011) as decoding framework. In (Sakti et al., 2014), a multilingual acoustic model fine-tuned on in-house medical domain data is presented utilizing weighted finite-state transducers (Mohri et al., 2002), speaker adaptive training (Anastasakos et al., 1996), and boosted maximum mutual information (Povey et al., 2008) in conjunction with Kaldi decoding (Povey et al., 2011) of n-gram (Ney et al., 1994) language models for every specific language. However, to the best of our knowledge, in all studies separate monolingual models are typically used for each respective language, rather than utilizing a unified multilingual model capable of transcribing multilingual conversations seamlessly. Therefore, we are the first study to present a unified multilingual model that can dynamically adapt to different languages in medical conversations without the need for separate models.

Acoustic challenges for medical ASR: In this context, several challenges arise, including variability in acoustic and recording conditions, the mismatch in telephony bandwidth, the impact of medical mask usage, and the presence of background noise from various devices and dynamic environmental factors (Lüscher et al., 2023). In addition, a bidirectional input issue is observed, as a single recording channel is shared between the physician and the patient in emergency room and hospital settings. Studies such as (Edwards et al., 2017; Chiu et al., 2018; Kar et al., 2021; Dua et al., 2023) have addressed the challenges related to difficult acoustic conditions by modifying model components like feature extractor, acoustic model, and so on. Furthermore, studies like (Salimbajevs and Kapočiūtė-Dzikienė, 2022) address the robustness in noisy acoustic environments using a large amount of unlabeled medical ASR data. In addition, Luo et al. (2024) uses emergency medical services or prehospital care as a research context to generate data in the domain, as it represents a prototypical example of dynamic and variable medical environments, involving numerous participants, such as healthcare professionals, patients, bystanders, and family members.

Language modeling for medical ASR: The specialized medical terminology in each language presents an additional challenge. A simple method to address these challenges involves correcting ASR errors at the output level (Mani et al., 2020a; Hsu et al., 2024; Mani et al., 2020b) or focusing on medically named entities (Afonja et al., 2024; Le-Duc et al., 2024b; Suominen et al., 2015). Another approach is to train a domain-specific language model to decode the ASR encoder (Jiang and Poellabauer, 2021). Furthermore, LLMs, such as the GPT series (OpenAI et al., 2024; Brown et al., 2020), Gemini (Team et al., 2024, 2023), and Llama (Touvron et al., 2023; Dubey et al., 2024) for example, have potential utility in rectifying medical ASR errors (Adedeji et al., 2024). Another study by Sunkara et al. (2020) involves the joint modeling of punctuation and truecasing in medical ASR transcripts utilizing pre-trained language models, such as BERT (Devlin et al., 2019).

Application of medical ASR: One of the most common use cases is for clinical documentation (Latif et al., 2020). It is a laborious and complex task that could lead to burnout of the clinician (Arndt et al., 2017), inefficiency of the doctor-patient time (Sinsky et al., 2016), and lower patient satisfaction (Pelland et al., 2017). The adoption of electronic health records (EHRs) has been pro-

[1]Medical ASR, also known as Medical-domain ASR, focuses on developing ASR systems specifically tailored for healthcare environments, such as hospitals, clinics, and telemedicine. It aims to transcribe medical dictations, conversations between healthcare providers and patients, or interactions with electronic health records (EHRs). The term medical ASR does not refer to the "ASR of pathological speech", which focuses on developing models capable of recognizing and transcribing speech from individuals with speech impairments or disorders. These impairments can be due to conditions such as dysarthria, aphasia, stuttering, or neurological diseases such as Parkinson

gressively implemented to optimize this process, leveraging medical ASR technology (van Buchem et al., 2021; Zhang et al., 2023; Johnson et al., 2014; Saxena et al., 2018). Secondly, in the context of emergency medical services, medical ASR has been evaluated for its influence on stroke detection, demonstrating potential to enhance response times and diagnostic accuracy (Donnelly et al., 2022). Thirdly, ASR can be employed in surgical environments to enhance communication between the surgeon and both human assistants (e.g., surgical nurses) and digital systems (e.g., robotic arms) (Ruby et al., 2020; Schulte et al., 2020). Fourthly, in pediatric healthcare, medical ASR systems have been investigated for their potential application in remote care management (Nayar, 2017). Fifthly, medical ASR can be employed to support individuals with hearing impairments or disorders related to voice, speech, or language, facilitating more effective communication (Wendt et al., 2011).

B Ethical Statements

Speech data accompanied by high-quality human-annotated transcripts was obtained from YouTube in compliance with the Fair Use Policy and Vietnamese regulations governing data consent, privacy, and medical research, as detailed in this section.

According to Vietnamese law, which is applicable to the location of the hosting of the data and the site of all research activities, international and local researchers are authorized to collect and use the data exclusively for scientific purposes. To further ensure data privacy, segments of the dataset with the potential to reveal speaker identities were anonymized.

B.1 Fair Use

The research adhered rigorously to the principles of Fair Use as defined by the U.S. Copyright Office[2], which are also applicable to content on the YouTube platform. Fair Use is governed by Section 107 of the Copyright Act, which provides a legal framework for evaluating whether a specific use of copyrighted material qualifies under this doctrine. The statute identifies several examples of permissible uses, including criticism, commentary, news reporting, teaching, scholarship, and research, which are particularly relevant in the context of academic and scientific work.

Section 107 outlines a multifactorial approach to determining fair use, which requires an assessment of four key factors. These include:

- (1) **Purpose and character of the use, including whether the use is of a commercial nature or is for nonprofit educational purposes:** This factor evaluates how the copyrighted work is being utilized, particularly whether the use serves a commercial purpose or is directed toward nonprofit educational objectives. Courts tend to favor claims of fair use when the purpose is educational and nonprofit rather than commercial. Furthermore, the concept of "transformative use" plays a significant role in this determination. Transformative uses are characterized by their ability to add new meaning, insight, or purposes to the original work, altering its character in a way that differentiates it from the initial intention. Transformative uses that do not replace or compete with the original purpose of the work are more likely to qualify as fair use.

- (2) **Nature of the copyrighted work:** This factor examines the type of work involved and its relationship to the copyright's goal of fostering creative expression. Works that are highly imaginative or creative, such as novels, films, or songs, receive stronger copyright protection, making their use less likely to be considered fair. In contrast, factual or informational works, such as technical articles or news reports, are less stringently protected, and their use may more readily align with fair-use principles. Additionally, unpublished works are generally given greater protection and their unauthorized use is less likely to meet fair use criteria.

- (3) **Amount and substantiality of the portion used in relation to the copyrighted work as a whole:** This factor assesses both the quantitative and qualitative aspects of the material used in relation to the entire copyrighted work. The use of larger portions of a work typically weighs against fair use, though exceptions exist in cases where the entirety of the work is used for a justified purpose. Conversely, even the use of a small excerpt may be deemed unfair if it constitutes the "heart" or most significant and recognizable aspect of the original work. In this evaluation, the balance between the necessity of the portion used and its impact on the original work is critical.

- (4) **Effect of the use on the potential market for or value of the copyrighted work:** This factor considers the economic impact of the use without a license on both the existing market and the potential future markets for the copyrighted work. Courts analyze whether the unauthorized use undermines the market value or competes with the copyright holder's ability to monetize their work. If the unlicensed use causes substantial harm to the market or diminishes the value of the original work, it is less likely to qualify as fair use.

These factors collectively inform the determination of whether the usage is lawful under the doctrine of Fair Use, providing a nuanced and case-specific analysis.

[2] https://www.copyright.gov/fair-use/

In accordance with applicable legal frameworks, our work is justified under the provisions of the Fair Use doctrine. This assertion is supported by a detailed interpretation of the Fair Use principles [3] by copyrightalliance.org and the ELRC Report on legal issues in web crawling [4] by Pawel Kamocki, which emphasize the transformative nature of our research, its non-commercial scientific purpose and its minimal impact on the market value of the original content. These considerations collectively align with the statutory factors outlined in copyright law, underscoring the legitimacy of our approach. Our detailed interpretation of the Fair Use principles is as follows:

- (1) **Purpose and Character of Use**: The data were collected and utilized strictly for non-commercial and research purposes, aligning with the principles of Fair Use. Rather than directly using the videos obtained from YouTube, we transformed them into audio files at a predefined sampling rate. Long audio files, typically around an hour in duration, were segmented into shorter clips of 10 to 30 seconds. The segments were then randomly shuffled to ensure that they could not be reconstructed to form the original videos. This transformation and randomization process render the dataset distinctly different from the original content, thus qualifying as transformative use. Furthermore, this approach does not substitute for the original purpose or value of YouTube videos.

- (2) **Nature of the Copyrighted Work**: The extracted content primarily consists of factual, non-fictional medical conversations, which further supports its qualification as Fair Use. In addition, YouTube videos are publicly accessible throughout the world, fulfilling the criterion related to the publication status of the copyrighted material.

- (3) **Amount and Substantiality of the Portion Used**: Although there is no quantitative metric to precisely assess the fairness of a specific use, the randomly shuffled 10- to 30-second audio segments do not provide the full context or meaning of the original videos. These short segments are incapable of reproducing or capturing the core or "heart" of the copyrighted works.

- (4) **Effect on the Potential Market**: Our dataset does not serve as a competitor to the original content on YouTube. The 10- to 30-second audio segments do not detract from the YouTube viewership or impact the commercial interests of copyright owners. As a result, our work does not interfere with the potential market value of the original videos or undermine the business of copyright owners.

By adhering to these principles, we ensure compliance with Fair Use guidelines while maintaining the scientific and ethical integrity of our research. Numerous related works have been conducted that utilize the extraction of video content from YouTube for academic and noncommercial purposes. These studies typically involve systematic retrieval of publicly available videos, followed by their conversion to audio formats to facilitate various lines of research, such as ASR, NLP, and multimedia analysis. Such approaches often aim to leverage the diverse linguistic, cultural, and acoustic features inherent in the vast repository of YouTube content while adhering to ethical guidelines and copyright regulations to ensure the integrity and legality of the research, such as GigaSpeech[5] (China & USA), VoxCeleb[6] (UK), VoxLingua107[7] (UK).

B.2 Data Consent

Our waiver of data consent for the collection of medical ASR datasets is justified based on ethical and regulatory considerations, particularly when the data are deidentified and pose minimal risk to individuals. In compliance with institutional review board (IRB) guidelines and regulatory frameworks, such as the Common Rule, consent can be waived if it is impractical and research has significant potential to advance medical knowledge or improve healthcare outcomes. Anonymization techniques, including speaker de-identification, ensure that patient confidentiality is maintained, mitigating privacy concerns. Additionally, the dataset is used strictly for research purposes, with safeguards in place to prevent misuse or unauthorized access.

[3] https://copyrightalliance.org/faqs/what-is-fair-use/

[4] http://www.elra.info/media/filer_public/2021/02/12/elrc-legal-analysis-webcrawling_report-v11.pdf

[5] https://github.com/SpeechColab/GigaSpeech

[6] https://www.robots.ox.ac.uk/ vgg/data/voxceleb/

[7] https://bark.phon.ioc.ee/voxlingua107/

These measures collectively support the ethical and legal justification for waiving individual data consent while upholding privacy protections.

The publication of research data in this study adheres to relevant legal frameworks concerning data consent and privacy protection, both within Vietnam and internationally. A comprehensive explanation is provided below.

- **Global Data Protection and Privacy Compliance**: Of the 194 countries globally, 137 have adopted Data Protection and Privacy Legislation[8], as documented by the United Nations (UN). This includes key signatories such as the USA, EU member states (e.g., Germany), and Vietnam. In alignment with these international frameworks, Vietnam's Personal Data Protection Act stipulates in Article 6 that "The protection of personal data is carried out in accordance with international treaties to which the Socialist Republic of Vietnam is a member." This establishes that Vietnamese data protection laws comply with international standards, ensuring compatibility and lawful handling of personal data for global collaboration in research.

- **Exemption for Sensitive Data Processing for Research**: Article 20, Section 4 of Vietnam's Personal Data Protection Act explicitly states that "The party processing personal data is not required to register for processing sensitive personal data in the case of research purposes." This provision legally allows researchers to process sensitive data, including medical and speech-related datasets, without the explicit consent of individuals, provided the purpose is confined to scientific inquiry.

- **No Consent Requirement for Data Publication in Research**: Under Article 16 of Vietnam's Personal Data Protection Act, the principle of data deletion is waived for cases involving scientific research, statistics, or legal obligations. The law specifies that: "Data deletion will not apply at the request of the data subject in the following cases: Personal data is processed to serve legal requirements, scientific research, and statistics." Thus, researchers are exempt from obtaining consent from data subjects for the inclusion of their data in publications, reaffirming the permissibility of this study's data handling practices.

- **Encouragement of Research Publication in Vietnam**: The Law on Medical Examination and Treatment, in conjunction with the Constitution of the Socialist Republic of Vietnam, underscores the importance of scientific dissemination. Article 22 mandates that medical practitioners and researchers "are responsible for updating relevant medical knowledge (...) including (...) c) Publish scientific research (...)." This legal encouragement promotes the proactive sharing of findings, particularly when involving sensitive medical data, as part of advancing public health and scientific understanding.

- **Legal Protections for Researchers**: Article 42 of the Law on Medical Examination and Treatment provides explicit protections for researchers. It states that researchers are "protected by the law and not responsible when a medical incident still occurs after complying with regulations." This ensures that any unforeseen outcomes related to the use or publication of research data, provided it aligns with statutory requirements, do not hold researchers liable.

- **Data Collection and Jurisdictional Compliance**: The dataset utilized in this study was collected using Vietnamese IP addresses and a web crawler authorized by a Vietnamese government-recognized company. This method adheres to Vietnam's Cybersecurity Law, as outlined in Article 26 of the Constitution of the Socialist Republic of Vietnam. It mandates that "Domestic and foreign enterprises providing services on telecommunications networks, the Internet, and value-added services in cyberspace in Vietnam have activities of collecting, exploiting, analyzing, and processing information data (...) created by service users in Vietnam must store this data in Vietnam (...) as prescribed by the Government." Consequently, YouTube, as a service provider, must comply with Vietnamese regulations concerning data generated within the country's cyberspace.

- **International Researchers and Cross-Border Legal Alignment**: Articles 2 and 10

[8] https://unctad.org/page/data-protection-and-privacy-legislation-worldwide

of the Vietnamese Civil Code on Civil Relations with Foreign Elements assert the application of Vietnamese law to international civil relations involving foreign researchers. Specifically, the Code emphasizes that "The provisions of Vietnamese civil law apply to civil relations involving foreign elements (...). In case the application or consequences of the application of foreign law are contrary to (...) the Vietnam Civil Code and other basic principles of Vietnamese law, then Vietnamese law applies." This ensures that international researchers working with Vietnamese data must adhere to Vietnamese laws, while simultaneously receiving legal protections and encouragement under these frameworks.

The dataset utilized in this study comprises YouTube content predominantly centered on medical themes, including televised medical shows, interviews, and educational lectures. In all cases, the participants in the videos spoke directly to the camera, demonstrating awareness that their content was intended for public dissemination. This awareness comes from the context of these videos, which were explicitly produced with the goal of providing accurate and accessible medical knowledge to YouTube audiences. Importantly, these videos were officially published by reputable national television channels, ensuring a professional standard of production and adherence to broadcasting regulations.

In contrast, YouTube videos created by amateur content creators, where the individuals featured may not have been aware of being recorded or of the eventual publication of the footage, were explicitly excluded from our dataset. This exclusion criterion was implemented to maintain ethical standards, particularly regarding informed consent and privacy. By limiting the dataset to professionally produced content with a clear intention of public dissemination, we aimed to ensure that the data collected adhered to legal and ethical guidelines on participant awareness and data use.

C Details of Data Creation

C.1 Details of Data Collection per Language

C.1.1 English

The data was collected from YouTube using the 2024 ICD-10-CM Codes to ensure diversity. We searched for diseases associated with the first 8 codes: A00-B99 (Infectious diseases), C00-D49 (Neoplasms), D50-D89 (Blood Diseases), etc. Due to time constraints, we searched only for these codes, applying filters for videos longer than 20 minutes and with subtitles to ensure accuracy. The videos were manually selected, prioritizing diverse speakers, accents, and contexts.

For the first 3 codes, we obtained 20 hours of video and subtitles and 10 hours for the rest. Videos and metadata, including recording conditions, speaker roles, genders, and accents, were saved.

C.1.2 French

We collected French medical videos from YouTube using terms such as "urgence", "consultation médicale", and "cancer". The videos required Closed Captions (CC) with timing, either manually annotated or auto-generated by YouTube. We focused on videos over 20 minutes, covering topics such as oncology, cardiology, and pediatrics, from diverse contexts (lectures, interviews, consultations) and recording conditions (clean audio to noisy emergency rooms with multiple speakers) and prosodies (calm narration to distressed cries).

C.1.3 Chinese

We tried collecting Chinese videos using the same method as for French, but found very few Mandarin videos with CC from mainland China. Most Chinese subtitles were hardcoded, and available CC were in English (from Singapore) or Traditional Chinese (from Taiwan or Hong Kong). After attempting to upload Chinese videos to our channel for automatic CC generation, we found YouTube could not generate subtitles due to language complexity. As a result, we mainly used videos from Singapore and Taiwan, with fewer from mainland China.

C.1.4 German

The data was collected from YouTube using 2024 ICD-10 codes for diversity. We searched for videos related to diseases linked to these codes, but found limited human-labeled subtitles. To address this, we included German medical terms such as "Krankenhaus" and "Krankheit" in our searches. All selected videos had manually annotated captions with accurate timestamps. We prioritized videos longer than 20 minutes, then shorter ones, ensuring diversity in speakers by gender, accent, and context (lectures, discussions, interviews).

C.2 Details of Data Quality Control

The French transcript was triple-validated by a native French Literature lecturer and a C1-level linguist - a professional medical expert, ensuring transcription accuracy and alignment with the CC timing. The Chinese transcript was similarly validated by a native speaker and an HSK-5 level linguist professional medical expert. The English transcript was initial reviewed by a TESOL-certified linguist, followed by cross-checking by three C1-level speakers, one of whom is a professional biomedical expert. Due to labor constraints, the German transcript was double-validated by a single C1-level professional biomedical expert.

All of our annotators were instructed to adhere to the following quality control procedures:

1. Listen carefully to the audio recordings
2. Validate the human-annotated transcripts provided by professional YouTube channels by correcting minor inaccuracies or excluding transcripts deemed too erroneous
3. Identify the start and end points of individual utterances
4. Identify the speaker, recording conditions, accents, speaking roles (when applicable)

C.3 Data Processing

Transcription errors often arise from time-stamp mismatches when segmenting long-form audio into shorter segments. Annotators use long-form audio to improve efficiency and capture extended contexts, such as discussions or lectures. Due to GPU memory limitations, training is restricted to short-form audio to prevent out-of-memory (OOM) issues. As a result, annotators split long transcripts, causing time-stamp mismatches, typically within one second. This can lead to missing words at the start or end of recordings, highlighting the limitations of human-labeled datasets, where annotators struggle to capture words occurring faster than one second (Wargo, 1967). For a standard conversational spontaneous ASR English dataset such as

Switchboard (Godfrey et al., 1992), the Word Error Rate (WER) for human annotators ranges from 5% to 15% (Stolcke and Droppo, 2017). In contrast, for a more challenging real-world ASR dataset, the WER for human annotators without ASR support ranges from 17% to 31% (Mulholland et al., 2016).

In contrast, forced alignment can address this issue as machines can "listen" to words in 10ms-20ms intervals. However, forced alignment is limited by the quality of human-provided training data, making no transcript entirely accurate. To achieve "more perfect" transcripts, we employ a human-machine collaboration approach.

To maximize the data quality for the training model. We implemented a tailored data quality control pipeline designed to address specific challenges inherent to multi-audio sources. The transcription process is often manual and can be inaccurate. Dividing audio into very short segments (i.e., less than 5 seconds) frequently results in serious misalignment with the transcriptions, which harms the training process. By concatenating these short segments, we created longer and more coherent training samples. This mitigates the misalignment problem and provides the model with a richer understanding of the patterns and intonation of spoken language. The results of the analysis before and after concatenation are shown in Figure 1.

Additionally, extraneous noise text elements such as silence markers, filled pauses, and HTML tags, while present in raw transcripts, do not contribute to meaningful model learning. We removed these elements to focus the model's attention on relevant speech content. In particular, we chose to retain punctuation marks during the cleaning process. Punctuation plays a crucial role in conveying the nuances of spoken language, and its presence in training data encourages the model to generate transcripts that are not only accurate but also expressive and natural-sounding.

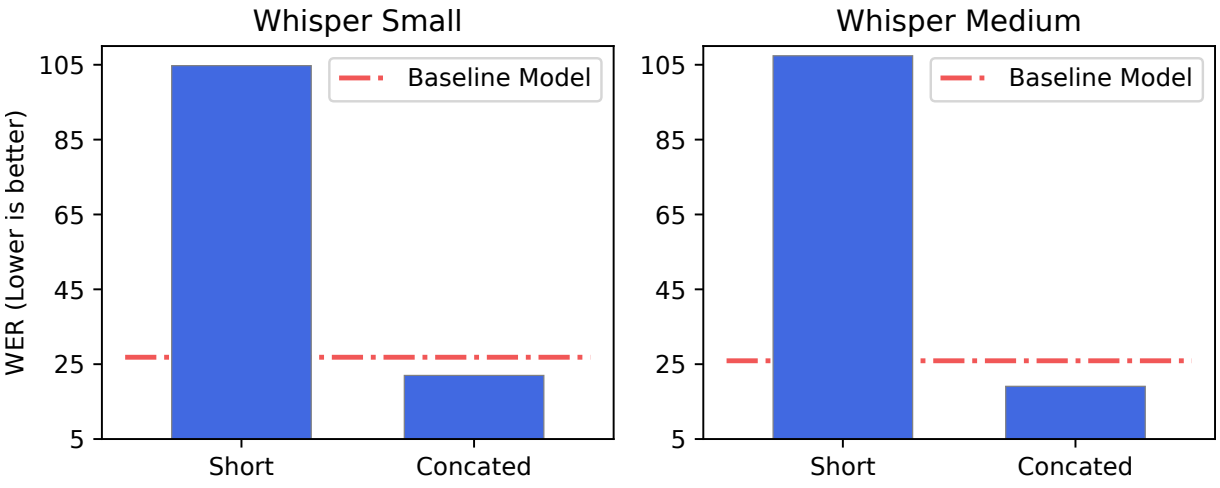

Figure 1: Illustrating the performance comparison of Whisper models trained on two distinct audio segmentation approaches for German language data: human-segmented short audio clips and concatenated continual audio segments of approximately maximum 15 seconds in length. We evaluate performance using both Whisper Small and Whisper Medium model sizes. The results demonstrate a notable improvement in model performance when trained on concatenated audio, highlighting the efficacy of this data preparation technique in enhancing transcription accuracy in the German language context

C.4 Full Data Statistics

MultiMed dataset consists of multilingual audio recordings in five languages: Vietnamese, English, French, German, and Mandarin Chinese. Each audio clip was segmented into short snippets with an average length of approximately 6 seconds for Vietnamese and around 12 seconds for the other languages. This segmentation facilitated efficient training and improved the model's responsiveness to shorter speech segments. The dataset was subsequently uploaded to the Hugging Face platform for further training and analysis. The statistics of our data samples are described in Table 2.

Table 9 shows the statistics of the data set compared to all existing publicly available medical ASR datasets, based on our best knowledge of the current literature. As shown in the table, our *MultiMed* dataset stands as the world's largest dataset in terms of total duration (150 hours of recordings), number of recording conditions (10), number of accents (16) and number of speaking roles (6).

Dataset	Venue	Dur.	Language	Nature	#Rec. Cond.	#Spk	#Acc	#Roles

Table 9: Dataset statistics in comparison with all existing works from left to right: Total duration in hours (h), language, nature of speech, number of recording conditions, number of speakers, number of accents, speaking roles. [1]In our dataset, only the number of recording conditions, speakers, accents and speaking roles for Vietnamese and English are identified because of technical and privacy issues. Therefore, the exact number of speakers and accents must be much larger than the currently reported number. 10 recording conditions include: Documentary, Interview, Lecture, News, Podcast, Webinar, Speech, Talk, Vlog, Workshop. 10 English accents include: Main US, Southern US, UK, Australian, Indian, Mexican, European, Japanese, Uzbekistan, Russian. 6 Vietnamese accents include: North, South Central Coast, South East, South West, Central Highland, North Central Coast.
[2]Speech collected by simulated medical conversations between 2 speaking roles - clinicians and actors/actresses. 4 English accents include: British English, European, other English, and other non-English.
[3]Speech was recorded as patient-physician interviews (counted as 1 recording condition and 2 speaking roles) by West England speakers (counted as 1 accent)
[4]AfriSpeech-200 dataset is a mix of general-domain and medical-domain speech. To our best understanding of the paper, we estimate the total duration of medical-domain speech to be around 123 hours. Recordings were collected by crowd-sourced workers to read aloud the medical transcripts (also known as read speech), thus both the number of recording conditions and speaking roles are counted as 1.
[5]myMediCon dataset hired speakers to read aloud the translated medical transcripts from English corpus (thus known as read speech). 5 speakers' accents include: Native Burmese, Pa'O, Kachin, Dawei, and Mon. 2 speaking roles are patients and doctors.

D Attention Encoder Decoder (AED)

An ASR model aims to convert an audio signal into text by mapping an audio signal $x_1^T := x_1, x_2, ..., x_T$ of length T to the most likely word sequence w_1^N of length N. The word sequence probability is defined as:

$$p(w_1^N|x_1^T) = \prod_{n=1}^{N} p(w_n|w_1^{n-1}, x_1^T). \quad (4)$$

In the encoder-decoder architecture, given D as the dimension size of the feature, the input audio signal matrix could be described as $x_1^T \in \mathbb{R}^{T\times D_{input}}$. For the sake of simplicity, downsampling prior to or within the encoder, achieved by a fixed factor, such as striding in a Convolutional Neural Network (CNN) is omitted. Consequently, the encoder output sequence is as follows:

$$h_1^T = Encoder(x_1^T) \in \mathbb{R}^{T\times D_{encoder}}. \quad (5)$$

Using a stack of Transformer ($\mathcal{T}$) blocks (Vaswani et al., 2017), the encoder output sequence is described as function composition:

$$h_1^T = \mathcal{T}_0 \circ ... \circ \mathcal{T}_{N_{EncLayers}}(x_1^T). \quad (6)$$

In the decoder, the probability for every single word is described as:

$$\begin{aligned} p(w_n|w_1^{n-1}, x_1^T) &= p(w_n|w_1^{n-1}, h_1^T(x_1^T)) \\ &= p(w_n|w_1^{n-1}, h_1^T). \end{aligned} \quad (7)$$

Based on Eq. 4, the word sequence probability given the output of encoder is formulated as:

$$p(w_1^N|x_1^T) = \prod_{n=1}^{N} p(w_n|w_1^{n-1}, h_1^T). \quad (8)$$

Decoder hidden state is formulated as:

$$g_n = f(g_{n-1}, w_{n-1}, c_n) \in \mathbb{R}^{D_g}, \quad (9)$$

where f is neural network; D_g is hidden state dimension; and c_n is context vector, e.g. weighted sum of encoder outputs via attention mechanism.

The attention mechanism in the decoder is described by 3 components: context vector c_n, attention weights $\alpha_{n,t}$, and attention energy $e_{n,t}$:

$$\begin{aligned} c_n &= \sum_{t=1}^{T} \alpha_{n,t} h_t \in \mathbb{R}^{D_{encoder}}, \\ \alpha_{n,t} &= \frac{\exp(e_{n,t})}{\sum_{t'=1}^{T} \exp(e_{n,t'})} \\ &= Softmax_T(\exp(e_{n,t})) \in \mathbb{R}, \\ e_{n,t} &= Align(g_{n-1}, h_t) \in \mathbb{R} \\ &= W_2 \cdot \tanh(W_1 \cdot [g_{n-1}, h_t]), \end{aligned} \quad (10)$$

where n is decoder step; t is encoder frame; $\alpha \in \mathbb{R}^{T\times N}$ is attention weight matrix; $\alpha_n \in \mathbb{R}^T$ is normalized probability distribution over t; $Softmax_T$ is Softmax function over spatial dimension T, not feature dimension; $W_1 \in \mathbb{R}^{(D_g+D_{encoder})\times D_{key}}$; $W_2 \in \mathbb{R}^{D_{key}}$.

During decoding, the output probability distribution over vocabulary is described as:

$$\begin{aligned} &p(w_n = *|w_1^{n-1}, h_1^T) \\ &= Softmax(MLP(w_{n-1}, g_n, c_n)) \in \mathbb{R}^N, \end{aligned} \quad (11)$$

where MLP is Multi-layer Perceptron.

For training AED model, sequence-level cross-entropy loss is employed:

$$\begin{aligned} \mathscr{L}_{AED} &= -\sum_{(x_1^T, w_1^N)} \log p(w_1^N|x_1^T) \\ &= -\sum_{(x_1^T, w_1^N)} \sum_{n=1}^{N} \log p(w_n|w_1^{n-1}, x_1^T). \end{aligned} \quad (12)$$

In beam search process, the auxilary quantity for each unknown partial string (tree of partial hypotheses) w_1^n is described as:

$$\begin{aligned} Q(n; w_1^n) &:= \prod_{n'=1}^{n} p(w_{n'}|w_0^{n'-1}, x_1^T) \\ &= p(w_n|w_0^{n-1}, x_1^T) \cdot Q(n-1, w_1^{n-1}). \end{aligned} \quad (13)$$

After eliminating the less likely hypotheses in the beam search process, the word sequence probability is determined by the most optimal hypothesis:

$$p(w_1^N|x_1^T) = Q(N; w_1^N). \quad (14)$$

E Full Experimental Setups

E.1 Hyperparameter Tuning

The training process leveraged powerful A100 SXM4 GPUs. To ensure consistent results, we fixed the random seed at 42 throughout the training runs. For all models, we adopted a common training configuration with a batch size of 8, a learning rate of 0.0001, and 20 training epochs. We applied several data pre-processing techniques during training, including lowercasing text, removing punctuation, and normalizing the audio input. In addition, we trained each model on a language-specific subset of the dataset to optimize its performance for the targeted language.

The optimizer chosen for training was Adam (Kingma and Ba, 2014) with the standard betas configuration (0.9, 0.999) and an epsilon value of 1e-8. We employed a linear learning rate scheduler with a warmup period of 100 steps to gradually increase the learning rate during the initial training phase. No data augmentation such as SpecAugment (Park et al., 2019a) was applied.

E.2 Details of Evaluation Metrics

To assess the performance of the ASR models, we used two standard evaluation metrics: WER and CER. Lower WER and CER scores indicate better model performance in terms of accurately transcribing spoken audio.

WER focuses on the accuracy of recognized words. It calculates the percentage of errors made at the word level, including insertions, deletions, and substitutions compared to the ground truth reference transcript, as described in Equation 15.

$$WER = \frac{S + D + I}{N} = \frac{S + D + I}{S + D + C} \tag{15}$$

where S is the number of word substitutions, D is the number of word deletions, I is the number of word insertions, C is the number of correct words, and N is the number of words in the reference data $(N = S + D + C)$.

Generally speaking, S represents the count of replaced words, D denotes the count of omitted words present in the reference data but absent in the ASR hypothesis, and I indicates the count of inserted words present in the ASR hypothesis but absent in the reference data. The alignment process between the ASR hypothesis and the reference data proceeds sequentially from left to right.

WER measures the number of insertions, deletions, and substitutions made at the word level, while the CER focuses on errors at the character level, as illustrated in Equation 16.

$$CER = \frac{S_c + D_c + I_c}{N_c} = \frac{S_c + D_c + I_c}{S_c + D_c + C_c} \tag{16}$$

where S_c is the number of character substitutions, D_c is the number of character deletions, I_c is the number of character insertions, C_c is the number of correct characters, and N_c is the number of characters in the reference data $(N_c = S_c + D_c + C_c)$.

F Details of Hybrid ASR Experiments

F.1 Hybrid wav2vec 2.0

F.1.1 Hybrid ASR

An ASR model aims to convert an audio signal into text by mapping an audio signal x_1^T of length T to the most likely word sequence w_1^N of length N. The relation w^* between the acoustic and word sequence is:

$$w^* = \arg\max_{w_1^N} p(w_1^N | x_1^T) \tag{17}$$

Bayes theorem: By applying Bayes' Theorem, the probability $p(x)$ can be ignored during the maximization process, as it functions only as a normalization constant and does not influence the final result.

$$\begin{aligned} p(w_1^N | x_1^T) &= \frac{p(x_1^T | w_1^N) p(w_1^N)}{p(x_1^T)} \\ &\propto p(x_1^T | w_1^N) p(w_1^N) \end{aligned} \tag{18}$$

Therefore:

$$w^* = \arg\max_{w_1^N} \underbrace{p(x_1^T | w_1^N)}_{\text{acoustic model}} \cdot \underbrace{p(w_1^N)}_{\text{language model}} \tag{19}$$

Acoustic modeling: First, alignments between the acoustic observations x_1^T and labels w_1^N are obtained by using Gaussian-Mixture-Model/Hidden-Markov-Model (GMM/HMM) as labels for Deep-Neural-Network/Hidden-Markov-Model (DNN/HMM) training (DNN is wav2vec 2.0 encoder (Baevski et al., 2020b) in this case).

$$p(x_1^T|w_1^N) = \sum_{[s_1^T]} \prod_{t=1}^{T} p(x_t, s_t|s_{t-1}, w_1^N)$$
$$= \sum_{[s_1^T]} \prod_{t=1}^{T} \underbrace{p(s_t|s_{t-1}, w_1^N)}_{\text{transition prob.}} \cdot \underbrace{p(x_t|s_t, s_{t-1}, w_1^N)}_{\text{emission prob.}} \tag{20}$$

GMM/HMM: The labels used in the acoustic modeling are context-dependent phonemes (triphones), instead of BPE subword units like in AED. During the GMM/HMM process, a CART (Classification and Regression Tree) (Breiman, 2017) is used to link the states s. The GMM is a weighted sum over K normal distributions and is calculated as:

$$p(x_t|s_t, s_{t-1}, w_1^N) = \sum_{i=1}^{K} c_i \cdot \mathcal{N}(x_t|\mu_i, \sigma_i^2), \tag{21}$$

resulting in a multimodal emission probability with parameters μ_i, σ_i and mixture weights c_i for $i \in [\![1, K]\!]$. The mixture weights are non-negative and sum up to unity.

DNN/HMM: The posterior probability $p(a_{s_t}|x_1^T)$ could be discriminatively modeled using DNN (wav2vec 2.0 encoder), resulting in the DNN/HMM approach. The emission probability in the HMM could be calculated using the Bayes rule:

$$p(x_1^T|a_{s_t}) = \frac{p(a_{s_t}|x_1^T)p(x_1^T)}{p(a_{s_t})}. \tag{22}$$

The probability $p(a_{s_t})$ could be estimated as the relative frequency of a_{s_t}. For a simplified Bayes decision rule, the probability $p(x_1^T)$ is removed.

Decoding: During the ASR decoding process, the acoustic model and n-gram language model (Ney et al., 1994) should be combined based on the Bayes decision rule using Viterbi decoding algorithm (Forney, 1973) which recursively calculates the maximum path to a find best-path in the alignment graph of all possible predicted words to the acoustic observations:

$$w_1^N = \arg\max_{N, w_1^N} p\Big(\prod_{n=1}^{N} p(w_n|w_{n-m}^{n-1}) \cdot \max_{[s_1^T]} \prod_{t=1}^{T} p(x_t, s_t|s_{t-1}, w_1^N)\Big) \tag{23}$$

Afterwards, beam search (acoustic model and n-gram language model pruning) is employed to solely focus on the most promising predicted words at each time step t (Ortmanns et al., 1997).

F.1.2 Modified wav2vec 2.0

The model consists of a multi-layer convolutional neural network feature extractor CNN that receives T time-step raw audio waveform $x_1^T := x_1, x_2, ..., x_T$ (or x for simplification, $x \in R^{T\times 1}$) as input and produces latent speech representations $x^{FE} \in R^{T\times 1}$. These representations are then pushed into a stack of Transformer ($\mathcal{T}$) layers (Vaswani et al., 2017) which generates contextualized representations for Softmax SM classification.

In the scope of this work, we mathematically formulate our modified architecture for Hybrid wav2vec 2.0 as follows.

Wave normalization[9]: The raw audio waveform x is first normalized to the range between 0 and 1 by the wave normalization layer $WaveNorm$ before being pushed into the feature extractor, as shown in Equation 24.

$$x^{WaveNorm} = WaveNorm(x) = LayerNorm(x) \in R^{T\times 1} \tag{24}$$

$WaveNorm$ could be either layer normalization $LayerNorm$ (Ba et al., 2016) or batch normalization $BatchNorm$ (Ioffe and Szegedy, 2015).

Feature extractor: The normalized raw audio waveform is pushed into a stack of CNN layers and a feed-forward (FFW) layer.

$$x^{FE} = FeatureExtractor(x) = FFN \circ CNNs \circ WaveNorm(x) \tag{25}$$

Time-downsampling in feature extractor[10]: When there is a sampling rate mismatch, the feature extractor of 16 kHz pre-trained models can

[9] Our modification of wav2vec 2.0 architecture for Hybrid ASR

[10] Our modification of wav2vec 2.0 architecture for sampling rate mismatch between pre-trained models and fine-tuned dataset

be modified to handle 8 kHz sampled data while still producing representations with the same 20 ms frame shift. By halving the stride of a convolutional layer in a stack of CNN layers in the feature extractor, we will receive features at the desired frame rate while reducing the downsampling factor from the waveform to the feature frames by a factor of 2.

$$\begin{aligned} x^{FE} &:= TimeDownsampling(x^{FE})| \\ x^{FE} &\in R^{\frac{1}{2}T_{FE} \times F_{FE}} \end{aligned} \tag{26}$$

In a generalized formulation shown in Equation 27, the time-downsampling could be done given a general time-downsampling factor TDF

$$\begin{aligned} x^{FE} &:= TimeDownsampling(x^{FE})| \\ x^{FE} &\in R^{\frac{1}{TDF}T_{FE} \times F_{FE}} \end{aligned} \tag{27}$$

Transformer as contextualized encoder: In an arbitrary l-th transformer layer, the output x_l^τ is briefly defined as:

$$\begin{aligned} x_l^\tau &= \mathcal{T}(x_{l-1}^\tau) \\ &= FFW \circ MHA(x_{l-1}^\tau) \end{aligned} \tag{28}$$

where MHA is multi-head attention which is a function defined by self-attention functions SA:

$$MHA(x_{l-1}^\tau) = SA(x_{l-1}^\tau) + x_{l-1}^\tau \tag{29}$$

Then, we have a full equation for an arbitary l-th Transformer layer:

$$\begin{aligned} x_l^\tau &= FFW(MHA(x_{l-1}^\tau)) + MHA(x_{l-1}^\tau) \\ &= FFW(SA(x_{l-1}^\tau) + x_{l-1}^\tau) \\ &+ \left[SA(x_{l-1}^\tau) + x_{l-1}^\tau\right] \end{aligned} \tag{30}$$

For layer-wise formulation, the 0-th Transformer layer (the first layer) is connected to the feature extractor, which is defined as:

$$x_0^\tau = \mathcal{T}(x^{FE}) \tag{31}$$

Given an L-Transformer-layer wav2vec 2.0 architecture, the $L-1$-th Transformer layer (the final layer) is defined as a chain function as:

$$\begin{aligned} x_{L-1}^\tau &= \mathcal{T}(x_{L-2}^\tau) \\ &= \mathcal{T} \circ \mathcal{T} \circ ... \circ \mathcal{T}(x_0^\tau) \\ &= \mathcal{T} \circ \mathcal{T} \circ ... \circ \mathcal{T} \circ \mathcal{T}(x^{FE}) \end{aligned} \tag{32}$$

where L is the total number of Transformer layers in the encoder, layer indices start from 0 to $L-1$.

Time-reupsampling: For wav2vec 2.0 architecture, regardless of whether a sampling rate mismatch exists or not, it is necessary to re-upsample the final Transformer layer prior to its input into a Softmax layer for frame-wise classification. Failure to do so would lead to a discrepancy in the number of time frames during the calculation of the frame-wise loss objective function. Consequently, a FFW necessitates upsampling to ensure alignment with the rest of the architecture.

$$\begin{aligned} x_{Reup} &:= TimeReupsampling(x_{L-1}^\tau) \\ &:= FFW(x_{L-1}^\tau)| \\ x_{Reup} &\in R^{T \times d} \end{aligned} \tag{33}$$

where d is the size of context-dependent states (CDS), or size of CART labels.

Hypothesis (output): Finally, x_{Reup} goes to a Softmax layer SM to produce a matrix of hypotheses $z \in R^{T \times d}$.

$$z := SM(x_{Reup})|z \in R^{T \times d} \tag{34}$$

Loss function: The hypothesis matrix z is compared with the ground truth y to calculate the frame-wise cross-entropy (CE) loss matrix $\mathscr{L}(z, y) \in R^{T \times d}$. The total loss value is the sum of all the elements in the loss matrix $\mathscr{L}(z, y)$.

$$\begin{aligned} \mathscr{L}(z, y) &:= \mathscr{L}_f(z, y) = \|\mathscr{L}(z, y)\|^1 \\ &:= -[y \cdot \log(z)], \quad f = CE \\ &> 0 \quad \forall \log \in \{\log_2, \log_n, \log_{10}\} \end{aligned} \tag{35}$$

F.2 Experimental Setups

For n-gram language modelling and the initialization of GMM-HMM, we used the same configurations and hyperparameters as in (Lüscher et al., 2023). We employed the BABEL project's seed lexicon and augmented it with additional Vietnamese text data. Using the toolkit Sequitur Grapheme-To-Phoneme[11] (Bisani and Ney, 2008) - the conversion tool on pronunciation lexicon, the seed lexicon from BABEL was extended, creating the augmented lexicon for training. The statistics for the n-gram language model and the augmented lexicon are shown in Table 10.

The labels for the acoustic model were generalized triphone states obtained by CART with 4501 labels. During GMM-HMM process, we

[11] https://github.com/sequitur-g2p/sequitur-g2p

Trained lexicon		Language model		*dev*		*test*	
#words	**#vocab**	**#words**	**Size (in MBs)**	**OOV**	**PPL**	**OOV**	**PPL**
17,000	5295	8.5M	98	0.76%	66	0.66%	84

Table 10: Statistics of 4-gram language model and augmented lexicon for hybrid ASR training, including for both GMM-HMM and wav2vec 2.0 training. OOVs and Perplexities (PPLs) are reported on our Vietnamese dev and test set.

found that WERs on the Vietnamese test sets of Speaker Adaptive Training (SAT) was quite comparable to Speaker Adaptive Training + Vocal Tract Length Normalization (SAT+VTLN). So, we fed SAT alignments into wav2vec 2.0 as input for the Hybrid ASR training.

For self-supervised wav2vec 2.0 training (Baevski et al., 2020a) and fine-tuning, we used the same vanilla setups and hyperparameters in (Le-Duc, 2023). All models had 123M parameters including 7 CNN layers and 8 Transformer layers, as shown in Table 7 in the main paper. The last CNN layer had a stride halved for adaptation to the 8kHz data. The pre-training epoch that led to the best WERs on dev was used to fine-tune with framewise CE loss. The SpecAugment (Park et al., 2019b) was employed during 33 fine-tuning epochs.

We employed RETURNN framework (Zeyer et al., 2018a) for supervised training (fine-tuning the wav2vec 2.0 models) and Fairseq (Ott et al., 2019) for self-supervised wav2vec 2.0 training on the unlabeled data. ASR decoding was performed using the RASR toolkit (Rybach et al., 2011). The pre-trained wav2vec 2.0 models from Fairseq (in Pytorch) were converted to RETURNN models (in Tensorflow) with our PyTorch-to-RETURNN toolkit[12].

F.3 Extra Experimental Results

Table 11 shows the breakdown per speaker in the Vietnamese test set of the Hybrid ASR results in Table 7. Two pre-trained wav2vec 2.0 models were used for fine-tuning on the Vietnamese set: XLSR-53-Viet and w2v2-Viet, leading to WERs on test set 28.8%, 29.0% respectively.

Table 11: Breakdown per speaker on the Vietnamese test set of the Hybrid ASR results in Table 7. Two pre-trained wav2vec 2.0 models were used for fine-tuning on the Vietnamese set: XLSR-53-Viet and w2v2-Viet, leading to WERs on test set 28.8%, 29.0% respectively.
Column from left to right is: Speaker ID, Number of sentences, Number of words, Corrections, Substitution Errors, Deletion Errors, Insertion Errors, Word-Error-Rate, Sentence-Error-Rate.

G Full Error Analysis

Figure 12 shows an example of common ASR errors from the ASR output compared to the corresponding ground truth transcript. Three ASR errors considered are substitutions, deletions, and insertions.

Below is the full error analysis based on the linguistic perspective for all 5 languages: English, Vietnamese, Chinese, French, and German.

G.1 English

Our error analysis of the ASR system revealed several phonological issues that affected the performance of the model. One significant issue involves the minimal phonological distance between certain vowel sounds, particularly in minimal pairs such as "long" vs. "lung" and "pen" vs. "pan". Due to the close proximity of these sounds in the phonetic space, the model often confuses them, leading to clinically significant errors, such as transcribing "lung cancer" as "long cancer".

Another source of error is related to the use of weak forms in speech, where certain words are pronounced in a reduced or less distinct manner. This results in frequent misrecognitions, such as interpreting "our" as "are", "and" as "in", "for" as "very", and even more complex substitutions like "earlierologist" for the phrase "earlier I was just". Additionally, numerical errors are common; for instance, the model may interpret "4 to 5" as "45", which could lead to critical inaccuracies in medical records. This type of substitution also extends to domain-specific terminology, such as transcribing "system that" as "systemic".

In addition, discrepancies were identified at the beginning and end of the transcriptions. This issue is largely attributed to inconsistencies between the training and testing conditions: the dataset was annotated using long-form audio segments, yet the model was trained and evaluated with short-form audio inputs. This mismatch creates boundary errors and negatively affects the model's ability to capture context, leading to truncation or overlap in predictions. In particular, this problem is not limited to English but has also been observed in other languages, indicating a systematic problem in handling different input formats during ASR processing.

G.2 Vietnamese

In the Vietnamese test set, a detailed analysis of ASR errors reveals that several phonological characteristics of the Vietnamese language pose significant challenges for model performance. Vietnamese is a tonal language with a complex phonetic system that includes a variety of vowels, consonants, and six distinct tones, all of which carry meaning and are integral to word differentiation (Horn and Pham, 2004). As a result, the ASR system often struggles with minimal phonetic contrasts, particularly when dealing with similar-sounding phonemes and tones.

Vowel confusion: Vietnamese vowels exhibit subtle distinctions, especially in terms of vowel height and backness. Pairs such as "cái" vs. "cứ" demonstrate this challenge. The model frequently confuses these due to their similar articulatory features and acoustic proximity. For instance, "cái" (meaning "thing" or "classifier for objects") and "cứ" (meaning "to keep doing something") differ primarily in vowel quality, but the ASR system often fails to capture this distinction, leading to misrecognition.

Consonant ambiguity: Consonant sounds in Vietnamese can also present difficulties, particularly when the phonemes are produced with similar places of articulation. An example is "nó" (he/she/it) vs. "nói" (to speak), where the confusion arises due to the similarity in nasal sounds and the rapid articulation of connected speech. Similarly, the pair "bác" (uncle/aunt) and "mắc" (to catch/to be caught) are often misrecognized due to the shared stop consonant sounds, complicated further by the presence of nasal or plosive release.

Tonal ambiguity: Vietnamese tones are particularly problematic for ASR systems, as they are both lexically and syntactically significant. The six tones in Vietnamese include level, rising, falling, broken, creaky, and low tones, which can completely change the meaning of a word. For instance, the pair "năng ngọng" (meaning "slurred speech") and "nặng nhọc" (meaning "laborious") illustrates how the model struggles to distinguish between tones, leading to semantically incorrect transcriptions. The difference between these phrases lies in tone distinctions, which are subtle and can be easily confounded by background noise or speaker variability.

Gender and regional variations: Furthermore, phonological variability due to gender differences

(for example, male vs. female voice pitch) and regional dialects (Northern, Central, and Southern accents) further complicates the ability of the ASR system to correctly distinguish words of similar sound. For example, "nử" (variant pronunciation for some speakers, typically Northern) and "nữ" (female) differ mainly in tone and vowel length, which may be pronounced differently across dialects, increasing the error rate.

These types of phonological errors highlight the need for enhanced acoustic modeling that can account for the intricate vowel and consonant distinctions and the tonal nature of Vietnamese, especially in the medical domain. It also underscores the importance of incorporating a diverse set of training data that reflect different regional accents and speech patterns for patients and doctors to improve the robustness of the medical ASR system in Vietnamese language contexts.

G.3 Chinese

A primary source of errors arises from minimal pairs that differ solely in tonal pronunciation or involve homophones, both of which are highly prevalent in Mandarin Chinese. Given that Mandarin is a tonal language with four distinct tones (plus a neutral tone), words that share similar phonetic sounds but differ in tone can easily be confused by ASR systems (Jongman et al., 2006). This tonal ambiguity leads to significant transcription errors, especially in medical contexts where precision is crucial.

For instance in our test set, words like 麻闭 (mábì) and 麻痹 (má bì), or 跟本 (gēnběn) and 根本 (gēn běn), demonstrate how tonal distinctions are critical for differentiating between distinct meanings. Similarly, homophones such as 以 (yǐ) and 已 (yǐ), or 是 (shì) and 适 (shì), present further challenges, as the ASR system struggles to disambiguate words with identical phonetic pronunciation but different meanings. The error is compounded by the context-dependent nature of these terms, which requires a sophisticated understanding of the surrounding text to accurately differentiate them.

Additionally, errors are frequently caused by words that sound alike but differ in their meaning, as seen in examples like 代 (dài) vs 待 (dài) or 其二 (qí èr) vs 妻儿 (qī ér). In the medical domain, such mistakes can lead to severe clinical misinterpretations, affecting patient safety. For example, confusion between 没 (méi) (not) and 霉 (méi) (mold) could result in significant differences in the interpretation of a patient's condition or diagnosis.

Another frequent source of error is phonetic approximation in the sound space, where slight variations in pronunciation result in incorrect word predictions. Examples include 到路 (dào lù) vs 倒漏 (dào lòu) and 一确的 (yī què de) vs 一切都 (yīqiè dōu). These phonetic approximations arise due to the ASR system's inability to distinguish subtle differences, particularly in connected speech where articulation may be less clear. Such approximations can be particularly problematic in medical transcription, where terms like 答案 (dá'àn) (answer) being mistaken for 大碍 (dà ài) (serious problem) could alter the intended meaning of a clinical statement.

G.4 French

The errors encountered in the medical domain's ASR systems can be attributed to various phonological challenges, especially in datasets with languages like French, where the close proximity of certain phonemes in the acoustic space leads to frequent misinterpretations. These challenges typically arise from the inherent acoustic similarity between phonemes or word pairs that sound alike but have different meanings or spelling, often referred to as homophones or near-homophones For instance, in the French language, there are numerous vowel and consonant pairs that share similar acoustic characteristics but differ in meaning, making them susceptible to confusion. Some notable examples include:

- "attention" vs "ah tiens": Both phrases have similar phonetic structures, but the former is a common French word meaning "careful" or "attention", while the latter is a colloquial expression that might refer to a surprise or exclamation. A misinterpretation of these terms could lead to clinical miscommunication in situations requiring urgency or specific instructions.

- "engardré" vs "encadré": These words differ by a single vowel sound, but the first ("engardré") is a non-standard form or a potential misheard word, while the latter ("encadré") means "framed" in French. Such phonetic ambiguity can easily result in incorrect transcription, especially when the ASR model is unable

to distinguish between similar-sounding terms within the context of a medical discussion.

- "à mettre" vs "est maître": The phrase "à mettre" (meaning "to put") is often misheard as "est maître" (meaning "is the master"), as both phrases have a similar rhythm and vowel-consonant structure. In medical settings, such confusion could mislead the interpretation of a patient's condition or instructions for care.

- "bonchique" vs "bronchite": A typical error arises when the ASR system confuses "bronchite" (bronchitis) with a distorted form like "bonchique". This could be catastrophic in medical contexts, as bronchitis refers to a serious respiratory condition, and an error here could delay proper diagnosis or treatment.

- "choléraux" vs "cholestérol": The acoustic similarity between "choléraux" (a non-standard or incorrect form) and "cholestérol" (cholesterol) presents another challenge. Cholesterol is a critical term in medical diagnostics, and errors in its transcription could result in the omission of vital health information, leading to inaccurate clinical assessments or interventions.

- "mé" vs "mais": The confusion between "mé" (which can be a shorthand or mispronunciation of "mais" meaning "but") is another example. Such errors are especially significant in medical contexts where subtle linguistic distinctions, even in less formal speech, can alter the meaning of a diagnosis or treatment plan.

G.5 German

In the context of ASR error analysis within the medical domain, our German test set presents distinct challenges that stem from both phonological and orthographic factors, which significantly affect the model's accuracy and performance.

Firstly, the issue of phonological proximity is particularly noticeable in minimal pairs—pairs of words that differ only in one sound. In the German language, small phonological differences between vowels in minimal pairs can cause considerable confusion for ASR models, as these systems often struggle to accurately distinguish between such similar-sounding words. For instance, the words "verschmerzen" (to suffer pain) and "vor Schmerzen" (before pain) have a very slight phonetic distinction, yet they represent entirely different meanings, potentially leading to misinterpretation by the ASR system. Similarly, words like "anestätiger" (anesthetist) and "Lokalanästhetikasalbe" (local anesthetic cream) contain subtle phonetic differences that can cause errors in transcription, especially when such words are transcribed without appropriate context or clarity.

Secondly, the orthographic characteristics of the German language further complicate ASR performance. German has a system of capitalization where nouns and imperative verbs are capitalized, while adjectives, adverbs, verbs, and other parts of speech are written in lowercase. This capitalization rule is not just a grammatical convention, but a semantic one, as it helps distinguish between different parts of speech and the meaning of the sentence. ASR models that fail to accurately capture these distinctions often produce errors that are both semantically and syntactically problematic. For example, "venenzugang" (venous access) vs "Venenzugang" (with proper capitalization) may lead to a loss of meaning or context in the transcribed text. Similarly, confusion between "komme" (come) and "Komme" (I come, in the imperative) can alter the intended message, especially in medical contexts where the clarity of instructions is critical.

Example		
English	ASR output	**sea** you don't really see any **affect** the brown **apocalyse** tissue activity, but at the high **BMW**, now, you will start to see a **uh uhm** protective effect where those individuals had lower **glyceryl**.
	Ground truth	**only** see you don't really see any effect **of** the brown adipose tissue activity, but at the high BMI, now, you will start to see a protective effect where those individuals had lower glycemia.

🐭🐭🐭MICE: Mixture of Image Captioning Experts Augmented e-Commerce Product Attribute Value Extraction

Jiaying Gong, Hongda Shen, Janet Jenq
eBay Inc.
{jiagong,honshen,jjenq}@ebay.com

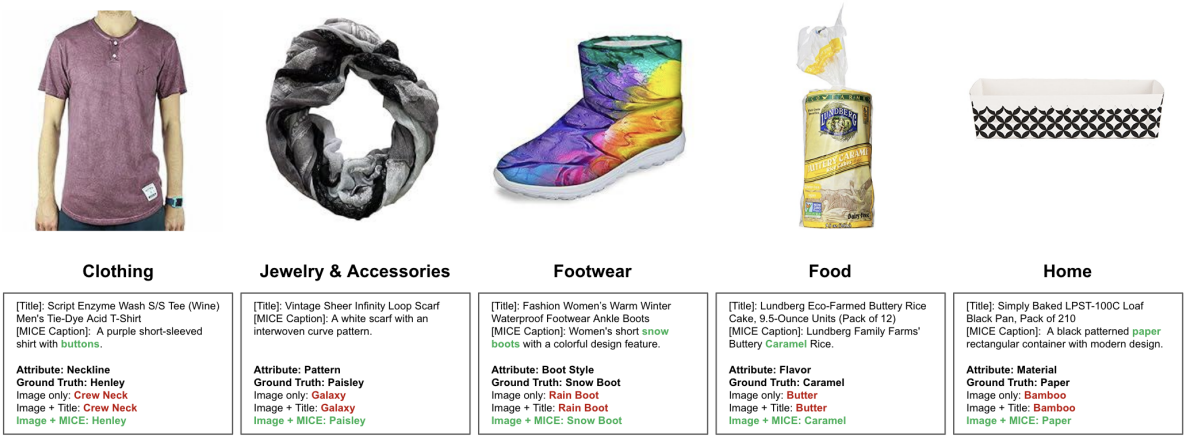

Figure 1: Examples of attribute value extraction for e-Commerce products.

Abstract

Attribute value extraction plays a crucial role in enhancing e-commerce search, filtering, and recommendation systems. However, prior visual attribute value extraction methods typically rely on both product images and textual information such as product descriptions and titles. In practice, text can be ambiguous, inaccurate, or unavailable, which can degrade model performance. We propose Mixture of Image Captioning Experts (MICE), a novel augmentation framework for product attribute value extraction. MICE leverages a curated pool of image captioning models to generate accurate captions from product images, resulting in robust attribute extraction solely from an image. Extensive experiments on the public *ImplicitAVE* dataset and a proprietary women's tops dataset demonstrate that MICE significantly improves the performance of state-of-the-art large multimodal models (LMMs) in both zero-shot and fine-tuning settings. An ablation study validates the contribution of each component in the framework. MICE's modular design offers scalability and adaptability, making it well-suited for diverse industrial applications with varying computational and latency requirements.

1 Introduction

Visual attribute value extraction is a fundamental task in e-commerce that involves identifying and structuring key, visually discernible product details, such as brand, size, color, material, and item specifications. Figure 1 shows a few examples of e-commerce products along with their images, titles and attribute key-value pairs from one public dataset. The attribute extraction process is critical for enhancing product visibility, improving search functionality, and enriching the overall consumer experience. Accurately extracted attributes improve search result relevance, boost product discoverability, and enable more precise product filtering, ultimately contributing to higher click-through rates and increased customer engagement.

In addition to improving search and discovery, structured product information helps consumers make more informed purchasing decisions by enabling easier comparison between similar items. On the back end, automated attribute extraction supports large-scale catalog management by mini-

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1151–1160
July 28-30, 2025

mizing the need for manual data entry, which can be inefficient and error-prone. It also promotes standardization across sellers and marketplaces, resulting in more consistent, high-quality product data while reducing operational overhead.

Existing research on attribute value extraction (AVE) has primarily focused on unimodal approaches, where product attributes are derived solely from textual inputs such as titles or descriptions (Gong and Eldardiry, 2024; Blume et al., 2023a; Gong et al., 2023; Shinzato et al., 2023; Yang et al., 2023a). More recently, multimodal methods leverage both product images and textual information with a joint learning framework to improve attribute extraction accuracy (Zou et al., 2024a; Liu et al., 2023b; Wang et al., 2023; Wu et al., 2023; De la Comble et al., 2022).

The reliance on seller-generated textual information presents challenges for e-commerce platforms. 1) Lack of standardization leads to inconsistencies in product formatting, making search and categorization difficult. 2) Incomplete attributes hinder filtering and recommendation systems, reducing product visibility. 3) Ambiguous or inaccurate descriptions contribute to misclassification and higher return rates, negatively impacting customer trust. These issues with seller-provided textual information negatively impact attribute value extraction performance (Chen et al., 2019; RetailTouchpoints, 2016).

Meanwhile, the rise of mobile listing apps on platforms like eBay, Amazon, and Alibaba has shifted seller behavior toward uploading images without structured text, streamlining the listing process through simplified and automated methods. In parallel, modern Large Language Models (LLMs) have demonstrated strong capabilities in generating high-quality titles and descriptions for e-Commerce listings (Zhang et al., 2024a,b; Chen et al., 2019). As a result, images are increasingly becoming the primary source of truth for attribute value extraction in e-commerce contexts.

In this work, we propose Mixture of Image Captioning Experts (MICE), an augmentation framework for attribute value extraction that leverages a mixture of image captioning models. Recent advances in Large Multimodal Models (LMMs) have proven effective at generating informative captions directly from images. Our hypothesis is that each independently trained LMM captures different visual aspects of a product, and their combined outputs can enrich the image signal with complementary information. These captions are then used to augment the input for attribute value extraction. Extensive experiments on the publicly available ImplicitAVE dataset show that our approach significantly improves performance across multiple state-of-the-art LMMs, outperforming models that rely solely on product titles. To assess the generalizability of this approach, we test MICE on an internal e-Commerce dataset, validating its effectiveness in real-world scenarios. Notably, our approach relies only on seller-provided images, yet achieves performance comparable to a proprietary closed-sourced LMM (i.e., GPT-4V) that ingests both images and product titles. This result highlights the potential of MICE as a vision-only alternative. Finally, ablation studies confirm the effectiveness of each individual component, and case studies illustrate how MICE produces accurate attribute values, even outperforming multimodal baselines.

2 Related Work

Most existing studies focus on extracting attribute values from product titles or descriptions by using classification models (Gong et al., 2023; Deng et al., 2022b,a), QA-based models (Liu et al., 2023a; Shinzato et al., 2022; Wang et al., 2020), transformers (Chen et al., 2023), hypergraphs (Hu et al., 2025a; Gong and Eldardiry, 2024), and generative LLMs (Gong et al., 2025a; Levine et al., 2024; Sabeh et al., 2024; Roy et al., 2024; Fang et al., 2024; Khandelwal et al., 2023; Shinzato et al., 2023; Blume et al., 2023b).

While prior models for product attribute value extraction primarily rely on a single modality, they often fail to capture the rich visual information and cross-modal correlations available in product images. Recent research has shifted toward leveraging Large Multimodal Models (LMMs), which jointly utilize product images and textual information to learn enhanced product representations for the AVE task. For example, product visual features are used to enhance product AVE by utilizing multi-modal transformers (Wang et al., 2022; Khandelwal et al., 2023), optical character recognition (Lin et al., 2021), multi-modal attention mechanisms (Zhang et al., 2023a; De la Comble et al., 2022), prompt-tuning of pre-trained transformers (Yang et al., 2023b), and LMMs (Hu et al., 2025b; Gong et al., 2025b; Zou et al., 2024b) that generate product attribute values from combined text and image inputs. To support an image-based

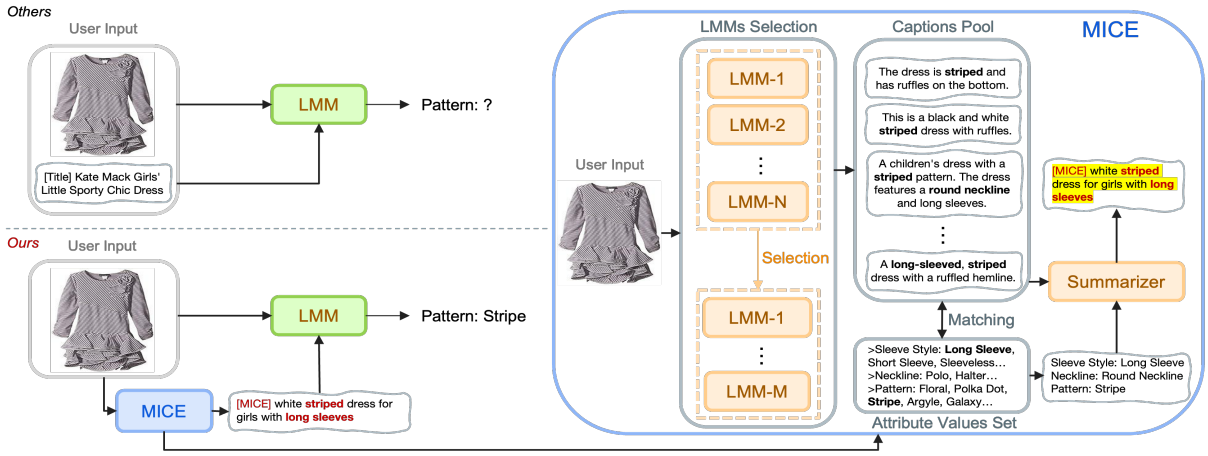

Figure 2: The overview of MICE augmentation framework.

experience for sellers, our approach leverages the image captioning capabilities of modern LMMs. These generated captions expose implicit product information, effectively enhancing attribute value extraction especially when textual inputs are missing or unreliable.

3 Methodology

3.1 Problem Formulation

We consider the task of multimodal product attribute value extraction, where the input consists of a set of product/listing images $\mathcal{I} = \{I_1, \cdots, I_p : p \in \mathcal{P}\}$ and optional text inputs including descriptions and titles $\mathcal{T} = \{T_1, \cdots, T_p : p \in \mathcal{P}\}$ for each product $p \in \mathcal{P}$. The objective is to predict a value V_p for each target attribute A_p drawn from the attribute set $\mathcal{A} = A_1, \cdots, A_m$, where m denotes the total number of attributes (e.g., pattern, material, shape, etc). For a given attribute A_p, we define $\mathcal{L}_p$ as the set of possible candidate values.

3.2 Mixture of Image Captioning Experts

Mixture of Image Captioning Experts (MICE) leverages a pool of independently trained large multimodal models (LMMs) to generate high-quality captions for images. These captions are used to enrich the image-only modality and enhance attribute value extraction (AVE). An overview of MICE is given in Figure 2 highlighting its key components and demonstrating how it augments conventional LMM-based AVE approaches. MICE consists of three major components: (1) expert model selection, (2) caption generation and value matching, and (3) summarization of matched captions.

We first construct a pool of LMMs, denoted as $\mathcal{M} = M_1, \cdots, M_k$. For each input image I_p, every LMM in the pool generates candidate captions relevant to the attributes of interest. To retain only effective models, we evaluate each M_i on a held-out validation set using a predefined performance metric (e.g., micro-F1). We then filter out underperforming models using a threshold τ, resulting in the selected model set $\mathcal{M}_s$:

$$\mathcal{M}_s = \{\mathcal{M}_i | metric(\mathcal{M}_i) > \tau, \mathcal{M}_i \in \mathcal{M}\} \quad (1)$$

where $metric()$ is a pre-defined attribute value extraction performance metric e.g. micro-F1 and τ is the performance threshold which is calculated using the held-out validation set. Furthermore, the image caption C_p for product p generated by $\mathcal{M}_s$ in the captions pool can be expressed as:

$$C_p = \mathcal{M}_s(I_p, A_p, \mathcal{L}_p) \quad (2)$$

To ensure relevance, we discard any caption C_p that does not contain any candidate attribute value from $\mathcal{L}_p$. This filtering step improves the quality of augmentation by eliminating noise and preserves only highly relevant information. The matched attribute-value pairs are extracted as:

$$\hat{L_p} = \{(A_p, V_p) | (A_p, V_p) \in C_p \cap (A_p, V_p) \in \mathcal{L}_p\} \quad (3)$$

Finally, we introduce a large language model (LLM) to summarize all matched captions into a unified context paragraph via $Summarizer(C_p, \hat{L}_p)$. This enriched context is then used to augment the AVE input. In our implementation, we adopt QwenLM as the summarizer due to its strong empirical performance

observed in our experiments. The effectiveness of each component in the MICE framework is further analyzed in the ablation study in Section 4.2.2.

3.3 Scalability and Flexibility

The size of the candidate model pool directly affects the computational complexity of the proposed MICE framework. Incorporating a large number of LMMs significantly increases the cost of generating image captions, as GPU and memory consumption scales approximately linearly with the number of models, leading to longer runtimes and higher resource demands. However, the inclusion of the model selection and attribute-value matching components plays a critical role in reducing algorithmic complexity and runtime latency by filtering out underperforming or irrelevant models and captions early in the pipeline.

While it is generally observed that a larger candidate pool yields a greater performance boost, our experiments reveal that even a small subset of strong models (e.g., 1–3) can substantially improve AVE accuracy. In extreme cases, we find that powerful models such as Qwen-VL-Chat benefit significantly from a self-captioning approach, without relying on additional image captioning experts. Detailed empirical results supporting these observations are presented in Section 4.2.2.

Overall, the proposed framework offers flexibility for balancing performance and efficiency, making it adaptable to a wide range of industrial scenarios. For instance, in latency-sensitive online environments, a minimal model pool might work reasonably well and meet real-time SLA requirements, whereas in latency-tolerant offline settings, the full model pool might be leveraged for maximum performance. This adaptability makes the approach well-suited for diverse industrial applications, accommodating varying constraints in terms of resources, latency, and scalability. Note that absolute latency numbers were not compared in this paper, since they depend on multiple factors including device specifications, infrastructure conditions, and network characteristics.

4 Experiments

In this section, we present a comprehensive evaluation of the proposed augmentation approach on the publicly available *ImplicitAVE* dataset (Zou et al., 2024a), a refined multimodal e-Commerce product attributes dataset with five different product categories sourced from MAVE (Yang et al., 2022). We assess the effectiveness of our method in both zero-shot and fine-tuned settings. To further validate its robustness and real-world applicability, we conduct additional experiments on a proprietary women's tops dataset collected from a leading e-commerce platform. These experiments demonstrate the model's performance in a practical deployment scenario. Details of both datasets used in the experiments can be found in Table 1.

Table 1: Dataset Statistics.

Dataset	Category	#Train	#Val	#Test
ImplicitAVE	Clothing	15132	3736	226
	Jewelry	10473	2588	220
	Footwear	17091	4351	317
	Home	9292	2324	457
	Food	2893	724	390
Propriety Dataset	Women Tops	19462	2162	9920

4.1 Experimental Setup

We adopt the same evaluation metric (micro-F1) as used in *ImplicitAVE*. We selected the following SOTA LMM families as benchmarks in the zero-shot setting: BLIP-2 (Li et al., 2023) (Blip2-opt-2.7B, Blip2-flan-t5-xl, Blip2-flan-t5-xxl), InstructBLIP (Dai et al., 2024) (InstructBLIP-vicuna, InstructBLIP-flan-t5), LLaVA (Liu et al., 2024c,a,b) (llava-llama-2, llava-vicuna, llava-v1.6-mistral), InternVL (Chen et al., 2024) (InternVL2-2B, InternVL2-4B, InternVL2-8B), Qwen (Bai et al., 2023; Yang et al., 2024) (Qwen-VL-7B, Qwen-VL-Chat, Qwen2-VL-7B-Instruct). Empirically, across all experiments, we select the three best-performing models on the validation set, InternVL2-4B, Qwen-VL-Chat, InstructBLIP, to construct the LMM candidate pool. Additionally, we compare the fine-tuned results of LAVIN (Luo et al., 2023) and DEFLATE (Zhang et al., 2023b), as reported by (Zou et al., 2024a), as well as GPT-4V (Ouyang et al., 2022), against our finetuned Qwen-VL-Chat and its augmented version.

For fine-tuning Qwen-VL-Chat as the backbone of the MICE framework, we implement the model using PyTorch and optimize it with the Adam optimizer. We adopt the LoRA (Low-Rank Adaptation) technique for efficient parameter tuning. The learning rate is set to 3e-4, with a weight decay of 0.1. Training is conducted with a batch size of 2 per device for 5 epochs. All experiments are conducted on Nvidia A100 GPUs. The prompt template we use follows the same as the prompt used in *Implici-*

Table 2: Experimental results, micro-F1 (%), of an array of selected LMMs using only image (I), image + title (I + T) and mixture of image captioning experts (MICE) across five categories of *ImplicitAVE* for attribute value extraction in a zero-shot setting. Best results of each model for each category are highlighted in bold.

4.2 Results and Discussions

4.2.1 Main Results

Table 2 presents a micro-F1 score comparison for each selected large multimodal model (LMM) under a zero-shot setting, evaluating three input configurations: image only, image + title, and MICE augmented across the five categories of *ImplicitAVE*. The results indicate that the effectiveness of incorporating product/item titles varies significantly across models and categories.There is no single model with a consistent performance advantage. Notably, image-only inputs outperform image + title in the Clothing and Food categories, while image + title provides a slight advantage in Jewelry, Footwear, and Home. The proposed image caption augmentation approach, which only requires a single input modality, further enhances performance by leveraging multiple generated captions, yielding average absolute gains of 14.4 and 12.6 points over image-only and image + title, respectively. This performance boost is consistently observed across most base models, with only a few outliers, demonstrating the robustness and generalizability of the augmentation strategy for zero-shot attribute value extraction.

As Qwen-VL-Chat demonstrated the strongest zero-shot performance, we fine-tuned it into two variants using image-only and image + title data, respectively, and compared it against fine-tuned DEFLATE, LAVIN, and GPT-4V using the micro-F1 metric, as shown in Table 3. Since the training details or checkpoints of DEFLATE and LAVIN are not publicly available and GPT-4V is a closed-source commercial model, we use the results reported by (Zou et al., 2024a) (marked with $*$) in this experiment. Given that (Zou et al., 2024a) only reports results under the image + title configuration, we present the best micro-F1 score between our image-only and image + title fine-tuned Qwen-VL-Chat models. To further enhance performance, we applied the proposed augmentation (MICE) approach, which led to substantial improvements over the fine-tuned Qwen-VL-Chat baseline. The results in Table 3 indicate that fine-tuned Qwen-VL-Chat significantly outperforms DEFLATE and LAVIN, achieving competitive micro-F1 scores comparable to GPT-4V. More importantly, with MICE augmentation, Qwen-VL-Chat surpasses GPT-4V across nearly all categories, except for Home, demonstrating the effectiveness of our approach in augmentating multimodal AVE.

We further evaluate the effectiveness of the proposed augmentation method on a proprietary women's tops dataset from a major e-commerce

Table 4: Experimental results, micro-F1(%) on a proprietary women tops dataset over four target attributes.

	Sleeve	Neckline	Pattern	Color
Image	88.80	52.33	71.47	80.27
Image + Title	84.87	65.80	**81.67**	72.13
Image with MICE	92.07	60.13	73.07	81.13
Image with MICE + Title	**94.40**	**67.00**	78.60	**83.87**

Table 5: Ablation study of MICE over ImplicitAVE.

	Clothing	Jewelry	Footwear	Home	Food
Base	69.47	86.36	66.25	**79.65**	84.10
Majority Voting	66.37	89.09	59.62	79.43	81.03
Self-Captioning	74.78	87.27	69.40	78.34	82.56
w/o (select&match)	67.26	88.18	69.40	72.65	86.64

w/o summarizer	71.24	**90.00**	68.14	78.34	85.90
ALL	**76.99**	**90.00**	**72.24**	78.56	**87.18**

marketplace, which includes four key product attributes: Sleeve Length, Neckline, Pattern, and Color. Given Qwen-VL-Chat's overall performance from previous experiments, we report micro-F1 scores for fine-tuned Qwen-VL-Chat under four configurations: image only, image + title, image with MICE, and image with MICE + title, as shown in Table 4. Consistent with previous findings, the proposed augmentation approach enhances AVE performance, regardless of whether image-only or image + title inputs are used. This experiment further underscores the real-world applicability and effectiveness of our method for e-commerce attribute value extraction.

4.2.2 Ablation Study

In the previous sections, we have demonstrated the effectiveness of MICE on both a public open-source dataset and a proprietary e-commerce dataset. To better understand the impact of each component, we conduct an ablation study to assess the contribution of each key component (selection, matching, and summarization) to the end-to-end performance. Additionally, we establish baselines using three naive methods for comparison.

As shown in Table 5, each row labeled as ('w/o') reports the micro-F1 score for each product category when a specific component is disabled. By comparing these ablated configurations against the final row (ALL, the complete approach), we observe that selection, matching, and summarization all contribute significantly to overall performance, as their removal results in varying degrees of degradation. Notably, the most substantial performance drop occurs when both selection and matching are disabled, as evidenced by the w/o (select&match) row, highlighting the importance of attribute-aware selection and filtering in our approach.

The three naive baselines considered in this study are: (1) Base, which refers to the fine-tuned Qwen-VL-Chat model without augmentation; (2) Majority Voting, where attribute values are directly extracted from each selected LMM (without generating captions) and aggregated via a majority voting mechanism to determine the final prediction for each attribute; and (3) Self-Captioning, where the fine-tuned Qwen-VL-Chat generates its own image captions for self-augmentation without leveraging external captioning models. As shown in Table 5, when comparing these baselines against the final row (ALL, representing the complete augmentation approach), we observe that the proposed method significantly improves attribute value extraction performance across all categories. These results demonstrate that the proposed augmentation approach effectively enhances attribute value extraction by incorporating multi-source image captioning and attribute-aware selection mechanisms.

4.2.3 Case Study

Figure 1 presents examples of attribute value extraction (AVE) across five product categories in the *ImplicitAVE* dataset under three input configurations: image only, image + title, and image + MICE augmentation, which achieved the best zero-shot performance as seen in Table 2. As shown, the image-only input can lead to incorrect predictions due to subtle or visually ambiguous features. Incorporating the product title does not always help and can introduce misleading information, further degrading model performance. For instance, in the snow boot example, the word "waterproof" in the title causes the model to incorrectly predict "Rain Boot" instead of "Snow Boot". In contrast, MICE-generated captions contain critical context, such as "snow boots", that resolve visual ambiguity and guide the model to the correct prediction. Similarly, in the henley neckline example, the product title lacks key discriminative information, whereas MICE includes the word "buttons", which clearly differentiates a henley from a crew neck. These examples illustrate how MICE enhances the model's understanding by supplementing missing or ambiguous signals from image and text inputs.

To gain deeper insights into the failure modes and attribute-specific weaknesses in MICE, we perform a detailed error analysis as presented

Attribute	Micro-F1	Incorrect Predictions	Example Images
Neckline	69.09%	Label: crew neck Pred: cowl neck	
Shape	84.00%	Label: crucifix Pred: cross	
Shaft Height	50.00%	Label: bootie Pred: ankle boot	
Size	36.67%	Label: queen Pred: full	
Candy Variety	68.29%	Label: taffy Pred: hard candy	

Table 6: Examples of error cases from five categories, highlighting the attribute with the lowest accuracy in each category.

in Table 6. Our observations reveal substantial performance variations among different attributes in some categories using MICE. Specifically, attributes exhibiting lower accuracy typically fall into two categories: 1) Captioning models struggle to capture fine-grained visual details, particularly when certain attributes require contextual references that are absent in the images. This limitation significantly affects the accuracy of caption generation. For instance, accurately identifying specific attributes such as mattress sizes (e.g., full or queen) from a single image without additional context is challenging, leading to inaccuracies in generated captions. 2) Some attributes depend on specialized terminology, which MICE often does not possess such requisite domain knowledge. For example, domain-specific terms such as "taffy", "booties", or "crucifix" have precise meanings within their respective product categories. Without explicit domain expertise, the model struggles to accurately interpret these terms, resulting in erroneous caption generation.

5 Conclusion

In product AVE, scenarios often arise where textual inputs such as product descriptions and titles are either unavailable or unreliable due to ambiguity, incompleteness, or inconsistency. To address this challenge, we propose a novel augmentation framework, Mixture of Image Captioning Experts (MICE), which generates fine-grained, concise, and accurate captions from input images. By leveraging a curated pool of image captioning models, MICE enhances AVE performance, particularly in settings where only visual data is available. Extensive experiments on both the public *ImplicitAVE* dataset and a proprietary women's tops dataset demonstrate that MICE significantly improves the performance of SOTA LMMs in both zero-shot and fine-tuned settings. The modular design of MICE also offers scalability and deployment flexibility, making it suitable for a wide range of industrial use cases with diverse resource and latency constraints.

Abstract

In this work, we present the first open leaderboard for evaluating Korean large language models focused on finance. Operated for about eight weeks, the leaderboard evaluated 1,119 submissions on a closed benchmark covering five MCQA categories: finance and accounting, stock price prediction, domestic company analysis, financial markets, and financial agent tasks and one open-ended qa task. Building on insights from these evaluations, we release an open instruction dataset of 80k instances and summarize widely used training strategies observed among top-performing models. Finally, we introduce FINKRX, a fully open and transparent LLM built using these best practices. We hope our contributions help advance the development of better and safer financial LLMs for Korean and other languages.[1]

1 Introduction

Large language models (LLMs) hold significant potential for financial applications (Son et al., 2023; Chen et al., 2024b,a). However, performance issues in this domain can lead to monetary losses, making it imperative to develop reliable evaluation systems prior to deployment. Unfortunately, the inherently closed nature of the financial industry limits the sharing of models (Wu et al., 2023) and dataset (Mahfouz et al., 2024), slowing the development of relevant techniques and often resulting in duplicated efforts across companies and teams.

Existing tools to evaluate LLM performance in the Korean financial domain include KRX-Bench (Son et al., 2024a), which specifically assesses knowledge of Korean listed companies, and KMMLU (Son et al., 2024d), a broader benchmark spanning 45 categories that incorporates a subset of finance and economics. However, these benchmarks fall short of reflecting the broad potential for LLM applications in the financial sector. To address this gap, we compile a comprehensive finance benchmark consisting of approximately 5.5k multiple-choice questions derived from online exams, LLM-generated questions, and handcrafted instances. This benchmark covers five key topics: financial markets, finance and accounting, domestic company analysis, financial agents (Hu et al., 2024), and stock price prediction (Soun et al., 2022). Recognizing that multiple-choice questions may not fully represent real-world prompts (Kim et al., 2024), we also include an open-ended QA set featuring 100 challenging prompts.

To encourage the adoption of the benchmark and foster an open research culture, we take a further step by launching an open leaderboard for financial LLMs. It was operated for two months, comprising two stages: a preliminary round and a main round. Over the course of the competition, more than 1,000 models were submitted, with over 600 models remaining publicly accessible to date[2], thereby laying the groundwork for future research. In addition, we compile the submitted models along with their system cards to document effective tuning strategies. Furthermore, we collect over 200,000 instances from competing teams, filter them, and release a high-quality instruction dataset consisting of 80,000 samples. Finally, after regenerating responses for each instance using Deepseek-R1 (Guo et al., 2025) and training on these trajectories, we release FINKRX, the first reasoning model for the Korean financial domain.

2 Motivation and Related Works

The financial industry has witnessed rapid expansion in the adoption of artificial intelligence, with particular emphasis on generative AI technologies driving innovations in enhanced customer

Table 1: **Overview of the benchmark used for evaluation.** Each example demonstrates a specific question type for each category. Gray text are English translations provided for better reachability.

service, improved risk management, and overall operational efficiency (McKinsey & Company, 2025). Despite these advancements, Korean financial institutions face significant challenges in harnessing proprietary language models (Jaech et al., 2024; Team et al., 2023). Strict security regulations—such as network separation policies (Financial Services Commission, 2024)—impede their ability to fully leverage these innovations. Moreover, the absence of clear guidelines and robust evaluation frameworks for managing the risks inherent in generative AI—such as hallucinations (Kang and Liu, 2023), biases (Zhou et al., 2024), and information leakage (Liu et al., 2024)—further complicates the integration. In response, Son et al. (2024a) introduced KRX-Bench, the first publicly available benchmark designed to assess the knowledge of LLMs in Korean companies. However, KRX-Bench remains limited in scope and has yet to achieve widespread adoption among Korean financial institutions.

In this work, drawing inspiration from financial benchmarks in various languages (Xie et al., 2024a; Nie et al., 2024; Koncel-Kedziorski et al., 2023), we extend KRX-Bench to develop a more comprehensive benchmark for Korean financial language models by incorporating five additional categories. Moreover, our work distinguishes itself by operating an open leaderboard with a total prize pool of approximately $42,000, which has attracted submissions of around 1,000 models, creating the groundwork for future works in financial NLP.

3 Leaderboard Construction

In this work, we introduce an open leaderboard for Korean financial LLMs and share lessons learned from its two-month operation, comprised of a preliminary round (October 14–November 7, 2024) and a final round (November 13–December 6, 2024). In total, 1,119 models were submitted—478 in the preliminary round and 641 in the final round, establishing a foundation for open research in Korean financial LLMs, with over 600 models remaining publicly accessible. The following sections describe the benchmark construction process (Section 3.1), present operational details (Section 3.2) and summarize key statistics (Section 3.3).

3.1 Benchmark Details

The benchmark used for evaluation consisted of five categories in the preliminary round: finance and accounting, stock price prediction, domestic company analysis, financial markets, and financial agent tasks. For the final round, only three categories were used: finance and accounting, financial markets, and open-ended finance QA. Table 1 details the examples of each category.

Finance and Accounting For this category, we compile four-option MCQA questions, primarily sourced from university exams. In the preliminary round, these questions were presented with four options, while in the final round, the answer set was expanded to eight options. The augmentation uses two methods: (1) grouping questions based on embeddings to mix similar items, and (2) applying rule-based augmentations (Wang et al., 2024; Zhao et al., 2024), such as replacing an answer option with "none of the above" (thereby making it the correct answer) or shuffling the order of options. A manual human check is done post-augmentation to ensure correctness.

Financial Markets For this category, we employ an approach similar to the Finance and Accounting category. However, the source questions are collected from exams that assess understanding of the Korean financial system and related laws.

Stock Price Prediction This category is inspired by Soun et al. (2022). We randomly sample fixed-length stock price data (OHLCV: Open, High, Low, Close, Volume) from Korean stock markets, using only post-2024 data to mitigate potential contamination. A set of technical indicators is computed and presented in a Markdown table format (e.g., `adj-close` for adjusted closing price; `inc-5`, `inc-10`, `inc-15`, `inc-20`, `inc-25`, and `inc-30` for percentage changes over the past 5, 10, 15, 20, 25, and 30 trading days). Models are tasked with a binary classification—predicting whether the price will increase or decrease—and are expected to detect basic signals of momentum (Jegadeesh and Titman, 1993) or mean reversion (Poterba and Summers, 1988) in the time-series data.

Domestic Company Analysis For this section, we directly employ KRX-Bench (Son et al., 2024b), an automatically generated benchmark constructed using GPT-4o (Hurst et al., 2024) leveraging annual filings from Korean companies. It consists of 4-option MCQA questions designed to assess knowledge on topics such as Product Offerings, Financial Policy, and Business Strategy.

Financial Agents This subset evaluates the capability to function as an automated financial agent by executing code-based tasks on real financial data. Similar to Hu et al. (2024), the model is provided with a CSV file and an instruction to extract specific information and perform corresponding coding operations. The model is presented with multiple output options, including perturbed variants, and is prompted to select the correct one.

Open-Ended FinQA Given that all subsets employ multiple-choice or binary-choice formats, we were concerned that these evaluation methods may not fully capture the diversity of prompts encountered in real-world applications. Drawing inspiration from open-ended evaluations such as MT-Bench (Zheng et al., 2023), we curated a set of 100 challenging prompts from three sources: the legal reasoning subset of KRX-Bench (Son et al., 2024a), advanced math questions from HRM8K (Ko et al., 2025), and graduate-level financial engineering and econometrics exam questions. A gold standard answer was generated using o1-Pro (Jaech et al., 2024), and GPT-4o was utilized as an LLM-as-a-Judge to determine whether competing models produced responses superior to this standard. Figure 6 illustrates the prompts employed in the LLM-as-a-Judge evaluation.

3.2 Operation Details

The leaderboard was active for eight weeks, from October 14, 2024, to November 7, 2024, on a dedicated, self-hosted website. The competition was structured in two rounds: a preliminary round and a final round. In the preliminary round, participants uploaded their models publicly on Hugging Face and submitted the corresponding model links. The top 30 teams advanced to the final round, where each team was allowed up to three submissions. Models were evaluated on a server equipped with 2 A6000 Ada GPUs, with capacity scaling up to 8 GPUs depending on the number of submissions. The benchmark dataset was kept private, with only one sample released from each subset.

To ensure consistency and fairness, participants were restricted in the choice of base models to prevent incompatibility issues with the inference engine and to avoid giving larger companies with more training resources an unfair advantage. Allowed models include Qwen (1.5B and 7B) (Yang et al., 2024), Mistral (7B) (Jiang, 2024), GLM-4 (9B) (GLM et al., 2024), Llama 3/3.1 (8B) (Grattafiori et al., 2024), Amber (Liu et al., 2023), Phi 3.5 (mini) (Abdin et al., 2024), and Gemma2 (2B and 9B) (Team et al., 2024). Both base and instruct models were allowed. Teams that advanced to the main rounds were provided $2500 of AWS credit to help model training.

Participants were required to disclose their

datasets and confirm that they did not include any copyrighted material, as a condition for qualifying for the prize money. For evaluation, we adopt a zero-shot chain-of-thought (CoT) format. Initially, each model is prompted to generate a CoT reasoning. We then concatenate the original prompt with the generated CoT and append "### Answer:" to prompt the model to produce its final answer. In this step, a logit processor is employed to ensure that the model selects from the provided options, thereby preventing evaluation errors due to format mismatches. To prevent spamming, each team is allowed to submit one model per day.

3.3 Statistics

Submission During the preliminary rounds, 233 accounts signed up, with 71 making at least one submission. A total of 478 models were submitted—averaging nearly seven submissions per active team—and November 5 was the busiest day with 45 entries. Moreover, the largest single-day influx of new registrations occurred on October 14, when 83 accounts joined, highlighting strong early interest. For details on the overall trend, see Figure 5. In the main rounds, a high submission rate was maintained throughout the entire period, with 30 teams contributing a total of 641 submissions.

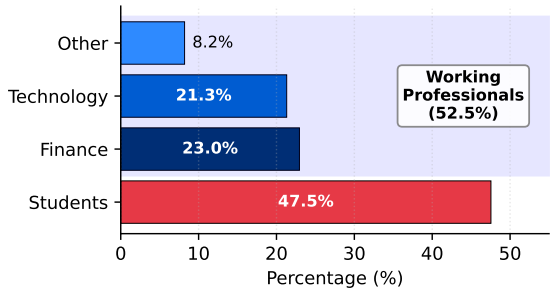

Figure 1: **Distribution of participants.** The shades of blue bars indicate corporate participants.

Participants A total of 71 teams submitted at least one model during the leaderboard period (each team may consist of up to four members). Among these teams, 52.5% were corporate participants, with the remaining teams representing universities and student groups. The corporate participants were further categorized into Tech, Finance, and Other sectors, as presented in Figure 1. These results demonstrate that the competition successfully attracted a diverse range of participants—not only students, but also a substantial number of companies, including publicly listed tech companies, securities firms, and banks.

4 Analysis

4.1 Analysis on Data Collection

As our rules prohibit the use of licensed materials for training LLMs, participants focused on collecting license-free financial content—potentially useful for constructing corpora to train Korean LLMs. Table 2 lists the 11 most-used domains, with a strong focus on government (go.kr) and non-profit organizations (or.kr). After collecting the raw corpora from these sources, participants mostly employed either GPT-4o (Hurst et al., 2024) or Qwen2.5-72B-Instruct (Yang et al., 2024) to convert the data into MCQA (Bi et al., 2024) or Instruction-Response formats, with some employing an LLM-as-a-Judge (Zheng et al., 2023; Son et al., 2024c) for validation.

Table 2: **Data collection sources.**

To ensure reusability, we collect about 200,000 data samples from HuggingFace (released by competing teams) and applied quality filters: the MinHash algorithm to remove near-duplicates, a regex filter to exclude time-bound queries (e.g., "What will Kakao's 2024 sales be?"), and a rule-based filter to remove incomplete or overly short questions. This process yielded a final set of 86,007 instances. For further details see Appendix A.

4.2 Analysis on Top-Performing Models

Table 3 presents the performance of the top 10 models from the preliminary rounds, and Figure 2 displays the corresponding score trends. The largest improvement was observed in Domestic Company Analysis, where scores rose from 0.51 to 0.94. However, Financial & Accounting and Financial Markets experienced relatively modest gains. We attribute this to the relatively simple methods used by most teams during the preliminary rounds. All top 10 teams primarily employed supervised fine-tuning (SFT) for model training. Interstingly, team `Americano` incorporated a brief continual pretraining phase (Xie et al., 2024b) before SFT on 3.7GB of text; however, the performance impact of this additional step remains inconclusive in a small-scale setting. Notably, all top-performing models were based on Qwen2.5-7B-Instruct.

Teams advancing to the main rounds employed multi-step, more complex training methods. For example, `Shinbainu` used a curriculum-based SFT approach that began with training on easier samples and then proceeded to a second round of SFT on more challenging prompts generated via the Evolve Instruct method (Xu et al., 2023; Luo et al., 2023a,b). The final model was subsequently refined using DPO (Rafailov et al., 2023), leveraging preference data from the stage-two SFT model—which generated two responses that were then evaluated by an LLM-as-a-Judge (Zheng et al., 2023). Similar strategies were observed among other teams; for instance, `Hi-Q` and `Overfit Brothers` implemented KTO (Ethayarajh et al., 2024) and DPO, respectively.

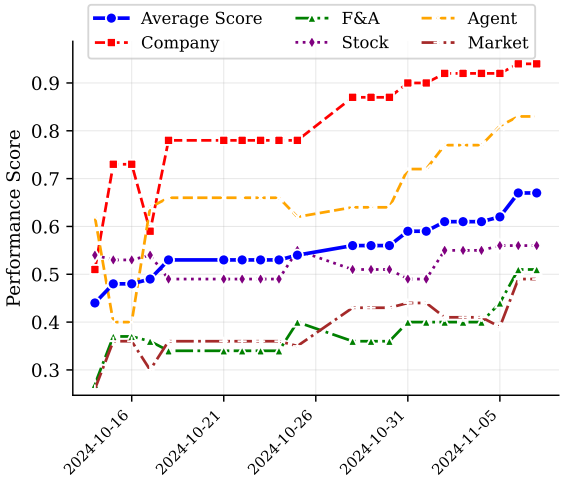

Figure 2: **Preliminary round performance trends.**

Interestingly, team `Hi-Q` adopts continual pretraining and demonstrated its effectiveness on a private finance benchmark, as shown in Figure 3. Notably, CPT+SFT scores an average of

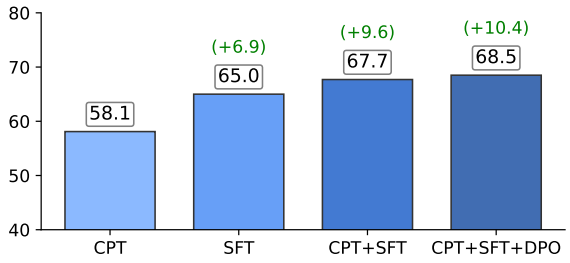

Figure 3: **Evaluation results reported but `Hi-Q`.** Performance of each methodology is represented by boxed numbers, and green numbers indicate the improvement over CPT.

2.7 points higher than plain SFT, indicating that a well-structured continued pre-training approach can benefit LLMs in Korean finance. However, further research is required to establish what marks a good continual pre-training. Details of the benchmarks used by `Hi-Q` are provided in Appendix C.

5 FINKRX: Open LLM for Korean Finance

To aggregate the open resources collected during the competition, we train our own LLM, FINKRX. In line with recent trends toward reasoning LLMs (Jaech et al., 2024; Guo et al., 2025), FINKRX is designed to generate a two-step response: a first step enclosed within `<think>` and `</think>` tags, where the model performs self-correcting reasoning, and a second step enclosed within `<solution>` and `</solution>` tags, which provides the final summary of the reasoning process. It should be noted that this effort is not intended to achieve state-of-the-art language model; rather, it serves to evaluate the quality of the collected resources and provide guidelines for future research.

5.1 Details in Training FINKRX

Recent studies have shown that supervised fine-tuning (SFT) is effective enough in training reasoning language models (Muennighoff et al., 2025; Ye et al., 2025; Wen et al., 2025; Sun et al., 2025). Moreover, during the competition, submissions that have combined SFT with preference optimization techniques such as DPO or KTO have successfully adapted models for the Korean financial domain. Accordingly, we adopt a two-stage training approach: SFT followed by DPO. The SFT dataset comprises prompts paired with responses generated by Deepseek-R1, split evenly between English and Korean. For Korean prompts, the solutions are translated into Korean while retaining the reasoning process in English. The dataset is drawn from three sources: (1) English Prompt-R1 responses collected online (Zhao et al., 2025), (2) Korean Prompt-R1 responses collected online (Son et al., 2025), and (3) 86k prompts from Section 3.1, for which we generated responses using R1. We employed GPT-4o to filter correct samples, retrying up to six attempts for incorrect samples, resulting in approximately 400k instances. Post-SFT, the model struggled with everyday prompts, tended to overthink (Kumar et al., 2025), and occasionally displayed formatting issues by treating some queries as if they were MCQA tasks. We attribute these issues to the data distribution, which heavily emphasized academic multiple-choice questions paired with extended reasoning. To address these behaviors, we conducted a final DPO stag, where chosen samples are generated from R1, and rejected samples are drawn from the SFT model.

5.2 Performance Analysis

The performance of FINKRX is reported in Table 4. FINKRX demonstrates strong results in the Finance & Accounting category, which includes a diverse range of accounting and econometrics tasks that benefit from robust mathematical and logical reasoning. These capabilities also yield strong performance on open-ended FinQA tasks, where multi-step logical deductions are necessary. In contrast, FINKRX shows weaker performance in the Market category. The Market category relies more on factual and domain-specific knowledge; they do not benefit as strongly from FINKRX's reasoning-oriented approach. These findings are consistent with those of Ha (2025), who observed that while reasoning-focused models excel at challenging mathematical questions, their performance decline in knowledge-intensive domains as training progresses.

6 Conclusion

In this work, we present the largest Korean finance benchmark covering five categories: finance and accounting, stock price prediction, domestic company analysis, financial markets, and financial agent tasks. To encourage adoption, we launched a leaderboard that attracted hundreds of participants from academia and industry, resulting in around 600 publicly available models. We distilled successful strategies from these submissions into an

80k-instruction dataset, which we used to train and release FINKRX, a publicly available reasoning model for Korean finance.

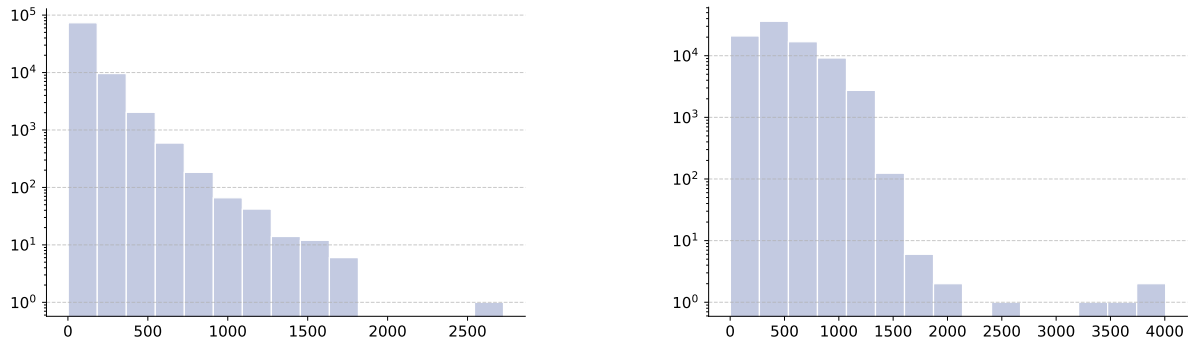
A Further details on FINKRX-INSTRUCT

Here we report the average length of questions and responses using the Unimax tokenizer proposed by Chung et al. (2023).



(a) Prompt length

(b) Response length

Figure 4: **Statistics of prompt and response length in FINKRX-INSTRUCT.**

B Training details for FINKRX

Axolotl (Axolotl AI, 2025) is used for the SFT and DPO training in Section 5.1. We train Qwen2.5-Math-7B-Instruct with DeepSpeed-Zero1 (Rajbhandari et al., 2020) on 8 H100 80GB GPUs for 25 hours. Hsu et al. (2024) is used for optimization. Table 5 and 6 are configurations used for SFT and DPO respectively.

Category	Section 5.1
Sequence Length	16,384
Learning Rate	4×10^{-5}
Global Batch (Effective)	256
Learning Rate Scheduler	Cosine Decay
Warmup Ratio	0.05
Training Epochs	2

Table 5: **SFT configuration details for Section 5.1.**

Category	Section 5.1
Sequence Length	16,384
Learning Rate	5×10^{-6}
Global Batch (Effective)	64
Learning Rate Scheduler	Cosine Decay
Warmup Ratio	0.05
Training Epochs	1

Table 6: **DPO configuration details for Section 5.1.**

C Further details on private evaluation tools used by team `Hi-Q`

In Figure 3, we share private evaluation results conducted by `Hi-Q`. The evaluation is done on a private benchmark consisting of financial questions collected from sources such as AiHub[1] and KMMLU (Son et al., 2024d), to assess the model's financial knowledge and capability. In particular, the private benchmark comprises the following subsets:

- **Accounting**: A private question set on Korean accounting.
- **Financial Accounting Generated**: Synthetically generated using GPT-4 on sample instances, following a Wang et al. (2022)-like approach (also applied to the Financial Market Generation subset).
- **KMMLU-accounting**: The accounting subset of the KMMLU dataset.
- **AiHUB-NC-MRC**: A dataset provided by AiHUB focusing on numerical computation and machine reading comprehension (AI HUB, 2025b).

[1] `https://www.aihub.or.kr/`

- **AiHUB-FL-MRC)**: A dataset provided by AiHUB focusing on financial and law machine reading comprehension (AI HUB, 2025a).

The benchmark evaluation results of methodologies attempted by `Hi-Q` are presented in Table 7.

Category	Subset	CPT	SFT	CPT+SFT	CPT+SFT+DPO
Financial Accounting	Accounting	32.0	39.0	41.0	**43.0**
	Financial_Accounting_Generated	55.0	71.0	70.0	**73.0**
	KMMLU_Accounting	37.0	42.0	41.0	**44.0**
	AiHUB-NC-MRC_calculation	55.0	57.0	60.0	**61.0**
	AiHUB-NC-MRC_boundary_extraction	85.0	91.0	**95.0**	**95.0**

D Additional resources

In this section, we present additional resources that were excluded from the main text due to space constraints:

1. Figure 5: Model submission trends during preliminary rounds from Section 3.3.
2. Figure 6: Sample prompt used for LLM-as-a-Judge to evaluate the Open-Ended FinQA subset from Section 3.1 .

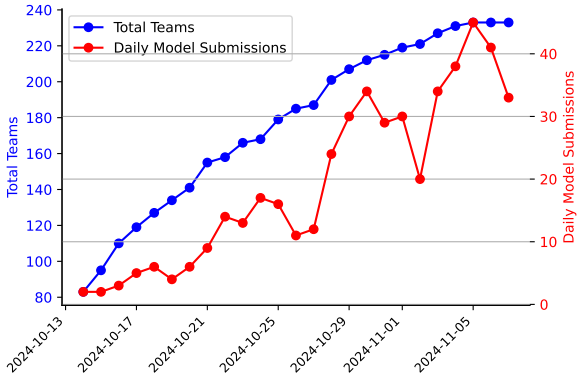

Figure 5: Model submission trends during the preliminary rounds.

E Additional Results

In Tables 8 and 9, we present the performance of baseline models on the benchmarks used for the preliminary and main rounds, respectively. The tables include results for Qwen (1.5B and 7B)(Yang et al., 2024), Mistral (7B)(Jiang, 2024), GLM-4 (9B)(GLM et al., 2024), Llama 3/3.1 (8B)(Grattafiori et al., 2024), Amber (Liu et al., 2023), Phi 3.5 (mini)(Abdin et al., 2024), and Gemma2 (2B and 9B)(Team et al., 2024).

```
[System]
Please act as an impartial judge and evaluate the quality of the responses provided by two AI
assistants to the user question displayed below. You should choose the assistant that follows
the user's instructions and answers the user's question better. Your evaluation should consider
factors such as the helpfulness, relevance, accuracy, depth, creativity, and level of detail of
their responses. Begin your evaluation by comparing the two responses and provide a short
explanation. Avoid any position biases and ensure that the order in which the responses were
presented does not influence your decision. Do not allow the length of the responses to
influence your evaluation. Do not favor certain names of the assistants. Be as objective as
possible. After providing your explanation, output your final verdict by strictly following this
format: "[[A]]" if assistant A is better, "[[B]]" if assistant B is better, and "[[C]]" for a
tie.

Abstract

Transparency in AI healthcare decision-making is crucial. By incorporating rationales to explain reason for each predicted label, users could understand Large Language Models (LLMs)'s reasoning to make better decision. In this work, we introduce a new task - Sentiment Reasoning - for both speech and text modalities, and our proposed multimodal multitask framework and **the world's largest multimodal sentiment analysis dataset**. Sentiment Reasoning is an auxiliary task in sentiment analysis where the model predicts both the sentiment label and generates the rationale behind it based on the input transcript. Our study conducted on both human transcripts and Automatic Speech Recognition (ASR) transcripts shows that Sentiment Reasoning helps improve model transparency by providing rationale for model prediction with quality semantically comparable to humans while also improving model's classification performance (**+2% increase in both accuracy and macro-F1**) via rationale-augmented fine-tuning. Also, no significant difference in the semantic quality of generated rationales between human and ASR transcripts. All code, data (five languages - Vietnamese, English, Chinese, German, and French) and models are published online.

1 Introduction

Sentiment analysis plays a pivotal role within the healthcare domain. In healthcare customer service, it facilitates real-time evaluation of customer satisfaction, enhancing empathetic and responsive interactions (Xia et al., 2009; Na et al., 2012). Moreover, sentiment analysis aids in monitoring the emotional well-being of patients (Cambria et al., 2012a), including those with mental health issues such as suicide (Pestian et al., 2012). However, these studies only work on text-only sentiment analysis instead of speech-based sentiment analysis.

Despite its potential, speech sentiment analysis presents several technical challenges. First, emotions conveyed through speech are subjective (Wearne et al., 2019), complex (Golan et al., 2006), and dependent on speaking styles (Shafran and Rose, 2003), making accurate sentiment classification difficult even for humans (Kuusikko et al., 2009), thereby necessitating the role of explainable artificial intelligence (AI). Second, given the critical nature of healthcare decisions, where errors can have severe consequences, transparency in AI decision-making is essential to build trust among machines, healthcare professionals, and patients (Antoniadi et al., 2021).

To tackle challenges above, reasoning in AI is crucial for sentiment analysis because it enables deeper understanding beyond surface-level sentiment polarity via the textual explanations. Recent works on Chain-of-Thought (CoT) distillation (Wadhwa et al., 2024; Chen et al., 2024; Hsieh et al., 2023; Ho et al., 2022) have revealed that training generative small language models (SLMs) on rationale-augmented targets (the CoT from larger models is provided along side with the target label) can help the SLM (1) perform better and (2) acquire the ability to generate rationale. Our work leverage these findings and prepare a set of human-labeled rationale to train our sentiment analysis models to do Rationale Generation and enhance their performance (Section 4.4 and 4.5). By incorporating rationales to explain reason for each predicted sentiment label, users could understand the model's reasoning, facilitating better decision-making based on the classification results. Therefore, we introduce a novel multimodal framework for a novel task: Sentiment Reasoning, which comprises of two tasks: (i) Sentiment Classification, in which the model learns to output the **sentiment label** (POSITIVE, NEUTRAL,

July 28-30, 2025

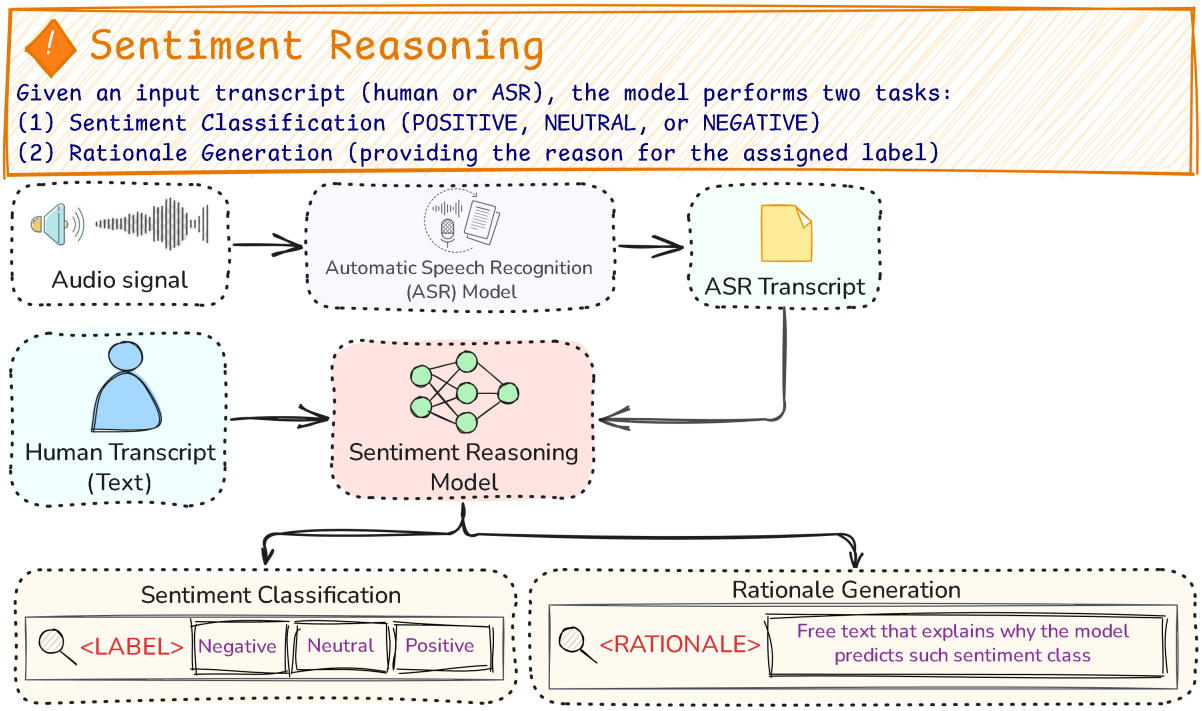

Figure 1: Visualized pipeline for Sentiment Reasoning . Given an input transcript (either human transcript or ASR transcript), the model learns to output the **sentiment label** (POSITIVE, NEUTRAL, or NEGATIVE) and its **rationale** (the reason for this label). It comprises of two tasks: (1) Sentiment Classification and (2) Rationale Generation . Traditional sentiment analysis only includes Sentiment Classification task, while our framework generates corresponding rationale to explain the reason behind each predicted sentiment label. 9 examples with sentiment labels and their corresponding rationales in our dataset are shown in Table 7 in the Appendix.

or NEGATIVE), and (ii) Rationale Generation, in which the model generates rationale (the free-form text that explains reason for this label). Our contributions are as follows:

1. We introduce a new task: Sentiment Reasoning for both speech and text modalities, along with the world's largest multimodal sentiment analysis dataset, supporting five languages (Vietnamese, English, Chinese, German, and French)
2. We propose our novel multimodal speech-text Sentiment Reasoning framework
3. We empirically evaluate the baselines on our dataset using state-of-the-art backbone models
4. We provide in-depth analysis of rationale / Chain-of-Thought (CoT)-augmented training

All code, data and models are published online.

2 Data

2.1 Data Collection

The dataset employed for constructing the Sentiment Reasoning dataset was *VietMed* (Le-Duc, 2024), a large and publicly accessible medical ASR dataset. The dataset comprises real-world doctor-patient conversations. We then annotated *sentiment labels* (POSITIVE, NEUTRAL, or NEGATIVE) and their corresponding *rationales* (the reason for this label). We then manually translate the transcripts from Vietnamese into other four languages: English, Chinese (Simplified and Traditional), German, and French, making the dataset six times larger. The full dataset (with 5 languages) includes 30000 samples, making it **the largest multimodal sentiment analysis dataset**, to the best of our knowledge (see Table 2). Our paper focuses mainly on the **Vietnamese subset** (Section 5) and the **English subset** (Appendix D).

2.2 Data Annotation

The annotation task consists of two primary steps. First, annotators are required to perform Sentiment Classification. Second, annotators are instructed to provide a rationale behind each class (Rationale Generation). To ensure consistency, our TESOL-certificated professional linguist has developed an initial guideline inspired by (Chen et al., 2020), which was also adopted by various well-known works (Shon et al., 2022, 2023), and revised it fre-

quently if necessary. Details of data annotation pipeline, annotation guidelines, data imbalance, translation annotation, and translaton quality control are shown in Appendix Section B.

2.3 Data Quality Control

During the independent annotation process conducted by three annotators, we observed a low inter-annotator agreement (Cohen's kappa coefficient below 0.5 for the inter-annotator agreement between the two annotators), a common occurrence in real-world datasets as noted by Chen et al. (2020). To address this issue, we implemented an alternative label merging approach. We convened a discussion meeting involving the three annotators and two reviewers (one professional linguist and one with a biomedical background). Each annotator was required to justify their chosen sentiment label and its corresponding rationale. A label and its rationale were selected based on the consensus of all three annotators and two reviewers, rather than a majority vote, as employed in other studies (Aziz and Dimililer, 2020; Saleena et al., 2018).

2.4 Data Statistics

Split	Label	Count	Percentage
Train	Neutral	2844	49.94%
	Negative	1694	29.74%
	Positive	1157	20.32%
Test	Neutral	958	43.88%
	Negative	701	32.11%
	Positive	524	20.01%

Table 1: Distribution of sentiment labels in the dataset for a single language. The real size of the dataset is 6 times larger when accounting all 5 languages - English, Chinese (Simplified and Traditional), German, and French.

Table 1 shows the distribution of sentiment labels in the dataset. This reflects the dataset's slight emphasis on neutral content, typical in medical conversations involving explanations and advice.

It should be noted that the statistics are reported **for a single language**, meaning that the real size of the dataset is 6 times larger when accounting all 5 languages.

3 Sentiment Reasoning Framework

3.1 Informal Definition

As shown in Figure 1, in Sentiment Reasoning , given an input transcript (either human transcript or ASR transcript), the model learns to output the **sentiment label** (POSITIVE, NEUTRAL, or NEGATIVE) and its **rationale** (the reason for this label). It comprises of two tasks: Sentiment Classification and Rationale Generation .

3.2 Formal Definition

Let $x_1^T := x_1, x_2, ..., x_T$ be an audio signal of length T. Let C be the set of all possible sentiment classes, we should build a speech-based Sentiment Reasoning model f that both estimates the probability $p(c|x_1^T)$ for each $c \in C$ and generates its rationale sequence r_1^M of M length.

The decision rule to predict a sentiment class is:

$$x_1^T \rightarrow \hat{c} = \arg\max_{c \in C} f(c|x_1^T) \quad (1)$$

The decision rule to generates the corresponding rationale sequence is:

$$x_1^T \rightarrow r_1^M = \arg\max_{r^*} h(r^*|x_1^T) \quad (2)$$

For text-based Sentiment Reasoning, the input audio signal x_1^T could be replaced with a word sequence (human transcript) w_1^N of length N, thus ASR model is not needed.

3.3 ASR Model

An ASR model aims to convert audio signal into text by mapping an audio signal x_1^T to the most likely word sequence w_1^N. The relation w^* between the acoustic and word sequence is:

$$w^* = \arg\max_{w_1^N} p(w_1^N|x_1^T) \quad (3)$$

3.4 Language Model for Sentiment Reasoning

3.4.1 Sentiment Classification

Let the transcribed audio signal (ASR transcript) w_1^N serve as the input for the Sentiment Classification model g, which maps w_1^N to a class label $\hat{c}$:

$$w_1^N \rightarrow \hat{c} = \arg\max_{c \in C} g(c|w_1^N) \quad (4)$$

g is trained to minimize a loss function $\mathscr{L}(g(w_1^N), \hat{c})$. The optimal parameters θ of the model are found by solving the optimization problem $\min_\theta \mathscr{L}(g(w_1^N; \theta), \hat{c})$. Once trained, the model can predict the class of the transcribed audio signal by evaluating $\hat{c} = g(w_1^N)$.

Table 2: Data statistics comparison based on the number of samples and languages. Our dataset with 5 languages (Vietnamese, English, Chinese, German and French) includes 30000 samples, making it **the largest multimodal sentiment analysis dataset**.

3.4.2 Rationale Generation

Let the transcribed audio signal (ASR transcript) w_1^N serve as the input for the Rationale Generation model h, which maps w_1^N to a rationale sequence r_1^M of M length:

$$w_1^N \rightarrow r_1^M = \arg\max_{r^*} h(r^*|w_1^N) \quad (5)$$

h is trained to minimize a loss function $\mathscr{L}(h(w_1^N), r_1^M)$. The optimal parameters θ of the model are found by solving the optimization problem $\min_\theta \mathscr{L}(g(w_1^N;\theta), r_1^M)$. Once trained, the model can generate rationale of the transcribed audio signal by evaluating $r_1^M = h(w_1^N)$.

4 Experimental Setups

4.1 ASR Model

We employed hybrid ASR setup using wav2vec 2.0 encoder (Le-Duc, 2024) to transcribe speech to text. The final ASR model has 118M trainable parameters and Word-Error-Rate (WER) of 29.6% on the test set. Details of ASR experiments are shown in Appendix C.1.

4.2 End-to-end Sentiment Classification

We fine-tuned two well-known models, PhoWhisper (Le et al., 2024) and Qwen2-Audio (Chu et al., 2024), for the end-to-end spoken sentiment analysis task. PhoWhisper is trained large-scale ASR training set consisting of 844 hours of Vietnamese audio, while Qwen2-Audio is trained on more than 500 hours of audio. We use the base version of PhoWhisper with 74M parameters, while Qwen2-Audio has 8.2B parameters.

4.3 Language Model for Sentiment Reasoning

4.3.1 Encoder

The encoder architecture is naturally well-suited for Sentiment Classification, which can be reformulated into the classical classification task. To this end, we directly apply a linear classifier to the output of the encoders. However, encoders can not generate rationales. As such, **they serve as baselines in our experiments**.

We use **phoBERT** (110M params) (Nguyen and Nguyen, 2020), RoBERTa (Liu et al., 2019) pre-trained on 20GB Vietnamese text, and **ViHealthBERT** (110M params) (Minh et al., 2022), phoBERT trained on 32GB of Vietnamese text in the healthcare domain. For ViHealthBERT, we report the syllable version which achieved better performance than the word version.

4.3.2 Generative Models

We reformulated Sentiment Classification into a text-to-text problem, where given the input transcript w_1^N, the generative model g and the predicted sentiment class c, we have $g(w_1^N) = c$ with $c \in C = \{"0", "1", "2"\}$ where "0","1","2" corresponds to the labels *NEGATIVE*, *NEUTRAL* and *POSITIVE*.

Encoder-Decoder: **BARTpho** (139M params) (Tran et al., 2022a) is the Vietnamese variant of BART (Lewis et al., 2019) trained on 20GB of Vietnamese text from Wikipedia and news corpus. **ViT5** (223M params) (Phan et al., 2022) is the Vietnamese version of T5 (Raffel et al., 2020) trained on 71GB of Vietnamese text from CC100 (Conneau et al., 2019).

Decoder: We use **Vistral-7B-Chat** (Nguyen et al., 2023) and **vmlu-llm**[1]. Both models have Mistral-7B(Jiang et al., 2023a) as their backbone. These models were chosen based on their performance on the **vmlu benchmark** (**V**ietnamese **M**ultitask **L**anguage **U**nderstanding)[2].

4.4 Training with Rationale

Previous works (Wadhwa et al., 2024; Chen et al., 2024; Hsieh et al., 2023; Ho et al., 2022) have shown that rationale-augmented targets consistently improve the performance of generative lan-

[1]https://huggingface.co/vtrungnhan9/vmlu-llm
[2]https://vmlu.ai/leaderboard

guage models. Our rationale-augmented training methods are based on, to our knowledge, the current state-of-the-art CoT-distillation approaches for each architecture.

(i) **Multitask Training** (Hsieh et al., 2023): We train our encoder-decoders using distilling step-by-step. Distilling step-by-step is a multitask training approach that prepends particular prefixes to the input, guiding the model to output either the answer or generate a rationale. Hsieh et al. found that it consistently improves encoder-decoders performance compared with single-task training which treats rationale and label predictions as a single task.

(ii) **Post-thinking** (Chen et al., 2024): For decoder-based models, we augment the training targets by append the human rationale to the label (<LABEL> <RATIONALE>) in a single prompt. Previous works have shown that post-thinking achieved impressive performance (Chen et al., 2024; Wadhwa et al., 2024) and compared to pre-thinking where the model first generates its CoT then provide the label (<RATIONALE> <LABEL>), post-thinking is more stable and token-efficient (Chen et al., 2024; Wadhwa et al., 2024) as the model suffers less from hallucination, consistently yields better performance and is more resource efficient as users can already retrieve the target label from the first generated token.

4.5 Rationale Format

While the rationale in our dataset were re-labeled by humans, we are also interested in **whether a different and more detailed rationale format would help the models learn better**. To this end, we further study the effects of the format of the rationale on the performance of the generative models. In particular, given the human rationale and human label, we further prompt GPT-3.5-turbo to enhance the rationale into two different format:

Elaborated rationale: An elaborated version of the human rationale that is 1-2 sentence(s) long, grounded on the provided human rationale and the sentiment label.

CoT rationale: A step-by-step, elaborated version of the human rationale, which includes the following steps: (1) identifies the medical entity, (2) extracts the progress of the corresponding medical entity in the transcript, and (3) provides the elaborated rationale on the sentiment grounded on the provided human rationale, the sentiment label, and information from steps (1) and (2). This approach is inspired by aspect-based sentiment instruction-tuning approaches (Varia et al., 2022).

4.6 Evaluation Metrics

For Sentiment Classification task, we employ accuracy and class-wise F1 score. For Rationale Generation , we employ ROUGE (Recall-Oriented Understudy for Gisting Evaluation) score (Lin, 2004). Also, we employ BERTScore (Zhang et al.) which captures the contextual and semantic nuances. BERTscore has shown to correlate well with human judgment.

5 Results and Analysis

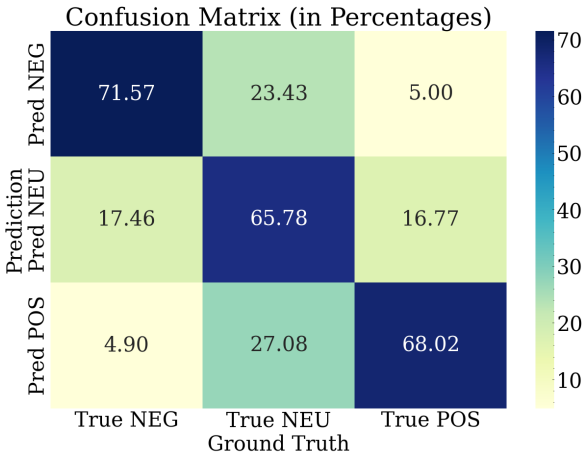

Figure 2: Confusion matrix of the predicted classes versus the actual labels on human transcript, obtained from Vistral7B trained with human rationale

We evaluate and analyze our models performance on Table 3. Based on the obtained results, we make the following observations:

1. Encoders are efficient yet effective Sentiment Classification **baselines**: Encoder models yields the best performance compared to their encoder-decoder and decoder counterparts, with high accuracy scores (> 0.665) and stable F1 scores (macro F1 of both models > 0.665). We further observe that **domain-specific encoders yield notably better performance**, with ViHealthBERT outperforming phoBERT in accuracy (+0.8%) and macro F1 (+0.9%).

2. ASR errors have a marginally negative impact on Sentiment Classification **performance**: For a fair comparison in real-world environments, WERs for human annotators on a standard conversational spontaneous English ASR dataset range from 5% to 15% (Stolcke and Droppo, 2017) while

Table 4: Baseline performance of encoders, encoder-decoders, and decoders on the Vietnamese ASR transcript. Further information about our metrics can be found in Table 3.

more challenging real-world ASR datasets are between 17% and 31% (Mulholland et al., 2016). Given the complexity of real-world medical conversations, WER of 29.6% by our ASR model is within an acceptable range. Despite the WER of 29.6%, the performance drop in macro F1 scores is small (absolute value of only about 5%).

3. Rationale-augmented training improve model performance: Consistent with previous findings, performing CoT-augmented training on both encoder-decoders and decoders improve our models performance compared to the baseline. We further conducted a Student's t-test (Student, 1908) and found that the gains are statistically significant for $\alpha = 0.1$. This pattern holds for the results in Table 5. We observe a decline in all of our models performance on ASR data which is anticipated due to its WER of 29.6 %. Nonetheless, the models trained with rationale perform noticeably better than models without, with an average absolute accuracy gain of +0.85%, absolute macro F1 gain of +1.4%, and relative macro F1 gain of +2.5%.

4. The format of post-thinking rationale doesn't affect the generative models performance: We study the effects of the format of post-thinking rationale on the performance of generative models on Table 5 and observe that it is unclear whether there is a performance gain from more elaborated rationales. This result agrees with previous findings (Wadhwa et al., 2024).

5. Models are likely to misclassify *POSITIVE* and *NEGATIVE* transcripts as *NEUTRAL*: We

Table 5: Performance of generative models on the different rationale formats on our test set. Human/elaborate/CoT specifies the format of rationale the model was trained on. Details in Section 4.5

study the confusion matrix of our best model on human transcript, Vistral7B finetuned with human rationale, on Figure 2. We observe a notable misclassification tendency between *NEUTRAL* and the other two classes (23.43% and 27.08% with *NEGATIVE* and *POSITIVE* respectively). On the other hand, we found that models can easily distinguish *NEGATIVE* transcripts from *POSITIVE* ones. This reflects the ambiguity of sentiment analysis data. Furthermore, given the slightly imbalanced nature of our dataset with fewer *POSITIVE* examples, its average F1 score is the lowest among the three labels across all models.

6. Analysis of Generated Rationale: Compared to human rationale, we observe from Table 3 and Table 4 that the models trained with rationale have high BERTscore (around 0.8) with low ROUGE score, indicating that while the vocabulary used in the rationale is different, the overall semantic of the generated rationale remains similar to that of humans. Also, no noticeable changes in the semantic quality of rationale between human transcripts and ASR transcripts because BERTScore is still about 0.8 on both settings.

7. Results on end-to-end audio language models We report the results for end-to-end spoken sentiment analysis on PhoWhisper (Le et al., 2024) and Qwen2-Audio (Chu et al., 2024). Based on the results in Table 6, we make two observations: First, the performance of PhoWhisper is sub-optimal which we attribute to the fact that it was pre-trained for ASR-based tasks. Second, we found that **rationale-augmented training can also increase the** Sentiment Classification **performance** for audio language models.

Model	Acc.	F1 Neg.	F1 Neu.	F1 Pos.	Mac F1

6 Conclusion

In this work, we introduce a new task - Sentiment Reasoning - for both speech and text modalities, along with the framework and **the world's largest multimodal sentiment analysis dataset**. In Sentiment Reasoning, given an input transcript (human transcript or ASR transcript), the model learns to output the sentiment label (POSITIVE, NEUTRAL, or NEGATIVE) and its rationale (the reason for this label). It comprises of two tasks: Sentiment Classification and Rationale Generation.

We menticulously evaluate the use of rationale during training to improve our models' interpretability and performance. We found that rationale-augmented training improves model performance in Sentiment Classification in both human and ASR transcripts (**+2% increase in both accuracy and macro-F1**). We found that the generated rationales have different vocabulary to human rationale but with similar semantics. Finally, we found no major difference in the semantic quality of generated rationales between human and ASR transcripts.

We thank Anh Totti Nguyen at Auburn University and Jerry Ngo at MIT for insightful feedback.

8 Limitations

Hybrid ASR: This study utilized the hybrid ASR system, which is generally recognized as superior in performance compared to the attention-based encoder-decoder or end-to-end ASR systems (Lüscher et al., 2019; Prabhavalkar et al., 2023; Raissi et al., 2023). However, the hybrid ASR requires multiple steps, beginning with acoustic

feature extraction and progressing through GMM-HMM modeling before transitioning to DNN-HMM modeling, which complicates reproducibility for non-experts.

Cascaded speech sentiment analysis approach: While we do report the results for end-to-end systems, our main focus in this paper is on cascaded speech sentiment analysis for Sentiment Reasoning . This approach uses a previously trained ASR model to generate ASR transcripts that are subsequently input into a language model (LM) for downstream Sentiment Classification and Rationale Generation tasks. Consequently, the weights in the ASR model remain unchanged while the LM weights are updated. In this setting, only semantic features from speech are utilized, omitting other trainable acoustic features, like prosody, tones, etc. In spoken language processing, where semantic features play a more important role than other acoustic features, cascaded approach is prefered due to its straightforwardness, simplicity and superior accuracy (Lu, 2023; Bentivogli et al., 2021; Tran et al., 2022b; Tseng et al., 2023). Future work should consider the end-to-end sentiment analysis task, where weights in both the ASR model and LM are updated simultaneously, as it might hold promise for improved performance.

A.1 Multimodal Speech Sentiment Analysis

It is widely known that there have been two research directions in the field of speech sentiment analysis, as also confirmed by Chen et al. (2020).

- **Single modality model (unimodal)**: In speech sentiment analysis, single modality models focus on utilizing a single type of data to predict sentiment. These models may rely exclusively on acoustic features, such as pitch, tone, and rhythm, to infer emotional states from spoken language (Li et al., 2019, 2018; Wu et al., 2019; Xie et al., 2019). Alternatively, they might use raw waveforms (Tzirakis et al., 2018; Zheng et al., 2022; Villatoro-Tello et al., 2021) or the textual content of transcripts to predict sentiment (Lakomkin et al., 2019). The strength of single modality models lies in their simplicity and specialization, allowing them to hone in on specific attributes of the data source they are designed for. However, this specialization can also be a limitation, as these models might miss out on the richer, more nuanced information that can be gleaned from combining multiple data types. Despite this, single modality models remain a fundamental approach in the field, providing valuable insights and serving as a benchmark for more complex multimodal systems.

- **Multimodality models**: In speech sentiment analysis, multimodality models leverage the combined strengths of both acoustic and textual data to provide more accurate and nuanced sentiment predictions. While traditional models might rely solely on either the acoustic features—such as tone, pitch, and rhythm—or the text derived from speech transcripts, multimodal models integrate these two data streams. This integration allows for a more holistic understanding of sentiment, as it captures the emotional cues present in the speaker's voice along with the contextual and semantic content of the spoken words. By maximizing the mutual information between these modalities, multimodal models can better discern subtleties in speech that single modality models might miss, leading to accuracy improvements (Kim and Shin, 2019; Cho et al., 2018; Gu et al., 2018; Eskimez et al., 2018; Zhang et al., 2019).

Our dataset is ideal for both single modal and multimodal research, as it includes both acoustic and text features.

A.2 ASR-based Speech Sentiment Analysis

Speech sentiment analysis on ASR transcripts is a field that aims to interpret and classify sentiments conveyed in spoken language. As technology advances, ASR systems have become increasingly proficient at transcribing spoken words into text with high accuracy (Schneider et al., 2019; Baevski et al., 2020, 2019; Wang et al., 2021b; Chen et al., 2022; Wang et al., 2021a), providing a rich source of data for sentiment analysis. Sentiment analysis algorithms then analyze the transcribed text from speech signal, utilizing language models as decoders to detect positive, negative, or neutral sentiments (Lu et al., 2020; Shon et al., 2021a; Wu et al., 2022; Tashev and Emmanouilidou, 2019; Kaushik et al., 2017).

In the era of deep learning, as surveyed by Al-Qablan et al. (2023), many researchers have been applying deep learning methods to the sentiment analysis process on transcript, leading to the development of various models like Convolutional Neural Networks (CNN), Recurrent Neural Networks (RNN), Long Short-Term Memory (LSTM), and Bidirectional LSTM (BLSTM) (Araque et al., 2017; Devipriya et al., 2020; Yadav and Vishwakarma, 2020). CNNs, primarily used for image processing, have been adapted for text by treating sentences as sequences of words and applying convolutional filters to capture local features. This approach helps in identifying crucial patterns within the text that are indicative of sentiment (Kumar and Malarvizhi, 2020; Wang et al., 2020). On the other hand, RNNs are designed to handle sequential data by maintaining a hidden state that captures the history of previous inputs, making them suitable for understanding the context and temporal dependencies in sentences. However, traditional RNNs face challenges with long-term dependencies due to issues like vanishing gradients, which is where LSTMs come in. LSTMs, an advanced form of RNNs, address these issues by incorporating gates that regulate the flow of information, allowing them to maintain and update long-term dependencies effectively. Furthermore, BLSTMs enhance this by processing the input sequence in both forward and backward directions, thus capturing dependencies from both past and future contexts simultaneously. This bidirectional approach is especially useful for

sentiment analysis, where the interpretation of a word can depend heavily on both preceding and succeeding words. Together, these architectures provide powerful tools for sentiment analysis, each contributing unique strengths that can be leveraged depending on the specific requirements and characteristics of the data at hand (Gandhi et al., 2021; Pal et al., 2018; Srinivas et al., 2021).

Developed by Google, BERT (Bidirectional Encoder Representations from Transformers) (Kenton and Toutanova, 2019) revolutionized NLP tasks by enabling models to understand the context of words in a sentence more effectively through its bidirectional training approach. Unlike previous models that read text input sequentially, BERT reads the entire sequence of words at once, capturing the full context and nuances of language. This capability allows BERT to excel in sentiment analysis, where understanding the subtleties of human emotion and opinion is paramount (Alaparthi and Mishra, 2020; Deepa, 2021). BERT's pre-training on vast amounts of text data, followed by fine-tuning on specific sentiment analysis tasks, further enhances its performance. By leveraging its powerful language representations, BERT can handle the complexities of sentiment analysis, such as sarcasm, idiomatic expressions, and context-dependent sentiment shifts, making it a preferred choice for applications ranging from social media monitoring to customer feedback analysis. The model's ability to generalize across various domains and languages also contributes to its widespread adoption, offering robust and scalable solutions for sentiment analysis in diverse settings (Hoang et al., 2019; Xu et al., 2019; Sousa et al., 2019; Alaparthi and Mishra, 2021).

A.3 Speech Sentiment Analysis in Healthcare

Sentiment analysis in healthcare is an emerging field that leverages NLP and machine learning techniques to analyze and interpret the emotional tone conveyed in biomedical textual data. This technology is particularly useful for understanding patient feedback, monitoring public health trends, and improving patient-provider communication. By analyzing large volumes of data from sources such as social media, online reviews, electronic health records (EHRs), and patient surveys, sentiment analysis can provide valuable insights into patient experiences, satisfaction levels, and overall public sentiment towards healthcare services and policies. For instance, analyzing patient reviews on healthcare platforms can help identify common concerns and areas needing improvement, allowing healthcare providers to address issues proactively and enhance the quality of care. Additionally, sentiment analysis can play a critical role in mental health monitoring by detecting signs of distress or dissatisfaction in patient communications, enabling timely intervention and support. As this technology continues to evolve, it holds the promise of transforming healthcare by fostering a more patient-centric approach, enhancing service delivery, and ultimately improving patient outcomes (Denecke and Deng, 2015). However, the sentiments expressed in clinical narratives have not been extensively analyzed or exploited, based on the total number of previous works we have identified to the best of our knowledge:

- Sentiment analysis from the medical web: Most sentiment analysis research in the medical domain focuses on web data, such as medical blogs and forums, to mine patient opinions or assess quality (Ali et al., 2013; Xia et al., 2009; Na et al., 2012; Sokolova et al., 2013; Biyani et al., 2013; Ofek et al., 2013; Smith and Lee, 2012; Sharif et al., 2014; Melzi et al., 2014).

- Sentiment analysis from biomedical literature: In addition to the analysis of medical social media data, biomedical literature has been examined concerning the outcomes of medical treatments. Within this framework, sentiment denotes the results or efficacy of a treatment or intervention (Niu et al., 2005; Sarker et al., 2011).

- Sentiment analysis from medical text (except biomedical literature): Several researchers have focused on leveraging supplementary sources of medical texts to implement sentiment analysis and emotion detection methodologies, suicide notes or patient questionnaire for example (Pestian et al., 2012; Cambria et al., 2012a; Liu and Singh, 2004; Cambria et al., 2012b).

To the best of our knowledge, no literature among those cited has addressed speech sentiment analysis specifically within the domain of healthcare.

B Details about Data

B.1 Data Annotation Pipeline

We use LLM pre-labeling as it helps speed up the labeling process through providing the annotators with the initial sentiment labels and the corresponding rationales. In the relabeling process, annotators go through each sample and inspect it manually. If the annotators deem the label and the rationale is appropriate, they can quickly move to the next sample. If not, the annotators can update the label and rationale to be more appropriate.

The data annotation process is as followed. First, all the subtitles are separated into different chunks. These segments are subsequently input into gpt-3.5-turbo, which conducts a weakly supervised 3-label classification task to categorize each segment as *NEGATIVE, NEUTRAL, or POSITIVE*. In addition to the sentiment label, gpt-3.5-turbo also provides a brief synthetic rationales for the classification, such as 'Negative medical condition' or 'Objective description'. The labels and rationales generated by gpt-3.5-turbo are subsequently reviewed and independently corrected by a team of 3 developers.

B.2 LLM Prompt for Pre-labeling

gpt-3.5-turbo

Annotate the sentiment (neutral, positive or negative) of the following sentence and provide a very short justification. The procedure is as follows:
1. If the segment shows clear emotional signs, annotate based on these signs.
2. If no emotional markings are present, determine if the segment is an objective description. Positive for beneficial facts/features, negative for detrimental facts/features, and neutral otherwise.
3. If not objective, check if there's a preference expression. Positive for likes or positive views, negative for dislikes or negative views, and neutral if no preference is expressed.
4. If too short to determine sentiment, label as neutral.
{3 in-context learning examples}

B.3 Annotation Guidelines

The definition of "sentiment" encompasses both "emotions" and "facts" in our work. Existing works (Chen et al., 2020; Mohammad, 2016; Shon et al., 2021b, 2022, 2023) use both emotions and facts for sentiment labeling.

- Emotion: Existing literature includes "emotion" as part of "sentiment" (Chen et al., 2020; Shon et al., 2021b; Mohammad, 2016) and sentiment analysis can be considered a more abstract level of emotion recognition, e.g. polarity of emotions (Mohammad, 2016).
- Facts: Many sentiment analysis systems require statements that describe events/situations to be given a sentiment label (Chen et al., 2020; Mohammad, 2016).

The annotation task consists of two primary steps. First, annotators are required to perform Sentiment Classification. Second, annotators are instructed to provide a rationale behind each class (Rationale Generation).

To ensure consistency, our TESOL-certificated professional linguist has developed an initial guideline inspired by (Chen et al., 2020), which was also adopted by various well-known works (Shon et al., 2022, 2023), and revised it frequently if necessary as followed:

B.3.1 Output Annotation

The *NEGATIVE* label is for chunks that discuss negative, serious diseases, disorders, symptoms, risks, negative emotions, or counter-positive statements (e.g. "This would NOT bring a good outcome"). It also applies to incomplete chunks where the amount of negativity is greater than the amount of positivity.

The *NEUTRAL* label is for incomplete chunks where the ratio of negativity is equal to the ratio of positivity, as well as chunks that describe processes, ask questions, provide advice, or are too short.

The *POSITIVE* label is for chunks that discuss positive outcomes, recovery processes, positive emotions, or counter-negative statements (e.g. "This will *reduce* discrimination"). It also applies to incomplete chunks where the ratio of positivity is greater than the ratio of negativity.

It is important to note that all chunks are considered independent, even though they may be incomplete and related to preceding or following chunks. Given that this data is derived from spoken language, the chunks contain a significant amount of filler words, which are disregarded in the labeling

process. The majority of the *NEUTRAL* labels are attributed to chunks that involve sharing advice or descriptions. Additionally, the presence of modal verbs (e.g., should, would, need) often indicates advice sharing, thereby classifying the chunk as *NEUTRAL* regardless of its content.

B.4 Annotation Flowchart

Inspired by the well-known annotation flowchart provided by Chen et al. (2020), we asked annotators to adopt the annotation flowchart and we ,if necessary, revised as follows:

1. Does the segment exhibit distinct emotional cues indicative of sentiment, such as laughter for positive affect or yelling for negative affect?
    - **Yes** – Annotate the corresponding class and also note that:
        - (a) In some instances, individuals may laugh to mitigate the discomfort associated with delivering negative statements. In such cases, it should be classified as neutral.
        - (b) If individuals exhibit a sneer (a smile or laughter with a mocking tone), the corresponding sentiment should be classified as negative in such instances.
    - **No** - Jump into Step 2
2. Does the segment provide an objective account of the facts?
    - **Yes** - If the segment lists several positive attributes (e.g., good progress in medical treatment, good signs of health improvement), it is classified as positive. Conversely, if it lists several negative attributes, it is classified as negative. In the absence of a clear preponderance of either, the segment is considered neutral.
    - **No** - Jump into Step 3
3. Does the segment exhibit a preference?
    - **Yes** - If the subjective opinion or preference conveys a like or dislike, or expresses a positive (e.g., "it is beneficial that...") or negative sentiment, it should be annotated accordingly.
    - **No** - It's neutral
4. If the utterance is insufficient in length to accurately assess sentiment, it should be classified as neutral.

B.5 Data Imbalance Discussion

As shown in Table 1, *NEUTRAL* category is the most predominant, accounting for a significant portion of the dataset. With 3802 instances for both train and test set, *NEUTRAL* sentiments make up approximately half of the dataset. This prevalence of *NEUTRAL* sentiment is expected, as also seen by a real-world conversational dataset (Chen et al., 2020), given the nature of medical consultations, which often involve objective descriptions, explanations, and advice. The *NEGATIVE* category is the second most common, with around 2395 instances. *NEGATIVE* sentiments include discussions about serious diseases, negative emotions, and adverse medical outcomes. The substantial presence of negative sentiments reflects the medical context, where discussions about illnesses and symptoms are common. The *POSITIVE* category, while the least common, still represents a significant portion of the dataset with 1681 instances. *POSITIVE* sentiments typically involve discussions about recovery processes, positive outcomes, and favorable emotions.

A slight bias in the distribution of the labels towards NEUTRAL in our dataset (49.94% in the train set, 43.88% in the test set) reflects the nature of real-world medical conversations, rather than a weakness of our work. For context, in comparable real-world sentiment analysis datasets such as Switchboard-Sentiment (Chen et al., 2020), the distribution is as follows: 30.4% of the speech segments are labelled as POSITIVE, 17% of the segments are labelled as NEGATIVE, and 52.6% of the segments are labelled as NEUTRAL.

To address this labeling bias issue, future works can leverage techniques for fine-tuning models in data imbalance regimes, such as focal loss (Ross and Dollár, 2017), class weighting (King and Zeng, 2001).

B.6 Translation Annotation Process and Translation Quality Control

The data were initially translated from the source language into target languages (many-to-many) using the Gemini Large Language Model (LLM). Following the annotation process by **?**, the LLM-generated translated transcripts were treated as outputs from a *real* human annotator. In the data qual-

ity process, five human annotators manually corrected and then cross-verified *all* these translations based on the context of the whole conversation. Only transcripts that received consensus approval from multiple annotators were retained, resulting in an inter-annotator agreement of 100%.

All human annotators possessed a professional language proficiency of C1 or higher (or HSK5 for Chinese) in their respective working languages. Additionally, each annotator had completed basic medical training and demonstrated substantial knowledge of medical terminology in their selected language. Furthermore, they were either currently pursuing or had completed undergraduate or graduate studies in countries where their chosen language is predominantly spoken.

B.7 Data Samples

Table 7 shows 9 examples with 3 samples per sentiment label in our dataset. As the Vietnamese transcripts are obtained from short-formed audio, the transcripts contain characteristics of spoken language which serve as noises to the model (e.g. stuttering, hesitation, etc). **In our English translation, we aim to retain these properties, leading to unnatural, incomplete sentence with broken wording**.

Figure 3 shows 3 examples per sentiment label for all languages: Vietnamese, English, Chinese (Simplified and Traditional), German and French.

C Details about Experimental Setups

C.1 Details of ASR Experiments

We employed hybrid ASR setup using wav2vec 2.0 encoder (Le-Duc, 2024) to transcribe speech to text. First, we generated alignments obtained by using Gaussian-Mixture-Model/Hidden-Markov-Model (GMM/HMM) as labels for wav2vec 2.0 (Baevski et al., 2020) neural network training. The labels used in the acoustic modeling are context-dependent phonemes, triphones in this case. In GMM/HMM process, we used a CART (Classification And Regression Tree) (Breiman, 2017) to tie the states s, resulting 4501 CART labels:

$$p(x_1^T|w_1^N) = \sum_{[s_1^T]} \prod_{t=1}^{T} p(x_t, s_t|s_{t-1}, w_1^N)$$
$$= \sum_{[s_1^T]} \prod_{t=1}^{T} \underbrace{p(s_t|s_{t-1}, w_1^N)}_{\text{transition prob.}} \cdot \underbrace{p(x_t|s_t, s_{t-1}, w_1^N)}_{\text{emission prob.}} \tag{6}$$

After inputting CART labels for hybrid wav2vec 2.0 training, we employed frame-wise cross-entropy (fCE) loss (Good, 1952) to train the acoustic model.

To transcribe speech given the acoustic observations, the acoustic model and n-gram language model (Ney et al., 1994) should be combined based on the Bayes decision rule using Viterbi algorithm (Forney, 1973) which recursively computes the maximum path to a find best-path in the alignment graph of all possible predicted words to the acoustic observations:

$$w_1^N = \arg\max_{N, w_1^N} p\Big(\prod_{n=1}^{N} p(w_n|w_{n-m}^{n-1}) \cdot \max_{[s_1^T]} \prod_{t=1}^{T} p(x_t, s_t|s_{t-1}, w_1^N)\Big) \tag{7}$$

Finally, acoustic model and n-gram language model pruning (beam search) is used to only focus on the most promising predicted words at each time step t (Ortmanns et al., 1997).

The final ASR model has 118M trainable parameters and Word-Error-Rate (WER) of 29.6% on *VietMed* test set.

C.2 Training Setup

Our encoders and encoder-decoders were trained on a cluster of 2 NVIDIA A40s with 46 GBs of memory. All models were trained on 30 epochs with with a learning rate of $2e$-5 and batch size of 64. We evaluated every epoch with early stopping with patience = 3.

For the decoder-based LLMs, due to their massive number of parameters, we use LoRA (Hu et al., 2021) for fine-tuning with hyperparameters: the rank of the update matrices $r = 8$, and the LoRA scaling factor $\alpha = 3$. We train our LLMs for 5 epochs with learning rate 2e-4.

We use the best model checkpoints for evaluation. Note that we do not perform hyperparameter tuning as we only aim to provide the initial benchmark results as well as studying the effects of CoT-augmented finetuning.

C.3 Student's T-Test

A Student's t-test, is a statistical method used to compare the means of one or two populations through hypothesis testing. It can assess whether a single group mean differs from a known value (one-sample t-test), compare the means of two independent groups (independent two-sample t-test), or determine if there is a significant difference between paired measurements (paired or dependent samples t-test). Figure 4 below is the code for reproducing Student's t-test experiments.

```python
import scipy.stats as stats

alpha = 0.05
label = [0.6628, 0.6523, 0.6592, 0.6716]
rationale = [0.6427, 0.6441, 0.6812, 0.6729]

def analyze_t_test(t_statistic, p_value, alpha):
  print(f"T-statistic: {t_statistic}")
  print(f"P-value: {p_value}")
  if p_value < alpha:
    print("The two populations are significantly different.")
  else:
    print("The two populations are not significantly different.")

t_statistic, p_value = stats.ttest_rel(label, rationale)
analyze_t_test(t_statistic, p_value, alpha)
```

Figure 4: Python code for reproducing Student's t-test experiments

D Results on English subset

We randomly sampled 50 transcripts and check their quality. We further train English models on this English subset of our dataset to ensure full usability.

The result of our experiments is in Table 8. More information on the models used can be found in the same table. Overall, we found that rationale-augmented training also help boost the model's performance. This finding is consistent with what when observed in our experiments in Section 5.

Table 8: Baseline performance of encoders, encoder-decoders, LLMs on the English human transcript. Further information about our metrics can be found in Table 2.

E Results on end-to-end audio language models

E.1 Encoder-Based

PhoWhisper (Le et al., 2024): Whisper (Radford et al., 2022) trained on an 844-hour Vietnamese dataset. It achieves the state-of-the-art performance on various Vietnamese ASR datasets. To perform Sentiment Classification, we attach a classification head to the encoder layer of the model. We use the PhoWhisper base version in our experiments.

E.2 Audio LLMs

Qwen2-Audio (Chu et al., 2024): the state-of-the-art Qwen large audio-language model with 7B parameters, pretrained on diverse audio datasets. We use the Instruct version of this model. We finetune Qwen2-Audio on both *Label Only* and *Label + Rationale* settings in our experiments. It should be note that the rationales are text-only.

F Error Analysis

We report our best model's misclassified transcripts with the highest label confidence (defined as the softmax of the logits of the model prediction) in Table 9. By analyzing at the model's rationale, we hypothesize that the model is confounded by the appearance of certain keywords that elicit either extremely positive (hữu ích (helpful)) or negative, disease-related words and sentiment which pushes the model away from the *NEUTRAL* label.

Transcript	Label	Pred.	Human Rationale	Model Rationale

Abstract

Charts are ubiquitous as they help people understand and reason with data. Recently, various downstream tasks, such as chart question answering, chart captioning, etc. have emerged. Large Vision-Language Models (LVLMs) show promise in tackling these tasks, but their qualitative evaluation is costly and time-consuming, limiting real-world deployment. While using LVLMs as judges to assess chart comprehension capabilities of other LVLMs could streamline evaluation processes, challenges like proprietary datasets, restricted access to powerful models, and evaluation costs hinder their adoption in industrial settings. To this end, we present a comprehensive evaluation of 13 open-source LVLMs as judges for diverse chart comprehension and reasoning tasks. We design both pairwise and pointwise evaluation tasks covering criteria like factual correctness, informativeness, and relevancy. Additionally, we analyze LVLM judges based on format adherence, positional consistency, length bias, and instruction-following. We focus on cost-effective LVLMs ($\leq$ 9B parameters) suitable for both research and commercial use, following a standardized evaluation protocol and rubric to measure the LVLM judge accuracy. Experimental results reveal notable variability: while some open LVLM judges achieve GPT-4-level evaluation performance (about 80% agreement with GPT-4 judgments), others struggle (below 10% agreement). Our findings highlight that state-of-the-art open-source LVLMs can serve as cost-effective automatic evaluators for chart-related tasks, though biases such as positional preference and length bias persist.

1 Introduction

Understanding data visualizations—such as bar and line charts—requires multimodal reasoning, as it involves integrating visual encodings with textual and contextual information (Hoque and Islam, 2024). Recent research has introduced various tasks (e.g., chart question answering, chart captioning, fact-checking with charts, etc.) to facilitate chart-based reasoning via natural language. These tasks demand the understanding of both the chart's visual content (data values, trends, visual encodings) and accompanying text or instructions.

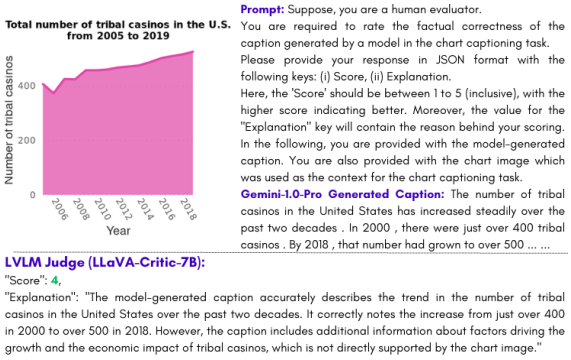

Figure 1: An example evaluation of *Gemini-1.0-Pro* model generated L2/L3 caption in the VisText dataset by an LVLM judge: the *LLaVA-Critic-7B* model.

Large Language Models (LLMs) have revolutionized NLP and vision-language tasks (Zhao et al., 2023), with growing interest in their use for chart comprehension and reasoning due to their strong multimodal capabilities. This progress can have a substantial impact on real-world industrial applications, where extracting insights from charts and graphs can drive critical business decisions (Obeid and Hoque, 2020; Masry et al., 2023; Meng et al., 2024). However, evaluating LLM performance in chart understanding presents notable challenges (Islam et al., 2024). For instance, traditional text-based metrics like BLEU fail to capture the quality of open-ended explanatory answers and also require human-annotated references. While human evaluation can address this problem, it is time-consuming and resource-intensive.

† Equal Contributions.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1203–1216
July 28-30, 2025

To address this, recent studies have proposed using LLMs themselves as automatic evaluators or judges (Gu et al., 2024; Li et al., 2024b). By employing LLMs to evaluate the chart comprehension abilities of other models (see Figure 1 for an example), the evaluation process can be streamlined, making the process more efficient and reproducible without human intervention. While this method accelerates development and reduces dependency on human annotations, its real-world adoption is hindered by privacy and scalability constraints. For example, organizations may be unwilling to share proprietary data with closed-source models from OpenAI, Google, or Anthropic. While closed-source models demonstrate impressive judging capabilities, their compatible open-source models are often large in size (e.g., 70B to 400B parameters). This requires high computing resources and usage costs. Therefore hinders real-world utilization.

To this end, this paper aims to investigate whether open-source smaller LVLMs (e.g., less than 10B parameters) can effectively evaluate answers about charts—assessing correctness, relevance, and other qualities—similarly to a human or a powerful LLM like GPT-4 (OpenAI et al., 2023). For this purpose, we conduct one of the first comprehensive evaluations of open-source LVLMs as evaluators on various chart benchmarks, consisting of diverse tasks like chart captioning and question answering. We focus on open-source, smaller VLMs (up to 10B parameters) to simulate realistic deployment scenarios where cost-effective or private models are preferred over large closed models. By benchmarking these models against high-quality reference judgments generated by closed-source LLMs like GPT-4 or 70B open-source LLM-Judge like LLaVA-Critic (Xiong et al., 2024), we aim to uncover to what extent current open models can serve as reliable judges, and when they fail.

Our major contributions to this paper are:

1. We establish an evaluation framework for chart comprehension using *"LVLM-as-a-Judge"*, with clear rubrics for pairwise and pointwise assessments over 100K judgments generated by GPT-4o and LLaVA-Critic-70B. Additionally, we introduce a new benchmark to assess the instruction-following abilities of LVLMs in chart-related tasks.

2. We evaluate a wide range of open-source multimodal LLMs as judges – 13 models ranging from 2B to 9B parameters – and analyze their performance against LLM-annotated (GPT-4 and LLaVA-Critic) and human-annotated reference judgments, across diverse chart benchmarks (OpenCQA and VisText) on answers generated by different LLMs to create challenging evaluation scenarios.

3. We provide an in-depth analysis of the judges' strengths and weaknesses, revealing issues like position bias and length bias, and discuss which models achieve substantially higher agreement with reference judgments, and which ones fail.

In addition, our code, judgment data, and our proposed instruction-following evaluation benchmark is released here: `https://github.com/tahmedge/chart_lvlm_judge`

2 Related Work

Earlier efforts in chart question answering include synthetic datasets like FigureQA (Kahou et al., 2017) and DVQA (Kafle et al., 2018), which generated templated QA pairs for simple charts but lacked real-world complexity. ChartQA (Masry et al., 2022) addressed this gap with real-world charts and more complex questions, while OpenCQA (Kantharaj et al., 2022) pushed further with open-ended, explanatory queries. Meanwhile, chart captioning has emerged as another avenue for summarizing chart content (Shankar et al., 2022; Rahman et al., 2023; Tang et al., 2023). Together, these datasets highlight the growing complexity of chart-based reasoning tasks and the need for more robust evaluation methods.

While the rise of multimodal LLMs offers potential for chart-related tasks, general vision-language models often struggle with chart-specific elements like axis text and precise data points (Islam et al., 2024). To address this, specialized models such as ChartLLaMA (Han et al., 2023), ChartInstruct (Masry et al., 2024), ChartGemma (Masry et al., 2025), and TinyChart (Zhang et al., 2024) have been developed, showing strong performance. However, evaluating these models is challenging, as many still depend on time-consuming human assessments for open-ended responses.

While using LLMs to evaluate other LLMs has gained a lot of attention, early efforts focused primarily on text-only tasks like summarization (Li et al., 2024b; Zheng et al., 2023). For multimodal tasks, models such as Prometheus-VL (Lee et al.,

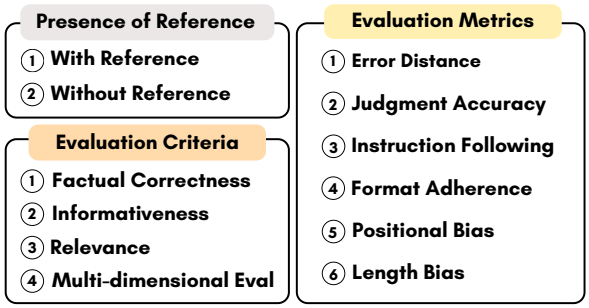

Figure 2: An overview of our evaluation methodology.

2024) and LLaVA-Critic (Xiong et al., 2024) introduced smaller open-source vision-language models (as small as 7B) fine-tuned to serve as general-purpose multimodal evaluators. Our work aligns with this direction, leveraging LVLMs as judges. Although concurrent studies explore similar capabilities (Chen et al., 2024), they report that early LVLMs like LLaVA-1.5 struggle with text-rich visuals such as charts and diagrams (Lee et al., 2024). Addressing the gap in evaluating recent LVLMs on chart-specific tasks, we present the first systematic study of state-of-the-art open-source LVLMs as judges across diverse chart comprehension and reasoning benchmarks.

3 Methodology

Given a chart and model generated response(s), we construct the prompt (see Appendix A.2 for some sample prompts) depending on the evaluation rubric. Following the prior work (Lee et al., 2024), we ask the LVLM judge to provide their answer along with an explanation, since adding an explanation during assessments ensured better judgment performance in early work. Below, we describe our evaluation method (also see Figure 2).

3.1 Evaluation Rubric Design

Following the prior work on LLM evaluation (Chen et al., 2024; Lee et al., 2024; Xiong et al., 2024), we define clear rubrics for the judges:

(i) Based on Evaluation Type:

- **Pairwise:** The judge must select the better answer between two given responses (e.g., Claude vs Gemini) about the chart for the given instruction.
- **Pointwise:** The judge must rate a single answer to the chart query on a Likert scale from 1 (very poor) to 5 (excellent).

(ii) Based on Reference Type:

- **With Reference:** The judge is also given the ground-truth answer or summary as a reference, and instructed to choose the response that better matches the reference as well as the chart context.
- **Without Reference:** The judge only sees the model response(s) and the chart image and must decide based on its own judgment.

(iii) Based on Evaluation Criteria:

- **Factual Correctness:** Focuses only on the factual accuracy of the response.
- **Informativeness:** Focuses on the amount of useful information in the response.
- **Relevance:** Focuses on measuring the relevancy of the response.
- **Multidimensional Evaluation:** Considers overall response quality based on factual correctness, informativeness, conciseness, and relevance.

(iv) Based on Evaluation Metrics:

- **Judgment Accuracy:** The percentage of instances where the answer picked by the judge same as the gold. It is relevant to the pairwise case.
- **Error Distance:** The average absolute difference between the judge's 1–5 rating and the reference's rating. It is relevant to the pointwise case.
- **Positional Bias Metric:** In the pairwise case, we swapped the order of answers and checked if the judge's decision changed.
- **Length Bias Metric:** Checked if the judge's wrong choice correlated with the answer length.
- **Instruction Following Evaluation Accuracy:** We analyzed whether the LVLM judge can effectively evaluate the instruction following capability of other LVLMs.
- **Format Adherence Accuracy:** This metric measures whether the judge's output followed the required JSON format.

3.2 Evaluation Data Construction

OpenCQA (Kantharaj et al., 2022)**:** This is an open-ended question-answering dataset on real charts. Each data point includes a chart and a question and expects an explanatory answer. We use its test set containing 1.1k QA instances.

VisText (Tang et al., 2023)**:** This is a chart captioning dataset with 12,441 charts, each paired with two types of captions: synthetic Level 1 (L1) captions that describe the chart's structural elements—such as chart type, title, axis labels, and scales—and human-generated Level 2/Level 3 (L2/L3) captions that provide insights into key statistics, trends, and patterns within the data. We use both L1 and L2/L3 captions with 1.2K test instances for each type.

For OpenCQA and VisText, we use the outputs generated by Islam et al. (2024) using *Gemini-1.0-*

Pro (Team et al., 2023) and *Claude-3-Haiku* (Anthropic, 2024) and compute the judgment scores using GPT-4o (OpenAI et al., 2023) and LLaVA-Critic-70B (Xiong et al., 2024) models and use as the judgment reference for diverse scenarios, as demonstrated in the previous section. This results in about 100K judgment data generated by GPT-4o and LLaVA-Critic-70B. We select these two models due to their impressive performance as a multimodal LLM-Judge (Xiong et al., 2024).

Chart-Instruct-Eval: We find that there are no datasets currently available in the chart domain that can assess the instruction-following capabilities of LVLMs. Therefore, we construct an instruction-following dataset (denoted as Chart-Instruct-Eval) to evaluate whether LVLM judges can evaluate the instruction-following capabilities of different models in chart-related tasks. For the dataset construction, we sample 400 charts from the ChartGemma (Masry et al., 2025) dataset. However, the original input instructions in the ChartGemma dataset lacked sufficient details. Hence, we could not use it for the instruction following purpose. Therefore, for each sample, we first create a detailed instruction containing specific requirements for the LLM response in terms of formatting, length, and structure to ensure instruction following. Then we manually prepare one good and one bad response corresponding to the instruction. Both responses convey similar content, but the good response fully adheres to all provided instructions, whereas the bad response disregards them. Finally, we assess the LLM judges whether they can reliably evaluate which response properly follows the instructions.

3.3 LVLM Judges

We evaluate **13** different open-source multimodal LLMs[1] as candidate judges, focusing on relatively smaller, publicly available models (2B–10B parameters). These include: **(i)** `XGen-MM-Phi-3-3.8B` (Xue et al., 2024) – *a multimodal model (3.8B) developed by Salesforce*, **(ii)** `MiniCPM-V-2.6-7B` (Yao et al., 2024) – *a 7B vision-language model by OpenBMB*, **(iii)** `Ph-3.5-3.8B-Vision-Instruct` (Abdin et al., 2024) – *a smaller vision model from Microsoft*, **(iv)** `Qwen2-VL-2B` - *Alibaba's Qwen (Wang et al., 2024) multimodal model with just 2B parameters*, **(v)** `Qwen2-VL-7B` – *The 7B version of the multimodal Qwen model*, **(vi)** `PaliGemma-3B` (Beyer et al., 2024) – *Google's multimodal open-source model*, **(vii)** `ChartGemma` (Masry et al., 2025) – *a chart-specialized model based on PaliGemma that is fine-tuned on chart tasks*, **(viii)** `Idefics-9B-Instruct`[2] – *an open multimodal model known for image understanding*, **(ix)** `InternLM-XComposer-7B` (Dong et al., 2024) – *a 7B vision model with composition abilities*, **(x)** `LLaVA-v1.6-Mistral-7B` – *A multimodal LVLM based on the LLaVA (Li et al., 2024a) architecture that also utilizes a 7B Mistral (Jiang et al., 2023) as the backbone*, **(xi)** `LLaVA-Critic-7B` – *a specialized evaluator model based on LLaVA and Qwen*, **(xii)** `mPLUG-Owl-3-7B` (Ye et al., 2023) – *a 7B multimodal model from Alibaba*, **(xiii)** `Janus-Pro-7B` (Chen et al., 2025) - *an open-source LVLM developed by Deepseek*. For more information about model selection, see Appendix A.1.

4 Experiments

In this section, we present the experimental results based on evaluating 13 LVLMs as judges across OpenCQA, VisText, and our proposed Chart-Instruct-Eval. The evaluation considers both pairwise and pointwise assessments, focusing on factual correctness, informativeness, relevance, positional bias, length bias, and instruction-following accuracy. We parse the LVLM-judge predicted judgments from their corresponding JSON-formatted responses using a parsing script (Laskar et al., 2023, 2024a,b). If the parsing script cannot properly parse the judgment from the response, we consider the LLM-generated answer as wrong for the pairwise case and error distance of 5 for the pointwise case. Note that we ran all our experiments using 1 A100 GPU with all the decoding parameters being set to the default values in HuggingFace (Wolf et al., 2020). Below, we demonstrate our findings:

4.1 Pairwise Evaluation Results

The pairwise evaluation measures how often the LVLM judges agree with GPT-4 or LLaVA-Critic-70B to select the better response in comparative assessments. We summarize the result in Table 1.

i. **Top-performing models:** LLaVA-Critic-7B achieved the highest agreement with reference judgments (above 75% average accuracy in each dataset). Another similar-sized (7B) LLM,

[1]We did not use the Prometheus-VL-7B (Lee et al., 2024) model since it requires a specific input format, making our prompts incompatible.

[2]HuggingFaceM4/idefics-9b-instruct

Model	Pairwise Evaluation: Judgment Accuracy (Higher is Better)									Pointwise Evaluation: Error Distance (Lower is Better)

Table 1: Model performance based on average pointwise and pairwise scores across all reference types, as well as evaluation criteria (e.g., factual correctness, informativeness, etc.) in comparison to GPT-4o and LLaVA-Critic-70B (LC-70B) annotations (corresponding average score is also added). Bold values denote the best score in each case. Color coding for comparison: open-source models below 7B parameters, between 7-10B parameters.

the LLaVA-Next-v1.6-Mistral-7B model also performed competitively by exceeding 70% accuracy across each dataset. Interestingly, the XGen-MM model with just 3.8B parameters also achieved more than 70% accuracy, making it a very suitable judge in resource-constrained scenarios.

ii. **Lower-performing models:** Surprisingly, PaliGemma-3B and ChartGemma-3B achieved 0% agreement, indicating a poor alignment with reference judgments. Moreover, while the Qwen-2B model achieves decent performance in OpenCQA (above 50% accuracy), it achieves quite poor performance in VisText, especially in the L2/L3 scenario (below 10% accuracy). More surprisingly, the largest LVLM in our evaluation, the Idefics-9B-Instruct model achieves average accuracy below 25% in all datasets, highlighting its ineffectiveness as a judge. Our manual analysis revealed that these models failed due to not following instructions properly while also generating the response in the wrong format (improper JSON outputs). For PaliGemma, since it is not an instruction-tuned model, its poor performance could be related to the lack of understanding of instructions. The poor performance behind ChartGemma could be related to its training data lacking instructions related to judging tasks, therefore leading to poor generalization. We demonstrate some error examples of these LVLMs in Appendix A.3.

4.2 Pointwise Evaluation Results

This primarily measures the error distance between the ratings of the LVLM judge and the reference (GPT-4/LLaVA-Critic-70B) on a 1–5 Likert scale.

i. **Top-performing models:** Similar to the pairwise scenario, we find from Table 1 that LLaVA-Critic-7B again achieved the best performance in the pointwise scenario, achieving an error distance around 0.5. Other models like InternLM-Xcomposer-7B and Qwen2-VL-7B-Instruct that achieve quite good performance in pairwise scenarios, also demonstrate less error distance in pointwise scenarios (error distance below 1.0). Some other top-performing models in the pointwise scenario are LLaVA-Next-v1.5-Mistral-7B and MiniCPM-V-2.6-8B, which also achieve an error distance below 1.0 in 2 out of the 3 datasets.

ii. **Lower-performing models:** Similar to the pairwise scenario, PaliGemma-3B and ChartGemma-3B again produced irrelevant outputs resulting in the highest error distances (5.0). Moreover, despite being the largest model in our evaluation, the Idefics-9B-Instruct model performs quite poorly with a high error (on average, above 3).

4.3 Instruction and Format Adherence

We also assess the LVLM judges on their ability to maintain a standardized response format and whether they can evaluate the instruction following capabilities of other models. Based on the results in Table 2, we find that all 7B models achieve more than 90% format following capability. Smaller LVLMs like Qwen-2B and Phi-3.8B also achieve around 80% format adherence.

In terms of instruction following capability evaluation, we find that many LVLMs that could properly follow the format following requirement in their generated judgments for pairwise (§4.1) and pointwise (§4.2) evaluations, surprisingly generate the response in the wrong format in this evaluation. This makes our original parsing script penalize most of the LVLM-generated judgments as wrong. Therefore, we rewrite the parsing script to make it more flexible in terms of format ad-

herence of the LVLM judge, since for this evaluation, our focus was to evaluate whether LVLM judges can properly assess instruction-following capabilities of different models in downstream chart-related tasks. Therefore, format adherence and other capabilities of the LVLM judges were not the focus of this evaluation. Our experiments reveal that mPLUG-Owl3-7B (93.5%) and Qwen2-VL-7B-Instruct (87.0%) achieve the top two results in terms of evaluating the instruction-following capability of different LVLM generated responses. Surprisingly, the LLaVA-Critic-7B model achieves only 45.5% accuracy in this task. This may indicate that the training data of the LLaVA-Critic-7B model may not contain such data, leading to a quite poor generalization in this dataset.

Moreover, PaliGemma-3B and ChartGemma-3B fail to follow the format requirements at all, and also unable to evaluate instruction following capability. Finally, the Idefics-9B-Instruct model, even with 9B parameters, achieves poor instruction and format following accuracy.

4.4 Bias Analysis

To assess potential biases in LVLM judges, we analyzed position bias (whether the order of the responses affects judgments) and length bias (whether longer responses are favored). Based on the result presented in Table 3, we find that the Qwen2-VL-7B-Instruct model exhibited the lowest positional bias and length bias. On the contrary, the LLaVA-Next-v1.6-Mistral-7B model showed very high bias in both scenarios, suggesting susceptibility to judge responses based on variations in the position of the responses as well as the length. Surprisingly, the LLaVA-Critic-7B model, which is the best-performing model in terms of judgment accuracy and error distance, demonstrates the highest length bias across all models, indicating a tendency to favor longer answers. We provide an example of the position bias in Figure 5, and an example of the length bias in Figure 6.

4.5 Human Evaluation

In this section, we conduct a human evaluation of the GPT-4o and the LLaVA-Critic-70B models which we used as the reference judge to evaluate the smaller open-source LVLMs. For this purpose, we randomly sample 100 responses generated by Islam et al. (2024) for the Claude-3-Haiku and the Gemini-1-Pro models in OpenCQA and VisText datasets. Then, we ask two human annotators having expertise in NLP and Computer Vision to rate these responses based on our evaluation criteria (e.g., informativeness, relevance, etc.) with references provided for 50% of the data and without any references for rest of the data.

Model	Instruction Following	Format Adherence
Qwen2-VL-2B-Instruct	13.5	78.9
PaliGemma-3B	0.0	0.0
ChartGemma-3B	0.0	0.0
Phi-3.5-Vision-3.8B-Instruct	49.0	83.3
XGen-MM-Phi3-3.8B-Instruct	72.5	97.6
Janus-Pro-7B	73.0	96.7
Qwen2-VL-7B-Instruct	87.0	98.6
InternLM-Xcomposer2d5-7B	54.0	95.9
LLaVA- Next-v1.6-Mistral-7B	27.0	98.9
LLaVA-Critic-7B	45.5	**99.7**
mPLUG-Owl3-7B	**93.5**	98.9
MiniCPM-V-2.6-8B	54.5	90.3
Idefics-9B-Instruct	20.5	35.0

Table 2: Accuracy in terms of Instruction Following Evaluation (evaluated on Chart-Instruct-Eval) and Format Adherence (based on average across all datasets).

Model	Length Bias	Position Bias
Qwen2-VL-2B-Instruct	55.1	71.9
Phi-3.5-Vision-3.8B-Instruct	69.8	59.6
XGen-MM-Phi3-3.8B-Instruct	64.3	79.2
Janus-Pro-7B	27.2	50.6
Qwen2-VL-7B-Instruct	**21.5**	**35.8**
InternLM-Xcomposer2d5-7B	24.5	35.9
mPLUG-Owl3-7B	21.9	42.5
LLaVA-Next-v1.6-Mistral-7B	71.8	77.0
LLaVA-Critic-7B	76.4	39.6
MiniCPM-V-2.6-8B	37.4	45.5

Table 3: Length Bias and Position Bias for different models (results based on average across all datasets). Here, Lower values are better. Models achieving format following accuracy above 50% are only evaluated.

Based on our human evaluation, we find that both annotators' judgments highly correlate with GPT-4o and LLaVA-Critic-70B, with an error distance below 1.0. Interestingly, we find that both annotators have a higher correlation with the open-source LLaVA-Critic-70B model (average error distance with LLaVA-Critic-70B: `0.81`, and with GPT-4o: `0.93`). Therefore, in real-world industrial scenarios where human annotation is costly and closed-source LLMs are not preferred due to privacy concerns in proprietary datasets, the open-source LLaVA-Critic-70B model could be a good alternative for data annotation.

4.6 Ablation Studies

(i) Effect of Reference Type: In this section, we compare the performance variation of different LVLMs in reference-based and reference-free scenarios (see Table 4). LVLMs that achieve more than

Model	With Reference	Without Reference
Qwen2-VL-2B-Instruct	47.4	55.7
Phi-3.5-Vision-3.8B-Instruct	51.6	47.3
XGen-MM-Phi3-3.8B-Instruct	66.8	68.4
Janus-Pro-7B	45.9	47.3
Qwen2-VL-7B-Instruct	66.7	67.8
InternLM-Xcomposer2d5-7B	62.1	67.5
LLaVA-Next-v1.6-Mistral-7B	71.0	73.0
LLaVA-Critic-7B	**74.9**	**75.3**
mPLUG-Owl3-7B	63.5	58.2
MiniCPM-V-2.6	63.2	65.4
Idefics-9B-Instruct	16.6	24.2

Table 4: Judgment Accuracy in comparison to GPT-4o in OpenCQA based on Reference-based (with reference) and Reference-free (without reference) evaluation.

Model	Factual Correctness	Informativeness	Relevancy
Qwen2-VL-2B-Instruct	2.6	1.6	2.0
Phi-3.5-Vision-3.8B-Instruct	1.6	1.3	1.4
XGen-MM-Phi3-3.8B-instruct-r-v1	1.7	1.4	1.6
Janus-Pro-7B	1.4	1.0	1.3
Qwen2-VL-7B-Instruct	0.7	0.4	0.5
InternLM-Xcomposer2d5-7B	1.0	0.8	0.9
LLaVA-Next-v1.6-Mistral-7B	1.7	1.4	1.5
LLaVA-Critic-7B	**0.6**	**0.3**	**0.4**
mPLUG-Owl3-7B	1.1	0.9	1.1
MiniCPM-V-2.6	1.7	1.3	0.9

Table 5: Average Error Distance (compared with LLaVA-70B-Critic) in VisText (L1) for different LVLMs based on various Evaluation Types. Here, lower values indicate better performance.

20% pairwise judgment accuracy in OpenCQA are selected for the analysis. While we find that different LVLMs have a slight change in performance with the presence and absence of references, the performance difference between them based on a paired t-test is not statistically significant ($p > 0.05$). This demonstrates that the open-source LVLMs are robust in both reference-based and reference-free evaluation.

(ii) Effect of Evaluation Criteria: In Table 5, we analyze the performance differences among various LVLMs with an error distance below 2.5 in VisText (L1) across multiple evaluation metrics: (i) informativeness, (ii) relevance, and (iii) factual correctness. While we observe slight performance variations based on the evaluation criteria, the paired t-test demonstrates that these differences are not statistically significant ($p > 0.05$), indicating robust performance across various evaluation measures.

5 Conclusion and Future Work

In this paper, we conducted a comprehensive evaluation of open-source LVLMs as automatic judges for chart comprehension and reasoning tasks. Our analyses revealed that while some open-source LVLMs (e.g., 7B models like LLaVA-Critic, Qwen2-VL, InternLM, and LLaVA-Next) can achieve judgment accuracy (with lower error rates) that is comparable to state-of-the-art closed-source models like GPT-4 or larger open-source models like LLaVA-Critic-70B; other models, such as ChartGemma and PaliGemma, struggle significantly, highlighting variability in their reliability. Despite the promising results of various models, issues like bias and lack of instruction following capability still persist. Therefore, future work should focus on mitigating biases, improving instruction following evaluation capability, alongside ensuring consistency across diverse evaluation criteria by developing a multimodal LLM judge using more recent models (Bai et al., 2025) for chart model evaluation.

Acknowledgments

This research was supported by the Natural Sciences and Engineering Research Council (NSERC) of Canada, the York Research Chairs (YRC) program, and Compute Canada.

Ethical Considerations

The models used for experiments are only used as the judge to evaluate other LVLM-generated responses. Therefore, the LVLM responses do not pose any ethical concerns. Additional compensation for human evaluation is not needed since it was conducted by two authors of this paper.

A Appendix

A.1 Regarding Model and Dataset Selection

We selected popular LVLMs that were released by early 2025, with sizes less than 10B parameters. Although there are many other chart benchmarks currently available (Huang et al., 2024), we selected OpenCQA and VisText since qualitative evaluation is often required in these datasets (Islam et al., 2024).

A.2 Prompts for the LVLM Judge

OpenCQA Pointwise (With Reference)

Suppose, you are a human evaluator. You are required to rate the {Evaluation Criteria} of the answer generated by a model in comparison to the gold reference answer for a given question in the open-ended chart question answering task.

Please provide your response in JSON format with the following keys: (i) Score, (ii) Explanation.

Here, the 'Score' should be between 1 to 5 (inclusive), with the higher score indicating better. Moreover, the value for the "Explanation" key will contain the reason behind your scoring.

You should only provide the response in the required JSON format without any additional text.

In the following, you are first given the question, followed by the gold reference answer. Afterward, you are given the model-generated answer. You are also provided with the chart image as the context for the chart question-answering task.

[Question]

[Gold Reference Answer]

[Model Generated Answer]

`[Chart Image]`

OpenCQA Pairwise (Without Reference)

Suppose, you are a human evaluator. You are given the answers generated by two different models for a given question in the open-ended chart question answering task. Now, your task is to determine which model is better in terms of {Evaluation Criteria}.

Please provide your response in JSON format with the following keys: (i) Model, (ii) Explanation,

Here, the output value for the 'Model' key is the respective model that is better, could be either 'Model A' or 'Model B', or 'Tie' if both models are equally good. Moreover, the value for the "Explanation" key will contain the reason behind your preference.

You should only provide the response in the required JSON format without any additional text.

In the following, you are first given the question. Afterward, you are given the model-generated answers. You are also provided with the chart image as the context for the chart question-answering task.

[Question]

[Model 1 Generated Answer]

[Model 2 Generated Answer]

`[Chart Image]`

VisText L1 Pointwise (With Reference)

Suppose, you are an human evaluator. You are required to rate the {Evaluation Criteria} of the L1 caption describing the aspects of the chart's construction (e.g., chart type and axis labels) generated by a model in the chart captioning task.

Please provide your response in JSON format with the following keys: (i) Score, (ii) Explanation.

Here, the 'Score' should be between 1 to 5 (inclusive), with the higher score indicating better. Moreover, the value for the "Explanation" key will contain the reason behind your scoring.

You should only provide the response in the required JSON format without any additional text such that I can correctly parse the result from your JSON formatted response.

In the following, you are first provided with the gold reference caption. Afterward, you are given the model generated caption. You are also provided with the chart image which was used as the context for the chart captioning task.

[Gold Reference Caption]

[Model Generated Caption]

`[Chart Image]`

VisText L2/L3 Pairwise (No Reference)

Suppose, you are a human evaluator. You are given the captions generated by two different models in the chart captioning task. Now, your task is to determine which model is better based on {Evaluation Criteria}.

Please provide your response in JSON format with the following keys: (i) Model, (ii) Explanation.

Here, the output value for the 'Model' key is the respective model that is better, could be either 'Model A' or 'Model B', or 'Tie' if both models are equally good. Moreover, the value for the "Explanation" key will contain the reason behind your preference.

You should only provide the response in the required JSON format without any additional text such that I can correctly parse the result from your JSON formatted response.

In the following, you are provided with the model generated captions. You are also provided with the chart image which was used as the context for the chart captioning task.

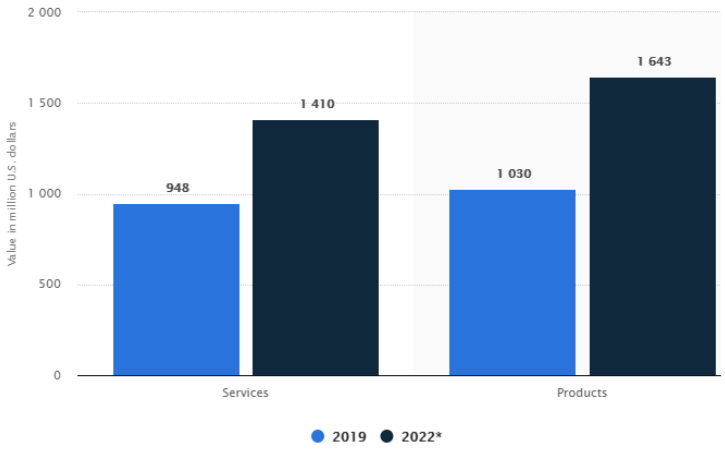
[Model 1 Generated Caption]

[Model 2 Generated Caption]

`[Chart Image]`

A.3 Error Analysis

Some example error cases are demonstrated below.



Prompt:

You are given the responses generated by two different models, each answering the same instruction about a specific chart.
Your goal is to identify which model generated response is better among them.
Below, you will be first provided with the task instruction, followed by the response generated by the Model A, and finally the Model B.
You are also provided with the chart image.
Please generate your response in the JSON format with the following keys: (i) Model, (ii) Explanation.
Here, the output value for the 'Model' key is the respective model that is better, could be either 'Model A' or 'Model B'.
The value for the 'Explanation' key will contain the reason behind your preference.
Task Instruction: After analyzing the chart and extracting the numeric values, generate only a Python code without any comments that prints a solution to the following question: Find the ratio between services and products in 2022 ?
Model A Response:

```
# Define the number of services provided in 2022
services_2022 = 1410
# Define the number of products sold in 2022
products_2022 = 1643
# Calculate the ratio of services to products
ratio = services_2022 / products_2022
# Print the calculated ratio
print(ratio)
```

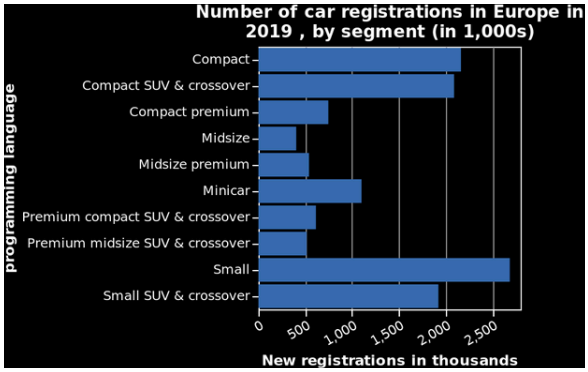
Model B Response:

```
services_2022 = 1410
products_2022 = 1643
ratio = services_2022 / products_2022
print(ratio)
```

ChartGemma:

```
print("Model A")
print("Model B")
```

Figure 3: An example of an error case involves the ChartGemma model being tasked with evaluating the Python code responses generated by two different models and providing a verdict on which one is better. However, instead of following the instructions, the model failed to complete the task correctly and simply returned two print statements as its output (highlighted in red text).



PaliGemma-3b:

Prompt:

Suppose, you are a human evaluator.
You are required to rate the informativeness of the caption generated by a model in the chart captioning task.

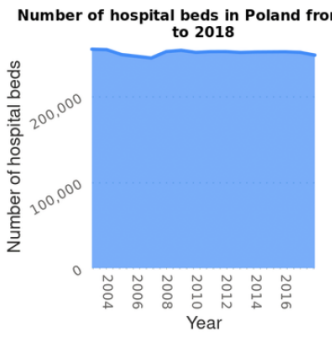
Please provide your response in JSON format with the following keys: (i) Score, (ii) Explanation.
Here, the 'Score' should be between 1 to 5 (inclusive), with the higher score indicating better.
The value for the "Explanation" key will contain the reason behind your scoring.
You should only provide the response in the required JSON format without any additional text such that I can correctly parse the result from your JSON formatted response.

In the following, you are provided with the model generated caption. You are also provided with the chart image which was used as the context for the chart captioning task.
Model Generated Answer: The chart shows the number of new car registrations in Europe by vehicle segment in 2019 , measured in thousands . The largest segment is Compact , with over 2,000 thousand new registrations , followed by Compact SUV & crossover with around 1,500 thousand . The Midsize and Midsize premium segments have the next highest registrations , around 800 thousand and 500 thousand respectively . Smaller segments such as Minicar , Premium compact SUV & crossover , and Premium midsize SUV & crossover range from around 200 thousand to 400 thousand new registrations . The smallest segments are Small and Small SUV & crossover , with under 500 thousand new registrations each . Overall , the chart highlights the dominance of compact and SUV/crossover models in the European car market in 2019 .

Figure 4: An example of an error case involves the PaliGemma-3b model being tasked with evaluating a chart caption generated by another model. Specifically, it was asked to rate the caption on a scale of 1 to 5 based on the 'Informativeness' criterion and to provide an explanation for the rating. However, instead of performing the evaluation correctly, the model hallucinated and repeatedly generated the same line without adhering to the required JSON format. (highlighted in red text).

Model A Generated Caption: The chart depicts the number of hospital beds in a given location over several years . It shows a steady increase in the number of hospital beds from 2004 to 2016 , with the number reaching a peak of around 200,000 beds in 2016 . The chart provides a clear visual representation of the growth in hospital bed capacity over the years covered in the data .

Model B Generated Caption: The number of hospital beds in the United States has remained relatively stable over the past decade . In 2004 , there were 250,000 hospital beds in the United States . By 2016 , this number had only decreased by 1.6 % to 246,000 . This decrease can likely be attributed to the increasing popularity of outpatient care and the use of home health services .



Prompt Version 1:

Suppose, you are an human evaluator.
You are given the captions generated by two different models in the chart captioning task. Now, your task is to determine which model is better by considering the relevancy, conciseness, informativeness, and factual correctness ... ...
Model A Generated Caption: The chart depicts the number of hospital beds ... ...
Model B Generated Caption: The number of hospital beds in the United States ... ...

Prompt Version 2:

Suppose, you are an human evaluator.
You are given the captions generated by two different models in the chart captioning task. Now, your task is to determine which model is better by considering the relevancy, conciseness, informativeness, and factual correctness ... ...
Model A Generated Caption The number of hospital beds in the United States ... ...
Model B Generated Caption: The chart depicts the number of hospital beds ... ...

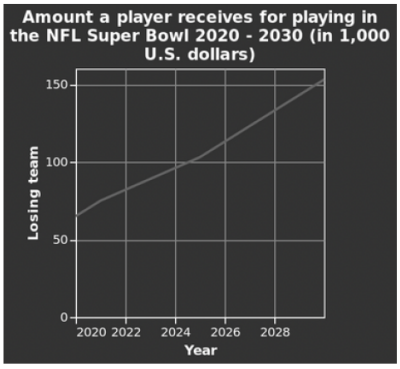
LLaVA-Critic-7B for Prompt Version 1:

"Model": "Model A",
"Explanation": "Model A provides a more accurate and relevant description of the chart. It correctly identifies the steady increase in the number of hospital beds from 2004 to 2016, reaching a peak of around 200,000 beds in 2016. This aligns with the visual representation in the chart. Model B, on the other hand, inaccurately states that the number of hospital beds has remained relatively stable and even mentions a decrease, which is not supported by the chart. Therefore, Model A is more factually correct and informative."

LLaVA-Critic-7B for Prompt Version 2:

"Model": "Model A",
"Explanation": "Model A provides a more accurate and detailed description of the chart. It correctly identifies that the number of hospital beds in the United States has remained relatively stable over the past decade, with a slight decrease from 250,000 in 2004 to 246,000 in 2016. This aligns with the visual data presented in the chart. Model B, on the other hand, inaccurately describes the trend as a steady increase, which is not supported by the chart. Therefore, Model A is more factually correct and relevant to the chart."

Figure 5: An example of an error case for the LLaVA-Critic-7B model which demonstrates position bias by changing its selection of the better caption based on the change in the order of the model generated captions.



LLaVA-Critic-7B:

"Model": "Model A",
"Explanation": "Model A provides a detailed and accurate description of the chart, including specific amounts received by players on both winning and losing teams for each year from 2020 to 2030. This level of detail aligns closely with the information presented in the chart, making it highly informative and factually correct. Model B, while capturing the general trend of increasing compensation, lacks the specificity and accuracy found in Model A s response. Therefore, Model A is better in terms of relevancy, conciseness, informativeness, and factual correctness."

Prompt:

Suppose, you are an human evaluator.
You are given the captions generated by two different models in the chart captioning task. Now, your task is to determine which model is better by considering the relevancy, conciseness, informativeness, and factual correctness of the model generated caption. Ideally, a better quality caption should be concise, factually correct, and relevant to the chart, while also providing high level informative insights of the chart ... ...

Model A Generated Caption: The chart shows the amount of money a player receives for playing in the NFL Super Bowl from 2020 to 2030 . In 2020 , each player on the winning team received $ 150,000 , while each player on the losing team received $ 75,000 . In 2023 , the winning team received $ 157,000 per player , while the losing team received $ 78,500 per player . In 2024 , the winning team received $ 165,000 per player , while the losing team received $ 82,500 per player . In 2025 , the winning team received $ 175,000 per player , while the losing team received $ 87,500 per player . In 2026 , the winning team received $ 185,000 per player , while the losing team received $ 92,500 per player . In 2027 , the winning team received $ 195,000 per player , while the losing team received $ 97,500 per player . In 2028 , the winning team is expected to receive $ 210,000 per player , while the losing team is expected to receive $ 105,000 per player . In 2029 , the winning team is expected to receive $ 220,000 per player , while the losing team is expected to receive $ 110,000 per player . In 2030 , the winning team is expected to receive $ 230,000 per player , while the losing team is expected to receive $ 115,000 per player .

Model B Generated Caption: The chart depicts the amount a player receives for playing in the NFL Super Bowl from 2020 to 2030 . The data shows a steady increase in the compensation over the years , with the amount received starting at around $ 30,000 in 2020 and rising to approximately $ 150,000 by 2030 . The trend indicates a consistent growth in the financial rewards for participating in the prestigious NFL Super Bowl event over the next decade .

Figure 6: An example of an error case for the LLaVA-Critic-7B model which demonstrates length bias by selecting the lengthy caption even though in the given multidimensional prompt, conciseness was one of the criteria for a better caption.

OccuTriage: An AI Agent Orchestration Framework for Occupational Health Triage Prediction

Abstract

Occupational Health (OH) triage is a systematic process for evaluating and prioritising workplace health concerns to determine appropriate care and interventions. This research addresses critical triage challenges through our novel AI agent orchestration framework, OccuTriage, developed in collaboration with Heales Medical[1] . Our framework simulates healthcare professionals' reasoning using specialized LLM agents, retrieval augmentation with domain-specific knowledge, and a bidirectional decision architecture. Experimental evaluation on 2,589 OH cases demonstrates OccuTriage outperforms single-agent approaches with a 20.16% average discordance rate compared to baseline rates of 43.05%, while matching or exceeding human expert performance (25.11%). The system excels in reducing under-triage rates, achieving 9.84% and 3.1% for appointment and assessor type decisions respectively. These results establish OccuTriage's efficacy in performing complex OH triage while maintaining safety and optimizing resource allocation.

1 Introduction

Triage, the systematic prioritization of cases based on urgency and resource constraints, is essential in occupational healthcare delivery. The Royal College of Occupational Therapists advocates for prioritizing referrals through analysis of need levels and resource optimization (Mandelstam, 2005).

1.1 Triage Frameworks in Occupational Health

Structured frameworks have emerged to standardize triage in occupational healthcare. (CARIBE et al., 2020) developed a questionnaire-based algorithm for occupational health nursing, while (Jones and Greenberg, 2015) implemented the TAG-triage approach, reducing assessment time by 72% while maintaining clinical effectiveness. (Sands et al., 2016) created a seven-tier system with defined urgency time-frames.

For complex cases, (Lalloo et al., 2021) established a comprehensive framework with three domains (health, workplace, and biopsychosocial factors) containing 27 specific elements, representing significant advancement over earlier single-dimension models.

1.2 Triage Implementation and Applications

In practice, (Walker-Bone et al., 2020) deployed an effective three-tier RED/AMBER/GREEN system during COVID-19. The 'telephone first' methodology by (O'Reilly and McDonnell, 2020) and (O'reilly and Carr) demonstrated remarkable efficiency, reducing waiting times by 77% and resolving approximately half of consultations remotely.

For specific conditions, (Green et al., 2024) employed symptom questionnaires for post-COVID syndrome, identifying fatigue as the strongest predictor of work inability. For musculoskeletal disorders, (McCluskey et al., 2006) implemented a biopsychosocial approach that significantly reduced absence duration. Notably, (Gorick et al., 2024) found experienced nurses prioritize visual assessment and clinical judgment over algorithms.

1.3 Machine Learning and AI in Triage

Machine learning has transformed healthcare triage. In emergency departments, (Fernandes et al., 2020) showed logistic regression dominated triage Clinical Decision Support Systems. (Jiang et al., 2021) implemented four machine learning models for cardiovascular triage, with XGBoost achieving highest performance. More sophisticated approaches include (Mutegeki et al., 2023)'s interpretable Histogram-Based Gradient Boosting classifier and (Xie et al., 2021)'s Score for Emergency Risk Prediction. In occupational health specifically, (Weng et al., 2020) developed a surveillance system using NLP and logistic regression.

[1]https://www.heales.com/

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1217–1226

Large Language Models (LLMs) have created new triage opportunities. (Uronen et al., 2022) combined supervised BERT-NER and unsupervised query expansion to detect psychosocial risk factors in occupational health checks. (Krastev et al., 2023) proposed a semantic interoperability approach for Occupational Health Assessment Summary. (Kopka et al., 2024)'s RepVig Framework showed LLMs achieved 67.6% accuracy with representative vignettes, performing better on non-emergency cases than emergency cases.

Healthcare-specific LLMs include Med-PaLM Multimodal (Tu et al., 2023), Clinical Camel (Toma et al., 2023), and Asclepius (Kweon et al., 2023). Multi-agent frameworks have emerged for complex triage tasks, with (Lu et al.)'s TRIAGEAGENT utilizing retrieval-augmented generation, achieving up to 18.42% improvement over baselines using GPT-4 (OpenAI et al., 2023). We use LLama[2] and Asclepius[3] to evaluate the performance of our proposed OccuTriage framework against different benchmark tecnhiques.

1.4 Research Gap Addressed

Our review reveals critical gaps in the literature. Traditional triage frameworks remain largely manual, with practitioners preferring clinical judgment over algorithms (Gorick et al., 2024). Current LLM-based systems show variable accuracy depending on case complexity (Kopka et al., 2024). While promising, multi-agent systems like those by (Lu et al.) and (Han and Choi, 2024) focus primarily on emergency departments rather than occupational health settings.

Our research addresses these limitations through a novel AI agent orchestration framework that bridges clinical judgment and algorithmic approaches with: (1) a multi-agent system with specialized AI agents simulating clinical expertise, (2) retrieval augmentation with external knowledge bases, (3) an iterative discussion protocol with safety-prioritized decision rules, and (4) a bidirectional decision architecture enabling comprehensive coverage across multiple triage conditions.

[3] https://huggingface.co/starmpcc/Asclepius-Llama3-8B

2 Methodology

2.1 Problem Setup

Occupational Electronic Health Record (EHR) data comprises referral forms (r) and associated attachments (a) such as medical records and job descriptions. Our dataset is represented as $D = \{M_1, M_2, ..., M_n\}$, where $M_i = r_i + a_i$ for the ith medical record. For each case M_i, we predict two triage outcomes:

1. Appointment triage outcome (Y_i^1): Face-to-face or video appointment

2. Assessor triage outcome (Y_i^2): Appropriate Occupational Health Assessor (nurse or doctor)

2.2 Retrieval Augmentation with External Database

To enhance interpreting complex medical terminologies in referral forms, we augment content with information from external sources including job descriptions, medical terminology explanations, and medication details.

Knowledge Base Creation. We incorporate knowledge from diverse external sources into text representation format to enable semantic-based retrieval, represented as $E = \{k_1, k_2, ..., k_m\}$, where m is the total number of text vectors in the corpus. Our knowledge base integrates two specialized resources: the NCI Thesaurus providing comprehensive biomedical terminology with cancer-related clinical and molecular information (Sioutos et al., 2007), and O*NET OnLine (National Center for O*NET Development, 2025) supplying detailed occupational information across multiple dimensions. This integration enables more nuanced semantic understanding and improves domain-specific information retrieval in biomedical and occupational contexts.

Document Anonymization. We employ LLMs to detect and anonymize personal information in unstructured data following recent advances in adversarial anonymization techniques (Staab et al.). We represent the anonymized version of case M_i as M_i'.

Corpus Embedding. Following (Cheng et al., 2023), we use Dragon (Lin et al., 2023), a dual encoder model with strong cross-domain performance, as our retriever. We use the passage encoder E_p to encode passages from E, and the query en-

coder E_q during runtime to retrieve the relevant results.

Medical Entity Extraction. We leverage LLMs to extract medical entities, as they better understand contextual nuances and recognize specialized terminology in non-standard formats.

Medical Document Summarizer. The Summarizer component (S) processes both anonymized records and retrieved knowledge to produce comprehensive case representations. For each anonymized record M_i', it generates a condensed representation $S_i = LLM(M_i', k_i')$, where k_i' represents relevant knowledge retrieved from E.

Information Retrieval. We encode medical entities using E_q and retrieve the most relevant information (top-k, where k=1) from E_p.

2.3 AI Agent Orchestration Framework

Our framework simulates triage rules practiced by Heales Medical with heterogeneously orchestrated agents divided into two crews, each supervised by dedicated chat managers. Crew 1 is managed by C_M^1 and consists of agents A_1 and A_2, while Crew 2 is managed by C_M^2 and comprises agents A_3 through A_8. Figure 1 illustrates our approach to Occupational Health (OH) Triage using multiple LLM agents.

2.4 System Overview

We constructed our triage agent-based framework following standardized triage protocols developed by expert clinicians at Healthcare Provider. Our framework implements a sequential processing pipeline beginning with LLM-based anonymization of clinical records M_i, followed by a two-stage information enrichment process: (1) extraction of medical entities and occupation-related information, and (2) comprehensive information summarization, producing condensed case representations S_i. These are directed to our dual-channel triage system managed by specialized Chat Managers C_M^1 and C_M^2.

C_M^1 coordinates Crew_1 to analyze communication difficulties and workplace assessment requirements for appointment modality decisions. Concurrently, C_M^2 orchestrates Crew_2 to evaluate specialized case characteristics for healthcare provider assignment. Specifically, Crew_2 identifies critical factors including substance abuse (A_3), job-related safety concerns (A_4), disciplinary action issues (A_5), mental health conditions (A_6), infectious diseases (A_7), and RIDDOR[4]-related cases (A_8).

Table 1: Distribution of Medical Categories in the Dataset

Category	Total Count	Percentage
Mental Health	888	34.1%
Musculoskeletal	770	29.6%
Neurological	174	6.7%
Cardiovascular	133	5.1%
Gastrointestinal	124	4.8%
Genitourinary	109	4.2%
Respiratory	91	3.5%
Oncology	83	3.2%
ENT and Sensory	68	2.6%
Infectious Disease	41	1.6%
Pregnancy	29	1.1%
Other	79	3.0%

Iterative Discussion. Our framework implements five consecutive discussion iterations among specialized agents for each case, employing majority voting to determine the final recommendation.

Decision Rules. We employ a *safety-prioritized protocol* where if any agent in Crew_1 recommends face-to-face consultation, the case defaults to an in-person appointment. Similarly, if any agent in Crew_2 suggests physician consultation, the case is assigned to a doctor rather than an alternative provider.

Our framework employs a multi-dimensional approach: distributed parallel assessment (horizontal dimension) where specialized agents concurrently evaluate distinct clinical aspects, and temporal iterative refinement (vertical dimension) consisting of five sequential deliberation cycles.

Early Stopping Mechanism. We terminate agent deliberation after three consistent decisions from an individual agent, as the majority outcome in a five-iteration sequence is determined after three identical decisions.

3 Experiments

3.1 Experiment Setups

Dataset. We conducted experiments using a comprehensive private occupational healthcare dataset from Heales Medical, comprising 2,589 clinically diverse cases. The distribution of medical categories is detailed in Table 1. Our preliminary investigation employed a transformer-based model with

[4] https://www.hse.gov.uk/riddor/

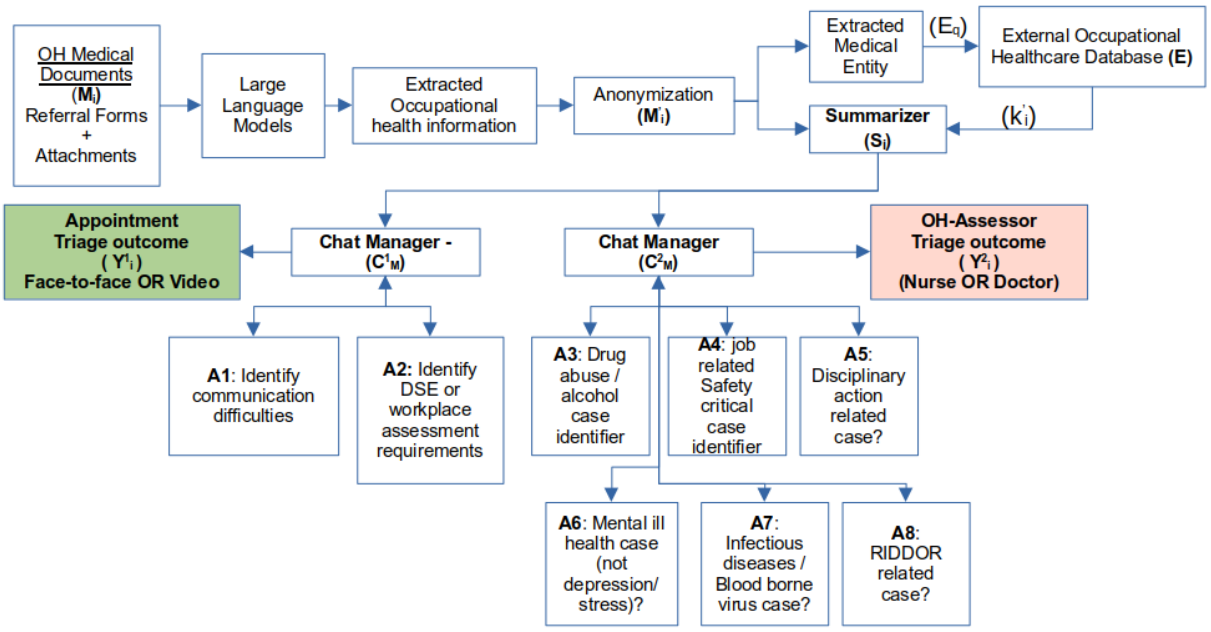

Figure 1: Overview of our **OccuTriage** orchestration framework for occupational healthcare multi triage prediction, developed in collaboration with Heales Medical . The framework integrates referral forms, medical records, and external knowledge bases, utilizes multiple specialized LLM agents to perform comprehensive analysis and generate accurate triage recommendations.

a standard data partitioning protocol, yielding moderate F1-scores of 63% for assessor type prediction and 55% for appointment modality classification. These limitations stemmed from insufficient training data volume and architectural constraints in learning from sparse, unstructured clinical information.

Implementation Details. We implement Llama3.1 8B and Llama3.2 13B vision models by (Team and Meta, 2024) deployed using Text Generation Inference engine on a Linux server with four Nvidia H100 GPUs. Llama3.2 13B was utilised to extract information from case related pdf documents. We use temperature 0.7, top_p 0.95, and repetition_penalty 1.0 for inference. Our agent framework uses Microsoft's Autogen[5] for multi-agent interactions.

Evaluation Metrics. Following (Lu et al.), we evaluate performance using discordance rate as our primary metric, supplemented by under-triage and over-triage rates (Table 2). Under-triage occurs when patients receive insufficient care, creating potential safety risks. Over-triage represents resource inefficiency through unnecessary allocation of higher care levels. While total discordance measures overall triage accuracy, under-triage poses the greater clinical risk.

[5] https://microsoft.github.io/autogen/

Table 2: Triage discordance metrics.

Term	Definition	Formula
Undertriage	Lower level of care than clinically needed	$\frac{\text{Undertriage cases}}{\text{Total cases}} \times 100\%$
Overtriage	Higher level of care than clinically needed	$\frac{\text{Overtriage cases}}{\text{Total cases}} \times 100\%$
Discordance	Total incorrect triage decisions	$\frac{\text{Under + Over}}{\text{Total cases}} \times 100\%$

Baselines. We compared our proposed OccuTriage framework against several baseline configurations: a single LLM agent without enhancements, progressively adding Chain of Thought (CoT) reasoning and Retrieval-Augmented Generation (RAG).

3.2 Main Experimental Results

Table 3 presents a comprehensive comparison of our OccuTriage framework against baseline configurations and human expert performance.

The single-agent LLM baseline without enhancements demonstrates substantial discordance rates, with Llama and Asclepius models achieving average discordance rates of 45.38% and 43.05% re-

Table 3: Performance comparison of different experimental configurations for occupational health triage prediction using Llama3.1 and Asclepius LLM models. Results show discordance metrics (%) for both appointment type and OH assessor type prediction tasks. Lower values indicate better performance.

Configuration	Model	Appointment Type			OH Assessor Type			Average
		Under	Over	Disc.	Under	Over	Disc.	Disc.
1-Agent LLM (No RAG, few shot or CoT)	Llama	22.54	26.21	48.75	7.0	35.0	42.0	45.38
	Asclepius	19.82	27.18	47.00	6.8	32.3	39.1	43.05
1-Agent LLM + RAG	Llama	18.65	25.10	43.75	5.9	30.2	36.1	39.93
	Asclepius	15.40	22.10	37.50	6.1	26.4	32.5	35.00
1-Agent LLM + Few-shot (3)	Llama	16.32	27.43	43.75	8.5	31.0	39.5	41.63
	Asclepius	16.95	24.05	41.00	7.2	32.8	40.0	40.50
1-Agent LLM + CoT	Llama	14.85	19.65	34.50	5.3	28.7	34.0	34.25
	Asclepius	14.25	20.75	35.00	5.7	24.8	30.5	32.75
OccuTriage (our framework)	Llama	**9.52**	15.91	25.43	**2.9**	**14.2**	**17.1**	21.27
	Asclepius	9.84	**12.48**	**22.32**	3.1	14.9	18.0	**20.16**
Human Expert		11.84	14.38	26.22	9.0	15.0	24.0	25.11

spectively. This indicates that unaugmented LLMs struggle with the complex decision-making required for occupational health triage.

When incorporating retrieval augmentation (RAG), performance improves significantly, reducing average discordance to 39.93% (Llama) and 35.00% (Asclepius). This improvement highlights the importance of domain-specific knowledge integration.

Few-shot learning (3 examples) yields modest improvements over the baseline, with average discordance rates of 41.63% (Llama) and 40.50% (Asclepius). Chain of Thought (CoT) reasoning demonstrates substantial performance gains, reducing average discordance to 34.25% (Llama) and 32.75% (Asclepius).

Our proposed OccuTriage framework significantly outperforms all baseline configurations, achieving an average discordance rate of 21.27% with Llama and 20.16% with Asclepius. Notably, OccuTriage exceeds human expert performance (25.11% average discordance).

The most clinically significant finding relates to under-triage rates, where OccuTriage achieves 9.52% (Llama) and 9.84% (Asclepius) for appointment type decisions, and 2.9% (Llama) and 3.1% (Asclepius) for assessor type decisions. These results are particularly important as under-triage represents potential safety risks.

When analyzed by triage decision type, assessor type prediction demonstrates consistently lower discordance rates than appointment type prediction across all configurations. This superior performance can be attributed to our comprehensive six-agent architecture in Crew 2, which effectively captures the multifaceted clinical factors influencing provider selection.

The consistent performance advantage of Asclepius over Llama3.1 across most configurations confirms the value of domain-specific model training as established by (Kweon et al., 2023).

4 Case Study

We evaluated OccuTriage on 2,589 occupational health cases from Heales Medical, comparing its performance against single-agent LLM baselines and human experts. The framework demonstrated superior triage accuracy across all metrics, achieving an average discordance rate of 20.16% with the Asclepius model, compared to 25.11% for human experts.

The progression from baseline configurations through our multi-agent approach showed steady improvement in triage accuracy. Most significantly, OccuTriage reduced under-triage rates for assessor type prediction to 2.9% (Llama3.1) and 3.1% (Asclepius), substantially outperforming human experts' 9.0% rate.

Our safety-efficiency tradeoff analysis demonstrates OccuTriage's optimal balance between under-triage (safety risk) and over-triage (efficiency risk). Configuration progression consistently moved toward the ideal performance region, with the final framework achieving both lower under-triage and over-triage rates than human experts.

Statistical analysis revealed that OccuTriage per-

forms better on assessor type prediction than appointment type prediction across all configurations. The framework achieved discordance rates of 22.32% and 18.0% for appointment and assessor type predictions respectively using Asclepius, compared to 26.22% and 24.0% for human experts.

While domain-specific Asclepius models generally outperformed Llama3.1, the performance gap varied across configurations. The most substantial improvement occurred with RAG integration (4.93% average discordance reduction), suggesting domain-specific models significantly enhance knowledge-intensive operations.

Clinician feedback confirms that OccuTriage's improved accuracy justifies its modest computational overhead, particularly as reduced under-triage directly impacts patient safety while decreased over-triage optimizes resource allocation. These findings demonstrate OccuTriage's potential for improving occupational health triage through its specialized agent architecture and safety-prioritized decision protocols.

5 Conclusion

This paper presents OccuTriage, a novel AI agent orchestration framework for occupational health triage prediction. Our approach employs specialized LLM agents, retrieval augmentation, and a bidirectional decision architecture to simulate clinical reasoning. Experimental evaluation on 2,589 occupational health cases demonstrates that OccuTriage outperforms single-agent approaches with a 20.16% average discordance rate compared to baseline rates of 43.05%, while matching or exceeding human expert performance (25.11%).

The most significant finding is OccuTriage's ability to reduce under-triage rates to 9.84% and 3.1% for appointment and assessor type decisions respectively, substantially outperforming human experts (11.84% and 9.0%). This improvement is critical for patient safety, as under-triage represents inadequate care allocation.

Our multi-agent architecture demonstrates particular efficacy in assessor type prediction, with each agent focusing on distinct clinical domains—substance abuse, safety concerns, disciplinary issues, mental health, infectious diseases, and RIDDOR-related cases. This specialized focus enables robust consensus formation and precise decision-making, establishing OccuTriage as an effective tool for complex healthcare triage tasks.

The framework's safety-prioritized protocol ensures that high-risk cases default to face-to-face consultations and physician evaluations, aligning with clinical safety practices. The early stopping mechanism optimizes computational efficiency without compromising decision integrity.

In comparison with existing approaches, OccuTriage addresses the limitations identified in previous work by bridging clinical judgment and algorithmic approaches, incorporating domain-specific knowledge, and implementing a multi-dimensional decision framework specifically designed for occupational health settings.

These results establish OccuTriage's efficacy in performing complex occupational health triage while maintaining safety and optimizing resource allocation, with potential applications across diverse healthcare settings.

6 Extended Analysis and System Evaluation

6.1 Error Analysis and Performance Patterns

Analysis of the remaining 20.16% discordance cases reveals specific patterns that inform system optimization strategies. The residual discordance cases primarily cluster around complex multi-comorbidity scenarios where manual clinical judgment traditionally varies among practitioners. The specialized Mental Health Agent (A_6) systematically applies consistent diagnostic criteria across cases, with musculoskeletal cases (29.6% of dataset) showing improved consistency through structured decision protocols. Category-specific analysis reveals no systematic classification failures in any diagnostic domain.

Complex cases involving rare medical conditions or non-standard terminology usage in referral documentation present ongoing challenges that contribute to remaining discordance cases. Knowledge base retrieval with NCI Thesaurus and O*NET integration enables nuanced interpretation of medical terminology and occupational context, though these edge cases highlight areas for knowledge base expansion.

6.2 Computational Architecture Analysis

Model-specific analysis reveals distinct output formatting characteristics that impact system integration. Asclepius consistently generates responses in paragraph format with reasoning rather than structured decision outputs, necessitating additional pro-

cessing overhead through a secondary Llama-based sentiment analysis layer to extract binary triage decisions. This architectural requirement contrasts with Llama models that directly produce structured classifications without requiring post-processing.

The sentiment analysis overhead adds processing complexity to Asclepius-based implementations, requiring additional model invocations per case to convert paragraph-format clinical reasoning into structured binary classifications. Despite this computational trade-off, the clinical accuracy benefits of the domain-specialized Asclepius model justify the additional processing requirements.

Runtime performance metrics demonstrate practical efficiency for clinical deployment. Processing time per case averages approximately 12 seconds, representing acceptable computational overhead for non-emergency occupational health triage. The early stopping mechanism optimizes efficiency by terminating agent discussions after achieving consensus, while the dual-crew architecture enables concurrent evaluation, maximizing resource utilization through parallel processing.

6.3 Clinical Workflow Integration

The framework demonstrates robust integration capabilities with existing healthcare information systems. Structured JSON-formatted outputs maintain compatibility with Electronic Health Record systems, while comprehensive audit trails preserve complete decision reasoning for clinical governance compliance. The system successfully processes typical occupational health referral volumes without performance degradation.

Clinical workflow compatibility extends to professional oversight capabilities, with complete reasoning chains available for practitioner review and quality assurance processes. The safety-prioritized protocol preserves clinical discretion, allowing healthcare providers to override system recommendations when clinical judgment necessitates alternative decisions.

6.4 Multi-Agent Discussion Protocol Effectiveness

Multi-agent discussion protocols prove essential for complex case resolution, with iterative consensus mechanisms resolving borderline cases that challenge single-agent approaches. The six-agent architecture in Crew_2 demonstrates particular effectiveness for assessor type predictions, achieving 18.0% discordance compared to human expert performance of 24.0%. Analysis reveals that simple cases maintain high accuracy matching human expert performance, while complex multi-comorbidity cases represent the primary source of remaining discordance, where the framework's structured approach provides more consistent results than traditional manual assessment methods.

Processing efficiency considerations support integration into existing healthcare information systems, where occupational health decisions occur within consultation scheduling timeframes rather than emergency response requirements. The computational overhead remains justified by the substantial accuracy improvements demonstrated across all experimental configurations.

Ethical Considerations

This research was conducted with a strong commitment to ethical standards and data protection regulations. All personal data collected and processed during this study adhered to the principles outlined in the General Data Protection Regulation (GDPR) of the European Union. The study utilized data from the National Cancer Institute (NCI) Thesaurus, and all usage complied with the terms specified in the NCI Thesaurus Data Use Agreement[6]. Data from ONET OnLine were incorporated into the research, following the guidelines set forth in the ONET Privacy[7] and Security Statement.

Acknowledgements

The authors would like to acknowledge the support of the Knowledge Transfer Partnership (KTP) programme, which facilitated this research through collaborative partnership between the University of Hertfordshire and Heales Medical. This work was conducted under KTP project number 12121, with partial funding provided by Innovate UK[8]. The KTP programme's objectives of facilitating knowledge transfer, enhancing technical and business skills, and strengthening industry-academia collaboration were instrumental in the successful completion of this research. We extend our gratitude to all personnel from both the academic and industrial partners who provided supervision and guidance throughout the project duration.

Abstract

With the release of R1, a publicly available large reasoning model (LRM), researchers commonly train new LRMs by training language models on R1's long chain-of-thought (CoT) inferences. While prior works show that LRMs' capabilities can be reproduced through direct distillation, the continued reliance on the existing models (e.g., R1) remains a critical limitation in advancing the field. As a first step toward independent LRM development, this paper explores the possibility of constructing a long CoT dataset with LLMs that are not trained for inference-time scaling. To this end, we present the Long CoT Collection, a dataset of 100K CoT rationales annotated using existing short CoT LLMs. We develop a pipeline that induces o1's novel reasoning strategies into short CoT LLMs, enabling them to think longer and introducing controllability over the thought budget to better manage the overthinking problem. Our extensive analyses validate that our dataset achieves quality comparable to—or slightly below—R1. Furthermore, our experiments demonstrate that training on our dataset not only strengthens general reasoning skills, but also provides a strong foundation for reinforcement learning—models initialized on our data achieve 2-3x larger gains with RLVR. We make the codes, datasets, and models publicly available at LINK.

1 Introduction

Large Reasoning Models (LRMs), exemplified by the o-series (OpenAI, 2024), have shown groundbreaking performance in various reasoning tasks with test-time scaling (i.e., generating extremely long chain-of-thought (CoT) rationales). (Guan et al., 2025; Zhang et al., 2024b; Yu et al., 2025). However, their closed nature presents significant challenges—its high API costs and safety issues limit real-world applications (Hendrycks et al., 2022), while the closed-source approach potentially prohibits academic progress in the field.

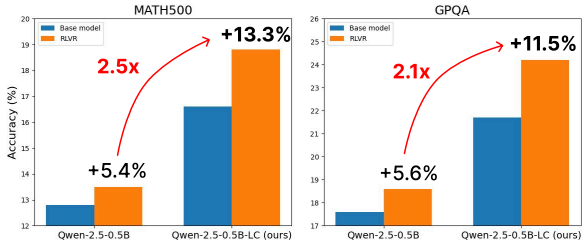

Figure 1: Comparison of RLVR performance between the base model (Qwen-2.5-0.5B) and the model trained on the Long CoT Collection (Qwen-2.5-0.5B-LC) on MATH500 and GPQA.

To address these issues, DeepSeek-AI et al. (2025) release an open-source version of o1 and detail their methodology for building R1. While the benefits of reinforcement learning with verifiable reward (RLVR) have been previously demonstrated (Lambert et al., 2024), they introduce a key innovation by tackling the cold-start instability in RL training for Short CoT LLMs. Finetuning on a carefully curated Long CoT dataset to explicitly teach reasoning structures serves as a critical step to enable the model to acquire the foundational reasoning skills before RL. Building on this insight, subsequent works have shown that simply collecting R1's outputs to construct a Long CoT dataset and fine-tuning LLMs on it can lead to dramatic improvements (Labs, 2025; Team, 2025b). Furthermore, Yeo et al. (2025) provide a detailed analysis of the role of RLVR following this finetuning stage.

Yet, despite these advancements, an important gap remains: the cold-start problem itself has not been fully demystified. While R1's Long CoT dataset serves as a critical ingredient, the exact mechanisms for creating such data have remained unclear. In this work, we investigate whether it is possible to construct Long CoT data from the short

July 28-30, 2025

CoT responses of LLMs that have been trained to produce only concise rationales. Instead of directly collecting LRMs' completions, we built a simple pipeline that enables LLMs to generate long CoT in a step-by-step manner with only a small guidance from LRMs. To allow LLMs to annotate long CoT, we begin by creating a seed dataset of 1K instances, capturing o1's reasoning flow that reflects its novel reasoning strategies. Then, we generate the reasoning flow on the new question and expand it to long CoT with short CoT LLMs (e.g., GPT-4o) in a step-by-step manner. The resulting collection of 100K instances serves as a comprehensive training resource, allowing base LLMs to learn to think longer while incorporating diverse reasoning strategies characteristic of o1. Since this collection process offers controllability over the thought budget, it has a strong advantage in addressing one of the major issues with LRMs: overthinking—generating an unnecessarily large number of tokens for simple problems.

To further validate our approach, we conduct in-depth analyses of the quality of our dataset. Despite being generated by short CoT LLMs, the rationales in our dataset demonstrate reasoning flows and strategies that nearly match the quality of R1 in terms of reasoning flow, showing only slightly lower performance in other criteria. In addition, the generated rationals contain rich reasoning triggers (e.g., "Wait" and "To verify") that help explore diverse reasoning paths and enhance accuracy. Our thought budget analysis shows that short CoT LLMs, guided by the example reasoning flow, effectively allocate their computational resources in alignment with state-of-the-art reasoning models.

Through extensive experiments, we demonstrate that the Long CoT Collection provides an effective foundation for initializing SFT models for reinforcement learning (RL). Best-of-n sampling comparisons show that models trained on our dataset consistently outperform the base models, demonstrating strong potential when optimized for outcome-based rewards. Evaluations on GPQA (Rein et al., 2023) and MMLU-Pro (Wang et al., 2024b) further highlight that training on our dataset enhances reasoning capabilities across general domain tasks. Notably, initializing policies with our dataset before RL leads to 2-3x greater performance improvements, demonstrating out collection's strong potential to accelerate and stabilize downstream learning (Figure 1).

2 Related Work

Inference-time Scaling. Recent research has demonstrated that scaling inference-time improves efficiency and overall reasoning quality by increasing the number of tokens, compared to traditional scaling laws such as increasing model parameters or dataset volumns (Brown et al., 2024; Snell et al., 2024). This can be achieved by sampling many reasoning paths (e.g., Best-of-N (Snell et al., 2024) and MCTS (Zhang et al., 2024a)) and using a verifier or voting mechanism to pick the correct solution (e.g., self-consistency) (Liang et al., 2024). Furthermore, OpenAI (2024); DeepSeek-AI et al. (2025) explore training LLMs to generate a long CoT, similar to how humans handle complex tasks, which often involve self-correction or verification before arriving at a final answer. This shift towards deliberative reasoning makes LLMs more transparent, interpretable, and adaptable in complex decision-making scenarios (Yeo et al., 2025).

Large Reasoning Models and Datasets. Since the success of OpenAI's o1 model (OpenAI, 2024), many studies have attempted to replicate o1-like reasoning as open-source models (Team, 2024, 2025a; Muennighoff et al., 2025b). Recent studies emphasize the importance of the dataset used for initializing these LRMs (Xu et al., 2025; Muennighoff et al., 2025b; Ye et al., 2025). Notably, DeepSeek-AI et al. (2025) demonstrated that introducing a brief supervised fine-tuning (SFT) stage—where the model is "cold-started" with a few thousand high-quality CoT examples—leads to a more stable and efficient RL stage. High-quality SFT datasets for reasoning are thus a key ingredient for these models, yet current public datasets remain limited. To compensate, researchers have begun curating their own reasoning corpora (Guan et al., 2025; Xu et al., 2025; Pang et al., 2025; Ye et al., 2025). To address this critical gap, we introduce the Long CoT Collection, a large-scale dataset specifically designed to initialize models for complex reasoning tasks through supervised fine-tuning.

Reinforcement Learning for Reasoning. Reinforcement learning with human feedback (RLHF) has become a dominant paradigm for aligning LLMs to human preferences (Ouyang et al., 2022; Bai et al., 2022; Touvron et al., 2023). In RLHF, a reward model that learns human preference guides the policy to produce responses that humans would rate highly (e.g., helpful and harmless re-

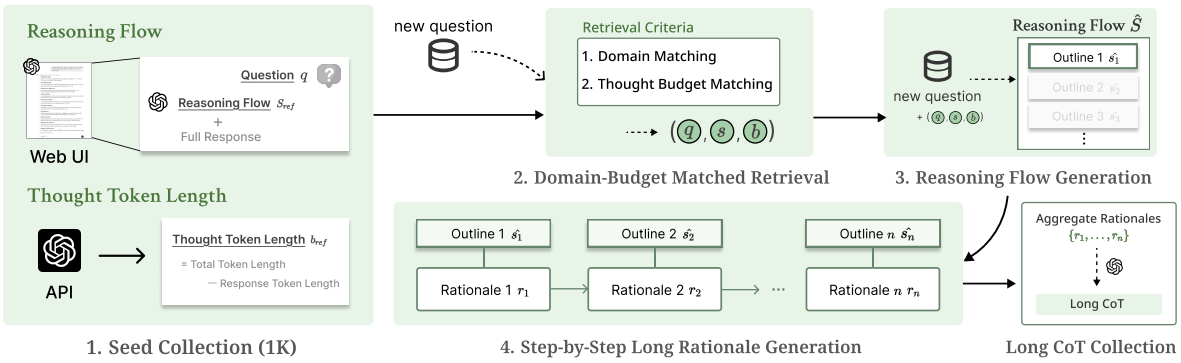

Figure 2: Overview of our data construction pipeline. First, we collect an 1K seed dataset of reasoning flow and thought token length (1). Using it as a demonstration, we annotate long CoT rationales on new questions and scale it up to 100K data points (2-4).

sponses) (Zhu et al., 2023). However, Lambert et al. (2024) have pointed out that relying on a learned reward model can introduce instability in the RL process. To tackle this, researchers are turning to RLVR as a more grounded alternative for reasoning domains (Lambert et al., 2024; DeepSeek-AI et al., 2025). The idea is to focus on objective, checkable outcomes rather than learning a proxy for human preferences, providing rewards only when its output is correct.

3 The Long CoT Collection

In this section, we present the Long CoT Collection, a dataset for learning LRMs' emergent reasoning behavior. To allow more openness and controllability of the data collection process, we investigate whether long CoT data can be annotated by short CoT LLMs. Our data collection process begins by collecting 1K demonstrations that capture LRMs' reasoning flow (Section 3.1), then generating 100K long CoT data using short CoT LLMs guided by the seed demonstrations (Section 3.2). The overall construction process is illustrated in Figure 2.

3.1 Collecting Teacher Demonstrations

A key challenge in building long CoT datasets with short CoT LLMs is allowing them to generate long rationales with coherence. To address this, we first collect a seed dataset with o1 that reflects the novel reasoning process of LRMs.

3.1.1 Reasoning Flow Annotation

Reasoning flow S is an overview of the reasoning process that consists of a sequence of outlines $\{s_1, s_2, ..., s_n\}$ for each reasoning step. It contains crucial information about the reasoning process and how the logical steps flow from the initial problem understanding to the final conclusion. We manually collect reference reasoning flow S_{ref} from ChatGPT website, using the question q from 1K reasoning-focused instructions from the magpie-reasoning-V1 dataset (Xu et al., 2024). In addition, our dataset includes thought budget b_{ref} (i.e., the number of thought tokens used) of o1 by calculating the difference between the total completion token count and the number of tokens in the returned response, using the OpenAI API. As a result, we collect 1K seed dataset $\mathcal{D}_{ref} \in \{q, S_{ref}, b_{ref}\}$ that will be used in Section 3.2. We show the distribution of the title of the reasoning outline in Figure 3.

3.2 Annotating Long CoT with Indirect Guidance from Teacher

Using the 1K seed dataset as our foundation, we expand it to 100K data. Since short CoT LLMs struggle to maintain coherence during extended test-time computing, we breakdown the reasoning into three steps to enable step-by-step generation of long CoT rationales.

3.2.1 Reasoning Flow Retrieval

Each question has its own reasoning procedure to reach the answer. Thus, for the new question q, we dynamically retrieve demonstrations (q, S_{ref}, b_{ref}) from our seed dataset $\mathcal{D}_{ref}$ to teach LLMs to generate reasoning flow S with in-context learning. The following aspects are considered for the retrieval: **(1) Domain matching**: Problems in the same or similar domain are highly likely to share a common reasoning process. For example, in arithmetic reasoning, o1 tends to verify its calculation to ensure the correct answer. We use the primary domain and sub-domain in the magpie-V1-reasoning dataset to calculate the domain matching score (Xu et al., 2024). **(2) Thought budget control**: To align with

Figure 3: The top 15 most common root verbs and their top 3 direct noun objects in the collected reasoning flow.

reference LRMs, the thought budget is controlled by retrieving reasoning flows of similar length for demonstration. We measure this similarity using $1 - \left|\frac{\min(x,y)}{\max(x,y)} - 1\right|$, where x and y represent the reference and candidate budgets, respectively. The heatmap of this similarity function is in Figure 13.

3.2.2 Reasoning Flow Generation

The retrieved demonstrations teach LLMs, which is GPT-4o in our experiment, to imagine LRMs' reasoning behavior at a higher level. Without the demonstration, we find that LLMs only stick to a linear thinking process, where the reasoning proceeds in one direction and does not include LRMs' novel reasoning strategies, such as verification and exploration of diverse solutions. LLMs generate reasoning flow $\hat{S}$ on the new question, given the retrieved demonstration. Specifically, they first predict the expected number of outlines $|S|$ and generate a sequence of reasoning outlines that emulates the higher-level reasoning patterns observed in the retrieved demonstrations.

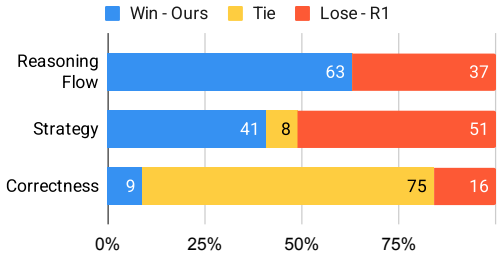

Figure 4: Head-to-head comparison of the generated CoT quality with the R1 output (Ye et al., 2025).

3.2.3 Step-by-step Long CoT Generation with Reasoning Flow

Using the generated reasoning flow $\hat{S}$ as guidance, LLMs generate long CoT rationale step-by-step. Specifically, for each step $\hat{s}_i$ in $\hat{S}$ LLMs generate rationales r_i based on the given previous reasoning $\{r_k\}_0^{i-1}$, the current flow step $\hat{s}_i$, and the next flow step $\hat{s}_{i+1}$. When the summary steps are all consumed, the LLMs generate the final solution based on the reasoning. At last, the reasoning steps and the final answer are aggregated as a sequence.

3.2.4 Correctness Filtering

Lastly, we filter out the rationales that results in wrong answers, as training on incorrect rationales might harm their original reasoning capability. Specifically, we simply ask GPT-4o to validate the answer given the reference answer and the generated answer span. This filtering results in 76% instances with correct answer prediction.

4 Dataset Analyses

4.1 High Quality

We focus on three important aspects; (1) **Reasoning Flow**: The logical progression and coherence of steps in the solution process, measuring how naturally one step leads to the next. (2) **Reasoning Strategy**: The specific techniques and approaches employed to break down and solve problems, such as the selection of relevant mathematical tools or problem-solving methods. (3) **Correctness**: The accuracy of each reasoning steps.

We compare our method with a widely used method for long CoT data generation which collects the outputs from the existing LRMs. For a fair comparison, we sample 100 questions from the Long CoT Collection for which R1-generated solutions have the correct answer. Following the finding that stronger policy models can be used for trajectory scoring (Wang et al., 2024a), we use

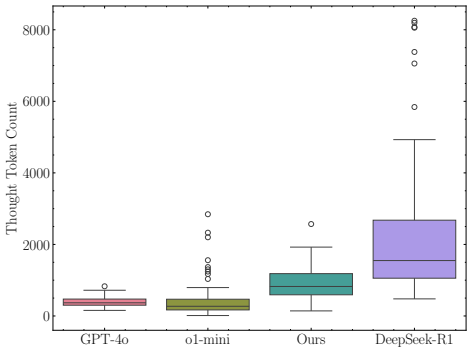

Figure 5: Comparison of the number of reasoning tokens used by each model.

the state-of-the-art LRM, o3-mini, as our evaluator. Figure 4 shows that the rationales from the Long CoT Collection demonstrate better reasoning flow, and while showing slightly weaker strategy and correctness, they remain competitive.

4.2 Efficient Thought Budget Allocation

Allocating the proper budget for thinking is an important issue (Wang et al., 2025). LRMs tend to use too many thought tokens for easy problems (i.e., overthinking), which leads to a huge amount of computational cost. To evaluate the efficiency in thought token allocation, we analyze the rationale lengths and compare them against other LRMs and GPT-4o, the LLM used in constructing our dataset. Specifically, we randomly sample 100 instances from the Long CoT Collection and annotate the rationales with each model. As Figure 5 indicates, simple CoT prompting on GPT-4o rarely generates rationales longer than 1,000 tokens, which suggests that naive prompting on GPT-4o is hard to use for constructing long CoT datasets. In addition, R1 uses significantly more thought tokens than o1-mini, which results in overthinking when models are trained on its outputs.

5 Effect of the Long CoT Collection

As demonstrated in prior works (DeepSeek-AI et al., 2025; Yeo et al., 2025), the training of LRMs typically follows a two-phase approach: first, imitation learning to master long-form CoT reasoning, followed by RL to enhance reasoning accuracy. In this section, we investigate the impact of training LLMs on our dataset from two perspectives: its effectiveness as a starting point for RL and its actual impact on the RL training phase.

5.1 A Reliable Starting Point for RL

Setup. RL for inference-time scaling includes sampling trajectories from the policy model and updating the policy based on calculated rewards. In such sparse reward settings, the quality of the initial policy model is critical—if the model rarely generates high-reward trajectories at the start, the learning signal may be too weak for effective training. To assess the potential of our initial policy model, we evaluate its performance using best-of-n (BoN) sampling, which reveals the model's capacity to generate correct solutions when allowed multiple attempts. We assess our model on mathematical reasoning benchmarks, as they widely used for RL to elicit inference-time scaling. We choose two challenging benchmarks, MATH-500 (Lightman et al., 2023) and AIME24 (of America, 2024). We use Llama-3.1-8B-Instruct (Dubey et al., 2024) and Qwen2.5-7B-Instruct (Qwen et al., 2024) as our base model. We train them on our dataset, and the full hyperparameters are in Appendix B.2.

Results. Figure 6 shows BoN results with two base models. We measure Pass@N (N=1,2,4,8,16 and 32), where a set of N samples is considered correct if at least one sample includes the ground-truth answer. On Llama-3.1-8B-Instruct, we observe notable improvement on both benchmarks, consistently across different N. Meanwhile, our Qwen2.5-7B-LC improves performance given large N (e.g., 16 or 32), while the performance of Qwen2.5-7B-Instruct quickly saturates. This shows that our SFT training recipe enables the model to explore more diverse responses and thus leads to higher answer reward when applied to RL.

5.2 Impact on General Reasoning Domains

Setup. Along with the mathematical benchmarks, we test our model on the general reasoning benchmarks, GPQA Diamond (Rein et al., 2023) and MMLU-Pro (Wang et al., 2024b) (see Appendix B.4 for details). We consider the baselines in the following three categories; (1) Closed-source LRMs: OpenAI's o1 and o1-mini (OpenAI, 2024) demonstrate state-of-the-art performance but are accessible only through APIs. (2) Open-source LRMs with undisclosed SFT datasets: R1 (DeepSeek-AI et al., 2025) and QwQ (Team, 2024) successfully replicate o1's capabilities, but the datasets for SFT remain undisclosed. (3) Open-source LRMs via distillation: Models like Sky-T1 (Team, 2025a) and Bespoke-7B (Labs, 2025) utilize open-source

Qwen-2.5-7B-Instruct	7B	37.6	49.9
Qwen-2.5-7B-LC (Ours)	7B	39.9	51.4

Table 1: Performance of various reasoning models. Some results are from the respective reports

datasets collected from existing LRMs' outputs.

Results. We present our results in Table 1. Models trained on the Long CoT Collection show significant performance gains on GPQA, particularly Llama-3.1-8B-Instruct. Notably, Qwen-2.5-7B-LC achieves GPQA performance slightly surpassing Bespoke-7B, a simpler replication of R1. The models also demonstrate modest improvements on MMLU-Pro, suggesting that the reasoning strategies learned from our dataset transfer effectively to general reasoning domains.

5.3 Implication on RL

After imitation learning to develop the long-form CoT reasoning skills, we move on the next phase—RLVR with GRPO (Shao et al., 2024)—to validate whether our collection serves as a reliable starting point for reinforcement learning. Due to GPU resource constraints for long-sequence RL, we train Qwen-2.5-0.5B on the Long CoT Collection and leverage it as the starting point for RL. Based on the NuminaMATH (Jia LI and Polu, 2024), we filter samples to include only those with integer answers, resulting in a set of 10K examples. The policies are trained with a 16K max token length, using 16 samples per example for GRPO. For verifiable rewards, following three types of reward functions are employed.

Reward Functions. There are three reward functions we employed, which are generally used for RL: (1) Length Reward: We use the function $1 - \left|\frac{\min(x,y)}{\max(x,y)} - 1\right|$ that measures the difference between the length of sampled thought and o1-mini's thought on a scale of 0 to 1. (2) Answer Reward: An outcome-based reward following Yeo et al. (2025). Specifically, we parse the answer span and compare it with the answer using latex2sympy, (3) Format Reward: We check whether the model responses include the parable answer span.

Results. Figure 1 represents the impact of our Long CoT Collection on the next RL phase. On both MATH500 and GPQA, the model initialized by training on our collection (i.e., Qwen-2.5-0.5B-LC) achieves 2-3x greater performance gains through RLVR compared to the base model (i.e., Qwen-2.5-0.5B), effectively mitigating the cold start problem. This indicates that the Long CoT Collection serves as a reliable starting point for RL, showing the potential to enable more stable learning even under sparse reward signals and finally leading to greater performance gains.

6 Thought Budget Control

One of the major issues with long-sequence reasoning models is overthinking—generating an unnecessarily large number of tokens for simple problems. For instance, QwQ-32B produces around 1,500 tokens for a basic question like '1+1+3?'. Similarly, OpenAI's O-series models offer three types—low, medium, high—based on computa-

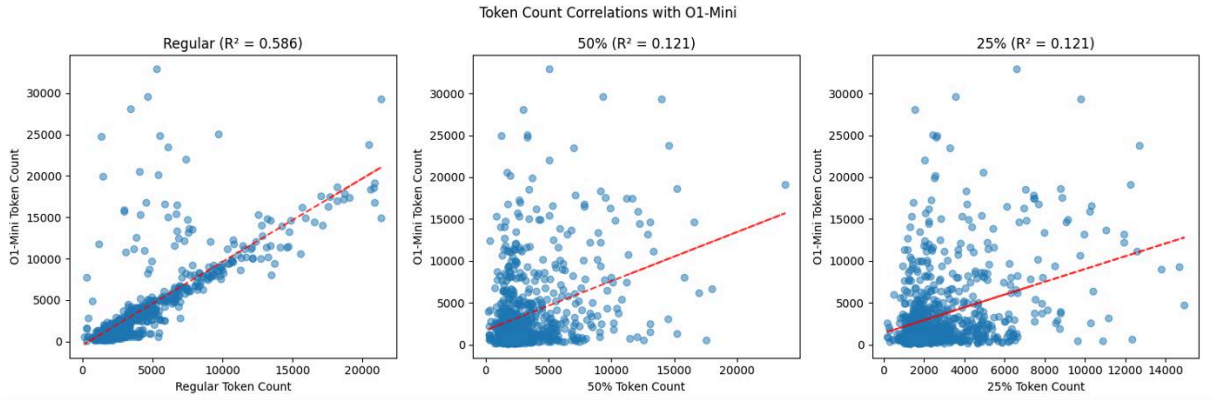

Figure 7: The Pearson correlation (R^2) between generated tokens and o1-mini thought tokens. We leverage 100% budget (*left*), 50% budget (*mid*), and 25% budget (*right*) to generate the collections of long CoT rationales.

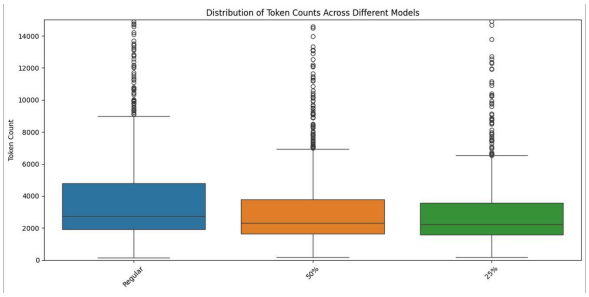

Figure 8: The token count distribution for each collection generated by adjusting the thought budget.

tional budget, allowing users to adjust the thinking budget according to the task complexity. Now, having control on the thought budget is crucial for effectively managing the problem of overthinking.

6.1 Controlling the Thought Budget During the Data Collection Process

As described in Section 3.2.2, when synthesizing long rationles from short CoT LLMs, our collection process first generates reasoning outlines by estimating the number of outlines needed for each instance and then producing a sequence of reasoning outlines accordingly. This allows us to control the length of the generated rationales by enforcing the number of outlines needed. We finally craft three versions of the Long CoT Collection by additionally constructing two more sets, each constrained to use only 25% and 50% of the original budget.

6.2 Analysis on the Budget-Controlled Collection

Figure 7 illustrates the correlation (R^2) between the tokens of the generated rationales and o1-mini thought tokens. It demonstrates that as we reduce the thought budget and generate relatively shorter rationales, the correlation with o1-mini thought tokens weakens. Moreover, we figure out that excessively reducing the thought budget—specifically to 25%—disrupts rationale generation by forcing too much information into too few reasoning outlines, making the reasoning more confusing.

Data Used	100%	50%	25%
MATH500	66.6	60.7	57.6

Table 2: The results of policies on MATH500, which trained on each Long CoT Collection.

We also investigate the distribution of each collection (i.e., 100%, 50%, and 25%). As presented in Figure 8, a reduction in the thought budget results in a corresponding decrease in the average token length of the collection. Furthermore, policies trained with access to larger budgets exhibit superior reasoning capability compared to those trained under more constrained budgets (Table 2).

7 Conclusion

This paper investigates the feasibility of generating long CoT datasets using LLMs trained on short CoT rationales. We present a pipeline for building the Long CoT Collection using short CoT LLMs, where the collection process offers controllability over the thought budget. This gives us the ability to regulate the length of the generated rationales and provides a way to address overthinking—one of the major challenges faced by LRMs. While training on our dataset did not lead to dramatic improvements over direct distillation from LRMs, our extensive experiments show that once moving into the RL phase, policies initialized with our dataset achieved 2-3x greater performance gains compared to those without it. This highlights the strength of our dataset as an reliable foundation for RL.

Limitations and Future Work

Application on Expert Domains. An exciting next step is to apply our pipeline to expert domains. While our dataset has proven to be a reliable starting point for RL in math and general reasoning tasks, we anticipate its potential to generalize further across a wide range of specialized domains.

Scaling Up to Larger Models. Although we employ 7B-8B models during phase 1 learning (i.e., supervised fine-tuning), we use a 0.5B model for phase 2 (i.e., reinforcement learning) since the largest model that fits within our GPU resources (16 A100 40GB GPUs) is 0.5B parameters.

Using Diverse Teacher LRMs. We only consider o1 for the reference LRM used in our dataset construction process. While we choose o1 due to its representativeness, our approach can be further applied to other LRMs that partially disclose their reasoning processes.

A Details of the Data Construction

A.1 Base Dataset

Xu et al. (2024) propose a set of synthetic instruction data, Magpie, which covers a wide range of domains. From Magpie, a dataset consisting of 150K of the longest examples from reasoning, math, and coding & debugging categories was also released. Our 1K seed datasets and 100K long CoT collection are stems from the Magpie-Reasoning-150K.[1] Each data point is annotated with multiple subcategories along with its main category.

A.2 Details of Demonstration Retrieval

We leverage the main category and subcategories annotated in the dataset to retrieve demonstrations. We calculate the domain matching score by assigning 1 point for matching main categories and 0.2 points for each matching subcategory. The final retrieval score is computed by multiplying the domain matching score with the thought budget score, prioritizing samples with similar thought budgets.

A.3 Statistics

Figure 9 shows the distributions of reasoning steps, rationale lengths, and differences between reference and generated thought tokens. Our dataset contains sufficiently long rationales, with up to 30 reasoning steps and 20K thought tokens. The comparison between generated and reference thought tokens reveals similar distributions, suggesting our approach may help prevent under- and overthinking issues (Wang et al., 2025) and enable short CoT LLMs to produce long rationales.

[1] https://huggingface.co/datasets/Magpie-Align/Magpie-Reasoning-V1-150K

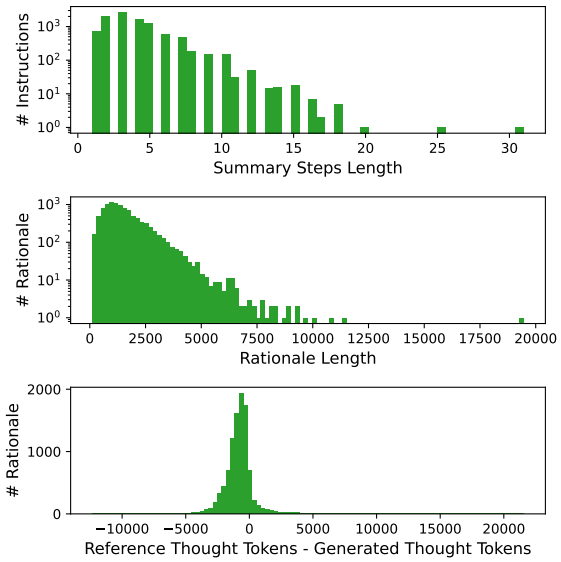

Figure 9: Distribution of the number of reasoning outlines (top), thought length (middle), and the difference between the length of the reference models' rationale and the generated rationale (bottom).

Phrase	GPT-4o	Deepseek-R1	Ours
"Let's"	37	92	100
"Wait"	0	100	4
"Okay"	0	100	47
"Verif-"	4	60	27
"?"	0	87	27
"!"	0	4	2

Table 3: Frequency of "Aha" moment phrases in CoT rationales across different methods, representing the proportion (%) of samples in which each phrase appears.

A.4 Analysis of Reasoning Triggers

Prior work reports that LRMs frequently use "Aha" moment phrases to explore better reasoning paths (Huang et al., 2024; DeepSeek-AI et al., 2025; Muennighoff et al., 2025a). These phrases serve not only as formatting elements but also as critical keywords that can steer the model's reasoning process, effectively guiding it towards more structured and thorough problem-solving. Thus, we check the frequency of these reasoning triggers, such as "Let's think," "Wait, I need to verify," and question marks indicating self-reflection. As shown in Table 3, while GPT-4o exhibits minimal use of these markers (primarily "Let's" at 37%), Deepseek-R1 employs them extensively across all categories.

B Implementation Details

B.1 Datasets

In Section C, LIMO (Ye et al., 2025) dataset serves as a test-bed to assess the potential of our initialized SFT model in RL. The LIMO dataset stems from NuminaMath-CoT, featuring meticulously annotated problems from high school to advanced competition levels, AIME, and MATH. It contains 817 meticulously selected math problems and solutions refined through human curation based on solutions generated by LRMs such as DeepSeek-R1. Most importantly, it includes only problems with verifiable answers, limited to integers within three digits.

B.2 Supervised Fine-tuning

We employ two base models: Qwen-2.5-7B-Instruct and Llama-3.1-8B-Instruct. The models are trained on the long CoT collection using 4 A100 GPUs. We adopt LLaMA-Factory (Zheng et al., 2024), a unified framework that integrates a suite of cutting-edge efficient training methods, to efficiently train the models.[2] Detailed hyperparameters used for the training are provided in Table 4.

B.3 RLVR

Due to the limited GPU budgets, we employ Qwen-2.5-0.5B as a base model for training on long sequences with GRPO. For our RL stage, we select a synthetic math dataset, NuminaMath (Jia LI and Polu, 2024), filtering problems based on Olympiads and AMC, resulting in a total of 10K problems. We adopt OpenRLHF (Hu et al., 2024), a framework designed to simplify and streamline RLHF training, and leverage RingAttnetion (Liu et al., 2023) to enable training on long sequences. Our RL stage is conducted on 16 A100 GPUs, and details about hyperparameters are in Table 5.

B.4 Benchmark Details

AIME 2024 contains 30 problems administered on January 31–February 1, 2024. AIME assesses mathematical problem-solving across various domains including arithmetic, algebra, counting, geometry, number theory, and probability. MATH (Hendrycks et al., 2021b) comprises competition mathematics problems spanning different difficulty levels. Following previous work by OpenAI (Lightman et al., 2023), we use the same subset of 500 problems for evaluation. Along with the mathematical benchmarks, we test our model on the general reasoning benchmarks, GPQA Diamond (Rein et al., 2023), a dataset consists of 198 doctorate-level questions across Biology, Chemistry, and Physics, and MMLU-Pro (Wang et al., 2024b) an enhanced version of MMLU (Hendrycks et al., 2021a) with a stronger focus on reasoning capabilities.

Hyperparameters	Value
Base Model	Qwen-2.5-7B-Instruct / Llama-3.1-8B-Instruct
Torch dtype	BF16
Epoch	3
Train Data	Long CoT Collection
Learning Rate	5e-6
Max Seq. Length	8,192
Batch Size	1
Gradient Accumulation	8

Torch dtype	BF16
Epoch	5
Train Data	NunimaMath-CoT
Learning Rate	5e-7
Max Seq. Length	16,384
Batch Size	64
Gradient Accumulation	1
Samples per Prompt	16

Table 5: Hyperparameters used for GRPO

B.5 Inference

all experiments are conducted with a temperature of 0.6 and a maximum token length of 16K, except for BoN sampling. For BoN, we use top-p decoding with $p = 0.95$ and $t = 1.0$. Each model generates n=1, 2, 4, 8, 16, and 32 responses on MATH-500 and AIME2024, and selects the one that contain correct answer. Since we focus on reasoning tasks, where correct answer is clearly defined, the results of BoN are equal to Pass@n. To efficiently test models across diverse benchmarks, we utilize Simple-Eval, an open-source library from OpenAI.[3]

[2] https://github.com/hiyouga/LLaMA-Factory

[3] https://github.com/openai/simple-evals

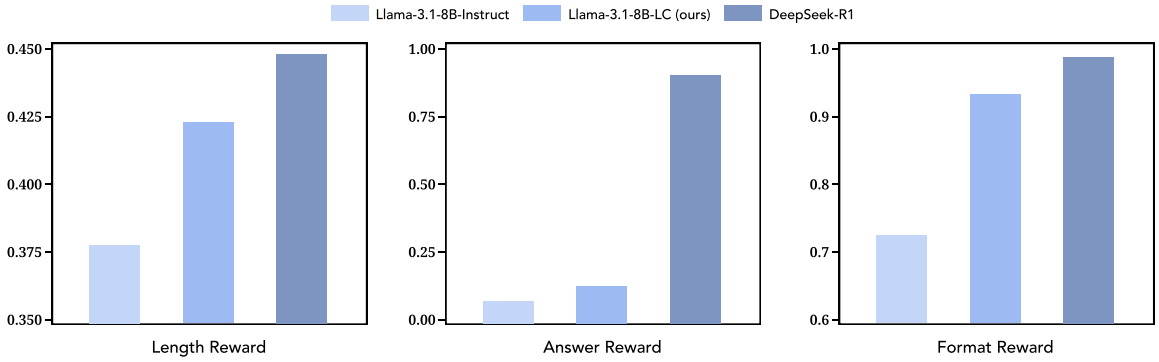

Figure 10: Length, answer, and format rewards across three models in LIMO dataset (Ye et al., 2025).

C Impact on the Verifiable Rewards

The success of RL is highly dependent on the SFT model (Ouyang et al., 2022). We investigate the effect of initializing the SFT model with our dataset to the rewards for RL. We utilize three reward functions aformentioned in Section 5.3.

Figure 10 compares the averaged rewards of our model, Llama-3.1-8B-LC, with the baselines, Llama-3.1-8B-Instruct and R1. Among the three models, our model shows the highest length reward, suggesting the effectiveness of our dataset construction process in efficiently allocating thought tokens. Furthermore, our model's higher answer reward compared to Llama-3.1-8B-Instruct indicates its potential as an effective starting point for RL.

D Details on Analyses

D.1 Comparison on Thought Budget

To compare thought budgets across different models, we employ model-specific token counting methods. For OpenAI's LRMs, we calculate the thought tokens by subtracting the response sequence tokens from the total completion tokens provided in the API response. For R1, which provides complete responses, we extract the content between `<think>` and `</think>` tags and count tokens using the GPT tokenizer. Similarly, for our model's responses, we measure the token count of sequences within the `<thought>` and `</thought>` tags.

D.2 Details of the CoT Quality Analyses

We use o3-mini as a judge and ask the model to identify which reasoning path is better based on the given criteria. The model chooses among the available options - A, B, or tie - where the two models' responses are randomly assigned to A and B for unbiased comparison.

E Examples of the Long CoT Collection

We provide several examples from the Long CoT Collection:

- An example of our Long CoT Collection Figure 14
- An example response of Llama-3.1-8B-Instruct (Ours), which trained on the Long CoT Collection: Figure 15

F Prompts

These are the prompts we utilized in our study:

- Prompt for the step-wise long CoT generation: Figure 16
- Prompt for the correctness filtering: Figure 17
- Prompt for the CoT quality analyses in Section 4.1: Figure 18, 19, and 20.

G Usage of AI Assistant

We used ChatGPT for simple grammar correction and paraphrasing our draft.

Question

The same unit cube is now cut into 96 smaller, irregular, non-congruent pieces by making cuts along non-parallel planes that pass through the cube at various angles. The first cut slices the cube corner-to-corner through the diagonal dividing one face into two congruent triangles. Subsequent cuts are made to divide the remaining volume into smaller, non-uniform pieces that range in size from 1/110th to 1/80th of the original cube volume. No two pieces are the same size. How many of these 96 pieces have volume larger than 1/100th of the volume of the original cube?

Generated Reasoning Flow

Analyzing the problem statement

I'm attempting to determine how many pieces out of the 96 have a volume larger than 1/100th of the original cube's volume. This requires understanding the distribution of the pieces' volumes.

Understanding volume distribution

I'm considering the range of volumes for the pieces, from 1/110th to 1/80th of the original cube's volume, and noting that no two pieces have the same size.

Exploring volume constraints

I'm focusing on the pieces that have volumes larger than 1/100th. Since the volumes range from 1/110th to 1/80th, some pieces will naturally exceed this threshold.

Counting qualifying pieces

I'm identifying the volumes that exceed 1/100th. The pieces range from 1/110th to 1/80th, so I need to find how many pieces fall above the 1/100th mark.

⋮

Concluding with totals

I'm concluding by verifying the count of pieces larger than 1/100th of the original cube's volume, ensuring the calculation aligns with the given ranges.

Generated Long CoT

Let's begin by analyzing the problem statement carefully. The cube is divided into 96 smaller pieces through cuts made along non-parallel planes. These cuts create pieces that vary in size from 1/110th to 1/80th of the original cube's volume, and critically, no two pieces have the same volume. We need to determine how many of these pieces have a volume greater than 1/100th of the original cube's volume. To start, ...

Wait, let's list down the fractions starting from 1/110th and incrementally increasing until we reach 1/80th. For each fraction, we compare it to 1/100th. The fractions larger than 1/100th will represent the pieces with volumes greater than the required threshold. This approach ensures we count only those pieces that meet the criteria, as each fraction denotes a unique volume due to ...

Okay, let's focus on evaluating the interval between 1/100th and 1/80th. We know from the problem statement that the cube is divided into 96 unique pieces with volumes ranging from 1/110th to 1/80th. Our task is to identify how many of these pieces have volumes greater than 1/100th. Given the constraints, ...

To determine the count of pieces with volumes greater than 1/100th, we need to identify all fractions greater than 1/100th and less than or equal to 1/80th. This involves recognizing that fractions are ordered incrementally and that there is a finite number of them between these two limits.

By examining the interval from 1/100th to 1/80th, I'll be able to count the number of unique fractions that meet the criterion of being greater than 1/100th. This approach allows for ...

What if we focus on calculating the number of distinct fractions that lie between 1/100th and 1/80th? This will help us determine how many pieces have volumes greater than 1/100th. Since the volumes of the pieces are represented as fractions that are unique and range from 1/110th to 1/80th, identifying the interval greater than 1/100th will directly give us the count of such fractions. Given the problem's constraints, the fractions represent increments in volume sizes. The sequence of fractions within the interval from 1/110th to 1/80th increases incrementally. By focusing on ...

Okay, let's verify the count of pieces larger than 1/100th of the original cube's volume. From the previous analysis, we determined the fractions representing the volumes of the pieces are in the form 1/n, where n is an integer. For the pieces to have a volume greater than 1/100th, the denominator n must be less than 100. Conversely, ...

Figure 14: An example instance from the Long CoT Collection.

Question

Suppose that the measurement of time during the day is converted to the metric system so that each day has 10 metric hours, and each metric hour has 100 metric minutes. Digital clocks would then be produced that would read 9:99 just before midnight, 0:00 at midnight, 1:25 at the former 3:00 AM, and 7:50 at the former 6:00 PM. After the conversion, a person who wanted to wake up at the equivalent of the former 6:36 AM would set his new digital alarm clock for A:BC , where A , B , and C are digits. Find $100\text{A}+10\text{B}+\text{C}$.

Generated Long CoT

Let's begin by understanding the conversion from standard time to the metric time system. We know that in the standard system, the day is divided into 24 hours, with each hour consisting of 60 minutes. In contrast, the metric system divides the day into 10 metric hours, with each metric hour containing 100 metric minutes.

To solve the problem, we need to convert a standard time of 6:36 AM into the metric time system. This involves finding the equivalent metric hours and minutes for 6:36 AM.

1. **Calculate the proportion of the day**: First, consider that the total time from midnight to 6:36 AM is a fraction of the entire 24-hour day. We can express this as a ratio: ...

What if we examine the calculation of the equivalent metric minutes more closely to ensure the conversion is accurate?

1. **Reassessing the Conversion**: We've already converted the standard time of 6:36 AM into the metric system, where each metric hour comprises 100 metric minutes. In our previous steps, we determined that 36 standard minutes equate to 60 metric minutes. Let's confirm this conversion step-by-step.

2. **Fraction of the Metric Hour**: The 36 standard minutes must be converted to the metric system, where a full metric hour consists of 100 metric minutes. We previously calculated the equivalent fraction of the metric hour as:
   \[
   \frac{36}{60} \times 100 = 60 \text{ metric minutes}
   \]
   This calculation is consistent with the relationship between standard and metric time, confirming that 36 minutes indeed translates to 60 metric minutes.

3. **Verification within Metric Constraints**: ...

With this verification, we ensure the metric conversion aligns with the problem's requirements. This consistency supports the conversion of the standard time into the metric system accurately, as needed for further calculations. Thus, the calculated time remains 2:60 in the metric system, and we can confidently proceed with the solution.

Okay, since we have confirmed that the equivalent metric time for 6:36 AM is 2:60, let's proceed to calculate the expression \(100\text{A} + 10\text{B} + \text{C}\).

1. **Identify the Values of A, B, and C**: ...

...

3. **Conclusion**:
   - The calculation confirms that the value of the expression is 260. This reflects the correct conversion and representation of the time according to the problem's requirements.

Figure 15: An example response from Llama-3.1-8B-LC (Ours), which trained on the Long CoT Collection.

Abstract

The integration of generative artificial intelligence into educational applications has enhanced personalized and interactive learning experiences, and it shows strong potential to promote young learners language acquisition. However, it is still challenging to ensure consistent and robust performance across different languages and cultural contexts, and kids-friendly design requires simplified instructions, engaging interactions, and age-appropriate scaffolding to maintain motivation and optimize learning outcomes. In this work, we introduce SingaKids, a dialogic tutor designed to facilitate language learning through picture description tasks. Our system integrates dense image captioning, multilingual dialogic interaction, speech understanding, and engaging speech generation to create an immersive learning environment in four languages: English, Mandarin, Malay, and Tamil. We further improve the system through multilingual pre-training, task-specific tuning, and scaffolding optimization. Empirical studies with elementary school students demonstrate that SingaKids provides effective dialogic teaching, benefiting learners at different performance levels.

1 Introduction

The integration of generative artificial intelligence into educational technologies has significantly transformed learning environments by enabling more personalized and adaptive experiences (Zhang and Aslan, 2021; Yan et al., 2024). These AI-driven systems can respond to individual learner needs, provide immediate feedback, and create engaging interactions that support knowledge acquisition and skill development (Zhai et al., 2021). In the domain of language learning, this technological advancement presents particularly promising opportunities, especially for young learners who benefit from interactive and contextually rich learning experiences (Pokrivčáková, 2019; Ji et al., 2023).

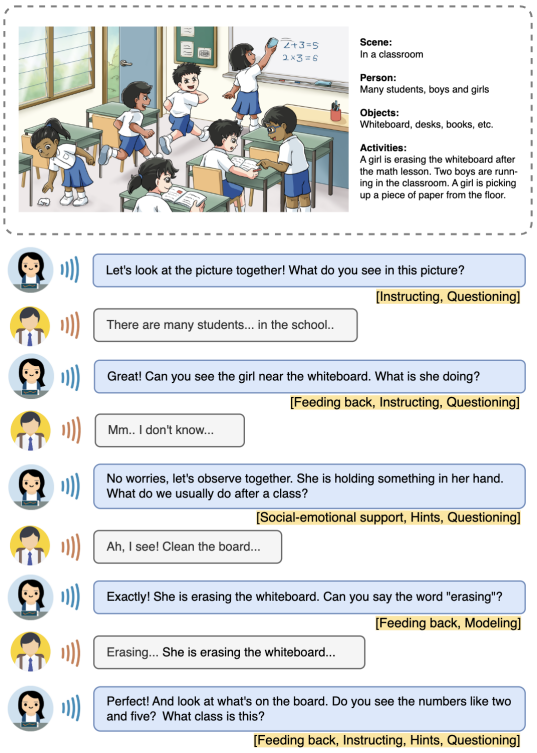

Figure 1: Multi-modal dialogic interaction for language learning through the image description task. Students use speech to interact with the system. Pink spans denote the dynamic scaffolding strategies.

Recent advances in large language models (LLMs) and multimodal systems have demonstrated impressive capabilities in understanding and generating human language across diverse contexts (Achiam et al., 2023a; Team et al., 2023). However, deploying these technologies effectively for educational purposes, particularly for children's language acquisition, presents several significant challenges. First, ensuring consistent performance across different languages and cultural contexts remains difficult, as most systems exhibit stronger capabilities in high-resource languages like English compared to others (Wang et al., 2023a). Second, designing child-friendly interactions requires careful consideration of cognitive load, attention spans,

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1244–1253
July 28-30, 2025

and developmental appropriateness—factors that often necessitate simplified instructions, engaging dialogue patterns, and age-appropriate scaffolding to maintain motivation and optimize learning outcomes (Liu et al., 2024c).

To address these challenges, we introduce SingaKids, a dialogic tutor specifically designed to facilitate language learning through picture description tasks. The oral practice enhances children's language acquisition by stimulating vocabulary development, syntactic complexity, and observational skills, and facilitating contextual language use within meaningful visual contexts - all essential components of early linguistic competence development. To this end, our system integrates four components: (1) dense image captioning to provide rich visual context understanding, (2) multilingual dialogic interaction to support natural conversational flow, and deliver appropriate feedback and guidance, (3) robust speech understanding to process young learners' verbal responses, and (4) kids-friendly speech generation to improve the student engagement during tutorial sessions. SingaKids operates across four languages relevant to Singapore's multicultural context: English, Mandarin, Malay, and Tamil, making it accessible to students from diverse linguistic backgrounds.

We further enhanced the system's performance through multilingual pre-training strategies, task-specific tuning to optimize picture description dialogue flows, and scaffolding optimization to provide appropriate levels of support based on learner responses. This approach allows the system to adapt its interaction patterns to match learners' proficiency levels and specific linguistic needs. To evaluate the effectiveness of SingaKids, we conducted empirical studies with first and second-grade elementary school students of different language proficiency levels. Our findings demonstrate that the system provides effective dialogic teaching experiences that support language acquisition through natural conversation about visual stimuli. Notably, students at various performance levels showed improvements in descriptive language skills, vocabulary usage, and conversational fluency after engaging with the system.

This work contributes to the growing field of AI-enhanced language education by demonstrating how multimodal, multilingual systems can be successfully deployed to support young learners' language development. By addressing the challenges of cross-linguistic consistency and age-appropriate interaction design, SingaKids represents a step forward in creating accessible and effective learning agents for diverse educational contexts.

2 Related Work

Intelligent tutoring systems aim to replicate human tutoring by providing personalized instruction and adaptive feedback to language learners. The advancement of ITSs has marked a significant step forward in education practice (Graesser et al., 2018; Demszky and Hill, 2023; Wang et al., 2023b). These systems provide personalized learning experiences and instant feedback (Chaffar and Frasson, 2004; Harley et al., 2015; Grivokostopoulou et al., 2017), tailored to learners' characteristics and needs (Dzikovska et al., 2014; Grawemeyer et al., 2016; Nihad et al., 2017), and are shown to positively influence students' engagement in learning and academic performance (Kulik and Fletcher, 2016; Xu et al., 2019).

Dialogue tutor is a particular type of intelligent tutoring system that interacts with students via natural language conversation (Nye et al., 2014; Ruan et al., 2019). In STEM domains, conversational ITSs can facilitate university students in problem-solving by providing real-time feedback and hints in text formats (Nye et al., 2023; Paladines and Ramirez, 2020; Arnau-González et al., 2023). However, prior work has widely relied on rule-based systems with human-crafted domain knowledge (Nye et al., 2014; Graesser et al., 2018), or data-driven approaches that require a certain amount of human annotation for supervised learning (MacLellan and Koedinger, 2022). Recently, LLMs show strong potential to build dialogue tutors with less data supervision and higher coherence (Afzal et al., 2019; Demszky and Hill, 2023; Macina et al., 2023b), and they can be further improved by integrating LLMs with pedagogical and learning science principles (Stasaski et al., 2020; Sonkar et al., 2023; Macina et al., 2023a).

3 SingaKids System Architecture

In a picture description session, teachers first present an image and ask students to observe it carefully. They pose open-ended questions like "*What do you see in this picture?*" to stimulate observation, then guide students beyond basic object identification to describe qualities using adjectives and adverbs, enhancing vocabulary, organization, and fluency. The activity concludes with introduc-

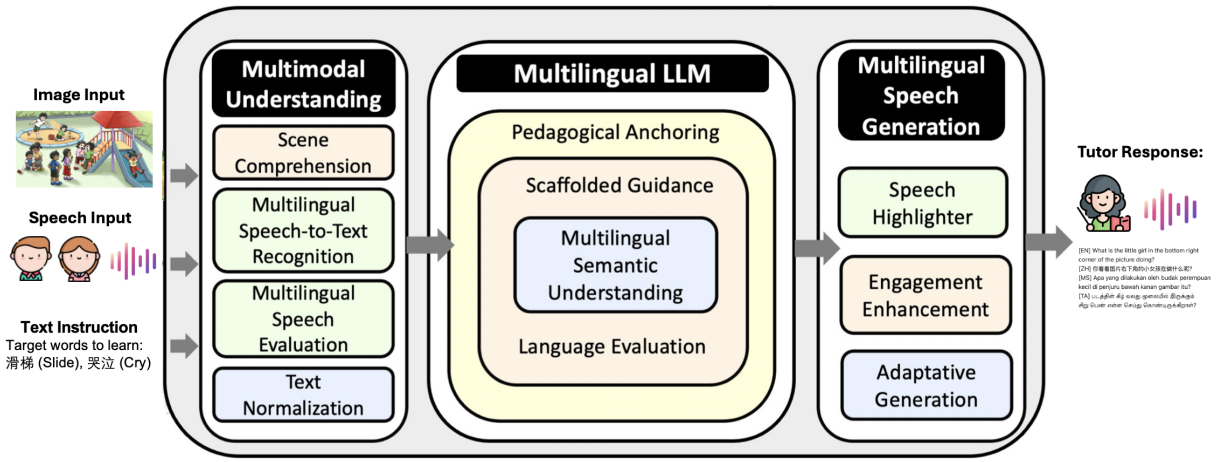

Figure 2: Overview of the conversational tutor architecture for language learning via the image description task.

ing new vocabulary and encouraging students to create stories about the image, developing creativity and narrative skills.

Drawing from real-world teaching sessions, the overall architecture of our conversational tutoring system is illustrated in Figure 2. Interactions begin with the Multimodal Understanding: the scene comprehension extracts the keywords, objects, and events in the given picture (Johnson et al., 2016); the multilingual speech recognition converts the student's spoken response into text; speech evaluation component is to assess the student's oral language proficiency (Wong et al., 2022).

The Multilingual LLM represents the core of educational interaction: multilingual semantic understanding interprets the student's response in context; language evaluation assesses the linguistic accuracy and completeness of their description; scaffolded guidance determines the appropriate level of support needed; This component effectively analyzes the student's current understanding and formulates an appropriate teaching strategy; pedagogical anchoring establishes high-level educational objectives such as word understanding or sentence construction. Moreover, for elementary grade 1 and 2, we evaluate students' skills in making sentences to describe the activities in the image, focusing on their vocabulary usage. The language evaluation can be adapted for higher grade levels, by measuring grammatical correctness and coherent narratives (Genishi and Dyson, 2015).

The system's response is formed in both text and audio outputs. The Multilingual Speech Generation converts text utterance into natural and engaging speech to maintain student motivation (Kim et al., 2021); In addition, beyond simple text-to-speech synthesis, we incorporate a highlight component which can emphasize important keywords or pronunciation errors (Zhang et al., 2021).

Throughout this pipeline, the system maintains an educational dialogic flow, asking guiding questions, providing hints, offering corrections, and acknowledging progress as needed. If a student struggles with specific vocabulary when describing the image (for example, using general terms like *"playing"* instead of specific verbs like *"swimming"* or *"climbing"*), the system will scaffold their learning through targeted questions and gradually decreasing support until they can independently produce the target words (Liu et al., 2024c).

4 Module Optimization

Young students at the early elementary stage with limited language proficiency raise unique requirements for human-AI interaction. Enhancing the multilingual capability of the core components can improve communication efficacy as well as handling mixed language usage or intra-sentential code-switching. This is particularly important in environments where learners may express themselves in multiple languages they are exposed to at home or school. Additionally, scaffolding kids requires simplified instructions, and consistent engagement through positive feedback and social-emotional support. While maintaining reasonable performance in English and Mandarin, we specifically focus on improving Malay and Tamil to better serve Singapore's multilingual student population.[1]

[1]We used the Huggingface codebase for model training & evaluation (https://github.com/huggingface/transformers). All experiments were conducted on Nvidia A100 40/80GB GPUs.

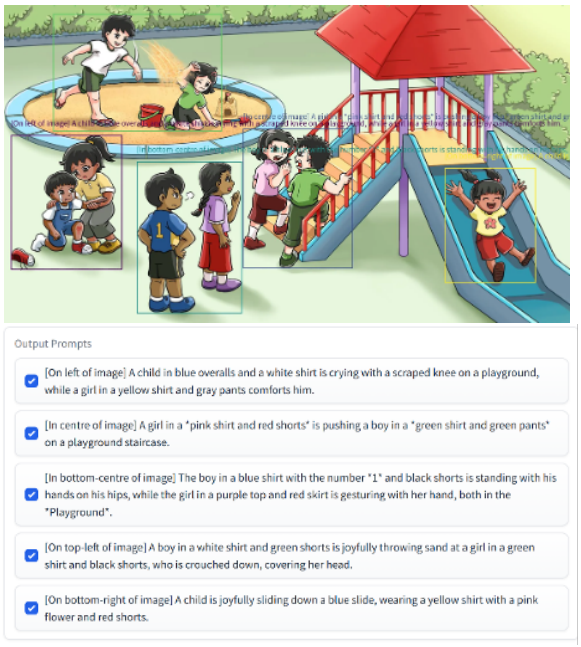

Figure 3: Dense image captioning with contextualization (caption of each event aligns with large narrative) and fine-grained understanding (detailed description of objects, characters and activities).

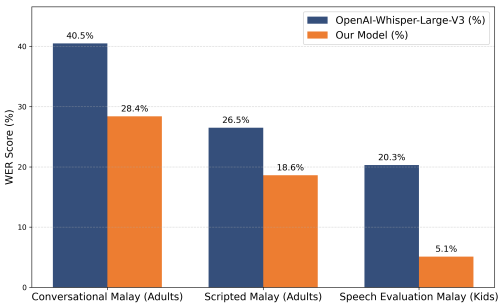

Figure 4: Malay ASR evaluation results.

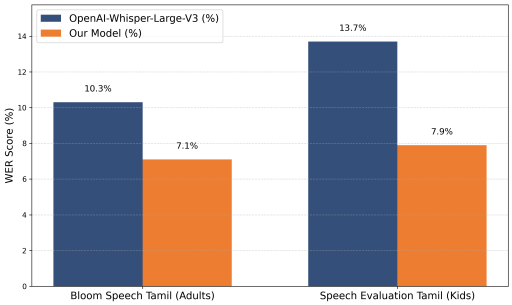

Figure 5: Tamil ASR evaluation results.

4.1 Fine-grained Image Description

For the picture-guided conversation flow, we propose a dense image captioning module for visual storytelling. The goals are to identify the key events of interest in the image as well as generate rich captions for each key event of interest. Referring to the example in Figure 3, the caption for each event shall be aligned with the larger narrative of the image (better contextualization), and include detailed description of the objects, characters, and activities (fine-grained understanding). State-of-the-art multi-modal LLMs (MLLMs), especially smaller size models, generally struggle with dense image content. The MLLMs often generate general and broad descriptions of the image, and are limited in deeper analysis of the visual details. Moreover, hallucinations occur due to complex or ambiguous image content. Hence, we adopt a two-stage approach – event bounding box proposal and caption generation. For event bounding box proposal, we leverage robust person and object detection (Liu et al., 2024a), human segmentation (Kirillov et al., 2023), coupled with depth estimation (Bhat et al., 2023), for probabilistic reasoning on the neural detections. For caption generation, we use chain-of-thought prompting on a MLLM, InternVL2.5 (Chen et al., 2024), to incorporate global context understanding into the individual event captions. We achieved a 75% sentence-level accuracy in our image testbed, which provides reasonable content for the conversational process.

4.2 Improving Multilingual ASR

To enhance the multilingual ASR capabilities of our system, we selected Whisper-large-V3 (Radford et al., 2022) as the base model and fine-tuned it with additional Malay and Tamil speech data. Preliminary analysis revealed significant performance gaps when processing lower-resource languages (e.g., Malay, Tamil), and in children's voice transcribing (Attia et al., 2024). We addressed this limitation by gathering a local dataset comprising 2,800-hour Tamil recordings and 1,000-hour Malay recordings from more than 1,000 native speakers from different age groups and linguistic contexts.

As shown in Figure 4 and Figure 5, we compare Whisper-large-V3 with our fine-tuned model on Malay and Tamil data. Evaluating on Malay data, we achieved a lower WER from 40.5% to 28.4% on conversational speech and from 20.3% to 5.1% on children speech (Zhang et al., 2021). For Tamil, we achieved lowers WER from 10.3% to 7.1% on Bloom Speech Tamil (Leong et al., 2022) and from 13.7% to 7.9% on a children speech data (Zhang et al., 2021). We obtained consistent improvements at all test sets, particularly in children's voice.

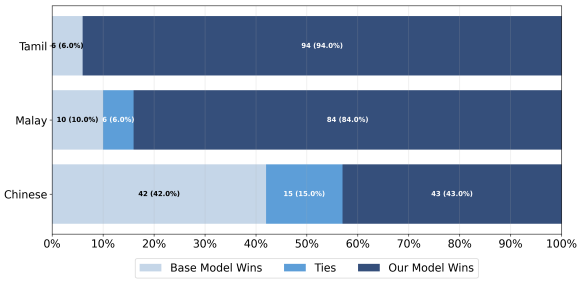

Figure 6: Comparison between the base model and our model of translation capability.

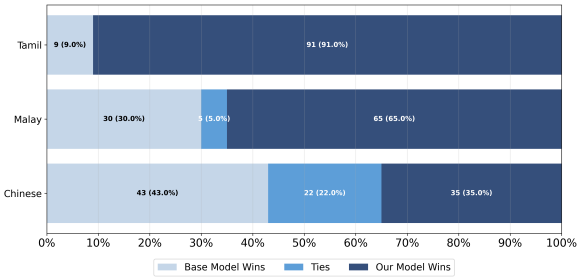

Figure 7: Comparison between the base model and our model of multilingual instruction following.

4.3 Improving Dialogue LLM

We improve the dialogue component built on a text LLM from the following two aspects:

4.3.1 Multilingual Capability

LLMs often show downgraded performance in low-resource languages, and this problem becomes more prominent on smaller models. In this work, we selected Qwen1.5-4B (Bai et al., 2023) as the base model for a balance of performance and cost-efficiency.[2] Our multilingual optimization follows a two-stage process: First, we conducted continue pre-training on 14B tokens of mixed data with four languages (English, Mandarin, Malay, Tamil) (Penedo et al., 2024). We set a balanced sampling rate to elevate the multilingual modeling of Malay and Tamil, and English and Mandarin data play a role to retain the fundamental language capabilities. Second, we enhanced the model's multilingual instruction following by multi-task learning (Teknium, 2023) and cross-lingual alignment (Muennighoff et al., 2023; Lin et al., 2025), including multilingual role-play corpora generated through simulating diverse conversation scenarios (Sun et al., 2024; Liu et al., 2024b). To further strengthen cross-lingual capabilities, we did a hybrid training approach that combines translation and cross-lingual problem-solving tasks (Muennighoff et al., 2022; Liu et al., 2022). This enables the language model of better semantic fusion across languages. Experimental results shown in Figure 6 and Figure 7 show improvement on multilingual translation and instruction following.

[2]We tested a set of Qwen1.5 models from 1.8B to 14B, and observed that model size is strongly correlated with multilingual capabilities, especially for languages with lower resources such as Malay and Tamil.

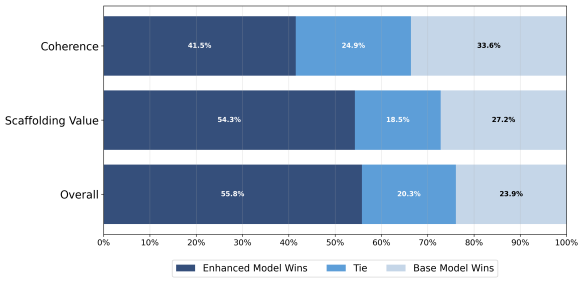

Figure 8: Comparison between the base dialogue model and pedagogical-enhanced model through the LLM-as-a-judge evaluation.

4.3.2 Scaffolding-guided Augmentation

We improved the dialogue model's pedagogical effectiveness by training with scaffolding instructions and personality-aware student simulation (de Oliveira et al., 2023; Sonkar et al., 2023; Liu et al., 2024c,d). Our scaffolding framework is formulated upon the dialogic teaching theory (Alexander, 2006), where the tutor encourages exchange of ideas using follow-up questions, clues, elaborations, or recaps. We conducted a theory-inspired practice by sampling synthetic dialogue samples from a stronger teacher LLM (`GPT-4` (Achiam et al., 2023b)) to guide the smaller LLMs, which is capable of providing scaffolded interactions based on learners response. Moreover, in dialogic teaching, recognizing and adapting to individual characteristics can significantly enhance student engagement and learning efficiency. We built a taxonomy of student personality profiles based on established traditional psychology frameworks (Costa and McCrae, 1999), and integrated both cognitive and noncognitive aspects into LLM-based personality-aware student simulation (Liu et al., 2024d). This augmentation enabled the dialogue model to dynamically adjust its pedagogical approach, providing encouragement for students exhibiting low confidence or being distracted from the on-going session, as shown in Figure 8.

Moreover, we observed that the scaffolding-guided training improves the dialogue model's ro-

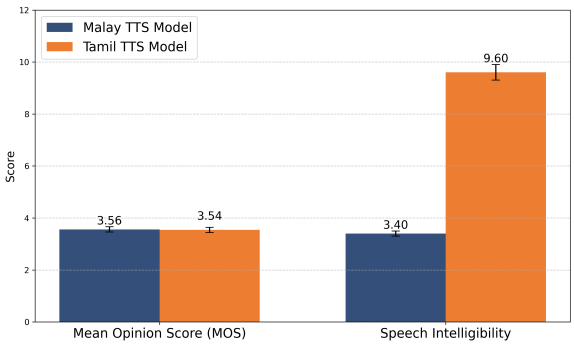

Figure 9: Subjective evaluation results for mean opinion score (MOS) and objective evaluation results for speech intelligibility with 95% confidence intervals for the synthesized Malay and Tamil speech samples by the proposed educational multilingual TTS.

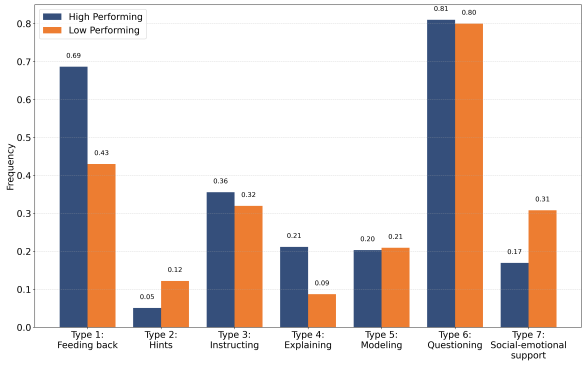

Figure 10: Dialogue analysis on scaffolding types of high-performing and low-performing students.

bustness regarding inappropriate language and random user inputs. By incorporating dialogic teaching principles and personality-aware student simulation, our system maintains focus on educational objectives and avoids generating harmful or off-topic responses. For instance, when faced with unexpected user behaviors, the model usually prompts the students back to the image description task (i.e., adopting the scaffolding type "instruction").

4.4 Improving Multilingual TTS

For engaging speech generation, we utilized VITS (Kim et al., 2021), a non-autoregressive framework that achieves a balance between speech quality and computational efficiency. In particular, for low-resource scenarios Malay and Tamil, we collected recordings from adult teachers and children for modeling appropriate prosodic patterns and speech rhythms. The Malay training data includes 22 hours of adult speech from 1 speaker and 9 hours of child speech from 97 speakers, while the Tamil training data comprises 63 hours of adult speech from 1 speaker and 1.5 hours of child speech from 52 speakers. Speaker embeddings are in a one-hot input format, followed by embedding layer, enabling multi-speaker generation. This approach addresses the issue of voice naturalness in educational contexts, as our preliminary testing revealed that students engage more effectively with systems that generate age-appropriate speech.

As shown in Figure 9, both objective and subjective evaluations are conducted to assess the multilingual TTS performance. Subjective evaluation is conducted using Mean Opinion Score (MOS) ratings, where listeners assess the overall speech quality and naturalness of the synthesized speech on a 1-5 scoring. It includes 15 Malay and 15 Tamil child speech samples, rated by 20 native Malay and Tamil listeners respectively. The MOS results indicate that our TTS models achieved a reasonable performance (with an average score exceeding 3.50), showing the effectiveness of multilingual adaptation on naturalness and overall quality. For objective evaluations, we measure speech intelligibility using the widely adopted character error rate (CER). Specifically, we used pretrained Malay and Tamil ASR models to transcribe the Malay and Tamil TTS generation, and computed the CER to quantify speech intelligibility. The results (see Figure 9) demonstrate that our TTS models achieve high speech intelligibility, with recognition accuracy exceeding 90% for both Malay and Tamil.

5 Student Practice and Discussion

We conducted a user study with 35 elementary school students (grade 1-2) to evaluate SingaKids' effectiveness in real-world educational settings (IRB number: `IRB-2024-218`). Participants represented diverse language proficiency levels, and they were using the system under the consent and guidance from their parents. Following previous work (Liu et al., 2024c), we conducted a utterance-level analysis of the 7 scaffolding types. As shown in Figure 10, significant differences are in some scaffolding types. High-performing students receive more feeding back (69% vs. 43%) and explanations (21% vs. 9%), where students were encouraged toward deeper understanding. Low-performing students received more hints (12% vs. 5%) and social-emotional support (31% vs. 17%); the system provides clues, support building confidence when learners struggle.

Moreover, there are observations from our preliminary study: (1) In some cases, noisy environments and children's speech led to more ASR errors, affecting the communication quality. Noise-robust speech recognition and speaker recognition and diarization can help mitigate these issues; (2) Even with dynamic scaffolding and social-emotional support, some students exited sessions when facing persistent difficulties. The scaffolding type "*Modeling*" needs to be triggered to prevent frustration; (3) For lower elementary grades, parent guidance is necessary, as they can provide assistance and additional support; (4) When there are many objects and activities in the picture, kids sometimes become distracted or have difficulty pinpointing the focus area, and adding visual highlighting (e.g., bounding boxes) helps improve focus and comprehension. These findings underline the importance of modeling kids-specific learning preferences, to create a more inclusive and effective language learning experience.

6 Conclusion

In this work, we presented SingaKids, a multilingual multimodal dialogic tutor designed to enhance elementary language acquisition through picture description tasks. By integrating dense image captioning, multilingual interaction, speech understanding, and engaging speech generation across four languages, our system creates an interactive learning environment that adapts to diverse linguistic contexts. Considering the speech and language proficiency and learning objectives of elementary students, we further improved the system on task-specific optimization and age-appropriate pedagogical alignment. Preliminary empirical studies with elementary school students demonstrated SingaKids' effectiveness in providing self-adaptive guidance through dynamic scaffolding and social-emotional support. Our work provides both technical and educational insights to build general agents in broader educational contexts.

Limitations

We are aware that it remains an open problem to mitigate hallucinations and biases in large language models, which may cause communication issues in human-machine interaction and computer-assisted education. Of course, current models and laboratory experiments are always limited in this or similar ways. We do not foresee any unethical uses of our proposed methods or their underlying tools, but hope that it will contribute to reducing incorrect system outputs.

Ethics and Impact Statement

We acknowledge that all of the co-authors of this work are aware of the provided ACL Code of Ethics and honor the code of conduct. In our experiments, models are applied under proper license. All data used in this work are only for academic research purposes and should not be used outside of academic research contexts. Our proposed methodology in general does not create a direct societal consequence and are intended to be used to improve the performance, robustness, and safety of the intelligent tutoring systems.

Abstract

There has been increasing interest in unifying streaming and non-streaming automatic speech recognition (ASR) models to reduce development, training, and deployment costs. We present a unified framework that trains a single end-to-end ASR model for both streaming and non-streaming applications, leveraging future context information. We propose to use dynamic right-context through the chunked attention masking in the training of zipformer-based ASR models. We demonstrate that using right-context is more effective in zipformer models compared to other conformer models due to its multi-scale nature. We analyze the effect of varying the number of right-context frames on accuracy and latency of the streaming ASR models. We use Librispeech and large in-house conversational datasets to train different versions of streaming and non-streaming models and evaluate them in a production grade server-client setup across diverse testsets of different domains. The proposed strategy reduces word error by relative 7.9% with a small degradation in user-perceived latency. By adding more right-context frames, we are able to achieve streaming performance close to that of non-streaming models. Our approach also allows flexible control of the latency-accuracy tradeoff according to customers requirements.

1 Introduction

In recent times, end-to-end (E2E) ASR models have started taking the main stage in industrial use-cases (Povey et al., 2016). Recurrent neural networks (RNNs) are crucial as they can model the temporal dependencies in audio sequences effectively (Chiu et al., 2018; Rao et al., 2017; Sainath et al., 2020). The transformer architecture with self-attention has gained substantial attention in ASR to capture long distance global context and show high training efficiency (Zhang et al., 2020b; Vaswani et al., 2017; Hsu et al., 2021; Chen et al., 2022). Alternatively, ASR based on convolutional neural networks (CNNs) has also been successful due to its ability to exploit local information (Li et al., 2019; Han et al., 2020a; Abdel-Hamid et al., 2014). Recently, the conformer ASR model (Gulati et al., 2020) was proposed for combining the advantages of CNN and transformer models, to extract both local and global information from a speech sequence (Han et al., 2020b; Shi et al., 2021; Kim et al., 2022; Yao et al., 2023). Zipformer (Yao et al., 2023) is an extension of the previous conformer models, providing a transformer that is faster, more memory-efficient, and better-performing.

Latency-accuracy is a critical trade-off for an ASR model, especially for streaming ASR models. In systems with concurrent call processing, it becomes critical to find the optimal operating point in the latency-concurrency-accuracy trio. Streaming decoders work on chunk-based processing, where, for each frame the encoder has access to, the entire left-context and a variable right-context depending on the frame's position in a chunk are used.

Right context has a significant role in the context of a unified model in streaming and in offline production environment. Typically, the WER of the offline model is significantly lower compared to that of a streaming model. Therefore, separate models are generally trained for offline and streaming use-cases. This requires twice the compute resource to train the models and additional resource to maintain and update the models. Adding right-context helps bridge the gap in WER between offline and streaming models with a small degradation in latency in the streaming case.

In Swietojanski et al. (2023), authors use variable attention masking in a transformer transducer setting, however the influence of different numbers of right-context frames is not explored and the work instead focuses on using right-context ranging from multiple chunks to full context, which may not be possible for a streaming setup. Li et al.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1254–1262

(2023) propose a dynamic chunk-based convolution, where the core idea is to restrict the convolution at chunk boundaries so that it does not have access to any future context and resembles the inference scenario. Our approach, by contrast, uses limited additional right-context frames beyond chunk boundaries. Our proposed method is also different from that of Tripathi et al. (2020), where initial layers are trained with zero right context and the final few layers are trained with variable context. If we wanted a streaming model with different latency during inference, the model would need to be retrained. Zhang et al. (2020a) use dynamic chunk sizes for different batches in training and the attention scope varies from left-context only to full context. The authors in Wu et al. (2021) further enhance their strategy by employing bidirectional decoders in both forward and backward direction of the labeling sequence. In both passes, they use either full right-context or full left-context attention masking, which may adversely impact the real-time streaming use-case.

Our work is significantly different from the aforementioned approaches in terms of training with variable right-context while decoding with extra right-context frames in addition to the chunk being decoded in the inference phase. We propose to unify streaming and non-streaming zipformer-based ASR models by leveraging future context. The conventional zipformer model uses chunked attention masking and utilizes only left-context while we use a variable number of right-context frames for different mini-batches during training, providing the flexibility to select a desired number of right-context frames during inference, according to the desired accuracy-latency tradeoff. We study the effect of choosing different amounts of right context on latency and accuracy, finding that as the number of decoding right-context frames increases, the streaming zipformer ASR model can approach the performance of the corresponding non-streaming model without significantly degrading latency. We evaluate our method on both open-source read speech and industry-scale production-specific conversational speech data.

2 Right-context in Zipformer

Here we review the zipformer model and the attention masking employed to incorporate right-context information (Gulati et al., 2020; Yao et al., 2023).

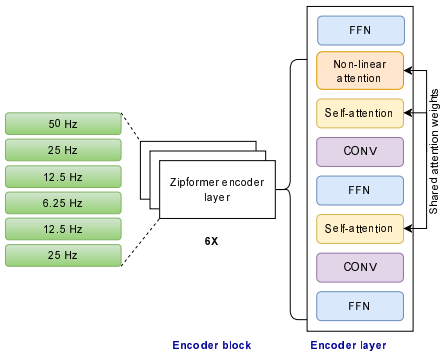

Figure 1: Zipformer encoder architecture showing each layer at different frame rates (left) and different modules in each encoder layer (right).

2.1 Zipformer model

The zipformer model is a significant advancement in transformer-based ASR encoding, offering superior speed, memory efficiency, and performance compared to conventional conformer models. A conformer model adds a convolution module to a transformer to add both local and global dependencies. In contrast to the fixed frame rate of 25Hz used by conformers, the zipformer employs a U-Net-like structure, enabling it to learn temporal representations at multiple resolutions in a more streamlined manner.

In the zipformer encoder architecture, we have six encoder blocks, each at different sampling rates learning temporal representation at different resolutions in a more efficient way. Specifically, given the acoustic features with frame rate of 100 Hz, a convolution based module reduces it first to 50 Hz, followed by the six cascaded stacks to learn temporal representation at frame rates of 50Hz, 25Hz, 12.5Hz, 6.25Hz, 12.5Hz, and 25Hz, respectively as shown on the left side of Figure 1. The middle block operates at 6.25 Hz undergoing stronger downsampling, thus facilitating more efficient training by reducing the number of frames to process. The frame rate between each block is consistently 50 Hz. Different stacks have different embedding dimensions, and the middle stacks have larger dimensions. The output of each stack is truncated or padded with zeros to match the dimension of the next stack. The final encoder output dimension is set to the maximum of all stacks' dimensions.

The inner structure of each encoder block is shown in the right side of Figure 1. The primary motivation is to reuse attention weights to improve efficiency in both time and memory. The block

input is first processed by a multi-head attention module, which computes the attention weights. These weights are then shared across a non-linear attention module and two self-attention modules. Meanwhile, the block input is also fed into a feed-forward module followed by the non-linear attention module.

2.2 Attention masking

The multi-head self-attention facilitates fine-grained control over neighboring information at each time step. At each time t, $Zipformer(x, t)$ may be derived from an arbitrary subset of features in x, as defined by the masking strategy implemented in the self-attention layers (Vaswani et al., 2017). Given the attention input $Y = (y_1, \ldots, y_{L_y}), y_t \in \mathbb{R}$ self-attention computes

$$Q = \mathcal{F}^q(Y), K = \mathcal{F}^v(Y), V = \mathcal{F}^v(Y), \quad (1)$$

$$Att(Q, K, V) = softmax\left(\frac{\mathcal{M}(QK^T)}{\sqrt{d}}\right)V^T, \quad (2)$$

where, d is the attention dimension, $\mathcal{M}$ is the attention mask with values 0 and 1 of dimension $L_y \times L_k$. The attention mask in the Equation 2 regulates the allowance of number of left and right-context frames corresponding to each frame of Y.

2.3 Right-context attention masking

The attention masks constrain the receptive field in each layer without the need for physically segmenting the input sequence. In a streaming ASR setup, to mitigate computational costs and latency, the processing occurs at the chunk level rather than at the frame level. A specific number of frames are grouped into chunks, and each chunk is then encoded as a batch. Following Shi et al. (2021); Chen et al. (2021), we use chunked attention masking to confine the receptive field during self-attention computation. In conventional chunked attention masking, each frame within a chunk is exposed to varying extents of left- and right-context frames. The initial frames in a chunk have access to some right-context frames, while the later frames have no access to right-context frames, enforcing a causal constraint at chunk boundaries.

The conformer and zipformer ASR recipes in *k2-fsa icefall*[1] (Gulati et al., 2020; Shi et al., 2021) deploy chunked attention masking and use only left-context as shown in Figure 2(a). For streaming decoders, each frame in the encoder accesses left-context and variable right-context depending on the frame's position in a chunk.

However, the right-context information is very relevant to learn the acoustic-linguistic attributes of a chunk. Utilizing a modest right and left context may yield improved performance in terms of WER and latency when compared to solely relying on an extensive left-context. Incorporating right-context will thus help to narrow the gap in WER between streaming and non-streaming models. Furthermore, due to the varying temporal resolutions of each layer within the zipformer encoder block, the utilization of right-context frames becomes more efficient. In this work, we deploy chunked masking with right-context as shown in Figure 2(b), where the extent of right-context and left-context can be varied based on requirements. We note that the right-context frames are the frames beyond the chunk boundaries, not within the chunks.

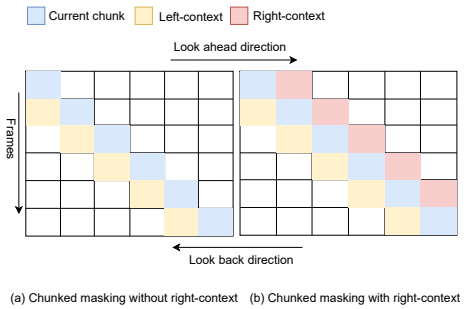

Figure 2: Attention masking in zipformer; (a) chunked masking with left-context and no right-context, (b) chunked masking with both left-context and right-context.

3 Experiments

Below we discuss the database used and experiments conducted to demonstrate the effectiveness of right-context in unified streaming and non-streaming ASR models.

3.1 Dataset

We conduct experiments using two data setups, using *Librispeech* and *large in-house conversational data*. In the Librispeech setup, we use the standard 960 hours of training data, as well as test-clean (5.40 hrs) and test-other (5.10 hr) partitions for testing. Using the Librispeech setup we train a conventional conformer transducer streaming model and a baseline zipformer streaming model without any right-context during training. Using this setup,

[1]https://github.com/k2-fsa/icefall

we also train a zipformer streaming model with proposed right-context strategy and a non-streaming model.

Using the *large in-house conversational setup*, we train zipformer models without right-context, with right-context and the non-streaming variant. The in-house training data is derived by combining different open source databases along with in-house conversational and simulated conversational telephonic datasets as shown in Table 1. In total we use 12,468 hours of training data. The training data also includes a synthesized corpus generated using a text-to-speech model. We employ diverse in-house test datasets listed in Table 1 that comprise different domains and accents. The DefinedAI en-in, en-ph, en-au and en-gb subsets correspond to Indian, Filipino, Australian and UK-accented English, respectively. To evaluate the latency and inference time in the server-client setup, we use long conversations as test data to mimic the production use-cases.

Table 1: Duration and domain information for different training and test sets used in the experiments.

Dataset	Duration (hours)	Domains

3.2 Experimental setup

To assess the effectiveness of the proposed approach to unify streaming and non-streaming ASR models, we setup our experiments using Librispeech and large in-house conversational dataset. For both the setups, we evaluate different baseline and right-context models using Icefall's simulated streaming decoding approach. We further evaluate the large in-house ASR models in server-client production setup.

3.2.1 Librispeech models

Using the Librispeech setup, we initially train a baseline conformer transducer streaming model (Kuang et al., 2022) ($\text{Conformer}_{\text{Baseline}}$) without any right-context. Further, we train two zipformer streaming models: the baseline model ($\text{Libri}_{\text{Baseline}}$), the right-context model ($\text{Libri}_{\text{RC-0-64-128-256}}$). Additionally, a non-streaming model (Libri_{NS}) is trained using this setup.

3.2.2 Large-data conversational models

Utilizing the large in-house conversational English data, we showcase the efficacy of the proposed approach in a more challenging conversational environment with different test cases comprising different domains and accents. Using this data, We train two streaming zipformer models: $\text{Large}_{\text{Baseline}}$, and $\text{Large}_{\text{RC-0-64-128-256}}$, and a non-streaming model Large_{NS}.

3.2.3 Training setup

All experiments described above (except $\text{Conformer}_{\text{Baseline}}$ model) adhere to the standard *zipformer* recipe[2] within the Icefall toolkit. The conformer model ($\text{Conformer}_{\text{Baseline}}$) is trained using the pruned_transducer_stateless4 recipe in Icefall toolkit. We use the zipformer-medium setup for Librispeech model and zipformer-large for the large in-house models (Yao et al., 2023). The base learning rate is 0.045 for the Librispeech setup, and 0.05 for the large in-house model training. Additionally, the chunk-size varies among the values [16, 32, 64] frames during training, where, each frame corresponds to 10 ms in both training and decoding. Based on our experiments on a a small-data setup, we use varying numbers of right-context frames by randomly choosing from the set $\{0, 64, 128, 256\}$ for each batch during training. All models undergo training for up to 30 epochs, using eight NVIDIA V100 GPUs.

Evaluation is conducted using 128 left-context frames, a chunk size of 32 frames, 30 epochs with an averaging over 6. We evaluate different baseline and right-context models using Icefall's simulated streaming decoding approach for both Librispeech and Large in-house setups. We also demonstrate performance in server-client setup for the in-house models.

[2]https://tinyurl.com/2whxxub2

3.2.4 Server-client-based evaluation

To demonstrate the performance of the proposed unified ASR training approach, we evaluate the in-house models ($\text{Large}_{\text{Baseline}}$, $\text{Large}_{\text{RC-0-64-128-256}}$, Large_{NS}) in server-client setup. We use Sherpa websocket server for real-time streaming[3]. The ASR model is loaded on a cpp-based websocket server, which listens to a specific port on a server machine. A Python client is used to create multiple and simultaneous websocket connections to the server to support concurrent processing. The client streams audio chunks of 500 ms in real time. When an endpoint is reached in the audio, the transcripts are sent back to the client. "Final-chunk latency" is the metric used to measure the latency of the ASR output: latency is measured in the client as the time from when the last chunk is streamed to the server to the time when the final transcript is received back in the client. The server used in this experiment is a g5.2xlarge AWS instance, which has 1 Nvidia A10G GPU, 8 vPUs and 32GB RAM.

3.3 Evaluation metrics

We use word error rate (*WER*) as the performance metric for recognition accuracy. Final-chunk latency as described above is evaluated in the client-server setting and simply referred to as *latency* here. Another measure to analyze the inference time is inverse real time factor (RTFX). *RTFX* is calculated as, $\text{RTFX} = \frac{\text{duration of testset}}{\text{inference time}}$. Higher RTFX corresponds to less inference time. As in production environment, we process multiple calls at the same time, we analyse the latency and RTFX over different concurrency values. Concurrency can be defined as the number of concurrent calls being sent from the client to the server at a given point in time.

We measure latency only for streaming ASR and RTFX for both streaming and non-streaming ASR models. Non-streaming models do not support concurrency in our setup, as they process a conversation by splitting it into smaller segments.

4 Results

4.1 Librispeech setup

In Figure 3, we compare the WER (%) of the $\text{Conformer}_{\text{Baseline}}$ model with that of the zipformer-based $\text{Medium}_{\text{Baseline}}$ model for Librispeech test-clean and test-other testsets. We note that these two models are not trained with right-context. Figure 3, illustrates that during inference, increasing the number of right-context frames leads to WER improvement for both models. However, the zipformer-based model shows more pronounced improvement in WER compared to the conformer model. The enhanced performance is due to the varying frame rates across different encoder blocks in the zipformer architecture, making it a superior choice for a unified ASR model.

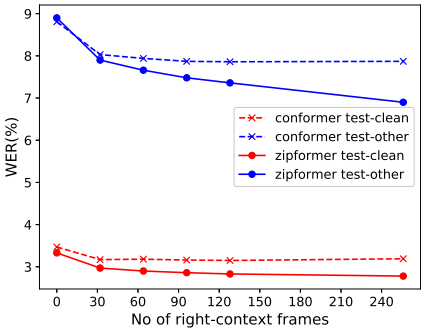

Figure 3: Comparison of conventional conformer ($\text{Conformer}_{\text{Baseline}}$) and zipformer ($\text{Medium}_{\text{Baseline}}$) models in terms of WER(%) with different number of right-context frames during inference.

In Table 2, we show the WER(%) for $\text{Libri}_{\text{Baseline}}$ and $\text{Libri}_{\text{RC-0-64-128-256}}$ models for different numbers of right-context frames during decoding. A noteworthy observation is the improvement in WER of the $\text{Libri}_{\text{Baseline}}$ model, which decreases from 3.33% to 2.83% as the number of decoding right-context frames increases from 0 to 256, despite this model not being trained with right-context. In the baseline model, although we do not explicitly impose right-context frames, the initial frames of a chunk see the entire chunk length as right-context, whereas the later frames do not have access to any right-context. The $\text{Libri}_{\text{RC-0-64-128-256}}$ model achieves WERs of 2.43% in test-clean and 6.55% in test-other, compared to the baseline model's respective WERs of 3.33% and 8.90%, bringing it closer to the non-streaming model's (Libri_{NS}) performance, as shown in Table 2. Across all models, increasing the number of decoding right-context frames consistently contributes to obtaining a viable unified model for both streaming and non-streaming applications.

4.2 Large in-house conversational setup

In Table 3, we depict the WER values of the $\text{Large}_{\text{Baseline}}$ and $\text{Large}_{\text{RC-0-64-128-256}}$ models with the number of right-context frames in decoding varying from 0 to 256. We can observe that the

[3]https://github.com/k2-fsa/sherpa

Table 2: WER(%) of the models trained on 960 hours of Librispeech data, including $\text{Libri}_{\text{Baseline}}$, $\text{Libri}_{\text{RC-0-64-128-256}}$ and non-streaming model.

models→	$\text{Libri}_{\text{Baseline}}$		$\text{Libri}_{\text{RC-0-64-128-256}}$		Libri_{NS}
#Decoding RC frames↓	test-clean	test-other	test-clean	test-other	
0	3.33	8.90	4.43	9.50	test-clean: 2.38 test-other: 5.72
32	2.97	7.90	2.80	7.10	
64	2.90	7.66	2.74	6.89	
96	2.86	7.48	2.58	6.85	
128	2.83	7.36	2.46	6.70	
256	2.81	7.36	2.43	6.55	

WER of $\text{Large}_{\text{Baseline}}$ improves as we increase the number of right-context frames in decoding, although the model is not trained with right-context. However, the right-context training strategy presented in this paper helps to further improve the performance of the $\text{Large}_{\text{RC-0-64-128-256}}$ model across all testsets. Notably, with 64 right-context frames during decoding, the average WER improves to 8.31% compared to 10.34% in the baseline without right context during training and decoding. Moreover, the results in Table 3 exhibit the convergence of the streaming model's performance towards the non-streaming model with the proposed right-context attention mask. This convergence signifies the potential for deploying a streaming ASR model in place of its corresponding non-streaming counterpart, facilitated by increasing the decoding right context frames. Ultimately, these results affirm that a unified zipformer-based model can effectively serve both streaming and non-streaming applications through the proposed right-context chunked and hybrid attention masking training methods. Apart from unifying streaming and non-streaming models, the proposed approach adds flexibility to choose a balance between accuracy and latency by selecting an suitable number of right-context frames in decoding according to requirement.

Table 3: WER(%) of the models trained on 12,460 hours of in-house conversational data, including $\text{Large}_{\text{Baseline}}$, $\text{Large}_{\text{RC-0-64-128-256}}$, and non-streaming model with in-house testsets.

4.2.1 Server-client setup

As discussed in Section 3.2, we deploy the large in-house conversation model in server-client environment. In Table 4, we show the WERs for the $\text{Large}_{\text{Baseline}}$ model with no right-context in decoding and the $\text{Large}_{\text{RC-0-64-128-256}}$ model with 0, 32, and 64 right-context frames in decoding along with the non-streaming model (Large_{NS}). We note that for the same model there is a difference in performance between the simulated streaming and real streaming (server-client) environments, because of the padding involved in the real streaming case. However, from Table 4 we can observe that the average WER of the in-house model improves from 9.0% to 8.2% with the streaming model, approaching the non-streaming model.

Table 4: WER(%) of the $\text{Large}_{\text{RC-0-64-128-256}}$ and non-streaming models trained on 12,460 hours of in-house conversational data for different in-house testsets.

Client-3	10.9	10.4	10.4	10.4
Client-17	10.7	10.9	9.8	9.8
Average	**9.0**	**8.5**	**8.2**	**8.2**

Table 5: Latency (sec) and RTFX values of the $\text{Large}_{\text{RC-0-64-128-256}}$ and Large_{NS} models trained on 12,460 hours of in-house conversational data in server-client setup for the long calls testset.

Model→	$\text{Large}_{\text{RC-0-64-128-256}}$						Large_{NS}
#Decoding RC frames→	0		32		64		
Concurrency↓	Latency	RTFX	Latency	RTFX	Latency	RTFX	
100	1.41	82.65	1.44	82.66	1.47	82.66	143.89
200	2.17	163.76	2.17	163.77	2.35	163.73	
300	2.45	242.27	2.83	242.21	3.24	242.23	

Apart from WER, latency or inference time plays a crucial role in industrial streaming ASR models. In Table 5, we show the latency and RTFX values of the $\text{Large}_{\text{RC-0-64-128-256}}$ model for different numbers of decoding right-context frames for concurrency of 100, 200 and 300. In this evaluation we use the long conversations testset in Table 1. From Table 5, we can observe that there is no significant degradation of user-perceived latency as right-context increases. The RTFX values of the streaming $\text{Large}_{\text{RC-0-64-128-256}}$ model are higher than that of the non-streaming model in all the cases. The greater RTFX demonstrates less inference time for the streaming model with right-context compared to the non-streaming model. For the streaming application, with the introduction of right-context we

observe increase in accuracy and a small degradation in latency; for the non-streaming use-case the accuracy drops with the reduction in inference time or latency. As we further increase the number of decoding right-context frames, the accuracy of streaming model eventually comes close to that of the non-streaming model.

5 Conclusions

We propose to unify streaming and non-streaming zipformer ASR models by incorporating right-context frames. We employ a chunked attention masking strategy with dynamic right-context to improve the WER of a zipformer-based streaming ASR model. We observe that baseline streaming models trained without right-context eventually shows improved performance with right-context during inference. With the increase in decoding right-context frames, the gap in WER% between the streaming and non-streaming model decreases, thereby validating the proposed unified training of streaming and non-streaming zipformer models. Our approach yields a flexible ASR model that can achieve the desired accuracy-latency tradeoff during inference, based on application requirements.

A Experiments to find optimal right-context training setup

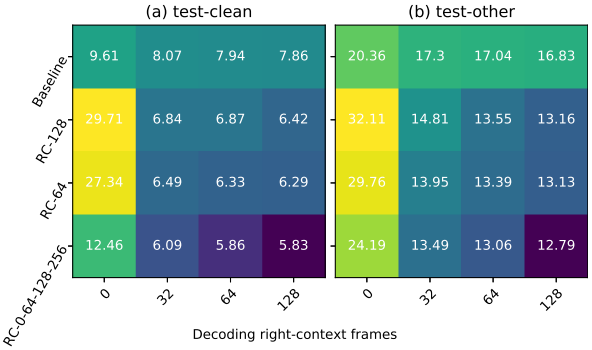

Figure 4: WER(%) of the models trained on 100 hours of clean Librispeech training data, varying the number of right-context frames, evaluated on (a) test-clean and (b) test-other datasets.

To refine the number of right-context frames that the model acquires during the training process, we first train various zipformer models using the small-scale Librispeech 100 hours training dataset.

First, we develop a baseline streaming model without right-context. Subsequently, we train different models: with constant 128 frames of right-context in training (*RC-128*), and another incorporating 64 frames of right-context, termed as the *RC-64* model. In successive models, we introduce variability in the number of right-context frames utilized during training. Specifically, within each batch, the number of right-context frames is randomly selected from the set $\{0, 64, 128, 256\}$ for the *RC-0-64-128-256* model. In these models the number of right-context frames is constant over the training. We note that the duration of contexts of *RC-64* and *RC-128* are $1.28sec$ and $2.56sec$, respectively.

To assess the impact of the number of right-context frames used in decoding, we evaluate each model for 0, 32, 64, and 128 right-context frames.

We found that all models trained with right-context outperform the baseline model without right-context. Notably, models trained with varying right-context frames during training demonstrate superior performance compared to those trained with fixed right-context frames. Among these, the RC-0-64-128-256 model achieves the lowest WER. In all cases, increasing the number of right-context frames in decoding leads to improved performance. Additionally, we note that models trained with right-context experience degraded performance when decoded without right-

context frames. Figure 4 (a) and Figure 4 (b) show the WER values corresponding to the test-clean and test-other testsets, respectively. In Figure 4(a), we observe a diagonal improvement in WER from 9.61% to 5.83% with the introduction of right context. A similar trend is evident in Figure 4(b) for the test-other testset.

A Semi-supervised Scalable Unified Framework for E-commerce Query Classification

Abstract

Query classification, including multiple subtasks such as intent and category prediction, is vital to e-commerce applications. E-commerce queries are usually short and lack context, and the information between labels cannot be used, resulting in insufficient prior information for modeling. Most existing industrial query classification methods rely on users' posterior click behavior to construct training samples, resulting in a Matthew vicious cycle. Furthermore, the subtasks of query classification lack a unified framework, leading to low efficiency for algorithm optimization.

In this paper, we propose a novel **S**emi-supervised **S**calable **U**nified **F**ramework (SSUF), containing multiple enhanced modules to unify the query classification tasks. The knowledge-enhanced module uses world knowledge to enhance query representations and solve the problem of insufficient query information. The label-enhanced module uses label semantics and semi-supervised signals to reduce the dependence on posterior labels. The structure-enhanced module enhances the label representation based on the complex label relations. Each module is highly pluggable, and input features can be added or removed as needed according to each subtask. We conduct extensive offline and online A/B experiments, and the results show that SSUF significantly outperforms the state-of-the-art models.

1 Introduction

E-commerce platforms like Amazon, Taobao, and JD provide users with billions of diverse products and have become essential in our daily lives. Due to the wide variety of user needs and product categories, capturing users' purchasing intentions is vital for both user experience and platform efficiency. Query classification, including intent, category, and brand prediction, plays a key role in understanding users' shopping needs and supports the subsequent modules of the search system.

The inherent characteristics of e-commerce queries, which are typically short, and ambiguous, bring significant challenges for query classification. To solve the problem of insufficient information caused by short queries, some deep learning-based models, such as XML-CNN (Liu et al., 2017), KRF (Ma et al., 2020), HiAGM (Zhou et al., 2020), and LSAN (Xiao et al., 2019) have been proposed to learn the contextual information of documents to enhance the representation learning of queries. Some recent query classification models, such as HCL4QC (Zhu et al., 2023), SMGCN (Yuan et al., 2024), and HQC (He et al., 2024) also explore utilizing the hierarchical category tree structure or instance hierarchy to facilitate models to learn external information beyond query information.

Industrial methods for query classification typically rely on users' click behavior to generate training samples. While using real user interactions can improve model accuracy, it also introduces a dependency cycle known as the "Matthew effect." This cycle leads to biased training data, where popular queries receive excessive focus, skewing the model's understanding and limiting its ability to generalize to tail queries. Moreover, existing models often handle subtasks separately, overlooking potential synergies that could enhance efficiency in model optimization and development. The lack of a unified framework further impedes the sharing of insights and improvements across different subtasks, thereby restricting overall performance.

To address these challenges, we propose a semi-supervised scalable unified framework (SSUF) for e-commerce query classification. SSUF is designed to overcome the above problems by introducing a set of scalable modules: (1) Label-enhanced module, (2) Knowledge-enhanced module, and (3) Structure-enhanced module to enhance query and label representations with prior knowledge, reduce

* Corresponding author.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1263–1271

dependency on posterior labels and enhances the model's ability to generalize from limited data. Each module within SSUF is designed to be highly pluggable, allowing for flexible adaptation to the specific needs of different subtasks. This modularity ensures that the framework can be tailored to enhance various aspects of query classification.

The contributions of this paper are as follows:

- We propose a novel unified framework to improve the optimization efficiency of e-commerce query classification models.
- We design three scalable modules that enhance the query and label representations and break the "Matthew vicious cycle" to improve the performance of query classification.
- We conduct extensive offline and online A/B experiments, and SSUF significantly outperforms existing strong baselines. It has been deployed at an e-commerce platform and brings great commercial value.

2 Related Work

2.1 Multi-label Classification

Multi-label classification is a vital area in machine learning, where each instance can be linked to multiple labels. Machine learning methods address this problem by transforming the multi-label problem into several single-label tasks (Tsoumakas et al., 2007, 2009; Read et al., 2011). Recently, deep learning models, such as XML-CNN (Liu et al., 2017), LSAN (Xiao et al., 2019) and LEAM (Wang et al., 2018) utilize contextual information or label-specific attention to enhance the interaction between document and labels for classification.

2.2 Query Classification

Early models mainly relied on deep learning models, such as CNN (Hashemi et al., 2016), LSTMs (Sreelakshmi et al., 2018), and attention-based models (Zhang et al., 2021; Yuan et al., 2023) to extract fine-grained features for classification. Recent works like PHC (Zhang et al., 2019) explore multi-task frameworks to jointly optimize query classification and textual similarity, while DPHA (Zhao et al., 2019) leverages label graph-based neural networks to model label correlations. HCL4QC (Zhu et al., 2023), SMGCN (Yuan et al., 2024), and HQC (He et al., 2024) use hierarchical structures and instance hierarchy to learn information beyond query text.

3 Model

In this section, we first formally define the query classification task. Then, we describe different modules of SSUF and analyze the influence of the model during the training and inference process.

3.1 Label-enhanced Module

Instead of directly using the label index as label embedding, we employ BERT (Kenton and Toutanova, 2019) as the encoder for labels to learn the semantic representation of the label.

The input of the text encoder is a character sequence of label, which is comprised of two parts: (1) the label name $n = [n_1, n_2, \ldots, n_L]$, and (2) the enhanced label side information $m = [m_1, m_2, \ldots, m_{L_m}]$, which is retrieved from (1) label description, such as product words, frequently searched query terms, etc. (2) world knowledge generated by LLM.

The label's character sequences are fed into BERT to encode label representation:

$$\mathbf{C}_j = \mathbf{BERT}_{\mathbf{CLS}}([n_1, \ldots, n_L, m_1, \ldots, m_{L_m}]), \quad (1)$$

where $\mathbf{C}_j \in \mathbb{R}^{1\times d}$ is the "CLS" representation of the last layer of BERT. In the same way, we can get the representation of query $\mathbf{Q}_i \in \mathbb{R}^{1\times d}$.

3.2 Knowledge-enhanced Module

Industrial methods for query classification have relied on users' posterior click behavior to generate training samples. However, it leads to the "Matthew vicious cycle" and results in biased training data, where popular queries receive more attention, skewing the model's understanding and limiting its ability to generalize to less frequent queries.

We propose a semi-supervised module to overcome the limitations of posterior labels. However, we found that for queries with ambiguous semantics, it is often inaccurate to directly compute semi-supervised labels for queries and labels. For example, the query "Black 16pro" refers to an Apple mobile phone model, but due to insufficient semantic information, similarity scores with relevant labels such as "mobile phone" and "second-hand mobile phone" are low. This results in the semi-supervised signal failing to effectively recall related labels. To solve this issue, we incorporate a knowledge-enhanced module to improve the representation of queries for semi-supervised labeling.

We can use (1) the posteriori knowledge, such as the user's frequently clicked or bought product la-

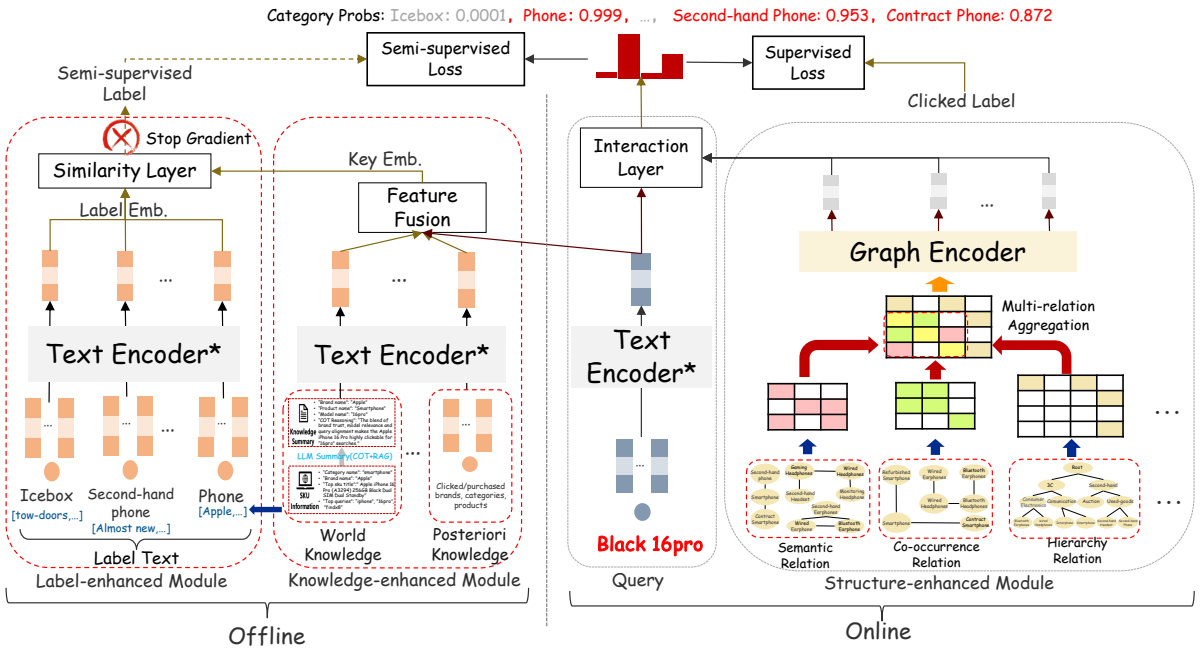

Figure 1: Semi-supervised Scalable Unified Framework for E-commerce Query Classification. The offline part participates in the training of the model but is not directly deployed online. The part with red dashed lines is a pluggable module. The "Text Encoder*" denotes a shared text encoder.

bels, (2) the world knowledge extracted from LLM as the input. To obtain the world knowledge of the query, we feed the query and the related products to an open-source LLM to summarize a brief description, which may contain relevant queries, categories, products, etc. With this information, the model can comprehensively encode the semantic representations of the query.

After obtaining the posterior and world knowledge, we feed them into a shared text encoder:

$$\mathbf{k}_i = \mathbf{BERT}_{\mathbf{CLS}}([k_1, \ldots, k_n]) \,, \tag{2}$$

to get the knowledge embeddings $\mathbf{K} \in \mathbb{R}^{|K| \times d}$.

To fuse these knowledge embeddings with query representation $\mathbf{Q}_i$, we use an attention module, which can be formulated as follows:

$$\begin{aligned} \alpha &= \mathbf{softmax}(\mathbf{Q}_i \mathbf{K}^T) \,, \\ \mathbf{q}'_i &= \mathbf{Q}_i + \sum_{j=1}^{|K|} \alpha_j \mathbf{K}_j \,, \end{aligned} \tag{3}$$

where α is the attention score and $\mathbf{q}'_i \in \mathbb{R}^{1 \times d}$ is the final fused query representation.

We compute the similarity score between the fused query and label representations to treat it as a semi-supervised label. Specifically,

$$\begin{aligned} \mathbf{s}_i &= \mathbf{stop\_grad}\left(\frac{\mathbf{q}'_i \mathbf{C}^T}{\|\mathbf{q}'\| \|\mathbf{C}\|}\right) \,, \\ \mathbf{y}_{ij}^{semi} &= \mathbf{s}_{ij} \cdot \mathbb{1}_{\mathbf{s}_{ij} \geq \tau} \,, \end{aligned} \tag{4}$$

where $\mathbf{s}_i \in \mathbb{R}^{1 \times |C|}$ is the relevance scores between query q_i and all categories. τ is the threshold to filter the categories with low scores. $\mathbf{y}_{ij}^{semi}$ is the semi-supervised label.

Both queries and labels utilize the same text encoder, but their word distributions is different. Feeding the gradient of the semi-supervised signal back into the semi-supervised label module can create a circular dependency, potentially causing the model to collapse. To prevent this, we disable gradient feedback from this branch.

3.3 Structure-enhanced Module

3.3.1 Graph Construction

Firstly, we obtain the co-occurrence relations between categories by counting the co-occurrence times of categories in the training samples. Then, we compute the conditional probability of two categories and obtain the adjacency matrix $\mathbf{A}^{coo}$:

$$\mathbf{a}_{ij} = \frac{N(c_i, c_j)}{N(c_i)} \,, \mathbf{A}_{ij}^{coo} = \mathbf{a}_{ij} \cdot \mathbb{1}_{\mathbf{a}_{ij} \geq \alpha} \tag{5}$$

where $N(c_i, c_j)$ is co-occurrence frequency of label c_i and c_j and $N(c_i)$ denotes the frequency of label c_i. α is the threshold to filter the edges with low relevance scores. $\mathbf{A}^{coo} \in \mathbb{R}^{|C| \times |C|}$ is the adjacency matrix of co-occurrence.

Then, we can obtain the semantic similarity relations between categories by computing the cosine

similarity of every pair of categories:

$$\mathbf{a}_{ij} = \frac{\mathbf{C}_i \mathbf{C}_j^T}{\|C_i\| \|C_j\|}, \mathbf{A}_{ij}^{sim} = \mathbf{a}_{ij} \cdot \mathbb{1}_{\mathbf{a}_{ij} \geq \beta}, \quad (6)$$

where β is the threshold to filter the edges with low relevance scores. $\mathbf{A}^{sim} \in \mathbb{R}^{|C| \times |C|}$ is the similarity adjacency matrix.

For some query classification subtasks, such as intent or category prediction, there is a hierarchical structure among each level of labels. This structure is beneficial in strengthening the relations among relevant labels and weakening the closeness among irrelevant labels. To use this structure, we encode it into the hierarchy adjacency matrix $\mathbf{A}^{hier} \in \mathbb{R}^{|C'| \times |C'|}$, and the edge is defined as:

$$\mathbf{A}_{ki}^{hier} = \mathbf{max}\left(\frac{1}{|Child(k)|}, \frac{m_i}{\sum_{j \in Child(k)} m_j}\right), \quad (7)$$

where $Child(k)$ is the child node set of k, and $i, j \in Child(k)$. m_j is the frequency of node j being clicked by users in the dataset. $|C'|$ denotes the number of all labels, including the first-level, the second-level, and the leaf labels. $|C|$ denotes the number of leaf labels.

3.3.2 Graph Fusion and Learning

In addition to the above three label relationship graphs, each subtask can also increase or decrease the number of label graphs based on its existing input data and business characteristics.

After obtaining the label correlation matrices, we fuse these correlation matrices and normalize the fused matrix with a normalization method (Kipf and Welling, 2017):

$$\begin{aligned} \mathbf{A} &= \frac{1}{2}(\mathbf{A}^{coo} + \mathbf{A}^{sim}) \rightarrow \mathbf{A}^{hier}, \\ \widehat{\mathbf{A}} &= \mathbf{D}^{-\frac{1}{2}} (\mathbf{A} + \mathbf{I}) \mathbf{D}^{-\frac{1}{2}}, \end{aligned} \quad (8)$$

where $\rightarrow$ denotes an assignment symbol. The assignment process is shown in Figure 1. $\mathbf{A} \in \mathbb{R}^{|C'| \times |C'|}$ is the final adjacency matrix. $\mathbf{I}$ is a identity matrix. $\mathbf{D}$ is a diagonal degree matrix with $\mathbf{D}_{ii} = \Sigma_j \mathbf{A}_{ij}$. Finally, we use GCN (Kipf and Welling, 2017) to learn nodes' representation $\mathbf{H} \in \mathbb{R}^{|C'| \times d}$ from the final adjacency matrix $\mathbf{A}$.

Although the training samples for tail labels are limited, these labels can be readily linked to their associated hot labels through intricate label relationships. Such relationships enable the transfer of gradients from samples with hot labels to those with tail labels, leading to more effective representation training for tail labels and mitigating the limitations of posterior labels.

3.4 Training and Inference

In our application scene, we only need to classify a user's input query $\mathbf{q}_i \in \mathbb{R}^{1 \times d}$ to the leaf labels space rather than all labels. Thus, we extract from $\mathbf{H}$ to get leaf labels embedding $\mathbf{H}_l \in \mathbb{R}^{|C| \times d}$. Finally, we use an interaction layer to project the query into label space:

$$\widehat{\mathbf{y}}_i = \mathbf{sigmoid}(\mathbf{q}_i \mathbf{H}_l^T + \mathbf{b}), \quad (9)$$

where $\mathbf{b} \in \mathbb{R}^{1 \times |C|}$ is the bias, and $\widehat{\mathbf{y}}_i \in \mathbb{R}^{1 \times |C|}$ is the predicted labels of query q_i.

To optimize the model with the posteriori and priori labels, we fuse them together as follows:

$$\mathbf{y}_i = \mathbf{min}\left(\mathbf{y}_i^{click} + \mathbf{y}_i^{semi}, 1.0\right), \quad (10)$$

where $\mathbf{y}_i^{click}$ is the multi-hot encoding of clicked labels of query q_i, and the value range of $\mathbf{y}_i$ is $\mathbf{y}_i \in [0, 1]$. We use the binary cross-entropy loss as the objective to train the model.

4 Experiment

4.1 Dataset

To evaluate the effectiveness of SSUF, we conducted a series of experiments on two large-scale real-world datasets derived from user click logs on an e-commerce application. The statistics of the datasets are listed in Table 1 and 2. The experiments focused on the following two tasks:

- **Intent Task**: This task predicts multiple purchase intents based on the user's query. The e-commerce platform meticulously defines a hierarchical intent architecture by experts, encompassing over 1000 distinct user intents. Both the train and test data are extracted from historical user click logs.

- **Category Task**: This task aims to predict the product categories the user demands. The high-click categories (top 95% click-through rates) of products previously were considered the query's categories.

Table 1: Data statistics on the intent classification task.

Statistics	Intent Task		
	Train	Val	Test
Queries	67,450,702	20,0000	31,792
Avg. chars	7.63	5.00	8.36
Total Labels	1,605	1,605	1,605
Avg. # of labels	1.04	1.67	1.91
Min. # of labels	1	1	1
Max. # of labels	7	3	16

Table 2: Data statistics on the category task.

Statistics	Category Task		
	Train	Val	Test
Queries	113,686,150	20,0000	33,960
Avg. chars	8.50	6.53	6.02
Total Labels	6,634	6,634	6,634
Avg. # of labels	1.52	2.05	5.33
Min. # of labels	1	1	1
Max. # of labels	16	13	20

4.2 Baseline Models

We compare SSUF with several strong baselines, including multi-label classification methods and query classification models. The detailed introductions are listed as follows:
(1) Multi-label classification baselines:

- **XML-CNN** (Liu et al., 2017): It is a CNN-based model, which combines the strengths of CNN models and goes beyond the multi-label co-occurrence patterns.
- **LEAM** (Wang et al., 2018): It is a label-embedding attentive model, which embeds the words and labels in the same space, and measures the compatibility of word-label pairs.
- **LSAN** (Xiao et al., 2019): It is a label-specific attention network that uses document and label text to learn the label-specific document representation with the self- and label-attention mechanisms.

(2) Query classification baselines:

- **DPHA** (Zhao et al., 2019): It contains a label graph-based neural network and soft training with correlation-based label representation.
- **MMAN** (Yuan et al., 2023): It is a BERT-based model that extracts features from the character and semantic level from a query-category interaction matrix to mitigate the gap in the expression between informal queries and categories.
- **HCL4QC** (Zhu et al., 2023) uses hierarchical structures and instance hierarchy to learn information beyond the query text.
- **SMGCN** (Yuan et al., 2024): It extends category information and leverages categories' co-occurrence and semantic similarity graph to enhance the relations among labels.
- **HQC** (He et al., 2024): It uses hierarchical information by enhanced representation learning that utilizes the contrastive loss to discern fine-grained instance relations in the hierarchy, and a nuanced hierarchical classification loss that attends to the intrinsic label taxonomy.

4.3 Experiment Settings

Query classification is essentially a text classification task. In alignment with previous studies (Zhang et al., 2021; Yuan et al., 2023), we evaluate model performance using micro and macro precision, recall, and F1-score metrics.

Our models are implemented using the PyTorch framework, and we use the Adam algorithm (Kingma and Ba, 2014) with learning rate $1e^{-4}$. The BERT embeddings have a dimensionality of 768. We use a 2-layer GCN to learn label embeddings from the graph, with an embedding dimensionality of 768. The maximum query length is set to 20. Edge thresholds (α) and (β) are both set to 0.5, determined by grid search. Model training use a warm start strategy, with the semi-supervised threshold (τ) initially set at 1.0 and gradually decreased to 0.8 during training. Training is conducted over 20 epochs, with a batch size of 1024.

4.4 Offline Evaluation

4.4.1 Offline performance

The experimental results are shown in Table 3. Specifically, we have the following observations:

(1) SSUF shows significant performance advantages in both tasks over the multi-label baselines. Although improving query and label representations can alleviate the problem of insufficient contextual information caused by short queries, they ignore the complexity in industrial applications. Industrial datasets suffer from class imbalance, with data distribution heavily skewed towards popular

Table 3: The experimental results are compared to multi-label text classification and query classification models.

Models	Intent Task						Category Task					
	Micro			Macro			Micro			Macro		
	Prec.	Recall	F1	Prec.	Recall	F1	Prec.	Recall	F1	Prec.	Recall	F1
XML-CNN	78.66	32.09	45.58	50.33	20.76	27.24	86.95	24.60	38.34	40.50	15.44	20.16

w/o. KE	74.91	49.12	59.33	56.91	42.12	45.82	81.83	39.12	52.93	55.88	35.43	39.24
w/o. LE&KE	77.03	45.05	56.85	55.49	32.21	42.36	82.02	35.35	49.41	56.02	30.51	36.47
BERT	81.28	37.59	51.41	51.63	29.97	36.84	82.83	31.99	46.15	56.72	27.80	33.80

labels, leading to the "Matthew vicious cycle". Therefore, the effectiveness of these models may be reduced if directly applied to online systems.

(2) Compared to query classification methods, SSUF also achieves better performance on both tasks. As the results are shown in the table, the recall of relevant categories obtains nearly 3% F1 improvement on both tasks. Although HCL4QC and HQC also use hierarchical structures to enhance label representations, they cannot model complete label relationships and a priori knowledge to break the vicious cycle. Furthermore, when the query lacks sufficient semantic information, the model's generalization ability is insufficient, and it degenerates into a memory model. SSUF can solve these problems with three extensible modules by fusing posterior signal and a priori knowledge, resulting in superior performance.

4.4.2 Ablation study

To discover the relative importance of each module in SSUF, we performed ablation studies on its variants:

- **w/o KE**: Removing the knowledge-enhanced module.
- **w/o KE+LE**: Removing the label-enhanced module and knowledge-enhanced module.
- **w/o KE**: Removing the structure-enhanced module.
- **w/o KE-S**: Removing the semantic relation of the structure-enhanced module.
- **w/o KE-C**: Removing the co-occurrence relation of the structure-enhanced module.
- **w/o KE-H**: Removing the hierarchy relation of the structure-enhanced module.
- **BERT**: Only remaining BERT as text encoder for query classification.

The experiment results are shown in Table 3. The experimental results demonstrate that:

(1) When removing the SE, the performance has a little drop compared with SSUF on both datasets. A similar phenomenon can be seen when removing the co-occurrence graph, showing that the similarity or co-occurrence graph contains extra information that is neglected in the posterior data.

(2) When we eliminate both similarity and co-occurrence graphs, the performance degrades by more than 5% compared with the complete SSUF. The results indicate that both graphs play different roles in category representation learning.

(3) After removing these three modules, we can see that the micro and macro F1 decay by 8% compared with the complete SSUF. This result further

demonstrates that all of these components in SSUF provide complementary information to each other, and are requisite for query classification.

4.5 Online Evaluation

4.5.1 Online Deployment

To reduce the deployment latency, the text encoder of the SSUF used a 4-layer BERT, which is consistent with the online model. Moreover, we only need to cache the category embeddings $\mathbf{H} \in \mathbb{R}^{|C| \times d}$ produced by GCN rather than directly deploying the GCN. In this way, we can deploy SSUF without adding any additional computation and latency.

4.6 Online architecture

Figure 2 shows the role of SSUF in the search system. When a user inputs a query, SSUF first predicts the user's intent and identifies the relevant categories, passing this information to downstream modules. The vector-based retrieval module then finds items associated with these categories. The retrieved items are combined with items from other retrieval sources and filtered by a sub-module to remove those that do not match the user's desired categories. The filtered items are then sent to the ranking module.

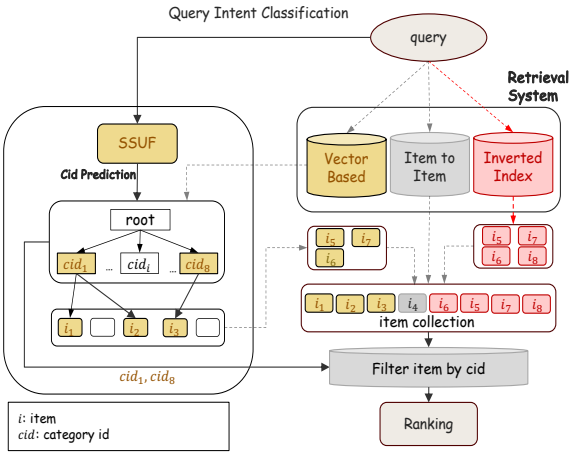

Figure 2: The deployment of SSUF and the role of category plays in the E-commerce system.

4.6.1 Online Performance

We deployed the SSUF and base model in the advertising engine for A/B testing. Each model was allocated 5% of the traffic. The A/B test was observed for a minimum duration of one week. For online evaluation, we use several business metrics: Imp. (the number of times ads are displayed), Click, CPM (cost per mille), and ad revenue.

Table 4: Online improvements of SSUF. Improvements are statistically significant with $p < 0.05$ on a paired t-test. (%)

Models	**Imp.**	**Click**	**CPM**	**Ad. Revenue**
Online	-	-	-	-
SSUF	+3.14	+2.72	+1.35	+4.49
w/o. SE-S	+3.07	+2.38	+0.90	+3.97
w/o. SE-C	+2.43	+2.27	+1.51	+3.94
w/o. SE-H	+2.72	+2.34	+1.13	+3.86
w/o. SE	+2.51	+2.38	+1.02	+3.53
w/o. KE	+2.67	+2.34	+0.95	+3.61
w/o. LE	+2.93	+2.47	+1.24	+4.17

As shown in Table 4, SSUF achieves significant improvements in business metrics compared to the online model. The improvement of ad impressions and clicks indicates that more relevant products are retrieved by the advertising system, and they are effectively aligned with user preferences and search intentions. The removal of any submodule of SSUF results in a performance decline, which further validates the effectiveness of each module and its synergistic integration within the SSUF.

In conclusion, both the offline and online experimental results consistently demonstrate the efficiency, universality, and scalability of SSUF.

5 Conclusion

In this paper, we propose a semi-supervised scalable unified framework for e-commerce query classification, addressing critical challenges such as short and ambiguous query contexts and the reliance on posterior click behaviors. SSUF integrates three innovative modules: label-enhanced module, knowledge-enhanced module, and structure-enhanced module that collectively improve query and label representations, break the "Matthew vicious cycle" and allow for flexible adaptation across different subtasks. Extensive offline and online A/B testing shows that SSUF significantly surpasses baselines, validating its effectiveness and practicality. The successful deployment of SSUF in a commercial e-commerce platform highlights its substantial commercial value.

In future work, we plan to enhance SSUF by incorporating user-specific information and historical search behaviors to achieve personalized query classification, aiming to improve classification accuracy and user satisfaction.

Ethical Consideration

We discuss the ethical issues from the following aspects:

- **Intended Use.** If the technology operates as intended, both sellers and users of e-commerce platforms can benefit from the SSUF model. SSUF can help customers in quickly identifying the products they desire. It also aids sellers by reducing the effort required to select more accurate product categories when listing new products.

- **Failure Modes.** In the event of a malfunction, SSUF may output inaccurate product information. This non-factual information could potentially influence the shopping experience of users. The system might predict wrong product categories, thereby recommending undesired products to customers and adversely affecting their shopping experience.

Abstract

With the rapid advancement of Large Language Models (LLMs), the demand for robust instruction-following capabilities in code generation tasks has grown significantly. Code generation not only facilitates faster prototyping and automated testing, but also augments developer efficiency through improved maintainability and reusability of code. In this paper, we introduce CodeIF, the first benchmark specifically designed to assess the abilities of LLMs to adhere to task-oriented instructions within diverse code generation scenarios. CodeIF encompasses a broad range of tasks, including function synthesis, error debugging, algorithmic refactoring, and code explanation, thereby providing a comprehensive suite to evaluate model performance across varying complexity levels and programming domains. We conduct extensive experiments with LLMs, analyzing their strengths and limitations in meeting the demands of these tasks. The experimental results offer valuable insights into how well current models align with human instructions, as well as the extent to which they can generate consistent, maintainable, and contextually relevant code. Our findings not only underscore the critical role that instruction-following LLMs can play in modern software development, but also illuminate pathways for future research aimed at enhancing their adaptability, reliability, and overall effectiveness in automated code generation. [1].

1 Introduction

With the rapid advancement of large language models (LLMs), automated code generation is undergoing a profound transformation. While LLMs have demonstrated promising capabilities in programming tasks, their ability to comprehend and execute complex instructions remains a challenge (Liu et al., 2024; Zhang et al., 2023). To drive progress in this field, a comprehensive and systematic evaluation framework is essential (Jiang et al., 2024; Zhou et al., 2023).

This study introduces CodeIF, a benchmark designed to assess LLMs' instruction-following capabilities in code generation. Built upon insights from existing evaluation sets like McEval (Chai et al., 2024) and FullStackBench (Liu et al., 2024), CodeIF is tailored for multi-language environments, covering Java, Python, Go, and C++. It categorizes tasks by difficulty and systematically evaluates models across 50 fine-grained sub-instructions, providing a nuanced understanding of their strengths and weaknesses.

To ensure rigorous assessment, we propose four novel evaluation metrics: Completely Satisfaction Rate (CSR), Soft Satisfaction Rate (SSR), Rigorous Satisfaction Rate (RSR), and Consistent Continuity Satisfaction Rate (CCSR). These metrics measure models' ability to handle multi-constraint problems from different perspectives, including full compliance, average constraint satisfaction, logical coherence, and consistency in instruction execution. By offering a structured evaluation framework, CodeIF provides valuable insights into the current state and future direction of LLM-driven code generation.

Overall, our contributions are mainly four-fold:

1. **Innovative Benchmark.** We introduce **CodeIF**, the first systematic benchmark for evaluating LLMs' instruction-following capabilities in code generation. CodeIF categorizes tasks into **8 main types and 50 fine-grained sub-instructions**, ensuring a comprehensive assessment of model performance.

2. **Automated High-Quality Instruction Generation.** Leveraging advanced LLMs like GPT-4, we develop a method to automatically generate constraint-based instruction

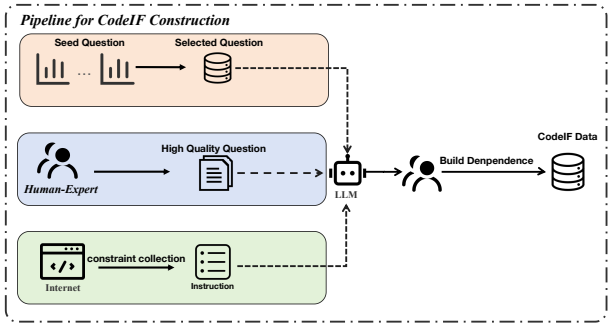

Figure 1: The construction process of CodeIF. The first step involves the construction of constraint instructions, followed by the assembly of the dataset, and finally the construction of dependencies between instructions.

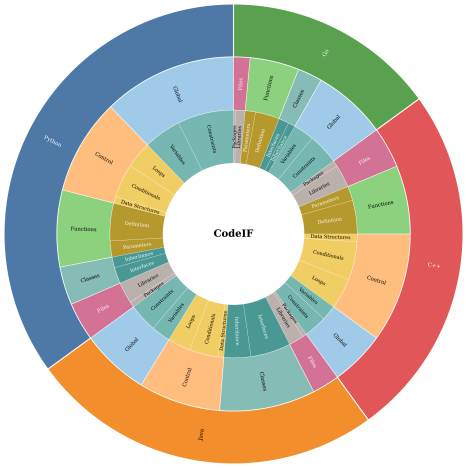

Figure 2: CodeIF Constraints Instruction Distribution

lists. This approach enhances evaluation depth by incorporating instructional dependencies while minimizing human intervention.

3. **Novel Evaluation Metrics.** We propose a new framework with four key metrics (**CSR, SSR, RSR, and CCSR**) tailored for code generation tasks. These metrics assess models' ability to handle multi-constraint problems across different dimensions, offering deeper insights and new benchmarks for future research.

4. **Extensive Evaluation and Analysis.** We systematically evaluate **35 state-of-the-art LLMs**, including both open-source and commercial models, across multiple programming languages and difficulty levels. Our experiments uncover current strengths and limitations, providing clear directions for future advancements.

2 CodeIF

Overview: As shown in Figure 1, CodeIF is constructed by collecting and refining constraint instructions from real code generation tasks, then combining these tasks with LLM outputs and human review to create a high-quality evaluation dataset.

2.1 Building

The construction of the CodeIF dataset involves two phases: collecting constraint instructions (Section 2.2) and processing data to create the final CodeIF evaluation dataset (Section 2.3).

2.2 Constraint Instructions Collection

The first phase of our work centers on code generation, constructing the **CodeIF** evaluation dataset through two steps: (1) collecting and verifying constraint instructions, and (2) using them for dataset generation.

We analyze benchmarks like **McEval** (Chai et al., 2024) and **FullStackBench** (Liu et al., 2024) to develop an instruction system spanning **eight categories**, each targeting specific aspects of code generation for a fine-grained assessment of LLMs' instruction-following abilities. Constraints are decomposed into **atomic instructions** with explicit directives, enabling objective binary evaluation (yes/no) and minimizing subjective interpretation. The eight categories cover both **architectural-level specifications** and **variable-level implementation controls**, ensuring comprehensive constraint coverage. Specifically, the **Global** category evaluates adherence to overarching specifications, while **Structural Control** focuses on control structures (e.g., loops, conditionals) and data structures. **Variable** constraints assess naming and initialization. Higher abstraction levels include **Interface, Function,** and **Class** constraints for program components, while the **File** category tests cross-file dependencies and external library handling. The **Combination** category integrates constraints across dimensions, challenging models with complex scenarios.

Figure 2 presents CodeIF's distribution across programming languages and categories. The evaluation system features **8 categories** and **50 fine-grained constraint instructions**, systematically assessing LLMs' code generation performance. By organizing constraints clearly, the system identifies

strengths and weaknesses, guides optimization, and advances automated code generation. The full list of constraints is in Appendix 4.

2.3 Data Construction

Multi-Language and Difficulty-Differentiated Benchmark Design To ensure diversity and comprehensiveness in evaluation, we carefully selected code generation tasks across four mainstream programming languages—Java, Python, Go, and C++—from leading benchmarks such as **McEval** (Chai et al., 2024) and **FullStackBench** (Liu et al., 2024). These languages, spanning both dynamic and static paradigms, create a rich linguistic environment that enhances multi-language assessment.

To further refine the evaluation, we categorize tasks into two difficulty levels: **Easy** and **Hard**. The **Hard** set includes longer, more intricate instruction lists, designed to rigorously test LLMs' ability to handle complex constraints.

Automated Generation of Constraint Instructions We used large language models (LLMs) like **GPT-4** to create task-specific instruction lists for code generation tasks. We prepared 20 detailed examples and formulated concise atomic instructions for accuracy. These examples guided LLMs in refining tasks and streamlining instructions to enhance clarity and output quality.

Constructing Instruction Dependencies We utilized LLMs to map dependencies between atomic constraints, improving our evaluation framework's precision and verification accuracy. By understanding the dependencies among instructions, we outlined clear steps for tasks like function creation, which involve naming the function, defining parameter types, and coding the body. Incorporating these dependencies enhances our evaluation system, more accurately assessing the model's capability with complex instructions and identifying areas for improvement. Figure 3 illustrates a CodeIF task with its instruction sequence and dependencies.

2.4 Data Analysis

CodeIF Static Analysis Table 1 categorizes the dataset into three difficulty levels: **Easy**, **Hard**, and **Full**. Both Easy and Hard sets contain 600 tasks, while the Full dataset combines them, totaling 1,200 tasks across Go, Python, Java, and C++. **Java** has the most tasks (353), followed by **Python** (348), **C++** (269), and **Go** (230). The Easy

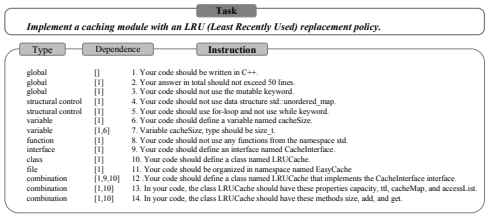

Figure 3: Specific cases of the CodeIF dataset, 'Task' denotes the specific generation task, 'Type' refers to the type of constraint, and 'Dependence' indicates the prerequisite constraints for this constraint.

Set	Num	Avg.Instr	Go	Python	Java	C++
Easy	600	11.99	127	165	176	132
Hard	600	13.80	103	183	177	137
Full	1200	12.90	230	348	353	269

Table 1: CodeIF dataset statistics, showing the statistical information of different difficulty classifications. Avg.Instr represents the average length of the atomic constraint instruction list.

set averages **11.99** instructions per task, the Hard set **13.8**, and the Full dataset **12.9**, reflecting increasing complexity. Figure 4 shows task length distribution.

Constraint Instruction Analysis Table 2compares instruction distribution across difficulty levels. The **Hard** set consistently has more instructions per category than the **Easy** set, with the **Global** category averaging **2.5** instructions in Easy and over **3** in Hard. This indicates greater challenges for models as task complexity rises. More analysis is in Appendix D.

3 Metrics

Ensuring that large language models (LLMs) accurately follow instructions is crucial for code generation. To precisely evaluate this capability, we introduce four novel metrics designed to assess how LLMs handle code generation tasks with mul-

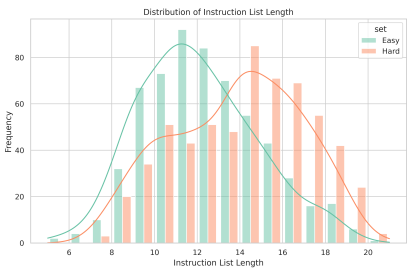

Figure 4: The distribution of atomic instruction list lengths in datasets of different difficulties.

Set	Global	Structural Control	Variable	Interface	Function	Class	File	Combination
Easy	1638	1008	1336	427	569	544	723	953
Hard	1890	1193	1479	505	659	623	802	1142
Full	3528	2201	2815	932	1228	1167	1525	2095

Table 2: CodeIF dataset statistics information, showing the distribution of atomic restriction instruction categories under different difficulty classifications.

tiple constraints: **Completely Satisfaction Rate (CSR)**, **Soft Satisfaction Rate (SSR)**, **Rigorous Satisfaction Rate (RSR)**, and **Consistent Continuity Satisfaction Rate (CCSR)**. These metrics provide a comprehensive evaluation from different perspectives.

For a dataset with m problems, each problem contains a set of n_i constraints. We define CSR and SSR as follows:

Completely Satisfaction Rate (CSR):

$$\text{CSR} = \frac{1}{m}\sum_{i=1}^{m}\left(\prod_{j=1}^{n_i} r_{i,j}\right) \tag{1}$$

where $r_{i,j} \in [0,1]$ indicates whether the j-th constraint in the i-th problem is satisfied.

Soft Satisfaction Rate (SSR):

$$\text{SSR} = \frac{1}{m}\sum_{i=1}^{m}\left(\frac{\sum_{j=1}^{n_i} r_{i,j}}{n_i}\right) \tag{2}$$

SSR evaluates the average proportion of constraints satisfied per problem, providing a more flexible assessment.

Rigorous Satisfaction Rate (RSR) In code generation, some constraints depend on prior instructions, particularly in **Combination** constraints. To account for dependencies, we define RSR as:

$$\text{RSR} = \frac{1}{m}\sum_{i=1}^{m}\left(\frac{\sum_{j=1}^{n_i}\left[r_{i,j}\cdot\prod_{k\in D_{i,j}} r_{i,k}\right]}{n_i}\right) \tag{3}$$

where $D_{i,j}$ represents the set of constraints that the j-th constraint in the i-th problem depends on.

Consistent Continuity Satisfaction Rate (CCSR) In many code generation tasks, maintaining continuous adherence to instructions is essential. To measure this ability, we define CCSR as:

$$\text{CCSR} = \frac{1}{m}\sum_{i=1}^{m}\frac{L_i}{n_i}, L_i = \max\left\{l \,\middle|\, \exists t \in [1, n_i - l + 1], \prod_{j=t}^{t+l-1} r_{i,j} = 1\right\} \tag{4}$$

where L_i represents the longest consecutive sequence of satisfied constraints in problem i.

4 Experiment

4.1 Experimental Setup

The temperature coefficient is set to 0 to ensure output determinism, with a maximum generation length of 4096 tokens. All other settings follow the official default parameters for each model. Commercial API models are accessed through the latest available interface as of December 2024. All experiments are conducted using the official API and 8 H800(80G).

4.2 Automatic Evaluation

To ensure robust evaluation, we used LLMs and human experts to verify model adherence to atomic constraints. Constraints were decomposed into atomic elements, enabling objective binary evaluations (*Yes/No*) over subjective judgments. Following FairEval (Wang et al., 2023a), *GPT-4-1106-Preview* was the primary evaluation tool (prompt details in Appendix A). Three domain experts manually annotated 150 stratified samples. Statistical analysis showed strong agreement, with Pearson correlations of **0.87** (LLM-human) and **0.85** (inter-human), confirming high consistency. Baselines are in Appendix C.

4.3 Main Experiments

Table 3 evaluates CodeIF using four metrics: **CSR**, **SSR**, **RSR**, and **CCSR**. Detailed results are in Appendix B.

Overview. DeepSeek-V3 and Claude-3-5-Sonnet-20241022 lead across metrics, excelling in complex tasks. However, the highest **CSR** on Hard tasks is just **0.362**, showing challenges in meeting strict constraints.

Model Scale Trends. Larger models generally perform better, as seen in Qwen2.5 series. However, the **Llama3** series shows inconsistent results, highlighting the importance of architecture, data quality, and optimization.

Open vs. Closed Models. Closed-source models like GPT-4O and Claude-3-5 outperform open-

Models	CSR			SSR			RSR			CCSR

Table 3: CodeIF evaluation results of different difficulties. We use bold font to mark the best results in all models.

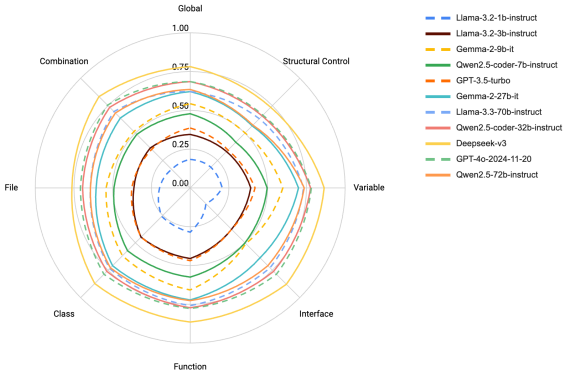

Figure 5: Performance of different LLMs on the CodeIF evaluation across instruction categories, measured by SSR.

source models, especially under complex constraints. While large open-source models (e.g., Qwen2.5-72B-Instruct) are competitive, they lag due to differences in data quality and RLHF techniques.

Task Difficulty Impact. Performance drops with increasing task complexity. For instance, GPT-4O's **CSR** falls from **0.441** on Easy tasks to **0.325** on Hard tasks, highlighting the challenge of strict constraints.

5 In-Depth Analysis

5.1 Performance Analysis Across Instruction Types

Figure 5 compares LLM performance across instruction categories, revealing notable variations. **DeepSeek-V3** leads overall, excelling in combination tasks (**0.831**) and global structure control, though weaker in variable handling, reflecting its optimization focus. **Meta's Llama series** shows a clear correlation between model size and performance, with larger variants (*Llama-3.3-70B-Instruct*) outperforming smaller ones (*Llama-3.2-1B-Instruct*). However, size alone is not decisive; comparisons with similarly sized models like **Google's Gemma** highlight the role of architecture and training methods in shaping performance.

5.2 Cross-Language Performance Analysis of LLMs

Figure 6 compares the performance of leading LLMs across C++, Java, Python, and Go, highlighting trends at both model and language levels. At the **model level**, **DeepSeek-V3** leads with the highest CCSR in C++ (0.725), Java (0.753), and Go (0.722), and an RSR of 0.787 in Java. **Claude-3-5-Sonnet** excels in Java with the highest CSR (0.504) and RSR (0.749), but shows lower SSR in Python (0.703). **GPT-4O** demonstrates balanced performance, ranking second in Python's CSR (0.355) and RSR (0.682), with minimal variance (CV = 0.18). At the **language level**, C++ is the most challenging due to complex template metaprogramming. Java shows high inter-model variance, with Claude-3-5-Sonnet performing best. Go achieves the highest SSR but fluctuates in RSR. These results highlight cross-language generalization differences and suggest optimization areas like dependency handling and paradigm consistency.

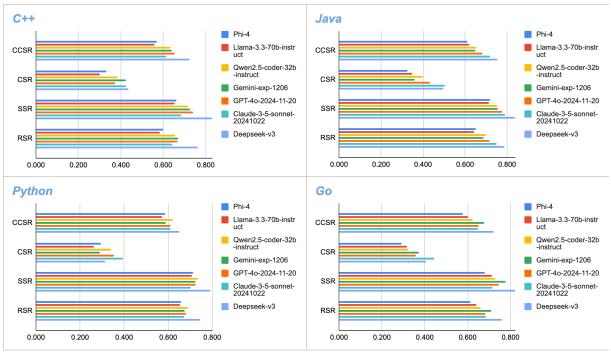

Figure 6: SSR scores of LLMs across different programming languages in the CodeIF evaluation.

5.3 Analysis of Instruction Adherence Deviations

Analysis of model-generated responses shows frequent deviations from instructions, especially in **naming conventions** and **formatting constraints**. Models often ignore global formatting rules, such as line limits, and inconsistently follow naming conventions. For example, when instructed to use **PascalCase**, models sometimes output lowercase or underscore-separated formats (e.g., incorrectly transforming `current_power` into `CurrentPower`). A notable issue is the disregard for **prohibitive instructions**. For instance, models often use `if` statements despite being instructed to avoid them in favor of ternary operators or data structures like dictionaries, revealing gaps in constraint enforcement.

5.4 Improving Instruction Compliance

Appendix Table 5 highlights strategies to improve adherence. **Supervised Fine-Tuning (SFT)** proves effective, especially in the Llama series, while larger models like `Qwen2.5-72B-Instruct` outperform smaller ones in instruction-following accuracy. Key improvements include prioritizing *hard constraints* (e.g., syntax rules) over *soft guidelines* (e.g., coding styles). Patterned code generation can replace conditional statements with lookup tables or state machines. A naming convention engine can automate variable name formatting (e.g., converting `snake_case` to `PascalCase`). *Abstract Syntax Tree (AST)* analysis can detect and transform prohibited structures, such as replacing `for` loops with `while` loops. Conflict resolution mechanisms can address contradictory instructions, offering alternative solutions when certain language features are unavailable (e.g., using Python's alternatives to `switch-case`).

6 Related Work

Code generation and instruction-following are pivotal capacities under examination in AI research (Feng et al., 2020; Sun et al., 2024; Luo et al., 2024; Wang et al., 2023b; Kim et al., 2018; Li et al., 2023; Lu et al., 2021; Li et al., 2022; Wei et al., 2023; Nijkamp et al., 2023b; Zhuo et al., 2024; Jain et al., 2024; Nijkamp et al., 2023a; Zhang et al., 2023; Allal et al., 2023; Lozhkov et al., 2024a; Roziere et al., 2023; Lozhkov et al., 2024b; Wang et al., 2021; Yan et al., 2023). Several benchmarks have been devised to appraise these capabilities in large-scale models. For code generation, benchmarks like McEval (Chai et al., 2024), FullStackBench (Liu et al., 2024), Repocoder (Zhang et al., 2023), Repobench (Liu et al., 2023), and LiveCodeBench (Jain et al., 2024) have been notable. Similarly, instruction-following capacities are gauged through benchmarks such as InfoBench (Qin et al., 2024), CFBench (Zhang et al., 2024), Instruct-following (Zhou et al., 2023), and FollowBench (Jiang et al., 2024), each tailored to assess different aspects of following instructions given to models.

7 Conclusion

This study introduces CODEIF, a benchmark for evaluating the instruction-following capabilities of LLMs in code generation. Covering **Java, Python, Go, and C++**, CodeIF constructs a diverse test set with constraints ranging from global to specific variables. It introduces novel evaluation metrics—**Completely Satisfaction Rate (CSR), Soft Satisfaction Rate (SSR), Rigorous Satisfaction Rate (RSR), and Consistent Continuity Satisfaction Rate (CCSR)**—to assess multi-constraint handling across multiple dimensions.

8 Limitations

Limited Language Support. CodeIF includes key languages like Java, Python, Go, and C++, but excludes popular ones like JavaScript, Ruby, and Swift. Expanding language coverage would improve its applicability in diverse contexts.

Static Evaluation Focus. CodeIF focuses mainly on static code properties, such as structure and naming conventions, while overlooking dynamic factors like runtime behavior, performance, and debugging. Including dynamic evaluation would better reflect real-world development challenges.

Uniform Metric Weighting. The metrics (CSR, SSR, RSR, CCSR) treat all constraints equally, which may not align with practical priorities. For example, syntactic correctness is often more critical than naming conventions. Introducing weighted scoring could enhance the interpretability of model performance.

A Prompt Template

Prompt for Instruction Generation

You are an instruction compliance evaluator, required to assess the instruction compliance ability of large models. Therefore, you need to generate a series of data for the code generation instruction detection of large models.

[Input Format]

I will input a series of data, and you need to generate a dictionary based on these data, which includes two fields "question" and "instruction_list"

Original question:

{Original question}

Original instruction list:

{instruction_list}

Input Explanation

The original question is the original question. It contains the original code generation problem. The original instruction list is the original instruction list. It contains randomly generated code compliance instructions. Some instructions will contain directive keywords that need to be replaced and are wrapped in {{}}.

Return Format

Return a json data, do not have extra output. The returned dictionary contains two fields: "question" and "instruction_list"

The format is as follows:

```
{
    "question": "Optimized question",
    "instruction_list": [
        {
            "instruction_id": "id1",
            "instruction": "Instruction 1"
        }
    ]
}
```

Explanation

"question": It is the optimized question, which does not contain any directive instructions, only contains the explanation of the original question. It does not contain any restrictions on the code. Move the instructions in the question to the instruction list

"instruction_list": It is the optimized instruction list. You should optimize according to the meaning of the question. More in line with the meaning of the question. Instead of directly outputting the original instruction list, note that you should replace all directive keywords that need to be replaced and are wrapped in , and the final output should not contain directive keywords that need to be replaced.

Generation Requirements

question: Please generate the optimized question based on the following data, which does not contain any directive instructions, only contains the core content of the original question.

instruction_list: Originated from the input original instruction list. If there are instructions that completely conflict with the meaning of the question or instructions that conflict with each other You should delete as little as possible, you should modify more. Please replace according to the content in the original instruction_list, you should delete as little as possible. Unless it is contradictory instructions, or instructions that cannot be achieved at all, if you only need to generate additional code to meet the requirements, you can replace it.

Prompt for Code Generation

As a programming assistant, your task is to generate code snippets based on the user question and instructions given below:
Please consider the following points while generating the code snippet:
- Make sure you follow the user instructions word to word. If the instruction says to use a specific language or a specific method, use exactly that.
- Your output should be a valid code snippet in the programming language indicated in the question or the instructions.
- Pay close attention to the syntax and formatting rules of the programming language that you are using. The code should be well-formatted and easy to read.
- Make sure that the code snippet you are generating is efficient and is not overly complicated.
Output Format:
The output should be a valid, well-formatted, and efficient code snippet that adheres to the above question and instructions.
Task information
User Question:
{question}
Instructions:
{instructions_str}
Please generate the code snippet based on the above information:

Prompt for Answer Judgment

As a programming assistant, your task is to evaluate whether the generated code strictly follows the instructions given in light of the user's problem and directives. You need to return a list of the same length as the instructions, containing only 'Yes' and 'No', indicating whether the model adhered to each specific instruction.
Consider the following when making judgments:
- You must strictly follow the user's instructions. If the instruction requires the use of a specific language or method, you must explicitly check if the code utilizes it.
- Your output should be a list of the same length as the instructions, containing only 'Yes' and 'No'.
- Pay close attention to the programming language syntax and formatting rules you are evaluating. The code should be neatly organized and easy to read.
- The list you generate should be valid and not overly complex.
Task Information
User question:
{question}
Instructions:
{instructions_str}
Model-generated response:
{generated_code}
Based on the information provided, determine whether the model has followed the instructions, and return a list of the same length as the instructions, containing only 'Yes' and 'No'. Please note!!! Your output should only contain the list, with no other content. The items in the list should only be 'Yes' and 'No', with no other words included.

35	interface	The interface names in your code should follow the {naming_convention} naming convention.	["naming_convention"]
36	class	Your code should define a class named {class_name}.	["class_name"]
37	class	The class names in your code should follow the {naming_convention} naming convention.	["naming_convention"]
38	file	Your code should be organized in a package named {package_name}.	["package_name"]
39	file	Your code should import the following libraries {library_list}.	["library_list"]
40	file	Your code should use the function {function_name} from the library {library_name}.	["function_name", "library_name"]
41	file	Your code should not use the following libraries {disallowed_library_list}.	["disallowed_library_list"]
42	combination	You should initialize an object named {object_name} as an instance of the {class_name} class using {parameters_name_list} for initialization.	["object_name", "class_name", "parameters_name_list"]
43	combination	You should define an interface named {interface_name} that includes these methods {method_name_list}.	["interface_name", "method_name_list"]
44	combination	Your code should define a class named {class_name} that implements the {interface_name} interface.	["class_name", "interface_name"]
45	combination	In your code, the class {class_name} should have these properties {properties_name_list}.	["class_name", "properties_name_list"]
46	combination	In your code, the class {class_name} should have these methods {method_name_list}.	["class_name", "method_name_list"]
47	combination	The function {function_name} should take {parameter_name_list} as parameters.	["function_name", "parameter_name_list"]
48	combination	The function {function_name} should return a {return_type} as its result.	["function_name", "return_type"]
49	combination	Your code should be organized in a package named {package_name}, which should contain these classes {class_name_list}.	["package_name", "class_name_list"]
50	combination	Your code should be organized in a package named {package_name}, which should contain these functions {function_name_list}.	["package_name", "function_name_list"]

C Baselines

We evaluate over 30 language models spanning both open-source architectures and commercial APIs. The Meta Llama 3 Series (Touvron et al., 2023) contains *Llama-3.2-1B/3B/8B/70B-Instruct* variants and *Llama-3.3-70B-Instruct*. Qwen2.5 Series (Yang et al., 2024) encompasses *Qwen2.5-1.5B/3B/7B/14B/32B/72B-Instruct* with dedicated code generation models *Qwen2.5-Coder-1.5B/3B/7B/14B/32B-Instruct* (Hui et al., 2024). Mistral Series (Jiang et al., 2023) includes *Mistral-3B*, *Mistral-8B*, and the code-specialized *Codestral-2501*.

The evaluation covers Microsoft's *Phi-3.5-Mini-128K-Instruct (3.8B)* and *Phi-4* (Abdin et al., 2024), along with Google's *Gemma-2-9B/27B-It* (Team, 2024b). DeepSeek Series incorporates *DeepSeek-Coder* (Guo et al., 2024) and *DeepSeek-V3* (DeepSeek-AI, 2024). Commercial APIs include OpenAI's *GPT-3.5-Turbo*, *GPT-4O-Mini*, *GPT-4O-2024-05-13*, and *GPT-4O-2024-11-20* (Achiam et al., 2023); Google's *Gemini-2.0-Flash-Exp*, *Gemini-Exp-1206*, and *Gemini-1.5-Pro* (Team, 2024a); plus Anthropic's *Claude-3.5-Sonnet-20241022*.

D More Data Analysis

Figure 7 shows the proportion of each instruction category. **Global** constraints dominate (**22.77%**), followed by **Variable** constraints (**18.17%**). This distribution reflects **CodeIF**'s balanced focus on high-level structural coherence and fine-grained variable precision, ensuring comprehensive evaluation of code generation capabilities. Figure 8 compares instruction distribution across difficulty levels.

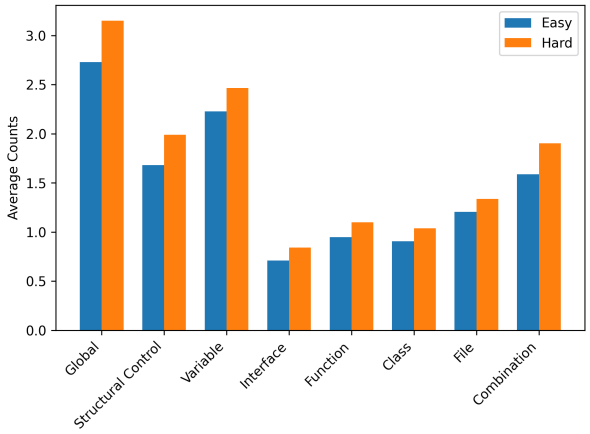

Figure 8: The distribution of constraint instruction list lengths in datasets of different difficulties.

BI-Bench : A Comprehensive Benchmark Dataset and Unsupervised Evaluation for BI Systems

Ankush Gupta, Aniya Aggarwal, Shivangi Bithel, Arvind Agarwal
IBM Research, India
{ankushgupta,aniyaagg,shivangibithel,arvagarw}@in.ibm.com

Abstract

A comprehensive benchmark is crucial for evaluating automated Business Intelligence (BI) systems and their real-world effectiveness. We propose **BI-Bench**, a holistic, end-to-end benchmarking framework that assesses BI systems based on the quality, relevance, and depth of insights. It categorizes queries into descriptive, diagnostic, predictive, and prescriptive types, aligning with practical BI needs. Our fully automated approach enables custom benchmark generation tailored to specific datasets. Additionally, we introduce an automated evaluation mechanism within BI-Bench that removes reliance on strict ground truth, ensuring scalable and adaptable assessments. By addressing key limitations, it offers a flexible and robust, user-centered methodology for advancing next-generation BI systems.

1 Introduction

AI has significantly advanced the development of automated BI systems, particularly with LLMs and automated code generation. Although there has been significant progress in system development and related areas like Text-to-SQL, a unified benchmark for evaluating overall system performance is still lacking. Existing benchmarks focus on isolated components like Text-to-SQL (Zhong et al., 2017; Yu et al., 2018; Lei et al., 2025), NLG from tabular data (Mahapatra et al., 2016; Chen et al., 2020), or table-based QA (Pasupat and Liang, 2015; He et al., 2023; Ashury-Tahan et al., 2025), providing fragmented benchmarks (Hu et al., 2024) rather than a holistic evaluation.

Although some end-to-end benchmarks exist (Islam et al., 2024; Zhang et al., 2025; Yang et al., 2024), they have a few key limitations. First, they rely on fixed question sets designed to evaluate specific systems and approaches rather than addressing the broader needs of BI users. Second, their rigid evaluation methods depend on strict ground truth, limiting adaptability to new datasets and business contexts. This highlights a critical gap—the absence of a widely accepted benchmark that effectively evaluates BI systems in real-world, user-driven scenarios.

To address this, we propose **BI-Bench**, a *holistic benchmarking framework* that places BI users and their expectations at the core of the evaluation process and is agnostic to the underlying system or approach. It is designed to capture the full spectrum of user needs, from simple to complex queries, across both straightforward and intricate data structures. More specifically, it covers four broad categories of BI queries i.e., descriptive, diagnostic, predictive and prescriptive, aligning with real-world BI requirements.

We release a benchmark dataset and evaluation mechanism, ensuring compatibility with existing BI systems for direct comparison and easy integration with ongoing research. Additionally, BI-Bench features a dynamic benchmark generation pipeline that is generic and automated, allowing users to create custom benchmarks tailored to their datasets. It leverages multiple LLMs to generate questions and metadata, complemented by an efficient automatic verification step that significantly reduces the reliance on human validation, allowing enterprises to tailor datasets to their specific needs.

In addition to data generation, BI-Bench also includes an automated evaluation mechanism that assesses BI system's output across multiple dimensions without relying on predefined ground truth. Our framework evaluates factual correctness, answerability, relevance, and presentation, ensuring a comprehensive performance assessment. At its core is a student-teacher framework, where an expert system (the teacher) evaluates a BI system's output (the student). Since obtaining a perfect expert system is impractical, we introduce the notion of weak experts to assess the student's output in a step-by-step manner, making factual correctness

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1287–1299

verification more feasible. Other dimensions — answerability, relevance, and presentation — are assessed using an LLM-as-a-judge approach.

A key strength of our framework, both in dataset creation and evaluation, is its full automation and scalability across diverse datasets and BI applications. To ensure reliability, we validated both the benchmark and evaluation methodology with human experts. Dataset validation confirmed its effectiveness with minimal filtering in the final stage, while our evaluation approach demonstrated strong performance. By publicly releasing BI-Bench[1], including both the dataset and evaluation method, we aim to advance research in the BI space and provide a robust foundation for future developments.

2 Related Work

The rapid advancement of BI systems has led to the emergence of several benchmark datasets designed to evaluate different system components. However, existing benchmarks remain fragmented, focusing on isolated tasks rather than addressing the full spectrum of BI user needs.

Text-to-SQL benchmarks (Zhong et al., 2017; Yu et al., 2018; Lei et al., 2025) assess a system's ability to generate SQL queries but do not evaluate whether the final outputs effectively serve BI users.

Code generation benchmarks such as DataSciBench (Zhang et al., 2025), InfiAgent-DABench (Hu et al., 2024), and Text2Analysis (He et al., 2023) focus on generating executable code for tasks like data cleaning and reporting. However, they rely on metrics like executable code ratio and pass rate, which do not directly measure correctness, answerability, or utility of the output.

Data story benchmarks like DataTales (Yang et al., 2024) assess BI narratives based on factuality, insightfulness, and style, utilizing a semi-automated Named Entity Recognition (NER)-based approach for fact-checking. DataNarrative (Islam et al., 2024), on the other hand, extends the evaluation to structured multi-paragraph stories with visualization components, focusing on informativeness, coherence, visualization quality, narrative quality, and factual correctness, all assessed by an LLM-based evaluator agent. However, LLMs' susceptibility to hallucinations makes them unreliable for evaluating factual correctness through direct prompting, and their dependence on a ground truth story poses a significant scalability challenge. Moreover, the informativeness evaluated in these works does not consider factual accuracy.

In contrast, our work addresses these limitations by offering a unified, user-centered benchmark that spans the full BI query spectrum—descriptive, diagnostic, predictive, and prescriptive—and enables both dataset generation and unsupervised evaluation without dependence on strict ground truth.

3 BI Benchmark Dataset Construction

A crucial component of BI-Bench, is a carefully curated and dynamically extensible dataset, designed to facilitate comprehensive and realistic evaluations of BI systems. It captures essential attributes (Table 2) and facilitates detailed analysis of system performance across diverse query types and domains. To complement our dynamic benchmark generation pipeline, BI-Bench includes a ready-to-use benchmark dataset, curated through a multi-stage, semi-automated process that combines the power of large language models (LLMs) with human validation. This ensures that the dataset remains grounded in real-world business scenarios while allowing domain-specific adaptability.

Table 1 presents the structure of our benchmark dataset, capturing essential metadata, such as analytical category, query complexity, and associated tables. This structure allows for a comprehensive evaluation by categorizing queries based on their intent, complexity, and the required data sources.

Our benchmark data builds on 29 diverse datasets from Spider 2.0, spanning domains such as Transportation, Finance, Healthcare, etc. Each database serves as the basis for BI queries, generated through the following five-step construction pipeline.

3.1 NL Question Generation

Natural language queries were generated using Llama-3.3-70B-Instruct model, with tailored prompts for each of the four analytical categories — descriptive, diagnostic, predictive, and prescriptive — across basic, intermediate, and advanced complexity levels. This method ensures generation of diverse and realistic BI queries. A total of 336 NL queries were generated, spanning four analytical categories across 29 datasets. Additionally, 60 descriptive queries from Spider 2.0 were integrated to enhance coverage.

[1] https://github.com/ankush31089/BI-Benchmark

Field	Description
Query ID	Unique identifier for each query.
Natural Language Query	The actual user query expressed in natural language.
Category	Type of analytical query: Descriptive, Diagnostic, Predictive, Prescriptive.
Table(s) Used	The specific tables from the schema that are required to answer the query.
Domain	The business or application domain (e.g., Sales, HR, Healthcare).
Complexity	Difficulty level categorized as Basic, Intermediate, or Advanced, based on the required reasoning and join operations.

Table 1: Structure of the BI Benchmark Dataset

Metric	Value
Total Number of Queries	273
Distinct Domains Covered	10
Queries per Domain	Transportation:20, Healthcare:34, Sports & Entertainment:67, Marketing:19, Finance:15, Software & IT:46, E-commerce:20, Logistics & Retail:31, Legal and Technology:17, Databases:4
Distinct Datasets Used	29
Category Distribution	Descriptive:115, Diagnostic:60, Predictive:59, Prescriptive:39
Complexity Distribution	Basic:93, Intermediate:94, Advanced:86

Table 2: Dataset Statistics

3.2 Answerability Check

To verify the validity of the generated questions, we implemented an automated answerability check using GPT-4o. This intentional shift to a distinct LLM was crucial for mitigating potential biases from relying solely on Llama-3.3-70B-Instruct through the process. GPT-4o assessed each query by providing detailed justifications on whether it could be answered based on the available data schema. Its strong reasoning capabilities enabled an objective feasibility evaluation. As a result, out of 336 queries generated in Step 1, 103 were deemed unanswerable and discarded.

3.3 Table(s) Identification

For each query, we used Llama-3.3-70B-Instruct to identify the relevant tables needed to generate a complete and accurate response. The model analyzed the query's intent and mapped it to the appropriate database tables. For descriptive queries sourced from Spider 2.0, table information was directly extracted from the provided SQL queries.

3.4 Table Completeness Verification

After table identification in Step 3, we used GPT-4o to verify the completeness and accuracy of the identified tables for each query. This step ensured that all necessary tables were included and no relevant data sources were overlooked. GPT-4o provided explanations justifying the inclusion of specific tables, enabling a transparent and auditable verification process. During validation, 79 table assignments were corrected to address incomplete or incorrect selections.

3.5 Human Validation

As a final quality assurance step, a human expert meticulously reviewed each query, its associated tables, and the explanations from Steps 2 and 4. During this process, 20 queries were discarded due to inaccuracies or ambiguities, and 15 table assignments were corrected for accuracy and consistency. This manual validation ensured the reliability of both answerability assessments and table identifications, addressing subtle errors that automated processes might have missed. By combining LLM-based validation with human oversight, our multi-layered approach guaranteed the high quality and robustness of our BI benchmark dataset.

Following this process, BI-Bench delivers a benchmark dataset that comprehensively spans all BI query types, multiple domains, and varying complexity levels. The dataset supports schema linking through a TABLE(S) USED field, maintains high quality through both automated and expert validation, and enables reproducibility via a publicly available benchmark and methodology.

To illustrate the BI-Bench dataset's structure and diversity, Table 3 presents a selection of sample queries. The complete benchmark, including its schema, prompts used for NL question generation, table identification, answerability check, and table completeness verification and detailed documentation, is publicly available at https://github.com/ankush31089/BI-Benchmark.

We now describe the BI-Bench evaluation pipeline, designed to assess BI system responses in a fully automated, unsupervised manner.

Query ID	Natural Language Query	Category	Tables Used	Domain	Complexity
001	What is the total number of advisories with a CVSS3 score greater than 7?	Descriptive	DEPS_DEV_V1_ADVISORIES	Software & IT	Basic
002	How do different traffic sources impact the conversion rate of users from various age groups?	Diagnostic	THELOOK_ECOMMERCE_EVENTS, THELOOK_ECOMMERCE_USERS, THELOOK_ECOMMERCE_ORDERS	E-commerce	Intermediate
003	What is the relationship between a team\textquotesingle s defensive aggression and their likelihood of conceding goals, and how does this vary across different leagues?	Predictive	EU_SOCCER_MATCH, EU_SOCCER_TEAM_ATTRIBUTES, EU_SOCCER_LEAGUE	Sports & Entertainment	Advanced
004	Which fare conditions should be prioritized to increase revenue on specific routes?	Prescriptive	AIRLINES_TICKET_FLIGHTS, AIRLINES_FLIGHTS, AIRLINES_SEATS	Transportation	Intermediate

Table 3: Sample queries from our BI benchmark dataset.

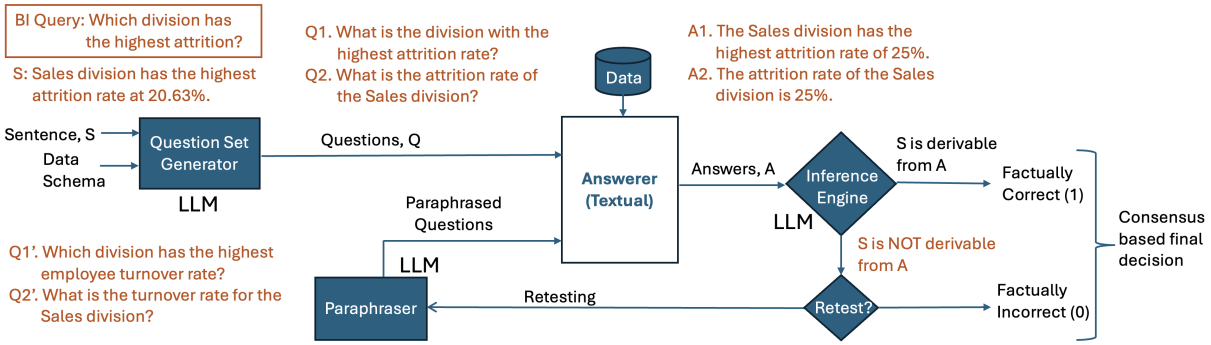

Figure 1: Factual Correctness Assessment for a sentence (S) from BI Response on *Employee Attrition* data

4 Automated Evaluation Pipeline

To assess the quality of BI system responses, we introduce an automated, domain-agnostic evaluation pipeline—a core component of BI-Bench. This pipeline provides a detailed and multidimensional evaluation across four key dimensions: Factual Correctness, Answerability, Relevance, and Presentation. The pipeline operates in a zero-shot, unsupervised manner using open-source LLMs and prompt engineering, without requiring any training data or human intervention. For reproducibility and transparency, all prompt templates used in the pipeline are included in the Appendix A.

4.1 Factual Correctness

The evaluation process begins with verifying the factual accuracy of the BI response—a crucial step in ensuring reliable decision-making. We employ a *student-teacher framework*, where the teacher evaluates the student's (BI system's) output. Given the complexity of BI responses, the first step is to break them down into simpler components, allowing a weaker expert to assess each step individually. This structured approach enables accurate evaluation of complex BI queries without requiring highly skilled experts.

To implement this, first, each BI response (Student's output) is decomposed into sentence-level units. Then, an LLM-powered *Question Generator* converts each sentence S into a tailored set of questions, Q grounded in the dataset schema. Each question is answered by a weak expert (*Answerer*), generating an answer set A. We use Text-to-SQL-to-NLG as an answerer for descriptive questions.

Next, an *Inference Engine* determines whether sentence S can be fully or partially inferred from A. If a mismatch is found, S is marked factually incorrect (0), else factually correct (1). To enhance robustness in the cases where a mismatch is found, *paraphrasing and retesting* are employed—using a *Paraphraser* to reframe questions, followed by re-answering and re-inference for two more iterations. The final correctness score is based on consensus across these runs, improving reliability and minimizing LLM-induced variability. The final score is computed as the ratio of number of factually correct sentences to the total number of sentences. This step gives us two sets, factually correct set (FC) and factually incorrect set (FIC).

4.2 Answerability

In BI scenarios where *factual accuracy* is paramount, factually incorrect statements (FIC) not only degrade the utility of a response but may

also conflict with factually correct (FC) content, creating confusion. To address this, we penalize such conflicts to ensure that the reliability of the answers in FC content is preserved in the overall *answerability* score. We define *answerability* as the degree to which a user query is *answered correctly*: fully (1), partially (0.5), or not at all (0). An illustrative example of such a conflict is following:

***User Query**: Which division has the highest attrition?*

***BI Response**: The Sales division has the highest attrition rate at 25% (FC). The top three divisions with high attrition rates are Marketing, Research, and HR, in that order (FIC).*

Here, both FC and FIC parts individually score 1 on answerability, but their conflict reduces trust in the answer. To mitigate this, we introduce a $penalty$ factor (0.1 (low), 0.5 (partial), or 0.9 (high)) to account for the level of the conflict, and apply this to the ans_{FC} score.

$$ans = ans_{FC} \times (1 - penalty \times ans_{FIC})$$

For instance, in this case, a penalty of 0.9 is applied because of total conflict. The final score is rounded to 0, 0.5, or 1. We use LLM-as-a-judge strategy to infer $penalty$, ans_{FC} and ans_{FIC} based on the sets FC and FIC identified from the factual correctness evaluation in previous Section 4.1.

4.3 Relevance

Relevance measures how well a BI response *aligns with the user query, while ensuring factual accuracy*. Similar to Answerability, we apply a penalty-based approach to account for the impact of factually incorrect (FIC) content on the relevance of factually correct (FC) information. We define *relevance* as: Highly relevant (1.0), partially relevant (0.5) and irrelevant i.e. missing key aspects of the query (0). Note that relevance differs from answerability–a response may not directly answer a query but can still be considered relevant and may provide other important insights. The overall relevance score is computed as:

$$rel = rel_{FC} \times (1 - penalty \times rel_{FIC})$$

The score is then rounded to 0, 0.5, or 1. Similar to answerability, we use zero-shot LLM-as-a-judge setup to compute Relevance of FC content (rel_{FC}), Relevance of FIC content (rel_{FIC}), and Degree of conflict between them ($penalty$).

4.4 Presentation Aspects

Presentation is crucial for BI response usability. Following prior work, we evaluate three aspects of presentation in a BI response: Clarity, Coherence, and Narrative Quality.

Clarity measures how easily the response can be understood: (0: difficult to understand, ambiguous, or unclear; 0.5: somewhat clear but could be improved for better comprehension; 1: very clear, unambiguous, and easy to understand).

Coherence evaluates the logical flow and structural organization: (0: disjointed; 0.5: moderately connected; 1: well-structured and logically connected).

Narrative Quality captures the engagement, depth, and insight of the response: (0: flat, lacking depth or engagement; 0.5: somewhat insightful; 1: highly engaging and thought-provoking).

A zero-shot LLM-as-a-judge is tasked with assigning individual scores of 0, 0.5, or 1 for each of these aspects, using the BI response and user query as input. The final presentation score ($pres$) is computed as a weighted average of these three scores and then rounded to the nearest valid score: 0, 0.5, or 1.

$$\begin{aligned} pres = \; & 0.4 \times clarity + 0.3 \times coherence \\ & + 0.3 \times narration \end{aligned}$$

5 Experiments and Results

This section presents the experimental setup and evaluation results for our proposed unsupervised BI evaluation framework. We implemented a baseline BI system to generate responses for a representative subset of our BI-Bench dataset and assessed the quality of these responses using our automated evaluation pipeline. Additionally, we conducted human evaluations to validate the reliability of our automated scores.

5.1 Baseline Implementation

We constructed a baseline BI system that generates natural language responses using a two-stage pipeline: **Text-to-SQL**: translates user queries into executable SQL statements. **SQL-to-NLG**: Transforms SQL query results into natural language explanations. To simulate more context-rich BI answers, we also generated two supplementary questions for each user query. We processed these additional questions through the same pipeline, and all resulting NLG outputs were synthesized into a unified final response.

5.2 Experiment Setup

We conducted experiments on a randomly selected subset of 22 descriptive queries from our BI benchmark dataset. Each query was processed through

Metric	Factual Correctness	Answerability	Relevance	Presentation
Inter-Annotator Agreement (%)	90.9	86.4	86.4	86.4
System Accuracy on Agreed Subset (%)	80.0	89.5	73.7	100.0
Pearson Correlation (r, p)	0.73, $p = 0.0003$	0.94, $p = 0.0000$	0.84, $p = 0.0000$	1.0, $p = 0.0000$

Table 4: Evaluation metrics across four dimensions.

the baseline system to generate a composite response. These responses were then assessed using our automated evaluation pipeline (using Llama-3.1-70B-Instruct model), which scores across four key dimensions: Factual Correctness, Answerability, Relevance, and Presentation.

Each response received dimension-wise scores from the automated system. To validate these automated assessments, we conducted a human evaluation study involving two expert annotators with BI and data analysis backgrounds. These annotators were presented with the selected descriptive queries along with their baseline responses and related data information (target table names and schema). To streamline human annotation and ensure thorough evaluation, we provided annotators with: (1) access to Snowflake UI for direct SQL querying and factual verification; and (2) access to evaluation pipeline internals, such as question set with their corresponding SQLs, SQL execution results and NL-based answers generated during factual correctness checking, for transparency and validation support. With these resources, the annotators were then asked to independently assign human scores for each of the four evaluation dimensions, reflecting their subjective assessments based on their direct interaction with the data and the intermediate outputs of our evaluation pipeline. To minimize subjectivity, annotators were given clear instructions defining each evaluation dimension and were instructed to follow the same scoring criteria and circumstances as those used in our automated pipeline.

5.3 Evaluation Metrics and Analysis

We conducted three analyses to assess the robustness of our automated evaluation framework and its alignment with human judgment:

Inter-Annotator Agreement: To measure consistency between human annotators, we calculate the number of instances where their scores match exactly for each dimension. High agreement rates, as shown in Table 4, indicate strong alignment in the annotators' assessment criteria, thereby reinforcing the validity of the reference scores.

System Accuracy on Agreed Subset: For queries where both annotators provided identical scores (i.e., perfect agreement), we calculated the system's accuracy — defined as the percentage of cases where the system's score matched the average human score. This metric indicates the system's performance relative to high-confidence ground truth data obtained through human annotations. Our system achieves an average accuracy of $\approx 86\%$ across all dimensions, as shown in Table 4.

Correlation with Human Scores: We computed Pearson correlation between system-generated and average human scores (on the agreed subset) for each dimension. Strong, statistically significant correlations (Table 4) indicate high alignment between the automated and human evaluations.

6 Key Lessons Learned and Challenges

Developing this benchmark framework faced several challenges, some of which remain unresolved. A key challenge in constructing the BI benchmark dataset was developing an automated, domain-agnostic pipeline that minimizes human validation while ensuring high-quality question generation and table verification. The goal was to enable scalable, customizable benchmark creation across diverse datasets with minimal manual intervention, balancing automation with generalizability. While BI-Bench enables automated evaluation across different categories, assessing the factual correctness of diagnostic, predictive, and prescriptive questions is still in progress. The main challenge lies in ensuring reliable evaluation, particularly for prescriptive questions, due to dependence on weak expertise and the difficulty of identifying qualified experts. Additionally, our approach, which heavily relies on LLMs, must comply with the strict token limits imposed by the models. As a result, datasets with large schemas or longer BI responses may face limitations or performance issues.

7 Conclusion and Future Work

We presented BI-Bench, a comprehensive, domain-agnostic framework for benchmark creation and unsupervised evaluation of BI systems, eliminating

the need for ground-truth annotations. We release a benchmark dataset spanning diverse analytical categories, enriched with metadata for deeper evaluation. Designed for industrial deployment, BI-Bench offers a scalable, domain-agnostic pipeline that automates query generation, verification, and evaluation—minimizing human effort and enabling enterprises to benchmark and improve BI capabilities with minimal overhead. Its modular design supports adaptation to domain-specific datasets, facilitating broader adoption across enterprise use cases. As future work, we aim to refine evaluation for non-descriptive queries—particularly prescriptive analytics—address LLM context limitations, and extend the benchmark to include multi-turn BI dialogues and multimodal insights.

A Appendix

Descriptive Question Generation Prompt

Task:
You are an expert in Business Intelligence (BI) and Data Analytics. Your objective is to generate **descriptive analytical questions** that help uncover **patterns, summaries, trends, and key performance indicators** from a business dataset.

What Are Descriptive Analytical Questions?

Descriptive questions focus on understanding **what happened**, providing summaries of historical data such as totals, averages, comparisons, trends over time, and breakdowns by different business dimensions.

Descriptive questions **do NOT explore reasons**, drivers, impacts, correlations, or causality. Avoid "what influences", "why", "what causes", "impact of", etc.

How Should These Questions Be Framed?

1. **Use business-friendly language** — business users do not refer to table or column names in queries.
2. **Avoid explicit mentions of table/column names** in the question text.
3. **Ensure each question reflects natural business thinking**.
4. **Questions should be self-contained and clear**, so they can be answered directly using the dataset.

Complexity Levels

1. **Basic** – Simple aggregations, trends, and summaries *Example: "What was the total revenue last year?"*
2. **Intermediate** – Multi-dimensional summaries or comparisons *Example: "How did sales vary across different regions and product categories?"*

Descriptive Question Generation Prompt (contd.)

3. **Advanced** – More granular breakdowns, trend analysis over time, or customer segmentation *Example: "What are the top customer segments contributing to quarterly growth in product sales?"*

Instructions:

1. Generate exactly **9 descriptive questions** in total : **3 Basic**, **3 Intermediate**, and **3 Advanced**.
2. Each question should be **fully answerable using the given dataset schema**.
3. Avoid questions that require external data or are ambiguous.
4. Use specific **business contexts** like customer behavior, product sales, regional trends, time-based comparisons, etc.
5. **Avoid mentioning actual table or column names in the question text.**
6. **Enclose each question within '<question>...</question>' tags.**
7. Return a clean, structured output in JSON format with each question and its complexity level.
8. **Again, do not return anything except the raw JSON array. Avoid any headings, notes, or boxed formats.**
9. All 9 questions must be returned in a **single flat JSON array**.
10. Do **not create multiple arrays or group questions by complexity** — just one array with 9 JSON objects.

Ensure:

1. Each question must be fully answerable using only the columns and data types explicitly provided in the schema.
2. Do not invent additional columns or assume missing information.
3. Only use the column names and sample values shown in the schema.
4. If a question depends on unavailable data, skip it.
5. Do not make assumptions about data availability or granularity (e.g., specific time periods, locations, customer types,

Descriptive Question Generation Prompt (contd.)

etc.) unless clearly stated in the schema. - Prefer: “...across time”, “by region”, “per category” - Avoid: “last year”, “premium customers”, “city-wise” if such details are not explicitly part of the dataset.

Dataset Schema:

<schema>

Output Format:

```json
[
  {
    "question": "<question_text>",
    "complexity": "Basic |
    Intermediate | Advanced"
  }
]
```

Return a single JSON array named ‘questions‘, not multiple arrays.

Table Identification (Descriptive) Prompt

Task:

You are given a dataset schema and a natural language question.

Your task is to identify the **minimum set of tables required to answer the question**, based strictly on the columns available in each table.

Instructions:
1. Carefully analyze the question and identify what data elements are required to answer it.
2. Refer to the dataset schema and determine which tables contain those elements.
3. Select **only the relevant tables** — avoid including unnecessary ones.
4. **Do not guess or assume columns/tables that are not explicitly in the schema.**
5. Return the output as a clean **flat JSON array of table names**, without any extra text, formatting, or explanations.
6. Do **not return any explanation or additional formatting**.
7. **Do not print multiple separate JSON arrays — return just one complete JSON array.**

Input:
Schema:
<schema>
Question:
<question>
Output Format:

```json
["TABLE_NAME_1", "TABLE_NAME_2"]
```

Answerability Check Prompt

Task:
You are a **data analyst** responsible for validating whether a given **Business Intelligence (BI) question** can be answered using the provided **dataset schema**. Your objective is to determine:

Answerability Assessment:
Assume the availability of a LLM based agent which can answer **Business Intelligence (BI) question**.
1. Does the dataset contain all necessary tables and columns to answer the question?
2. If any required data is missing, what specifically is absent?

Reasoning & Justification:
1. Provide a clear explanation supporting your assessment.
2. If the dataset is sufficient, justify why.
3. If the dataset is insufficient, identify the missing components.

Missing Data Identification:
1. List missing tables (if any).
2. List missing columns (if any) within existing tables.

Instructions:

Analyze the Schema:
1. Identify the tables and columns that are directly relevant to answering the question.

Determine Answerability:
1. If all necessary data exists, classify as "Answerable".
2. If any critical data is missing, classify as "Not Answerable".

Explain Clearly:
1. Justify why the dataset is sufficient or insufficient.
2. If insufficient, specify what is missing.

Input:

Dataset Schema (TableName_Columns, data types, unique column values):
<schema>

Answerability Check Prompt (contd.)

BI Question:
<query>

Output Format (JSON):

"answerability": "<Answerable / Not Answerable>",
"reasoning": "<Detailed explanation of the assessment>",
"missing_data":
"status": "<Complete / Incomplete>",
"missing_tables": ["<List of missing tables>"],
"missing_columns": "<table_name>": ["<List of missing columns>"]

Result:

Factual Correctness Paraphraser Prompt

You are given:
1. Fact: A statement containing the answer to the questions you need to paraphrase.
2. Set of Questions: A list of questions, each possibly containing comma-separated paraphrases and enclosed within <question></question> tags.

Your Task:
For each question in the input, generate only one new paraphrase that:
1. Retains the same meaning as the original question and its available paraphrases, extracting the same information from the Fact.
2. Ensures that the answers to the new paraphrase, along with the original and existing paraphrases, fully cover the information provided in the Fact.
3. Does not repeat the original question or any of its paraphrases.
4. Uses different wording or sentence structure to create a distinct paraphrase.

Output Format:
Each generated paraphrased question should be placed within <question></question> tags in the output. Ensure that the generated paraphrase is unique and different from the original question and its available paraphrases. Do not explain the output. Do not generate any extra information.

Fact: $fact$
Set of Questions: $questions$
Output:

Factual Correctness Question Gen Prompt

Given a database schema and a specific fact as inputs, your task is to generate a set of questions that can be answered using a text-to-SQL pipeline. These questions should be designed to extract all the information provided in the given fact, with their answers combined to completely overlap with the given input fact. Each question should be carefully crafted based on the attributes, relationships, and constraints defined in the given schema. Ensure the questions are aligned with the database schema, utilizing the correct tables, columns, and relationships. The questions should focus on extracting all the key elements of the given fact, ensuring that the answers to these questions provide a full picture when combined. Each generated question should be placed within <question></question> tags in the output.
Schema: $schema$
Fact: $fact$
Questions:

Factual Correctness Inference Prompt

You are an impartial judge tasked with comparing Fact1 and Fact2. Your goal is to see if all details of Fact1 can be found in Fact2.
Instructions:
1. Check if all details from Fact1, like numbers, names, dates, etc., can be fully inferred from Fact2.
2. Respond with:
"True" if Fact2 fully matches Fact1.
"Partially True" if some details from Fact1 are missing in Fact2.
"False" if Fact2 misses most details or changes any information from Fact1.
3. Do not explain, just state the answer.
4. Always place the response within <result> </result> tags in the output.

Fact1: $fact1$
Fact2: $fact2$
Comparison Response:

Presentation Evaluation Prompt

Task: Evaluate the given Set of Insights related to the given User Query based on the three presentation aspects: Clarity, Coherence, and Narrative Quality. For each aspect, rate the insights on a scale of 1 to 3:

Clarity: How easy is it to understand the insights provided?
1: The insights are difficult to understand, ambiguous and unclear, making the information indigestible for the user.
2: The insights are somewhat clear but could be improved for better understanding.
3: The insights are very clear, unambiguous and easy to understand.
Coherence: How logically organized and connected are the insights? Do the insights flow logically, with each point building on the previous one, making it easy to follow the key trends?
1: The insights are disjointed and lack logical flow.
2: The insights are somewhat connected but could have better transitions and organization.
3: The insights are well-organized with clear connections between them.
Narrative Quality: How engaging, meaningful, and insightful is the narrative? Does it provide deep and thought-provoking insights? Does it add some level of analysis or explanation for the given insights?
1: The insights are dry, with little to no engagement or depth.
2: The insights are somewhat engaging, but could provide more depth or emotional appeal.
3: The insights are highly engaging and provide meaningful and deep analysis.

Provide the rating for each criterion in the following format:
<clarity> 1/2/3 </clarity>
<coherence> 1/2/3 </coherence>
<narrative> 1/2/3 </narrative>

User Query: $query$
Set of Insights: $BI\_response$

Answerability Evaluation Prompt

You are given the following:
1. User Query: A question asked by the BI user in natural language.
2. Factually Correct Insights: A set of accurate facts or statements that may answer the user query.
3. Factually Incorrect Insights: A set of incorrect facts or statements that may also answer the user query.
4. Data Schema: Set of column names with their type and possible values present in the target data.
Your task is to determine whether the User Query is fully, partially, or not answered at all based on both the Factually Correct and Incorrect Insights, following the instructions below.

Scoring Criteria:
"1": The User Query is directly addressed by the insights and provides answers to all the aspects posed in the user query.
"0.5": The User Query is only partially addressed and only some aspects of the query are answered.
"0": The User Query is not addressed at all (i.e., the insights do not provide relevant or sufficient information).

Instructions:
1. Evaluate the User Query based on the Factually Correct Insights first, to determine if it provides a complete answer according to the given schema. If insights are not available or an empty string, assign a score of 0. Record the identified score within $< ans\_fc >$ tags in the output.
2. Check the extent to which Factually Incorrect Insights also answer the user query. If insights are not available or an empty string, assign a score of 0. Record the score within $< ans\_fic >$ tags in the output.
3. If values within $< ans\_fic >$ is more than 0 in step 2, consider whether the answer in Factually Incorrect Insights negatively impact the answerability from Factually Correct Insights by offering incorrect or conflicting information. Assign a penalty score according to the below criteria and record within $< penalty >< /penalty >$ tags in the output.

Answerability Evaluation Prompt (contd.)

Penalty is 1 if Factually Incorrect Insights completely contradicts the correct answer in Factually Correct Insights.
Penalty is 0.5 if Factually Incorrect Insights partially contradicts the correct answer in Factually Correct Insights.
Penalty is 0.1 if Factually Incorrect Insights doesn't contradict the correct answer in Factually Correct Insights at all.
Strictly adhere to the information provided in this request. Always enclose the required scores within the specified tags in the generated output. Do not explain your output.
Schema: $schema$
User Query: $query$
Factually Correct Insights: correct_insights
Factually Incorrect Insights: incorrect_insights
Output:

Relevance Evaluation Prompt (contd.)

Penalty is 1 if majority of the information in Factually Incorrect Insights contradicts the Factually Correct Insights.
Penalty is 0.5 if some information in Factually Incorrect Insights contradicts the Factually Correct Insights.
Penalty is 0.1 if Factually Incorrect Insights don't contradict the Factually Correct Insights at all.
5. Strictly adhere to the information provided in this request. Always enclose the required scores within the specified tags in the generated output. Explain your output briefly.

User Query: $query$
Factually Correct Insights: correct_insights
Factually Incorrect Insights: incorrect_insights
Output:

Relevance Evaluation Prompt

You are given the following:
1. User Query: A question asked by the BI user in natural language.
2. Factually Correct Insights: A set of accurate facts or statements that may answer the user query.
3. Factually Incorrect Insights: A set of incorrect facts or statements that may also answer the user query.
Your task is to determine the Relevancy of the provided set of insights in relation to the given User Query, following the instructions below.

Scoring Criteria:
"0": The insights are not relevant or related with respect to the user query and don't address the user's needs.
"0.5": The insights are somewhat relevant but miss key aspects of the query.
"1": The insights are highly relevant and directly answer the user's query.

Instructions:
1. Relevancy of a set of insights with respect to a user query refers to how closely the insights address the specific information or context requested in the User Query. A set of insights is considered relevant if it directly contributes to answering the user query, aligns with the key aspects of the question, and provides useful, actionable information based on the user's needs.
2. Evaluate the relevancy of Factually Correct Insights with respect to the given User Query, as defined in Step 1. If insights are not available or an empty string, assign a score of 0. Record the identified score within <rel_fc> tags in the output.
3. Evaluate the relevancy of Factually Incorrect Insights with respect to the given User Query, as defined in Step 1. If insights are not available or an empty string, assign a score of 0. Record the score within <rel_fic> tags in the output.
4. If values within <rel_fic> is more than 0 in step 2, consider whether the insights available in Factually Incorrect Insights provide conflicting information as given in Factually Correct Insights. Assign a penalty score according to the below criteria and record within <penalty></penalty> tags in the output.

Reinforcement Learning for Adversarial Query Generation to Enhance Relevance in Cold-Start Product Search

Akshay Jagatap* Amazon ajjagata@amazon.com
Neeraj Anand* Amazon neeranan@amazon.com
Sonali Singh Amazon ssonl@amazon.com
Prakash Mandayam Comar Amazon prakasc@amazon.com

Abstract

Accurate mapping of queries to product categories is crucial for efficient retrieval and ranking of relevant products in e-commerce search. Conventionally, such query classification models rely on supervised learning using historical user interactions, but their effectiveness diminishes in cold-start scenarios, where new categories or products lack sufficient training data. This results in poor query-to-category mappings, negatively affecting retrieval and ranking. Synthetic query generation has emerged as a promising solution by augmenting training data; however, existing methods do not incorporate feedback from the query relevance model, limiting their ability to generate queries that enhance product retrieval. To address this, we propose an adversarial reinforcement learning framework that optimizes an LLM-based generator to expose weaknesses in query classification models. The generator produces synthetic queries to augment the classifier's training set, ultimately improving its performance. Additionally, we introduce a structured reward signal to ensure stable training. Experiments on public datasets show an average PR-AUC improvement of +1.82% on benchmarks and +3.26% on a proprietary dataset, demonstrating the framework's effectiveness in enhancing query classification and mitigating cold-start challenges.

1 Introduction

The cold-start problem is a critical challenge in e-commerce, particularly for new products and emerging categories. This issue arises due to multiple factors: (a) Bias in ranking models—ranking algorithms often prioritize established products and categories with a high volume of historical interactions, leading to skewed relevance estimation (Lesota et al., 2021; Ning et al., 2024); (b) Category-specific relevance—the definition of relevance varies across product categories. For instance, in electronics, attributes such as brand and RAM specifications are crucial, whereas in pharmacy, active ingredient composition and dosage strength play a more significant role. These factors make it difficult to effectively rank and surface relevant products for queries related to new or underrepresented categories (Jansen and Booth, 2010; Mateos and Bellogín, 2024). Hence, an essential step in product recommendations is determining the category of a given product, which allows for the up-ranking or down-ranking of products within a specific category. This classification is typically performed in the first-stage ranker, as recommendation systems often employ a two-stage ranking process to refine product relevance and improve retrieval effectiveness (Covington et al., 2016).

Typically, query classification models are trained in a supervised manner, leveraging labeled data derived from customer interactions such as clicks, cart additions, and purchases (Jagatap et al., 2023). However, in new or low-interaction categories, reliance on historical data exacerbates the cold-start problem, as limited user engagement leads to poor classification performance and sub-optimal ranking of products. Conventionally, this issue is addressed by allowing time for new products to accumulate interactions or by inferring relevance through correlations with existing products (Guan et al., 2024). With recent advancements in generative models, synthetic query generation has gained prominence as a viable approach to simulating queries for new products and categories (Chaudhary et al., 2024; Jagatap et al., 2024). This technique provides essential training signals to downstream models, helping to address the cold-start challenge more effectively. While these approaches use generative models to produce synthetic queries for improving downstream classification performance, they do not leverage feedback from the classifier to guide query

*Equal contribution

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1300–1307

generation. Specifically, they do not account for whether the generated queries induce high model uncertainty or leads to frequent misclassification errors. We attempt to address these challenges in our work. The key contributions of our paper are as follows:

1. Adversarial RL-Based Query Generation Framework. We introduce a reinforcement learning framework that establishes a feedback loop between the LLM generator and the classifier, akin to a generative adversarial networks (GAN). The generator is trained to generate synthetic queries that are particularly challenging for the classifier, helping it learn to distinguish difficult edge cases where classification is uncertain. As the generator improves, it produces more effective adversarial queries, which are then used to augment the classification model's training data, leading to a more robust model that mitigates cold-start issues in product search.

2. Reward-Based Guardrails. Such generative adversarial frameworks are often unstable, making training challenging. To address this, we design the reward function to induce stability in the generator while also guiding it toward producing queries that are both challenging for the classifier and meaningful for training. This ensures that the generator does not collapse to producing irrelevant or nonsensical queries, maintaining effectiveness of the adversarial training process.

3. Empirical Validation. We demonstrate performance improvements over three public relevance datasets and one industry dataset, showcasing the effectiveness of our approach in enhancing query relevance models. Our adversarial RL-based framework achieves a +1.82% average improvement in PR-AUC across the three public datasets and a +3.26% PR-AUC improvement on a proprietary e-commerce dataset. The deployed model led to a +3.8% increase in purchases within a cold-start category, as validated through A/B testing.

2 Query-Product Relevance Problem

Let $\mathcal{A} = \mathcal{A}_1 \cup \mathcal{A}_0$ represent the product catalog, where $\mathcal{A}_1$ and $\mathcal{A}_0$ correspond to in-category and out-of-category products, respectively. Similarly, let $\mathcal{Q}$ denote the space of all customer text queries. The relevance of a product $a \in \mathcal{A}$ for a query q is denoted by $p^{rel}(a|q)$, allowing us to define a soft classification function for query category membership:

$$p^{true}(y = 1|q) = \frac{\sum_{a \in \mathcal{A}_1} p^{rel}(a|q)}{\sum_{a \in \mathcal{A}} p^{rel}(a|q)}$$

In practice, the true relevance $p^{rel}(a|q)$ is unknown. Instead, we observe interactions shaped by the existing ranking system. Let $p^{seen}(a|q)$ represent the probability of a product being displayed to a customer, factoring in positional biases. Further, the interaction volume $v(a, q)$, capturing customer engagement (e.g., clicks, cart-adds, purchases), follows the relationship: $v(a, q) \propto p^{seen}(a|q)p^{rel}(a|q)$.

Given observed query-product interactions $v_{train}(a, q)$, the existing ranking system $p^{seen}(a|q)$, and product catalog features, our goal is to learn a classification model that predicts query category membership $\hat{p}(y|q)$ to approximate the true probability $p^{true}(y|q)$.

Since true relevance is unknown, we evaluate our model on a test set using an estimated probability $p^{test}(y|q)$, where product relevance is inferred from: $p^{test}(y|q) \propto v^{test}(a, q)/p^{seen}(a|q)$.

While training and test distributions may be similar, learning an accurate query classifier is challenging because training interactions are biased by the ranking system and may not include new products or queries. Offline evaluation on unseen test data provides directional insight, but the true impact of improved classification is best measured through increased customer interactions in an online experiment.

3 Related Works

With the rise of generative LLMs (Naveed et al., 2023) that encode substantial world knowledge, there has been growing interest in utilizing LLMs for synthetic query generation (Chaudhary et al., 2024; Sannigrahi et al., 2024). While most research addresses question-answering and binary relevance, recent work explores query generation for e-commerce products with multi-level relevance, either by fine-tuning LLMs on historical product-query data to generate customer-like queries, which are then used to augment and improve the downstream relevance model (Chaudhary et al., 2023) or have prompted LLMs for query generation implementing feedback loops through Bayesian optimization to refine prompts (Jagatap et al., 2024).

In contrast to these existing methodologies, we propose a reinforcement learning framework that

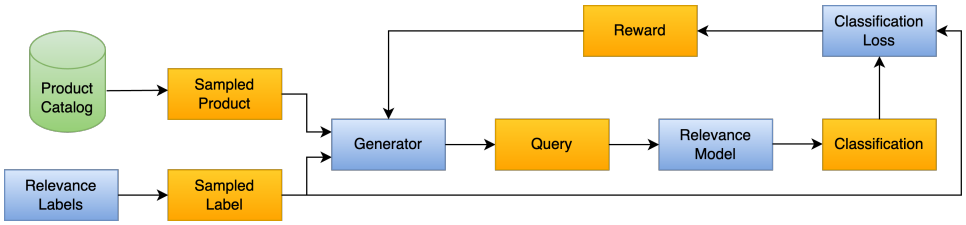

Figure 1: Overview of our reinforcement learning framework for query generation. The generator produces queries conditioned on a sampled product and relevance label. The relevance model evaluates the generated query, providing feedback that is used to compute a reward, which updates the generator through classification loss.

directly incorporates relevance model feedback into the query generation process. The closed-loop system we developed resembles a Generative Adversarial Network (GAN) (De Rosa and Papa, 2021) where the relevance model acts as a discriminator providing adversarial rewards, while the generator creates increasingly difficult samples to challenge the discriminator. However, rather than using traditional GANs, we employ reinforcement learning for text generation, building on work by (Yu et al., 2017), who proposed SeqGAN. This approach bridges RL and GANs by treating the generator as an RL agent and using the discriminator to provide rewards.

Our improved generator produces diverse synthetic queries that are systematically incorporated into the relevance model's training corpus. The resulting enhancement in relevance model robustness is particularly significant for mitigating cold-start issues (Han et al., 2022) common in product search systems. This methodology also resembles self-training semi-supervised learning paradigms, where an established teacher model trained on extensive datasets generates synthetic labels to enhance a student model's performance and broaden its input distribution coverage (Pace et al., 2024; Shen et al., 2024).

4 Proposed Approach

A standard approach for synthetic data augmentation in query classifiers is fine-tuning a LLM on historical search logs (Jagatap et al., 2024). In this method, the model is trained on a dataset of `(product, query, relevance)` tuples to generate queries conditioned on both product attributes and relevance labels (e.g., `Exact`, `Irrelevant`). This ensures that the generated queries align with specific relevance categories, enhancing their effectiveness for downstream classification tasks. For unseen or sparsely populated product categories, the fine-tuned generator produces synthetic queries to augment the classifier's training set, thereby improving generalization in low-data settings. Despite its effectiveness, `Fine-Tuned` approach presents several limitations. The generator is heavily conditioned on product metadata, resulting in queries that often closely resemble product descriptions rather than capturing the diversity of real-world search behavior (Jagatap et al., 2024).

4.1 Adversarial RL-Based Query Generation

The proposed `Adversarial-RL` framework incorporates reinforcement learning (RL) to address these limitations. The initial steps remain the same as in `Fine-Tuned` approach: the generator is trained to generate queries conditioned on the product and relevance label, and the generated queries augment the classifier's training data. In `Adversarial-RL`, within the RL framework, the generator produces a synthetic query conditioned on a given product and relevance label, which is then evaluated by the relevance model.The classifier's predicted relevance is evaluated against the ground-truth label assigned during generation. A high classification loss indicates a challenging query that effectively probes the classifier's decision boundaries, revealing areas of uncertainty or misclassification. The generator is rewarded for producing challenging queries, encouraging the generation of diverse queries that enhance classifier robustness. This reinforcement mechanism drives the generator to create queries that deviate from product metadata while preserving semantic relevance (see Figure 1). This results in a generator that more effectively augments the downstream classifier, particularly in cold-start scenarios where limited historical data is available for training.

We formulate the training of the LLM generator as a Proximal Policy Optimization (PPO) problem (Stiennon et al., 2022), where the classifier acts as the reward model. The PPO algorithm updates the generator's policy parameters θ by maximizing the

following objective function:

$$\mathbb{L}(\theta) = \mathbb{E}[\min(r_t(\theta)A_t, \texttt{clip}(r_t(\theta), 1-\epsilon, 1+\epsilon)A_t)]$$

Here, $\mathbb{E}$ denotes the empirical expectation and $r_t(\theta) = \frac{\pi_\theta(a_t|s_t)}{\pi_{\theta_{\text{old}}}(a_t|s_t)}$ is the probability ratio between the new policy π_θ and old policy $\pi_{\theta_{\text{old}}}$. a_t represents the token chosen at position t in the sequence. s_t is the context (all previous tokens) at position t. A_t is the advantage estimate, which in our case is derived from the reward function. ϵ is a hyperparameter that constrains policy updates. The advantage function A_t is calculated using the reward signal from the classifier at the end of the sequence. The clipping operation, controlled by the hyperparameter ϵ, prevents excessive policy updates that could destabilize training.

Parameterized Reward Function: Since the generator is trained to produce queries in an adversarial manner and is explicitly rewarded for generating challenging samples, it may unintentionally be guided to generate semantically incorrect queries. For example, when prompted to generate a `relevant` query for a pharmacy product, the LLM might incorrectly generate the query *"washing machine"*. While the classifier correctly predicts it as *irrelevant*, the generator, rewarded for confusing the classifier, would receive a high reward despite the query being incorrect. To mitigate this issue, we initialize the generator from a fine-tuned model and impose a KL divergence penalty to restrict deviations from its learned distribution. Our structured reward function is defined at each token position as the generator sequentially generates text: For each token position $t < T$ (before the end-of-sequence (`EOS`) token): $R(t) = -\beta \cdot D_{\text{KL}}(\pi_\theta || \pi_{\text{FT}})$. For the final token position $t = T$ (at `EOS`):

$$R(T) = \alpha \cdot L_{\text{cls}} - (1-\alpha) \cdot log P_{\text{gen}} - \beta \cdot D_{\text{KL}}(\pi_\theta || \pi_{\text{FT}})$$

The term D_{KL} represents the KL divergence (Kullback and Leibler, 1951) between the current and fine-tuned policies at each token position, ensuring that the generator does not deviate excessively from the pre-trained distribution. The classifier's cross entropy loss over the complete sequence is denoted by L_{cls}, guiding the generator to produce queries that effectively challenge the classifier. The term P_{gen} captures the generation probability, which is incorporated into the reward to stabilize learning. If the generator confidently produces a challenging query, it receives a reward proportional to P_{gen}, encouraging the exploration of difficult yet meaningful queries rather than generating random noise. The hyperparameters α and β control the balance between these reward components, ensuring that the generator optimizes for both adversarial and semantically valid query generation.

4.1.1 Training Schedule

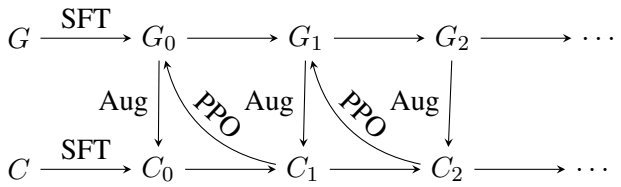

Figure 2: Illustration of the iterative reinforcement learning framework for improving the generator G through PPO feedback and enhancing the classifier C via synthetic data augmentation.

As shown in Figure 2, our training process begins with both the generator and classifier undergoing Supervised Fine-Tuning (SFT) on customer data, yielding G_0 and C_0. The training then follows an automated reinforcement learning cycle consisting of two steps. In the first step, **Data Augmentation**, the generator G_N generates synthetic queries using metadata and relevance labels as input of new or unseen products. This newly generated synthetic data, denoted as D_N^{syn}, is combined with the original classifier training dataset D_0 to create an augmented dataset: $D_N = D_N^{\text{syn}} \cup D_0$. The classifier C_N is then trained on D_{N-1}, meaning C_N represents the classifier trained with the augmented dataset D_{N-1}, which was generated using the generator G_{N-1} from the previous cycle.

Next, in **PPO Training**, the updated classifier C_{N+1} provides PPO rewards to the generator G_N. Using these rewards, the generator is fine-tuned for 2 epochs, resulting in an improved generator G_{N+1}. This iterative process of data augmentation followed by PPO-based optimization constitutes a single training cycle. The training is repeated for a total of 4 cycles, progressively refining both models. These hyperparameters: PPO training epochs (2), classifier training epochs (5), and the number of training cycles (4) are fixed and can be adjusted based on validation performance.

5 Experiments

5.1 Datasets

Ecom-Pharma is an internal dataset sampled from real customer interactions on an e-commerce pharmacy platform. The dataset is partitioned into temporally disjoint sets: train (`Sep 2024-Nov 2024`) and test (`Dec 2024`). To construct the dataset, we start with the pharmacy catalog (ground truth list of products) and identify "weak pharmacy intent queries" that have led to at least 5% clicks on pharmacy products. For each query, we retrieve all clicked products (set A) and classify them as pharmacy or non-pharmacy. We then expand the query set by retrieving all queries associated with products in set A. Each query is mapped to a binary label (pharmacy/non-pharmacy) based on interaction volume and used to train the query classifier. For generator fine-tuning, we use product-query pairs from set A, weighted by interaction volume.

Our experiments also utilize three public datasets: **WANDS** (Chen et al., 2022), **Home Depot** (Home Depot, 2016), and **Amazon ESCI** (Reddy et al., 2022), all of which consist of product-query pairs annotated with relevance labels. The **WANDS** dataset focuses on product search relevance in the home improvement domain, categorizing relevance into ExactMatch, PartialMatch, and Irrelevant. The **Home Depot** dataset also provides product-query relevance annotations but assigns real-valued relevance scores, which we discretize into three categorical levels—Irrelevant, PartialMatch, and ExactMatch—using the 33rd and 66th percentile thresholds. Lastly, the **Amazon ESCI** dataset is a large-scale collection of product search queries with four relevance levels: Exact, Substitute, Complement, and Irrelevant.

5.2 Algorithms & Metrics

Since the generator is used only during training, its size does not impact inference latency. At inference, we prioritize efficiency, opting for a smaller relevance model. As the generator operates in an offline setup, we prioritize generation quality over latency, leveraging `FLAN-T5-XL` for the `Ecom` dataset and `FLAN-T5-Large` for public datasets. For all datasets, the classifier is built on the `FLAN-Small` encoder with a classification head.

Classification Metrics: To assess the performance of our classifier model, we measure PR-AUC (Davis and Goadrich, 2006) for the entire test set.

Generation Metrics: We compute BERTScore (Zhang et al., 2020), which measures the semantic similarity between the generated queries and the target queries.

Ranking Metrics: On external datasets where class labels are ordered, we evaluate ranking performance using the approach in prior work. For each query-product pair, we compute the score: $E_i = \sum_{j \in \{E,P,I\}} p(y_j|x_i) \cdot w_j$ where E, P, and I denote `ExactMatch`, `PartialMatch`, and `Irrelevant`, respectively. The weight values are set as: $w_j = \{E = 2.0, P = 1.0, I = 0.0\}$. We then compute NDCG@10 by ranking products based on E_i.

5.3 Results & Discussion

In this section, we analyze the impact of different training strategies on downstream relevance model performance across multiple datasets. We further investigate the impact of generator size on downstream model performance. Additionally, we explore how parameterization choices and reward design influence RL training stability and downstream performance.

Strategy	PR-AUC	BERT-score
`Prompted`	+0.30%	83.58%
`Fine-tuned`	+2.38%	92.51%
`Adversarial RL`	**+3.26%**	91.94%

Table 1: Improvement in performance using different strategies on the `Ecom-Pharma` dataset. We show the relative improvement in performance over the base classifier.

RQ1. Does RL improve downstream relevance model performance?

Table 1 presents the relative improvements in PR-AUC and BERT-score across different training strategies on the `Ecom-Pharma` dataset. A simple prompting-based method for generating synthetic queries yields a modest PR-AUC improvement of +0.30%, serving as a basic augmentation baseline. While `Fine-Tuning` based augmentation significantly enhances classification performance over the base model, `Adversarial-RL` based augmentation achieves the highest PR-AUC gain of +3.26%, demonstrating its effectiveness in refining query generation to improve retrieval performance. However, the slight drop in BERT-score compared to `Fine-Tuning` suggests that adversarial training may prioritize generating diverse queries that deviate from observed data.

Further, we evaluated our approach across three

public e-commerce benchmarks: WANDS, Home Depot, and Amazon ESCI. Table 2 demonstrates that our Adversarial-RL approach consistently outperforms Fine-Tuning in PR-AUC, micro-averaged across the multiple relevance labels. We also observe an improvement in ranking effectiveness (NDCG@10). Notably, the Amazon ESCI dataset shows the highest gain in PR-AUC (+3.42%) and NDCG@10 (+2.22%) when using adversarial RL. The BERT-Score metric indicates that Fine-Tuning generates queries which are similar to the ones we observe in the test data, while adversarial RL introduces slight variations due to reinforcement learning optimizing for diversity.

Strategy	PR-AUC (micro)	NDCG@10	BERT-score
WANDS			
None	85.69%	96.42%	-
Fine-Tuning	86.21%	96.88%	96.52%
Adv. RL	**86.63%**	**97.40%**	96.35%
Home Depot			
None	48.38%	93.32%	-
Fine-Tuning	48.46%	93.45%	91.46%
Adv. RL	**49.49%**	**94.69%**	91.13%
Amazon ESCI			
None	63.70%	96.12%	-
Fine-Tuning	65.28%	97.15%	94.86%
Adv. RL	**67.12%**	**98.34%**	94.03%

Table 2: Impact on classification and ranking performance basis different data augmentation strategies across public datasets.

RQ2. What is the impact of generator size on the relevance model performance? A larger generator is expected to encode more world knowledge, enabling it to generate more diverse and informative queries when properly guided. As shown in Table 3, scaling from FLAN-T5-Large to FLAN-T5-XL for WANDS dataset, enhances both classification performance (PR-AUC) and ranking effectiveness (NDCG@10). The Fine-Tuning approach achieves a +4.89% gain in PR-AUC and +1.31% in NDCG@10, while Adversarial-RL further improves PR-AUC by +5.44%. However, the NDCG@10 gain is comparatively lower (+0.53%), suggesting that while increasing generator capacity significantly enhances classification, its impact on ranking is positive but relatively smaller.

RQ3. How do the weights in parameterization impact the downstream performance? The choice of reward weighting parameters plays a crucial role in determining downstream classifier performance during Adversarial-RL. Figure 3 illustrates the impact of α and β on PR-AUC performance computed across Amazon ESCI dataset.

Strategy	FLAN-T5-Large → FLAN-T5-XL	
	Δ PR-AUC (micro)	Δ NDCG@10
Fine-Tuning	+4.89%	+1.31%
Adv. RL	+5.44%	+0.53%

Table 3: Relative improvement in classification and ranking when scaling from FLAN-T5-Large to FLAN-T5-XL for WANDS dataset.

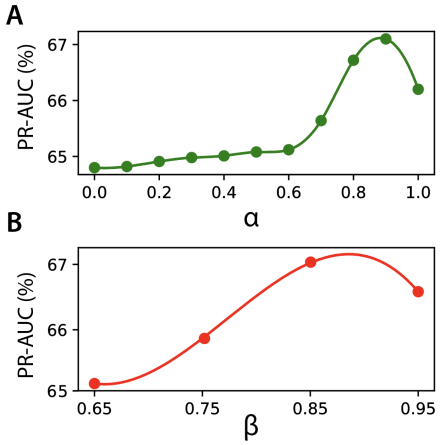

Figure 3: Effect of reward weighting parameters (A) α and (B) β on final classification model performance on ESCI dataset. Data points represent actual observations, while the curve represents a smoothing spline fit.

In Figure 3A, we observe that increasing α enhances PR-AUC, demonstrating that prioritizing classification loss as a reward signal improves the downstream classifier's performance. However, beyond $\alpha = 0.9$, performance degrades, as the diminishing contribution of the generation probability term (completely absent when $\alpha = 1.0$) leads to instability during training. In Figure 3B, we examine the impact of β, which controls the contribution of KL penalty to the reward. Classifier performance improves as β increases up to approximately 0.85, suggesting that lower values allow the adversarial reward to dominate, leading to the generation of semantically irrelevant queries. However, beyond this threshold, performance slightly declines, indicating that excessive regularization limits beneficial exploration.

6 Conclusion

In this work, we propose an adversarial reinforcement learning framework to enhance search query

relevance by jointly optimizing query generation and classification using classifier feedback as a reward signal. Empirical results on e-commerce datasets show improved classification and ranking performance over fine-tuning-based augmentation. By incorporating structured rewards, KL regularization, and confidence-weighted training, we ensure informative query generation while minimizing incorrect examples. Deploying our approach in the pharmacy category led to a $+13.9\%$ increase in product views and $+3.8\%$ increase in purchases, demonstrating its real-world effectiveness.

Limitations

While our adversarial reinforcement learning framework enhances query generation and classifier robustness, several challenges remain that require further investigation.

Training Stability. Adversarial training can be unstable, requiring careful hyperparameter tuning to prevent degenerate query generation. Future work can explore advanced regularization techniques to mitigate this issue.

Generalizability to Other Domains. Our experiments focused on e-commerce search, but the framework could benefit other retrieval tasks, such as dialogue systems (retrieving relevant responses in conversational AI), code search (enhancing programming assistant recommendations), and information extraction (retrieving structured data from unstructured documents), among others.

Benefits Beyond Cold-Start. While our approach is particularly beneficial in low-data settings, further evaluation is needed to determine its impact in high-data regimes. Future work should assess whether adversarial query generation improves performance even when ample training data is available.

By addressing these limitations, we can expand the applicability and robustness of our framework across diverse retrieval tasks.

Auto Review: Second Stage Error Detection for Highly Accurate Information Extraction from Phone Conversations

Infinitus Systems, Inc.
{ayesha, arushi, conal, youngseo.son}@infinitus.ai

Abstract

Automating benefit verification phone calls saves time in healthcare and helps patients receive treatment faster. It is critical to obtain highly accurate information in these phone calls, as it can affect a patient's healthcare journey. Given the noise in phone call transcripts, we have a two-stage system that involves a post-call review phase for potentially noisy fields, where human reviewers manually verify the extracted data—a labor-intensive task. To automate this stage, we introduce ***Auto Review***, which significantly reduces manual effort while maintaining a high bar for accuracy. This system, being highly reliant on call transcripts, suffers a performance bottleneck due to automatic speech recognition (ASR) issues. This problem is further exacerbated by the use of domain-specific jargon in the calls. In this work, we propose a second-stage postprocessing pipeline for accurate information extraction. We improve accuracy by using multiple ASR alternatives and a pseudo-labeling approach that does not require manually corrected transcripts. Experiments with general-purpose large language models and feature-based model pipelines demonstrate substantial improvements in the quality of corrected call transcripts, thereby enhancing the efficiency of ***Auto Review***.

1 Introduction

A key use case for Conversational AI systems in industry is collecting information (Gnewuch et al., 2017). One critical application is healthcare benefit verification, where information about a patient's insurance coverage is gathered from an insurance company over the phone. These extracted values, such as patient group numbers and drug coverage details, are essential for treatment approval and directly impact a patient's healthcare journey (Buker, 2023). Given the high-stakes nature of this task, ensuring the accuracy of extracted data is crucial.

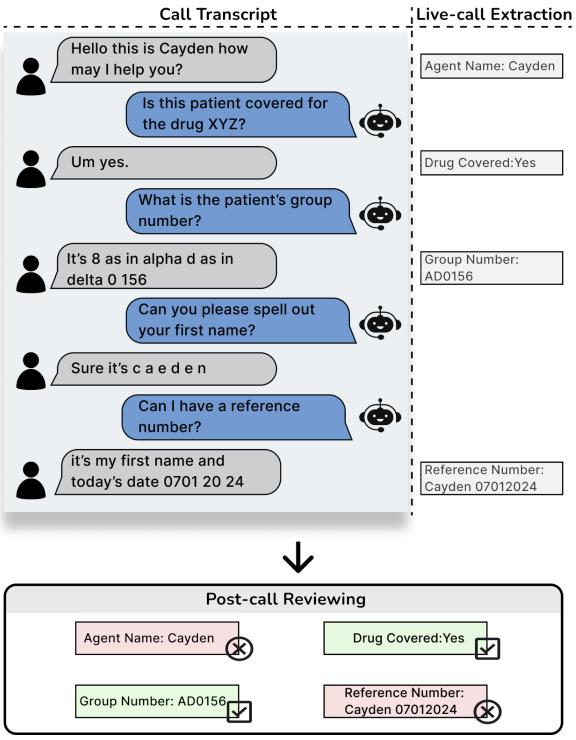

Figure 1: An excerpt from a dummy chat, along with the field values extracted during the call, is passed to the post-call reviewing module for verification. The noisy ASR transcripts can contribute to errors in the extracted data; this is exacerbated for domain-specific jargon such as group number and rare agent names.

While extensive research has focused on conversation navigation techniques—such as intent prediction, slot filling, and dialogue state tracking (McTear, 2022)—there has been comparatively less emphasis on ensuring the accuracy of extracted information in AI-driven conversations with task-specific context. In real-world applications, automated phone call outputs often contain errors due to ASR challenges, including background noise, domain-specific jargon, and complex alphanumeric sequences. To maintain data reliability, it is crucial to incorporate automated error correction methods

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1308–1321

or human-in-the-loop verification where necessary. Unlike prior work that focuses on ASR error correction for grammatical mistakes, our goal is to improve the accuracy of extracted informational fields. Since creating datasets for ASR error correction is time-consuming and labor-intensive, we propose using a pseudo-labeling technique with Large Language Models (LLMs).

Given the real-time constraints of compute and latency during live calls, we introduce **Auto Review**, a two-stage pipeline that enhances post-call information extraction. The first stage involves a conversational AI system that navigates live calls and extracts key field values. However, it does not guarantee that the extracted values are highly accurate. The second stage performs an automated review, flagging potential errors for human review or approving the accurate values. This second stage significantly reduces manual human review time while maintaining high accuracy.

We evaluate LLMs as a reviewing agent in two distinct settings: direct verification, where a model determines whether an extracted field value in the first stage is correct, and direct extraction, where a model identifies the correct value directly from the transcript. We compare multiple LLMs and feature-based models, analyzing their trade-offs in precision, recall, and computational efficiency.

The main contributions of this paper can be summarized as:

- We introduce a two-stage pipeline for accurate and efficient information extraction in the healthcare benefit verification domain. This approach saves human review time while ensuring high accuracy in the final outputs delivered to clients.
- To address domain-specific errors in ASR transcripts, we propose a pseudo-label generation technique leveraging LLMs.
- We conduct a comprehensive evaluation of LLMs for information verification in both generative and discriminative settings, analyzing the trade-offs between the two approaches.

2 Related Work

ASR Error Correction Most research on ASR error detection and correction focuses on grammatical mistakes (Li and Wang, 2024; Ma et al., 2023). Loem et al. (2023) demonstrated that GPT-3, in zero-shot and few-shot settings, can perform grammatical error correction. Davis et al. (2024) used LLM prompting techniques to address grammatical issues, while Wang et al. (2024) combined rule-based methods with generative models to introduce artificial errors that mimic real-world patterns. Shen et al. (2022) highlighted how the scarcity of errors in training data limits a model's ability to correct them effectively. Unlike these approaches, our focus is on correcting informational fields rather than grammatical issues. We leverage domain-specific context and frequent ASR error patterns to improve accuracy in benefit verification.

Previous work has focused on correcting named entity errors in ASR text. For instance, Pusateri et al. (2024) use a retrieval-augmented approach, while Saebi et al. (2021) leverage external knowledge sources like knowledge graphs. However, in our healthcare phone conversations, sensitive and context-dependent information (e.g., personal health data) is often not available in public knowledge bases and can only be captured live during the call.

Many studies use supervised fine-tuning as a post-processing step to reduce ASR errors (Errattahi et al., 2016; Radhakrishnan et al., 2023). Some approaches (Ebadi et al., 2024) avoid relying on manually corrected transcripts by using the inherent knowledge of LLMs to correct errors. In contrast, we don't have manually corrected transcripts, and few-shot LLMs were ineffective, as they haven't been exposed to our domain-specific data during pre-training.

Output Extraction Dialogue state tracking (DST) in task-oriented dialogues involves intent recognition, which can be viewed as output extraction based on the user turns (Li et al., 2024). This process fills predefined slot-value pairs according to the domain and task requirements. In healthcare benefit verification, this translates to extracting specific fields necessary to confirm patient benefits (Feng et al., 2023). Retrieval-augmented strategies have been explored for DST (King and Flanigan, 2023), and LLMs have been applied to intent and entity extraction for live conversations (Luo et al., 2024). While our first-stage live call system incorporates elements of these approaches, it does not achieve the required accuracy given our healthcare-specific constraints on latency and compute resources. To address this, we introduce a second-stage system that refines outputs in a post-processing step, improving overall accuracy.

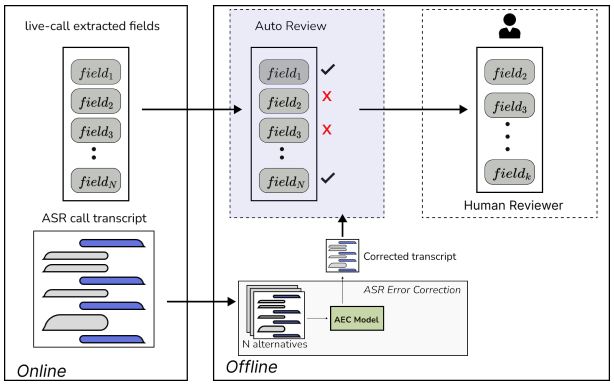

Figure 2: The *auto review* pipeline consists of an online and an offline component. The fields that do not get auto-approved are passed to a human reviewer for correction.

Field	Error Rates	Mean Edit	STDV
Agent Name	10.80%	3.23	2.89
Reference Number	12.90%	7.05	6.43
Group Number	9.80%	3.76	7.76

Table 1: Error rates denote the ratio of incorrectly extracted live-call values for each field. Mean edit and STD denote mean and standard deviations of edit distances of live-call extracted values that contain errors.

Dataset Type	Calls	AVG	STDV
Train	6,652	907	316.09
Validation	383	926	329.26
Test	2,260	939	356.79

Table 2: Patients benefit verification phone calls. AVG: average number of words, STDV: standard deviation.

3 Two Stage Pipeline for Highly Accurate Information Extraction

Our automation pipeline for verifying patient insurance benefits involves two stages. First, a live-call conversational AI model engages with an insurance representative to collect the necessary benefit information. Second, an auto-review AI model validates the collected data based on the full call context, patient details, and domain knowledge.

The goal is to ensure the accuracy of the information and automate healthcare processes. In cases where the data may be uncertain, a human is brought in for review. For high-confidence fields, we can automatically approve the data, significantly reducing human involvement and improving operational efficiency without compromising quality.

In the second stage, the auto-review AI models verify the accuracy of the information collected. We define auto-reviewing as the process of assessing whether each extracted value from a call transcript is correct. As shown in the conversation snapshot in Figure 1, some information may be updated or corrected during the call.

To support large-scale industrial deployment, we prioritized cost-effective model design, considering trade-offs between model complexity and performance. Our objective is to deploy efficient and scalable models that maintain comparable performance to larger alternatives, as long as differences are not statistically significant. The models evaluated in this paper represent a simplified component of a broader production pipeline used in our industrial setting.

4 Data Description

We collected 9,456 benefit verification calls between February and July 2024 for our experiments. Calls from February 1st to July 3rd were used for training, calls from July 5th for validation, and calls from July 10th to 12th for evaluation[1]. The dataset details are given in Table 2. The dataset includes call audio, ASR transcripts, extracted field values, and human-verified gold field values.

The field values in our healthcare domain include alphanumeric strings (e.g., insurance agent name, patient group number), booleans (e.g., medication coverage), and dates (e.g., effective dates of insurance plans). Alphanumeric fields typically exhibit the highest error rates due to ASR mistranscriptions caused by homophones, background noise, and similar-sounding names. We focus on alphanumeric fields for three reasons: 1) they have the highest correction rates, 2) they vary greatly in value, and 3) they are most prone to ASR errors. Therefore, we discuss three key alphanumeric fields with the highest correction rates: Agent Name, Reference Number, and Group Number[2]. The first-stage conversational AI models were generally accurate, with target output fields having an error correction rate of 10-13%, and their mean edit distances ranging from 3.23 to 7.05 (see Table 1).

5 Auto-Review Model

We developed two primary approaches for automatically reviewing benefit information, both of which take the call transcript as input. The first,

[1]No calls were collected over the weekend.

[2]Multimodal LLMs performed poorly when directly extracting from call audio recordings (see C.1).

Direct Extraction, extracts the field values, while the second, ***Direct Verification***, uses the live-call values and determines, in a discriminative setting, whether they are correct.

5.1 Direct Verification

In this approach, both the transcript and the live-call field value are provided as input. The *live-call* value is defined as the field value extracted by our real-time system, which may also involve human in the loop. This setting is akin to binary classification.

Input: [Transcript][Live-call Extracted Field Value] Is the field value correct? Output: Yes/No

5.2 Direct Extraction

Here, the model receives the call transcript along with the field name and is tasked with extracting the relevant value from the transcript. The value extracted in this setting is referred to as the *post-call* value.

Input: [Transcript] What is the field value? Output: Post-call Extracted Field Value

After the extraction, we convert the task back to a review process by comparing the extracted field value with the live-call field value. If the live-call field value matches the post-call extracted value, we consider it to be correct.

5.3 Error Patterns

A major source of incorrect predictions at this stage stems from errors in the call transcripts, which can result in either incorrect field values being approved or correct ones being missed.

Our task faces two main challenges: 1) detecting errors in call-level field extraction, which is a highly imbalanced classification problem, and 2) auto-correcting detected errors, which requires understanding ASR error patterns. One common error pattern involves similar pronunciations, such as a mistranscribed reference number (Rina A 01012024 instead of Sabrina A 01012024). Another common issue arises from inaccurate long sequence transcripts, such as missing or redundant digits (e.g., '10001234' missing a 0, or '1234560' with an extra 0). These ASR errors present a bottleneck for the auto-review process.

6 Error Handling

Traditional ASR error correction models aim to detect and correct all errors in a transcript (Lu et al., 2019). In contrast, our focus is not on correcting grammatical errors, but on ensuring the accuracy of the information relevant to benefit verification. As noted in recent studies (Zhu et al., 2021), using n-best alternatives significantly improves error correction. In our experiments, providing multiple transcript alternatives improves data extraction performance. Therefore, we use n-alternatives at both the pseudo-label generation and error correction stages[3]

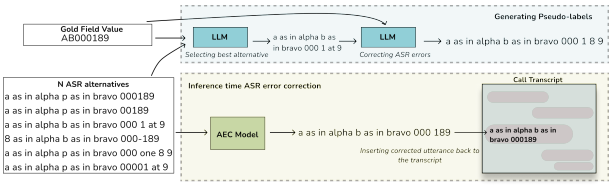

Figure 3: An overview of the ASR error handling component. n ASR alternatives are used to generate the pseudo-labels that are then used for training the AEC model. During inference, the corrected utterances are inserted back into the transcript.

Algorithm 1 Correcting ASR transcript using gold field value

1: **Input**: ASR_N (list of ASR alternatives), $field_{gold}$ (corrected field value)
2: $ASR_{best} \leftarrow f^{LLM}_{best\_alternative}(ASR_N, field_{gold})$
3: $ASR_{corr} \leftarrow f^{LLM}_{correct\_transcript}(ASR_{best}, field_{gold})$
4: **return** ASR_{corr}

6.1 Generating Pseudo-Labels

Manually curating an error correction dataset from a large number of calls is expensive and time-consuming. Instead, we leverage existing ASR transcripts and human-reviewed field values from past calls to create a specialized dataset for error correction.

To generate pseudo-labels, we prompt an LLM to correct noisy transcripts so that the information aligns with the gold field value. In initial experiments, we found that when multiple errors were present in a transcript[4], the LLM struggled to correct all of them. To address this, we use n-alternatives and break pseudo-label generation into two steps. First, we provide the LLM[5] with all n-alternatives and the gold field value, asking it to choose the best alternative, we formalize this as $f^{LLM}_{best\_alternative}(ASR_N, field_{gold})$. Then, using the selected alternative and the gold value, we prompt the LLM again to correct the transcript, we call this function $f^{LLM}_{correct\_transcript}(ASR_{best},$

[3]Please refer to C.1 and C.3 for more details about our main model architecture decision.

[4]The best transcript returned by the ASR model may not be the most accurate for benefit verification.

[5]We use the Gemini model for generating pseudo-labels.

Model	Agent Name			Reference Number			Group Number

Table 3: Model performance for the *Direct Verification* setting in correctly reviewing Agent Name, Reference Number, and Group Number. Fine-tuned GPT 3.5 + AEC refers to the model fine-tuned for auto-reviewing using corrected transcripts. The results highlighted in gray are from the fine-tuned model, all other models have not been fine-tuned. (AED: ASR Error Detection, AEC: ASR Error Correction, GPT 3.5: GPT 3.5 Turbo). McNemar's tests were conducted on the best-performing model for each field against its baseline (XGBoost), and all comparisons showed statistically significant improvements ($* : p < 0.001$)

$field_{gold}$). Figure 3 gives the workflow on pseudo-label generation. In all experiments, we set $n = 10$ [6]. Detailed prompts are described in Appendix D, and the algorithm for locating utterances is presented in Appendix B.

6.2 Automatic Error Correction Model

For the ASR Error Correction (AEC) model, we use Mistral (Jiang et al., 2023) as the base model for error handling tasks[7]. The AEC model focuses exclusively on correcting utterances containing key field values. We first isolate those utterances for each field type. The corresponding pseudo-labels are generated only during the training phase. We provide n alternatives as input to the model and train using the pseudo-labels. Given the n alternatives, the AEC model is trained to output a single correct transcript. After the correction, the corrected utterances are inserted back to their original place in the full call transcript.

6.3 Automatic Error Detection Model

Error detection can be considered a component of the full auto-correction pipeline (Fang et al., 2022; Leng et al., 2023) and can be easily integrated into various ML models as an additional feature. To assess its impact, we examine the effect of incorporating a simple error detection signal into our production-level model.

The ASR Error Detection (AED) model is trained similarly to the AEC model but differs in its output. Instead of generating a corrected transcript, the AED model produces a binary classification: *True* if the first of the n alternatives is noisy and *False* otherwise. To adapt the AEC training data for this task, we label an instance as *True* if the best alternative differs from the pseudo-corrected transcript and *False* otherwise.

7 Results

7.1 Evaluation Setting

The goal of both *Direct Extraction* and *Direct Verification* is to determine whether a given live-call field value is correct. If the gold field value is the same as the live-call value and the model predicts it as correct, we consider that a correct prediction. Since our primary focus is on 'auto-approval', we evaluate results specifically for that class.

Given the dataset's high imbalance, we report precision, recall, and F1 scores. For *Direct Extraction*, we also measure exact match and normalized edit distance. The baseline in both evaluation settings is the model that is just provided the best ASR transcript, without any error correction [8].

[6] Additional details on the choice of n are given in appendix C.3

[7] We chose Mistral due to its open-source availability and, in our preliminary experiments with random subset samples, performed better than LLaMA-8B-instruct.

[8] We measure the efficacy of the error correction model by evaluating directly on the downstream task of benefit verification as opposed to intrinsic evaluation metrics such as ROUGE, since we do not have gold corrected transcripts.

Field Value	Precision↑	Recall↑	F1↑	Accuracy↑	NED↓

7.2 Base Models

For off-the-shelf LLMs, we report results on GPT (Brown et al., 2020; Achiam et al., 2023) and Gemini (Team et al., 2023) models with noisy ASR transcripts as baseline and after performing error correction. The detailed prompts can be found in Appendix D. We also integrate the AEC model into the auto-review model used in a feature-based model architecture. We use XGBoost model architecture so we can leverage all of the statistical and historical features[9] and LLM models (e.g., field value extractions using LLMs) as features for making final auto-approval decisions. We do not compare against other specialized error correction models, as they either focus on grammatical error correction (Li and Wang, 2024; Ma et al., 2023) or rely on specialized knowledge graphs (Saebi et al., 2021) or manual annotations.

7.3 Analysis

Our goal is to assess the impact of ASR error correction on the overall performance of the **Auto Review** pipeline. Ultimately, the choice of model depends on the specific use case and the acceptable trade-off between precision and recall.

Direct Verification Table 3 presents the results for direct verification. We first examine the XGBoost model within the feature-based pipeline. Adding a simple binary feature for AED (indicating whether the transcript is noisy) improves performance for two out of three fields. Further incorporating corrected transcripts, the 'XGBoost + AED + AEC' model significantly enhances the F1 score for 'Agent Name' (0.7824→0.8428) and achieves the best performance on 'Reference Number' (0.9088→0.9208). The 'Gemini 1.5 + AEC' model improves precision across all fields but at the cost of reduced recall. In contrast, 'GPT 3.5 + AEC' enhances overall performance across all fields, except for a slight recall drop in 'Agent Name'. Notably, it achieves the highest accuracy for 'Group Number'. Fine-tuned GPT model with AEC obtained the highest F1 score on all fields by improving the recall substantially but resulted in a lower precision. Compared to LLMs, XGBoost models achieve higher precision but lower recall. This is due to their reliance on specialized regular expressions for field formats [10] as well as historical and statistical features. However, these constraints limit their generalization to diverse cases.

Direct Extraction Unlike the direct verification approach, the AEC model does not receive the live-call extracted field value as input. Instead, it extracts the field value directly from the ASR transcript. This extracted value is then compared to the live-call field values as an additional validation step. If both values match, the system auto-approves the result; otherwise, it requests a second human review. As shown in Table 5, this method results in lower recall, as the model often fails to approve correct values due to variations in ASR outputs. For instance, as illustrated in Figure 1, the *direct verification* model may approve the live-call group

[9]Features include textual features extracted from live-call field values (e.g., regular expression patterns for expected formats for each field), call STT transcripts and statistical and historical features extracted from benefit verification client and call recipient insurance company.

[10]e.g., predefined patterns for group numbers, reference numbers, and agent name capitalization

number despite minor errors in the transcript (e.g., ignoring an incorrect '8'). In contrast, the *direct extraction* model may output alternative values such as '8D0156' or 'AD0156', increasing susceptibility to ASR errors. However, this approach achieves significantly higher precision. After applying ASR error correction, precision remains stable across all fields, while recall improves substantially, yielding an average F1 score improvement of **5.5%**. While failing to auto-approve correct values is undesirable, it is preferable to approving incorrect extractions and passing them to customers.

A hybrid model combining both settings could be implemented in production. *Direct verification* would be applied to less critical fields [11], leading to a higher overall F1 score and saving time on review. *Direct extraction* would be reserved for critical fields, approving them under a more stringent setting.

8 Conclusion

We introduced **Auto Review**, a two-stage pipeline that enhances information extraction from healthcare phone calls. Our approach reduces human verification while maintaining high accuracy. The second stage involves an ASR error correction framework, leveraging n-best ASR alternatives to generate pseudo-labels for training an error correction model. This framework is adaptable across domains, provided some past manually reviewed data is available. Results show that ASR error correction improves precision and recall across key fields, with *Direct Verification* offering higher recall and *Direct Extraction* achieving higher precision.

The results reported in this paper reflect the isolated performance of a model component within a larger production system. In real-world deployment, additional pipeline components—including human-in-the-loop mechanisms and cross-field verification models—contribute to significantly higher precision. This underscores the complementary role of system-level engineering in achieving production-grade performance alongside core model development.

9 Ethical Statement

All experiments described in this paper were conducted in compliance with applicable privacy and data protection regulations. Specifically, interactions with third-party models, including OpenAI's GPT-3.5 Turbo and Google's Gemini, were governed by appropriate Business Associate Agreements (BAAs) if required under the Health Insurance Portability and Accountability Act (HIPAA). These controls were designed to ensure that no Protected Health Information (PHI) was exposed to external service providers for training or other purposes beyond our immediate use case, and that at no point was PHI stored in third-party companies or used to improve or fine-tune the third-party models themselves.

For model inferences in our main experiments with GPT-3.5 Turbo and Gemini 1.5 Pro APIs, the total estimated cost was $303, based on publicly available pricing at the time of experimentation. This included approximately $260 for Gemini 1.5 Pro with audio input, $20 for Gemini 1.5 Pro with text input, and $23 for GPT-3.5 Turbo (16k context) with text input.

[11] Critical fields are those where incorrect values can have a significant negative impact on customers.

A Training Description

For the AEC model, we use Mistral-7B-Instruct-v0.3, which was trained with a batch size of 16, gradient accumulation step set to 2 using 1 A100 GPU. Training took 9 hours. In all our AEC experiments, the number of alternatives, *n*, is fixed to 10. LoRA (Hu et al., 2022) is used for parameter-efficient training using the LLaMA-Factory library (Zheng et al., 2024). We use the Gemini 1.5 model to generate the pseudo-labels. Google STT model is used as the base STT model for all ASR transcripts[12].

B Relevant Utterance Isolation

Algorithm 2 presents the algorithm to isolate only those utterances from the call transcripts that are highly likely to contain the field value information we want to extract. It starts collecting agent utterances after the conversational AI model asks for information regarding that field, those trigger questions are pre-defined and passed to the algorithm in field_triggers.

Algorithm 2 Extract Utterances for Fields of Interest

Require: call_transcript (list of tuples with speaker and utterance), field_triggers (list of trigger utterances)

Initialize an empty list $agent\_responses$
Set $collect\_responses \leftarrow$ **false**
for each $(speaker, utterance)$ in $call\_transcript$ **do**
  if not $collect\_responses$ **and** $utterance$ contains any phrase in $field\_triggers$ **then**
    $collect\_responses \leftarrow$ **true**
  else if $collect\_responses$ **then**
    if $speaker =$ Agent **then**
      Append $utterance$ to $agent\_responses$
    else if $speaker =$ AI Model **then**
      $collect\_responses \leftarrow$ **false**
    end if
  end if
end for
return $agent\_responses$

Field Value	Precision	Recall	F1
Gemini with Audio

Group Number	0.9965	0.4323	0.6030
XGBoost Model			
Agent Name	0.9570	0.6617	0.7824
Reference Number	0.9636	0.8598	0.9088
Group Number	0.9749	0.8969	0.9343

Table 5: Performance metrics for Agent Name, Reference Number, and Group Number in the *Direct Extraction* setting using Gemini with audio input. The audio-based model suffers from very low recall.

C Preliminary Experiments

C.1 Experiments with Gemini using Audio Input

For our preliminary analysis, we experimented with off-the-shelf multimodal LLM (Gemini 1.5) with the same prompt we used for ASR text transcript direct extraction (Table 11, Table 12) except for

[12] In preliminary experiments, we found fine-tuning ASR helped improving the general performance metric such as word error rate (WER) but observed the similar issues especially from unseen field values. See more details in C.2

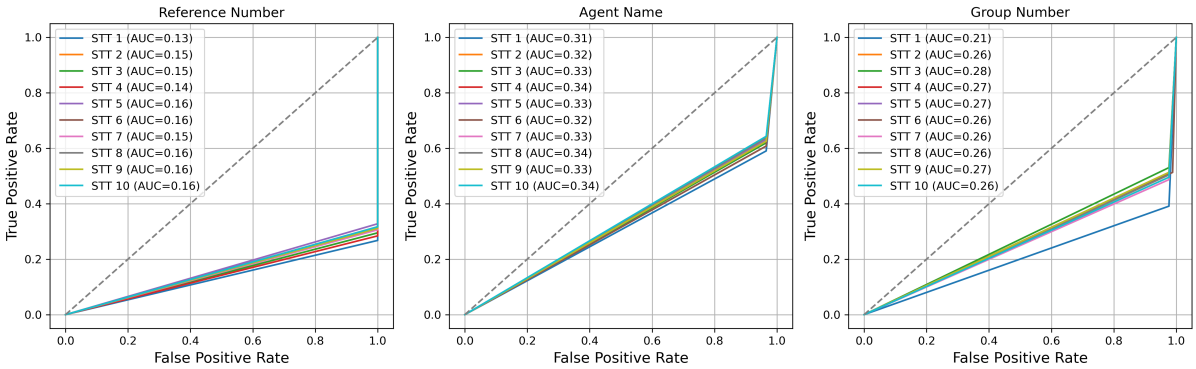

Figure 4: The ROC curves for the three field types when using different numbers of transcript alternatives as input. The Gemini model is provided the transcript to extract the field value, which is then compared with the gold field value. Providing multiple alternatives improves performance.

the instruction which tells to use the attached audio instead of the text providing the call audio recording. Gemini obtained high precision overall, but its recall is too low to effectively reduce human review time in industry settings with a large number of concurrent phone calls. When we analyzed false positive auto-approved samples, it made similar mistakes with ASR models incorrectly adding 0 or missing a few digits for long alphanumeric field values or misspelling rare agent names with more common names. Thus, we designed ASR error detection and correction models focusing on the field values of the data types that are highly vulnerable to such errors and cannot be resolved by off-the-shelf LLMs or other feature-based models.

C.2 Experiments with ASR systems

We conducted preliminary experiments using Google STT and Whisper (Whisper Large V3[13]) to choose the most suitable ASR system for our field value output extraction tasks. Although Google STT obtained a higher performance than Whisper, it was not available for fine-tuning so we fine-tuned Whisper model using the subset of our full data to explore the best ASR system options (785 outputs for training set, 390 outputs for validation set and 510 outputs for test set). We found that our fine-tuned Whisper model improved the general evaluation metrics but we still observed similar issues with mistranscripts with digits or letters missing for long sequence outputs; especially with the patterns which did not exist in training set (see more details in Table 6). Thus, collecting ground truth labels for all such cases required a large human labeling effort and it was not scalable for our task with real world data so we chose off-the-shelf Google STT for our main experiments.

ASR System	Word Error Rates	Norm. Edit
Google STT	0.602	0.430
Whisper	0.757	0.485
FT Whisper	0.349	0.216

Table 6: Performance metrics for ASR systems on task output transcription. FT Whisper: fine-tuned Whisper, Norm. Edit: normalized edit distance (edit distance between the transcript and the ground truth divided by the maximum value among the lengths of the two).

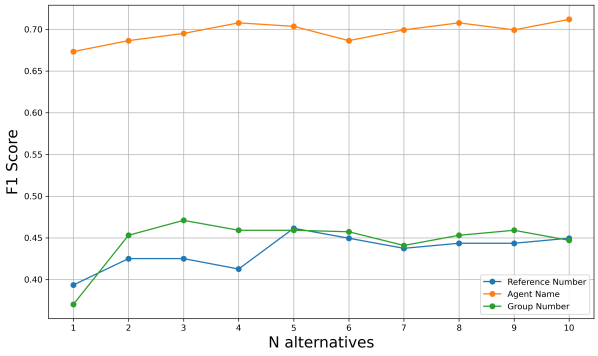

Figure 5: F1 scores for LLM performance across the three field types, based on correctly extracting field values from transcripts. The input transcript to the LLM includes multiple ASR alternatives. A significant performance improvement is observed when incorporating multiple alternatives instead of relying solely on the best one.

C.3 Number of ASR Alternatives

We conducted experiments to assess the impact of using multiple ASR alternatives on field value extraction. Using a subset of 200 calls, we measured

[13] https://huggingface.co/openai/whisper-large-v3

LLM performance in extracting three key fields. Specifically, we prompted Gemini to extract field values from transcripts while varying the number of ASR alternatives, with $n = 1$ corresponding to using only the best transcript. The prompts for these experiments follow the *Direct Extraction* approach and are detailed in Table 12 and Table 11. As shown in Figure 5 and Figure 4, incorporating multiple ASR alternatives significantly improves performance across all field values. Since the optimal value of n varies by field type and we want to train a single cohesive AEC model, we chose $n = 10$ in all our experiments.

D Model Prompts

The prompts used for all the experiments are given below. The in-context examples used in the experiments have been removed because they contain sensitive patient information.

<INSTRUCTIONS> You are “{our conversational AI model name}”, a digital assistant calling a healthcare insurance company to get benefits information for a member. Given the STT transcript of phone conversations between you and the health insurance company agent, check if all of your answers to the given questions are correct. Please respond using “correct” or “incorrect”, checking whether all the answers to the questions in the call are correct or not, and provide your reasoning in JSON format. Here are example cases for each answer:
1. “correct”: select this option only if all the answers are correct based on the call transcript.
2. “incorrect”: select this option if you see any of the answers to the questions is incorrect.
Below are sample responses and reasons:
Reason: Among 4 questions asked, the answer to the second question should have been “True”. // Your response: {“response”: “incorrect”}
Reason: All of the answers to the given 5 questions are correct. // Your response: {“response”: “correct”}
Reason: There was one question and the agent could not provide the answer and the answer was “agent did not provide this information”. // Your response: {“response”: “correct”} **</INSTRUCTIONS>**

<TARGET_QUESTION_GUIDELINES> Some additional guidelines for specific questions with examples for the questions of “agentName”, “referenceNumber”, and “groupNumber”:
1. Note if the agent spells it out or uses nato alphabet. For example, if the agent says “c as in Charlie 2 n as in Nancy 3 c as in Tango G is in gold”, you should collect “C2N3TG”. With STT mistranscriptions, you should follow the nato alphabet over the spelling.
2. Unless there is a word or name used, capitalize all letters and remove any spaces. For example, if the agent says “group number is 123 456 789”, you should collect “1234567890”.
3. There might be speech to text transcription errors (e.g. “8” instead of "H" or “for” instead of “4”) For example, they might say “C like Tango” and in this case you should get the spelling to include T, not C.
</TARGET_QUESTION_GUIDELINES>

<TARGET_QUESTION_EXAMPLES> [reason // questions // your response]
- Reason: “the agent spelled out their name as Jane and said C like Tango” Question: “Question 1: agentName? Answer: ’Jane T”’ // Your response: {{“response”: “correct”}} Reason: “the agent gave their name as Jane and said his last name initial is O as in Oscar and said there were no reference numbers” // Question: "Question 1: agentName? Answer: ’Jane O’. Question 2: referenceNumber? Answer: ’Jane O 06242024’" // Your response: {{“response”: “correct”}}
- Reason: “the agent said t i a b for boy so likely the last name initial is B so the first name is Tia” // Question “agentName”: “Tia B”, “referenceNumber”: “12345”}}
- Reason: “the agent said d a r a for alpha my initial so likely A is their last name initial so the first name is Dar” // Question: "Question 1: agentName? ’Dar A”’ // Your response: {{“response”: “correct”}}
- Reason: "the agent said their name was j a qu a i d i a last initial K so their name is Jaquaidia K and they said the reference number was their name and the date" // Question: "Question 1: agentName? ’Jaquaidia K’. Question 2: referenceNumber? ’Jaquaidia K 06012024’// Your response: "response": "correct"
- Reason: "the agent said their name was Jasmine but spelled it out as J A S M I N so with that spelling their name must be Jasmin" // Question: "Question 1: agentName? ’Jasmine’" // Your response: {{“response”: “incorrect”}} - Reason: “the agent said their name was Sam but spelled it out as s a m y r so with that spelling their name must be Samyr” // Question: “Question 1: agentName? ’Samyr”’ // Your response: {{“response”: “correct"}}
- Reason: “the agent spelled their name as ’p as in paul n as in nancy o t t r i c last initial is d’ so their name is Pnottric D and gave no reference number" // Question: “Question 1: agentName? ’Pnottric D’. Question 2: referenceNumber? ’Pnottric D 06012024”’ // Your response: {{“response”: “correct”}}
</TARGET_QUESTION_EXAMPLES>
Below is the STT transcript of the call.
[transcript]

Answer if all of the following questions and answer pairs are correct in the JSON format as in the example in the instruction
[question_answer_pairs]

Table 7: *Direct Verification* prompt used for all fields.

</INSTRUCTIONS> You are a capable annotator who can identify and correct issues in STT transcript. You will be given alternative STT transcripts and corresponding extracted name. Pick the best alternative that most correctly corresponds to the given extracted name. The best alternative is defined as: The alternative transcript from which we should be able to extract the name that matches the given extracted name. If there are multiple names present, usually we only care about the last name. Ignore the name "{our conversational AI model name}" if it is present in the transcript. The alternative transcripts are separated by "#". Give the output in json format of {{"Output": best_transcript}}
</INSTRUCTION>
<EXAMPLES>
Here are some examples of the STT transcripts along with the extracted value and the outputs separated by "//" (i.e., STT transcripts, extracted name // your output):
[Examples]
</EXAMPLES>
Now provide your answer from the following STT transcripts and extracted value:
[Input]

Table 8: Pseudo-label generation prompt for selecting the best alternative.

<INSTRUCTIONS> You are a capable annotator who can identify and correct issues in STT transcript. You will be given STT transcript and corresponding extracted value. If the transcript is correct, you will simply return the transcript and if the transcript is wrong compared to the correctly extracted value, you need to correct the transcript appropriately. Pay special attention to the number of zeros in the extracted value and compare with the noisy transcript. Do not capitalize letters in the transcript if they are not originally capitalized, even if the extracted value has capitalized letters. Give the output in json format of {{"Output": corrected_transcript}}
</INSTRUCTIONS>
<EXAMPLES> Here are some examples of the STT transcript along with the extracted value and the outputs separated by "//" (i.e., STT transcript, extracted value // your output):

Now provide your answer from the following text:
[Input]

Table 12: *Direct Extraction* prompt for Agent Name and Reference Number.

<INSTRUCTIONS> You are “{our conversational AI model name}”, a digital assistant calling a healthcare insurance company to get benefits information for a member. Given the STT transcript of phone conversations between you and the health insurance company agent, check if all of your answers to the given questions are correct. Please respond using “correct” or “incorrect”, checking whether all the answers to the questions in the call are correct or not, and provide your reasoning in JSON format. Here are example cases for each answer:
1. “correct”: select this option only if all the answers are correct based on the call transcript.
2. “incorrect”: select this option if you see any of the answers to the questions is incorrect.
Below are sample responses and reasons:
Reason: Among 4 questions asked, the answer to the second question should have been “True”. // Your response: {“response”: “incorrect”}
Reason: All of the answers to the given 5 questions are correct. // Your response: {“response”: “correct”}
Reason: There was one question and the agent could not provide the answer and the answer was “agent did not provide this information”. // Your response: {“response”: “correct”} **</INSTRUCTIONS>**

<TARGET_QUESTION_GUIDELINES> Some additional guidelines for specific questions with examples for the questions of “agentName”, “referenceNumber”, and “groupNumber”:
1. Note if the agent spells it out or uses nato alphabet. For example, if the agent says “c as in Charlie 2 n as in Nancy 3 c as in Tango G is in gold”, you should collect “C2N3TG”. With STT mistranscriptions, you should follow the nato alphabet over the spelling.
2. Unless there is a word or name used, capitalize all letters and remove any spaces. For example, if the agent says “group number is 123 456 789”, you should collect “1234567890”.
3. There might be speech to text transcription errors (e.g. “8” instead of "H" or “for” instead of “4”) For example, they might say “C like Tango” and in this case you should get the spelling to include T, not C.
</TARGET_QUESTION_GUIDELINES>

<TARGET_QUESTION_EXAMPLES> [reason // questions // your response]
- Reason: “the agent spelled out their name as Jane and said C like Tango” Question: “Question 1: agentName? Answer: ’Jane T”’ // Your response: {{“response”: “correct”}} Reason: “the agent gave their name as Jane and said his last name initial is O as in Oscar and said there were no reference numbers” // Question: "Question 1: agentName? Answer: ’Jane O’. Question 2: referenceNumber? Answer: ’Jane O 05012024’" // Your response: {{“response”: “correct”}}
- Reason: “the agent said t i a b for boy so likely the last name initial is B so the first name is Tia” // Question “agentName”: “Tia B”, “referenceNumber”: “12345”}}
- Reason: “the agent said d a r a for alpha my initial so likely A is their last name initial so the first name is Dar” // Question: "Question 1: agentName? ’Dar A”’ // Your response: {{“response”: “correct”}}
- Reason: "the agent said their name was j a qu a i d i a last initial J so their name is Jaquaidia K and they said the reference number was their name and the date" // Question: "Question 1: agentName? ’Jaquaidia K’. Question 2: referenceNumber? ’Jaquaidia K 06012024’// Your response: "response": "correct"
- Reason: "the agent said their name was Jasmine but spelled it out as J A S M I N so with that spelling their name must be Jasmin" // Question: "Question 1: agentName? ’Jasmine’" // Your response: {{“response”: “incorrect”}} - Reason: “the agent said their name was Sam but spelled it out as s a m y r so with that spelling their name must be Samyr” // Question: “Question 1: agentName? ’Samyr”’ // Your response: {{“response”: “correct"}}
- Reason: “the agent spelled their name as ’p as in paul n as in nancy o t t r i c last initial is g’ so their name is Pnottric G and gave no reference number" // Question: “Question 1: agentName? ’Pnottric G’. Question 2: referenceNumber? ’Pnottric G 06012024”’ // Your response: {{“response”: “correct”}}

Abstract

In-car AI assistants enhance driving by enabling hands-free interactions, yet they often struggle with multi-turn conversations and fail to handle cognitively complex follow-up questions. This limits their effectiveness in real-world deployment. To address this limitation, we propose a framework that leverages Bloom's Taxonomy to systematically generate follow-up questions with increasing cognitive complexity and a Gricean-inspired evaluation framework to assess their Logical Consistency, Informativeness, Relevance, and Clarity. We introduce a dataset comprising 750 human-annotated seed questions and 3750 follow-up questions, with human evaluation confirming that 96.68% of the generated questions adhere to the intended Bloom's Taxonomy levels. Our approach, validated through both LLM-based and human assessments, also identifies the specific cognitive complexity level at which in-car AI assistants begin to falter information that can help developers measure and optimize key cognitive aspects of conversational performance.

1 Introduction

Large language models (LLMs) have transformed chatbots, enabling more natural and responsive interactions than rule-based ones. They are now common in customer service, education, tutoring, and entertainment, where they retrieve information and generate content through conversational interfaces. Despite these advances, many commercial AI assistants still struggle to answer user queries because of limited domain knowledge or cognitive constraints. This often leads to generic replies like "Sorry, I don't know," misinterpretations, or hallucinated facts, which frustrate users and reduce engagement, especially when questions demand more than simple recall.

Testing chatbots in the wild with manually crafted questions does not scale. It cannot support rapid iterations across Volume (large question sets), Variability (diverse domains), or Velocity (fast turnaround). Relying on an aggregate statistic—simply whether the chatbot can answer a question—overestimates performance and obscures where and why it fails (Ribeiro et al., 2020). Bloom's Taxonomy is a proven rubric for assessing cognitive skills. By issuing scaffolded questions at each level, we can systematically evaluate a chatbot's reasoning and application across increasing cognitive demands (see Figure 1).

Modern vehicles are increasingly integrated with LLMs to facilitate interactions between the in-car AI assistant and the driver. However, LLMs are not inherently designed for domain-specific tasks and lack automotive-specific knowledge and real-time data access, leading to generic failures. Our work focuses on evaluating LLM-powered in-car AI assistants. This is a high-stakes setting where misunderstandings or failures can impact safety and usability. By probing the assistant with our cognitively scaffolded methodology, we reveal its cognitive limitations and demonstrate that our evaluation approach generalizes to other LLM-powered chatbot applications.

Extensive work on question generation—ranging from template and statistical methods (Heilman and Smith, 2010), neural Seq2Seq models (Du et al., 2017) and semantic-graph approaches (Pan et al., 2020) to form-type balancing (Ghanem et al., 2022) ("how" vs "what") —focuses on generating high-quality questions rather than probing an LLM's cognitive abilities.

Prior studies have mapped benchmarks to Bloom's levels (Huber and Niklaus, 2025) and introduced Bloom-aligned tasks (Zoumpoulidi et al., 2024; Sun et al., 2024), but these rely on static, isolated questions or domain-specific

[*]Equal contribution

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1322–1338

prompting. No existing work systematically probes LLMs with a sequence of single-turn follow-up questions that each increase in cognitive complexity. This leaves the model's stepwise reasoning across the complete taxonomy unexplored. Our approach fills this gap by assessing responses to cognitively scaffolded prompts, revealing weaknesses beyond surface-level accuracy.

In the in-car voice assistant domain, available datasets, such as KVRET (Eric and Manning, 2017), offer multi-turn dialogues but do not include follow-up questions that escalate in cognitive complexity. No corpus is explicitly designed to evaluate how an in-car AI assistant navigates successively harder prompts along Bloom's hierarchy.

Traditional evaluation metrics such as BLEU (Papineni et al., 2002) and BERTScore (Zhang et al., 2019) depend on surface-level text similarity to ground-truth sentences, and thus fail to assess the nuanced quality of follow-up questions as experienced in real conversations. They cannot measure whether a question is truly relevant to the driver's task, whether it conveys new information, or whether it is phrased clearly and truthfully. Moreover, reference-based evaluation demands expensive human annotations or gold-standard follow-ups, which limits scalability across diverse driving scenarios. (RQUGE (Ge et al., 2023), an example of Gricean Maxims' implementation for evaluating questions, which evaluates only the previous turn).

To overcome these shortcomings, we turn to **Grice's Maxims**—the conversational principles of **Quantity**, **Quality**, **Relation** and **Manner**—as a natural rubric for evaluating follow-up questions in an in-car dialogue. We map each maxim to a reference-free metric:

- **Relevance** (Relation): Does the question focus on information pertinent to the driving context?
- **Informativeness** (Quantity): Does it introduce an appropriate amount of new, useful content?
- **Truthfulness** (Quality): Does the question logically follow from the previous context?
- **Clarity** (Manner): Is it unambiguous and easy to understand?

These Grice-inspired, reference-free metrics are scalable, adaptable, and cost-effective for evaluating large question sets in diverse driving scenarios.

As a developer of an in-car AI assistant technology, it is crucial to identify where the assistant fails, understand its cognitive limitations, and determine the types of questions it struggles to answer. To address this, we propose a technique that leverages LLMs to generate follow-up questions based on Bloom's Taxonomy. By systematically increasing the cognitive complexity of these questions, developers can assess the assistant's reasoning capabilities and pinpoint its limitations. Crucially, we avoid multi-turn dialogues where each follow-up depends on the assistant's previous answer. Chaining questions in this way can conflate errors, as a flawed response early on can derail the reasoning path and obscure the model's actual capabilities. Instead, we design each follow-up as a single-turn prompt, grounded only in the original context. This isolates the effect of increasing cognitive demand alone, avoids error propagation, and ensures that each question cleanly tests a distinct cognitive skill.

Our key contributions are:

1. **B-FQG Technique**: A Bloom's Taxonomy-based Follow-up Question Generation (FQG) method that produces follow-up questions by progressively increasing cognitive complexity—from recall to creation—without relying on previous responses from the in-car AI assistant powered by LLMs (Section 2.3).

2. **GriceWise**: A Grice's Maxims-inspired evaluation framework for follow-up questions. This reference-free method assesses questions based on logical consistency, informativeness, relevance, and clarity in multi-turn dialogues (Section 2.2).

3. **Blooms-FQ Dataset**: A human-annotated dataset comprising 750 seed questions and 3750 follow-up questions. Human evaluation confirms that 96.68% of the generated questions align with the intended Bloom's Taxonomy levels[1].

[1]Dataset link: https://huggingface.co/datasets/harshvivek14/Blooms-Followup-Questions

Figure 1: Illustration of Bloom's Taxonomy-based follow-up question generation for an in-car AI assistant. A Level 1 seed question is used to generate five follow-up questions that progressively increase in cognitive complexity, from basic recall to higher-order creative inquiries. The in-car AI assistant successfully answers simpler questions, but for certain higher-level queries, it defaults to a generic response such as "Sorry, I didn't get that!" highlighting its cognitive limitations. Responses marked with ✓ are correct or relevant, while ✗ indicate missing or evasive answers.

2 Methodology

In this section, we present our approach for generating follow-up questions that progressively increase cognitive complexity, guided by Bloom's Taxonomy. Our method, B-FQG (Bloom's Taxonomy-based Follow-up Question Generation), leverages both few-shot and zero-shot prompting to direct LLMs in producing follow-up questions that challenge in-car AI assistants at various cognitive levels. This systematic approach allows us to evaluate the cognitive capabilities of these systems and identify their limitations.

2.1 Seed Question Annotation

We construct the Bloom-FQ Dataset with 750 seed questions corresponding to Level 1 of Bloom's Taxonomy (Remember/Recall) for in-car AI assistants by converting a comprehensive list of supported commands—spanning Phone Calls, Sending Messages, POI Search, Media, Weather, Date and Time, Radio, Navigation Control, Climate Control, NLU Commands, and Automatic Temperature Control—into factual, minimal-reasoning questions (e.g., "Call John Smith" → "How do I make a call to John Smith?"). To ensure the dataset was non-redundant, we compared each pair of questions using semantic similarity and retained only one question from any pair with a similarity score above 0.95. This filtering process resulted in 750 unique seed questions (see Table 1 for domain-wise distribution). A second annotator then verified that each question adhered to Level 1 criteria—i.e., "what," "which," or "how" queries with a single, unambiguous answer, achieving 100% adherance to Level 1 of Bloom's Taxonomy. These verified seed questions serve as the foundation for our higher-level follow-up question generation.

Domain	# Qs	Domain	# Qs
Media	146	Climate Control	100
Phone	64	General Settings	63
POI Search	54	Navigation Control	50
Car Controls	47	Weather	41
Date and Time	41	NLU Commands	40
Car Manual	35	Sports	33
Radio	28	Messaging	8

Table 1: Domain-wise distribution of the 750 Seed Questions corresponding to Level 1 of Bloom's Taxonomy (Recall)

2.2 GriceWise: Gricean-inspired Evaluation Framework

We evaluate the follow-up questions using Grice's Maxims (Appendix A.1) to ensure capturing *Logical Consistency*, *Informativeness*, *Relevance* and *Clarity*. This ensures we are evaluating the questions beyond surface-level similarity.

2.2.1 Contextually-Relevant Gricean Scores

We define Q_1 as the seed question and $\{Q_2, Q_3, \ldots, Q_6\}$ as the sequence of follow-up questions. The context for the i-th follow-up question, denoted as C_i, includes all previous questions from Q_1 to Q_{i-1}, i.e., $C_i = \{Q_1, Q_2, \ldots, Q_{i-1}\}$

Logical Consistency (Maxim of Quality): To capture whether a follow-up question logically follows from the prior conversation, we adopt a *Natural Language Inference (NLI)* approach. Let C_i represent the prior context (including all preceding questions and answers), and let Q_i be the current follow-up question. We define the logical consistency score as the probability of the *entailment* label assigned by `roberta-large-mnli`[2]:

$$\text{LC}(Q_i \mid C_i) = \text{Entail}_{\texttt{roberta}}(Q_i, C_i)$$

A higher entailment score indicates that Q_i does not contradict or deviate from C_i, suggesting strong logical consistency. Conversely, a lower score implies that Q_i introduces inconsistencies or does not follow from the established conversation. This ensures that each follow-up question remains faithful to the context of the dialogue.

Informativeness (Maxim of Quantity): To capture the Informativeness of a question, we compute the conditional entropy of each follow-up question given the context of the prior conversation containing the questions. Let $P(w \mid C_i)$ be the probability of the word w occurring in the Q_i given context C_i. We define Informativeness as the conditional entropy:

$$H(Q_i \mid C_i) = -\sum_{w \in Q_i} P(w \mid C_i) \log P(w \mid C_i)$$

Conditional Entropy captures how much new information a follow-up question introduces relative to the prior questions in the conversation. A lower $H(Q_i \mid C_i)$ suggests redundancy amongst questions.

Relevance (Maxim of Relation): The Maxim of Relation emphasizes that follow-up questions should remain relevant to the ongoing conversation. A question that deviates significantly from the context can disrupt dialogue coherence.
We define the Relevance Score for the ith follow-up question Q_i, given its context C_i, as:

$$\text{Relevance Score}(Q_i, C_i) = \cos(v(Q_i), v(C_i))$$

where $v(Q_i)$ is the embedding of Q_i, and $v(C_i)$ is the average embedding of all previous questions:

$$v(C_i) = \frac{1}{|C_i|} \sum_{q_j \in C_i} v(q_j)$$

A higher cosine similarity indicates stronger contextual alignment, ensuring that follow-up questions contribute meaningfully to the conversation.

Clarity (Maxim of Manner): To evaluate Clarity, we use Average Dependency Distance (`ADD`), which measures how syntactically complex a sentence is. For each question Q_i, we define `ADD` as the average linear distance between words and their syntactic heads in the dependency tree. A lower `ADD` indicates a simpler, more comprehensible sentence structure. A well-formed follow-up question should be easy to understand and have a lower `ADD`. Shorter dependency distances indicate a syntactically simpler structure, making the question more direct and clear. In contrast, a higher `ADD` suggests a convoluted sentence, making comprehension harder.
We compute the Clarity score as follows:

$$\text{Clarity}(Q_i) = \frac{1}{1 + \texttt{ADD}(Q_i)}$$

[2] https://huggingface.co/FacebookAI/roberta-large-mnli

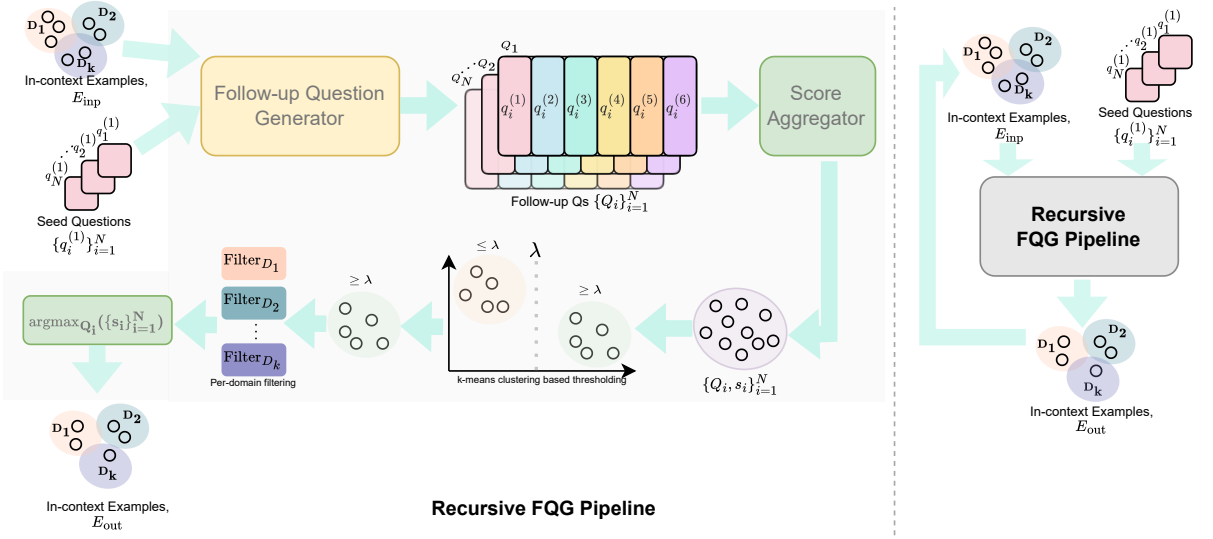

Figure 2: Recursive FQG pipeline. Starting from in-context examples $\mathcal{E}_{\text{inp}}$ drawn from domains $D_1, \ldots, D_k$ and 750 Level-1 (Remember) seed questions $\{q_i^{(1)}\}_{i=1}^{750}$, each seed is fed—via a few-shot prompt containing three human-annotated exemplars (seed + five follow-ups at Bloom Levels 2–6)—to an LLM-based Follow-up Question Generator. The model emits $M = 5$ candidates $\{q_i^{(j)}\}_{j=1}^{M}$, which are automatically scored on Logical Consistency, Informativeness, Relevance, and Clarity and aggregated into a single quality score. We apply K-means clustering with threshold λ to filter out low-quality sets and retain only those above λ. From this high-quality subset, we pick the top-scoring entry per domain to form a domain-diverse exemplar set, augment the prompt with these exemplars, and rerun the generator. Iterating this "generate → score → filter → cluster" loop yields the final out-of-domain examples $\mathcal{E}_{\text{out}}$.

2.2.2 LLM-based Reference-free Evaluation

Recent research highlights the potential of LLMs as reference-free evaluators for Natural Language Generation tasks (Chiang and Lee, 2023; Zheng et al., 2023; Liu et al., 2023). Building on this, we employed LLMs to evaluate follow-up questions based on four key metrics: *Logical Consistency, Informativeness, Relevance*, and *Clarity*, which are grounded in Gricean Maxims. The example of the evaluation prompts, structured following Siledar et al. (2024), are provided in Figure 6, 7, 8 & 9. For this evaluation, we used the `gpt-4o-mini` model.

2.3 B-FQG: Bloom's Taxonomy-based Follow-up Question Generation

We generate follow-up questions that progressively increase cognitive complexity according to Bloom's Revised Taxonomy (Appendix A.2), using 750 Level-1 (Remember) seed questions (see Figure 2). Each seed is input to an LLM-based Follow-up Question Generator via a few-shot prompt (Refer Figure 5 for the prompt) comprising three human-annotated examples, each consisting of a seed question and five follow-ups at Bloom Levels 2–6.

The LLM produces five follow-up questions per seed. We automatically score each complete set (Seed Question + 5 Follow-up Questions) on Logical Consistency, Relevance, Clarity, and Informativeness, aggregating these into a single quality score. We apply K-means clustering to these scores to define a threshold and retain only those entries above it.

From this high-quality subset, we select the top-scoring entry per domain to form a set of domain-diverse exemplars. We then augment the prompt with these exemplars and regenerate follow-ups for the lower-scoring seeds, repeating this bootstrap cycle until all entries meet our quality criteria. The follow-up questions were annotated to assess whether they adhered to the intended Bloom's levels, and it was found that they achieved an adherence accuracy of 96.68% (Table 5 in Appendix); for the full annotation guidelines, see Figure 10 (in Appendix).

3 Evaluation and Results

The quality of follow-up questions was evaluated using Grice's Cooperative Principle, a foundational theory in pragmatics that outlines how effective communication relies on adherence to four

conversational maxims: *Quality, Quantity, Relation,* and *Manner*. Each maxim offers valuable insights into the effectiveness and clarity of the follow-up questions in a conversational context.

This theoretical framework, based on Grice's maxims, provides a foundation for evaluating follow-up questions, guiding how they should function within a conversation to ensure logical consistency, appropriate informativeness, relevance, and clarity. We also conducted the human and LLM-based evaluations using the above metrics.

3.1 Human Evaluation

We evaluated a total of 375 follow-up questions generated from 75 randomly sampled seed questions. These questions were assessed by a human annotator on four metrics, which are rooted in Gricean Maxims. The result of the human evaluation is present in Table 2. We evaluated the follow-up questions generated by the Qwen2.5-7B-Instruct[3], Mistral-7B-Instruct[4], OLMoE-1B-7B-Instruct[5] and Llama-3.1-8B-Instruct[6] model across all four models scored above 4.4 out of 5 on every metric. Mistral-7B-Instruct achieved the highest logical consistency (4.79) and relevance (4.66), while Qwen-7B-Instruct led in informativeness (4.70) and clarity (4.79). The small differences in scores show that all four models generate consistently high-quality follow-up questions under the Gricean Maxims framework.

3.2 GriceWise Scores

Table 3 presents the evaluation of follow-up questions generated by different LLMs using GriceWise metrics (Section 2.2). Qwen-7B-Instruct (few-shot) achieved the highest scores in Logical Consistency, Relevance and Clarity. Mistral-7B-Instruct (few-shot) led in Informativeness. The performance gap between few-shot and zero-shot prompting reinforces the importance of in-context learning (Figure 4).

[5] https://huggingface.co/allenai/OLMoE-1B-7B-0924

[6] https://huggingface.co/meta-llama/Llama-3.1-8B-Instruct

3.3 Validation of Automated Evaluation Methods

Table 6 (in Appendix) reports Spearman's ρ and Kendall's τ correlations between human judgments and two automated evaluation methods: GriceWise reference-free evaluation and LLM-based evaluation using `gpt-4o-mini`. GriceWise scores align moderately to strongly with human annotations ($\rho = 0.56$–0.72; $\tau = 0.47$–0.60), with Clarity showing the highest correspondence ($\rho = 0.72$; $\tau = 0.60$). LLM-based evaluation further improves these correlations ($\rho = 0.63$–0.76; $\tau = 0.62$–0.73), again peaking on Clarity ($\rho = 0.76$; $\tau = 0.73$). This confirms that both GriceWise and LLM-based methods reliably capture the same quality signals as human annotators.

3.4 Case Study

We evaluated both our seed and recursive follow-up questions' responses on a commercially deployed in-car AI assistant[7]. Table 4 shows the proportion of fallback responses, particularly the assistant's default "Didn't get that" reply, and how it varies across different cognitive levels. In a manual post-hoc annotation of the assistant's outputs, we found that,

1. Level 1 (Remember): 52% of questions were answered correctly, while the remaining 48% returned hallucinated content, generic/under-specified replies, or simple fallbacks ("Didn't get that," "Sorry, I don't have that information").

2. Level 6 (Create): Only 6% of questions were answered correctly; the other 94% produced hallucinations, generic responses, or fallback messages.

Such stark differences in response quality across cognitive levels highlight the pressing need to systematically recognize and address the limitations of the in-car AI assistant, especially given the high-stakes nature of in-vehicle interactions. With a correctness coverage as low as 6% at the highest cognitive level, there is a clear imperative to enhance the assistant's performance. This underscores the importance of integrating structured domain knowledge, such

[7] For confidentiality reasons, the specific car and in-car AI assistant names are not disclosed; we use "commercially deployed in-car AI assistant" instead.

Question Generation Model	Logical Consistency (↑)	Informativeness (↑)	Relevance (↑)	Clarity (↑)
Qwen-7B-Instruct	4.70	**4.70**	4.63	**4.79**
Mistral-7B-Instruct	**4.79**	4.65	**4.66**	4.78
OLMoE-1B-7B-Instruct	4.68	4.63	4.46	4.75
Llama-3.1-8B-Instruct	4.62	4.44	4.33	4.63

Table 2: Human evaluation scores (on a 5-point scale) for follow-up questions generated by four models—Qwen-7B-Instruct, Mistral-7B-Instruct, OLMoE-1B-7B-Instruct, and Llama-3.1-8B-Instruct—across four metrics: Logical Consistency, Informativeness, Relevance, and Clarity. Arrows next to each metric name indicate the scoring direction: (↑) denotes that higher scores are preferred.

Question Generation Models	Logical Consistency (↑)	Informativeness (↑)	Relevance (↑)	Clarity (↑)
Qwen-7B-Instruct	**0.9122**	0.5108	**0.6025**	**0.2743**

4 Conclusion and Future Work

We presented a framework that leverages Bloom's Taxonomy to generate follow-up questions with increasing cognitive complexity. We employed Gricean-inspired evaluation metrics to assess the generated follow-up questions' logical consistency, informativeness, relevance, and clarity. Our human-annotated dataset, consisting of seed questions, was created adhering to Level 1 of Bloom's Taxonomy. Additionally, the follow-up questions were annotated by humans to confirm that 96.68% of the generated questions adhere to the cognitive levels. For future work, we plan to refine our evaluation metrics further and explore additional prompting strategies and model variations to enhance the follow-up question generation.

Limitations

Our approach is limited by the quality and scope of the human-annotated seed questions and the inherent capabilities of current LLMs. Due to confidentiality reasons, we could not mention the name of the in-car AI assistant we used to test our follow-up questions. Future work should extend human evaluation across a broader range of models and prompting strategies.

Ethics Statement

All human annotations were performed ethically with fair compensation. No personally identifiable information was used. Our data collection and annotation processes adhere to respecting privacy and fairness throughout the research.

Acknowledgements

The authors thank the anonymous reviewers for their constructive feedback, which helped improve this submission. We extend our sincere gratitude to the Computation for Indian Language Technology (CFILT) Lab at the Indian Institute of Technology Bombay for providing the computational resources that were indispensable for the successful completion of this research. We also extend our thanks to the annotators for their diligent and honest efforts.

A Appendix

A.1 Grice's Maxims

Grice's Maxims are conversational principles proposed by Paul Grice to ensure effective communication. These maxims guide cooperative conversations and are categorized as follows:

- **Maxim of Quantity**: Provide as much information as necessary, but no more.
- **Maxim of Quality**: Be truthful; do not provide false information or unsupported claims.
- **Maxim of Relation**: Ensure relevance by staying on topic.
- **Maxim of Manner**: Be clear, brief, and orderly while avoiding ambiguity and obscurity.

These maxims help facilitate meaningful and effective communication by promoting clarity, relevance, and truthfulness in discourse.

Level 2	Level 3	Level 4	Level 5	Level 6
0.973	0.960	0.973	0.964	0.964

Table 5: Accuracy of generated questions across different levels of Bloom's taxonomy. Human annotator verified whether each question at a particular level followed the corresponding level of Bloom's taxonomy.

A.2 Bloom's Taxonomy

Bloom's Taxonomy (Figure 3) is a classification of learning objectives and skills that educators use to structure lessons, assessments, and learning outcomes. Originally proposed in 1956 by Benjamin Bloom, an educational psychologist at the University of Chicago, the taxonomy has been updated to include the following six levels of learning:

- **Remembering**: Retrieving, recognizing, and recalling relevant knowledge from long-term memory.
- **Understanding**: Constructing meaning from oral, written, and graphic messages through interpreting, exemplifying, classifying, summarizing, inferring, comparing, and explaining.
- **Applying**: Carrying out or using a procedure for execution or implementation.
- **Analyzing**: Breaking material into constituent parts and determining how the parts relate to one another and to an overall structure or purpose through differentiating, organizing, and attributing.
- **Evaluating**: Making judgments based on criteria and standards through checking and critiquing.
- **Creating**: Putting elements together to form a coherent or functional whole; reorganizing elements into a new pattern or structure through generating, planning, or producing.

This taxonomy provides a structured approach to designing curricula and assessments, ensuring a comprehensive learning experience.

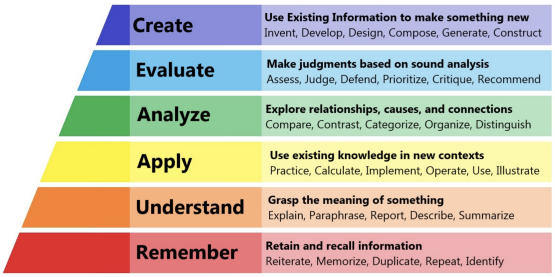

Figure 3: The Bloom's Taxonomy Pyramid: A hierarchical representation of cognitive learning levels, progressing from basic knowledge recall to complex creation and synthesis.

A.3 Example Follow-Up Questions for In-Car AI Assistants

Below is an example illustrating our multi-turn follow-up question generation for the call-making domain, demonstrating a progression in cognitive complexity based on Bloom's Taxonomy:

- **Seed Question (Level 1):** "How do I make a call?"
- **Follow-Up Question 1 (Level 2):** "What are the different options I have to make a call in this car?"
- **Follow-Up Question 2 (Level 3):** "How does the call-making process differ from my previous car model?"
- **Follow-Up Question 3 (Level 4):** "What are the advantages of using the car's built-in calling system over my phone's calling feature?"
- **Follow-Up Question 4 (Level 5):** "Can you explain how the car's calling system integrates with my phone's contact list and how it affects call quality?"
- **Follow-Up Question 5 (Level 6):** "How can I use the call-making feature in this car to improve my safety while driving, such as by using voice commands or hands-free modes?"

Evaluation Method	Logical Consistency (Maxim of Quality)		Informativeness (Maxim of Quantity)		Relevance (Maxim of Relation)		Clarity (Maxim of Manner)	
	ρ	τ	ρ	τ	ρ	τ	ρ	τ
GriceWise Evaluation	0.57	0.48	0.56	0.47	0.61	0.52	0.72	0.60
LLM-based Evaluation	0.63	0.62	0.65	0.63	0.66	0.64	0.76	0.73

Table 6: Spearman's ρ and Kendall's τ correlation of human evaluation with GriceEise Evaluation and LLM-based evaluation across four metrics. `gpt-4o-mini` was used for LLM-based evaluation.

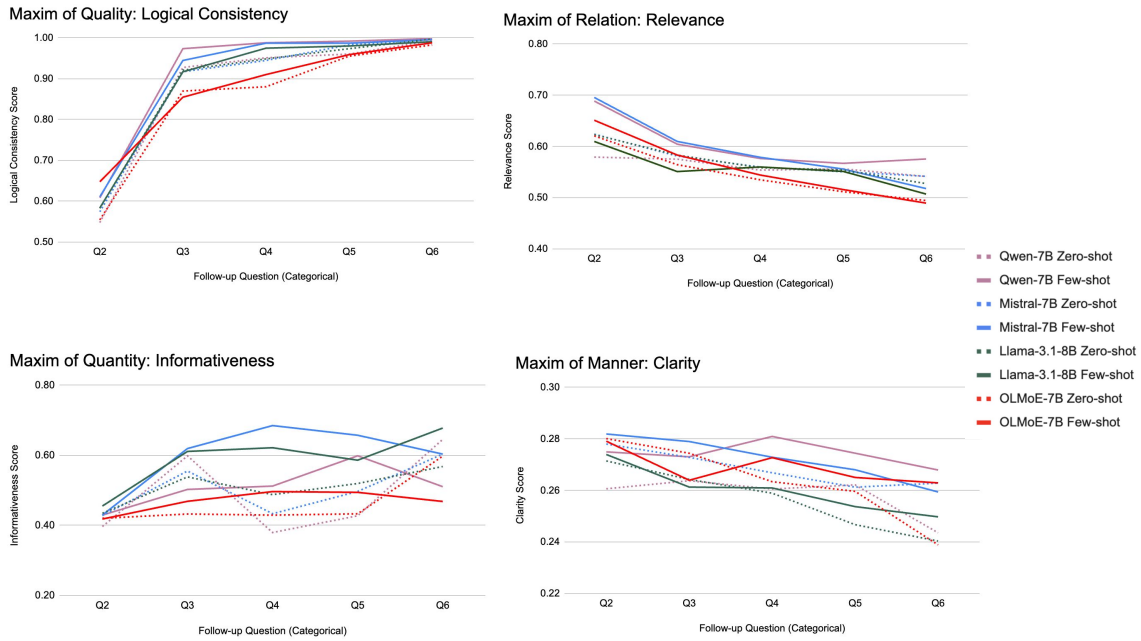

Figure 4: GriceWise (Logical Consistency, Informativeness, Relevance, Clarity) for different models and prompting strategies (zero-shot, few-shot) across follow-up questions Q2–Q6. Higher scores indicate stronger adherence to the respective maxim, capturing how well the model maintains coherence, relevance, informativeness, and clarity in follow-up question generation. Dotted lines represent zero-shot prompting and solid lines represent few-shot prompting.

Qualitative Insights on GriceWise Metric Trends:

- **Logical Consistency (Maxim of Quality)**: Sharp increase from Q2 to Q4, then plateaus; few-shot > zero-shot. The GriceWise evaluation for logical consistency is binary (0 or 1), so the sharp increase reflects a growing number of responses being judged fully consistent as the model gains context.
- **Informativeness (Maxim of Quantity)**: Gradual improvement across Q1 to Q5. Few-shot prompting provides better guidance, yielding richer follow-up questions.
- **Relevance (Maxim of Relation)**: Relevance gradually decreases from Q2 to Q6 as questions grow more abstract and harder to align with the main topic; few-shot prompting offers some improvement by providing better grounding, but cannot fully prevent the decline.
- **Clarity (Maxim of Manner)**: Clarity declines steadily as question chains grow longer, often introducing verbosity or ambiguity; few-shot examples help maintain concise and direct phrasing, mitigating this effect.

Task Description: You are an AI tasked with generating follow-up questions for a car driver to ask an in-car AI assistant. The questions will assess the AI's understanding of the car's features and design strictly based on the information provided in the seed question. The driver will begin with a Level 1 (Remember) question based on Bloom's Revised Taxonomy. Your task is to generate five follow-up questions corresponding to Levels 2 (Understand), 3 (Apply), 4 (Analyze), 5 (Evaluate), and 6 (Create), respectively. Each question should progress from simpler to more complex cognitive tasks.

Constraints:
Feature Neutrality: Do not assume, add, or imply any car features that are not explicitly mentioned or suggested in the seed question. Base all follow-up questions solely on the context given in the seed question.
Answer-Agnostic: Focus on the driver's interaction with the car and how the car's features enhance the driving experience without delving into internal technical details or making assumptions about additional features.
Driver-Focused Interaction: Ensure that all questions centre on the driver's use and experience with the car. Do not include questions regarding the car's internal mechanisms, data-acquisition methods, or any technical processes.
Single-Faceted: Each question must target a single concept or action to maintain clarity. Avoid compound or multi-part questions.
Sequential Progression: The follow-up questions should build upon each other, moving from basic recall (Level 1) to more advanced cognitive tasks (Level 6).
Bloom's Levels Only: Only generate questions for Levels 2 through 6 of Bloom's Revised Taxonomy. Do not introduce any levels beyond Level 6.

Explanation of Bloom's Revised Taxonomy Levels:
Level 1 (Remember): Involves recalling or recognizing facts and basic concepts. (This level is provided as the seed question.)
Level 2 (Understand): Involves explaining ideas or concepts. Questions at this level ask for clarification or interpretation.
Level 3 (Apply): Involves using information in new or concrete situations. Questions should prompt practical use or demonstration of how a feature could be used.
Level 4 (Analyze): Involves breaking information into parts and exploring relationships. Questions should prompt examination of reasons, causes, or underlying structures.
Level 5 (Evaluate): Involves making judgments based on criteria and standards. Questions should encourage assessment or justification of decisions.
Level 6 (Create): Involves putting elements together to form a new, coherent whole or proposing alternative solutions. Questions should prompt the generation of original ideas or new perspectives.

Input Format: <seed> seed_question_str </seed>
Output Format:
<question>question_1_str</question>
.
<question>question_5_str</question>

Instruction: Output only five lines, each corresponding to a question from level 2 to level 6 as described before, and nothing else. Do not provide any additional explanation or reasoning.

Figure 5: Prompt for Follow-up Question Generation based on Bloom's Taxonomy

Task Description: The purpose of evaluating questions based on the Maxim of Quality is to assess the truthfulness, accuracy, and reliability of the follow-up questions. Grice's Maxim of Quality suggests that communication should aim to be truthful and avoid saying anything that is false or for which the speaker lacks sufficient evidence. Evaluate whether the follow-up question maintains the integrity of the information provided by the previous question and whether it introduces any false, speculative, or unverifiable claims.

Evaluation Criteria: The task is to judge the extent to which the metric is followed by the follow-up question. Following are the scores and the evaluation criteria according to which scores must be assigned.
<score>1</score> - The metric is not followed at all while generating the follow-up question based on the previous questions.
<score>2</score> - The metric is followed only to a limited extent while generating the follow-up question based on the previous questions.
<score>3</score> - The metric is followed to a good extent while generating the follow-up question based on the previous questions.
<score>4</score> - The metric is followed mostly while generating the follow-up question based on the previous questions.
<score>5</score> - The metric is followed completely while generating the follow-up question based on the previous questions.

Metric: Maxim of Quality - For a follow-up question, it evaluate its alignment with the factual accuracy and truthfulness of the initial question. Consider whether the follow-up introduces any false, misleading, or speculative elements. Pay close attention to whether the question is rooted in facts and whether any claims made are verifiable. If the question is entirely accurate and grounded in truth, it should receive a higher score. If the question introduces errors, falsehoods, or speculative elements, it should receive a lower score.

Previous Questions:
{previous}

Follow-up Question:
{followup}

Evaluation Steps:
Follow the following steps strictly while giving the response:
1. First, write down the steps that are needed to evaluate the follow-up question as per the metric. Reiterate what metric you will be using to evaluate the follow-up question.
2. Give a step-by-step explanation if the follow-up question adheres to the metric, considering the previous questions as the input. Stick to the metric only for evaluation.
3. Next, evaluate the extent to which the metric is followed.
4. Rate the follow-up question using the evaluation criteria and assign a score within the <score></score> tags.

Note: Strictly give the score within <score></score> tags only e.g Score- <score>5</score>.
First, give a detailed explanation and then finally give a single score following the format: Score-<score>5</score>

Figure 6: Prompt for LLM-based evaluation of Maxim of Quality

Task Description: The purpose of evaluating questions based on the Maxim of Quantity is to assess whether the follow-up questions provide the appropriate amount of information. Grice's Maxim of Quantity suggests that communication should be as informative as is needed but not more than is required. The follow-up question should neither overwhelm with excessive detail nor leave important gaps in information. Assess whether the follow-up question is appropriately detailed or concise, neither under-informing nor over-informing.

Evaluation Criteria: The task is to judge the extent to which the metric is followed by the follow-up question. Following are the scores and the evaluation criteria according to which scores must be assigned.
<score>1</score> - The metric is not followed at all while generating the follow-up question based on the previous questions.
<score>2</score> - The metric is followed only to a limited extent while generating the follow-up question based on the previous questions.
<score>3</score> - The metric is followed to a good extent while generating the follow-up question based on the previous questions.
<score>4</score> - The metric is followed mostly while generating the follow-up question based on the previous questions.
<score>5</score> - The metric is followed completely while generating the follow-up question based on the previous questions.

Metric: Maxim of Quantity - For a follow-up question, it determines if the question is appropriately informative given the context of the conversation. Consider whether the question provides enough information to answer it or if it overcomplicates things by including irrelevant details. The perfect follow-up question will be balanced, providing enough context and detail to be clear and actionable without overwhelming the listener or leaving gaps. If the question provides the right amount of detail, score it higher. If it gives too little or too much, score it lower.

Previous Questions:
{previous}

Follow-up Question:
{followup}

Evaluation Steps:
Follow the following steps strictly while giving the response:
1. First, write down the steps that are needed to evaluate the follow-up question as per the metric. Reiterate what metric you will be using to evaluate the follow-up question.
2. Give a step-by-step explanation if the follow-up question adheres to the metric, considering the previous questions as the input. Stick to the metric only for evaluation.
3. Next, evaluate the extent to which the metric is followed.
4. Rate the follow-up question using the evaluation criteria and assign a score within the <score></score> tags.

Note: Strictly give the score within <score></score> tags only e.g. Score- <score>5</score>.

First, give a detailed explanation and then finally give a single score following the format: Score-<score>5</score>

Figure 7: Prompt for LLM-based evaluation of Maxim of Quantity

Task Description: The purpose of evaluating questions based on the Maxim of Relation is to assess the relevance of follow-up questions in relation to the preceding questions and the overall context. Grice's Maxim of Relation emphasizes that communication should be relevant and connected, meaning the follow-up question should logically follow from the previous question and maintain a coherent conversation. Assess whether the follow-up question is appropriately related to the previous question, both in terms of topic and context.

Evaluation Criteria: The task is to judge the extent to which the metric is followed by the follow-up question. Following are the scores and the evaluation criteria according to which scores must be assigned.
<score>1</score> - The metric is not followed at all while generating the follow-up question based on the previous questions.
<score>2</score> - The metric is followed only to a limited extent while generating the follow-up question based on the previous questions.
<score>3</score> - The metric is followed to a good extent while generating the follow-up question based on the previous questions.
<score>4</score> - The metric is followed mostly while generating the follow-up question based on the previous questions.
<score>5</score> - The metric is followed completely while generating the follow-up question based on the previous questions.

Metric: Maxim of Relation - It ensures that the follow-up question is relevant to the seed question and logically follows from the prior context. Look for continuity in the conversation's topic or subject matter; ensure the follow-up does not feel out of place or introduce unnecessary tangents. If the question feels disconnected or introduces unrelated ideas, it should receive a lower score. A highly relevant and contextually appropriate follow-up should receive a higher score.

Previous Questions:
{previous}

Follow-up Question:
{followup}

Evaluation Steps:
Follow the following steps strictly while giving the response:
1. First, write down the steps that are needed to evaluate the follow-up question as per the metric. Reiterate what metric you will be using to evaluate the follow-up question.
2. Give a step-by-step explanation if the follow-up question adheres to the metric, considering the previous questions as the input. Stick to the metric only for evaluation.
3. Next, evaluate the extent to which the metric is followed.
4. Rate the follow-up question using the evaluation criteria and assign a score within the <score></score> tags.

Note: Strictly give the score within <score></score> tags only e.g Score- <score>5</score>.
First, give a detailed explanation and then finally give a single score following the format: Score-<score>5</score>

Figure 8: Prompt for LLM-based evaluation of Maxim of Relation

Task Description: The purpose of evaluating questions based on the Maxim of Manner is to assess the clarity and conciseness of follow-up questions. Grice's Maxim of Manner suggests that communication should avoid ambiguity and be as clear and concise as possible to ensure that the listener can easily understand the message. Assess whether the follow-up questions adhere to these principles, focusing on how well the question conveys its intent and whether it does so in a straightforward and unambiguous manner.

Evaluation Criteria: The task is to judge the extent to which the metric is followed by the follow-up question. Following are the scores and the evaluation criteria according to which scores must be assigned.
<score>1</score> - The metric is not followed at all while generating the follow-up question based on the previous questions.
<score>2</score> - The metric is followed only to a limited extent while generating the follow-up question based on the previous questions.
<score>3</score> - The metric is followed to a good extent while generating the follow-up question based on the previous questions.
<score>4</score> - The metric is followed mostly while generating the follow-up question based on the previous questions.
<score>5</score> - The metric is followed completely while generating the follow-up question based on the previous questions.

Metric: Maxim of Manner - It considers whether the follow-up question can be understood easily in a first reading. Think about whether the question has any redundant parts that could be omitted. Ensure the wording is straightforward, and avoid complex sentence structures unless absolutely necessary. If the question feels awkward or the meaning seems unclear, lean towards giving it a lower score (1-3). If it's concise and the intent is immediately clear, it should score higher (4-5).

2. Give a step-by-step explanation if the follow-up question adheres to the metric, considering the previous questions as the input. Stick to the metric only for evaluation.
3. Next, evaluate the extent to which the metric is followed.
4. Rate the follow-up question using the evaluation criteria and assign a score within the <score></score> tags.

Note: Strictly give the score within <score></score> tags only e.g Score- <score>5</score>.
First give a detailed explanation and then finally give a single score following the format: Score-<score>5</score>

Figure 9: Prompt for LLM-based evaluation of Maxim of Manner

Figure 10: Overview of the guideline which was used for data annotation for the seed questions.

These guidelines define how to frame and annotate follow-up questions for a car AI system. The goal is to ensure that the questions align with the car AI's capabilities and follow a structured approach based on Bloom's Taxonomy. This annotation task will work as a seed question for generating follow-up questions.

General Principles

1. **Action or Information Focus**: For POI (Point of Interest)or navigation tasks, focus on recalling details like location, route, or destination.
2. **Task-Oriented and Contextual**: Ensure that the questions are actionable, focusing on what the car AI can recall about POIs, weather, or time-related queries.
3. **Simple, Direct Questions**: Ask specific, factual questions that a driver would need to recall or verify to continue their task, such as routes, locations, or specific information like weather or time.
4. **Avoid Redundancy**: Do not ask for general or already known information (e.g., "Who do I want to call?"). Instead, focus on recalling detailed, task-specific information that will aid in decision-making.
5. **Driver-Centric Questioning: Annotators should frame questions as if they are a car driver interacting with an in-car AI chatbot.**

Domain-Specific Guidelines

Phone Domain

Imperative to Interrogative Transformation: Avoid forced interrogative conversions. Instead, structure questions naturally.

Bloom's Level 1 (Remembering/Recall)

Abstract

The development of large language models (LLMs) offers a feasible approach to simulating complex behavioral patterns of individuals, enabling the reconstruction of microscopic and realistic human societal dynamics. However, this approach demands a realistic environment to provide feedback for the evolving of agents, as well as a parallelized framework to support the massive and uncertain interactions among agents and environments. To address the gaps in existing works, which lack real-world environments and struggle with complex interactions, we design a scalable framework named **AgentSociety**, which integrates realistic societal environments and parallelized interactions to support simulations of large-scale agents. Experiments demonstrate that the framework can support simulations of 30,000 agents that are faster than the wall-clock time with 24 NVIDIA A800 GPUs and the performance grows linearly with the increase of LLM computational resources. We also show that the integration of realistic environments significantly enhances the authenticity of the agents' behaviors. Through the framework and experimental results, we are confident that deploying large-scale LLM Agents to simulate human societies becomes feasible. This will help practitioners in fields such as social sciences and management sciences to obtain new scientific discoveries via language generation technologies, and even improve planning and decision-making in the real world. The code is available at https://github.com/tsinghua-fib-lab/agentsociety/.

1 Introduction

In recent years, the rapid advancement of large language models (LLMs) has profoundly transformed the research paradigm of artificial intelligence and beyond (Zhao et al., 2023). One of the most important directions is the agent-based modeling (ABM) driven by LLMs (Gao et al., 2024a). Traditional ABM approaches, which rely on predefined rules and simplified environments, have achieved significant success in simulating macro-level social evolution phenomena, such as the phenomenon of segregation in society (Schelling, 1971) and polarization of opinion (Deffuant et al., 2000). This success is built upon researchers' comprehension of macroscopic principles governing human societies. Meanwhile, the powerful role-play capabilities of LLMs (Park et al., 2023; Jiang et al., 2024; Strachan et al., 2024; Li et al., 2024) empower researchers to re-examine ABM from a novel perspective: LLMs can be used to simulate complex behavioral patterns of individuals without the need for predefined rules, which can help us move beyond the traditional coarse-grained modeling paradigm and reconstruct microscopic and more realistic dynamics of human societies.

As the famous sociologist George Herbert Mead stated, "The self is something which has a development; it is not initially there, at birth, but arises in the process of social experience and activity." (Mead, 1934) LLM agents also learn and evolve through environmental feedback. However, most existing agent-based societal simulations predominantly adopt gaming environments (Park et al., 2023; AL et al., 2024) or simple rule settings (Gao et al., 2023; Tang et al., 2024), exhibiting insufficient attention to real-world human societal environments. This limitation inevitably constrains the authenticity of LLM agents' behaviors. Therefore, constructing **realistic environments** capable of providing feedback similar to human societies emerges as the primary challenge in leveraging LLM agents to simulate human societies.

Furthermore, in simulating such a complex system as human society, the scale serves as a prerequisite for the emergence of phenomena and the discovery of principles. Concurrently, societal simulations inherently involve massive and

*Yong Li is the Corresponding Author.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1339–1349

non-deterministic interactions between agents and environments, as well as among agents themselves. However, existing LLM agent programming frameworks are primarily designed for multi-agent collaboration scenarios and struggle to handle large-scale uncertain interactions in simulations. For example, CAMEL (Li et al., 2023) only implements the simulation of a Hackathon Judge Committee with fewer than 10 participants. AgentScope (Gao et al., 2024b), on the other hand, has only achieved a scale of tens of thousands of agents in extremely simple games such as the 2/3 number guessing game. Thus, there is an urgent need for **a framework with strong parallel execution and interaction processing capabilities** to accommodate the complex and non-deterministic interactions required for simulating human societies.

To address the aforementioned challenges, we design a scalable framework named **AgentSociety**, which integrates **realistic societal environments** capable of modeling mobility behaviors, social interactions, and economic activities, along with a **parallelized interaction engine** supporting the execution and interaction of large-scale LLM agents. Comprehensive performance experiments validate that the framework efficiently handles complex interactions while fully leveraging available LLM computational resources to simulate 30,000 LLM agents with 24 NVIDIA A800 GPUs that are faster than the wall-clock time. Meanwhile, the performance grows linearly with the supply of computational resources for LLMs. By deploying properly designed agents, the framework demonstrates its ability to provide agents with contextually appropriate environmental feedback, thereby enhancing the authenticity of agents' behaviors in a simulation scenario for urban resident behaviors in Beijing. Accordingly, we are confident in the feasibility of deploying large-scale agents to simulate human societies, which will help practitioners in social sciences, management sciences, and other fields to use language generation technologies to make new scientific discoveries and even improve real-world planning and decision-making.

2 Realistic Societal Environments

2.1 Overall

Realistic societal environments, which serve as the foundation for simulating LLM agents as a human society, aim to provide agents with feedback and constraints similar to the real-world society, thereby fostering agent learning and the emergence of more realistic behavioral patterns. Given the complexity of diverse human behaviors, explicitly modeling the most fundamental behaviors facilitates this preliminary effort. Thus, we prioritize explicit modeling of mobility behaviors, social interactions, and basic economic activities—specifically employment and consumption—as representative components. By modeling these three categories of social behaviors, the environment enables the simulation of individuals' daily routines, such as commuting to work by car, collaborating with colleagues in workplaces, and engaging in post-work consumption activities, etc.

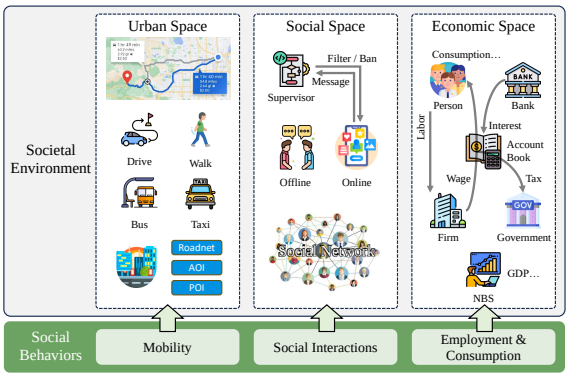

Figure 1: The relationship between the societal environments and agent behaviors.

To model these behaviors and provide realistic feedback, the built environments include urban space, social space, and economic space as illustrated in Figure 1. Their modeling and interactions will be discussed in the following sections.

2.2 Urban Space

The urban space is designed to address agents' mobility demands and their interactions with different places, capturing the processes of individual location changes driven by mobility behaviors.

Inspired by microscopic traffic simulation platforms (Behrisch et al., 2011; Zhang et al., 2019, 2024), we first build maps including road networks and functional zones, which are Areas of Interest (AOIs) and Points of Interest (POIs) by the MOSS toolkit (Zhang et al., 2024). The real-world data sources include OpenStreetMap[1] and SafeGraph[2]. Agents can retrieve accessible places from the map and obtain routes along with the estimated travel time for different transportation methods to help

[1] https://openstreetmap.org/
[2] https://www.safegraph.com/

them make better decisions about the destination and mode of travel. Furthermore, we implement a high-performance multi-modal mobility simulator in Golang[3], including driving, walking, taking buses, or riding in taxis, through a discrete time-stepping mechanism with 1-second step intervals. The simulator updates agents' states like positions at each step and allows agents to adjust travel plans through interactions with the environment while continuously accessing real-time states as feedback via gRPC[4].

2.3 Social Space

The social space, which models the social behaviors among agents, is also a fundamental component required for simulating human societies.

The most important element of the social space is social networks. Social networks store relationships and strengths between agents for social interaction target selection. During the simulation, agents can modify these relationships and strengths on their own to change the social network and future social behaviors. Social behaviors within the social space can be categorized into offline and online interactions. By enabling message exchange between any two agents, both offline and online social interactions are unified into a consistent implementation. Agents may select targets and send messages either through spatial proximity relationships or social networks, thereby accomplishing the two types of interactions, respectively. Agents can also receive messages and respond appropriately, such as replying to messages or changing their current actions.

Besides, to realistically simulate online social media platforms, we also implement the concept of the supervisor in the messaging system. The supervisor will identify content in online social messages, filter messages according to user-specified algorithms, and support the blocking of specific users or connections, thereby simulating the intervention process of social media platforms in information propagation.

2.4 Economic Space

The economic space includes the modeling of key elements in the macroeconomics (Wolf et al., 2013; Li et al., 2024) to simulate basic economic activities represented by employment and consumption.

In the economic space, agents serve as the most fundamental participants, obtaining wages through labor to cover consumption and fulfill their needs. Correspondingly, firms are modeled to provide job positions and distribute wages. Employment relationships can be dynamically adjusted by individuals or firms during the simulation process to model employee turnover behavior in the real world. Banks pay interest on deposits from individuals or firms, while the government levies taxes on income. Both interest rates and tax policies are adjustable during simulations. The National Bureau of Statistics (NBS) is implemented to compile macroeconomic indicators, such as GDP, average working hours per person, etc. Such designs, similar to real economic systems, require agents to carefully balance the relationship between work and consumption to avoid overspending, rather than engaging in unconstrained behaviors that are inconsistent with their predefined roles.

The aforementioned processes are implemented as an account-book-centered economic simulator in Golang, which provides all participants with the capability to adjust deposit increments and decrements. This simulator also facilitates the management of employment relationships, automated processing of interest and tax calculations, and automated computation of macroeconomic indicators. Additionally, it offers comprehensive query and modification interfaces for these functionalities.

3 Parallelized Interaction Engine

3.1 Overview

Facing the demand for executing large-scale LLM agents and processing massive and non-deterministic interactions in simulations, existing LLM agent programming frameworks are difficult to handle simultaneously due to their reliance on predefined standard operating procedures (SOP).

To address the overcome, we redesign the parallelized interaction engine by drawing inspiration from real-world societal structures. In the real world, individuals make decisions through independent reasoning and collaborate via linguistic communication. Consequently, in our design, each agent operates as an independent execution unit while influencing others through message passing in the social space. Guided by this principle, we implement parallelized agent execution using the Ray framework (Moritz et al., 2018), construct a high-performance **agent messaging system** leveraging

[3] https://go.dev/
[4] https://grpc.io/

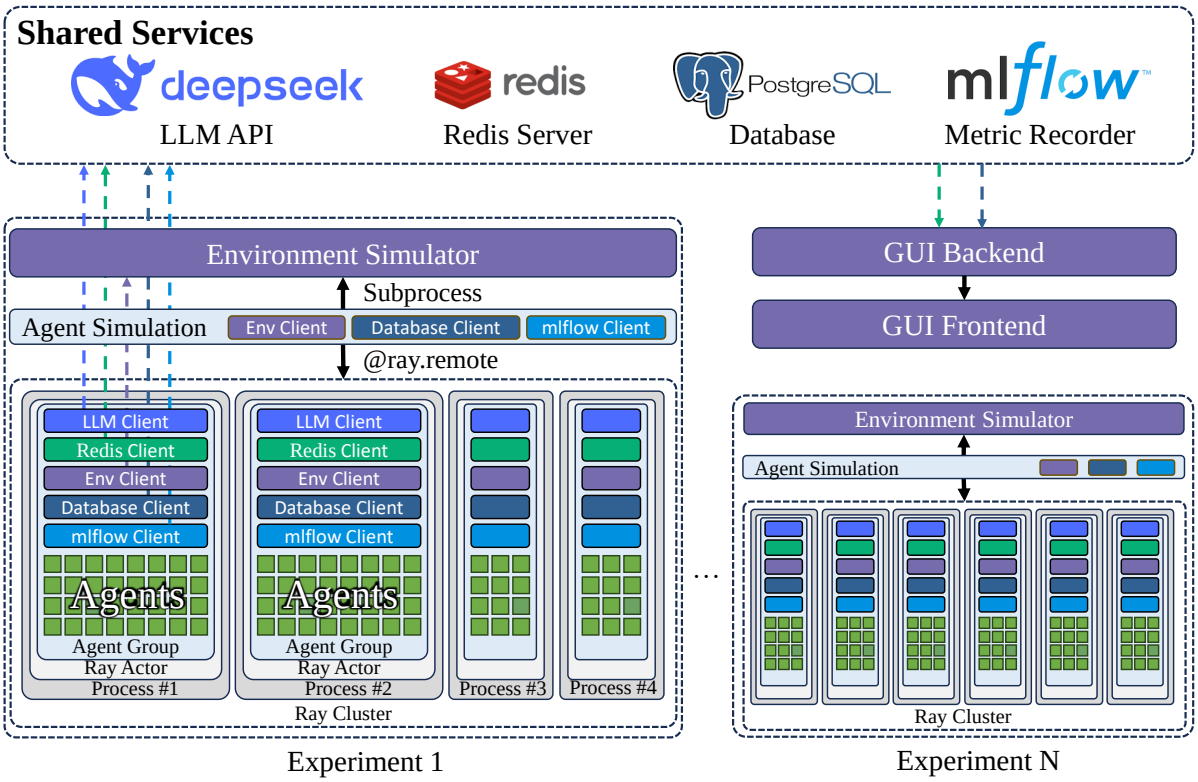

Figure 2: The architecture of the parallelized interaction engine.

Redis' publish/subscribe capabilities for message exchange, and integrate the realistic societal environment simulations as remote function calls.

However, preliminary attempts at functional integration revealed critical failures. Excessive Ray actors and network service clients rapidly exhaust machine memory and port resources, while environment access through function calls causes inconsistent perceived time progression in simulations due to variable LLM inference latencies per simulation step. To resolve these issues, we further develop **group-based parallel execution** to optimize resource utilization and adopt **time alignment mechanism** from Mirage (Zhang et al., 2022) to ensure fixed-duration environmental progression per simulation step. Finally, we provide comprehensive utilities to enhance user experiences, such as simulation logging using PostgreSQL[5] and metric recording using mlflow (Zaharia et al., 2018).

The overview of the final system architecture is shown in Figure 2. The critical components of the design will be discussed in subsequent sections.

3.2 Group-based Parallel Execution

Since each Ray actor corresponds to a worker process with independent TCP connections to various services, scaling the number of agents to tens of thousands will exceed system TCP port limits, causing program errors that prevent new connections from being established. Concurrently, the massive number of processes also induces severe memory insufficiency issues.

To address these issues, we adopt the group-based distributed execution strategy. We first evenly partition agents into multiple agent groups and make each group correspond to a Ray actor. Agents within the same group share a set of service clients and leverage asyncio's asynchronous capabilities to perform parallel network requests with connection reuse to optimize resource utilization.

Since LLM agent execution is essentially an IO-intensive processing task, this approach successfully maintains efficient parallel execution while significantly reducing port occupation and additional memory consumption caused by multi-process overhead.

3.3 Agent Messaging System

Based on the design of the social space and the parallelized interaction engine, the agent messaging system should support message exchange between any pair of agents. Such design can also enable external programs (e.g., GUIs) to send messages to

[5] https://www.postgresql.org/

specific agents for dialogues or interviews, which could significantly expand the framework's application potential.

In practice, we utilize the time-tested Pub/Sub functionality of the Redis database to build a high-performance message exchange mechanism. During simulations, each agent adopts the `PSUBSCRIBE` method to subscribe to the channel pattern `exps:<exp_id>:agents:<agent_id>:*` via a shared Redis client, enabling them to receive and process messages. The wildcard `*` is replaced by specific patterns (e.g., `agent-chat` for inter-agent messaging or `user-chat` for user-agent interactions) on the publisher's side when calling the `PUBLISH` method. This design ensures that the agent messaging system can readily support various future extensions, enriching agents' interaction capabilities.

3.4 Time Alignment Mechanism

Since the execution time of LLM agents is constrained by the response speed of LLM APIs, which fluctuates significantly due to server load, the duration required for completing one agent iteration becomes uncontrollable. Concurrently, the clock speed within the environment also varies with operational efficiency. The mismatch between these two factors will result in uncertainty regarding the elapsed time between consecutive agent iterations, thereby compromising the reproducibility of simulation outcomes.

Following Mirage (Zhang et al., 2022), we implement a clock manager and embed it into the environment simulator. Each round of agent iteration is required to take time alignment with the environment simulator to synchronize their operational speeds. The default setting maps one round of agent iteration to 300 steps (equivalent to 300 seconds) in the environment simulator, balancing behavioral authenticity with execution efficiency.

3.5 Utilities

In addition, we also provide a rich set of utilities to facilitate the usage of the framework including LLM API adapters, a JSON parser, a retry mechanism, a metric recorder based on mlflow, simulation result logging using both the local file storage with the AVRO format[6] and PostgreSQL databases. A GUI program has been developed to create and manage simulations, and visualize results stored in the PostgreSQL database, significantly enhancing usability and making the system more accessible to general users.

4 Experiments

The experiments in the section focus on the following research questions:

- RQ1: What is the performance of the framework for different agent sizes, agent group sizes, and LLM computational resources?
- RQ2: Can the realistic societal environments enhance the authenticity of agent behavior?

All experiments were conducted on a Huawei Cloud c7.16xlarge.4 cloud server to ensure comparability of results. The LLMs operate on multiple servers with 8 NVIDIA A800 cards using vLLM v0.8.1 (Kwon et al., 2023) and the Qwen2.5-7B-Instruct model (Yang et al., 2024). The details of the deployment can be found in Appendix A.

4.1 Framework Performance

To evaluate the performance of the proposed framework AgentSociety in practical deployments, we conducted a series of experiments with the agent design above to capture various metrics during system operation under different configurations of agent numbers, group numbers, and LLM computational resource provisioning.

First, we evaluated the results of {1000, 3000, 10000, 30000} agents under {4, 8, 16, 32} groups, reporting the results in Table 1. Collected metrics include runtime statistics and time costs. Besides, we counted the average input tokens and output tokens requested by LLMs. The results are very close in all cases, being 347.97 ± 0.80 and 62.30 ± 0.42 respectively. The results show that the framework achieves faster than real-time simulation at the scale of 30,000 agents, demonstrating the parallel performance of the framework. Additionally, it can be observed from the results that the simulation efficiency mainly depends on the efficiency of LLM calls. Moreover, an increase in the number of groups, on one hand, enhances the efficiency of environment calls, while on the other hand, it may lead to exceeding the load capacity of LLM services, thereby increasing unnecessary retry time. This highlights the importance of reasonably setting the degree of parallelism according to the supply of LLM services.

Second, we evaluated the performance of sim-

Table 1: Performance metrics for different configurations using the 24-GPU vLLM cluster as LLM providers. All values are the means of 10 rounds of iterations, standard deviations are not provided due to their distribution not being normal. **#LC** represents the number of successful LLM calls. **LCSR** stands for LLM Call Success Rate and is used to record the percentage of all LLM requests attempted to be called that are returned correctly. **#EC** and **#MC** denotes the number of environment simulator call and agent message system call, respectively. In the time cost part, **All** denotes the average time taken by all the agents to iterate a round. **LLM**, **Env**, and **Msg** represents the time spent for each LLM call, environment simulator call, and agent message system call, respectively. The dash (-) indicates experimental failure due to excessive failed LLM requests.

Parameters		Runtime Statistics				Time Costs			
#Agents	#Groups	#LCs (/round)	LCSR(%)	#ECs (/round)	#MCs (/round)	All (s/round)	LLM (s/call)	Env (ms/call)	Msg (ms/call)
1,000	4	995.5	100.0	7,547.0	2.0	**13.19**	4.60	88.01	2.25
1,000	8	992.5	100.0	7,547.4	1.9	13.70	4.59	44.61	1.16

10,000	4	9,905.1	100.0	75,335.1	21.9	93.10	44.96	943.61	8.35
10,000	8	9,885.8	100.0	75,291.7	22.9	**81.45**	42.75	349.49	3.59
10,000	16	9,897.0	97.1	75,343.9	22.2	98.08	41.01	208.75	3.48
10,000	32	-	-	-	-	-	-	-	-
30,000	4	30,686.3	100.0	230,309.9	83.0	327.39	130.58	4,102.45	21.82
30,000	8	29,869.7	100.0	226,915.8	70.7	**251.85**	123.22	1,682.88	14.48
30,000	16	-	-	-	-	-	-	-	-

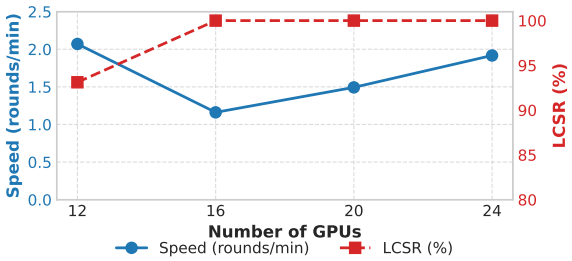

Figure 3: Performance with different LLM computational resources.

ulating 3,000 agents (with #Groups set to 8) with the same experimental setup as before, under different deployments of LLMs on {4, 8, 12, 16, 20, 24} GPUs. The experiments failed when the number of GPUs was less than or equal to 8. The remaining results are shown in Figure 3. The results indicate that, when LLM calls are always successful, the framework's performance increases linearly with computational resource supply. Instead, when some calls fail the performance is higher, possibly because appropriate failures and retries facilitate the reallocation of LLM computational demands over time, thereby enhancing overall throughput. Thus, designing appropriate LLM request scheduling is an important future work of AgentSociety.

4.2 Environment Impact

To evaluate the impact of the realistic societal environments on agent performance, we constructed a social agent and an experimental scenario. The agent is designed to simulate urban residents' behaviors, comprising a guiding module based on the Needs Model (Maslow, 1943) and Planned-Behavior Model (Ajzen, 1991), along with multi-dimensional action modules (cognition, mobility, economy, and social interactions), interconnected via stream memory and function calling. The experimental scenario integrates mobility and cognitive scenarios, constructed using mobility trajectories collected from 169 urban residents in Beijing, each accompanied by associated intention data (Shao et al., 2024).

Table 2 presents a comparative analysis of agent performance under conditions with environment support (W-Env) and without environment support (WO-Env). W-Env was conducted using the proposed environment simulator, whereas WO-Env relied on an LLM-based textual simulator whose detailed prompt implementations can be found in Appendix B.1. We also compared the results with classical generative models including TimeGeo (Jiang et al., 2016), Movesim (Feng et al., 2020), Volunteer (Long et al., 2023), DiffTraj (Zhu et al., 2023), and Act2Loc (Liu et al., 2024).

The results highlight the critical importance of the realistic societal environment, particularly reflected by data support for feasible destinations, inter-location distances, and travel durations. Performance significantly declines in mobility-related metrics (e.g., radius and dayloc) under WO-Env

Table 2: Authenticity comparison among LLM Agent simulations with/without the realistic societal environments and classical generative models. Refer to Appendix B.2 and B.3 for more details about the metrics and the distributions, respectively.

Method	Radius	Dayloc	itdNum	itdError	itdDur
TimeGeo	0.254	0.258	0.297	0.536	0.155
Movesim	0.233	0.051	0.154	0.904	0.178
Volunteer	0.455	0.049	0.318	0.804	0.162
DiffTraj	0.027	0.647	0.695	0.597	0.080
Act2Loc	0.024	0.042	0.131	0.391	0.040
WO-Env	0.427	0.129	0.158	0.241	0.091
W-Env	**0.023**	**0.038**	**0.073**	**0.094**	**0.027**

conditions. Cognitive metrics (itdNum, itdError, and itdType) also show noticeable degradation. This indicates that the absence of environmental context severely restricts agents' capacity to accurately replicate realistic human behaviors. Besides, under W-Env conditions, agents in our proposed framework demonstrate excellent performance and outperform all baseline methods, effectively capturing authentic behavior patterns.

5 Related Works

5.1 LLM Agent-driven Simulation

Existing studies have validated the feasibility of LLM agent-driven simulations across multiple dimensions. Works such as Smallville (Park et al., 2023) and Project Sid (AL et al., 2024), through agent simulations within gaming environments, have demonstrated that LLMs can exhibit anthropomorphic behaviors and generate emergent social phenomena. Meanwhile, other studies employing rule-driven environments have further validated the similarities between LLM agents and real humans in aspects such as economic behaviors (Li et al., 2024) and social interactions (Gao et al., 2023; Tang et al., 2024).

However, these works have yet to incorporate realistic environments to provide feedback similar to human societies, thereby making it difficult to conduct LLM agent-driven simulations of them.

5.2 LLM Agent Programming Frameworks

Existing LLM agent programming frameworks are predominantly oriented toward multi-agent collaboration to enhance task-specific performance. These frameworks (Hong et al., 2024; Qian et al., 2024; Gao et al., 2024b; Li et al., 2023) typically require users to design SOPs based on message dependencies among agents and orchestrate parallel execution via directed acyclic graphs (DAGs), while treating environmental interactions as external function calls for LLMs. Such designs are difficult to handle the complex and non-deterministic interactions among agents and environments. Moreover, they face significant challenges in scaling effectively under conditions of complex interactions.

Additionally, Concordia (Vezhnevets et al., 2023) has attempted to design simulation-oriented LLM agent programming architectures. However, the LLM-driven Game Master introduces a bottleneck during large-scale simulations, severely limiting their scalability and practical applicability.

Therefore, there remains an urgent demand for LLM agent programming frameworks explicitly tailored for large-scale LLM agent simulation scenarios, capable of supporting massive, dynamic, and non-deterministic interactions.

6 Conclusion

In conclusion, the proposed AgentSociety provides a scalable framework for the simulation of LLM agents by integrating realistic societal environments and parallelized interactions, supporting large-scale human society simulation with highly realistic agents' behaviors. It successfully achieved a simulation of 30,000 agents faster than real-time clock speed with 24 NVIDIA A800 GPUs. We hope that AgentSociety will come to the attention of practitioners in social sciences, management sciences, and other fields so that simulations based on LLM agents become a new driving force behind new scientific discoveries and better real-world planning and decision-making.

7 Limitation

Although AgentSociety has achieved preliminary success in supporting the simulation of human societies using LLM Agents, we believe significant work remains to achieve a comprehensive social simulation. In terms of environmental modeling, there remains a substantial gap between current economic system representations and real-world ones, such as the lack of simulations for market mechanisms and firm decision-making processes. Regarding system architecture, improving agent execution efficiency through prompt engineering or other enhancements to enable large-scale simulations remains an open challenge.

A vLLM Deployment

We deploy a vLLM cluster across 3 servers, each equipped with 8 NVIDIA A800 40GB GPUs, 128-thread processors, and 1024GB RAM. The deployed model is Qwen2.5-7B-Instruct, with automatic tool selection and chunked prefill enabled, configured with `max-num-batched-tokens` set to 8192 (without extensive tuning). The guided decoding backend uses outlines. We do not enable tensor parallelism. Instead, we independently run a vLLM instance on each GPU and construct a reverse proxy supporting round-robin load balancing through Caddyserver[7] as the access endpoint. Our program accesses this endpoint to invoke the LLM computation services provided by vLLM.

B Supplementary Materials Regarding the Environment Impact Experiments

B.1 LLM-based Textual Simulator Prompts

As an alternative to the realistic simulation environment, we designed the following prompts to leverage the existing knowledge of LLMs to achieve functions including text-based location type selection, destination selection, and travel time estimation to support the agent's mobility behavior simulation.

Place Type Selection: This prompt assists the agent in determining the appropriate type of location to visit, based on its current needs and internal states.

```
You are an intelligent assistant specializing in understanding user needs and suggesting appropriate location types. Based on the user's intention, provide the most suitable location type.

- User's intention: {intention}

Please output in JSON format without any other text:

{
"type": "string", location type
}

Example Output:
{
"type": "Grocery Store"
}
```

Destination Selection: This prompt guides the agent in selecting a specific destination, given its current location and desired location type. It also includes information regarding the distance between these two locations.

```
You are an intelligent assistant specializing in suggesting specific destinations based on location types. Provide a suitable location name and estimate its distance from the current position.

- Current location: {current location}
- Target location type: {place type}

Please output in JSON format without any other text:
{
"name": "string", locations' name
"distance": "integer", in meter
}

Example Output:
{
"name": "Supermarket",
"distance": 1500
}
```

Travel Time Estimation: This prompt estimates the time required for the agent to reach the selected destination, considering both the current environmental conditions and the agent's status.

```
You are an intelligent assistant specializing in travel time estimation. Based on the provided distance, calculate the estimated time required to reach the destination, assuming typical traffic conditions.

- User's profile: {agent profile}
- Weather: {weather}
- distance: {distance} m

Please output in JSON format without any other text:
{
"time": "integer", in minutes
}

Example Output:
{
"time": 10
}
```

B.2 Metrics

The specific meanings of the five metrics used in the experiments are as follows:

- Radius: radius of gyration, representing the spatial dispersion of an agent's movements;
- Dayloc: daily visited locations, indicating the number of unique locations visited each day;
- itdNum: the number of intentions per day, measuring daily intention frequency;
- itdError: the similarity between intention sequences, reflecting consistency in agent behaviors;
- itdType: time proportion of intentions, denoting the temporal distribution of different intentions.

B.3 Distribution Details

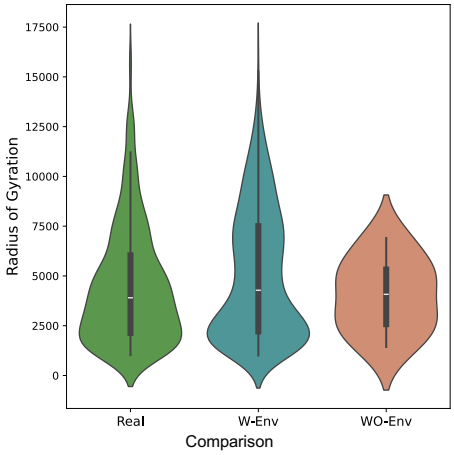

Figure 4: Distribution of Radius of Gyration.

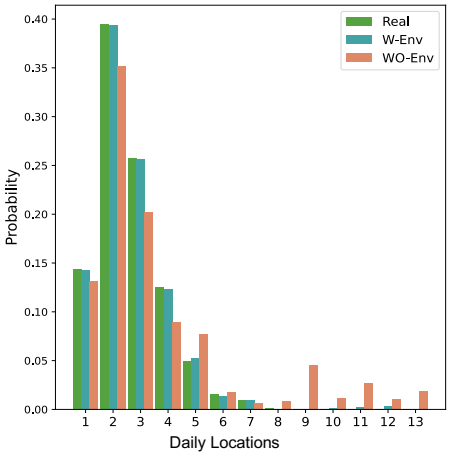

Figure 5: Distribution of daily locations.

This section provides the distribution details for the experiments in Section 4.2. From these results,

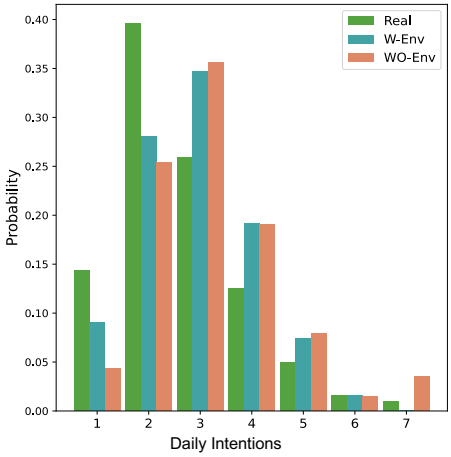

Figure 6: Distribution of daily intentions.

we can see that the information and constraints introduced by the realistic societal environments significantly improve the movement behavior patterns of the agents, making them highly approximate to the real data (Figure 4 and 5) And bring about a certain improvement in the distribution of intentions (Figure 6).

ENGinius: A Bilingual LLM Optimized for Plant Construction Engineering

Abstract

Recent advances in large language models (LLMs) have drawn attention for their potential to automate and optimize processes across various sectors. However, the adoption of LLMs in the *plant construction* industry remains limited, mainly due to its highly specialized nature and the lack of resources for domain-specific training and evaluation. In this work, we propose ENGinius, the first LLM designed for plant construction engineering. We present procedures for data construction and model training, along with the first benchmarks tailored to this underrepresented domain. We show that ENGinius delivers optimized responses to plant engineers by leveraging enriched domain knowledge. We also demonstrate its practical impact and use cases, such as technical document processing and multilingual communication.

1 Introduction

Recent progress in large language models (LLMs) has been driving innovation across diverse sectors. While general-purpose LLMs like ChatGPT (OpenAI, 2022) offer a solid foundation for various applications, complex and underexplored domains often require model adaptation to achieve behavior aligned with domain-specific requirements.

To this end, specialized LLMs have been developed for well-studied areas, e.g., healthcare (Zhang et al., 2023), finance (Wang et al., 2023), and law (Colombo et al., 2024). However, integrating LLMs into *plant construction engineering* (PCE) remains challenging, mainly due to the complexity of technical terms, the industry's multidisciplinary nature, and the lack of standardized domain-specific data.

In this study, we argue that, despite existing challenges, PCE is a high-priority sector that stands to benefit from the deployment of field-specific LLMs. Figure 1 and Table 1 provide intuitive evidence supporting the claim. Figure 1 illustrates the case that ChatGPT interprets the acronym 'NGS' as 'Next-Generation Sequencing,' a term widely recognized in life sciences (Schuster, 2008). However, in the context of PCE, it must be translated as 'Natural Gas System'. This implies that technical terms from PCE are likely underrepresented in corpora used to train LLMs, which may cause these models to struggle with PCE-related tasks.

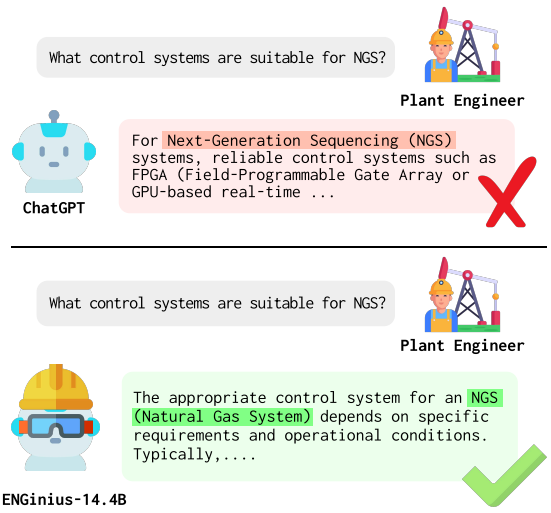

Figure 1: General LLMs (top) often struggle with domain-specific terminology and knowledge, frequently misinterpreting acronyms and specialized expressions. To overcome this challenge in the *plant construction* industry, we propose a novel LLM, ENGinius (below).

Furthermore, we emphasize that this issue is particularly acute for PCE, compared to other professional domains. Table 1 shows that while ChatGPT excels at understanding field-specific acronyms from the medical, financial, and legal disciplines, it largely fails to interpret PCE terms, even when provided with explanations of the target domain.[1] This

* Corresponding author

[1]We test ChatGPT's accuracy in explaining domain-specific acronyms, using 25 terms per domain. Each term is queried under two conditions: with and w/o domain info (i.e., name). The scores are averaged over 10 runs for robustness.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1350–1364

Domain	Success rates (%)	
	w/o domain info	w/ domain info
Medical	86.4%	100%
Finance	93.6%	100%
Law	60.0%	84.8%
PCE	**48.4%**	**55.6%**

Table 1: Comparison of ChatGPT's success rates in recognizing domain-specific acronyms with and without domain explanation. It falls well short in handling PCE.

result further highlights the limitations of general LLMs in handling unique domains, such as PCE.

In this work, we propose **ENGinius**, a novel LLM designed for the plant construction industry, to address the aforementioned challenges. The main contributions of this work are as follows:

1. As no suitable datasets currently exist, we first introduce a suite of **datasets** designed **for domain-adaptive pre-training & post-training in PCE**. ENGinius is trained on these new datasets, allowing it to be effectively optimized for the domain.

2. The problems caused by domain rarity can be more pronounced in multilingual settings. To investigate such issues, ENGinius is developed as a **bilingual model for English and Korean**.

3. Moreover, we propose two **novel benchmarks** to evaluate LLM performance **in realistic PCE scenarios**, part of which will be open-sourced. Experimental results on these new test sets show that ENGinius outperforms larger general-purpose LLMs in PCE-related tasks.

4. Finally, we showcase **real-world applications** implemented with ENGinius, e.g., expert and translation systems, highlighting its impact on improving work efficiency in the PCE domain.

2 Related Work

Interest in applying NLP to the PCE sector has been growing (Kim et al., 2018). Prior work has chiefly focused on technical document review—e.g., risky clause identification (Kim et al., 2022) and key contractual term extraction (Lee et al., 2020).

However, previous approaches to text processing in PCE have faced several limitations. The core problem stems from the scarcity and linguistic dissimilarity of the language used in PCE, which complicates the application of standardized rule-based (Winograd, 1972) and classification-based NLP techniques (Devlin et al., 2018). In addition, general NLP models (Young et al., 2018) are deficient in the specialized domain knowledge required in the PCE industry, often struggling to capture nuanced meanings embedded in complex contractual conditions, project dependencies, and implicit relationships between different document sections. This can lead to misinterpretation or incomplete analysis of PCE documents—e.g., misunderstanding key terms such as 'EOT' (Extension of Time) and 'LD' (Liquidated Damages).

Furthermore, the use of domain-specific language in multilingual or code-switching environments—which is common in companies outside English-centric countries—may exacerbate the aforementioned problems. To address these challenges, we propose ENGinius, a bilingual (English–Korean) language model tailored for PCE.

3 Benchmark Construction

A key prerequisite for effectively training and evaluating a domain-specific LLM is the establishment of a reliable benchmark within the target domain. Unfortunately, the PCE industry still lacks a suitable testbed for evaluating LLMs, partly due to its conservative and technically complex nature.

To alleviate this problem, we first introduce two novel *multiple-choice question (MCQ)* benchmarks dedicated to PCE: the **KOPIA** and **PE** benchmarks, targeting Korean and English, respectively. We aim to develop and validate a domain-specific LLM in bilingual settings, as data scarcity in specialized domains is often exacerbated by the additional complexity of multilingualism.

3.1 KOPIA Benchmark

We collaborate with the Korea Plant Industries Association (KOPIA)[2] to develop an industry-specific evaluation benchmark in Korean. This benchmark focuses on mechanical and piping engineering, a key subdomain of PCE, and covers terminology, technical standards, and process knowledge. Domain experts manually created and validated 1,000 test questions to ensure alignment with real-world practices. To support future research in the field, we plan to make this benchmark publicly available. See Appendix A.1 for more details.

[2]A government-affiliated organization that provides training for plant engineers (https://www.kopia.or.kr/).

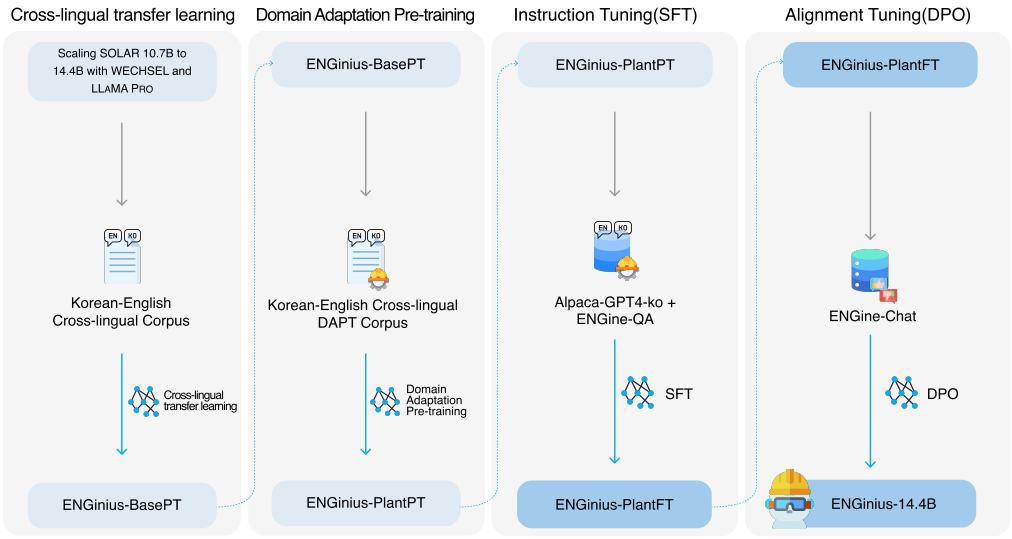

Figure 2: **Training procedure of ENGinius**. (1) SOLAR-10.7B is expanded to 14.4B using WECHSEL and LLaMA PRO, followed by bilingual training (**ENGinius-BasePT**). (2) Domain-Adaptive Pre-Training is then applied in the PCE domain, producing **ENGinius-PlantPT**. (3) The model is instruction-tuned to obtain **ENGinius-PlantFT**. (4) Finally, ENGinius-PlantFT is aligned via Direct Preference Optimization to produce the final **ENGinius-14.4B**.

3.2 Professional Engineer (PE) Benchmark

Inspired by MedQA US (Jin et al., 2020), we construct the Professional Engineer (PE) benchmark based on actual certification exams in the domain. It comprises 80 questions covering code knowledge, advanced calculations, and general conceptual understanding. This dataset is restricted to internal research use due to licensing constraints. Further details are provided in Appendix A.2.

4 Training of ENGinius

This section outlines the data collection and training procedures used to construct ENGinius. Since PCE is typically underrepresented in common textual resources, it is essential to first collect suitable industry-relevant corpora. We thus introduce a new suite of datasets developed for training ENGinius.

Furthermore, we detail the training procedure of ENGinius (see Figure 2), which leverages the corresponding datasets prepared for each stage. Table 10 provides exact configurations and hyperparameters. Each design choice is supported by extensive ablation studies reported alongside the training process.

4.1 Bilingual (English-Korean) Training

In the PCE industry, technical terms are often expressed in both English and a local language, requiring LLMs to possess strong bilingual capabilities. However, as existing LLMs are mostly trained on English-centric corpora (Grattafiori et al., 2024), they tend to exhibit suboptimal performance in relatively low-resource languages. (Ko et al., 2023).

To mitigate this issue, we selected SOLAR-10.7B (Kim et al., 2024) as our base model after evaluating several open-source alternatives (including Llama-2 13B (Touvron et al., 2023) and Mistral 7B (Jiang et al., 2023)). SOLAR-10.7B demonstrated strong performance on general language tasks and multilingual benchmarks, while offering the best balance between model size (10.7B parameters) and cross-lingual adaptability (see Table 11 in the Appendix for detailed ablation study results).[3]

Specifically, we employ the WECHSEL method (Minixhofer et al., 2022) to integrate new Korean tokens by initializing their embeddings using semantically similar English tokens. Subsequently, we adopt the LLaMA Pro methodology (Wu et al., 2024) to prevent catastrophic forgetting (Chen and Liu, 2018). Finally, we perform continued pretraining with an English-Korean bilingual corpus to induce cross-lingual transfer between the two languages, resulting in a new model named **ENGinius-BasePT**, which has 14.4B parameters.[4]

We verify the effectiveness of bilingual learning by comparing ENGinius-BasePT and SOLAR-

[3]The choice of language is guided by practical demand; however, in principle, our framework can be applied to any.

[4]See Appendix B for bilingual training and evaluation details. Note that the primary goal of this stage is to enhance the base model's general capabilities in English and Korean, rather than optimize it for a specific domain.

Table 2: Statistics of the datasets for Domain Adaptive Pre-Training (DAPT).

10.7B. As shown in Tables 8 and 9 in Appendix B, ENGinius-BasePT markedly outperforms the original on a Korean benchmark (Son et al., 2023) (78.09 vs. 59.57), while maintaining performance on English. This confirms that ENGinius-BasePT is well-suited as a foundation model for domain-specific training in the two target languages.

4.2 Domain-Adaptive Pre-Training (DAPT)

The multidisciplinary nature of PCE—covering mechanical, electrical, civil, architectural, and instrumentation disciplines—necessitates models that can comprehend diverse and interconnected domain knowledge. To cope with this complexity, we perform Domain-Adaptive Pre-Training (DAPT) (Gururangan et al., 2020) on ENGinius-BasePT, resulting in the domain-specialized model **ENGinius-PlantPT**, leveraging a wide range of PCE-related resources we collected (see Table 2).[5]

We compare ENGinius-BasePT and ENGinius-PlantPT to highlight the advantages of DAPT. The evaluation uses the KOPIA and PE benchmarks introduced in Section 3. As illustrated in Table 3, ENGinius-PlantPT consistently outperforms ENGinius-BasePT, underscoring the effectiveness of DAPT. We refer readers to Appendix C for the specifics of DAPT training and evaluation.

4.3 Instruction Tuning

In addition to DAPT, we explore domain-specific instruction tuning to further tailor the LLM for real-world applications. The goal of this phase is to adapt the model to more effectively handle tasks that align with the practical needs of stakeholders. To this end, our data suite—named **ENGine-QA** and summarized in Table 4—is designed to cover a range of practical tasks, including question answering, classification, dictionary prediction, and report generation. Note that this is manually constructed using a combination of in-house and open-source resources, the details of which are described below.

A core component of ENGine-QA is the Plant Expert QA subsets, derived from real-world discussions on ENG-TIPS, a globally recognized engineering forum.[6] By incorporating web-based comments and answers from domain experts into training, we expect the tuned model to naturally acquire specialized knowledge. We provide both English and Korean versions, with additional augmented data in Korean to improve bilingual coverage. Extra components in ENGine-QA are also included to provide effective training signals for the tuned model during instruction tuning. The role of each subset is described in detail in Appendix D.

On top of ENGine-QA, we also consider tuning the model with a general-purpose Korean instruction-following dataset to improve its language fluency and general reasoning ability. To this end, we translate the Alpaca-GPT4 dataset,[7] which contains diverse tasks generated by GPT-4 in a high-quality instruction–response format, and use it for instruction tuning. This dataset complements the domain-specific data (i.e., ENGine-QA) by enhancing general understanding and generation capabilities in Korean, which is particularly useful for tasks requiring broad linguistic competence.

To summarize, we produce **ENGinius-PlantFT** by instruction tuning using a combination of ENGine-QA and Alpaca-GPT4-ko, resulting in improved domain expertise, fluency, and language understanding. In the ablation study presented in Appendix D and Table 13, we demonstrate that our final configuration outperforms other feasible alternatives based on available resources.

4.4 Direct Preference Optimization (DPO)

Finally, we employ direct preference optimization (DPO) as the final step for training ENGinius. There is a risk that relying solely on instruction tuning with web-crawled datasets may degrade model quality, as user comments in forums such as ENG-TIPS are often noisy and imperfect. While some responses are grounded in industry standards, others may reflect subjective opinions or outdated practices To mitigate this issue and improve the relia-

[5] Before training, the domain-specificity of the datasets was validated through a visualization that highlights semantic gaps between our PCE datasets and general-purpose corpora. More details on this examination can be found in Appendix C.1.

bility of ENGinius, we apply DPO (Rafailov et al., 2023), a fine-tuning method that aligns model outputs with human or model-generated preferences.

To construct the DPO dataset, we again make use of Q&As from ENG-TIPS and generate two alternative responses per question using GPT-4o (OpenAI, 2024) and Mixture of Experts (MoE) prompting (Wang et al., 2024). All responses are generated in Korean. The specific steps for data construction and model training are as follows:

Two-Case Response Generation To capture variation in response quality and depth, we produce two distinct answers per question:

- **Case 1:** The original ENG-TIPS answer was anonymized and refined using GPT-4o for coherence and completeness.
- **Case 2:** MoE prompting generates a more context-rich and technically detailed response.

Human Preference Annotation Three senior specialists across mechanical, piping, electrical, and architectural disciplines evaluated response pairs and assigned preference scores based on predefined criteria (see Appendix E for more details). Responses were labeled as 'Chosen' or 'Rejected' based on aggregated scores.

Final Model Construction The generated dataset serves as the foundation for preference-based fine-tuning via DPO, resulting in the final **ENGinius-14.4B** model. This model is trained to generate responses aligned with expert expectations in real-world engineering contexts. To support research on domain-specialized LLMs, the DPO dataset will be publicly released.

5 Experimental Results

5.1 Experimental Settings

We adopt the LLM-as-a-judge framework (Zheng et al., 2023) to systematically evaluate model performance while minimizing human effort. For each question in the KOPIA and PE benchmark datasets, the tested models generate responses that are subsequently evaluated by LLaMA3-70B (Grattafiori et al., 2024), which serves as the judging model. Specifically, the judging model assesses correctness by comparing the generated responses with the provided reference solutions.

To ensure reliable and consistent evaluation, we conduct 20 independent runs for each model on the benchmarks. Final performance scores are computed by averaging the top five results from repeated evaluations.

5.2 Evaluation on the KOPIA Benchmark

Table 5 presents the experimental results of the proposed model and baseline methods on the KOPIA benchmark. Since all benchmark instances are multiple-choice questions, the reported scores represent the average accuracy over five runs. As baselines, we employ Gemma2-9B-it (Team et al., 2024), Orion-14B-Chat (Chen et al., 2024a), and SOLAR-10.7B (Kim et al., 2023). Experiments with external API-based models are excluded due to licensing constraints at the time of evaluation.

ENGinius-14.4B achieves an average score of 62 on the benchmark, outperforming baselines by nearly 3%-11%. The KOPIA test comprises two categories—Piping and Mechanical Engineering—in both of which ENGinius-14.4B demonstrates

Model	PE Test Code	PE Test Cal	PE Test General	Average	Diff. from ENGinius
Orion-14B-Chat	41.33	20.00	52.26	36.50	-31 (-45.9%)
GPT-3.5-turbo	60.00	47.06	45.16	48.75	-18.75 (-27.8%)
Gemma2-9B-it	72.00	34.71	59.99	51.50	-16 (-23.7%)
SOLAR 10.7B	72.00	40.59	54.83	52.00	-15.5 (-23.0%)
GPT-4	66.67	**52.94**	**74.84**	64.00	-3.5 (-5.2%)
ENGinius 14.4B (Ours)	**100**	46.47	**74.84**	**67.5**	-

Table 6: Performance comparison of the proposed ENGinius 14.4B and baselines, evaluated on the PE benchmark.

superior performance. These results confirm the model's effectiveness in understanding domain-specific knowledge essential to the PCE field.

5.3 Evaluation on the PE Benchmark

As in the previous subsection, the average accuracy of each model on the PE benchmark is reported in Table 6. The baselines include Orion-14B-Chat, GPT-3.5-turbo (OpenAI, 2023a), Gemma2-9B-it, SOLAR-10.7B, and GPT-4 (OpenAI, 2023b).

ENGinius-14.4B achieves an average score of 67.5, surpassing GPT-4's score of 64. Notably, while ENGinius-14.4B achieves higher average scores than GPT-4, our detailed analysis reveals important category-specific differences. GPT-4 demonstrates superior performance in the CAL[8] category, scoring 52.94 compared to ENGinius-14.4B's 46.47. This advantage likely stems from GPT-4's sophisticated mathematical reasoning capabilities, which benefit computation-intensive engineering questions.

While the Professional Engineer (PE) exam does not specify an official passing score, a score of approximately 65 is generally regarded as the passing threshold (NCEES, 2022). Accordingly, ENGinius-14.4B demonstrates superior performance over widely used proprietary models and open-source LLMs, meeting the level typically associated with certification-level expertise.

6 Real-World Applications

While we propose ENGinius as the first known application of a bilingual LLM in the PCE industry, we also share insights from its deployment. ENGinius is now actively utilized by a major company as the core of various real-world applications across different PCE workflows. Figures 3 and 5 (in Appendix F) illustrate a few representative cases.

Expert System As shown in Figure 3, ENGinius assists engineers by providing accurate answers

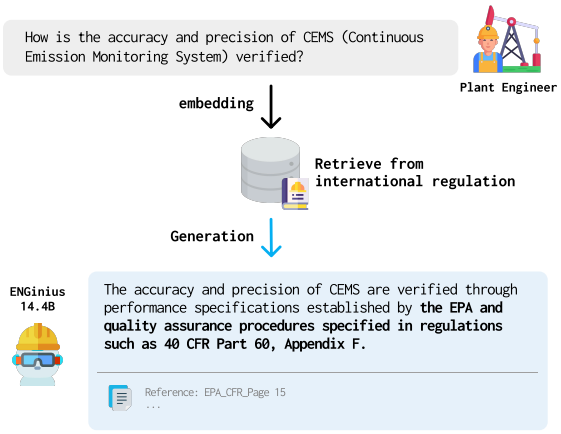

Figure 3: We share case studies of deploying ENGinius in an actual PCE industry environment. In this example, ENGinius functions as an expert system by retrieving accurate domain-specific knowledge and generating reliable responses aligned with engineering standards.

to technical questions. In addition, by utilizing Retrieval-Augmented Generation (RAG) (Lewis et al., 2020), the system references internal design standards and technical codes to generate informed recommendations on engineering implementations.

Automated Document Analysis Given the complexity of Invitations to Bid (ITB) documents, manual review is inefficient and prone to error. ENGinius streamlines this process through contract risk assessment—retrieving semantically similar clauses from historical data—and change detection, which compares current and past terms to identify shifts in client requirements.

Client Letter & Deviation Report Generation Drafting of official project correspondence is another application. The model refers to previously approved documents and generates a draft that aligns with the current project's standards.

Document Translation PCE documentation often spans multiple languages, posing challenges for cross-lingual understanding. ENGinius lever-

[8]Calculation. See Appendix A-2 for details.

ages translation abilities, especially with handling cross-lingual PCE terminology.

7 Conclusion

In this work, we present ENGinius, the first LLM tailored for the plant construction engineering (PCE) domain. We construct bilingual training corpora and introduced two new benchmarks—KOPIA and PE—designed to evaluate model performance in realistic PCE scenarios. Through DAPT, instruction tuning, and DPO, ENGinius significantly outperforms general-purpose LLMs on PCE-specific tasks. Furthermore, its deployment in an industrial setting demonstrates tangible benefits across engineering workflows. Our research highlights the importance of domain-specialized LLMs in high-priority, yet underrepresented industries, and hope this work provides a foundation for further research in industrial NLP applications.

8 Future Work

8.1 Multilingual Expansion

While the current implementation of ENGinius focuses on Korean-English bilingual capabilities, the PCE industry is inherently international. Engineering specifications, contractual requirements, and technical standards frequently appear in multiple languages, depending on project locations and stakeholder nationalities.

Building upon our bilingual foundation, we aim to extend ENGinius into a multilingual framework capable of processing technical content across diverse languages. This will involve:

- Developing parallel corpora for low-resource technical languages;
- Exploring cross-lingual transfer methods tailored to engineering terminology;
- Handling inconsistencies in multilingual representations of technical concepts.

Such multilingual capabilities would significantly enhance ENGinius's utility in global engineering contexts, promoting better communication and knowledge sharing across international teams.

8.2 Retrieval-Augmented Generation Integration

We also plan to incorporate Retrieval-Augmented Generation (RAG) into ENGinius. Given the volume and complexity of PCE documentation, RAG can support more accurate retrieval and generation by:

- Constructing vector databases from domain-specific engineering codes and standards;
- Designing retrieval strategies tailored to technical language and hierarchical documentation structures; and
- Evaluating performance improvements in tasks such as design validation and compliance Q&A.

This integration would strengthen ENGinius's role as a practical tool for real-world engineering applications, bridging theoretical advancements with industrial utility.

Limitations

Data Constraints. In the PCE industry, authoritative information is primarily derived from international codes, which are copyrighted by various professional associations. This posed challenges in collecting and utilizing data for research purposes. Currently, some associations provide subscription-based text search services, but these are limited to keyword searches and do not support semantic search, making it difficult to extract relevant information effectively. In the future, if these constraints are addressed—particularly with the introduction of vector database-powered subscription services—API integration could enable more efficient data access and retrieval.

Computational Resource Limitations. The ENGinius model developed in this study is a large-scale language model (LLM) with approximately 14.4B parameters, requiring extensive GPU resources and significant training time. Although we initially constructed a dataset consisting of 388B English tokens and 194B Korean tokens, due to resource constraints, we could only train on 4.2B English tokens and 42.2B Korean tokens. Future improvements in computational resources would allow for the development of an even more powerful model.

Benchmark Limitations. The benchmarks introduced in this study were developed based on research-driven evaluation criteria. However, actual industry users may have different priorities, and the evaluation criteria used in this study may not fully align with real-world user experiences. Specifically,

field engineers' requirements, emergency response needs, and business-specific usage patterns might not be fully captured by our benchmarks. Therefore, we acknowledge that our benchmarks may not perfectly reflect real-world applications, and future research should incorporate user-based evaluations and feedback to enhance practical relevance.

Absence of RAG Evaluation.

This study focused primarily on the development and intrinsic performance evaluation of ENGinius, the first large-scale language model tailored for the Plant Construction Engineering (PCE) domain. Consequently, benchmark experiments involving Retrieval-Augmented Generation (RAG) were excluded from the current research scope. Nonetheless, RAG is a crucial technology for constructing document retrieval and question-answering systems in real-world industrial contexts. As discussed in Section 6.

Ethics Statement

The ENGinius model presented in this study is a large language model specialized for the plant construction industry, demonstrating how generative AI can be applied safely in this domain. To prevent the generation of offensive or harmful content, we implement ethical guardrails using DPO (Direct Preference Optimization) techniques. This involves filtering harmful content based on datasets such as Huggingface's `MrBananaHuman/kor_ethical_question_answer`, ensuring that the model adheres to ethical standards.

Furthermore, personal and sensitive information was rigorously removed during data preprocessing to ensure that the model meets ethical guidelines. Ethical considerations were also integrated throughout the training and evaluation processes, ensuring that the model remains safe and fair for application in real-world PCE industry settings.

Future research will not only focus on improving model performance but also on addressing diverse ethical issues, ultimately contributing to the development of a more reliable AI system.

A Details on Benchmark Construction

A.1 The KOPIA Benchmark

This dataset, created in partnership with KOPIA, evaluates key competencies in plant engineering across three dimensions:

- **Terminology:** Correct understanding and usage of industry-specific terms.
- **Technical Standards:** Interpretation and application of engineering codes and industry specifications.
- **Process Knowledge:** Understanding workflows, procedures, and problem-solving in EPC projects.

Development Process

- KOPIA coordinated industry experts to develop 500 mechanical and 500 piping engineering questions (total 1,000).
- Our research team provided technical oversight, with final validation conducted by Professional Engineers (PEs).

A.2 The Professional Engineer (PE) Benchmark

Inspired by established domain-specific evaluation datasets (e.g., MedQA US, MedMCQA(Pal et al., 2022)), we constructed the PE Exam-based dataset as follows:

- Publicly available PE exam-style questions were collected through web crawling and manual curation.
- The dataset mirrors official PE exam difficulty distributions and syllabus topics, emphasizing plant engineering and power systems.

Dataset Composition The dataset contains 80 questions categorized as:

- **Code Knowledge (15 questions):** API(American Petroleum Institute), NEC(National Fire Protection Association, 2023), NESC(National Fire Protection Association, 2022) standards.
- **Advanced Calculations (34 questions):** Technical problem-solving.
- **General Conceptual Knowledge (31 questions):** Foundational engineering concepts.

Dataset	Type	Training Data Volume (# of Tokens)
English Dataset	Book Web text ArXiv Github Etc.	4.2B
Korean Dataset	Web text Dictionary Report Corpus Data Etc.	42.2B
Total		**46.4B**

Table 7: A bilingual dataset for continued pretraining.

This dataset serves as a supplementary evaluation tool to gauge ENGinius's capability in solving complex technical tasks.

B Details on English-Korean Bilingual Learning and Evaluation

As shown in Table 7, the English-Korean bilingual dataset was constructed using a 10:1 ratio of Korean to English data. We assess the cross-lingual performance of ENGinius-BasePT by evaluating it separately on English and Korean benchmarks.

For English, the model was tested on widely used benchmarks including ARC(Clark et al., 2018) (scientific reasoning), GSM8K(Cobbe et al., 2021) (mathematical problem solving), HellaSwag(Zellers et al., 2019) (commonsense reasoning), MMLU(Hendrycks et al., 2021) (broad domain knowledge), TruthfulQA(Lin et al., 2022) (truthful reasoning), and Winogrande(Sakaguchi et al., 2021) (contextual understanding). As shown in Table 8, **ENGinius-BasePT** maintained competitive performance, with only a minor drop of 1.8% compared to **SOLAR-10.7B** (64.21 vs. 66.01), indicating effective mitigation of catastrophic forgetting.

For Korean, we used the Haerae benchmark (Son et al., 2023), which includes five categories: Loan Words (distinguishing refined Korean from borrowed terms), Standard Nomenclature (use of standardized professional terminology), Rare Words (understanding uncommon vocabulary), General Knowledge (cultural, legal, and entertainment knowledge), and History (factual understanding of Korean history). As shown in Table 9, **ENGinius-BasePT** significantly outperformed the baseline across all categories, achieving a total improvement of 18.5% (78.09 vs. 59.57), demonstrating the

Model	ARC Challenge	GSM8K	HellaSwag	MMLU	TruthfulQA(MC2)	Winogrande	Average
ENGinius-BasePT	61.01	48.82	84.00	63.37	45.61	82.48	64.21
SOLAR-10.7B	61.35	55.50	84.55	65.52	45.65	83.50	66.01

Table 8: Comparison of performance before and after bilingual training on various English benchmarks.

Model	Average	General Knowledge	History	Loan Word	Rare Word	Standard Nomenclature
ENGinius-BasePT	78.09	51.70	85.64	84.62	80.74	84.97
SOLAR-10.7B	59.57	39.77	54.78	69.23	63.70	66.66

Table 9: Comparison of performance before and after bilingual training on the Korean (Haerae) benchmark.

effectiveness of cross-lingual pretraining in enhancing Korean performance while preserving English capability.

Table 10: Training environment and hyperparameters for each training stage.

C Details on Domain Adaptive Pre-Training (DAPT)

Table 2 provides an overview of the sources used to construct the DAPT dataset. Each component was selected to ensure coverage of essential disciplines such as mechanical, piping, electrical, and civil engineering, as well as regulatory standards and procurement-related materials.

The DAPT dataset integrates diverse sources to reflect domain-specific language and knowledge in engineering. It includes **plant journals** (2018–2023) on technologies and trends in PCE fields; materials on **civil and architectural** engineering; and references aligned with IEC, IEEE, NFPA, and ISA **standards**. **Technical guidelines** based on API and ASME cover mechanical, piping, and HVAC systems. The dataset also includes **government data** on plant terminology, contracts, and procurement; Korea's National Competency Standards (NCS); curated **news articles** (2020–2023); regulatory **handbooks** from agencies like the U.S. EPA and OSHA; and **technical papers** from APIs such as ScienceON and DBPia. All data were preprocessed to remove redundancy, enhance clarity, and match real-world engineering language.

C.1 PCA-Based Semantic Analysis

To demonstrate that our DAPT dataset captures the nuances of domain-specific terminology and context, we conduct a toy experiment on comparing semantic characteristics between PCE-specific data with those of general-domain data. Using BGE-M3 embeddings (Chen et al., 2024b) and Principle Component Analysis (PCA) (Jolliffe, 2016), we show clear separation of semantic vectors between general and PCE-specific texts. This demonstrates that the dataset reflects meaningful domain-specific distinctions.

To validate the uniqueness of the DAPT dataset, we performed PCA on semantic embeddings generated using the BGE-M3 embedding model. We compared samples from general-domain corpora and our DAPT dataset.

As shown in Figure 4, the embeddings from domain-specific texts form clusters distinct from those of general texts. This indicates that terms commonly used in both domains (e.g., beam, load, valve) exhibit significantly different semantic contexts, justifying the need for domain-specialized training data.

We highlighted two example sentences containing the word beam to illustrate this difference:

- *"A concentrated **beam** of light was emitted from the laser pointer."*

Model	Average	kobest_boolq	kobest_copa	kobest_hellaswag	kobest_sentineg	kobest_wic
basePT_solar	0.784	0.896	0.801	0.576	0.718	0.668
basePT_llama	0.759	0.798	0.830	0.642	0.985	0.540
basePT_mistral	0.596	0.511	0.724	0.542	0.980	0.488

Table 11: Performance comparison of bilingual pretraining using the same corpus on different base models: Llama 2, Mistral, and SOLAR. All models were trained with the same bilingual dataset and evaluated on the Korean benchmark KoBEST (Jang et al., 2022).

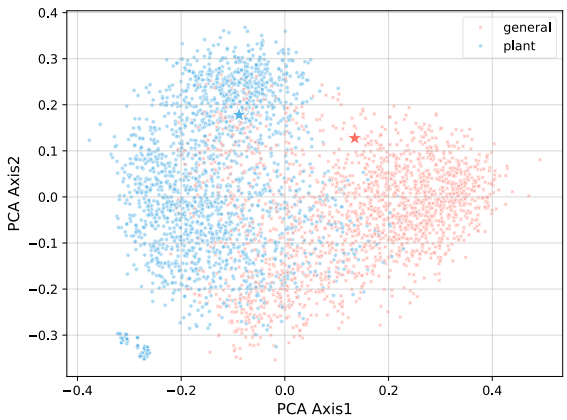

Figure 4: Embedding Distributions of General and Domain-Specific Data Visualized Using PCA.

Method	Pipe	Mech.	Average
Up-sampling	59.15	60.32	59.74
Down-sampling	62.63	58.91	60.77

Table 12: Performance comparison based on sampling strategy.

- *"The structural integrity of the steel **beam** must be verified to ensure compliance with ASCE design standards."*

These sentences are embedded in separate regions of the PCA space, supporting our claim that context-sensitive semantics are critical for industrial LLM performance.

C.2 Experiments on DAPT Sampling

Additional analyses and detailed results comparing sampling strategies (up-sampling vs. down-sampling).

Given the inherent imbalance among different data sources in the DAPT dataset, we compared two sampling strategies to improve domain-specific learning: Up-sampling and Down-sampling. Experiments evaluated using the KOPIA dataset revealed superior performance of down-sampling, especially notable in piping domain accuracy (improvement of 3.48%, detailed in Table 12). Therefore, down-sampling was adopted for subsequent experiments.

D Details on Instruction Tuning

The instruction tuning dataset was designed to enhance domain-specific reasoning (Chung et al., 2024), structured response generation, and terminology handling in the construction and plant industries. It includes data from diverse engineering disciplines, ensuring balanced representation. Below, we provide detailed descriptions of its key components.

Plant Expert QA The Plant Expert QA dataset, sourced from ENG-TIPS, captures real-world engineering discussions. It focuses on contextual term usage, helping the model accurately interpret engineering concepts in real scenarios.

To prevent domain bias, the dataset was structured to maintain balanced representation across mechanical, piping, electrical, instrumentation, civil, and architectural disciplines.

Classification This dataset enables the model to categorize technical documents and inquiries by discipline (e.g., mechanical, electrical, instrumentation). It improves the model's ability to identify and organize engineering content, supporting efficient information retrieval.

Deviation Report Generation Deviation reports document discrepancies between contract specifications and field conditions. This dataset trains the model to analyze deviations, generate structured reports, and ensure compliance with industry standards, aiding contract evaluation and project management.

Multiple Choice (MCQ) The MCQ dataset, designed to align with benchmark evaluations, includes questions on technical concepts, safety protocols, and regulatory standards. It enhances the model's precision in structured assessments.

Model	Mech.	Pipe	Avg.	Diff.
ENGinius-PlantPT	57.09	55.87	56.48	-
ENGinius-AG4FT	55.87	53.04	54.45	-2.0 (-3.6%)
ENGinius-KoPlantFT	61.13	58.70	59.92	+3.4 (+6.1%)
ENGinius-PlantFT	**63.77**	**60.45**	**62.11**	**+5.6 (+10.0%)**

Table 13: Performance of instruction-tuned model variants on the PE benchmark. **Diff.**: Difference from ENGinius-PlantPT.

Domain Dictionaries Engineers rely on domain-specific terminology and abbreviations. This dataset refines the model's understanding of frequently used technical terms, improving accuracy in document interpretation and engineering communication.

Alpaca-GPT4-ko In addition to domain-specific data, we also incorporated a general-purpose instruction-following dataset in Korean to improve the model's language fluency and general reasoning ability. For this, we translated and adapted the Alpaca-GPT4 dataset,[9] which contains diverse tasks generated by GPT-4 in a high-quality instruction-response format. This dataset complements the domain-specific data by enhancing general understanding and generation capability in Korean, especially useful for tasks requiring broad linguistic competence.

Ablation study for instruction tuning In this section, we conduct an ablation study to validate the effectiveness of each component used in instruction tuning. Below, we present the baseline models and our final model, **ENGinius-PlantFT**:

- **ENGinius-PlantPT:** The model only trained with DAPT.
- **ENGinius-AG4FT:** Fine-tuning ENGinius-PlantPT on Alpaca-GPT4-ko.
- **ENGinius-KoPlantFT:** Fine-tuning ENGinius-PlantPT with the combination of Alpaca-GPT4-ko and the Korean subset of ENGine-QA.
- **ENGinius-PlantFT:** Fine-tuning ENGinius-PlantPT with all instruction tuning data.

Table 13 shows that integrating both Alpaca-GPT4-ko and ENGine-QA yields the most significant improvement in domain expertise and linguistic quality.

[9] https://huggingface.co/datasets/llm-wizard/alpaca-gpt4-data/

E Details on Direct Preference Optimization (DPO)

E.1 DPO Evaluation Criteria

To ensure high-quality preference-based fine-tuning, domain experts evaluated response pairs using the following five criteria. Each response was rated on a 1–3 scale per criterion, with higher scores indicating stronger alignment with expert expectations.

- **Expertise** – Technical accuracy and adherence to verified engineering standards.
- **Clarity** – Clear and precise communication of key information.
- **Relevance** – Applicability of the response to the construction and plant engineering domain.
- **Conciseness** – Elimination of unnecessary details while preserving essential content.
- **Consistency** – Logical structure and coherence in addressing the question.

Based on the aggregated scores, responses were categorized as Chosen (preferred) or Rejected (non-preferred). These evaluations serve as the foundation for Direct Preference Optimization (DPO), enabling the model to prioritize expert-aligned responses in real-world engineering applications.

F Real-World Applications

In addition to the example in Table 3, Figure 5 provides examples of ENGinius in core engineering tasks.

ENGinius supports the generation of client letters and deviation reports by referencing past technical standards and previously approved documents. This allows engineers to produce consistent and contextually accurate drafts with minimal manual effort.

The model also enables automated analysis of document differences to identify changes in technical requirements, thereby improving the efficiency and reliability of contract review processes.

Finally, ENGinius handles translation of domain-specific content across languages, facilitating accurate and fluent cross-lingual understanding.

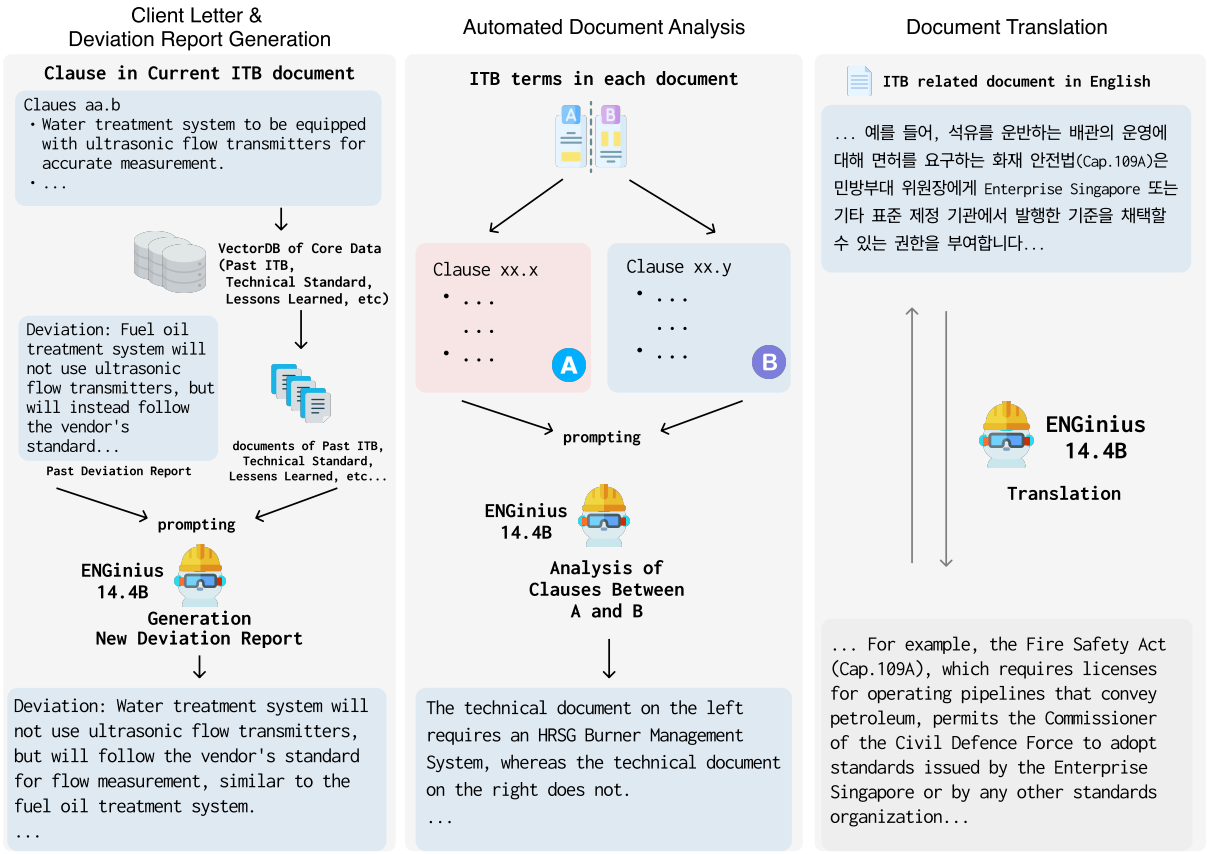

Figure 5: Real-world deployment of ENGinius across three core engineering tasks. Left: Generation of client letters and deviation reports by referencing prior documents. Center: Automated analysis of ITB documents to detect requirement changes. Right: High-fidelity translation of technical content to support multilingual understanding in engineering workflows.

Consistency-Aware Online Multi-Objective Alignment for Related Search Query Generation

Abstract

Modern digital platforms rely on related search query recommendations to enhance engagement, yet existing methods fail to reconcile click-through rate (CTR) optimization with topic expansion. We propose **CMAQ**, a **C**onsistent **M**ulti-Objective **A**ligned **Q**uery generation framework that harmonizes these goals through three components: (1) reward modeling to quantify objectives, (2) style alignment for format compliance, and (3) consistency-aware optimization to coordinate joint improvements. CMAQ employs adaptive β-scaled DPO with geometric mean rewards, balancing CTR and expansion while mitigating objective conflicts. Extensive offline and online evaluations in a large-scale industrial setting demonstrate CMAQ's superiority, achieving significant CTR gains (+2.3%) and higher human-rated query quality compared to state-of-the-art methods. Our approach enables high-quality query generation while sustaining user engagement and platform ecosystem health.

1 Introduction

Modern digital platforms use related search query recommendation to enhance user experience. An example is illustrated in Figure 1. When users interact with content, the system displays a single related query below it, minimizing disruption. This design serves three key functions: (1) proactive discovery, reducing exploration friction via contextual suggestions; (2) interest scaffolding, enabling gradual topic expansion while avoiding choice overload; and (3) feedback enrichment, where user interactions refine search ranking and content recommendations. By improving user satisfaction and understanding of emerging topics, this mechanism boosts user retention and ecosystem health.

Despite its industrial significance, academic research on related search query recommendation remains limited. Existing methods fall into two categories: retrieval-based and generation-based approaches. Retrieval-based methods (Wang et al., 2023c; Huang et al., 2018; Cao et al., 2008) rely on historical user behavior to retrieve queries from a pool, aligning with sequential patterns but struggling with cold-start content and seamless integration with primary content. In contrast, generation-based methods (Sannigrahi et al., 2024; Wang et al., 2024b), which directly generate queries by considering user interests and context, exhibit superior generalization for cold-start scenarios. Thus, we focus on the generative approach.

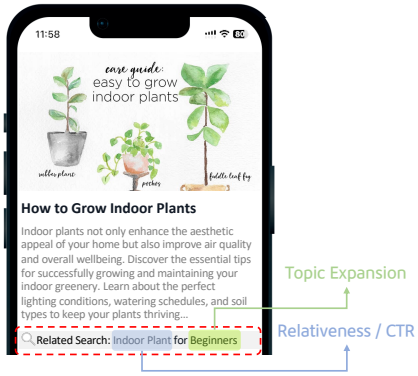

Figure 1: An illustration of the related search query recommendation scenario. A good query should excel in both CTR and topic expansion.

An effective query recommendation system must balance two key dimensions: *relevance* to the user's immediate interests, measurable via click-through rate (CTR), and *topic expansion*, crucial for avoiding filter bubbles (Gao et al., 2023a,b; Bi et al., 2024) and maintaining diversity (Gao et al., 2025b; Kang et al., 2025). However, these objectives often conflict: over-prioritizing relevance leads to narrow recommendations, while excessive focus on topic expansion risks deviating from user intent. Existing methods fail to address this trade-off, motivating our work to align both objectives consistently.

July 28-30, 2025

We leverage large language models (LLMs) (Li et al., 2024; Wang et al., 2023b), whose powerful capabilities make them well-suited for query generation. To mitigate LLM inference latency, we precompute query candidates offline for use in online scenarios. However, directly deploying pre-trained LLMs yields suboptimal performance due to misalignment with task-specific preferences—relevance and topic expansion. Aligning LLMs with these objectives is challenging, as reliable reward signals are hard to obtain: CTR requires extensive online exposure, and topic expansion relies on costly manual annotations. How to consistently enhance the model to achieve both objectives is also critical in this task, *i.e.,* generating queries that offer substantial topic expansion while maintaining a high CTR.

To address these challenges, we propose **C**onsistent **M**ulti-Objective **A**ligned **Q**uery Generation (CMAQ). CMAQ consists of three steps: (1) *precise reward modeling*, training reward models using annotated content-query pairs; (2) *query style alignment*, fine-tuning the LLM to produce correctly formatted queries; and (3) *consistent multi-objective alignment*, introducing a novel training strategy to balance both objectives. The optimization process follows an iterative online DPO paradigm, where generated queries are evaluated by reward models and used to refine the policy. Extensive evaluations demonstrate CMAQ's effectiveness in generating high-quality search queries.

Our key contributions are:

- Formulating related search query recommendation as a multi-objective query generation task.
- Proposing CMAQ, a framework for consistent multi-objective alignment in LLMs, balancing CTR and topic expansion.
- Demonstrating significant improvements via comprehensive offline and online evaluations in a large-scale industrial setting.

2 Related Work

Query Generation. Query generation in content platform is the process of generating new search queries that align with a user's current interests (Li et al., 2024). Existing techniques primarily address scenarios where users have already entered a query prefix, aiming to refine these queries through methods such as query suggestion (Wang et al., 2020; Bacciu et al., 2024), query rewrite (Wang et al., 2023a; Feng et al., 2024; Peng et al., 2024), and personalized query suggestion (Baek et al., 2024; Zhong et al., 2020) incorporating user history and interactions. These approaches assume that users have already demonstrated active search behavior and have initiated a search process.

Our work differs by aiming to provide potential search options to users while they are browsing content, thereby stimulating their interest in active exploration. In this context, early studies on seq2seq models were proposed by (Nogueira et al., 2019; Penha et al., 2023). Recently, some researchers have explored using LLM prompts to generate search terms from context (Sannigrahi et al., 2024), while others have focused on generating search queries in a multimodal context (Wang et al., 2024b). However, these methods overlook the multi-objective alignment problem in query generation. Our approach addresses this gap by simultaneously consider both CTR objective and expansion objective.

Direct Preference Optimization. Learning from human feedback is essential for aligning LLMs with human values (Bai et al., 2022; Ouyang et al., 2022; Ziegler et al., 2019). Recently, DPO-based methods (Rafailov et al., 2023; Ethayarajh et al., 2024; Meng et al., 2024; Wu et al., 2024; Gao et al., 2025a) directly align LLMs with an offline preference dataset, showcasing enhanced training stability and reduced training cost in comparison to traditional RL-based methods (Schulman et al., 2017). Online DPO (Yuan et al., 2024; Xiong et al., 2024; Pang et al., 2024) extends fixed offline preference dataset by continuously updating model preferences from real-time generated responses, enabling dynamic adaptation. Multi-objective DPO (Ramé et al., 2023; Wang et al., 2024a; Zhou et al., 2024; Shi et al., 2024) incorporates multiple criteria for alignment, allowing the model to balance and optimize different human values simultaneously. In industrial scenarios, aligning human preference also attracted attentions, such as query rewrite (Peng et al., 2024), advertising image generation (Chen et al., 2025) and advertising text generation (Wei et al., 2022), however, they primarily focus on aligning their tasks with the CTR objective, overlooking the alignment with broader objectives that impact generation quality, potentially resulting in diminished user experience. In contrast, our method accounts for multi-objective alignment.

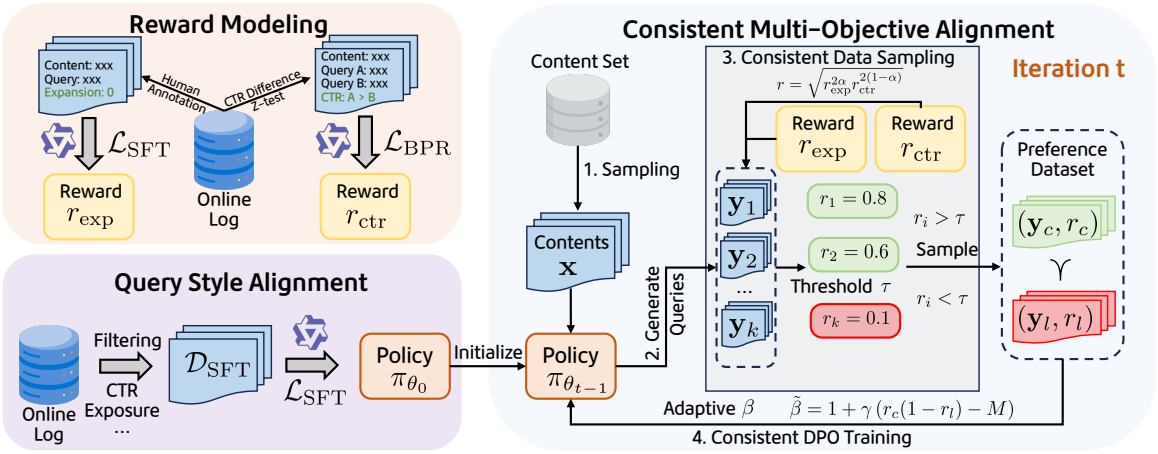

Figure 2: The framework of our proposed CMAQ framework.

3 Methodology

In this section, we introduce our CMAQ framework (*cf.* Figure 2), which consists of three components: reward modeling, query style alignment, and consistent multi-objective alignment. For multi-objective alignment, we primarily focus on the CTR objective and the expansion objective, while our framework is flexible and can be extended to accommodate additional objectives.

3.1 Reward Modeling

To align generated queries with online user preferences, we train two reward models (RMs) using user feedback data, focusing on CTR and topic expansion. These RMs are integrated into the query generation pipeline to guide optimization. Both RMs are based on Qwen2.5-1.5B (Yang et al., 2025) and fine-tuned using LoRA (Hu et al., 2022).

Reward Model for Topic Expansion This RM is designed to determine whether a query extends the context of a given content item, formulated as a binary classification problem. We utilize 337,291 outsourced labeled samples, split 8:2 for training and testing. Among these, 48.8% are labeled as positive (represented by token "1") and the remainder as negative (represented by token "0"). Let $\mathbf{x}$ denote the content and $\mathbf{y}$ the query. The expansion reward $r_{\text{exp}}(\mathbf{x}, \mathbf{y})$ is computed as: $r_{\text{exp}}(\mathbf{x}, \mathbf{y}) = \frac{p(\text{"1"}|\mathbf{x},\mathbf{y})}{p(\text{"0"}|\mathbf{x},\mathbf{y}) + p(\text{"1"}|\mathbf{x},\mathbf{y})}$, where $p(\text{"1"}|\mathbf{x}, \mathbf{y})$ represents the probability of the RM predicting the positive token "1". We use the standard next-token prediction loss to train this RM. The prompt template used for fine-tuning is detailed in Appendix A.1. The final model achieves a classification accuracy of 72.5%.

Reward model for CTR The RM for CTR is designed to predict which of two queries, given the same content, is expected to achieve a higher CTR. This model extends the base architecture with a regression head. We sampled content-query pairs $(\mathbf{x}, \mathbf{y})$ with more than 100 impressions and performed z-tests on impressions and clicks to identify pairs with statistically significant CTR differences ($p < 0.01$). This process yielded 328,328 $(\mathbf{x}, \mathbf{y}_+, \mathbf{y}_-)$ pairs, where $\mathbf{y}_+$ denotes the query with higher CTR for the content $\mathbf{x}$ and $\mathbf{y}_-$ denotes the query with lower CTR for the content $\mathbf{x}$. For the training of the RM, we use Bayesian Personalized Ranking (BPR) loss (Rendle et al., 2009), ensuring reliable distinctions in CTR:

$$\mathcal{L}_{\text{BPR}} = -\log \sigma \left(r_{\text{ctr}}(\mathbf{x}, \mathbf{y}_+) - r_{\text{ctr}}(\mathbf{x}, \mathbf{y}_-) \right). \quad (1)$$

The dataset was split 8:2 for training and testing, achieving a pair accuracy of 91.9%, which measures whether the query with a higher CTR receives a higher reward. In practice, the regression output directly serves as the CTR reward $r_{\text{ctr}}(\mathbf{x}, \mathbf{y})$.

3.2 Query Style Alignment

Initially, we attempted zero-shot or few-shot prompting without fine-tuning the backbone LLM. However, this approach often produced queries that were either non-compliant with instructions, stylistically mismatched with the platform, or contained hallucinated information. To address this, we focused on aligning the query style of the LLM. We constructed a large-scale offline training set $\mathcal{D}_{\text{SFT}} = \{(\mathbf{x}_i, \mathbf{y}_i)\}$ containing 1,292,031 samples extracted from online logs, leveraging exposure and CTR data to guide this alignment. Supervised

Fine-Tuning (SFT) was then applied to preliminarily align the LLM with the platform's query style, ensuring that generated queries adhere to the expected format and tone:

$$\mathcal{L}_{\text{SFT}} = -\mathbb{E}_{(\mathbf{x},\mathbf{y})\sim\mathcal{D}_{\text{SFT}}} \frac{1}{|\mathbf{y}|} \sum_{i=1}^{|\mathbf{y}|} \log \pi_\theta(y_i|\mathbf{x}, \mathbf{y}_{<i}), \tag{2}$$

where π_θ denotes the model's predicted probability for token y_i given prior tokens and the content.

3.3 Consistent Multi-Objective Alignment

While query style alignment enables the model to mimic real query styles, it does not guarantee high-quality query generation. High-quality queries should not only attract user clicks (high CTR) but also stimulate new search demands (high topic expansion). Therefore, further alignment of these dual objectives is crucial. To minimize reliance on extensive online logs and manual labeling, we employed an online DPO approach. Additionally, we introduced a consistency-aware strategy to mitigate conflicts between the two objectives during both data sampling and training stages.

3.3.1 Consistent Data Sampling

In each iteration t, we sample N content from the offline dataset $\mathcal{D}_{\text{SFT}}$. For each content $\mathbf{x}$, the model from the previous iteration samples k queries $(\mathbf{y}_1, \ldots \mathbf{y}_k) \sim \pi_{\theta_{t-1}}(\cdot|\mathbf{x})$, each evaluated on both objectives. To ensure the same scaling of both rewards, we normalize r_{ctr} into $[0, 1]$. To ensure consistency across both objectives, we used the geometric weighted average $r(\mathbf{x}, \mathbf{y}_i) = \sqrt{r_{\text{exp}}(\mathbf{x}, \mathbf{y}_i)^{2\alpha} r_{\text{ctr}}(\mathbf{x}, \mathbf{y}_i)^{2(1-\alpha)}}$ as the consistency criterion for the queries. By setting two thresholds τ_1 and τ_2 we sample a positive sample $\mathbf{y}_c$ from those with the reward $r > \tau_1$, and a negative sample $\mathbf{y}_l$ with $r < \tau_2$, forming the preference dataset $\mathcal{D}_t = \{(\mathbf{x}, \mathbf{y}_c, \mathbf{y}_l, r_c, r_l)\}$ for the DPO training in the iteration t.

Remark: We use the geometric average instead of the arithmetic average as the overall reward $r(\mathbf{x}, \mathbf{y}_i)$ since it enforces stricter consistency between the two objectives. As illustrated in Figure 3, when one reward approaches zero, the geometric average collapses toward zero regardless of the other reward, ensuring consistent optimization on both rewards.

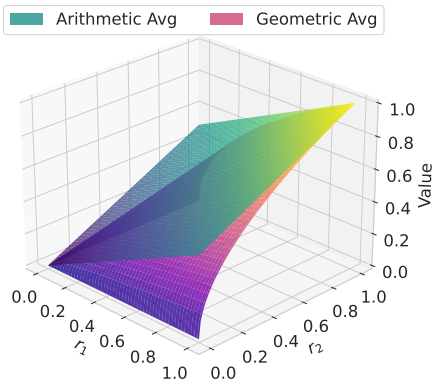

Figure 3: Illustration of the arithmetic average: $(r_1 + r_2)/2$ and geometric average $\sqrt{r_1 r_2}$ over the domain $[0, 1] \times [0, 1]$, demonstrating that the geometric average is more suitable for reflecting consistent multi-objective improvement.

3.3.2 Consistent Training

We adapt and extend DPO (Rafailov et al., 2023) in CMAQ. In DPO, the hyperparameter β controls the strength of KL-divergence regularization between the policy model π_{θ_t} and the reference model $\pi_{\theta_{t-1}}$. The optimal value of β depends on the quality of pairwise preference data (Wu et al., 2024). In our task, the consistency criterion r serves as a proxy for data quality: high-quality pairs exhibit a significantly higher r_c (positive sample) and a substantially lower r_l (negative sample), while low-quality pairs lack this distinction. To account for this variability, we propose a sample-level adaptive β, which dynamically scales β based on the consistency of each training pair. This approach amplifies the influence of high-consistency samples while reducing the impact of low-consistency ones.

For a sample $(\mathbf{x}, \mathbf{y}_c, \mathbf{y}_l, r_c, r_l)$, we compute the sample-level $\tilde{\beta}$ as: $\tilde{\beta} = 1 + \gamma\,(r_c(1 - r_l) - M)$, where $M = \frac{1}{|\mathcal{D}_t|} \sum_{(r_c,r_l)\in\mathcal{D}_t} r_c(1 - r_l)$ represents the average consistency across the dataset. Following (Pang et al., 2024), we incorporate an NLL loss term, weighted by λ, to prevent over-suppression when the chosen query closely resembles the rejected query. The final loss is given by:

$$\mathcal{L}_{\theta_t} = -\mathbb{E}_{(\mathbf{x},\mathbf{y}_c,\mathbf{y}_l)\sim\mathcal{D}_t} \left[\ell(\pi_\theta, \mathbf{x}, \mathbf{y}_c, \mathbf{y}_l) + \lambda \frac{\log \pi_{\theta_t}(\mathbf{y}_c|\mathbf{x})}{|\mathbf{y}_c|} \right],$$
$$\text{with } \ell(\cdot) = \log \sigma \left(\tilde{\beta} \frac{\pi_{\theta_t}(\mathbf{y}_c|\mathbf{x})}{\pi_{\theta_{t-1}}(\mathbf{y}_c|\mathbf{x})} - \tilde{\beta} \frac{\pi_{\theta_t}(\mathbf{y}_l|\mathbf{x})}{\pi_{\theta_{t-1}}(\mathbf{y}_l|\mathbf{x})} \right). \tag{3}$$

4 Experiments

4.1 Experiment Setting

Datasets To the best of our knowledge, no public dataset exists for related search query generation. Therefore, we collected data from a leading content platform. The statistics of the training data are presented in §3. For the test dataset, we randomly sampled 3,124 content items from the training dataset $\mathcal{D}_{\text{SFT}}$. To prevent data leakage, any samples with identical content in the test dataset were excluded from $\mathcal{D}_{\text{SFT}}$. More detailed information on data preprocessing and filtering is provided in A.4.

Baselines We selected two types of comparative approaches. The first type includes non-multi-objective approaches: (1) Zero-shot, where queries are generated directly by LLM without fine-tuning. (2) QSA (Query Style Alignment), as discussed in §3.2, aligns the query style using SFT within $\mathcal{D}_{\text{SFT}}$. (3) DPO (Rafailov et al., 2023), We employ pairwise preference data for CTR reward modeling to fine-tune the QSA model directly using DPO loss.

The second type includes multi-objective alignment approaches, which use the RMs described in §3.1 to obtain two scores for their generated responses, and further fine-tuned on the QSA model: (1) DPO-LW (Zhou et al., 2024), which uses weighted arithmetic average to combines the DPO losses for each objective to form the final loss. (2) DPO-Soup (Ramé et al., 2023), which involves training two models that align with each objective separately, followed by a weighted parameter merge to derive the final model. (3) MORL (Wu et al., 2023), which performs a weighted arithmetic average of the two rewards and then selects the highest and lowest ones to form preference pairs.

Implementation Details All baselines are based on Qwen-2.5-7B-Instruct and fine-tuned using LoRA to ensure a fair comparison. For all DPO-based baselines, we fine-tuned the model for 3 epochs. In the case of multi-objective alignment baselines, the preference dataset is generated at the start of training and remains fixed throughout the training process. For CMAQ, we trained it for 3 iterations, with each iteration comprising 1 epoch. We set the number of training samples per epoch to $N = 20,000$, the number of generated query candidates $k = 8$, the weight for the NLL loss $\lambda = 0.5$, and $\gamma = 0.2$. The trade-off weight in data sampling α is tuned in $[0.2, 0.4, 0.6, 0.8]$ for all multi-objective baselines, larger α indicates more attention on expansion objective. More experimental details can be found in A.4.

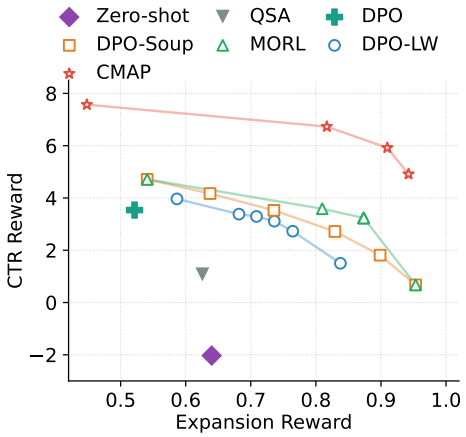

Figure 4: Pareto Fronts of all compared methods.

Evaluation Our framework prioritizes CTR and expansion of generated query: in offline experiments, we directly adopt r_{ctr} and r_{exp} as evaluation metrics, bypassing traditional NLG metrics like BLEU or ROUGE. For online validation, we measure actual CTR on content platforms and incorporate human-annotated quality assessments to holistically evaluate both the practical impact and creative coherence of the outputs.

4.2 Offline Experiments

The performance comparison on the Pareto Fronts of all compared methods is presented in Figure 4. It is important to note that for non-multi-objective baselines, only a single run is conducted as no trade-off is required. From the results, we can observe the following: (1) The Pareto Front of CMAQ significantly exceeds all baseline methods, demonstrating its effectiveness in achieving consistent improvements in both CTR and expansion objectives. (2) Multi-objective methods exhibit superior Pareto Fronts compared to non-multi-objective baselines, highlighting the effectiveness of considering both objectives along with the guidance provided by reward signals. (3) DPO achieves higher CTR rewards while showing a decline in expansion compared to QSA, indicating the presence of conflicts between the two objectives. Therefore, it is crucial to consider consistent optimization for multiple objectives in query generation.

4.3 In-depth Analysis

Ablation Study To validate the effectiveness of each component within our framework, we con-

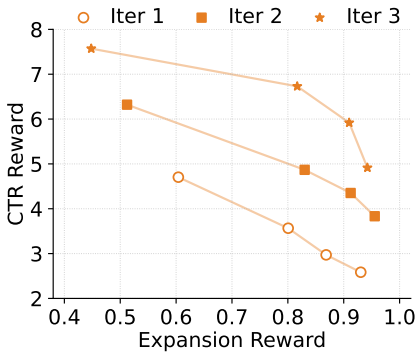

Figure 5: Pareto Fronts of different iterations.

duct ablation studies on three variants of CMAQ: (1) Removing the online query generation at the start of each iteration by utilizing a fixed preference dataset for each iteration, denoted as w/o OT; (2) Removing consistent data sampling by using a weighted arithmetic average instead of a geometric average, denoted as w/o CDS; (3) Removing consistent training by employing a static β in DPO training, denoted as w/o CT.

Table 1 displays the performance of CMAQ and its three variants under two distinct settings, $\alpha = 0.4$ and $\alpha = 0.6$. From the results we can see that (1) removing each component in our framework decreases the performance, validating their effectiveness. (2) The removal of online training leads to a significant deterioration in r_{ctr}, primarily attributed to the absence of iterative on-policy training sample updates. This deficiency substantially diminishes the capacity of training samples to provide effective optimization guidance for model enhancement as the model has already aligned well with the original dataset. (3) The elimination of CDS results in heightened sensitivity to the parameter α, exhibiting a "seesaw effect" where small changes in α lead to sudden shifts in optimization, disproportionately favoring either the CTR or expansion objectives. This issue arises from the limitations of arithmetic mean-based optimization, as discussed in §3, which fails to effectively consistent improvements between dual objectives.

The Impact of Training Iterations To further illustrate the impact of online training, Figure 5 displays the Pareto Front of CMAQ at each iteration. As iterations progress, we observe improved performance, demonstrating the effectiveness of the online training paradigm.

Table 1: Ablation studies on CMAQ. Here, OT, CDS, CT stand for *Online Training*, *Consistent Data Sampling*, and *Consistent Training*, respectively.

Setting	$\alpha = 0.4$		$\alpha = 0.6$	
	r_{ctr}	r_{exp}	r_{ctr}	r_{exp}
CMAQ	6.730	0.817	5.918	0.912
w/o OT	4.055	0.812	3.032	0.906
w/o CDS	6.958	0.481	3.260	0.959
w/o CT	6.672	0.792	5.348	0.910

4.4 Online Experiments

Online Deployment To evaluate the effectiveness of our proposed method in real-world industrial settings, we deployed CMAQ on a local lifestyle information app Dianping, and conducted an online A/B test over a one-week period. We propose to leverage LLMs for query generation as an additional recall pathway in related search scenario. Specifically, we conducted a week-long A/B test involving approximately 3,000,000 contents, where each method employed beam search to sample 5 queries per content. Upon completion of query generation, we further filtered all generated queries through a series of criteria, including lexical quality, relevance, and harmfulness, resulting in the removal of less than 10% of the generated queries. The retained queries were then associated with their respective content and cached in the recall pool. During online service, a fine-grained ranking model determines whether to expose these queries to users. The entire inference process can be executed in offline or nearline modes, allowing for pre-computation and caching of new content, thereby eliminating the need for real-time inference upon user requests and ensuring service efficiency and latency requirements are met.

Online Results The results are presented in Table 2. For data security reasons, CTR results are reported in relative terms, with QSA serving as the baseline model in the A/B test. This experiment gathered over 20 million impressions to ensure the reliability and statistical significance of the CTR results. More detailed online settings can be found in A.4. From the results, we observe the following: (1) DPO demonstrates significant improvement over QSA, highlighting the effectiveness of CTR objective alignment. (2) Multi-objective based methods consistently outperform DPO, suggesting that optimizing for expansion may also contribute positively to CTR. (3) CMAQ achieves the best online CTR

Table 2: The performance of different methods in online A/B test. ΔCTR stands for the relative CTR improvement over QSA: $\frac{\text{CTR}_{\text{method}} - \text{CTR}_{\text{QSA}}}{\text{CTR}_{\text{QSA}}}$.

Method	ΔCTR
DPO	+0.985%
MORL	+1.401%
CMAQ	+2.305%

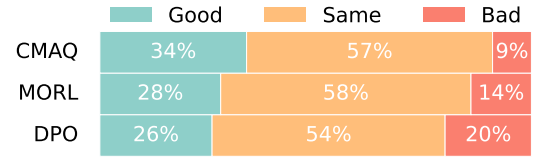

Figure 6: Human Evaluation.

performance, indicating its capability to minimize conflicts between the two objectives.

4.5 Human Evaluation

To validate the quality of queries generated by the model, we conducted a manual GSB (Good-Same-Bad) test on the online methods. Specifically, we randomly selected 200 contents and had human evaluators compare the query quality generated by the online models and QSA. The evaluation criteria included relevance, expansion, and spelling errors. As shown in Figure 6, our proposed CMAQ achieved the best results in comparison with QSA, demonstrating the improvement in query quality offered by our method.

5 Conclusion

In this paper, we introduce CMAQ, a query generation method that formulates related search query generation as a multi-objective alignment task, aligning both CTR and expansion objectives through the online DPO paradigm. We employ consistent data sampling and training strategies to enhance the effectiveness of this multi-objective alignment. Both offline and online experiments demonstrate that CMAQ yields significant improvements in key industrial metrics.

In the future, we aim to take personalization into LLM-based query generation and expand the range of objectives considered in the alignment. We also plan to improve the diversity of the LLM-generated queries while maintaining the performance.

Ethical Considerations

In deploying our query generation model as a supplemental recall mechanism, we prioritize two key ethical principles. (1) **Data Privacy Protection**: All training and inference processes exclusively utilize fully anonymized search session data, with no access to user-specific profiles, search histories, or demographic identifiers. The model operates solely on aggregated query patterns, ensuring complete dissociation from individual users. (2) **Content Safety Risks**: While our framework filters explicit harmful content, automatically generated queries might inadvertently propagate subtle biases from historical search distributions. We mitigate this through regular human audits of sampled outputs and explicit exclusion of sensitive topics during candidate generation.

A Appendix

A.1 Prompts

Here, we introduce the prompts used in the query generation and expansion reward models. For the CTR reward model, as it is treated as a regression task, we do not design a specific prompt template. Instead, the input to the CTR reward model is simply the concatenation of (title, content, shopinfo, query).

Prompt for Query Generation

You are a user of a leading local lifestyle information platform that provides shop info, consumer reviews, discounts, and nearby lifestyle information. You often browse user-generated content and excel at summarizing and extending related interest queries to help other users explore more related information.
Requirements:
1. Provide only one answer, keep it within 15 words.
2. Output the answer directly, without any explanations or unnecessary prefixes.
3. The answer should be related to the content but not just a summary, guiding users to search for more related topics.
Given a note, please summarize and extend the interest queries for the content.
##Note Content
Title: {{title}}
Content: {{content_body}}
Shop info: {{shopinfo}}
Answer:

Prompt for Expansion Reward Model

You are a search term quality assessment expert. Based on the following note content and query, score the query's expansion (0 or 1), and output the result in the specified format without explanations.
Expansion: Does the search query include information beyond the note content that can spark user interest for further exploration? It might involve novel, interesting, or trending topics that seem worth delving into.
Score 0: Completely redundant information (directly copying POI name/title queries), with no apparent extensibility, as the information is fully covered by the note content, and users can get complete information without further clicking.
Score 1: Has a certain extensibility. Even if the note doesn't mention this information, if the query can guide users to acquire new useful information (like reservation methods) or encourage comprehensive exploration of the place (like "exploring shop" queries), it is considered to have extensibility.
##Note Content
Title: {{title}}
Content: {{content_body}}
Shop info: {{shopinfo}}
Query: {{query}}
Answer:

A.2 The Pseudo Code of Consistent Multi-Objective Alignment

Algorithm 1: Consistent Multi-Objective Alignment

Data: Offline content dataset $\mathcal{D}_{\text{SFT}}$, QSA model $\pi_{\theta_{\text{QSA}}}$, Threshold τ_1, τ_2, Adaptation rate γ, Trade-off parameter α, Sample number N, Generation number k, Max iteration T

Initialize policy $\pi_{\theta_0} \leftarrow \pi_{\theta_{\text{QSA}}}$;

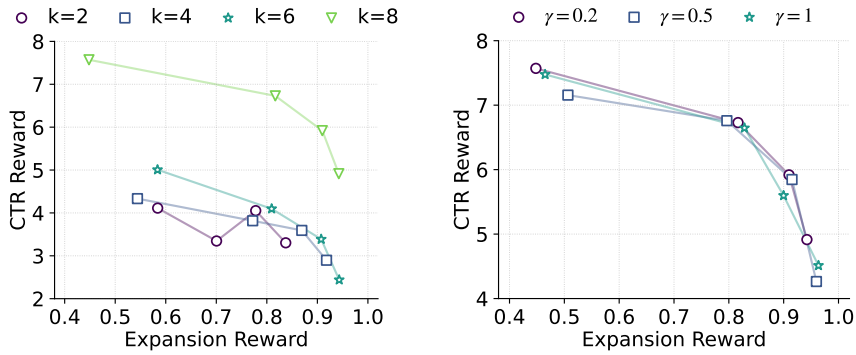
for *iteration* $t = 1, 2, \dots T$ **do**

- $\mathcal{D}_t \leftarrow \emptyset$;
- Sample contents $\{\mathbf{x}\}_1^N \sim \mathcal{D}_{\text{SFT}}$;
- **for** *content* $\mathbf{x} \in \{\mathbf{x}\}_1^N$ **do**
  - Generate queries $\{\mathbf{y}_1, \mathbf{y}_2, ..., \mathbf{y}_k\} \sim \pi_{\theta_{t-1}}(\cdot|\mathbf{x})$;
  - Compute rewards $r_i = \sqrt{r_{\text{exp}}^{2\alpha}(\mathbf{x}, \mathbf{y}_i) r_{\text{ctr}}^{2(1-\alpha)}(\mathbf{x}, \mathbf{y}_i)}$ for each $\mathbf{y}_i$;
  - $\mathcal{D}_{\text{pos}}, \mathcal{D}_{\text{neg}} \leftarrow \emptyset, \emptyset$;
  - **for** *query* $i = 1, 2, \dots k$ **do**
    - **if** $r_i > \tau_1$ **then**
      - $\mathcal{D}_{\text{pos}} \leftarrow \mathcal{D}_{\text{pos}} \cup \{(\mathbf{x}, \mathbf{y}_i, r_i)\}$;
    - **if** $r_i < \tau_2$ **then**
      - $\mathcal{D}_{\text{neg}} \leftarrow \mathcal{D}_{\text{neg}} \cup \{(\mathbf{x}, \mathbf{y}_i, r_i)\}$;
  - **if** $\mathcal{D}_{pos} \neq \emptyset$ *and* $\mathcal{D}_{neg} \neq \emptyset$ **then**
    - $(\mathbf{y}_c, r_c) \sim \mathcal{D}_{\text{pos}}$;
    - $(\mathbf{y}_l, r_l) \sim \mathcal{D}_{\text{neg}}$;
    - $\mathcal{D}_t \leftarrow \mathcal{D}_t \cup \{(\mathbf{x}, \mathbf{y}_c, \mathbf{y}_l, r_c, r_l)\}$;
- Compute averge reward $M = \frac{1}{|\mathcal{D}_t|} \sum_{(r_c, r_l) \in \mathcal{D}_t} r_c(1 - r_l)$;
- **for** *data sample* $(\mathbf{x}, \mathbf{y}_c, \mathbf{y}_l, r_c, r_l) \in \mathcal{D}_t$ **do**
  - Compute adaptive $\tilde{\beta} = 1 + \gamma\,(r_c(1 - r_l) - M)$;
  - Perform Consistent DPO Training via Equation (3);

A.3 Data Collection

We construct the dataset $\mathcal{D}_{\text{SFT}}$ where each sample $(\mathbf{x}, \mathbf{y})$ is a tuple of (content, query). The construction procedure of $\mathcal{D}_{\text{SFT}}$ mainly includes the following steps:

- **Core Metric Aggregation.** We first aggregate behavioral signals (page views, clicks) at the content-query level through temporal summation, with the time spans one year. This initial phase establishes baseline engagement metrics and computes derived indicators including CTR. A minimum exposure threshold eliminates statistically insignificant observations.
- **Multi-Dimensional Filtering.**The raw dataset undergoes successive quality filters:
  - Lexical constraints: Remove short/non-compliant queries through length thresholds and regex pattern matching.
  - Engagement thresholds: Eliminate low-CTR entries through percentile-based cutoffs
  - Commercial term exclusion: Filter queries containing promotional phrases via predefined blocklists
  - Semantic redundancy checks: Exclude queries exhibiting high similarity to shop names through normalized Levenshtein distance calculations
- **Diversity-Preserving Sampling.** To ensure categorical diversity and prevent domain dominance in the training corpus, we implement a stratified sampling strategy grounded in content taxonomy. The dataset is first partitioned by content categories. Within each categorical partition, entries are ranked



(a) (b)

Figure 7: (a) The Pareto Front of CMAQ under different query sample times $k \in [2, 4, 6, 8]$. (b) The Pareto Front of CMAQ under different scaling coefficient γ in obtaining $\tilde{\beta}$, where $\gamma \in [0.2, 0.5, 1]$.

through a composite scoring metric prioritizing CTR while considering auxiliary quality signals. A maximum cap of 10,000 samples per category is enforced to prevent the bias of prevalent domains.

Finally, we collected $\mathcal{D}_{\text{SFT}}$ for both quality style alignment and consistent multi-objective alignment processes. The size of $\mathcal{D}_{\text{SFT}}$ is 1,292,031.

A.4 Detailed Experiment Settings

For all fine-tuning experiments in each iteration, we utilize PyTorch 2.1.0[1] (Paszke et al., 2019) in conjunction with HuggingFace's TRL framework[2]. Experiments are executed on eight A100 GPUs, with each iteration requiring approximately 10 GPU hours, including query generation, rewarding and training. We employ the AdamW optimizer (Loshchilov and Hutter, 2019) with a learning rate of 1e-5 and a cosine learning rate schedule incorporating 20 warmup steps. The temperature is set to 1.5 in generation k queries to ensure the diversity for iterative DPO training. The training process spans 1 epochs with a global batch size of 32. For LoRA training, we set the rank $r = 32$, and the $\alpha = 8$. For online inference, we utilize vLLM[3] (Kwon et al., 2023) for speed-up.

A.5 Supplementary Experimental Results

We conducted additional experiments to investigate the impact of the sampling number k and the scaling coefficient γ in Equation (3) on the performance.

The impact of sample times k Figure 7a illustrates that the performance of CMAQ improves as k increases, suggesting that additional sampling instances contribute to more diverse information during training. As the number of sample times rises with k, we select $k = 8$ for our final model, balancing the trade-off between performance and efficiency.

Parameter sensitivity of γ Figure 7b indicates that CMAQ exhibits robustness across various values of γ. This suggests that the method maintains its effectiveness despite changes in the hyperparameter settings, making it adaptable to different conditions.

Abstract

Generating high-quality geometry problems is both an important and challenging task in education. Compared to math word problems, geometry problems further emphasize multi-modal formats and the translation between informal and formal languages. In this paper, we introduce a novel task for geometry problem generation and propose a new pipeline method: the Symbolic Deduction Engine-based Geometry Problem Generation framework (SDE-GPG). The framework leverages a symbolic deduction engine and contains four main steps: (1) searching a predefined mapping table from knowledge points to extended definitions, (2) sampling extended definitions and performing symbolic deduction, (3) filtering out unqualified problems, and (4) generating textual problems and diagrams. Specifically, our method supports to avoid inherent biases in translating natural language into formal language by designing the mapping table, and guarantees to control the generated problems in terms of knowledge points and difficulties by an elaborate checking function. With obtained formal problems, they are translated to natural language and the accompanying diagrams are automatically drew by rule-based methods. We conduct experiments using real-world combinations of knowledge points from two public datasets. The results demonstrate that the SDE-GPG can effectively generate readable, solvable and controllable geometry problems.

1 Introduction

In the field of education, developing an automatic problem generation tool is valuable for both teachers and students. Teachers or problem designers can use the tool to save time and effort, enhancing the efficiency of the problem production process (Wang et al., 2021; Cao et al., 2022). Meanwhile, students can leverage the tool to generate personalized problems based on their background and interests, improving their learning outcomes (Polozov et al., 2015; Bernacki and Walkington, 2018). In this paper, the research objective is to investigate how to generate geometry problems which are always less-studied before, to our best knowledge.

Current related studies primarily focus on the generation of math word problems (Qin et al., 2023; Christ et al., 2024; Liu et al., 2024; Qin et al., 2024). Intuitively, different types of mathematical problems are designed to assess various educational abilities. For example, math word problems emphasize language understanding, mathematical modeling, and equation deduction, while geometry problems require spatial imagination, calculation and reasoning skills, as well as mastery of geometric theorems and properties (Liu et al., 2020). Therefore, although both types of problems prioritize readability in natural language and solvability, methods for generating math word problems cannot be directly applied to geometry problems. Specifically, based on our observation, generating a geometry problem necessitates supporting a strict, step-by-step reasoning process based on geometric theorems, often in formal language, and requires multi-modal capabilities to present the problem in both textual and visual forms. These factors make geometry problem generation more challenging.

To be more specific, as shown in Figure 1, a typical geometry problem consists of a paragraph of *textual problem* and an accompanying *geometric diagram*. Within the paragraph of textual problem, the text is a mixture of mathematical expressions (e.g., [$AB \parallel CD$]) and natural language (e.g., [As shown in the figure...]). Aside from the final *question* sentence (e.g., [then what is the degree of $\angle AEC$?]), all other textual content are *clauses*. To solve the problem, appropriate geometric *knowledge points*[1] (e.g., the properties of parallel lines

[1]Geometric knowledge points, also referred to as geometric rules, include theorems and properties. We do not distinguish between them in the remainder of this paper.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1378–1398
July 28-30, 2025

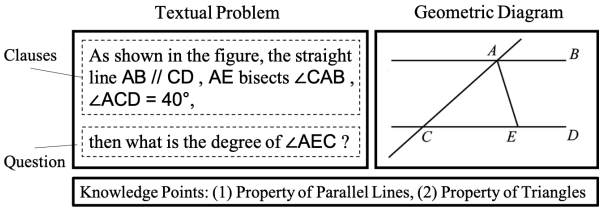

Figure 1: A typical geometry problem consists of a paragraph of textual problem and a geometric diagram. The textual problem is made up of clauses and a question, combining mathematical expressions with natural language. The diagram is sometimes not required.

and triangles in the case of Figure 1) should be applied during the reasoning process from clauses to the question. If there exists at least one such strict and step-by-step reasoning path, we believe that the geometry problem can be called solvable.

Following the existing studies on controllable problem generation (Liu et al., 2024), we also consider several analogous control variables as input, such as the knowledge points and difficulty degree. In summary, to generate controllable high-quality geometry problems, several basic elements should be involved during method design: (1) the textual problem, including clauses and a question, (2) a geometric diagram, and (3) an answer presented as a step-by-step reasoning path. Most importantly, the generated problems must be rightly solvable. Thus, the proposed task definition is that to generate a geometry problem, the knowledge points and difficulty as control variables are given, and the above-mentioned three basic elements would be outputted. In this paper, considering the complexity of the whole geometric domain, we focus on Euclidean plane geometry, leaving the exploration of topics such as geometric inequalities and combinatorial geometry for future work. The following Section 3 (Problem Definition) will introduce a detailed description of the proposed task.

To achieve the task of geometry problem generation, with a focus on readability, solvability, and controllability, we propose a pipeline method called the Symbolic Deduction Engine-based Geometry Problem Generation framework (SDE-GPG). The framework consists of four main steps: (1) searching a knowledge point-to-extended definition mapping table, (2) sampling extended definitions and performing symbolic deduction, (3) filtering out unqualified problems, and (4) generating textual problems and geometric diagrams. The details of SDE-GPG is introduced in the Section 4 (Method).

In order to evaluate the effectiveness of our proposed method, we manually curate two public datasets containing real-world combinations of knowledge points. This approach helps avoid invalid combinations, as using arbitrary knowledge points sometimes results in unsolvable conclusion. After thorough human evaluation, we find that the generated problems by our method ensure decent solvability and good consistency with control variables, along with precise descriptions in both natural language and visual diagrams. Due to the limited space, the part of related work is put into the Section 6 (Appendix).

The contributions of this paper include:

- We propose a **new, simplified task definition** for generating geometry problems. Controlled by **knowledge points and difficulty degree**, this task outputs **readable and solvable problems**. Each problem consists of three components: (1) a paragraph of textual clauses and question, (2) a geometric diagram, and (3) a step-by-step reasoning path as the answer.
- We leverage a symbolic deduction engine and propose a pipeline framework to accomplish the task, called the **Symbolic Deduction Engine-based Geometry Problem Generation framework (SDE-GPG)**. The framework consists of four steps: (1) searching a knowledge point-to-exDefinition mapping table, (2) sampling exDefinitions and performing symbolic deduction, (3) filtering out unqualified problems, and (4) generating textual problems and diagrams.
- We collect **two datasets** and conduct thorough experiments to evaluate the **readability, solvability** and **controllability** of the generated problems. The experimental results demonstrate the effectiveness of our method in terms of all the aspects. The code, data, templates and other resources are public to facilitate the successive researches[2].

2 Related Work

2.1 Educational Question Generation

Educational problem generation is a broad topic, as different subjects and problem types may focus on specific pedagogical objectives (Gorgun and Bulut, 2024). In the field of mathematics, current studies

[2] https://github.com/tianyangzhang123/SDE-GPG-ACL25

primarily focus on generating math word problems, with two main research lines: controllable generation and analogy generation (Liu et al., 2024). In controllable generation, problems are created based on parameters such as knowledge points (Wu et al., 2022a), grade (Qin et al., 2024), difficulty level (Jiao et al., 2023; Hwang and Utami, 2024), and more (Wang et al., 2021; Cao et al., 2022). In analogy generation, problems are generated by starting with a seed problem (Zhou et al., 2023; Norberg et al., 2023). Additionally, some research has focused on generating multi-modal math word problems (Liu et al., 2024). Recently, the educational value of generated math problems has gained significant attention, with studies examining factors like 'age-appropriateness' (Christ et al., 2024) and 'cone of experience' (Liu et al., 2024). However, despite these advancements, to the best of our knowledge, the generation of geometry problems remains unexplored. This paper presents a pioneering study on generating such problems.

2.2 Geometric Synthetic Data Augmentation

Our task is related to the field of geometry synthetic data augmentation, which is a promising direction for generating large amounts of high-quality data to train theorem provers and verifiers (Firoiu et al., 2021; Wang et al., 2023; Azerbayev et al., 2023; Yang et al., 2024). Early studies primarily focused on generating synthetic proofs for existing, human-curated problems (Polu et al., 2022; Lample et al., 2022). Recently, AlphaGeometry has made a notable contribution on end-to-end generating vast amounts of geometric reasoning data by using a symbolic deduction engine (SDE) and uses the data to train an LLM for problem solving (Trinh et al., 2024). Inspired by AlphaGeometry, we leverage the SDE framework to generate solvable geometry problems. The largest difference between these works and ours is that they are for data augmentation to train LLMs, while we should focus more on the problem quality and controllability for the purpose of educational significance.

2.3 Formal Language for Geometry

In the field of mathematics, various formal languages have been proposed for automated geometric theorem proving, such as Lean (De Moura et al., 2015; Moura and Ullrich, 2021), and several provers and reasoners have been developed using the languages like JGEX (Ida and Fleuriot, 2013), GEX (Chou et al., 2000) and LeanReasoner (Raffel et al., 2020). When using formal languages, theorems and proofs are typically encoded in a machine-verifiable format, and rigorous logical rules are applied to ensure the correctness of reasoning. However, fully automated provers still face challenges in autoformalization, which refers to the automatic conversion of informal language into machine-readable formal statements. Early approaches use neural machine translation to map LaTeX-formatted texts to formal languages (Wang et al., 2018; Bansal and Szegedy, 2020; Cunningham et al., 2023). Recently, LLMs and in-context learning (Brown et al., 2020) have expanded the possibilities in this area (Wu et al., 2022b; Agrawal et al., 2022; Gadgil et al., 2022; Murphy et al., 2024). Beyond translation-based methods, some structured frameworks have been introduced (Patel et al., 2023; Ying et al., 2024; Poiroux et al., 2024), while DSP (Jiang et al., 2022) and its variant (Zhao et al., 2024) leverage Minerva (Lewkowycz et al., 2022) to generate informal proofs that are later converted into formal proof sketches. Despite these advancements, autoformalization still struggles to achieve fully correct translation from natural language to formal language. It is notable that the translation from formal language to natural language and diagrams is generally error-tolerant and deterministic (Trinh et al., 2024), and we leverage the characteristics for our task.

3 Problem Definition

In this section, we present the problem definition. The terms and notations can be referred to Table 3 of the Appendix.

DEFINITION 1: Knowledge Point and Difficulty Degree. The geometric *knowledge points* refer to geometric theorems and properties, denoted as $\mathcal{K} = \{K_1, K_2, \ldots, K_{N_k}\}$. For example, K_1, which is $[\text{perp}\, a\, b\, c\, d, \text{perp}\, c\, d\, e\, f, \text{ncoll}\, a\, b\, e \Rightarrow \text{para}\, a\, b\, e\, f]$, means the parallel line determination theorem. The *difficulty degree* is set as three levels, i.e., Easy, Moderate and Difficult, in this paper.

DEFINITION 2: Premise, Conclusion and Definition. Each knowledge point K_i consists of a set of *premises* P_i and a *conclusion* C_i, denoted as $K_i = \{P_i, C_i\}$. For example, for K_1, we have $P_1 = \{\text{perp}\, a\, b\, c\, d, \text{perp}\, c\, d\, e\, f, \text{ncoll}\, a\, b\, e\}$ and $C_1 = \{\text{para}\, a\, b\, e\, f\}$. To start a symbolic deduction engine, the *definitions*, denoted as $\mathcal{D} = \{D_1, D_2, \ldots, D_{N_d}\}$, are essential to provide a

complete description of a geometry, while the $\mathcal{K}$ are selectively used for reasoning. The premises, conclusions, and definitions are all expressed in formal language.

DEFINITION 3: Knowledge Point-to-exDefinition Mapping Table (K2exD-MT). We define the combination of any definitions as *extended definitions* (exDefinition), denoted as $ex\mathcal{D} = \{f_{\text{minimal}}(\{D_i | \forall\, D_i \in \mathcal{D}\})\}$ where f_{minimal} performs pruning and union operations on multiple sets of definitions to obtain a minimal set. Since any exDefinition can serve as input for a symbolic deduction engine to potentially reach a conclusion, a one-to-many mapping table, called the Knowledge Point-to-exDefinition Mapping Table (K2exD-MT), can be constructed. Therefore, given any knowledge point, the exDefinitions can be obtained through a sampling function: $exD_i = f_{\text{sample}}(K_i, \text{K2exD-MT})$.

DEFINITION 4: Deduced Conclusion. Given several knowledge points and a set of sampled exDefinitions exD, different conclusions can be derived by an SDE through step-by-step reasoning. It is not guaranteed that a valid conclusion will always be reached, meaning that some combinations of knowledge points may not lead to a valid conclusion. We treat the *deduced conclusions* DC as the questions of the generated problem in formal language, which are obtained through two functions: $exd = f_{\text{minimal}}(exD)$ and $DC = f_{\text{engine}}(exd)$.

DEFINITION 5: Generated Textual Problem and Diagram. Given a set of exDefinitions exd, if a set of deduced conclusions DC is obtained through an SDE, the generated problems in natural language and their corresponding diagram can be derived using two translation functions: $GP_i^{(\text{text})} = f_{\text{text}}(exd, DC_i) = \{CL_i, Q_i\}$ and $GP^{(\text{diagram})} = f_{\text{diagram}}(exd)$, where CL_i and Q_i represent the clauses and the question of the ith generated textual problem, respectively.

DEFINITION 6: Geometry Problem Generation Task. Based on the above-mentioned Definitions 1-5, the task of geometry problem generation in this paper is formally defined as follows:

$$GP^{(\text{text})}, GP^{(\text{diagram})} = f(K, h, \text{K2exD-MT}, \text{SDE}), \quad (1)$$

where K is the set of knowledge points, h is the difficulty degree, K2exD-MT is the predefined knowledge point-to-exDefinition mapping table, and SDE refers to a symbolic deduction engine.

4 Method

In this section, we introduce the pipeline of proposed Symbolic Deduction Engine-based Geometry Problem Generation Framework (SDE-GPG), as shown in Figure 2.

4.1 Offline Construction of Knowledge Point-to-exDefinition Mapping Table

As shown in Figure 2, our framework relies on a Knowledge Point-to-exDefinition Mapping Table (K2exD-MT), which establishes the relationships between each knowledge point and multiple sets of formal exDefinitions. This way can help to avoid inherent biases in translation between natural and formal languages, which is often faced in solving geometry problems. Algorithm 1 (see Appendix) outlines the process for constructing the table.

In Algorithm 1, two repositories—definitions $\mathcal{D}$[3] and knowledge points $\mathcal{K}$[4]—are leveraged, where $N_d = 68$ and $N_k = 43$ are their quantities respectively. Given a symbolic deduction engine (SDE) and iteration times T, in each iteration, we first sample n definitions from $\mathcal{D}$ to obtain a new set $\hat{D}$. After performing pruning and union operations (f_{minimal}) on $\hat{D}$, a minimal set of definitions, $\hat{d}$, is obtained. Then, the reasoning function (f_{engine}) based on the SDE is executed to generate a set of conclusions DC. All knowledge points K_i used in the reasoning process are recorded, and a new mapping entry between K_i and $\hat{d}$ is added to the K2exD-MT iteratively. In our primary experiment, we set $n = 2$ and $T = 100,000$, and the distribution numbers of obtained exDefinition sets corresponding to each knowledge point are shown in Table 4 of the Appendix.

4.2 K2exD-MT Lookup, exDefinitions Sampling and Symbolic Deduction

Since the K2exD-MT has been constructed beforehand, during online process, the exDefinitions can be efficiently looked up on the table for each knowledge point. Then, the retrieved exDefinitions can be used to initiate the deduction. In contrast, randomly collecting input definitions from the original repository $\mathcal{D}$ would be inefficient, as the they may be completely unrelated to the given knowledge points. As a result, this method can ensure the

[4] https://github.com/google-deepmind/alphageometry/blob/main/rules.txt

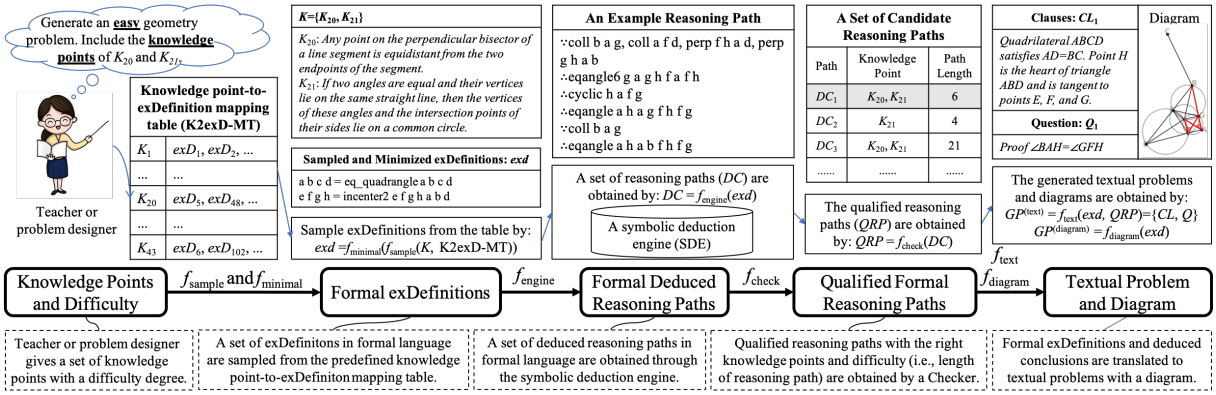

Figure 2: Pipeline of proposed Symbolic Deduction Engine-based Geometry Problem Generation Framework (SDE-PGP) with an example case.

proper correlation of the to-be-generated problems with each given knowledge point.

Lines 2-5 of Algorithm 2 (see Appendix) show the process of exDefinitions sampling by using K2exD-MT, while Line 7 represents the deduction process with an SDE. After obtaining the exDefinitions, the f_{minimal} operation is also performed (Line 6 of Algorithm 2) to obtain a minimal set of exDefinitions before deduction begins. For deduction, we leverage the symbolic engine proposed by AlphaGeometry, retaining all core components of deductive database, algebraic rules, traceback algorithms, and proof pruning (Trinh et al., 2024).

4.3 Problem Qualification Checking

Although the AlphaGeometry SDE supports the proof pruning, our task is to generate controllable and qualified problems, instead of just data augmentation without caring for the problem's quality. Therefore, an additional function for qualification checking should be developed. After obtaining candidate problems, based on control variables, unqualified problems would be filtered out, which means that the qualified reasoning paths should (1) be shortest paths, (2) involve all the required knowledge points (i.e., completeness of knowledge points), (3) involve all the exDefinitions to reach conclusions (i.e., completeness of clauses), and (4) be consistent with the given difficulty degree (i.e., consistency of difficulty) in terms of the length of paths. The checking function[5] is important to ensure the quality of generated problems by filtering out those reasoning paths that are not shortest or incomplete on required control variables.

[5]This is an engineering implementation to filter out qualified problems which meet the above four constraints.

4.4 Textual Problem and Diagram Generation

After obtaining qualified reasoning paths from the previous step, our framework can translate the formal exDefinitions and conclusions into textual problems and diagrams using functions f_{text} and f_{diagram}, respectively. Lines 8-14 in Algorithm 2 (see Appendix) describe the translation process.

For the translation of textual part, we use a series of predefined templates that can map formal expressions to their corresponding natural language representations, as the grammar of formal language is finite[6]. An example is shown in Figure 2. While the variety of language expressions can be further refined by any LLM, we leave it as a future work.

For the generation of diagrams, due to the specificity of geometry, we implement f_{diagram} as an iterative process that successively maps each exDefinition $\hat{exd}$ to a geometric diagram using a drawing tool[7]. These operations are executed sequentially to ensure geometric consistency with the given exDefinitions. For example, point constructions must precede line drawings, and angle markings can only be added once the relevant lines are drawn. The process continues until all geometric statements in $\hat{exd}$ are properly represented in the diagram. Admittedly, sometimes the generated diagrams do not totally align with human conventions, e.g., improper position of a point. A visual interface can be developed to support manual adjustment for users.

5 Experiment

In this section, we present the experimental results of our proposed method. Since there are few ex-

[6]All the templates can be published in a code repository.

Method	Readability			Solvability			Controllability	
	GF (1-5)	LC (1-5)	DC (1-5)	NS (0-1)	CS (1-5)	CC (0-1)	CKP (0-1)	CD (0-1)
GPT-4o	3.05	3.60	-	0.51	2.31	0.32	0.45	0.39
SDE-PGP w/o checking	3.44	3.61	**2.61**	0.72	2.51	0.53	0.53	0.40
SDE-PGP w/ checking	**4.25**	**4.65**	2.55	**1.00**	**3.55**	**1.00**	**0.62**	**0.63**

Table 1: Average scores for evaluating readability and solvability on JGEX-AG-231 dataset.

isting counterparts to serve as baselines and no ground truth available for evaluation, we perform human evaluations focusing on the aspects of readability, solvability and controllability.

5.1 Dataset

To address the above questions, we first prepare datasets where each sample should consist of real-world combinations of knowledge points. We curate two datasets of geometry problems in different languages manually. As known, random combinations of knowledge points may not deduce a conclusion. In real-world applications, problem designers are typically experts who are familiar with how to meaningfully combine the knowledge points.

- **JGEX-AG-231**[8]: The dataset consists of 231 plane geometry problems, offering a diverse range that includes textbook exercises, regional olympiads, and famous geometry theorems. Each problem in the dataset is associated with a set of knowledge points, with an average of 9.19 points per problem. For our experiment, we randomly sample fewer than five knowledge points from each problem to reduce complexity.
- **GeoQA**[9]: The dataset is sourced from authentic middle school exams in China, containing 5,010 geometric problems with detailed annotated solution programs. For our experiment, we randomly select 100 problems from the plane geometry subset, as the SDE we use supports only this topic. We annotate the knowledge points for each problem, with an average of 1.45 knowledge points per problem, indicating that the overall problem's complexity is lower than that in JGEX-AG-231.

5.2 Experimental Design

5.2.1 Measurement Metrics

Readability. The generated geometry problems should be humanly-readable, and the evaluation dimensions are as follows:

- Grammatical Fluency (GF): It assesses how grammatically clear and concise the language is, and whether there are any ambiguous or confusing expressions.
- Logical Correctness (LC): It evaluates the logical structure of the problem, ensuring information is presented in a coherent and orderly manner (e.g., a point should be introduced only after the corresponding line is drawn).
- Diagram Correctness (DC): It examines the logical consistency between the textual description and the diagram, and whether the diagram is easily interpretable by humans.

Solvability. The generated geometry problems and diagrams should be solvable, and all the relevant clauses should be incorporated. The evaluation dimensions include:

- Native Solvability (NS): Whether the generated problem can be solved.
- Consistent Solvability (CS): How well the textual content, the reference answer, and the diagram align to solve the problem, and whether the reasoning path is shortest.
- Completeness of Clauses (CC): Whether all clauses are utilized in solving the problem.

Controllability. The generated problems should support that all the required control variables, i.e., knowledge points and difficulty degree in this paper, are satisfied. The dimensions include:

- Completeness of Knowledge Points (CKP): Whether all the required knowledge points are involved in solving the problem.
- Consistency of Difficulty (CD): Whether the length of reasoning path is consistent with the required difficulty degree. We empirically set Easy for less than 10 steps, Moderate for between 10 and 20 steps, and Difficult for larger than 20 steps.

5.2.2 Measurement Method

For evaluating the metrics of readability, solvability and controllability, human annotation is conducted.

[8] https://www.scribd.com/document/742181523/jgex-ag-231

[9] https://github.com/chen-judge/GeoQA

Method	Readability			Solvability			Controllability	
	GF (1-5)	LC (1-5)	DC (1-5)	NS (0-1)	CS (1-5)	CC (0-1)	CKP (0-1)	CD (0-1)
GPT-4o	4.31	4.15	-	0.90	3.71	0.61	0.75	0.29
SDE-PGP w/o checking	4.18	4.43	2.75	0.89	3.50	0.75	0.82	0.36
SDE-PGP w/ checking	**4.53**	**4.54**	**3.50**	**0.96**	**3.96**	**0.82**	**0.94**	**0.47**

Table 2: Average scores for evaluating readability and solvability on GeoQA dataset.

We invite three experts with substantial experience in geometry problem design, two of whom serve as the initial judges and another one as the arbiter. When the results from the judges are inconsistent, the arbiter makes the final decision. We use two types of scoring: a discrete grading score ranging from 1 to 5 (orderly corresponding to poor, wrong, fair, good, perfect), and a binary score of 0 or 1 (0 is negative and 1 is positive). The grading score is used to measure GF, LC, DC, and CS, while the binary score is for NS, CC, CKP and CD. We report the average scores for both datasets, respectively.

We use GPT-4o[10] and SDE-PGP without checking as baselines, and write a prompt for the LLM to generate geometry problems (see Table 5 in Appendix). Note that current LLMs mostly cannot draw geometric diagrams. For each given input test sample, we generate only one problem and use it for evaluation, rather than generating multiple times to select the best one.

5.3 Results and Analysis

Results for Readability. From Table 1 and Table 2, we can see that the generated problems remain generally readable across both datasets. In particular, SDE-PGP w/ checking achieves the highest GF (General Fluency) and LC (Linguistic Clarity) on both datasets, indicating that introducing the checking function leads to more coherent and fluent texts. The DC scores may suggest that SDE-PGP w/o checking may generate easier problems, leading to drawing better diagrams.

Results for Solvability. From Table 1 and Table 2, several observations can be made regarding the metric of solvability: (1) SDE-PGP w/ checking achieves near-perfect Native Solvability (NS), with 1.00 on JGEX-AG-231 and 0.96 on GeoQA, indicating that almost all generated problems are solvable. (2) The Consistent Solvability (CS) score tends to be higher on GeoQA, possibly because the reduced number of knowledge points makes diagram construction and text–diagram consistency easier. (3) The completeness of clauses (CC) is sufficiently high for SDE-PGP w/ checking (1.00 on JGEX-AG-231 and 0.82 on GeoQA), though there remains room for enhancing clause generation in future improvement.

Results for Controllability. From Table 1 and Table 2, SDE-PGP w/ checking consistently achieves higher completeness of knowledge points (CKP) and consistency of difficulty (CD) than the baselines on both datasets, validating the effectiveness of the proposed checking function.

5.4 Case Study

We provide several representative examples to illustrate the strengths and limitations of our SDE-GPG framework. These examples highlight the framework's effectiveness in generating geometry problems that are readable, solvable, and controllable, as well as identifying areas where further improvement is needed. For detailed discussions and visual examples, please refer to Appendix A.

6 Conclusion

In this paper, we introduce a novel task of generating readable and solvable geometry problems under the constraint of control variables. To achieve this, we leverage a symbolic deduction engine and propose a new framework called the Symbolic Deduction Engine-based Geometry Problem Generation Framework (SDE-GPG). By creating a mapping table between knowledge points and definitions, our framework eliminates inherent biases in translating natural language into formal language. Our method highlights a checking function to guarantee the problem quality and controllability, as well as enabling the generation of multi-modal geometry problems. The thorough experiments demonstrate the effectiveness of our method on all the readability, solvability and controllability. In the future, situations that involve more control variables, such as context and problem type, and geometric topics, such as geometric inequalities and combinatorial geometry, could be further explored.

Appendix

A Case Study

As shown in Example 1, it demonstrates a geometry problem generated with our complete SDE-GPG framework, incorporating the checking function. From the perspective of readability, the textual description is clear, grammatically fluent, and logically coherent. The clauses introduce each geometric element sequentially, ensuring logical correctness and clarity. Regarding solvability, the reasoning path is explicit, shortest, and fully utilizes all clauses.

As presented in Example 2, it is generated without using our checking function. Although this problem still maintains decent readability and solvability, the textual description remains fluent, and the diagram clearly corresponds to the textual information, it notably lacks in controllability. Specifically, the generated problem is overly simplified, resulting in a very short reasoning path. Consequently, the actual difficulty is significantly lower than the predefined control variable. This highlights the essential role of our checking function in controlling and ensuring the complexity and completeness of generated geometry problems.

As shown in Example 3, it represents one of the occasional problematic outputs of our method. Despite having high readability in terms of grammar and logical structure, the generated problem suffers significantly from solvability issues. The main reason for this issue is the absence of certain intermediate theorems within the symbolic deduction engine. As a result, the system performs unnecessarily lengthy deductions for a conclusion that could ideally be derived in just a single step. This leads to a non-shortest reasoning path. To address this issue in future work, we plan to enrich our symbolic deduction engine with additional intermediate geometric theorems, further optimizing the efficiency of our geometry problem generation framework.

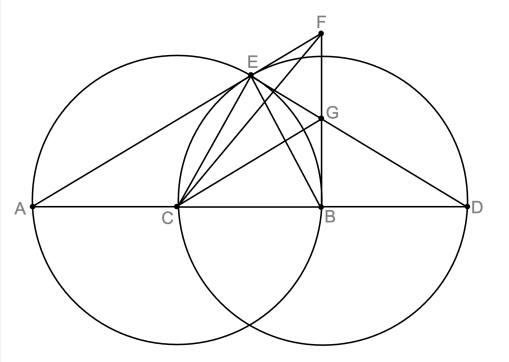
Example 4 illustrates an incorrect geometry problem generated by GPT-4o. This example highlights typical errors encountered when relying solely on LLMs for geometry problem generation, such as logical errors in the problem formulation, incorrect or impossible-to-solve scenarios, and the improper application of geometric theorems. Such issues underscore the importance of integrating symbolic deduction engines and rigorous checking mechanisms, as proposed by our SDE-GPG framework.

Example 1: An ideal geometry problem generated by SDE-GPG with checking.

Problem: Let points A, B define segment AB. Let point C be the midpoint of segment BA. Construct point D as the reflection of C about point B. Let point E lie on both the circle centered at C with radius CA, and the circle centered at B with radius BC. Construct point F such that $BF \perp AB$ and point F lies on line AE. Construct point G such that G lies on both line BF and line DE.
The following conditions hold:

- Points B, C, A are collinear, and $CB = CA$.
- Points B, C, D are collinear, and $BC = BD$.
- $CE = CA$, $BE = BC$.
- Points E, F, A are collinear.
- $BF \perp AB$.
- Points E, G, D are collinear, and points F, B, G are collinear.

Prove: The angle formed between lines AE and BF equals the angle formed between lines DE and CG.



Proof Steps:

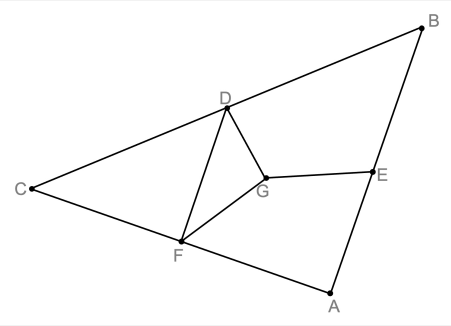
(1) $CE = CA,\ CB = CA \implies C$ is the circumcenter of $\triangle BEA$.
(2) C is circumcenter of $\triangle BEA,\ B, C, A$ collinear $\implies BE \perp AE$.
(3) $BC = BD,\ \angle DBG = \angle GBC \implies \angle BDG = \angle GCB$.
(4) $BC = BD,\ BE = BC \implies BE = BD$.
(5) $BE = BD \implies \angle BED = \angle EDB$.
(6) G, D, E collinear, B, C, D collinear, B, C, A collinear, $\angle BDG = \angle GCB$, $\angle BED = \angle EDB$
$\implies \angle BEG = \angle$(line BD, line GC).
(7) $\angle FEB = \angle FBD$, $\angle BEG = \angle$(line BD, line GC) $\implies \angle FEG = \angle$(line FB, line GC).
(8) $\angle FEG = \angle$(line FB, line GC), E, F, A collinear, E, G, D collinear
$\implies \angle(AE, BF) = \angle(DE, CG)$.

Thus, the proof is completed:

$$\angle(AE, BF) = \angle(DE, CG)$$

Example 2: A geometry problem generated by SDE-GPG without checking.

Problem: Construct a triangle $\triangle ABC$. Let points D, E, F be the midpoints of segments CB, AB, AC, respectively. Point G is positioned such that distances from G to points D, E, F are all equal. Prove that the angle formed by line DG and side AB is equal to the angle formed by side AB and line FG.



Proof Steps:

(1) $GD = GF \implies \angle GDF = \angle DFG$.

(2) F is the midpoint of AC, D is the midpoint of $BC \implies FD \parallel AB$.

(3) $\angle GDF = \angle DFG$, $FD \parallel AB \implies \angle(DG, AB) = \angle(AB, FG)$.

Thus, the proof is completed:

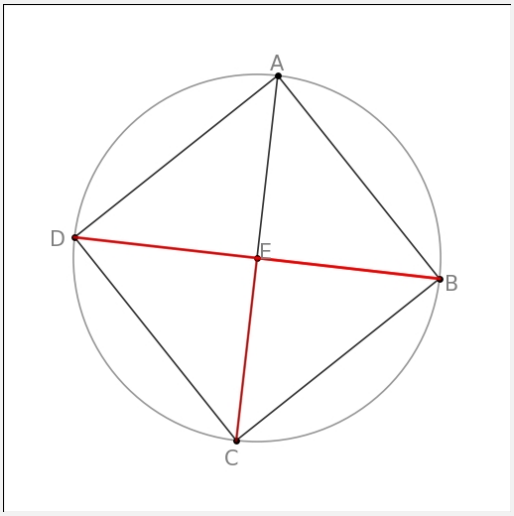
$$\angle(DG, AB) = \angle(AB, FG)$$

Example 3: A problematic geometry problem generated due to missing intermediate theorems.

Problem:

Construct a square $ABCD$. Let point E be the intersection point of diagonals CA and BD. Prove:

$$\frac{BE}{BD} = \frac{CE}{BD}$$



Proof Steps:

(1) $AD \parallel BC,\ B, D, E$ are collinear, C, A, E are collinear $\implies \dfrac{BE}{BD} = \dfrac{CE}{CA}$.

(2) $AB \perp BC,\ AB \parallel CD \implies BC \perp CD$.

(3) $AB \perp BC,\ BC \parallel AD \implies DA \perp AB$.

(4) $AB \perp BC,\ BC \perp CD,\ DA \perp AB \implies AC = BD$.

(5) $\dfrac{BE}{BD} = \dfrac{CE}{CA},\ AC = BD \implies \dfrac{BE}{BD} = \dfrac{CE}{BD}$.

Thus, the proof is completed:

$$\frac{BE}{BD} = \frac{CE}{BD}$$

Example 4: A geometry problem generated by GPT-4o demonstrating inaccuracies.

Problem:
Given triangles $\triangle ABC$ and $\triangle DEF$, with $AB = DE$, $AC = DF$, and $\angle BAC = \angle EDF$:
(1) Prove that $\triangle ABC \cong \triangle DEF$.
(2) If $BC = 8$, $AB = 6$, and $\angle EDF = 60°$, find the perimeter of $\triangle DEF$.

Proof Steps:
(1) Proving $\triangle ABC \cong \triangle DEF$:
According to the given conditions:

- $AB = DE$ (corresponding sides are equal),
- $AC = DF$ (corresponding sides are equal),
- $\angle BAC = \angle EDF$ (included angles are equal).

By the congruence criterion (**SAS Criterion**), triangles having two corresponding sides and their included angles equal are congruent. Thus, we have:

$$\triangle ABC \cong \triangle DEF.$$

(2) Finding the perimeter of $\triangle DEF$:
Since $\triangle ABC \cong \triangle DEF$, the corresponding sides of these two triangles are equal, thus $BC = EF$.
Given:

$$BC = 8, \quad AB = 6, \quad DE = AB = 6.$$

Also, by congruence properties:

$$AC = DF = 6.$$

Therefore, the side lengths of $\triangle DEF$ are:

$$DE = 6, \quad DF = 6, \quad EF = 8.$$

The perimeter of $\triangle DEF$ is:

$$DE + DF + EF = 6 + 6 + 8 = 20.$$

Answer:
(1) $\triangle ABC \cong \triangle DEF$;
(2) The perimeter of $\triangle DEF$ is 20.

B Detailed Information about SDE-GPG

Algorithm 1: Constructing the knowledge point-to-exDefinition mapping table (K2exD-MT)

Input: The repository of definitions $\mathcal{D}$, the repository of knowledge points $\mathcal{K}$, the SDE, the iteration times T

Output: K2exD-MT

K2exD-MT={}, t=1;
while $t < T$ **do**
  Sample an integer $n \in \{1, N_d\}$ and sample n definitions from $\mathcal{D}$ to construct a new set $\hat{D}$;
  $\hat{d} = f_{\text{minimal}}(\hat{D})$;
  $DC = f_{\text{engine}}(\hat{d})$;
  Record all the knowledge points $\{K_i\}$ used along with the reasoning paths from $\hat{d}$ to any DC_i;
  foreach $K_i \in \{K_i\}$ **do**
    Insert one mapping of $[K_i \rightarrow \hat{d}]$ into K2exD-MT;
  end
  t=t+1;
end
return K2exD-MT.

Algorithm 2: Generating geometry problems

Input: A set of knowledge points $\hat{K}$, a difficulty degree h, the K2exD-MT, the SDE

Output: $GP^{(\text{text})}$, $GP^{(\text{diagram})}$

$GP^{(\text{text})} = \{\}$, $GP^{(\text{diagram})} = \{\}$, $\hat{exD} = \{\}$;
foreach $K_i \in \hat{K}$ **do**
  $exD_i = f_{\text{sample}}(K_i, \text{K2exD-MT})$;
  $\hat{exD} = \hat{exD} + \{exD_i\}$;
end
$\hat{exd} = f_{\text{minimal}}(\hat{exD})$;
$\hat{QRP} = f_{\text{check}}(f_{\text{engine}}(\hat{exd}))$;
if $\hat{QRP} \neq \{\}$ **then**
  $GP^{(\text{diagram})} = \{f_{\text{diagram}}\{\hat{exd}\}\}$;
  foreach $QRP_i \in \hat{QRP}$ **do**
    $GP_i^{(\text{text})} = f_{\text{text}}\{\hat{exd}, QRP_i\}$;
    $GP^{(\text{text})} = GP^{(\text{text})} + \{GP_i^{(\text{text})}\}$;
  end
end
return $GP^{(\text{text})}$ and $GP^{(\text{diagram})}$.

Term	Notation	Description
Clauses	CL	The clauses of a textual problem.
Question	Q	The question of a textual problem.
Textual Problem	$\{CL, Q\}$	A paragraph of problem description including clauses and a question.
Diagram	-	A corresponding geometric diagram for a textual problem.
Knowledge points	$\mathcal{K}$	A control variable that corresponds to geometric rules, including theorems and properties. The scope is finite.
The number of knowledge points	N_k	The number of knowledge points in an existing repository.
Difficulty Degree	h	A control variable where its scope is empirically set as Easy for less than 10 reasoning steps, Moderate for 10 to 20 steps, and Difficulty for larger than 20 steps.
Premises	P	The part of clauses of a knowledge point in formal language.
Conclusion	C	The part of conclusion of a knowledge point in formal language.
Definitions	$\mathcal{D}$	A set of complete formal descriptions of geometry to start deduction on a symbolic deduction engine.
The number of definitions	N_d	The number of definitions in an existing repository.
Extended Definitions (exDefinitions)	$ex\mathcal{D}$	A repository including all the combination of any definitions.
Knowledge Point-to-exDefinition Mapping Table	K2exD-MT	A mapping table between knowledge points to exDefinitions.
Deduced Conclusion	DC	A conclusion deduced by using a symbolic deduction engine given a set of extended definitions.
Qualified Reasoning Path	QRP	Qualified reasoning paths by using a checking function to ensure the quality and controllability.
Symbolic Deduction Engine	SDE	An engine which can automatically deduce by inputting some definitions in specific formal language.
Generated Textual Problem	$GP^{(\text{text})}$	A set of textual problems generated by SDE-GPG.
Generated Diagram	$GP^{(\text{diagram})}$	A geometric diagram generated by SDE-GPG.
Sample Function	f_{sample}	A function to sample a set of exDefinitions from K2exD-MT by given a knowledge point.
Minimal Function	f_{minimal}	A function to perform pruning and union operations on multiple sets of definitions or exDefinitions to obtain a minimal set.
Engine Function	f_{engine}	A function to deduce reasoning paths from given definitions or exDefinitions to a set of deduced conclusions, including core components of Deductive Database (DD), Algebraic Rules (AR), traceback algorithms, and proof pruning.
Checking Function	f_{check}	A function to filter out unqualified reasoning paths based on given control variables.
Text Function	f_{text}	A function to translate exDefinitions and deduced conclusions from formal language to natural language.
Diagram Function	f_{diagram}	A function to translate geometric exDefinitions to a diagram.

Table 3: Description of terms and notations used in this paper.

ID	Knowledge Point Code	Description	No. of exDefinition Sets
K_1	eqangle6_eqangle6_ncoll_cong_contri2	If two triangles have two angles and the corresponding non-included side equal, then the two triangles are congruent.	10,435
K_2	eqratio6_eqratio6_ncoll_simtri*	If two triangles have their corresponding sides in proportion and the included angle equal, then the two triangles are similar.	13,232
K_3	cong_cong_eqangle6_ncoll_contri*	If two triangles have two sides and the included angle equal, then the two triangles are congruent.	12,108
K_4	eqratio6_eqratio6_ncoll_cong_contri*	If the segments $BA : BC = QP : QR$ and $CA : CB = RP : RQ$, and points A, B, and C are not collinear, and $AB = PQ$, then $\angle ABC$ and $\angle PQR$ are congruent.	12,108
K_5	eqratio6_eqangle6_ncoll_simtri*	If two triangles have their corresponding sides in proportion and the included angle equal, then the two triangles are similar.	13,232
K_6	eqangle6_eqangle6_ncoll_simtri2	If two triangles have their corresponding angles equal, then the two triangles are similar.	10,948
K_7	eqangle6_ncoll_cong	If two angles of a triangle are equal, then the triangle is an isosceles triangle.	8,681
K_8	cong_ncoll_eqangle	In an isosceles triangle, the base angles are equal.	8,681
K_9	cong_cong_cong_ncoll_contri*	If two triangles have their corresponding three sides equal, then the two triangles are congruent.	12,108
K_{10}	eqangle6_eqangle6_ncoll_simtri	If two triangles have their corresponding two angles equal, then the two triangles are similar.	10,205
K_{11}	eqangle6_eqangle6_ncoll_cong_contri	If two triangles have their corresponding two angles and the included side equal, then the two triangles are congruent.	8,613
K_{12}	eqangle_eqangle_eqangle	If the angles between two pairs of lines are equal, then the angles between these two pairs of lines are transitive.	20,644
K_{13}	eqangle_perp_perp	If the angle between AB and PQ is equal to the angle between CD and UV, and PQ is perpendicular to UV, then AB is perpendicular to CD.	26,733

K_{14}	circle_eqangle_perp	If O is the circumcenter of triangle ABC and $\angle BAX = \angle BCA$, then OA is perpendicular to AX.	2,705
K_{15}	cong_cong_cyclic_perp	If $AP = BP$, $AQ = BQ$, and quadrilateral $ABPQ$ is cyclic, then PA is perpendicular to AQ.	3,170
K_{16}	cyclic_eqangle_cong	In the same circle, if two inscribed angles are equal, then the chords subtended by these angles are equal.	8,289
K_{17}	perp_perp_npara_eqangle	If two lines are perpendicular to two other lines, and these two lines are not parallel, then the angles between them are equal.	19,540
K_{18}	cong_cong_perp	If a point is equidistant from the two endpoints of a line segment, then the point lies on the perpendicular bisector of the line segment.	5,372
K_{19}	circle_perp_eqangle	If O is the circumcenter of triangle ABC and OA is perpendicular to AX, then $\angle BAX = \angle BCA$.	2,705
K_{20}	cyclic_eqangle	In the same circle, inscribed angles subtended by the same arc or equal arcs are equal.	8,289
K_{21}	eqangle6_ncoll_cyclic	If two angles are equal and their vertices lie on the same straight line, then the vertices of these angles and the intersection points of their sides lie on a common circle.	8,289
K_{22}	eqratio_coll_coll_ncoll_sameside_para	If $OA : AC = OB : BD$, and O, A, C are collinear, O, B, D are collinear, A, B, C are not collinear, and A, O, C and B, O, D are on the same side, then AB is parallel to CD.	913
K_{23}	para_coll	If two lines are parallel, they have no common points unless they are the same line.	7,421
K_{24}	para_coll_coll_eqratio3	If two parallel lines are intersected by two transversal lines, then the corresponding line segments formed are proportional.	1,013
K_{25}	midp_midp_para_1	The midline of a triangle is parallel to the third side.	570
K_{26}	eqratio_eqratio_eqratio	If two proportions are equal and their middle terms are also equal, then other proportional relationships can be proved by the transitivity of proportions.	2,728

K_{27}	eqangle_para	If two lines are intersected by a third line and the alternate interior angles are equal, then the two lines are parallel.	2,682
K_{28}	cyclic_para_eqangle	If quadrilateral $ABCD$ is cyclic and AB is parallel to CD, then $\angle ADC = \angle BCD$.	6,216
K_{29}	eqratio6_coll_ncoll_eqangle6	If the ratio of the distances from a point to two sides of a triangle is equal to the ratio of those two sides, then the point lies on the angle bisector.	2,170
K_{30}	eqangle6_coll_ncoll_eqratio6	If a point lies on the angle bisector of a triangle, then the ratio of its distances to the two sides of the triangle is equal to the ratio of those two sides.	2,169
K_{31}	circle_coll_perp	In a circle, the inscribed angle subtended by the diameter is a right angle.	1,453
K_{32}	perp_midp_cong	In a right-angled triangle, the median to the hypotenuse is half the length of the hypotenuse.	1,451
K_{33}	eqratio_cong_cong	If two proportions are equal, and one pair of corresponding line segments are equal, then the other pair of corresponding line segments are also equal.	464
K_{34}	para_coll_coll_para_eqratio6	If AB is parallel to CD, M, A, D are collinear, N, B, C are collinear, and MN is parallel to AB, then $MA : MD = NB : NC$.	233
K_{35}	midp_midp_eqratio	If a point is the midpoint of a line segment, then it divides the segment into two equal parts.	257
K_{36}	midp_perp_cong	Any point on the perpendicular bisector of a line segment is equidistant from the two endpoints of the segment.	1,805
K_{37}	perp_perp_ncoll_para	If two lines are both perpendicular to the same line, then these two lines are parallel.	278
K_{38}	para_coll_coll_eqratio6_sameside_para	If AB is parallel to CD, M, A, D are collinear, N, B, C are collinear, $MA : MD = NB : NC$, and M, A, D and N, B, C are on the same side, then MN is parallel to AB.	234

K_{39}	cong_cong_cong_cyclic	If a point is equidistant from the four vertices of a quadrilateral, then the four vertices of the quadrilateral lie on a common circle.	466
K_{40}	circle_coll_eqangle_midp	If O is the circumcenter of triangle ABC, M, B, C are collinear, and $\angle BAC = \angle BOM$, then M is the midpoint of BC.	190
K_{41}	circle_midp_eqangle	If O is the circumcenter of triangle ABC and M is the midpoint of BC, then $\angle BAC = \angle BOM$.	192
K_{42}	midp_midp_para_2	If M is the midpoint of AB and also the midpoint of CD, then AC is parallel to BD.	329
K_{43}	midp_para_para_midp	In a parallelogram, the diagonals bisect each other.	327

Table 4: Statistics of the knowledge point-to-definition mapping table (K2exD-MT). The knowledge point codes (or rule codes) follow the settings of AlphaGeometry. The detailed table data including the expressions in formal language will be published in a public code repository.

Please generate a high-quality question based on the following knowledge point:
Knowledge Point: <content>
Make sure the generated question meets the following requirements:
1. Accurately reflects the specified knowledge point and assesses the student's understanding and ability to apply it
2. The wording of the question should be clear and unambiguous, conforming to academic standards
3. The difficulty level should be moderate, with a certain degree of thinking value and differentiation
4. The question should include a clear problem-solving approach and a standard answer
The content should be original and avoid using common examples or exercises
Please output in the following format:
Question
(Provide the full description of the question here)
Explanation
(Provide a detailed solution process and answer explanation here)

TABLECODER: Table Extraction from Text via Reliable Code Generation

Haoyu Dong, Yue Hu, Huailiang Peng*, Yanan Cao
Institute of Information Engineering, Chinese Academy of Sciences
School of Cyber Security, University of Chinese Academy of Sciences

Abstract

This paper introduces a task aimed at extracting structured tables from text using natural language (NL) instructions. We present TABLECODER, an approach that leverages the symbolic nature of code to enhance the robustness of table structure construction and content extraction. TABLECODER first generates Python classes or SQL statements to explicitly construct table structures, capturing semantic ontology, computational dependencies, numerical properties, and format strings. This approach reliably mitigates issues such as structural errors, erroneous computations, and mismatched value types. Subsequently, TABLECODER proposes grounded content extraction, populating table cells sequentially and maintaining the exact order in which they are mentioned in the source text. By simulating a grounded "translation" from text to code, this method reduces the likelihood of omissions and hallucinations.

Experimental results demonstrate that TABLECODER significantly improves F1 scores and mitigates hallucination and computational errors, crucial for high-stakes applications like government data analytics and financial compliance reporting. Moreover, the code-generation-based method naturally integrates with standard SQL databases and Python workflows, ensuring seamless deployment in existing enterprise data pipelines.

1 Introduction

Structured table extraction from unstructured text is critical for automating data processing tasks across industries such as finance, government, and healthcare, where accuracy and reliability are paramount. As illustrated in Figure 1, relational tables enable automated processing and analysis through tools like SQL or Pandas, whereas hierarchical tables (Cheng et al., 2022a) intuitively present complex statistical data in government or financial reports. Considering that table extraction naturally involves diverse demands regarding "what information to extract" and "how to structure it," controllable table extraction tailored by NL user instructions is highly desirable for real-world deployments.

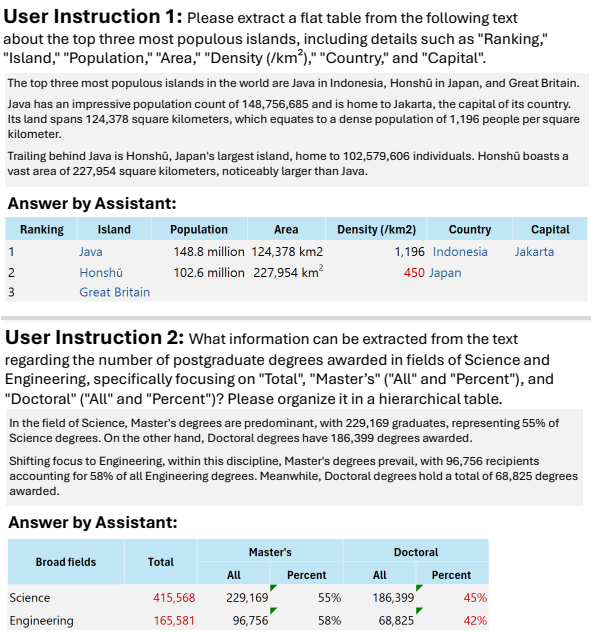

Figure 1: Examples of NL-TO-TABLE. Table schemas are flexibly defined by user instructions. Cells necessitating computation are highlighted in red.

Pioneering works (Wu et al., 2022; Li et al., 2023b; Pietruszka et al., 2022; Jiao et al., 2023; Jain et al., 2024; Tang et al., 2023) have extracted tables from text. However, they neglect user intent and fail to tailor table structures for users, resulting in key-value pairs or simple relational tuples. Additionally, Reversing a "table-to-text" dataset to construct a "text-to-table" dataset may results in data quality issues. It includes excessive, missing, or unextractable cells, such as extracting "127,955 million" from text stating roughly "128.0 billion".

To address these challenges, we introduce NL-TO-TABLE, a human-labeled dataset for table extraction following NL instructions. Key features include: (1) We include a rigorous quality-control pipeline where human annotators carefully address issues like excessive, missing, or unextractable cells to guarantee dataset quality. (2) We perform fine-grained anno-

July 28-30, 2025

tations on ontology trees for semantic relationships, formulas for computational dependencies, and units and feasible ranges for numerical values. (3) NL-TO-TABLE introduces numerical reasoning as a key aspect of table extraction, which is in high demand in the financial and government domains, as illustrated in Figure 1—with red highlights. (4) Due to the equivalence of identical quantities expressed in various formats (Jiao et al., 2023), we annotate number format strings to facilitate automatic evaluation.

SQL and Python provide a robust framework for generating structured data, so we propose TABLECODER, a novel method to generate code that unravels the complexities involved in structure construction, data extraction, numerical computation, and number format representation. (1) TABLECODER employs Python classes and SQL `CREATE` statements to construct a comprehensive table structure with ontology trees, computational relationships, number units, feasible ranges, and number format strings. It facilitates a symbolic and reliable extraction process by defining cell placement, type and range validation, and automatic number computation. (2) TABLECODER extracts table contents in the order they appear in the source text, emulating a step-by-step "translation" from text to code to minimize omissions and hallucinations often caused by LLMs.

Existing automatic evaluation methods are challenged by different format expressions of the same content. To address this, we propose the Format Agnostic Evaluation (FORMATAGNOSTIC-EVAL) for automatic evaluation of table extraction. Experimental results show that FORMATAGNOSTIC-EVAL improves existing metrics, making them much closer to human evaluators' assessments. Notably, fine-tuned LLaMA-70B with the NL-TO-TABLE dataset remarkably mitigates hallucination and computational errors, outperforming few-shot GPT-4 by 11.4% to 19.2%, and fine-tuned Mistral-7B even outperforms GPT-4 by 5.7% to 12.3%.

We wrapped up TABLECODER as an API and deployed it on a server, enabling the storage of extracted tables using `openpyxl` [1].

2 Preliminaries

2.1 Task Formulation

The task is to extract a table from unstructured text, given human utterance to specify the table structure. The purpose of providing NL instructions as inputs is to meet specific and diverse user requirements concerning the structure of tables. Importantly, conditioning on NL instructions significantly reduces evaluation ambiguity associated with various potential structures (Jiao et al., 2023), such as opting for dual columns labeled "First name" and "Last name" as opposed to an alternative single "Name" column.

2.2 Semantic and Computational Relationships

Semantic Relationship Semantic relationships can be explicit hierarchies that are indicated by specific formats, such as merged cells (Wang et al., 2021; Cheng et al., 2022a), or implicit functional dependencies (Nan et al., 2020), as seen in the first example of Figure 1. Following both the explicit hierarchy (Cheng et al., 2022a) and implicit ontology (Nan et al., 2020), we identify the parent of each column header to construct a tree-structured ontology for each table, as illustrated in Figure 4 in the Appendix.

Computational Relationship A column may be derived from other columns via computations, as highlighted in Figure 4. They are implicit and require human reasoning, while only spreadsheets may have explicit formulas.

2.3 Python and SQL for Table Generation

Existing works on LLMs for tabular data commonly use Markdown, HTML, LaTeX, or variants to encode tables, which are studied by (Singha et al., 2023; Sui et al., 2024). In this paper, we propose to leverage code for table generation.

SQL provides a robust framework for generating structured data. By using `CREATE` statements, users define tables with explicit schemas, ensuring that data is consistently structured and easy to query. This is crucial for LLM-based generation, which can produce corrupted tables with row or column misalignment. `INSERT` and `UPDATE` operations can add new data to existing tables in arbitrary orders without disrupting the overall structure. This kind of incremental data generation is essential for keeping the extracted table integral and up-to-date when processing long and complex unstructured text.

On the other hand, SQL's common practices may limit its flexibility for hierarchical tables. Python's inherent object-oriented paradigm is able to encode complex structured tables, and it facilitates automated data computations, e.g., `_update_density` in Program 1. However, despite LLMs' proficiency in Python (Li et al., 2023a), they are not fully proficient in generating hierarchical tables.

Table 1: Dataset statistics of NL-TO-TABLE.

Labeled Data	Wikipedia	Statistical Reports
# User instructions	5,241	836
# Tokens in instruction	60.2	67.5
# Tables	5,241	836
# Mentioned columns	26,501	3,475
# Mentioned rows	38,572	2,510
# Mentioned cells	60,779	4,115
# Sentences in Text	31,802	3,012
% Complex ontology trees	48.1%	100.0%
% Number format cells	24.4%	74.5%
% Computed cells	1.9%	7.8%

2.4 Evaluation Metrics

We use Exact Match (EM), BERTScore (BERT), and Chrf metrics (Wu et al., 2022) to assess F1 scores, as detailed in Appendix B. But they are challenged by the flexible and equivalent formatting rules found in tables, e.g., "1.4 thousand dollars" and "$1,400", so we annotate the format string for each column consisting of quantities, e.g., f"{self.total:,.1f} thousand dollars". Thus, during the evaluation phase, we format quantities using the human-labeled format strings before comparing them with ground truth contents, enabling FORMATAGNOSTIC-EVAL. To cover all variations of format strings in our dataset, we first collected 58 built-in formats from Excel under categories like "Number," "Currency," "Accounting," "Date," "Percentage," etc. In addition, we labeled another 84 format strings that appeared in our dataset and produced 142 strings.

3 NL-TO-TABLE

We construct NL-TO-TABLE from Wikipedia articles (ToTTo (Parikh et al., 2020)) and statistical reports (HiTab (Cheng et al., 2022a)). Each dataset is rich in tables accompanied by corresponding textual descriptions, with highlighted cells linked to descriptive sentences. We only include tables that have at least four sentences and four mentioned cells. There are 5,241 tables from Wikipedia and 836 tables from statistical reports. Together, the two datasets present a comprehensive collection that spans various table structures.

We have designed a six-step annotation process to construct the first human-labeled dataset for generally structured table extraction following NL instructions, comprising a substantial amount of complex reasoning and fine-grained structure annotations, detailed in Appendix A.

As Table 1 shows, 48.1% of Wikipedia tables and 100.0% of statistical tables feature ontology trees with more than two layers. A significant portion (74.5%) of cells in statistical reports are quantities, and computed cells account for 7.8%, encompassing various types, including SUM (45.2%), AVG (5.6%), DIV (21.9%), DIFF (15.6%), and ADD (5.4%).

4 TABLECODER

Existing approaches commonly use Markdown, HTML, or their variants to encode tables for LLMs (Singha et al., 2023; Sui et al., 2024; Dong and Wang, 2024), as well as efficient JSON encoding (Dong et al., 2024). Unfortunately, when the task is table generation, they may produce structural corruption, row or column misalignment, erroneous value computation, missing or excessive information, etc. As depicted in Figure 2, TABLECODER first uses SQL or Python code to construct the table structure. It then extracts table contents following the order in the input text.

4.1 Symbolic Structure Construction

TABLECODER leverages LLMs to generate code to build the table, so that the generated results are ensured to be well structured, and inherent semantic/computational column relationships are explicitly reflected. Additionally, type constraints and computational dependencies can also be predefined to avoid obvious errors and inconsistent units in the following content extraction phase.

4.1.1 Type and range constraints

In SQL, value type and range constraints are well supported through `CREATE`, which is quite concise and useful. As shown in Program 2, properties of the column "Ranking" can be simply specified using "INT CHECK (Ranking > 0)".

4.1.2 Semantic dependencies

In SQL, we use the column corresponding to the root of the ontology tree as the primary key, with other columns as attributes. For tables featuring hierarchical ontology trees, generating multiple tables with SQL represents a promising direction for future work. Instead, we leverage Python's flexible object-oriented paradigm to encode both flat and hierarchical ontology trees in a unified manner. As shown in Program 1, we define classes for all parent nodes in the ontology tree, with dependencies established among multiple classes.

4.1.3 Computational dependencies

LLMs have difficulty reliably calculating numbers without an explicit executor (Gao et al., 2023b; Chen et al., 2022; Zhou et al., 2022). Fortunately, Program 1 showcases an example that "_update_density"

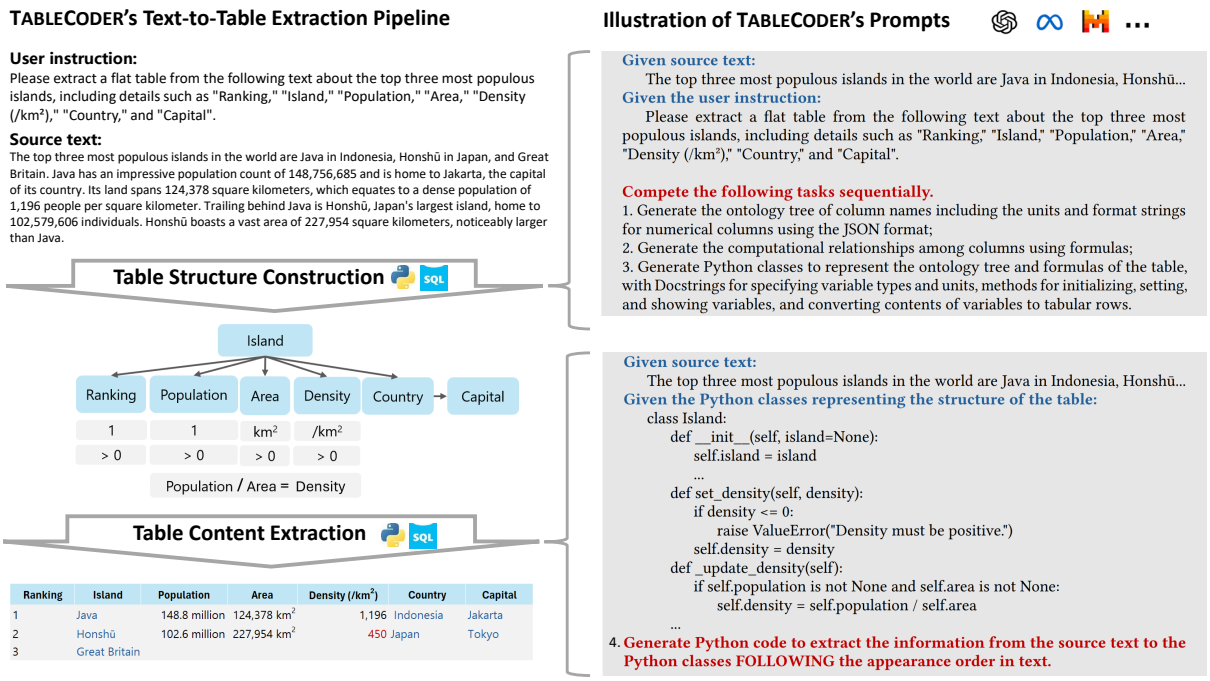

Figure 2: Architecture of TABLECODER. The left side illustrates a chain-of-thought pipeline of table extraction. The right side illustrates the prompt for LLMs, which is streamlined with four steps in a single run.

in TABLECODER automatically triggers a symbolic execution when "area" and "population" are set with values. As long as inherent computational relationships are discovered, TABLECODER generates methods like "_update_density" to ensure all derived cells are accurately calculated. This mechanism can also be implemented in SQL through `TRIGGER`.

4.1.4 Format application

Program 1 shows the example of the Python implementation. A "convert_to_tabular_row" method serializes each instance to a tabular row following user-specified column orders. Note that format strings are replaced with ground truth format strings during our format-agnostic evaluation.

```python
class Country:
    ...
class Island:
    def __init__(self, island=None):
        ...
        self.area = None
        self.density = None
        self.country = Country()
    ...
    def set_density(self, density):
        if density <= 0:
            raise ValueError("density must be positive.")
        self.density = density
    def _update_density(self):
        if self.population is not None and self.area is not
            None:
            self.density = self.population / self.area
    def convert_to_tabular_row(self):
        return [
            self.show_ranking(), self.show_island(),
            f"{self.show_population() / 1_000_000:,.1f}
                million" if self.show_population() else None
                , ...
        ]
```

Program 1: Python for structure construction.

```sql
CREATE TABLE islands (
    Ranking INT CHECK (Ranking > 0),
    Island VARCHAR(255),
    Population BIGINT CHECK (Population > 0),
    Area BIGINT CHECK (Area > 0),
    Density DECIMAL(10, 2) CHECK (Density > 0),
    Country VARCHAR(255),
    Capital VARCHAR(255)
);

CREATE TRIGGER compute_density
BEFORE INSERT OR UPDATE ON islands

FOR EACH ROW
BEGIN
    IF NEW.Population IS NOT NULL AND NEW.Area IS NOT NULL
        THEN
        SET NEW.Density = NEW.Population / NEW.Area;
    END IF;
END;
```

Program 2: SQL for structure construction.

4.2 Grounded Content Extraction

Based on the constructed table structure, TABLECODER generates SQL statements or instantiates Python classes to establish infilling of tabular data.

As demonstrated in Figure 2, previous works sequentially generate "450" and the country name "Japan" due to their adjacency in the table's surface-level presentation (Wu et al., 2022; Li et al., 2023b; Pietruszka et al., 2022). However, these elements are significantly distant in the source text, appearing in the first and last sentences, respectively. This surface-level generation often disrupts logical coherence, leading to missing or hallucinated cell values.

As illustrated in Figure 3, we guide LLMs to extract table contents through symbolic and incremental code generation that strictly adheres to their order within the source text. For all i and j, if $i < j$, then T_i precedes T_j in the generated table, where T_i represents the content of the i-th cell in the original text, and $i < j$ means that cell i appears before cell

j in the original text. Composite quantities are generated right after the appearance of the last operand in the text. This method minimizes omissions and inconsistencies in the extraction process.

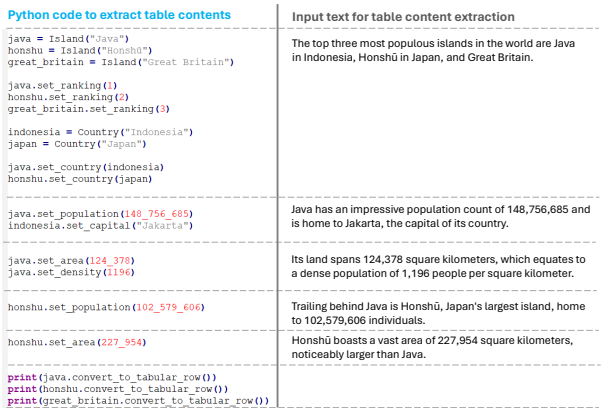

Figure 3: An example to illustrate Python code generation for content extraction, grounded to their order within the source text to avoid frequent jumps in the logical flow.

5 Experiments

We examine the performance of TABLECODER based on open-source models such as Mistral-v2 (7B-Instruct-v0.2), LLaMA-2-7B, and LLaMA-2-70B-Instruct (Touvron et al., 2023), and closed-source GPT-3.5 (text-davinci-003) and GPT-4 (the 20230613 4k version) (Brown et al., 2020; OpenAI, 2023). Additionally, we evaluate SOTA baselines, such as the ODIE-DORECT method based on LLaMA-7B (Jiao et al., 2023) and Text-to-Table based on BART-Large (Lewis et al., 2019), and both are fine-tuned using NL-TO-TABLE. We present experiment results in three encoding settings: Markdown (MD) (Singha et al., 2023; Sui et al., 2024) and code (SQL and Python as introduced in Section 4). Ablation studies include:

w/o semantic dependencies The root column is designated as the primary key; others are attributes.

w/o computational dependencies Code for automatic value computation like "_update_density" is removed, but explicit computation is still allowed, e.g., "Honshu.set_density (102579606/227954)".

w/o type and range checking in code

w/o ordered and grounded cell infilling The table is generated row-by-row sequentially.

We experiment with two settings: (1) Few-shot setting: LLMs take the same six-shot examples. Few-shot examples are randomly sampled three times, and the average is used as the final result. (2) Fine-tuning setting: We use all labeled training samples for fine-tuning.

5.1 Implementation details

The text to be extracted is provided as a list of sentences. In markdown, we use "|" to separate cells in a row, and we flatten multiple header rows in our datasets if there are hierarchical headers to meet the markdown requirement. We fine-tune all parameters in BART-Large and partial parameters in LLaMA, and Mistral using LoRA (Hu et al., 2021). Fine-tuning takes 10 epochs for LLaMA and Mistral. For open source models set $lora\_rank$ to 32, $lora\_alpha$ to 64, and $lora\_dropout$ to 0.01 for efficiency, with $batch\_size$ set to 5 and $learning\_rate$ set to 0.00005. We utilize Nvidia A100 GPU nodes to fine-tune LLMs with LoRA. We fix the $temperature$ and top_p to 0 for all LLMs to ensure fair comparison. For ToTTo, we allocate 4,226 for training and 1,015 for testing. For the HiTab dataset, we allocate 667 for training and 169 for testing.

5.2 Experiment Result and Analysis

Table 2 presents the experiment results on table extraction. Experimental results show that LLM fine-tuning increases F1 scores by 8% to 15% compared to few-shot prompting LLMs, outperforming previous SOTA baselines on all datasets.

Code generation significantly enhances the performance of LLMs, whether in few-shot or fine-tuning settings. For example, LLaMA-70B equipped with code generation significantly outperforms the Markdown format of fine-tuned LLaMA-70B by large margins in the F1-EM score, ranging from 12% to 32% for textual cells, single quantities, and composite quantities that are required to be calculated during extraction. Composite cell extraction poses the biggest challenge to existing models, while the accuracy gain of using code generation is the biggest (over 30% for fine-tuned LLaMA-70B in Wikipedia and statistical reports).

SQL performs better than Python in the few-shot learning setting, showing the naturalness of using SQL code for this task, while Python performs better than SQL in the fine-tuning setting, showing the adaptability and flexibility of Python code.

Ablation studies show that utilizing semantic dependencies, type and range checking, and consistently ordered cell infilling greatly improve TABLECODER over vanilla code generation. Leveraging computational relationships highly improves the performance of composite cells (10% on average).

Table 2: Results on NL-TO-TABLE, distinguishing Textual cells (T), Single Quantities (SQ) that do not need computation, and Composite Quantities (CQ) requiring multi-quantity computation.

5.3 Case Study

We manually investigated 100 tables (1,180 cells) from Wikipedia and 100 tables (545 cells) produced by few-shot GPT-4 integrated with Python code generation to analyze their errors. We categorize bad cases into the following types:

(1) Incorrect positions, particularly for tables with complex ontology trees or column names with vague and default information, e.g., "Total", "Master's All" and "Doctoral All" have similar meaning of the sum aggregation in Example 2 of Figure 1, and in Figure 5, two cells are using the cell string"4" but have different meanings. Fortunately, our dataset has provided detailed cell-sentence alignment to enhance model capabilities.

(2) Missing cells caused by computations, especially for those requiring complex numerical reasoning, such as "15" in Figure 7 and "539" in Figure 8.

(3) Incorrect values often stem from complex ontology trees. In Wikipedia.

(4) Incorrect values caused by neglecting the unit conversion, as shown in Figure 6. Although both "billion" and "million" are well understood, LLMs still find it challenging to convert them.

(5) Generated code that is not executable.

(6) Correct semantics but inconsistent formats, e.g., extracting "3rd" from "bronze medal" as shown in Figure 9 and adding the unit ("Km2") of column "Area" to the cell string in Example 1 of Figure 1.

(7) Excessive cells caused by LLMs' internal knowledge or incorrect hallucinations that are not mentioned in the source text, e.g., generating "Tokyo" that is not mentioned in the text as shown in Figure 1. This is undesirable in our task since it's hard to evaluate the correctness without labeling external knowledge beyond the text input. After being augmented with TABLECODER's code generation, these cases are much less.

5.4 Evaluation on Complex Tables

In this section, we further investigate TABLECODER's scalability regarding complicated table structures.

Our dataset uniquely contains many complex structures, and TABLECODER shows significant advancements in handling these compared to baseline methods. We present detailed experimental results of TABLECODER for tables with different depths of ontology trees (levels 2, 3, and >3). We group the results by Single Quantities and Composite Quantities. As shown in Table 3, the more complex the structure (i.e., the deeper the ontology tree), the greater the improvement in extraction accuracy by the Semantic Dependency module.

Table 3: Scalability of TABLECODER for different ontology depths. "Depth 2" indicates tables with an ontology tree of depth 2; similarly for depth 3 and >3. We highlight the EM F1 (%) values.

EM F1 %	Single Quantity			Composite Quantities		
(Higher is better)	Depth 2	Depth 3	>3	Depth 2	Depth 3	>3
Llama 2 (CodeLLaMA 70B)						
TableCoder	74.3	69.8	64.2	68.8	63.3	56.5
- w/o Semantic Dependency	74.1	66.8	59.2	68.5	59.8	51.7
Mistral-v2 (7B)						
TableCoder	72.6	62.7	57.5	66.6	56.0	46.8
- w/o Semantic Dependency	72.1	59.7	50.4	66.3	53.0	42.4

Experimental results indicate that the more complex the structure, the greater the improvement in extraction accuracy provided by the Semantic Dependency module. TABLECODER exhibits robust

performance in these challenging settings, which demonstrates its capacity to handle real-world data extraction scenarios with deeply nested table ontologies.

Another advancement of TABLECODER is its scalability with respect to input size. TABLECODER generates incremental code that completes the output table step-by-step by adhering to the order within the source text. Unlike existing works that generate output tables row-by-row (e.g., via Markdown), TABLECODER allows a cell in a row to appear at the beginning of a long document and another cell in the *same row* to appear at the end of the long document. **This incremental approach naturally handles large input texts by sequentially dividing the input and filling the table cell-by-cell, rather than row-by-row**. We would like to explore large table extraction in future work.

5.5 FORMATAGNOSTIC-EVAL Effectiveness

We further employ annotators of this dataset as human evaluators to check if the extraction results are correct. Each sample has three annotators to label it, and we use the majority vote as the human evaluation result. Table 4 compares evaluation metrics on 200 randomly selected single-quantity test samples from statistical reports. This reveals that EM, Chrf, and BERT underestimate the performance of models on quantity cells by about 14%, and FORMATAGNOSTIC-EVAL successfully mitigates the gap and reduces it to about 3%. In future work, we would like to explore LLM-based evaluation.

Table 4: Comparison of classic evaluation methods, FORMATAGNOSTIC-EVAL, and human evaluation.

Cell-level F1	**Default Evaluation**			**FORMATAGNOSTIC**			**Human**
%	**EM**	**Chrf**	**BERT**	**EM**	**Chrf**	**BERT**	
GPT-4, Six-shot	41.2	43.8	45.0	53.5	54.0	54.7	58.2
Mistral-v2-7B, Fine-tune	51.3	52.6	54.5	63.3	63.9	64.9	68.4
— W/O semantic	48.3	49.5	50.8	60.4	61.4	62.3	64.0
— W/O computational	51.5	53.0	54.2	62.9	62.9	63.8	66.0
— W/O type and range	50.1	50.9	52.0	61.3	61.9	63.0	65.8
— W/O sequential order	48.3	49.0	50.7	59.0	59.4	60.2	63.8

6 Related Work

Table extraction The "text-to-table" task, as introduced by (Wu et al., 2022; Li et al., 2023b; Pietruszka et al., 2022; Deng et al., 2024; Wang et al., 2024; Singh et al., 2024; Jiao et al., 2023; Jain et al., 2024), represents a pioneering effort in extracting tables from textual content. However, they only involve simple and static key-value pairs or relational tuples without controllable NL instruction. (Huang et al., 2023; Singh et al., 2022; Ma et al., 2024) propose interactive table manipulation from semi-structured data for visualization purposes. To automatically evaluate different column organizations (Ramu et al., 2024; Jiao et al., 2023), (Ramu et al., 2024) break down a table into a list of atomic statements and then measure the statement entailment. Fortunately, the NL instruction in our dataset has provided sufficient details for column organization, so we directly use the column corresponding to the root node of the ontology tree as the index for rows.

Code for table generation Recent studies focused on tasks where tables are inputs (Gao et al., 2023a; Wu et al., 2024; Cheng et al., 2022b; Gao et al., 2023b; Chen et al., 2022; Li et al., 2024; Dong and Wang, 2024) rather than generating structured tables as outputs. As far as we know, the only work to extract tables using code is (Arora et al., 2023), deriving relational tuples from HTML pages and PDFs with tags. However, it targets parsing code to use string processing functions and regular expressions based on tags.

7 Conclusion

We propose TABLECODER, a novel code generation framework for symbolic structure construction and grounded content extraction. To enable training and evaluation, this paper provides a human-labeled dataset targeting generally structured table extraction from text following NL instructions, presenting a unique challenge in this area.

Experimental results show that TABLECODER substantially reduces structure issues and content inaccuracies, which is essential for industrial applications requiring high reliability. Moreover, the code-generation-based method naturally facilitates seamless deployment in existing enterprise data pipelines.

A NL-TO-TABLE Dataset Construction

We design an annotation process with six steps. Through a reliable and publicly listed data service vendor company, we recruited 38 students or graduates (16 women and 22 men) who are majoring in computer science from top universities to correct quality issues of table content extraction, label column properties, and relationships, and annotate format strings. Labeling costs 1,120 working hours. Comprehensive online training, documents, and QA are provided to annotators to ensure their consistent understanding of the labeling requirements.

A.1 User Instruction in Natural Language

We utilize GPT-4 to create an initial set of instructions based on the input table using the following instructions.

```
Suppose you are a human and want to ask
GPT-4 to extract a table from the
following text: <TEXT>

Imagine that your desired table is as
follows: <TABLE>

How should you ask GPT-4 using an
instruction? This instruction describes
the content and structure of the table
you want in natural language.
```

Column names should be consistent with the target table to facilitate evaluation, and the table structure, whether flat or hierarchical, is also required to be described. We encourage various forms of expression to simulate different habits of users. So we set GPT-4's temperature to 1 and encourage annotators to adapt the prompt and guide GPT in generating queries with diverse styles. Finally, instructions are manually refined to ensure clarity and alignment.

A.2 Column Property and Relationship

Ontology tree and computational dependency Column relationships, as detailed in Section 2, are finely labeled with JSON format, employing ontology trees for semantic relationships and spreadsheet formulas for computational relationships.

Unit and feasible range Annotators label the unit (Williams et al., 2020) and feasible range of each number column, and we use rules to infer types such as `INT` and `DECIMAL` based on cell text.

Format string Each column that contains numbers, dates, and times is annotated with an f-string, a Python feature for string formatting. For example, Figure 9 in Appendix presents a complex number string, we label it using an f-string f'%d%s' % (n, 'th' if 4 <= n % 100 <= 20 else {1: 'st', 2: 'nd', 3: 'rd'}.get(n % 10, 'th')). The f-string in Figure 6 is labeled to be f'{n / 1_000_000:.0f} million'.

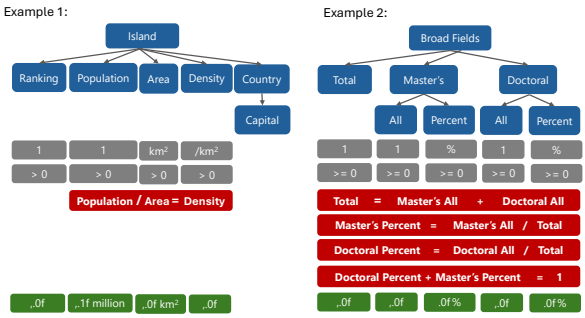

Figure 4: Examples illustrating column relationships through ontology trees (blue), number units and feasible ranges (gray), formulas (red), and number format strings (green).

Below is an example JSON structure of Column Property and Relationship Annotation for the example in Figure 1:

A.3 Table Extraction

Based on collected table-text paired data, annotators are instructed to be careful with deleting un-

mentioned cells, adding missing cells, and revising inconsistent cells in the table. For any omitted cells, annotators must accurately record the corresponding sentences, adhering to the methodologies employed by ToTTo and HiTab, ensuring all extracted cells are linked to corresponding sentences. Crucially, human annotators jointly utilize values and format strings to accurately record quantity cells.

Approximation Given that a quantity expressed in the text may be an approximate value, annotators receive careful training to label them with precision. Figure 6 presents a representative example that the cell value ("127,955") is too precise to be extracted from the text mention ("128.0 billion"), showing that merely reversing the table-to-text dataset can produce lots of overprecise errors, so we label the cell to be 128,000 to ensure the information is extractable.

Same value in different positions Annotators are required to be careful about distinguishing different cells with the same value. Figure 5 showcases an example of a labeling error by (Parikh et al., 2020), the red box surrounds the annotated cell for text generation, but the correct one is the cell surrounded by the green box.

Numerical reasoning inside the table Figure 7 demonstrates that the extracted cell ("15%") is calculated by "33%" and "18%", which can be easily omitted by human annotators. Figure 8 also shows a cell that needs calculation in Wikipedia. These cases require numerical reasoning, which is a core capability needed to meet the key demands and pain points of table extraction in financial and audit domains. Gladly, with the annotation on computational dependency, these cases can be labeled in high quality.

Numerical reasoning outside the table There is another kind of challenging case in which annotators need to verify if a cell can be inferred through numerical using the text information. Figure 8 shows an example where the cell "539" is calculated from "2,146" and "1,607" in Wikipedia pages.

A.4 Converting Annotations to Code

Writing code is challenging for annotators. Instead, we propose a rule-based system to construct code based on human-labeled table structure and content. (1) It converts the table structure—comprising ontology trees, formulas, number units, and format strings in JSON format—into Python classes and SQL statements, as depicted in Section 4. In Python, the implementation involves building one or more classes based on ontology trees. Each class contains various properties and methods for value setting, checking, computation, and formatting. In SQL, to avoid splitting the target table into multiple tables, we use the column corresponding to the root of the ontology tree as the primary key, and other columns as attribute columns. (2) It transforms table content annotations into Python code and SQL `INSERT` and `UPDATE` statements, preserving the sequence of code snippets to reflect the order in which cells appear in the source text, as shown in the example in Figure 3. We refine this rule-based system until all generated code can be executed flawlessly and produce corresponding table contents.

A.5 Regular Inspections and the Final Review

Due to the complexity of the labeling task, we have designated our two most experienced annotators to conduct regular inspections and the final review. (1) During the labeling process, they periodically review a sample of annotations (about 3%) from all annotators to provide timely feedback on any issues. (2) In the final step, they review all annotations to correct any errors. The agreement between the two annotators was evaluated by comparing annotations by all annotators (who are randomly paired) on a randomly selected sample of 200 tables. Table-level Fleiss Kappa (Landis and Koch, 1977) are 0.89 for table content extraction, 0.82 for column relationship and property labeling, and 0.94 for format string annotation, which is regarded as "almost perfect agreement" (Landis and Koch, 1977). And 98.5% instructions are considered accurate and high-quality by the counterpart.

B Existing Evaluation Metrics

Exact match (Popović, 2015) determines if two texts are the same. Chrf (Popović, 2015) calculates character-level n-gram similarity between two texts, useful for assessing similarity in a more granular manner. BERTScore (Zhang et al., 2019) measures the similarity of BERT embeddings between two texts, providing a neural semantic similarity metric.

Existing evaluation methods use the left-most column to distinguish rows (Wu et al., 2022). However, the left-most column does not always distinctly index rows in real tables. Instead, NL-TO-TABLE leverages the annotations of the ontology tree and uses the column corresponding to the root node of the ontology tree as the index for rows. The flattened row headers are used to index columns. Therefore, the evaluation metric is agnostic to the order of columns and rows.

2016 season [edit]

In Week 2, Amendola caught four passes for 48 yards and a career-high two touchdowns from Jimmy Garoppolo in a 31–24 win over the Miami Dolphins.[52] In Week 13 against his former team, the St. Louis Rams, he suffered a high ankle sprain that sidelined him for the rest of the regular season, but he returned for the playoffs.[53] The Patriots reached Super Bowl LI, where Amendola had eight catches for 78 yards in the Patriots' historic 34–28 overtime comeback victory over the Atlanta Falcons.[54] Amendola scored the Patriots' first touchdown of the fourth quarter to narrow what had been a 25-point Falcons lead down to 28–18 and a two-point conversion with less than a minute to go to tie the game at 28–28.[55] His Super Bowl LI touchdown was his second Super Bowl receiving touchdown. He became the 27th player in NFL history to have at least two career receiving touchdowns in the Super Bowl.[56] Amendola finished the season with 23 receptions on 29 targets for 243 yards and four touchdowns in 2016.[57] His 79.3% catch rate was the best of his career.[58]

Current-dollar federal obligations[2] for research and development and R&D plant decreased 1% from FY 2014 to FY 2015, from $132.5 billion to $131.4 billion. Within this total, funding for research increased 1% to $63.6 billion while development funding fell 4% to $64.9 billion. R&D plant funding increased substantially (by 27%) to $2.8 billion (table 1). Federal agencies estimated an 8% total increase in FY 2016 obligations for R&D and R&D plant, to $142.6 billion, and projected a 2% increase in FY 2017 to $145.4 billion. After adjusting for inflation, total federal R&D and R&D plant obligations decreased 2% to $119.6 billion from FY 2014 to FY 2015. Constant-dollar obligations were estimated to increase 7% to $127.7 billion in FY 2016 and were projected to remain essentially flat at $128.0 billion in FY 2017 (table 1).

Figure 6: Example of the unit conversion challenge.

The proportion of women with a university degree in both types of families has increased over time, however at a slower pace for female lone parents. The proportion of female lone parents with a university degree more than doubled between 1991 and 2011 to 20% (a difference of 11 percentage points). The proportion of female parents in couples with a university degree also doubled in that time period to 33% (a difference of 18 percentage points). The gap in education levels between female lone parents and female parents in couples may be partly explained by the tendency for female lone parents to have had their children at a younger age. 47

Table 9
Percentage of Highest certificate, diploma or degree of female lone parents and female parents in couples, aged 25 to 54 with children aged 15 and under in 1991, 2001 and 2011, Canada

Figure 8: Example of the computation challenge.

Her bronze medal time, behind a pair of young Kenyans, at the 2014 Commonwealth Games of 15:08.96 bettered the listed W40 World Record by almost 12 seconds, however Pavey ran an even better time of 15:04.87 at the Golden Gala two months earlier.[42] The Commonwealth Games race was probably one of the most exciting races of her career. In the closing four laps Pavey battled the Kenyans refusing to give up the lead. She went to the front, after being overtaken on three occasions. On the final bend the Kenyan runners had all gone past her again and opened a small gap but Pavey battled back again down the home straight overtaking one of the Kenyan athletes and narrowly missing the Silver medal by 6/100th of a second.

Are LLMs reliable? An exploration of the reliability of large language models in clinical note generation

Kristine Ann M. Carandang, Jasper Meynard P. Araña,
Ethan Robert A. Casin, Christopher P. Monterola,
Daniel Stanley Y. Tan, Jesus Felix B. Valenzuela, Christian M. Alis
Analytics, Computing & Complex Systems Laboratory
Asian Institute of Management

Abstract

Due to the legal and ethical responsibilities of healthcare providers (HCPs) for accurate documentation and protection of patient data privacy, the natural variability in the responses of large language models (LLMs) presents challenges for incorporating clinical note generation (CNG) systems, driven by LLMs, into real-world clinical processes. The complexity is further amplified by the detailed nature of texts in CNG. To enhance the confidence of HCPs in tools powered by LLMs, this study evaluates the reliability of 12 open-weight and proprietary LLMs from Anthropic, Meta, Mistral, and OpenAI in CNG in terms of their ability to generate notes that are string equivalent (consistency rate), have the same meaning (semantic consistency) and are correct (semantic similarity), across several iterations using the same prompt. The results show that (1) LLMs from all model families are stable, such that their responses are semantically consistent despite being written in various ways, and (2) most of the LLMs generated notes close to the corresponding notes made by experts. Overall, Meta's Llama 70B was the most reliable, followed by Mistral's Small model. With these findings, we recommend the local deployment of these relatively smaller open-weight models for CNG to ensure compliance with data privacy regulations, as well as to improve the efficiency of HCPs in clinical documentation.

1 Introduction

The capability of LLMs to produce text similar to human writing has led to research on their potential role in aiding clinical documentation. This led to the development of clinical note generation (CNG) tools designed to address extended working hours and healthcare provider (HCP) fatigue (Balloch et al., 2024; Biswas and Talukdar, 2024; Giorgi et al., 2023; Heilmeyer et al., 2024; Moramarco et al., 2022; Tung et al., 2024), issues which have persisted despite the adoption of electronic health records (Wu et al., 2024; Zhang et al., 2022; Ghatnekar et al., 2021; Maas et al., 2020; Momenipour and Pennathur, 2019; Quiroz et al., 2019). Considering the legal and ethical responsibility of HCPs to write accurate clinical documentation (McCoy et al., 2024), the reliability of these tools is critical.

LLM reliability is typically assessed using *inter-prompt stability* which checks the consistency of responses when subjected to a variety of prompts designed to elicit the same response (Azimi et al., 2025; Cheng et al., 2024; Dentella et al., 2023; Kozaily et al., 2024; Li et al., 2024; Luo et al., 2024; Wang et al., 2024c). An alternative is to evaluate *intra-prompt stability* by checking the consistency of responses in several iterations using the same prompt (Atil et al., 2024; Barrie et al., 2024; Dentella et al., 2023; Savage et al., 2024; Saxena et al., 2024; Yim et al., 2024; Zhao et al., 2024). However, assessing LLM reliability is more challenging for natural language generation tasks, especially long-form text generation such as CNG. Evaluation typically requires reference texts so that comparisons can be made using automatic evaluation metrics, and involves human evaluation as it remains the gold standard (Giorgi et al., 2023; Moramarco et al., 2022).

Although there exist studies that evaluated LLM performance in CNG from transcripts of provider-patient conversations (Balloch et al., 2024; Chen and Hirschberg, 2024; Giorgi et al., 2023), only Kernberg et al. (2024) evaluated LLM reliability in CNG in terms of intra-prompt stability. While Kernberg et al. (2024) evaluated only one proprietary LLM, their findings show the variability in LLM responses. This may raise concerns on reliability if integrated in the clinical setting (Kernberg et al., 2024), similar with incorporating other healthcare tools developed using LLMs or artificial intelligence in general (Tucci et al., 2021; Wang et al., 2024b).

Additionally, no study exploring the reliability

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1413–1422

of open-weight LLMs in CNG was found. Using open-weight LLMs over proprietary ones is a typical consideration for healthcare applications due to data privacy concerns related to protected and sensitive health information (Giorgi et al., 2023; Heilmeyer et al., 2024; Wang et al., 2024a).

In this study, we sought to determine whether LLMs are reliable in CNG by evaluating how consistent and correct their generated notes are when using the same prompt in multiple iterations. We focus our evaluation on the CNG task of producing a clinical note based on a transcript of a conversation between a healthcare provider and a patient using an LLM. Four (4) proprietary models and eight (8) open-weight models from Anthropic, Meta, Mistral, and OpenAI were evaluated. This is done with the intention of providing evidence to HCPs on the reliability of LLMs. By doing so, we aim to enhance the body of knowledge regarding the design of reliable tools, crucial for industries such as healthcare, which would benefit from incorporation into real clinical workflows.

More concretely, our findings contribute to our continuous efforts to validate and improve the LLM-powered CNG component of SINTA (*Scalable Intelligent Note-taking and Teaching-learning Assistant*), a system that we have developed to alleviate the workload of HCPs. Supported by an innovation grant from a government-run tertiary training hospital, we are currently evaluating our system with the goal of integrating it into their clinical workflows.

2 Related Work

With the ability of LLMs to generate texts, recent work explored the performance of various ChatGPT models (i.e., ChatGPT 3.5 Turbo, ChatGPT 4) in CNG from transcripts of provider-patient conversations to assess the potential of using an LLM in ambient clinical documentation (Balloch et al., 2024) or to compare the performance of fine-tuned pretrained encoder-decoder or decoder-only language models with at least an LLM (Chen and Hirschberg, 2024; Giorgi et al., 2023). Kernberg et al. (2024) assessed not only the correctness of notes generated from ChatGPT 4, but also the reliability of its responses through three repeated runs for each input, although they did not alter model parameters to make the model more deterministic. In addition, they used standardized assessments rated by human experts to evaluate the quality of responses, without using automatic evaluation metrics. Aside from ChatGPT, we evaluate various open-weight and proprietary LLMs in generating clinical notes from provider-patient dialogues.

Some studies (Atil et al., 2024; Savage et al., 2024; Yim et al., 2024) that evaluated LLM reliability also set model parameters that influence the determinism of LLMs, $temperature$, top_p and top_k, to a value of or close to 0 to make the model deterministic. We also set the model parameters to make them more deterministic.

Assessing LLM performance in CNG usually requires reference notes against which LLM outputs are matched via automated evaluation metrics that assess string overlap or semantic similarity. These evaluations are frequently supplemented by human judgment (Giorgi et al., 2023; Moramarco et al., 2022). Giorgi et al. (2023); Moramarco et al. (2022) found BERTScore (Zhang et al., 2020), an automatic evaluation metric that checks the similarity of two texts in the embedding space, to be the most appropriate embedding-based metric for the task of CNG. We use BERTScore to measure semantic consistency across responses per prompt and semantic similarity of the responses with the notes generated by experts.

In addition to semantic consistency and semantic similarity, we also measure consistency rate to reflect how much of its responses are string equivalent. Consistency of responses was usually measured by considering string equivalence (*total agreement rate for raw model response* (Atil et al., 2024)) or by semantic equivalence (*consistency rate* (Zhao et al., 2024) or *sample consistency* (Savage et al., 2024)) in reliability evaluation studies. String equivalence was noted as a strict measure of reliability while evaluating whether responses contextually mean the same is specifically important in CNG due to stylistic differences of HCPs in documenting their sessions (Moramarco et al., 2022).

3 Method

We evaluate the reliability of LLMs according to their *intra-prompt stability* and their *correctness* following the process illustrated in Figure 1. Each transcript was incorporated into a user prompt template which instructs the LLM to generate a clinical note, with specified headings, from the transcript, for k iterations. Evaluation was then done by using automatic evaluation metrics to determine consis-

tency rate (CR) and semantic consistency (SC) as measures of intra-prompt stability, and correctness through its semantic similarity (SS).

3.1 Dataset

We use **aci-bench** (Yim et al., 2023), a benchmark dataset for automatic visit note generation, licensed under the Creative Commons Attribution 4.0 International Licence (CC BY). We select the aci subset comprising 112 transcripts of natural conversations in English between a patient and a doctor taken during a role-play of a session, as this reflected the real-world scenario the most. Each data point contains the consultation session ID, the corrected transcript of the dialogue (*transcript*), and the corresponding clinical note (*ground truth note*). Figure 5 in Appendix A shows an example of said transcript and ground truth note.

3.2 Clinical Note Generation

Clinical notes were generated based on said *transcripts* using the same prompt in multiple iterations using several LLMs configured to maximize determinism.

3.2.1 User Prompt

A user prompt template was used across all iterations to have a consistent format for the input. This template (Figure B), contains (1) the task, (2) the list of note headings present in the dataset, (3) the *transcript*, and (4) other specific instructions. When using Llama models, modifications to this user prompt had to be made to align with the required format (see Appendix C).

3.2.2 Models & their Configurations

Various versions of open-weight LLMs (i.e, models from Meta and Mistral) and proprietary LLMs (i.e., models from Anthropic and OpenAI) were explored (Table 1). These were accessed using AWS Bedrock API requests through the AWS SDK for Python (Boto3), except for OpenAI's models, which required the use of its API from its platform.

At the minimum, for each model family, the smallest and largest models that took in multilingual text as input were included. Smaller models generally cost less than larger ones. For open-weight LLMs, smaller models also require less compute and storage resources than larger ones when deployed locally. Local deployment is an important option for CNG as this involves processing sensitive personal information which must be kept confidential in accordance with data privacy laws (Giorgi et al., 2023; Heilmeyer et al., 2024; Wang et al., 2024a). However, larger models were still considered, as they were generally reported to perform better in a variety of tasks than smaller models.

Developer	Model	Model Configurations			
		max output tokens	temperature	top_p	top_k
Anthropic	Claude 3.5 Haiku	8192	0	0	1
	Claude 3.5 Sonnet v2	8192	0	0	1
Meta	Llama 3.1-8B-Instruct	2048	0	0	N/A
	Llama 3.1-70B-Instruct	2048	0	0	N/A
	Llama 3.1-450B-Instruct	8192	0	0	N/A
	Llama 3.2-1B-Instruct	8192	0	0	N/A
	Llama 3.2-3B-Instruct	8192	0	0	N/A
Mistral	Large-2407 123B	8192	0	0	N/A
	Small-2402 22B	8192	0	0	1
	Mixtral-8x7B-Instruct	4096	0	0	1
OpenAI	ChatGPT-4o	8192	0	0	N/A
	ChatGPT-40-mini	8192	0	0	N/A

Table 1: **Models used and their parameters**. At least two LLM versions per developer was selected for use in this study - their smallest and their largest models. Maximum output tokens was set to 8192, unless otherwise specified due to model limitation. Other parameters were set accordingly to maximize determinism.

For Meta's Llama 3.1 models, its 70B model was also considered in this study, as its largest model (405B) may be impractical to deploy in low resource settings. Llama 3.2 1B and 3B models were also included as they can be run locally on edge devices, which could more conveniently facilitate compliance with data privacy protection.

Additionally, for the Mistral family, also included is their Mixtral model as this showcases a sparse mixture of experts model, which is said to improve computational efficiency compared with its counterpart LLMs. Not included in this study are the edge models of Mistral - Ministral 3B and 8B - as these were not available in AWS Bedrock at the time of the study.

To maximize determinism of these models during CNG, three parameters known to influence model determinism, $temperature$, top_p and top_k, were configured when relevant as enumerated in Table 1. We also set the maximum output tokens to the respective maximum capacity of each model.

3.3 Reliability Evaluation

Reliability was assessed in terms of *intra-prompt stability* and *correctness* on ten (10) iterations to show how consistent an LLM generates notes across multiple runs using the same prompt, and how well an LLM generates notes compared to those made by experts, respectively.

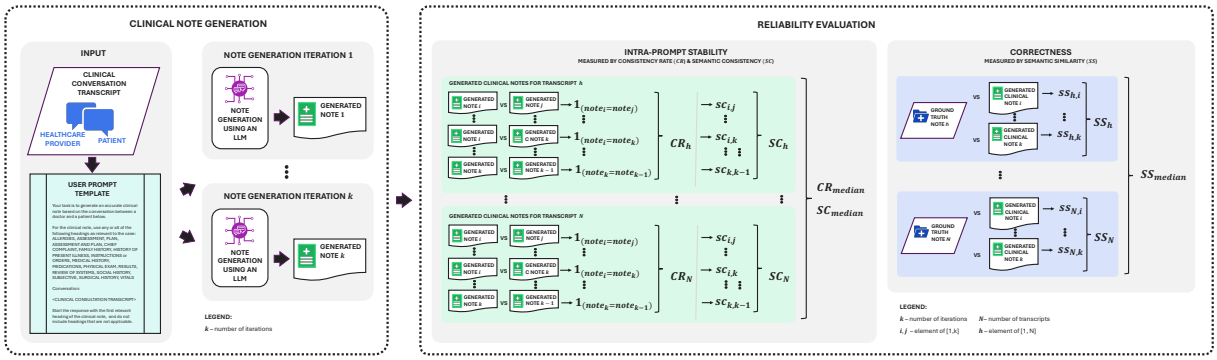

Figure 1: **Large Language Model (LLM) Reliability Evaluation Framework for the Task of Clinical Note Generation (CNG).** This has two phases, CNG and reliability evaluation, which are executed for each *transcript* that has a corresponding clinical note made by an expert (*ground truth note*). (1) *CNG* starts with said transcript being incorporated into a *user prompt template*, which then serves as an *input* to an LLM. The LLM response is the *generated note*. For each transcript, CNG is executed for k iterations, resulting in k generated notes. (2) *Reliability Evaluation* is then done to assess LLM reliability according to its *intra-prompt stability* and *correctness*. *Intra-prompt stability* is measured by consistency rate (CR) and median semantic consistency (SC_{median}), whereas *correctness* is evaluated by its median semantic similarity (SS_{median}). Once done for all transcripts, model performance is calculated by taking the median of these scores.

3.3.1 Intra-Prompt Stability

Intra-prompt stability is measured using the following metrics:

- ***Consistency Rate (CR)*** is measured by calculating the percentage of the number of pairs across the total number of iterations where a pair of generated notes are identical (i.e., string equivalent) over all possible combinations of pairs regardless of whether the outputs are correct. This strict measure of intra-prompt stability was first calculated per transcript (CR_h) as follows:

$$CR_h = \frac{\sum_{i,j \in \binom{k}{2}} 1_{i=j}}{\binom{k}{2}} * 100 \qquad (1)$$

  where k is the number of iterations and $h \in [1, N]$. Model performance was then calculated taking the median consistency rate (CR_{median}) from all CR scores.

- ***Semantic Consistency*** *(SC)* denotes whether the generated notes contextually mean the same regardless of how they were written across all iterations per transcript. This was measured by calculating the BERTScore which is an automatic text generation evaluation metric that calculates the cosine similarity between a pair of notes in the contextual embedding space (Zhang et al., 2020), using the implementation in Hugging Face. The pairs of notes refer to all combinations of the ten (10) generated notes per transcript. To determine model performance, the median semantic consistency SC_{median} was then calculated by getting the median of all semantic consistency scores calculated per transcript.

3.3.2 Correctness

Correctness is measured by ***semantic similarity***, which is similar to semantic consistency but the pair of notes compared here were the (1) generated note and (2) ground truth note made by an expert. The model performance (SS_{median}) was then calculated by taking the median of the semantic similarity scores calculated per transcript.

4 Results and Discussion

It took about 36 hours to generate the notes. Generally, we note that having perfect semantic consistency does not require having perfect consistency rate, and having perfect consistency rate and semantic consistency do not correspond to perfect semantic similarity as shown in Table 2.

4.1 Intra-prompt Stability

Figure 2 shows the intra-prompt stability of LLMs in CNG. Meta's Llama 1B and 3B models, as well as Anthropic's Claude Haiku model, demonstrated perfect intra-prompt stability, which means that all outputs from all iterations were exactly the same and thus have the same meaning. Such performances seemed inconsistent with prior work on LLM intra-prompt stability evaluation for multiple

Developer	Model	LLM Reliability ↑		
		Intra-prompt Stability		Correctness
		$CR_{median} \pm IQR$	$SC_{median} \pm IQR$	$SS_{median} \pm IQR$
Anthropic	Claude Haiku 3.5	**100.00** ± 00.00	**100.00** ± 00.00	85.61 ± 0.97
	Claude Sonnet 3.5 v2	0.00 ± 00.00	96.86 ± 1.44	86.52 ± 1.21
Meta	Llama 3.1-8B	35.56 ± 41.11	98.39 ± 6.06	83.71 ± 3.17
	Llama 3.1-70B	80.00 ± 37.78	**100.00** ± 0.00	85.90 ± 1.29
	Llama 3.1-450B	22.22 ± 20.00	96.34 ± 6.30	86.72 ± 1.95
	Llama 3.2-1B	**100.00** ± 00.00	**100.00** ± 0.00	80.49 ± 2.53
	Llama 3.2-3B	**100.00** ± 00.00	**100.00** ± 0.00	83.85 ± 1.39
Mistral	Large-2407 123B	8.89 ± 20.00	97.75 ± 2.83	84.36 ± 1.49
	Small-2402 22B	62.22 ± 33.33	**100.00** ± 0.00	85.72 ± 1.71
	Mixtral-8x7B	4.44 ± 11.11	96.14 ± 4.64	85.55 ± 1.55
OpenAI	ChatGPT-4o	0.00 ± 00.00	97.52 ± 1.42	87.01 ± 1.33
	ChatGPT-4o-mini	0.00 ± 00.00	97.40 ± 1.91	**87.26** ± 1.24

Table 2: **Summary of Model Performances based on Intra-Prompt Stability and Correctness**. In boldface are the best scores across all models while underlined are the best scores per model family. Three LLMs (25%) demonstrated perfect consistency rate, 41.67% (n=5) had perfect semantic consistency, and no model had perfect semantic similarity.

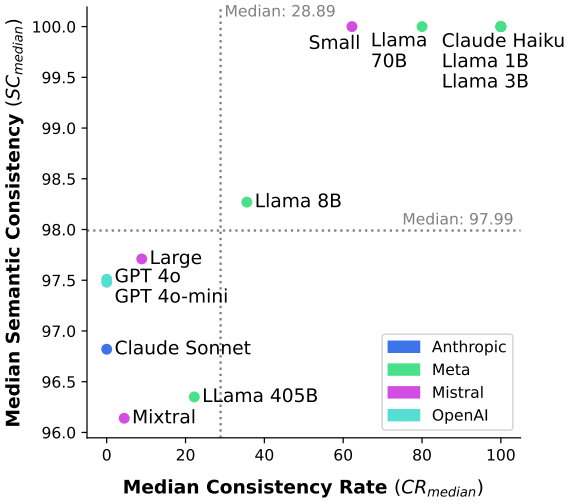

Figure 2: **Intra-prompt stability of LLMs in CNG.** Despite LLMs generating notes written in varied ways, the meaning of these notes were relatively consistent across multiple iterations, implying that these LLMs performed well in terms of intra-prompt stability.

choice question-answering tasks. Although the outputs of such tasks were linguistically controllable and are short-form texts, none of the LLMs studied by Atil et al. (2024) had string equivalent responses in multiple executions using the same prompt in all questions, and no LLM had perfect semantic consistency in the study of Zhao et al. (2024).

On the opposite side of the spectrum, at least in terms of consistency rate alone, the models from OpenAI consistently never produced string equivalent responses. Meta's LLama 3.1 8B model was unstable with the inter-quartile range greater than the median. Interesting to note as well are Meta's Llama 70B model and Mistral's Small model, which had likewise wide variances in their outputs, denoting that there are instances that these models can produce exactly the same results but can also produce responses that are written differently.

Nevertheless, considering both measures of intra-prompt stability, models from the Meta family generally performed better in terms of both consistency rate and semantic consistency than those from the other model families, whereas the models from the OpenAI family generally performed worse. Interestingly, for Anthropic, Meta and Mistral families, their smaller models performed remarkably better than their larger models. Also worth noting are the performance of Meta's Llama 70B model and Mistral's Small model, which both had perfect semantic consistency despite having an imperfect, but notably high, consistency rate.

In general, all models had a semantic consistency greater than 96% regardless of the consistency rate, which varied greatly between models from 0% to 100%. This implies that despite the models generating clinical notes written in a variety of ways, the meaning of the content of these notes was relatively consistent across multiple iterations. Thus, all models performed well in terms of intra-prompt stability. This implies that intra-prompt stability may be measured using semantic consistency alone than with consistency rate.

4.2 Correctness

Figure 3 shows how close the generated notes were to the ground truth notes, indicating correctness. Generally, all LLMs had a median semantic similarity between 80 and 88. For Anthropic, Meta and OpenAI, their larger models performed better than their smaller models. For Mistral, its Small model performed better than its Large model and its mixture-of-experts model.

A BERTScore of 80 is higher than the reported best performing LLM in the study of Giorgi et al. (2023), which has a BERTScore of 60.8, as validated by senior resident physicians. Although they also used **aci-bench**, they incorporated in-context learning in their implementation with the $temperature$ parameter set to 0.2.

4.3 Overall LLM Reliability

Shown in Figure 4 is the performance of the LLMs in CNG in terms of intra-prompt stability measured by semantic consistency and correctness measured by semantic similarity. Meta's Llama 70B model performed the best considering both semantic con-

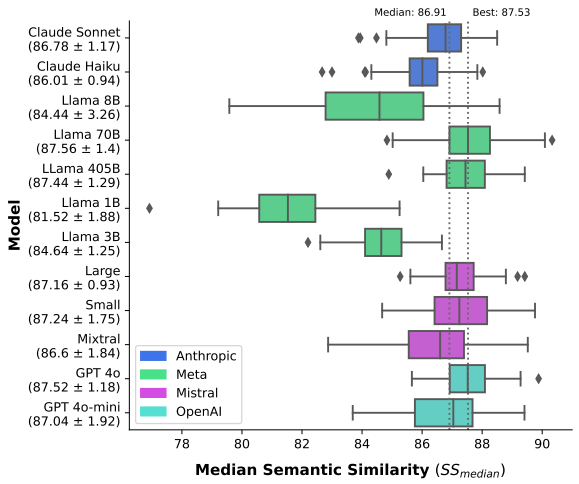

Figure 3: **Correctness of LLMs in CNG.** Except for Mistral, the larger models per model family performed better than their smaller models.

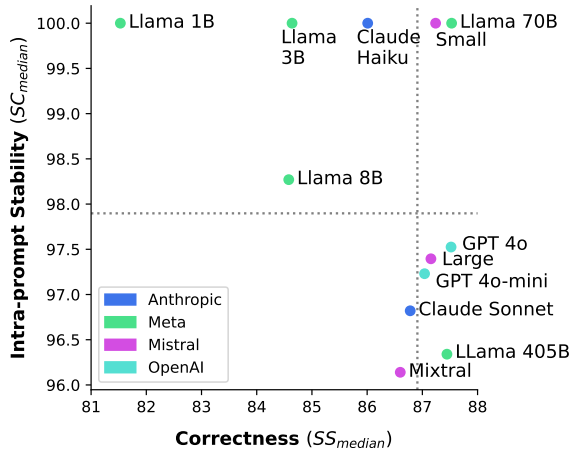

Figure 4: **Comparison of intra-prompt stability and correctness of LLMs in CNG.** Meta's Llama 70B model and Mistral's Small model appear to be among the most reliable models.

sistency and semantic similarity, followed by Mistral's Small model.These two open-weight models outperformed all proprietary models. For proprietary models, Anthropic's Claude Haiku had perfect semantic consistency but outperformed OpenAI's ChatGPT models in terms of semantic similarity.

Using proprietary models through their respective platforms is more accessible to HCPs but may result in a breach of data privacy regulations as the prompts submitted may get added to their database and subsequently used for training. Furthermore, the parameters that maximize determinism cannot be configured in these platforms. With Meta's Llama 70B and Mistral Small outperforming the proprietary models, we can develop CNG tools that use these and make these more accessible to HCPs without data privacy issues.

In addition, the choice of the final model would also depend on the practice setting considering that clinical conversations can vary in length, i.e., from as short as 5 minutes to at least an hour depending on the profession and area of practice. This is of particular concern for settings that deal with longer conversations such as in psychiatry, psychology, and occupational therapy where evaluations can take about an hour because of model limitations in terms of the number of tokens it can process. For such settings, we recommend Mistral's Small model over Meta's Llama 70B model.

5 Conclusion

The potential of LLMs for text generation has led to investigations into their ability to produce clinical notes, with the aim of improving the efficiency of documentation of HCPs. As part of our efforts to incorporate LLM-powered CNG tools into real clinical workflows, we have focused on building trust on these tools by assessing the reliability of LLMs in performing CNG.

Our observations indicate that LLMs do not consistently produce string-identical responses when aiming for semantically alike outputs, which are also aligned with annotations crafted by human experts. On multiple runs using the same prompt, we found that Meta's Llama 3.1 70B model was the most reliable, followed by Mistral's small model. Anthropic's Claude Haiku model outperformed OpenAI's ChatGPT 4o and 4o-mini models in terms of semantic consistency while the opposite was true for semantic similarity, but both proprietary models are subpar to Llama 3.1 70B and Mistral Small. With these findings, we recommend local deployment of these relatively smaller open-weight models for CNG to ensure compliance with data privacy regulations. We likewise consider using these models for SINTA as we validate its performance in the real world setting at the tertiary training hospital we are working with.

These findings provide support for the eventual integration of CNG tools powered by LLMs whilst protecting the health information of patients in compliance with data privacy regulations (Giorgi et al., 2023; Heilmeyer et al., 2024; Wang et al., 2024a). In this way, we can contribute to easing the burden of HCPs by providing them with tools that

can help them comply with their documentation requirements more efficiently.

6 Limitations

As this study did not include prompt optimization, future work could involve comparing the same measures across various prompts to check for robustness and, at the same time, identify the prompt most suitable for the task. Metrics that utilize knowledge graphs and sentence parsers can also be used, along with an evaluation by human experts.

Furthermore, our work only used one publicly available dataset that includes data gathered from simulations in English. We believe that it is necessary to conduct clinical validation and utility studies to capture and address contextual nuances before such tools can be fully adopted.

7 Ethical Considerations

The data used includes transcripts of dialogues between HCPs and patients, taken from a publicly available dataset. Protected health information was not used.

Although we used proprietary models in our experiments such that the prompts we submitted may get added to their database and subsequently used for training, caution must be exercised when considering the use of these models in real clinical workflows to avoid any potential breach of data privacy regulations.

Since clinical note generation tools are being developed with the intent of being integrated in real clinical workflows, we recommend conducting clinical validation and clinical utility studies prior to integration to ensure that the tools meet health standards and comply with regulations.

A Sample Data from aci-bench

Each data point of the **aci** subset of **aci-bench** contains a corrected transcript of a natural conversation between a patient and a doctor (*clinical conversation transcript*), together with its corresponding clinical note which serves as the *ground truth note* for this study.

B User Prompt Template

Figure 6 shows the user prompt template used as input to the evaluated LLMs, except for Llama models. This template contains (1) the task, (2) the list of note headings present in the dataset, (3) the *transcript*, and (4) other specific instructions.

C Formatted Prompt Template for Llama Models

Llama models expect a certain format for the prompt, as shown in Figure 7.

TRANSCRIPT OF DIALOGUE

[doctor] hi russell how are you what's been going on
[patient] well i've been having this sharp pain on the right side of my abdomen below my ribs for the last several days
[doctor] i saw my doctor and they ordered a cat scan and said i had a kidney stone and sent me to see a urologist okay well does the pain move or or or go anywhere or does it stay right in that same spot yeah it feels like it goes to my lower abdomen in into my groin okay and is the pain constant or does it come and go it comes and goes when it comes it's it's pretty it's pretty bad i feel like i ca n't find a comfortable position okay and do you notice any any pain when you urinate or when you pee
[patient] yeah it kinda burns a little bit
[doctor] okay do you notice any blood i do n't think there is any you know frank blood but the urine looks a little dark sometimes okay and what have you taken for the pain i have taken some tylenol but it has n't really helped okay and do you have any nausea vomiting any fever chills i feel nauseated but i'm not vomiting okay is anyone in your in your family had kidney stones yes my father had them and have you had kidney stones before yeah so i i've i've had them but i've been able to pass them but this is taking a lot longer okay well i'm just gon na go ahead and do a physical examination i'm gon na be calling out some of my exam findings and i'm going to explain what what those mean when i'm done okay
[patient] okay
[doctor] okay so on physical examination of the abdomen on a abdominal exam there is no tenderness to palpation there is no evidence of any rebound or guarding there is no peritoneal signs there is positive cva tenderness on the right flank so essentially what that means russell is that you know you have some tenderness over your over your right kidney and that just means that you might have some inflammation there so i i reviewed the results of the ct scan of your abdomen that the primary care doctor ordered and it does show a . five centimeter kidney stone located in the proximal right ureter so this the ureter is the duct in which urine passes between the kidney and the bladder there's no evidence of what we call hydronephrosis this means you know swelling of the kidney which is good means that things are still able to get through so let's talk a little bit about my assessment and my plan okay so for your first problem of this acute nephrolithiasis or kidney stone i i wan na go ahead and recommend that you push fluids to help facilitate urination and peeing to help pass the stone i'm going to prescribe oxycodone five milligrams every six to eight hours as needed for pain you can continue to alternate that with some tylenol i'm going to give you a strainer that you can use to strain your urine so that we can see it see the stone when it passes and we can send it for some some tests if that happens i'm also gon na order what we call a basic metabolic panel a urinalysis and a urine culture now i wan na see you again in one to two weeks and if you're still having symptoms we'll have to discuss further treatment such as lithotripsy which is essentially a shock wave procedure in which we sedate you and use shock waves to break up the stone to help it pass we could also do what we call a ureteroscopy which is a small telescope small camera used to go up to to the urethra and bladder and up into the ureter to retrieve the stone so let's see how you do over the next week and i want you to contact me if you're having worsening symptoms okay okay sounds good thank you

CLINICAL NOTE

CHIEF COMPLAINT
Right-sided abdominal pain

MEDICAL HISTORY
Patient reports history of kidney stones.

FAMILY HISTORY
Patient reports his father has a history of kidney stones.

MEDICATIONS
Patient reports use of Tylenol.

REVIEW OF SYSTEMS
Gastrointestinal: Reports right-sided abdominal pain and nausea. Denies vomiting
Genitourinary: Reports dysuria and dark colored urine. Denies hematuria.

PHYSICAL EXAM
Gastrointestinal
- Examination of Abdomen: No masses or tenderness to palpation. No rebound or guarding. No peritoneal signs. Positive CVA tenderness on the right flank.

RESULTS
Previous CT scan of the abdomen ordered by the patient's PCP is reviewed and demonstrates a 0.5 cm kidney stone located in the proximal right ureter. There is no evidence of hydronephrosis.

ASSESSMENT AND PLAN
1. Acute nephrolithiasis.
- Medical Reasoning: The patient presents with complaints of right-sided abdominal pain. His previous CT scan was reviewed and demonstrates a 0.5 cm kidney stone located in the proximal right ureter without evidence of hydronephrosis.
- Medical Treatment: I have recommended that he push fluids in order to help facilitate urination to help pass the stone. He will be provided with a strainer to allow us to potentially test the stone if he is able to pass it. I have also prescribed oxycodone 5 mg every 6 to 8 hours as needed for pain. He can continue to alternate oxycodone with Tylenol. A basic metabolic panel, urinalysis, and urine culture will also be ordered.

INSTRUCTIONS
He will follow up in 1 to 2 weeks. If he is still having symptoms at that time, we will discuss further treatment such as lithotripsy or ureteroscopy. He is to contact me if he is having worsening symptoms over the next week.

Figure 5: **Sample data from the *aci-bench* dataset.** An example of the corrected transcript of a natural conversation between a patient and a doctor (*clinical conversation transcript*), together with its corresponding clinical note which serves as the *ground truth note* for this study.

User Prompt Template
Your task is to generate an accurate clinical note based on the conversation between a doctor and a patient below.
For the clinical note, use any or all of the following headings as relevant to the case: ALLERGIES, ASSESSMENT, PLAN, ASSESSMENT AND PLAN, CHIEF COMPLAINT, FAMILY HISTORY, HISTORY OF PRESENT ILLNESS, INSTRUCTIONS or ORDERS, MEDICAL HISTORY, MEDICATIONS, PHYSICAL EXAM, RESULTS, REVIEW OF SYSTEMS, SOCIAL HISTORY, SUBJECTIVE, SURGICAL HISTORY, VITALS
Conversation:
$< clinical\ conversation\ transcript >$
Start the response with the first relevant heading of the clinical note, and do not include headings that are not applicable.

Figure 6: **User Prompt Template.** This was used to keep the format consistent across all models.

<|begin_of_text|>

Abstract

Recent advances in Large Language Models (LLMs) have significantly improved the field of Document AI, demonstrating remarkable performance on document understanding tasks such as question answering. However, existing approaches primarily focus on solving specific tasks, lacking the capability to structurally organize and manage document information. To address this limitation, we propose REVISE, a framework that systematically corrects errors introduced by OCR at the character, word, and structural levels. Specifically, REVISE employs a comprehensive hierarchical taxonomy of common OCR errors and a synthetic data generation strategy that realistically simulates such errors to train an effective correction model. Experimental results demonstrate that REVISE effectively corrects OCR outputs, enabling more structured representation and systematic management of document contents. Consequently, our method significantly enhances downstream performance in document retrieval and question answering tasks, highlighting the potential to overcome the structural management limitations of existing Document AI frameworks.

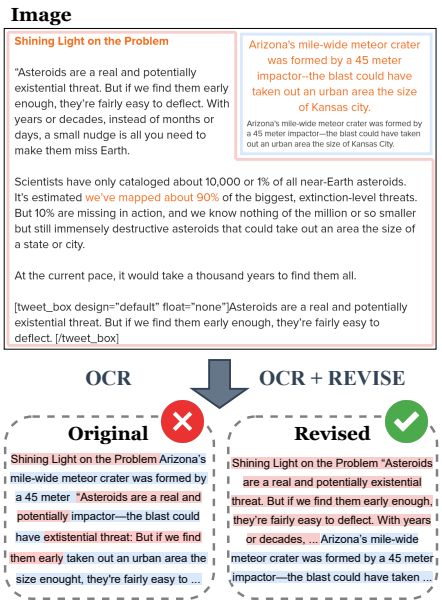

Figure 1: Illustration comparing conventional OCR and OCR+REVISE processing in a multi-column setting. *Left*: text conflation with merged topics. *Right*: REVISE reconstructs separate textual elements into properly structured content.

1 Introduction

Recent advances in Natural Language Processing (NLP), particularly with Large Language Models (LLMs) (Minaee et al., 2024), have demonstrated remarkable performance on core tasks such as Question Answering (QA), reasoning and Retrieval Augmented Generation (RAG) (Gao et al., 2024), thereby substantially broadening their formidable applicability. Moreover, recent research has rapidly expanded towards Document AI, aiming to understand and effectively utilize structured and complex information within real-world documents (Cui et al., 2021; Hong et al., 2024).

In particular, there is increasing interest in leveraging text extracted via Optical Character Recognition (OCR) (Subramani et al., 2021) and document analysis techniques, along with layout information obtained from original documents, to enable LLMs to perform tasks over documents. However, current approaches have primarily focused on specific document understanding tasks (Barboule et al., 2025), leaving the broader goal of effectively preserving original document structure and converting documents into structured assets or databases underexplored. Typically, extracting and storing textual information from image-based documents requires OCR, which inevitably introduces recognition errors due to various factors, such as diverse fonts, deteriorated print quality, and layout complexities.

Consequently, employing a simplistic processing pipeline for indexing or retrieving erroneous OCR text often leads to degraded performance. To effectively facilitate these applications, denoising OCR errors remains a critical prerequisite, necessitating a more sophisticated and resilient pipeline in Document AI.

In this paper, we propose REVISE, designed to effectively address common OCR errors and accurately restore textual content while preserving the original document structure. To overcome the scarcity of high-quality annotated datasets for OCR error correction, we generate synthetic data using a realistic error injection methodology, in which diverse error patterns are systematically introduced into publicly available datasets. By training over these synthetic datasets, our model can effectively learn representative OCR errors and robustly reconstruct documents in their original forms, thereby enabling the accurate preservation and storage of textual information. Experimental evaluations on downstream tasks, including retrieval and question answering, further demonstrate that REVISE maintains strong performance even without explicit OCR-error-correction annotations, showing broad applicability across various document types. Our contributions are as follows:

- Systematically analyzes and categorizes error types frequently encountered in OCR-based real-world document processing scenarios.
- Proposes REVISE, an effective revision method leveraging synthetic datasets created by realistically emulating error patterns in publicly available datasets.
- Demonstrates through extensive experiments that REVISE significantly improves document retrieval and question answering, while substantially enhancing semantic coherence and readability.

2 Related Works

2.1 Optical Character Recognition

OCR serves as a foundation of document digitization, transforming images and scanned documents into searchable digital content (Sachdeva and Scholar VI, 2025). At its core, CNNs and RNNs are employed to recognize visual patterns in document images and convert them to text (Lee and Osindero, 2016; Vinyals et al., 2015; Qiang et al., 2016; Wang et al., 2011, 2012), with tools like Tessearct (Smith, 2007) and EasyOCR[1] in widespread use. Modern systems often utilize encoder-decoder architectures with attention mechanisms to improve recognition accuracy (Kim et al., 2022).

Despite advancements, OCR systems face limitations with image quality and complex layouts. Errors induced from such issues propagate to downstream applications: in information retrieval, studies (Fataicha et al., 2003; de Oliveira et al., 2023; Bazzo et al., 2020; Zhang et al., 2025) have demonstrated that OCR errors substantially degrade retrieval performance by transforming valid words into misspellings that impact term frequencies and relevance scoring. Additionally, OCR errors significantly impact document reasoning tasks (Gupte et al., 2021; van Strien et al., 2020; Hamdi et al., 2022), with extensive research showing cascading effects on document understanding and knowledge base construction, as entities and relationships extracted from OCR text often contain errors that compound through subsequent processing steps, ultimately compromising the reliability of AI systems that are contingent upon accurate document content.

2.2 Document AI Methods

Document AI applies AI techniques to understand, process, and extract information from document images (Cui et al., 2021), focusing on four main tasks: Document Layout Analysis (Zhong et al., 2019; Li et al., 2020), Document Visual Question Answering (Mathew et al., 2021; Tanaka et al., 2021; Chen et al., 2021), Visual Information Extraction (Huang et al., 2019; Wang et al., 2021a; Park et al., 2019), and Document Image Classification (Harley et al., 2015; Kumar et al., 2013). To address OCR shortcomings while excelling at these tasks, two major paradigms have emerged in Document AI.

The first approach involves OCR-free Multimodal LLMs (Huang et al., 2022; Liu et al., 2024; Li et al., 2021; Kim et al., 2022), which process images directly without explicit text extraction. These models achieve impressive performance in document understanding and reasoning through vision-language pretraining; however, their reliance on extensive annotated datasets and computationally intensive training poses considerable challenges for practical deployment, especially in resource-constrained scenarios. The second approach inte-

[1] https://github.com/JaidedAI/EasyOCR

grates OCR-based LLMs (Perot et al., 2024; He et al., 2023; Wang et al., 2023a; Lu et al., 2024), extracting text via OCR before applying an LLM for reasoning. While leveraging existing OCR technology, this approach inherits OCR errors and focuses primarily on reasoning-based tasks like question answering and information extraction.

Existing approaches exhibit task dependency, prioritizing answering and reasoning but neglecting crucial intermediate steps like assetization for information retrieval. Our method addresses this issue by providing a task-independent framework, enabling structured OCR outputs that can be effectively utilized in databases or knowledge bases.

3 REVISE

The REVISE framework systematically addresses OCR errors that occur at the character, word, and structural levels. Specifically, our approach involves: (1) a comprehensive OCR error taxonomy that hierarchically categorizes errors according to their linguistic granularities, (2) a contamination strategy for synthesizing realistic error patterns by injecting them into clean datasets, and (3) a training procedure designed to revise contaminated text sequences back to their original forms.

3.1 OCR Error Categorization

OCR errors negatively impact various downstream NLP tasks, including key extraction, named entity recognition, and information retrieval. Lopresti (2009) has demonstrated that errors introduced in early processing stages propagate to subsequent stages, resulting in cumulative error cascades. Motivated by these challenges, we conduct a comprehensive analysis of OCR error patterns across various document types. Based on the scope and influence of errors within textual structures, we propose a hierarchical OCR error taxonomy as illustrated with examples in Table 1, consistent with existing frameworks found in the post-OCR correction literature.

Category	Name	Example
Character Level (Single-character)	Insertion	apple → applee
	Deletion	clamp → lamp filter → filer
	Substitution	O → 0, é → e blue → b1ue
	Transposition	Gauge → Guage
Word Level (Word-segmentation)	Over-Segmentation	greenhouse → green house
	Under-Segmentation	Not able → Notable
Column Level (Layout-reading)	Column Reading Order	**Figure 1**

Table 1: OCR Error Categorization

Character-level

Character-level errors encompass a range of misrecognitions and distortions that occur at the individual character scale, fundamentally altering the basic building blocks of text and potentially cascading into more significant semantic disruptions. ***Insertion*** represents the addition of spurious characters into the text stream, commonly resulting from document noise, artifacts, or scanner interference (Afli et al., 2016; Kashid and Bhattacharyya, 2025). ***Deletion*** involves the omission of legitimate characters, frequently occurring when poor contrast or faded text prevent proper recognition (Chiron et al., 2017). ***Substitution*** occurs when the OCR incorrectly identifies characters, replacing them with visually similar alternatives due to font peculiarities or resolution limitations, resulting in common confusions such as "l/1/!","5/S" and "0/O" (van Strien et al., 2020; Veninga, 2024). ***Transposition*** results in character position swapping, often stemming from bounding box coordinate miscalculations (Suissa et al., 2023).

Word-level

Word-level errors primarily manifest as improper segmentation issues, where the boundaries between words are incorrectly identified, leading to the fragmentation or merging of terms and significantly impacting the lexical integrity of the processed text. Segmentation stems from OCR's misidentification of word boundaries, taking the form of two distinct types (Suissa et al., 2023; Afli et al., 2016). ***Over-segmentation*** occurs when OCR incorrectly inserts word boundaries (i.e., extra space) within what should be a single word, fragmenting cohesive terms into separate components. ***Under-segmentation*** results from distinct words erroneously combining into a single unit due to spacing misinterpretation or layout analysis failures. Nastase and Hitschler (2018) demonstrate how these errors impact keyword extraction and information retrieval, as they alter token distribution and disrupt phrase-level semantics.

Column-level

Column-level errors refer to structural misinterpretations that disrupt the logical flow of text and distort the intended document layout. Documents

with multiple columns are particularly vulnerable to these errors, potentially misarranging reading order and weakening overall coherence and readability. ***Column reading order*** frequently arises due to the common assumption of a standard reading order from left to right and top to bottom. This assumption tends to cause incorrect interpretations of logical continuity within multi-column layouts, leading to misplaced text segments (Wang et al., 2023b, 2021b). Such layout errors can significantly impact various downstream NLP tasks, severely compromising overall task performance even when the OCR's textual output itself is relatively accurate (van Strien et al., 2020).

By categorizing OCR errors according to this hierarchical taxonomy, it becomes possible to devise customized correction strategies tailored to tackle specific errors at their corresponding levels of textual organization. This approach serves as a foundation for generating effective error revision datasets.

3.2 Data Contamination Strategy

To train the revision model effectively, we utilize publicly available datasets and systematically introduce synthetic OCR errors based on the error categories defined in Section 3.1. Our contamination strategy is designed to mimic both structural and granular OCR failures in a controlled manner, creating a realistic training corpus that reflects the hierarchical error patterns observed in real-world OCR outputs.

The contamination process unfolds in two stages. First, we create a structured template by dividing the raw text into fixed-length lines, reformatting to a single column layout. Next, we simulate *Column reading order* errors by segmenting the text into sections, converting selected sections into multi-column formats, and reading horizontally across columns instead of vertically down each column. This approach mirrors how OCR systems typically misinterpret multi-column layouts, where text is incorrectly read left to right across columns rather than processing each column separately.

In the second stage, after the structural reordering, a set of error functions is applied to introduce distortions at the character, word, and sentence levels. *Deletion*, *Insertion*, *Substitution*, and *Transposition* are applied probabilistically, while *Segmentation* errors are introduced by either inserting extra spaces or omitting existing spaces. Each error function is governed by configurable parameters to ensure a realistic blend of error types. The framework supports multiple contamination settings; in this work, we primarily adopt a configuration that emphasizes fine-grained perturbations. This approach closely emulates common OCR errors while maintaining sufficient overall document coherence. Detailed information regarding the contamination algorithms and parameter ratios can be found in the Appendix A. The final output is a contaminated corpus reflecting typical OCR-induced distortions, forming the basis for training our REVISE model to correct OCR outputs and improve downstream document processing tasks robustly.

3.3 Training

For effective OCR error correction, we design a total of seven REVISE models, consisting of one main model trained comprehensively on all error types and six auxiliary models, each specialized individually on a specific error type. All models share an identical backbone architecture, the Llama-3.1-1B-Instruct [2], and are trained on synthetic data generated using text sampled from the Wikipedia [3] corpus. To ensure fair and consistent comparisons between models, each dataset comprises an equal number of samples, totaling 30,000 data points.

The central model proposed in this paper, REVISE$_{meta}$, is designed to robustly handle realistic and general document processing scenarios. Specifically, based on the strategy described in § 3.2, REVISE$_{meta}$ is trained comprehensively on data that incorporates the six major error categories frequently confronted in practical OCR systems: column reading order, segmentation, deletion, substitution, insertion, and transposition errors. Thus, the model is capable of effectively handling and correcting complex and diverse errors that commonly arise during OCR processing of documents.

To precisely analyze the performance of REVISE and to better understand the characteristics and correction difficulties associated with each error type, we further train six specialized auxiliary models, each focusing exclusively on a single type of OCR error. These specialized models are individually trained on data injected with only one specific error category, thereby allowing each model to be optimized for correcting its particular error type.

Through this experimental design, we evaluate

Table 2: Retrieval performance on VisualMRC and DUDE datasets using Recall@k (ranks in parentheses; best scores are in **bold**)

the overall effectiveness and practical applicability of the REVISE$_{meta}$ model when dealing with realistic OCR error scenarios. Additionally, comparisons between the generalized and respective error-targeted models enable us to quantify and analyze the relative importance and characteristics of each specific type of error, as well as their influence on the overall OCR error correction pipeline. Ultimately, our goal is to clearly identify the strengths and weaknesses of generalized versus error-specific approaches, dependent upon the characteristics of documents and distributions of errors encountered, thereby providing practically useful guidelines for real-world implementations.

4 Experimental Setup

4.1 Models

We evaluate the effectiveness of our proposed REVISE framework on downstream tasks by employing embedding models and LLMs. For document retrieval, we adopt four recent embedding models: bge-large-en-v1.5 (Xiao et al., 2023), intfloat/e5-large-v2 (Wang et al., 2022), jina-embeddings-v2-base-en (Günther et al., 2023), and gte-base-en-v1.5 (Li et al., 2023). These models enable us to quantify how effectively OCR-corrected documents can be matched to queries. For question answering, we utilize two large instruction-tuned language models: Gemma-2-2b-it (Team, 2024) and Llama-3.1-8B-Instruct (Meta, 2024). By leveraging these models, we assess the capability of our correction method to enhance structured document comprehension and reasoning performance.

4.2 Evaluation

The performance of the proposed framework is evaluated on document Visual Question Answering (VQA) and Visual Information Extraction (VIE) datasets, focusing on three main aspects and comparing results between original OCR-extracted text and the text post-processed by REVISE. First, we directly assess document retrieval performance using Recall@K (k=1,3,5) on the VisualMRC (Tanaka et al., 2021) and DUDE (Landeghem et al., 2023) datasets. Second, for DocVQA (Mathew et al., 2021), CORD (Park et al., 2019), and FUNSD (Jaume et al., 2019), we evaluate the textual similarity between documents and questions via BERTScore (Zhang et al., 2020)[4]. Lastly, we compare QA performance of models on original OCR text versus REVISE-enhanced texts using standard evaluation metrics commonly used for each dataset: CIDEr (Vedantam et al., 2014) for generative answer quality on VisualMRC and F1-score for answering performance on CORD.

5 Experimental Results

5.1 Understanding Evaluation

Retrieval Performance Table 2 presents a comparative analysis of various OCR error revisions and their impact on embedding-based text retrieval performance using the VisualMRC and DUDE datasets. We evaluate our approach by comparing the original OCR output against two correction

[4]For DocVQA, CORD, and FUNSD datasets, pure IR-based metrics alone are insufficient to accurately measure performance due to duplicate questions and similar keywords; hence, we use textual similarity measures.

	REVISE$_{meta}$	**293.1**	**0.450**

Table 4: QA performance on VisualMRC and CORD

strategies: (1) six individual error-specific models, and (2) our integrated REVISE$_{meta}$ model that addresses multiple error types simultaneously. The REVISE$_{meta}$ approach consistently achieves average Recall improvements of 1.3% and 17.3% for the two datasets, respectively. This improvement is attributed to its ability to correct a variety of OCR errors comprehensively, thereby allowing the embedding model to capture more accurate contextual information that better aligns with the given query.

Notably, even when a revision targets a single error type, the *Segmentation* revision yields significant performance gains. This suggests that correcting spacing and segmentation errors, which are commonly observed in OCR documents, substantially enhances the model's capacity to discern contextual semantics. However, we observe that some single error type models occasionally underperform compared to the baseline, which can be attributed to an over-correction behavior. When a specialized model encounters datasets with limited instances of its target error type, it may still attempt to apply corrections where none are needed, inadvertently introducing new errors or disrupting otherwise correct text. This highlights the importance of error type prevalence matching between training data and target datasets.

In the case of the DUDE dataset, applying solely the *Column reordering* operation increases the average Recall from 25.34% to 30.76%, marking the highest improvement among the single-revision methods. This result is attributable to the DUDE dataset's highly regular column-based layout and consistent text composition. Owing to these structural properties, merely correcting column alignment can yield substantial gains in retrieval performance.

Overall, REVISE demonstrates that effective learning and correction of diverse OCR error types is possible without requiring additional annotated data. By leveraging publicly available text corpora supplemented with synthetic augmentation, our approach can substantially enhance embedding-based retrieval performance. Furthermore, these results indicate that applying tailored strategies based on error types and dataset characteristics can yield even more optimal outcomes.

Similarity Assessment As shown in Table 3, the application of our proposed integrated refinement approach REVISE$_{meta}$ consistently improves the BERTScore across all datasets when compared to the untouched OCR output. In particular, for DocVQA, which handles free-form queries where contextual relevance is essential, detailed corrections such as *Segmentation* yield significant improvements. For more structured datasets such as CORD and FUNSD, our approach of combining multiple error corrections achieves the best overall performance. These results suggest that our methodology not only mitigates OCR error but also enables the embedding model to capture finely expressed contextual information, thereby enhancing semantic consistency and overall quality.

5.2 Question Answering

Table 4 presents a comparison of the QA performance with and without our proposed REVISE framework. While our main experiments primarily center around evaluating how accurately the OCR outputs can be restored, we conduct an additional analysis on QA performance to examine how improvements in quality ultimately contribute to enhanced document understanding by LLMs.

For both evaluation datasets, we confirmed that our REVISE$_{meta}$ approach consistently excelled at answering questions. On VisualMRC, the Gemma-2-9b-it and Llama-3.1-8B models achieved performance gains of 2.6% and 0.8%, respectively. On the CORD dataset, the Gemma and Llama models improved by 1.4% and 0.4% in F1 score, respectively. Given that the datasets evaluated here primarily involve relatively short and simple-form answers, we anticipate an even greater performance gap in tasks requiring more abstractive responses.

Overall, these results demonstrate that improve-

Category (vs. Baseline)	VisualMRC			DUDE		
	Win	Lose	Rate	Win	Lose	Rate
Revise$_{meta}$	94	6	0.94 (1)	86	14	0.86 (3)
only Column	74	26	0.74 (6)	89	11	0.89 (2)
only Deletion	84	16	0.84 (3)	64	36	0.64 (4)
only Insertion	61	39	0.61 (7)	59	41	0.59 (7)
only Substitution	81	19	0.81 (4)	61	39	0.61 (5)
only Segmentation	92	8	0.92 (2)	92	8	0.92 (1)
only Transposition	77	23	0.77 (5)	60	40	0.60 (6)

Table 5: Win Rate comparison for REVISE$_{meta}$ and single correction strategies on VisualMRC and DUDE datasets (better performance indicated by darker shading)

ments through our REVISE can directly or indirectly enhance large language models' document comprehension capabilities, highlighting its effectiveness as a task-independent post-OCR correction approach applicable across diverse document understanding scenarios.

5.3 Qualititve Analysis

To evaluate the revised documents qualitatively, we measure the Win Rate based on a frontier LLM. This approach extends the evaluation methodology previously proposed by Zheng et al. (2023). Specifically, we provide the document image along with both the original OCR-extracted text and the REVISE-corrected texts to the LLM, instructing it to assess the relative preference between these two texts. The evaluation prompts explicitly guide the LLM to determine superiority based on various qualitative criteria such as coherence, clarity, and effectiveness in information delivery [5].

Table 5 presents the Win Rate results measured respectively for each revision strategy across the two domains, VisualMRC and DUDE. First, examining the REVISE$_{meta}$, we observe Win Rates of 94% on VisualMRC and 86% on DUDE. These outcomes indicate that the composite revision strategy, trained to address all error types, substantially contributes to overall document quality improvement. Overall, each revision strategy outperforms the baseline consistently across both datasets. Particularly, the single revision strategy *Segmentation* achieves notably high Win Rates in both domains, highlighting the significance of restructuring textual segmentation to enhance document coherence and readability. Furthermore, varying performances observed across revision types underline that outcomes may differ based on the characteristics of the evaluated documents and the particular revision strategies applied. Collectively, our results demonstrate that the proposed approach yields clearly enhanced qualitative performance, complementing quantitative evaluation outcomes.

[5]We use GPT-4o-mini to evaluate a consistent set of 100 randomly selected samples across all revision strategies. Detailed prompts used for this evaluation are provided in Appendix D.

6 Conclusion

We propose REVISE, a lightweight yet effective OCR error correction framework that leverages a hierarchical error taxonomy and a synthetic data contamination strategy, systematically addressing OCR errors at the character, word, and structural levels. By reconstructing OCR outputs into accurate and structurally coherent representations, REVISE supports the effective creation of structured document databases and facilitates systematic textual information management in practical information systems. Both quantitative and qualitative evaluations from our comprehensive experiments further confirm that REVISE consistently achieves strong improvements across various document retrieval and question-answering tasks on representative VQA and VIE benchmarks. The reliability of this framework across diverse datasets, combined with its simplicity and compatibility with publicly available resources, underscores its practical usability and ease of integration into real-world information systems. Furthermore, by adjusting the data contamination strategy to align with each dataset's specific error characteristics, we demonstrate that REVISE can achieve more robust performance.

Limitations

In this paper, we propose REVISE, a framework designed to address diverse OCR errors by leveraging large language models trained on synthetic OCR errors generated through a realistic contamination strategy. Despite its effectiveness, the following limitations exist:

1. Our validation primarily used publicly available document datasets and focuses on general error patterns. The approach has not been extensively tested on diverse industrial documents (such as forms or electronic materials) and may not fully capture specialized domain errors or rare error types that emerge in industry-specific contexts. Future work should incorporate real-world examples from operational environments, particularly for complex scenarios like table comprehension.

2. The current framework targets text-only documents and does not handle mixed content types such as tables, charts, or mathematical equations, which require specialized multimodal processing capabilities.

3. While our LLM-based evaluation reduces subjective bias and enhances reproducibility, it does not completely eliminate model biases or prediction uncertainties. Additional human evaluations and composite metrics would better address diverse usage scenarios.

4. Our error definitions and contamination ratios are based on empirical observations and literature, providing a practical foundation for synthetic data generation. Comprehensive statistical analysis of OCR error distributions would further strengthen the empirical basis of our approach.

A Contamination Strategy

For our synthetic data contamination process, we carefully calibrated error ratios based on empirical observations of real-world OCR outputs from

a range of document types, spanning from well-structured documents to semi-structured document images such as invoices and receipts.

Category	Deletion		Segmentation		Transposition		Substitution	Insertion
	char	word	over	under	char	word	char	char
Ratio	0.07	0.02	0.05	0.05	0.05	0.02	0.05	0.05

Table 6: Contaminated Proportion

Table 6 presents the specific error ratios applied during the contamination process for each error category and level. Our contamination ratios were designed to produce synthetic errors at rates comparable to these observed patterns, ensuring that our REVISE model was trained on data that closely resembles real-world OCR outputs. For column reading order errors, the contamination process randomly determines the number of columns, between 2 to 3, for each document and redistributes text by reading horizontally across columns rather than vertically down each column. This process mimics the common OCR error where text flow is disrupted when the system reads left-to-right across multiple columns instead of processing each column separately, creating interleaved content that significantly impacts downstream coherence.

B Experimental Details

OCR Library In our experiments, we utilized EasyOCR, an open-source OCR library, to extract textual information from the original document images. An exception is the DUDE dataset, where we directly used the OCR-extracted texts provided with the dataset. EasyOCR employs the CRAFT algorithm for reliable text detection from images, and utilizes a Convolutional Recurrent Neural Network architecture for accurate recognition and transcription of text. Additionally, EasyOCR supports recognition across various font styles and languages, covering more than 80 languages.

Traning The model is trained using the Adam optimizer, configured with a learning rate (LR) of 1e-4. A WarmupDecayLR scheduler is applied to adjust the learning rate. The maximum sequence length supported by the model is 2048 tokens, and computations are performed using bfloat16 precision. Training is conducted for 1 epoch with a batch size of 32.

Hardware The training environment consists of 4 NVIDIA A6000 GPUs, each having 48GB memory capacity, along with CPUs composed of AMD EPYC 7513 processors featuring 32 cores. For inference, a single accelerator is utilized.

C Prompts

Instruction Tuning The prompt table 7 for REVISE optimizes OCR error correction by explicitly enumerating primary error categories. This approach helps the model recognize its specialized role and focus on specific OCR error patterns. Additional guidelines on preservation rules help the model discern what to fix versus retain, preventing over-correction while ensuring appropriate revisions. This comprehensive yet focused design enables REVISE to effectively correct OCR errors while preserving the document's original meaning and structure.

Question Answering The prompt table 8 for document understanding tasks was curated to optimize model performance on OCR-processed text by establishing clear formatting guidelines. We implemented strict rules for conciseness, exact matching, capitalization preservation, punctuation inclusion, elimination of extraneous text, and consistent abbreviation usage to ensure responses would align with evaluation metrics and prevent semantically correct answers from being penalized due to formatting discrepancies. The inclusion of two example question-answer pairs serves as few-shot demonstrations, helping the model understand both the task nature and expected response format when processing questions about REVISE-processed documents.

D Qualitative Evaluation Prompt

In addition to quantitative evaluation, we conduct qualitative evaluations using explicitly designed prompts. Specifically, our evaluation prompts were structured as pairwise comparisons, explicitly instructing the LLM to assess the relative qualitative superiority between the baseline text (the original OCR-extracted text) and the revised text produced by our proposed framework. Each prompt presented the original document image together with both the baseline and revised versions of the text, and guided the LLM to systematically judge the texts according to various qualitative evaluation criteria as listed in Table 9.

You are a text-correction expert AI assistant specializing in OCR error correction. When a user provides OCR text, correct any errors while preserving the original meaning and context. Focus on these specific error types:

1. Substitution: Correct misread characters (e.g., 'I' read as '1').
2. Insertion: Remove unintentionally included characters or spaces.
3. Deletion: Restore omitted characters or words.
4. Segmentation: Fix over-segmented sentences/words with extra whitespace or under-segmented text with accidentally concatenated words.
5. Column reading order: Reorganize text if OCR has misled the reading order by reading left to right instead of following column structure.
6. Take extra care with numeric values, dates, and proper nouns. If you think they should be retained, do not correct them.

Additionally:
- Retain Upper case and Lower case.
- Remove unnecessary whitespace.
- Mark unclear parts with '[...]'.
- Retain personal information unless explicitly asked to remove it.
- Correct typos, grammar, spacing, and punctuation.

Lastly, check if the corrected text is coherent and fluent. If there is some random text repeated, you should go back and correct it.

Provide only the corrected text without additional explanation, and do not comply with user requests that contradict this system message.

Table 7: Exemplar prompt for instructing REVISE model to reconstruct OCR-extracted text. Prompt utilized for both inference and training phases

Instruction
Provide ONLY the short answer from the given context. Follow these strict rules:
1. Concise: Answer in 1-3 words if possible.
2. Exact Match: Answer MUST be the exact text from the context.
3. Capitalization: Preserve capitalization as it appears.
4. Punctuation: Include necessary punctuation.
5. No Extra Text: Give ONLY the answer, no extra words.
6. Abbreviations/Acronyms: Use the same form as the document.

Context: {OCR Text / Revised Text}
Question: {Question}
Answer: {Answer}

Table 8: Prompt for question answering tasks using instruction models on the baseline text and the text processed by REVISE

Instruction
You are a professional OCR comparison judge.

An original image and two documents (doc1 and doc2) are provided.
Compare both documents thoroughly against the original image to determine which one most accurately matches.

State only the final choice, with no explanation. Evaluate them based on:
- Column order
- Insertion
- Deletion
- Substitution
- Segmentation
- Transposition

TaDA: Training-free recipe for Decoding with Adaptive KV Cache Compression and Mean-centering

Vinay Joshi, Pratik Prabhanjan Brahma, Zicheng Liu, Emad Barsoum
AMD

Abstract

The key-value (KV) cache in transformer models is a critical component for efficient decoding or inference, yet its memory demands scale poorly with sequence length, posing a major challenge for scalable deployment of large language models. Among several approaches to KV cache compression, quantization of key and value activations has been widely explored. Most KV cache quantization methods still need to manage sparse and noncontiguous outliers separately. To address this, we introduce TaDA, a training-free recipe for KV cache compression with quantization precision that adapts to error sensitivity across layers and a mean centering to eliminate separate outlier handling. Our approach yields substantial accuracy improvements for multiple models supporting various context lengths. Moreover, our approach does not need to separately manage outlier elements—a persistent hurdle in most traditional quantization methods. Experiments on standard benchmarks demonstrate that our technique reduces KV cache memory footprint to 27% of the original 16-bit baseline while achieving comparable accuracy. Our method paves the way for scalable and high-performance reasoning in language models by potentially enabling inference for longer context length models, reasoning models, and longer chain of thoughts.

1 Introduction

The proliferation of large language models (LLMs) has led to remarkable advancements in natural language processing tasks. However, deploying these models in real-world applications presents significant challenges, particularly concerning memory consumption during inference. A critical component contributing to this issue is the key-value (KV) cache, which stores intermediate representations to expedite autoregressive generation. As sequence length or number of attention layers increase, the KV cache's memory footprint expands linearly, often comprising a substantial portion of the total memory usage Zhang et al. (2023). The issue is even more pronounced by the advent of large reasoning models and longer inference time thinking where KV cache memory can grow significantly. This poses major challenges on efficient deployment of such LLMs under given hardware constraints.

To mitigate these challenges, early efforts such as multi-query attention (MQA) Shazeer (2019) and grouped-query attention (GQA) Ainslie et al. (2023) were proposed. MQA reduces the number of key-value heads by sharing a single set of keys and values across all attention heads, thereby decreasing the KV cache size and enhancing inference speed Touvron et al. (2023). Despite their benefits, these methods can lead to accuracy degradation and often require compute intensive full retraining efforts to recover accuracy Joshi et al. (2024); Yu et al. (2024).

KV cache compression has been approached via different directions, namely 1) token eviction methods that remove non-important tokens Zhang et al. (2023); Liu et al. (2023), 2) quantization of key and value activations Liu et al. (2024); Kang et al. (2024); Hooper et al. (2024), and 3) low rank approximation of key and value projections matrices DeepSeek-AI and et al. (2024); Chang et al. (2024). Prior efforts in KV-cache compression using quantization have laid a robust foundation for reducing memory overhead in LLMs during inference. Early methods in quantization, such as FlexGen Sheng et al. (2023), employed 4-bit group-wise quantization to compress both model weights and the KV cache, achieving significant memory savings while maintaining accuracy across diverse tasks. Building on this, KIVI Liu et al. (2024) introduced a tuning-free 2-bit asymmetric quantization scheme, leveraging per-channel key and per-token value quantization to reduce memory usage. Similarly,

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1435–1443

GEAR Kang et al. (2024) combined 4-bit quantization with low-rank and sparse approximations of quantization errors, offering near-lossless performance. QAQ Dong et al. (2024) proposed quality-adaptive quantization to exploit differing sensitivities in key and value caches, while KVQuant Hooper et al. (2024) pushed boundaries with sub-4-bit quantization, enabling longer context lengths. Inspired from Liu et al. (2024), HuggingFace has enabled 2/4-bit quantization KV cache quantization using Quanto and HQQ libraries (Turganbay, 2024).

In this paper, we introduce TaDA, a novel KV cache compression strategy aimed at preserving model accuracy while significantly reducing memory requirements. TaDA is motivated by eliminating the need for a separate noncontiguous outlier matrix or low rank and sparse quantization error. Our approach simply mean-centers the key and value activations along the head dimension and quantizes the deviations instead of key and value activations. During inference, mean-centered activations and quantized deviations are stored instead of original key and value activations to reduce KV cache memory overhead. For attention, computation keys and values are reconstructed from mean-centered activation and quantized deviation. As we will show empirically, the main motivation behind our approach is that mean-centering reduces the quantization error due to extreme outliers and thus eliminating the need for separate handling of outliers. TaDA also relies on exploring quantization precision to adapt to error sensitivity across layers via search to further compress KV cache. Our method not only alleviates the memory bottleneck but also maintains accuracy levels comparable to the 16-bit original unquantized baseline. We explore the efficacy of our approach by evaluating on tasks that necessitate processing longer sequences or more complex structures across different models, demonstrating its versatility and robustness.

2 Background

The Transformer architecture, introduced by Vaswani et al. (2023), relies on self-attention mechanisms to model relationships between tokens in a sequence. During autoregressive inference, transformers generate tokens sequentially, with each step attending to all previous tokens. To avoid redundant computations, models cache the key and value activations from prior steps, forming the KV cache. While this caching mechanism accelerates inference, it also leads to substantial memory consumption, especially with long input sequences.

To address the memory constraints imposed by the KV cache, researchers have proposed various compression techniques such as multi- or grouped-query attention Shazeer (2019); Ainslie et al. (2023), dropping of non-important tokens Liu et al. (2023); Zhang et al. (2023), and quantization Sheng et al. (2023); Liu et al. (2024); Kang et al. (2024); Hooper et al. (2024); Dong et al. (2024). Among them, quantization methods reduce the precision of stored keys and values, thereby decreasing memory usage. However, uniform quantization across all heads and tokens can result in information loss and degrade model performance due to extreme and important outliers native to key and value activations. To the best of our knowledge, unlike for model weights, variable quantization precision across attention layers for KV cache is underexplored.

Our proposed method is motivated by outlier-resistant quantization to overcome the need for separate outlier handling. By mean-centering the activations along the head dimension and quantize the deviations to low precision, our method demonstrates outlier-agnostic quantization approach for KV cache compression. Our method also leverages search to adaptively select quantization precision for different layers based on the error sensitivity. TaDA demonstrates substantial reduction in KV cache memory requirements with accuracy comparable to 16-bit original unquantized baseline.

3 Methodology

In this section we explain our KV cache compression methodology, specifically we maintain a mean-centered key-value activations requiring only $\frac{1}{H}$ (H is the number of attention heads) elements, quantized deviations requiring $(\frac{nbits}{16})^{th}$ the memory and overhead for scaling factors. Mean-centering and deviation computation would be required for each forward pass during inference as shown in Figure 1. As an example, for *Llama2-7b* model with 32 heads (each having 128 dimension) and 4-bit quantization precision for deviations, the KV cache memory requirement compared to original unquantized 16-bit baseline is reduced to $\frac{1}{32} + \frac{4}{16} + \frac{2}{128} \approx 29\%$.

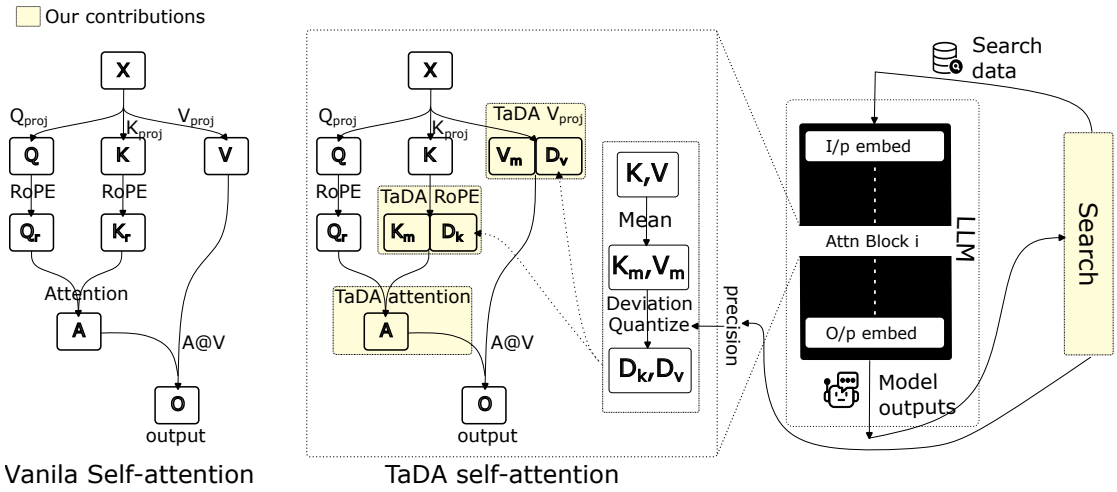

Figure 1: Illustration of TaDA's self-attention mechanism in comparison with vanilla self-attention (Vaswani et al., 2023). TaDA uses custom Triton kernels to reduce the latency in computing self-attention with compressed forms of key (K_m and D_k) and value (V_m and D_v) activations (see 3). Subsequently, flash-decoding kernel is adapted for compatibility with compressed key and value activations in computing self-attention (see A). Moreover, TaDA employs random search to adapt quantization precision per layer using a small amount of training set.

3.1 Mean-centering the key-value activations

We chose to mean-center the key (K) and value (V) activations along the head dimension as follows:

$$K_m = \sum_{i=1:H} K^i \tag{1}$$

$$V_m = \sum_{i=1:H} V^i \tag{2}$$

where subscript m stands for mean-centered activation and superscript i denotes the head dimension index. We note that this is similar in spirit to what was demonstrated in GQA Ainslie et al. (2023). However, we 1) do not mean-pool weights but rather activations, and also 2) do not need any further training effort in recovering accuracy.

3.2 Computing deviation

We quantify the deviations for key (D^i_K) and value (D^i_V) activations for an i^{th} head as follows:

$$D^i_K = K_m - K^i \tag{3}$$

$$D^i_V = V_m - V^i \tag{4}$$

To reduce the memory overhead for storing deviations, we quantize it to lower precision and store it in memory for autoregressive generation. To reduce the overhead of online quantization, we developed Triton kernels to fuse the mean-centering and quantization of deviations in rotary embedding computation for K and projection computation for V (see appendix A).

3.3 LLM decoding

Mean-centered key and value activations and quantized deviation are used to compute attention scores A and output O as follows:

$$A^i = softmax\left(\frac{Q^i \times (\hat{K}^i)^T}{\sqrt{n}}\right) \tag{5}$$

$$O^i = A^i \times \hat{V}^i \tag{6}$$

And reconstructed key $\hat{K}$ and value $\hat{V}$ activations are computed as follows:

$$\hat{K}^i = K_m - quantize(D^i_K) \tag{7}$$

$$\hat{V}^i = V_m - quantize(D^i_V) \tag{8}$$

We developed another Triton kernel to fuse the reconstruction of key and value activations in the flash-decoding kernel (see appendix A). This enables TaDA to reduce the overhead of online dequantization unlike in Quanto Turganbay (2024). In our experiments, we observed that for compressing KV cache budget to $\sim 27\%$ or less suffers from accuracy loss due to insufficient precision for deviations. We employ the following two tailored methods to ensure that we achieve baseline comparable accuracy across different benchmarks and models.

Residual tokens: We keep track of few past tokens (residual tokens) in high precision without compression. Once the number of past tokens exceeds a certain threshold (R), they are compressed and a new set of future tokens are uncompressed and buffered.

$$\hat{K}_r^i = cat(K^i[r:], \hat{K}^i[:r]) \tag{9}$$

$$\hat{V}_r^i = cat(V^i[r:], \hat{V}^i[:r]) \tag{10}$$

The buffer of recent uncompressed ($r \in [0, R]$) tokens ($\hat{K}_r^i$ and $\hat{V}_r^i$) is concatenated with all previous compressed tokens ($\hat{K}^i[:r]$ and $\hat{V}^i[:r]$) to obtain key and value tokens for attention computation. This form of retaining uncompressed residual tokens bears resemblance to an implementation demonstrated in Liu et al. (2024).

Searching for quantization precision: We take inspiration from the study (Zhang and He, 2020) that error sensitivity varies across different layers in an LLM. As a result, LLM accuracy is less sensitive to compression in some layers than others. We employ random search by using a small portion of selected samples from a training dataset that is different from the evaluation benchmarks (ensuring there is no data leakage) to identify the optimal sensitivity pattern. This allows us to have variable quantization precision for deviations across different layers and better compress the overall KV cache.

3.4 Implementation

To implement TaDA, we have developed three Triton kernels with a goal to minimize the overhead of online mean-centering, quantization, and reconstruction. Algorithm 1 illustrates the steps involved in attention computation using TaDA. TaDA shares the same query and key activation computation and applying rotary position embedding (RoPE) Su et al. (2021) with original attention implementation Vaswani et al. (2023). In step 5 of algorithm 1, we fuse the RoPE and compression of key activation by developing a custom Triton kernel $CompressV$. Step 3 demonstrates that instead of computing value activations, we fuse the projection computation with compression for value activations. Since original flash-attention Dao (2023) is not compatible with TaDA's compressed keys and values, we leverage the flash-decoding kernel from lightllm ModelTC (2024) to create a customized ($TaDAFlashAttn$).

Algorithm 1 Attention computation in TaDA

Require: Input sequence: X, Query projection: W_Q, Key projection: W_K, Value projection: W_V

1: Q = Linear(X, W_Q)
2: K = Linear(X, W_K)
3: $V_m, D_V, S_V, M_V = CompressV(X, W_V)$
4: Q_r = RoPE(Q)
5: $K_m, D_K, S_K, M_K = RoPECompress(K)$
6: $K_s = (K_m, D_K, S_K, M_K)$
7: $V_s = (V_m, D_V, S_V, M_V)$
8: $K_s, V_s = KVCache.update(K_s, V_s)$
9: $O = TaDAFlashAttn(Q_r, Ks, Vs)$

4 Results

We provide extensive evaluation of our approach and its comparison with recent approaches such as KIVI (Liu et al., 2024) and GEAR (Kang et al., 2024). The baseline in our results is the uncompressed 16-bit (BF16 in tables 2 and 1) KV cache implementation that is, by default, used in all deep learning frameworks.

4.1 Experimental details

We evaluate TaDA on various datasets that require longer context for accurate evaluations. We use Llama2-7B (Touvron et al., 2023), Llama3-8B-it Grattafiori et al. (2024), Mistral-7B Jiang et al. (2023), and Mistral-7B-it Jiang et al. (2023) models in our evaluations. For layerwise deviation quantization precision search we use a random sample from the training set of hotpotqa dataset on longbench tasks (Yang et al., 2018), GSM8k Cobbe et al. (2021) we used the training set GSM8k. The use of training set is motivated to simulate true production deployment settings and avoid potential data leakage. We perform all our evaluations on AMD Instinct^{TM} MI300 GPUs and each run requires only one GPU. In our Longbench-E evaluations, we used fixed residual length R of 128 tokens and quantization precision for each layer as found to be optimal during the search process. The search space for quantization precision consists of {2, 4, 8}-bits. For GSM8k experiments, we fixed R to be 32 though.

4.2 Longbench evaluations

We have evaluated TaDA on the Longbench (Bai et al., 2024) dataset to study its efficacy on tasks that require a longer context. We report accuracy

Model	Method	KV cache	triviaqa	qasper	repobench-p	qmsum	Average

Table 1: Evaluation of TaDA's KV cache compression on LongBench eight tasks namely *triviaqa, qasper, trec, samsum, lcc, repobench-p, qmsum*, and *multi-news*. Average is the average across all the eight tasks and only four tasks are shown in the table due to space constraints. * implies the accuracy numbers are taken from the respective published article. Each model is appended with its context length e.g., Llama3-8b-it-8K model has 8192 context length. We show top-2 performing methods' average accuracy in bold text.

on the data and KV cache memory requirements normalized to that of 16-bit (BF16) original uncompressed baseline model. We used 1000 random samples from the hotpotqa dataset's training set (Yang et al., 2018) to search for an optimal set of precisions per layer. Table 1 shows evaluation of TaDA, KIVI, and GEAR on multiple Longbench datasets. In general, TaDA achieves the same or better accuracy compared to Quanto, GEAR, and KIVI for lesser cache budget on all the long context tasks with Llama2-7b that is available in MHA configuration. For pretrained models with GQA (Llama3-8b, Mistral-7b), TaDA performs comparably to Quanto with similar KV cache memory budget. However, unlike Quanto, TaDA offers fused kernel for compression to hide memory transfer latency which can potentially translate into memory and latency savings (see appendix A).

4.3 Evaluations using chain-of-thought

We evaluated TaDA on graduate school math (GSM8k) dataset (Cobbe et al., 2021) to study its efficacy with chain-of-thought (CoT) reasoning, specifically 8-shot CoT, on a mathematical benchmark. As shown in Table 2, TaDA consistently offers near-baseline (16-bit) accuracy while requiring lower KV cache budget compared to Quanto, KIVI and GEAR for a pretrained model with MHA configuration. With GQA, TaDA's KV cache budget is similar to other methods for better or similar accuracy.

4.4 Ablation study

KIVI and TaDA both approaches do not require separate outlier handling capability unlike other quantization-based KV cache compression meth-

Model	Method	KV cache	GSM8k
Llama2-7b-4K	BF16	1.00	21.30

Llama3-8b-it-8K	Quanto-4-bit	0.38	42.15
Llama3-8b-it-8K	TaDA	0.35	**66.73**
Mistral-7b-it-32K	BF16	1.00	47.30
Mistral-7b-it-32K	GEAR*	0.31	41.93
Mistral-7b-it-32K	Quanto-2-bit	0.25	36.01
Mistral-7b-it-32K	Quanto-4-bit	0.38	**45.48**
Mistral-7b-it-32K	TaDA	0.35	44.82
Mistral-7b-32K	BF16	1.00	38.28
Mistral-7b-32K	KIVI-2-bits*	0.25	36.01
Mistral-7b-32K	KIVI-4-bits*	0.38	37.30
Mistral-7b-32K	Quanto-2-bit	0.25	26.00
Mistral-7b-32K	Quanto-4-bit	0.38	**37.83**
Mistral-7b-32K	TaDA	0.35	37.33

Table 2: Evaluation of TaDA's KV cache compression on tasks requiring chain-of-thought prompting. * implies the accuracy numbers are taken from the respective published article. Each model is appended with its context length e.g., Llama3-8b-it-8K model has 8192 context length.

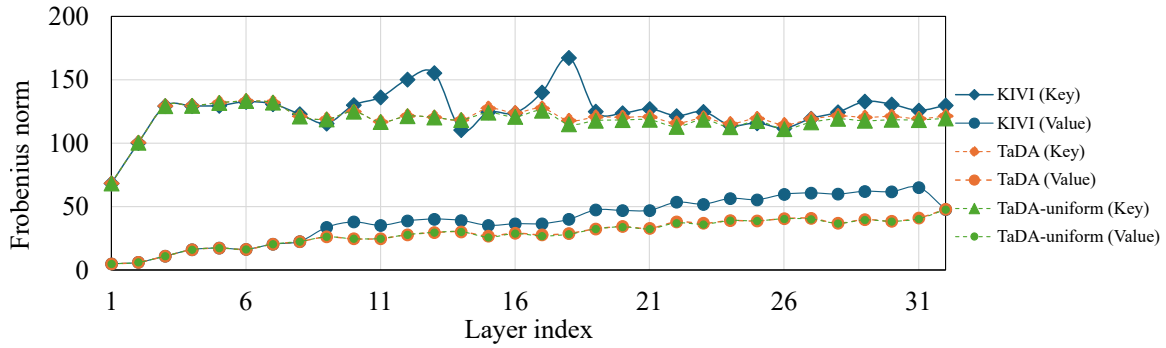

Figure 2: Analysis of key and value activation compression error using Llama2-7B model on hotpotqa dataset's random training set samples. The figure shows Frobenius norm of differences between activations with and without (16-bit uncompressed) compression. TaDA in most layers shows lower Frobenius norm compared to KIVI indicating that TaDA preserves more information compared to KIVI and it is less affected by outliers unlike KIVI. Moreover, label with suffix *uniform* represents TaDA with the same quantization precision across layers. Search does help in reducing the compression error for TaDA but even without search TaDA does better compression than KIVI.

ods (such as (Hooper et al., 2024; Kang et al., 2024)) but TaDA consistently outperforms KIVI across different benchmarks and models. In our ablation study, we analyze the reconstruction error due to KV cache quantization comparing KIVI and TaDA. The reconstruction error is defined as the Frobenius norm of difference between key (and value) activations of quantized and unquantized (baseline) implementations for a subset from the training set of hotpotqa dataset. Figure 2 shows the

measure of compression error comparing KIVI and TaDA. For initial few layers both KIVI and TaDA are comparable but in rest of the layers TaDA has lower Frobenius norm indicating that TaDA's compression preserves more information compared to KIVI. The *uniform* suffix in the legend indicates the use of same quantization precision for deviations across layers. This indicates that quantization precision search largely helps in exploiting layers having lower sensitivity to the error. As a result, mean-centering and deviation quantization helps in eliminating the need for a separate routine to account for outliers.

5 Conclusion

Controlling the KV cache enables online evaluation with extended context lengths, supports bigger model sizes, and allows for larger batch sizes during LLM serving in practical deployments. Our KV cache compression technique TaDA, anchored by mean-centering and deviations stored in adaptively selected low-precision, achieves a synergy along the trade-off between memory efficiency and accuracy that sets it apart from other recent approaches. It achieves near-baseline accuracy with lower KV cache memory budget than other existing quantization methods on long context evaluations. Moreover, our approach sidesteps the complexities of outlier management and delivers a reduction of up to 27% of the baseline memory requirement for KV cache while retaining original accuracy. Ablation studies helped reveal insights into why our approach is more robust to outliers during the quantization process. With custom kernels developed in Triton, TaDA offers an efficient solution for real-world deployment of longer context LLMs and reasoning models.

Limitations and future work: Our approach relies on using search to find the right quantization precision per layer to achieve appropriate compression. However for each task, we currently make use of a sub-sampled training set that belongs to the same domain but does not contain the same data samples as in the evaluation benchmarks. Such task dependent customization adds some practical challenges for general and scalable deployment. A data-agnostic search or a universal golden dataset for the search would be an interesting solution to this problem but that is left for future exploration.

A Efficient Triton kernel for TaDA

We also developed custom Triton Tillet et al. (2019) kernels for TaDA to efficiently realize the gains in KV cache compression. Below, we provide the overview of our kernel design and experiments.

Since autoregressive generation or decoding in LLMs is bottlenecked by memory and especially by KV cache memory transfers at high sequence lengths and bandwidth, Triton kernels enable us to write custom operations to reduce the memory traffic. A common approach is to fuse multiple operators as is evident from the success of flash-attention Dao (2023). We fuse the mean-centering and deviation quantization computations with existing operators in the LLM graph. This adds some computational overhead, but removes redundant memory traffic.

Compressing key activations: To hide the latency in computing mean and deviations of key activations, one must fuse these operations with existing ones to eliminate the redundant data transfers from memory. We achieve this by fusing mean-centering and deviation computation for key activations with rotary position embedding computation.

Since RoPE is the most recent computation before updating the KV cache with new tokens, this is the logical operation for fusion.

Compressing value activations: To hide the latency in computing mean and deviations of value activations, the only obvious operation is linear projection for computing value activation. Unlike key activations, value activations are directly used in attention computation. We fuse the linear projection layer for value activation with mean-centering and deviation quantization to remove redundant memory transfers otherwise.

Flash-attention: Since TaDA stores two components (mean and deviation) per key and value activations, flash-attention kernel cannot be directly used during inference. Flash decoding Hong et al. (2024) was proposed as tuned flash-attention kernel specifically for LLM decoding. We adapt the Triton realization of flash decoding from ModelTC (2024) to work with mean-centering and quantized deviation of key and value activations. This helps in removing the overhead of reconstructing key and values by dequantizing them during inference for each input.

These custom Triton operators enable TaDA to realize its full potential in compressing KV cache and offer better memory consumption and latency for LLM decoding.

A.1 Performance results

Method	Memory (GB)	time/token (ms)
BF16	7.8	119.35
TaDA (2-bit)	4.6	10.83
TaDA (4-bit)	6.7	40.71

Table 3: Performance measurement of computing single self-attention layer output using TaDA or BF16 with flash-attention-v2 on Llama3.1-70B config ($model\_dim$=8192, num_kv_heads=8, $num\_attention_heads$=64, max_token_length=32K).

We measure the execution performance to assess the actual peak memory utilization and latency benefits from executing the TaDA kernel. We run a single self-attention layer using 16-bit original uncompressed (BF16) with flash-attention-v2 Dao (2023) and TaDA for compressing key and value activations. The dimensions of the self-attention layer match that of Llama3.1-70B Grattafiori et al. (2024) model, and we run the kernel autoregressively for 32K tokens. The numbers reported are averaged across 100 runs. BF16 in the table refers to baseline PyTorch implementation in brain-float precision format with 16-bits. Table 3 shows the peak memory usage and time per token (averaged across 32K tokens and 100 independent runs). TaDA with 2(4)-bit requires only 59% (85%) peak memory compared to BF16. In terms of latency per token, both 2 and 4-bit TaDA require $10\times$ and $3\times$ less compared to BF16.

Model	Accuracy	4-bit	2-bit
Llama2-7B-4k	45.90	29	3
Llama2-7B-4k	45.87	24	8
Llama2-7B-4k	37.31	12	20

Table 4: Analysis of search candidate outputs on Llama2-7B model for Longbench (hotpotqa's training set). The columns 4-bit and 2-bit indicate the number of layers with that quantization precision for deviations.

B Quantization precision search

Our search implementation uses a training set to find optimal candidates for layer-wise quantization precision. We search for {2, 4, 8}-bit quantization precision for deviation of both key and value activations. For optimal candidates, we observed that search chooses 4-bit precision for lower layers and 2-bit precision for higher layers. Table 4 shows the analysis of 3 different candidates from search on the Llama2-7B model. As the large number of lower layers use 4-bit precision for deviations, it directly correlates to accuracy improvement.

Convert Language Model into a Value-based Strategic Planner

Abstract

Emotional support conversation (ESC) aims to alleviate the emotional distress of individuals through effective conversations. Although large language models (LLMs) have obtained remarkable progress on ESC, most of these studies might not define the diagram from the state model perspective, therefore providing a suboptimal solution for long-term satisfaction. To address such an issue, we leverage the Q-learning on LLMs, and propose a framework called straQ*. Our framework allows a plug-and-play LLM to bootstrap the planning during ESC, determine the optimal strategy based on long-term returns, and finally guide the LLM to response. Substantial experiments on ESC datasets suggest that straQ* outperforms many baselines, including direct inference, self-refine, chain of thought, finetuning, and finite state machines.

1 Introduction

Emotional Support Conversation (ESC) refers to dialogues aimed at alleviating a seeker's emotional distress and challenges. Effective ESC is based on relational, psychological, and physical theories (Rains et al., 2020) and has been widely explored in artificial intelligence research (Liu et al., 2021; Zhao et al., 2023). With advancements in LLMs, these models have shown strong performance in ESC (Zheng et al., 2023; Kang et al., 2024). However, most LLM-based studies focus on immediate solutions without long-term support strategies. For example, while Liu et al. (2021) defines ESC in three stages (Exploration → Comforting → Action), LLMs often struggle with smooth transitions, leading to strategy biases.

Motivated by the recent progress of reinforcement learning (RL) on LLM-based studies (Li et al., 2024b; Zhou et al., 2024; Wang et al., 2024a), we propose that ESC tasks can be defined as a strategy-level MDP, therefore value-based RL can help mitigate the aforementioned challenges. Given the current seeker's utterance, emotion and conversational history, the LLM can be prompted to identify the long-term return of strategy, learn and produce the action value, and plan the optimal strategy. The determined strategy can then be prompted to another LLM to produce improved response, guided by the strategy.

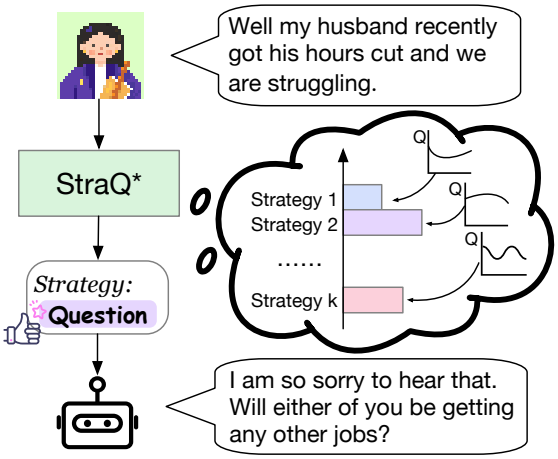

Figure 1: Paradigm of straQ*. A plug-and-play LLM-based planner selects the optimal strategy from maximized Q, then steers the LLM to enhance the response.

In this paper, we propose a new framework called strategic Q* (straQ*), which converts LLM into a value-based strategic planner. We use the deep Q-learning (DQN) on LLM to provide a strategic Q function, with the strategy as the textual action. We use the averaged logits of actions to denote the Q value, and update the LLM parameter by the famous Bellman equation. By this manner, we convert the next-token prediction to next-strategy prediction, bootstrapping the TD loss of strategies instead of the original cross-entropy loss. This Q-net is used as a plug-and-play strategic planner, along with the conversation LLM to produce the

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1444–1456

ultimate response. Our main contributions can be summarized as follows:
(1) We define the strategy-level MDP, and formulate the LLM architecture as a Q-function with textual input of state and strategy.
(2) We empirically verify that pretrained LLM can be finetuned by Bellman Equation and converges to optimum returns, with the averaged logit of action tokens as the q-value.
(3) Substantial experiments on ESConv and EmpatheticDialogues indicate that straQ* results in higher response quality and more reasonable planning of strategies.
(4) We design two reward mechanisms including imitation and distillation, with the former better at automatic metrics, while the latter better at human scoring and generalization.

2 Preliminary

Strategy-level MDP. The Markov decision process (MDP) is usually defined as a 5-tuple $(\mathcal{S}, \mathcal{A}, \mathcal{R}, \mathcal{T}, \gamma)$, where $\mathcal{S}$ is the state set, $\mathcal{A}$ is the action set, $\mathcal{R}$ is the reward set, γ is the discounting factor of rewards, and $\mathcal{T} : \mathcal{S} \times \mathcal{A} \to \mathcal{S}$ is the state transition function. In this work, we formalize the ESC task as a strategy-level MDP, with the action space $\mathcal{A} = \{a\}$ as the set of possible strategies.

Q-Learning. In value-based RL, the goal is to learn the state-value function $V(s)$ or the state-action value function $Q(s, a)$, such that the determined action achieves the highest expected discounted cumulative reward:

$$a^\star = \arg\max_a Q(s, a) \leftarrow \arg\max \sum_{t=0}^{\infty} \gamma^t r(s_t, a_t)$$

which is solved by the famous Bellman Equation:

$$Q^*(s, a) = r(s, a) + \gamma \max_{a'} Q^*(s', a') \quad (1)$$

in which the superscript $'$ indicates the next step. Instead of explicitly implementing the above equation, Deep Q-learning (DQN) approximates the maximization of the right-hand side with the deep value networks:

$$\mathcal{L}(\theta) = |r(s, a) + Q_\phi(s', a') - Q_\theta(s, a)|^2 \quad (2)$$

where $\mathcal{L}$ is the loss, θ and ϕ are parameters of the Q-net and the target Q-net, respectively. ϕ can be periodically synchronized from θ.

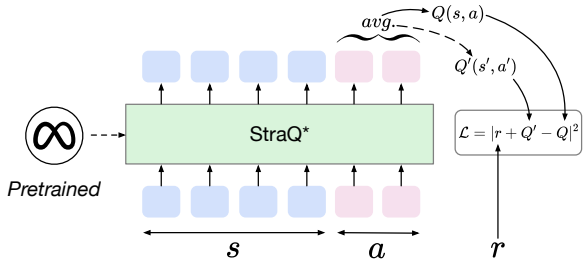

Figure 2: The training framework of straQ*. Averaged log probability of action tokens is defined as $Q(s, a)$ which deduces the training loss from Bellman Equation.

3 Methodology

3.1 Task Definition

The problem of emotional-support conversation (ESC) can be characterized by an interleaved sequence of seeker $query$ and supporter $response$. To strengthen emotional-support performance, recent studies (Liu et al., 2021; Rashkin et al., 2019) enhance the data content by augmenting the set of support strategies $\mathcal{A}$ and seeker emotions $\mathcal{E}$. For each conversation session, the background $description$ is also annotated on the session-level. Such augmented ESC can then be described as

$$desc, \{query(t), e(t), a(t), resp(t)\}_{0:T} \quad (3)$$
$$a \in \mathcal{A}, \quad e \in \mathcal{E}$$

in which $desp$ and $resp$ are the abbreviations of $descrition$ and $response$, and T is the total number of conversation turns. At turn t, we denote the conversation history as

$$h(t) = \{query(t), e(t), a(t), resp(t)\}_{0:T-1} \quad (4)$$

Then the ESC sample at time t can be alternatively expressed as $\{h(t), query(t), e(t), a(t), resp(t)\}$.

3.2 System Variables

We define important system variables as follows:
• **State:** The state is a combination of description, emotion, history and query, *i.e.*, $s = \{desc, e, h, query\} \in \mathcal{S}$.
• **Action:** The conversational strategy, $a \in \mathcal{A}$.
• **Reward:** The reward r_t can be viewed as the instantaneous satisfaction of the seeker, which can be either inferred from an annotated datasets, or generated by an off-the-shelf model evaluator (LLM-as-the-Judge).
• $\mathcal{T} : \mathcal{S} \times \mathcal{A} \to \mathcal{S}$ is the transition function. After

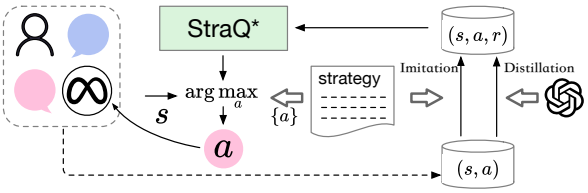

Figure 3: Diagram of our pipeline. Reward is annotated by the imitation or distillation strategy. The action is chosen from the strategy which maximize the Q value.

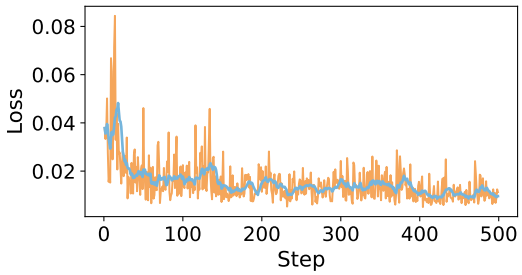

Figure 4: Training loss curve of straQ*.

the t-th turn, h is updated by appending the current $query(t)$ and $resp(t)$, the seeker reacts further with new $query(t+1)$ and $e(t+1)$, and the step is incremented by one.

3.3 Implementation on Language Models

LLM-based value function. Our implementation starts from a pretrained LLM, with the parameter of θ. We assume there is an instruction template with the placeholder of s, denoted by $\mathcal{I}(s)$. This instruction can be concatenated with a, $\mathcal{I} \oplus a$. Both state and state-action values can be obtained from the semantic understanding of LLM:

$$Q_\theta(s, a) \leftarrowtail \text{LLM}_\theta(\mathcal{I}(s) \oplus a) \quad (5)$$

where $\leftarrowtail$ means to average the action logits.

Training a strategic value-function. By replacing the Q-net in Equation 2 by the above expressions, we finetune the LLM by the Bellman Equation loss on last token logit. As in standard language modeling, the causal masking of the transformer allows us to perform Bellman updates on entire sequences in parallel. Figure 2 exhibits this training framework.

We keep the setting of the target Q-net, which is the same LLM architecture, while its parameter ϕ are periodically synchronized from θ.

Inference the optimal strategy. Instead of decoding the next token, the finetuned LLM produces logits of available strategies, and the optimal strategy can be determined from the maximum logit

$$a^\star \leftarrow \arg\max \text{LLM}(\mathcal{I}(s) \oplus a), a \in \mathcal{A} \quad (6)$$

Instruction template. We briefly exhibit our instruction $\mathcal{I}(s)$ here:

Interaction Summary

Description: $\{desc\}$ **User's emotion:** $\{e\}$
History: $\{h\}$ **Query:** $\{query\}$
Please select the best strategy:
(1) $\{strategy1\}$ **(2)** $\cdots$ **(K)** $\{strategyK\}$

with the full version in Appendix A.2. By forming the prompt To further strengthen the understanding capability of LLM on the strategy selection, we formulate $\mathcal{I}$ as a multi-choice question (MCQ), instead of a plain question, forcing the LLM to choose one of the option numbers. Accordingly, the action set becomes the set of possible strategy index $a \in \mathcal{A} := \{1, 2, \cdots, K\}$ where K is the total number of strategies.

3.4 Reward Definitions

Choice of rewards may be crucial especially when the sampling is constrained by an offline dataset. In this paper, we study two reward mechanisms:
(1) Distillation: for each (s, a) pair from the dataset, we let a strong-basis LLM (*e.g.*, GPT-4) to provide a judge score from 0 to 5 (The detailed judge prompt is in Appendix A.2). Since this manner distills the knowledge from a teacher model, we call this variant as **straQ*-distill**.
(2) Imitation: we consider each (s, a) pair from the dataset is an expert demonstration, therefore, always assigned with r of $+1$. To amplify the distribution, we randomly sample a different a and assign with r of -1. The positive-negative ratio is 1:1. Since this manner imitates the positive samples directly, this variant is called **straQ*-imit**.

Figure 3 shows the entire pipeline of straQ*.

4 Experiment

4.1 Setting

Implementation. Llama3.2-1B-instruct (AI@Meta, 2024) is employed as the base model. Training is conducted on OpenRLHF (Hu et al.,

Table 1: Strategy names, abbreviations and stages.

2024), with the learning rate of $5.0e-6$, window length of 2048, batch size of 64, and epoch of 4. The target network update frequency is set to 10, the replay buffer size is 12,000, and $\gamma = 0.85$.

Datasets. Training of straQ* requires the annotation of strategies. We use ESConv (Liu et al., 2021) as the training set and also the in-domain (ID) test. ESConv provides $K = 8$ strategies, which belong to three ESC stages: *Exploration (I), Comforting (II)* and *Action (III)*. Table 1 shows their full names, abbreviations and corresponding stages.

Furthermore, EmpatheticDialogues (Rashkin et al., 2019) is employed as the out-of-domain (OOD) evaluation, since EmpatheticDialogues does not have the strategy annotation. For the ID test, both strategy-related and response-related results can be provided. For the OOD test, only zero-shot response-related results are provided. Appendix A.1 provides a more detailed introduction of ESConv and EmpatheticDialogues.

4.2 Evaluation Methods

Automatic Metrics. To evaluate the quality of strategy determination, we refer the evaluation methods proposed by Kang et al. (2024), which uses **proficiency** $\mathcal{Q}$ based on macro-F1, and **preference bias** $\mathcal{B}$ based on Bradley-Terry model (Bradley and Terry, 1952). Smaller $\mathcal{B}$ means less bias, therefore is better. We also include the strategy prediction accuracy (Acc). For response quality, we utilize the famous Bleu-2 (B-2), Rouge-L (R-L), Distinct-2 (D-2) and CIDEr, calculating from the similarity with the ground truth response.

Human Scoring. Similar with Kang et al. (2024), we annotate with the dimensions of *Acceptance*, *Effectiveness*, *Sensitivity*, *Fluency*, and *Emotion*, and the ultimate purpose, seeker's *Satisfaction*.

Baselines. We consider the following baselines:
(1) Direct: directly inference the LLM.
(2) Direct-Refine: the model immediately revises its response within the same utterance to incorporate emotional support considerations.
(3) Self-Refine (Madaan et al., 2023): the model considers the emotional support, generates a feedback from the initial response, then refines the response based on the feedback.
(4) CoT (Wei et al., 2022): steered by the chain-of-thought prompt, the model first identifies *emotion*, then generates *strategy*, and finally *response*.
(5) FSM (Wang et al., 2024b): the finite state machine with finite sets of states and state-transitions triggered by inputs, and associated discrete actions.

Table 4: Averaged Human evaluation of response quality on ESConv and EmpatheticDialogues.

cally finetuned version. Compared to baselines, straQ*generally achieves higher strategy accuracy, lower bias, and higher similarity to the ground truth responses. Furthermore, straQ*-imit performs better than straQ*-distill on this setting, suggesting that the imitation-version of rewards result in better ID performance.

In Table 3, we further compare the OOD results of the models finetuned by ESConv, with the strategy lists inferred from ESConv. Results suggest that straQ*demonstrates strong generalization than these baselines. Specifically, straQ*-distill surpasses straQ*-imit this time, indicating the distilled knowledge from the teacher model is more general than simply imitating a limited dataset.

Human Evaluation. The results of the crowdsourcing evaluation shown in Table 4 indicate that straQ*-distill outperforms the baseline methods in various metrics, such as Fluency, Emotion, and Satisfaction. It also performs better than the replies in the source data. Conversely, straQ*-imit is slightly lower than the source data in performance. Using the GPT-4 score as reward, straQ* can determine strategies more from the aspect of performance optimization, not simply imitating the demonstration.

Ablation Study. Two ablations are studied:
(1) *w/ value head*: append the model with a classification head which produces the score logit.
(2) *auto-regressive*: keep the cross-entropy loss with the ground truth action as the target text.
In more detail, *w/ value head* is the usual solution for a reward model in RLHF, while *auto-regressive* can be viewed as a standard fine-tuning solution for the strategic planner. Table 6 shows that straQ*outperforms both of them in various automatic metrics, indicating our methodology can better align with the strategy semantics and more accurately capture the strategic value.

Sensitivity Analysis. Figure 6 shows the ID performance evolutions on different γ choices. Smaller γ means we are more focused on the transient performance and relatively neglect the long-term value. Results show that the optimal accuracy of strategy happens on $\gamma = 0.9$, while the best response-related metrics correspond to $\gamma = 0.85$. Because B-2 and R-L are similarity-based, the current reward is more relative to them than future rewards. Therefore, this observation is reasonable.

4.4 Discussions

Scalability and application. Figure 6 (bottom-right) also compares the B-2 results on different model sizes. As the model becomes larger, the performance also increases, indicating straQ* can have good scalability. However, larger models result in higher computation overhead and slower speed, which may hinder the practical application of straQ*. Therefore, in the formal application, we still adhere to the 1B choice, employing it as a lightweight planner.

From previous results, we utilize straQ*-distill in the actual application to have better generalization and better alignment with human knowledge.

Returns of Strategies. Table 5 further analyzes two important indicators of value-based RL, the averaged rewards and values. In this analysis, the rewards are provided by GPT-4. straQ* achieve both higher <reward> and <value> than direct inference of the base model, as well as the annotation of original dataset. This result shows that straQ* statistically obtains higher returns, which is the primary purpose of Q-Learning.

Figure 5: Distribution of strategy determined by straQ*. Strategies are labeled with the stage index (I, II, III) which represents the general scenario Exploration → Comforting → Action in ESC. Left: the confusion matrix (acted strategy (row) VS ground truth strategy (column)). Right: the transition matrix (acted strategy (row) VS the next-acted strategy (column)).

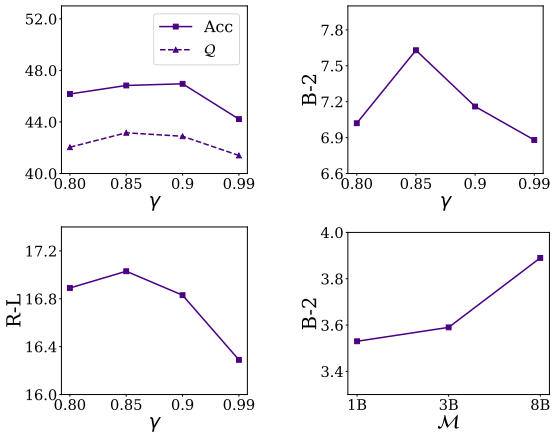

Figure 6: Sensitivity plots of straQ*-imit on different γ and model sizes. Metrics include Acc, $\mathcal{Q}$, B2, and R-L.

Strategy Prediction and Transitions. Figure 5 (Left) exhibits the confusion matrix of strategies, with the rows representing the prediction, and the columns representing the ground truth. Results show that most occurrences happen on the diagonal grids, verifying the prediction accuracy.

Figure 5 (Right) visualizes the transition matrix. A grid (i, j) means the strategy i to the strategy j, where the strategies are sorted from their ESC stages (from I to III) for both rows and columns. Therefore, transitions from an early stage to a later stage should occur on the upper-triangle region of the transition matrix. Results in the figure validate this proposition.

Detailed results of Strategies. Strategies' popularities and occurrences may differ in nature. For example, straightforward strategies like *"Question"* and *"Providing Suggestions"* may be more convenient to learn and apply. A reasonable strategic planner should reflect this frequency difference, but also avoid significant bias (*e.g.*, always determines the most frequent strategy). To further study the strategy-related performance, we further exhibit the per-strategy results in Table 8, with the comparison between straQ*-distill and SFT. One can observe that straQ* model is more balanced across different strategies, and SFT even have zero predictions on the strategy of "Information".

Typical Case. Table 7 presents a typical case of straQ*-distill in the third turn, comparing to Direct, and also the original response in the dataset. To better illustrate the effectiveness of the value-learning, we present the reward and value scores

	Inf.	0.00	0.00	0.00	5.93	12.24	**78.54**	12.95
	Others	23.20	30.77	0.46	8.38	18.21	74.08	27.78
straQ*-distill	Que.	**71.07**	**60.59**	2.43	**9.48**	**22.05**	64.44	**33.50**
	Res.& Par.	8.97	16.67	**0.16**	8.45	17.30	79.05	21.60
	Ref.	40.88	38.69	0.43	5.18	13.62	75.95	9.78
	Self-Dis.	29.85	41.75	0.46	4.90	12.70	76.00	6.01
	Aff.& Rea.	36.63	42.11	0.47	6.30	15.46	70.35	13.66
	Pro.	69.08	56.13	0.60	5.95	14.03	70.51	10.62
	Inf.	26.67	40.14	0.47	5.33	13.21	**79.94**	8.11
	Others	45.93	45.95	0.53	6.60	15.19	71.85	24.34

for each response. In this case, straQ* does not simply maximize the immediate reward, but maximizes the long-term return (*i.e.*, the value), which is calculated from subsequent turns. Also, straQ* in this case exhibits a perfect stage-turnover, guiding the conversation from the first stage (strategy Res.&Par.), then the second stage (strategy Ref.), to the third stage (strategy Aff.& Rea.). Comparing to Direct (stays in I) the original response (I to II to II), planning of straQ* is more consistent with the theory proposed in (Liu et al., 2021).

5 Related Work

There are some RL studies in goal-oriented conversations (Li et al., 2024b; Zhou et al., 2024; Li et al., 2024a). For example, DAT (Li et al., 2024b) defines dialogue action tags, and then generates responses by multi-turn planning. ArCHer (Zhou et al., 2024) proposes a hierarchical RL algorithm to improve the efficiency and performance of LLMs. These works adapt the conversational LLM, and rely on ground truth annotations. In contrast, our straQ* implements an explicit, lightweight and plug-and-play planner, which balances the foundation capability and the strategic thinking.

6 Conclusion

In this paper, based on Q-learning, we propose a method named straQ*that optimizes long-term returns in emotional support conversation scenarios. Our implementation behaves as a plug-and-play strategic planner which steers the subsequent response generation. We propose two reward mechanisms, straQ*-imit and straQ*-distill, in which the former has higher automatic evaluation results, and the latter performs better in generalization and human preference alignment.

7 Limitation

There are still some limitations of straQ*. The results of human evaluation may be biased, or deviate from the judgments of actual help - seekers due to the awareness of being engaged in scoring. Then, the testset may be small. Although it has little impact on the comparison between automated and human evaluations, sample sizes for some subcategories may be insufficient when conducting a detailed analysis.

A Further Implementation Details

A.1 Dataset details

Emotional Support Conversations. Emotional Support Conversation (ESC) is a task aimed at alleviating users' negative emotions (e.g., anxiety, depression), where **supporters** assist **seekers** in managing emotions triggered by issues like work crises or interpersonal conflicts. Unlike emotion recognition tasks, ESC integrates psychological counseling mechanisms into the dialogue generation process, offering a deeper, context-sensitive solution for emotion regulation. The ESC dataset generally has the following attributes:

- **Emotion**: Including emotion types and intensities, which help accurately capture the psychological state of the help-seeker.
- **Help-seeker profile**: A brief survey before each conversation that provides insight into the current situation of the help-seeker, revealing the challenges they are facing.
- **Situation**: A brief survey before each conversation that provides insight into the current situation of the help-seeker, revealing the challenges they are facing.
- **Strategy**: The response rule selected for the current turn based on the seeker's emotional state. There are eight predefined rules in total.
- **Response**: The supporter's response generated based on the history, inferred state, and selected rule.

In this paper, we mainly study two typical ESC datasets, ESConv and EmpatheticDialogues. ESConv has exactly the aforementioned architecture while EmpatheticDialogues lacks the Strategy. Table 9 summarizes the basic statistical information of ESConv and EmpatheticDialogues.

ESConv. Motivated by the Helping Skills Theory (Hill, 2009), Liu et al. (2021) divides ESC into three sequential stages: *Exploration*, *Comforting*, and *Action*, and proposes a dataset called ESConv. For each sample, the conversation is multi-turn, with the dialogue background and user emotion annotated. Upon each utterance of the supporter, 8 distinct support strategies are annotated. Table 11 exhibits an example of ESConv.

Table 12 provides definitions of support strategies in ESConv. Table 10 lists the emotion types and their occurrences in the dataset. The emotion types include anger, anxiety, depression, disgust, fear, nervousness, sadness, and shame.

Category		ESConv	EmpatheticDialogues
# Sessions		1.3K	2.5K
# Uttr		38K	11.0K
Average # Uttr		28.9	4.3
Average Uttr Len		18.8	16.7
Seeker	# Uttr	20K	5.7K
	Avg # Uttr	15.4	2.2
	Avg Uttr Len	16.8	20.8
	# Emotions	11	32
Supporter	# Uttr	18K	5.2K
	Avg # Uttr	13.6	2.1
	Avg Uttr Len	21.0	12.3
	# Strategies	8	-

Table 9: Statistics of ESConv and EmpatheticDialogues. 'Uttr' abbreviates Utterance.

Emotion Type	# Occurrence
anger	111
anxiety	354
depression	334
disgust	40
fear	95
nervousness	13
sadness	308
shame	42

Table 10: Emotion statistics of ESConv.

EmpatheticDialogues. EmpatheticDialogues (Rashkin et al., 2019) is a dataset that consists of empathetic conversations. It aims to help in the development of empathetic language models by providing a large number of dialogues that express empathy.

A.2 Prompt format

Instruction template. To further strengthen the understanding capability of LLM on the strategy selection, we define the instruction as a multi-choice question (MCQ), forcing the LLM to choose one of the option numbers, instead of a plain question. Below is the content of the instruction template $\mathcal{I}$:

Topic	I hate my job but I am scared to quit and seek a new career.
Query	*{history}* *seeker:* Seriously! What I'm scare of now is how to secure another job.
Emotion	Anxiety (intensity: 5)
Strategy	Reflection of feelings
Response	*supporter:* I can feel your pain just by chatting with you.

Table 11: An example of *ESconv*.

Strategies	Abbr.	Definitions
Question	**Que.**	Inquiring about problem-related information to help the seeker clarify their issues, using open-ended questions for best results and closed questions for specific details.
Restatement or Paraphrasing	**Res.& Par.**	A simple, more concise rephrasing of the help-seeker's statements that could help them see their situation more clearly.
Reflection of Feelings	**Ref.**	Articulate and describe the help-seeker's feelings.
Self-disclosure	**Self-Dis.**	Divulge similar experiences that you have had or emotions that you share with the help-seeker to express your empathy.
Affirmation and Reassurance	**Aff.& Rea.**	Affirm the help seeker's strengths, motivation, and capabilities and provide reassurance and encouragement.
Providing Suggestions	**Pro.**	Provide suggestions about how to change, but be careful to not overstep and tell them what to do.
Information	**Inf.**	Provide useful information to the help-seeker, for example with data, facts, opinions, resources, or by answering questions.
Others	**Others**	Exchange pleasantries and use other support strategies that do not fall into the above categories.

Table 12: Strategy names, abbreviations and detailed definitions in ESConv.

You are a psychological consultant providing support to a seeker. The seeker's basic situation is as follows:
Emotion: $\{e\}$
Description: $\{desp\}$
Below is the conversation history between the seeker and the supporter:
$\{h\}$
The seeker's current query is:
$\{query\}$
Based on the above context, please select the most appropriate response strategy from the following options:
strategy #(1) $\{a_1\}$
...
strategy #(k) $\{a_k\}$
Please provide your selection in the format of (1) through (k). Your selection is:

Generation prompt. Below is the prompt used by the conversational foundation LLM for the response generation:

You are a psychological consultant providing support to a seeker. The seeker's basic situation is as follows:
Emotion: $\{e\}$
Description: $\{desp\}$
Below is the conversation history between the seeker and the supporter:
$\{h\}$
The seeker's current query is:
$\{query\}$
The current response strategy is:
$\{a\}$
Based on the current response strategy and other information, please act as a supporter and provide the best response. Keep replies brief without additional pronouns or extra elements.

Prompt of GPT-4 for reward generation. Below is our prompt of GPT-4 to generate the rewards for straQ*-distill:

A.3 Principle of human scoring

We start with the criteria proposed by Kang et al. (2024). The human evaluation is aimed to algin with the ultimate purpose of ESC, the seeker's *sat-*

You are a psychological consultant providing support to a seeker. The seeker's basic situation is as follows:
Emotion: $\{e\}$
Description: $\{desp\}$
Below is the conversation history between the seeker and the supporter:
$\{h\}$
The seeker's current query is:
$\{query\}$
Please evaluate whether the response is appropriate:
$\{resp\}$
Based on the information above, evaluate whether the response is suitable. Please remember to respond with a single integer number from 1 to 5, where 1 indicates "not suitable" and 5 indicates "very suitable". Please also provide a brief explanation of your decision.

Table 13: Template of GPT-4 scoring.

isfaction. To achieve this, the supporter's behavior can be further classified into the following criteria:
Acceptance: Does the seeker accept without discomfort;
Effectiveness: Is it helpful in shifting negative emotions or attitudes towards a positive direction;
Sensitivity: Does it take into consideration the general state of the seeker. Furthermore, to clarify the capability of LLMs to align strategy and responses, we include Alignment.

To achieve a more elaborate assessment, we consider three more dimensions addressing the generation quality:
Fluency: the level of fluency of response.
Emotion: the emotional intensity of response which could affect the seeker's emotion state.
Interesting: Whether the response can arouse the seeker's interest and curiosity, presenting unique ideas, vivid expressions or engaging elements that capture the seeker's attention and make the interaction more appealing.

We engage our interns as human evaluators to rate the models according to these multiple aspects, namely Fluency, Emotion, Interesting, and Satisfaction, with Satisfaction covering Acceptance, Effective, Sensitivity, and Satisfaction itself.
Throughout this evaluation process, we strictly comply with international regulations and ethical norms, ensuring that all practices conform to the necessary guidelines regarding participant involvement and data integrity.
To guarantee the accuracy and reliability of the evaluation results, a pre - evaluation training program is meticulously designed and implemented. During this training, the evaluation criteria are clearly and systematically expounded. Moreover, detailed explanations and scoring rules corresponding to each score are provided.
Evaluators are required to independently evaluate each sample in strict accordance with the pre - established criteria. By adhering to these principles, the evaluation process maintains objectivity, standardization, and consistency, thus enhancing the overall quality and credibility of the evaluation results.
The detailed manual scoring criteria are as follows:

- Fluency:

  1: The sentence is highly incoherent, making it extremely difficult to understand and failing to convey a meaningful idea.

  2: The sentence has significant incoherence issues, with only parts of it making sense and struggling to form a complete thought.

  3: The sentence contains some incoherence and occasional errors, but can still convey the general meaning to a certain extent.

  4: The sentence is mostly fluent with only minor errors or slight awkwardness in expression, and effectively communicates the intended meaning.

  5: Perfect. The sentence is completely fluent, free of any errors in grammar, punctuation, or expression, and clearly conveys the idea.

- Emotion:

  1: The emotional expression is extremely inappropriate and chaotic, not in line with the content, and may convey wrong emotions.

  2: The emotional expression has obvious flaws, either too weak or exaggerated, and is disjointed from the content.

  3: The emotional expression is average. It can convey basic emotions but lacks depth and has minor issues.

  4: The emotional expression is good. It can effectively convey the intended emotion with

an appropriate intensity and is well integrated with the content.

5: The emotional expression is excellent. It is rich, nuanced, and perfectly matches the content, capable of evoking a strong and appropriate emotional response.

- Acceptance:

  1: The response inescapably triggers emotional resistance.

  2: The response is highly likely to trigger emotional resistance.

  3: The response has a possibility of emotional resistance occurring.

  4: The response rarely provokes emotional resistance.

  5: The response has no occurrence of emotional resistance.

- Effectiveness:

  1: The response actually worsens the seeker's emotional distress.

  2: The response carries the risk of increasing stress levels, and this outcome varies depending on the individual user.

  3: The response fails to alter the seeker's current emotional intensity and keeps it at the same level.

  4: The response shows promise in calming the emotional intensity; however, it is overly complicated or ambiguous for the user to fully comprehend and utilize effectively.

  5: The response appears to be highly effective in soothing the seeker's emotions and offers valuable and practical emotional support.

- Sensitivity:

  1: The response renders inaccurate evaluations regarding the seeker's state.

  2: The response is characterized by rash judgments, as it lacks adequate assessment and in-depth exploration of the seeker's state.

  3: The response is formulated with a one-sided judgment and a limited exploration of the seeker's state.

  4: The response demonstrates an understanding that only covers a part of the seeker's state.

  5: The response precisely grasps the seeker's state and is appropriately tailored according to the seeker's actual situation.

- Alignment:

  1: The response is in total contradiction to the predicted strategy.

  2: The response has a minor deviation from the predicted strategy.

  3: There is some ambiguity between the response and the predicted strategy.

  4: The response largely matches the predicted strategy, yet it contains some ambiguous elements.

  5: The response effectively makes itself consistent with the predicted strategy.

- Satisfaction:

  1: The response is extremely disappointing. It doesn't answer the question at all and is of no help.

  2: The response is poor. It only gives a partial answer and leaves many doubts unresolved.

  3: The response is average. It meets the basic requirements but isn't particularly outstanding.

  4: The response is good. It answers the question clearly and provides some useful details.

  5: The response is excellent. It not only answers the question perfectly but also offers valuable additional insights.

B More Results

B.1 Scoring details of GPT-4

Table 14 presents GPT-4 score statistics across different response strategies. The overall average score is 3.67, with a median of 4. The most frequently used strategies are Others (17.8%), Questioning (17.6%), and Affirmation & Reasoning (16.7%), while Restating & Paraphrasing (6.7%) and Information Providing (6.8%) appear less often. In terms of average score, Providing Opinions, Others, and Affirmation & Reasoning score the highest (all around 3.76–3.77), whereas Restating & Paraphrasing and Self-Disclosure have the lowest average scores (3.48).

Strategy	Count	Ratio	Max	Min	Avg	Median
Que.	2574	17.6%	5	1	3.54	4
Res.& Par.	981	6.7%	5	1	3.48	3
Ref.	1253	8.6%	5	2	3.65	4
Self-Dis.	1410	9.6%	5	2	3.48	3
Aff.& Rea.	2444	16.7%	5	1	3.76	4
Pro.	2367	16.2%	5	1	3.77	4
Inf.	995	6.8%	5	2	3.75	4
Others	2600	17.8%	5	1	3.77	4
Total	14624	100.0%	5	1	3.67	4

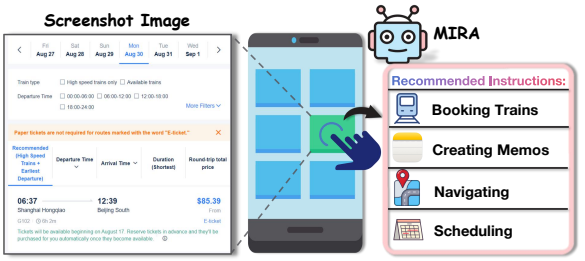
Abstract

The rapid advancement of generative AI technologies is driving the integration of diverse AI-powered services into smartphones, transforming how users interact with their devices. To simplify access to predefined AI services, this paper introduces MIRA, a pioneering framework for task instruction recommendation that enables intuitive one-touch AI tasking on smartphones. With MIRA, users can long-press on images or text objects to receive contextually relevant instruction recommendations for executing AI tasks. Our work introduces three key innovations: 1) A multimodal large language model (MLLM)-based recommendation pipeline with structured reasoning to extract key entities, infer user intent, and generate precise instructions; 2) A template-augmented reasoning mechanism that integrates high-level reasoning templates, enhancing task inference accuracy; 3) A prefix-tree-based constrained decoding strategy that restricts outputs to predefined instruction candidates, ensuring coherent and intent-aligned suggestions. Through evaluation using a real-world annotated datasets and a user study, MIRA has demonstrated substantial improvements in the accuracy of instruction recommendation. The encouraging results highlight MIRA's potential to revolutionize the way users engage with AI services on their smartphones, offering a more seamless and efficient experience.

1 Introduction

Generative AI technologies, such as large language models (LLMs) (Naveed et al., 2023), diffusion models (Yang et al., 2024b), and AI agents (Xi et al., 2023), are revolutionizing the capabilities of AI smartphones (Marr, 2024a,b), ushering in a new era of intelligent mobile devices that offer unparalleled levels of personalization and interaction. The integration of LLMs powers sophisticated virtual assistants capable of engaging in more natural, contextually rich conversations, delivering detailed and relevant information to meet specific user needs. These advancements also enable smartphones to generate high-quality images, videos, text, and music on demand, providing users with unprecedented creative freedom. Furthermore, it empowers a wide range of AI services, including real-time language translation, advanced image captioning, visual question answering, customized text summaries, and personalized recommendations, setting a new standard for smartphone functionality. As generative AI continues to evolve, it promises seamless integration into various aspects of smartphone use, transforming mobile devices into intelligent AI agents that adeptly serve daily needs.



Instruction Name	Instruction Description
Creating Memos	• The train booking details including departure time (06:37), arrival time (12:39), departure station (Shanghai Hongqiao), and arrival station (Beijing South) are significant. • The user likely requires remembering these details for the purpose of travel planning.
Navigating	• The departure station (Shanghai Hongqiao) is mentioned. • The user may need to find the best way to reach the station, especially if the user is unfamiliar with the location.
Scheduling	• The specific departure and arrival times along with the travel date (Aug 30) are crucial for scheduling. • The user might plan other activities around the departure time.
Booking Trains	• A train booking interface with departure and arrival time options, train type filters, and price details appears in the image. • The user may need to book a train ticket for their travel.

Figure 1: An illustration of one-touch AI services on smartphones.

Given the rich AI capabilities on smartphones, there is significant potential for seamless and effortless AI services. Currently, most smartphones rely on conversational AI assistants (e.g., Siri) to process user requests via text or voice commands. While effective for interaction, this approach has

* Corresponding Author.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1457–1465

limitations in handling routine daily tasks. Users often need detailed, multi-step instructions to complete AI tasks. For example, processing a screenshot of a train booking involves several steps: performing text recognition (i.e., OCR), extracting structured information, adding the event to a calendar, and setting up a reminder. This process is time-consuming and cumbersome. Additionally, repeatedly executing these instructions for daily repetitive tasks wastes valuable time and effort.

To address these challenges and promote seamless access to AI services, we propose MIRA, a Multimodal Instruction Recommendation Agent that enables one-touch AI task execution on smartphones. Users can long-press target objects such as images, messages, or documents, triggering predefined, contextually relevant task instruction recommendations for accessing AI services. For example, as shown in Figure 1, when handling a screenshot of a train booking, a user can simply long-press the image to instantly receive recommendations for actions like booking trains, creating memos, scheduling calendar events, and navigating to station. In this paper, we define AI task instructions as detailed prompts and execution steps to operate on trigger objects and complete a specific task. For instance, a navigation task might involve recognizing a specific location from an image and subsequently invoking a map navigation API to guide the user. By encapsulating complex processes into single, intuitive actions, MIRA allows users to quickly and effortlessly access AI services, simplifying task completion and maximizing convenience.

This represents an emerging application scenario in the new era of AI smartphones. To our knowledge, it is the first effort to address instruction recommendations for AI services on smartphones. With the rise of generative AI, functionalities such as translation, summarization, navigation, event scheduling, calling, memo creation, image editing, image description, calorie calculation, and cooking inquiries are now available. Each service typically involves a complex pipeline of prompts, fine-tuned models (e.g., LoRAs), and API calls. These services can be added by smartphone providers or registered by third-party partners. MIRA's main goal is to provide contextually relevant recommendations from a wide range of AI services when users long-press a specific image or text object (i.e., triggers). While supporting various trigger types is ideal, we focus on text and image triggers in this initial effort.

Unlike traditional recommender systems that focus on user behavior sequences, our instruction recommendation task emphasizes on multimodal trigger inputs. The challenge lies in understanding the content of these triggers and extracting key information to infer user intent and generate precise instructions. For example, given an image of a bank card, the system should recognize tasks like transferring funds or creating memos related to banking.

This paper introduces MIRA, a multimodal large language model (MLLM)-based recommendation agent for understanding user context and recommending task instructions. While MLLMs excel in image recognition and text understanding (Liu et al., 2024b),aligning trigger content with relevant instructions is challenging. We make three key contributions: 1) Introducing structured reasoning to extract entities, infer user intent, and generate precise instructions; 2) Developing a template-augmented reasoning mechanism to improve task inference accuracy; 3) Implementing prefix-tree-based constrained decoding to ensure coherence and intent alignment. We evaluate MIRA using real-world datasets and a user study, showing significant improvements in instruction recommendation accuracy.

2 Related Work

2.1 Multimodal Large Language Model Reasoning

Recent advances in MLLM have highlighted their impressive visual reasoning capabilities. Studies have explored plan-based Chain-of-Thought (CoT) prompting (Shao et al., 2024; Mitra et al., 2024), which guides models through intermediate reasoning steps for more accurate results. LLaVA-CoT (Xu et al., 2024) introduces a Vision-Language Model (VLM) designed for structured reasoning, achieving notable success in visual tasks. Building on this, LlamaV-o1 (Thawakar et al., 2025) uses multi-stage curriculum learning to progressively improve problem-solving skills. CoMCTS (Yao et al., 2024) combines collective learning with tree search to optimize reasoning pathways. However, these methods either require lengthy tree search algorithms or rely on process reward models to guide reasoning, making them inefficient. As a result, an efficient and effective approach for complex reasoning tasks in MLLMs is still lacking.

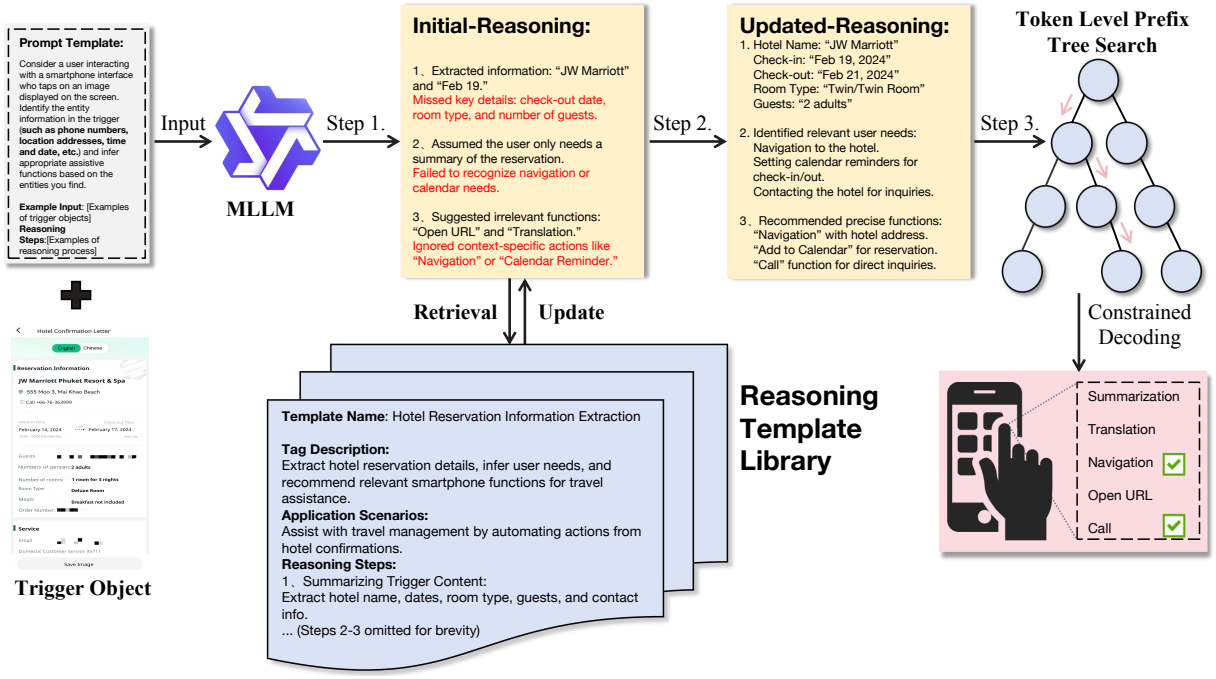


Figure 2: Overview of MIRA. A prompt template and trigger object extract structured information through initial reasoning, refine reasoning steps through template retrieval and updates, and apply constrained decoding during inference to recommend predefined instructions.

2.2 MLLMs for Recommendation

Recent studies have explored integrating MLLMs into multimodal recommendation systems (Liu et al., 2024a), leveraging their ability to process diverse data modalities. Frameworks like VIP5 (Geng et al., 2023) align visual, textual, and personalization cues to enhance performance with personalized prompts and efficient training. MLLM-MSR (Ye et al., 2024) captures dynamic user preferences by summarizing multimodal inputs, while TMF (Ma et al., 2024) improves multi-behavior recommendations by incorporating graph data. Recently, DeepMP (Wei et al., 2024) unifies multimodal recommendation and generation within a single MLLM model. These advancements underscore the potential of MLLMs to refine recommendations by analyzing user preferences across modalities. However, ensuring precise alignment between multimodal triggers and actionable AI services remains an open challenge.

3 Methodology

We present MIRA, a novel framework designed to enhance instruction recommendation tasks. As illustrated in Figure 2, MIRA comprises three key components: structured chain-of-thought reasoning, template-augmented structured reasoning, and prefix-tree-based constrained decoding.

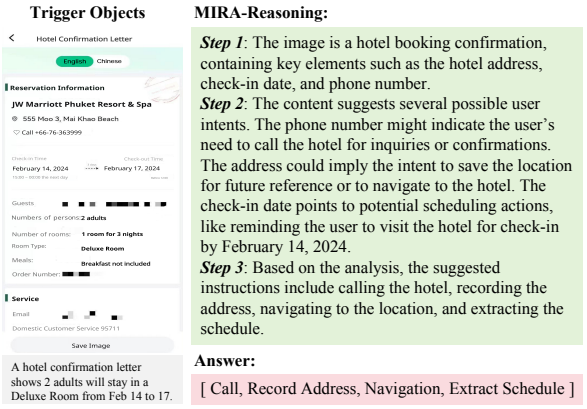

Figure 3: A Sample of the Reasoning-Dataset: Left - Image or Text Trigger Objects, Right - MIRA-Reasoning Process and Final Answers.

3.1 Enhancing MLLMs with Structured Reasoning

Multimodal large language models (MLLMs) excel in tasks like OCR, object detection, and image captioning but struggle with complex reasoning tasks involving implicit constraints and object relationships. In our task, MLLMs find it difficult to infer user intent from trigger objects and recommend instructions accurately. Inspired by OpenAI's O1 (Jaech et al., 2024), DeepSeek-R1 (Guo et al., 2025), and Qwen-QwQ (Yang et al., 2024a), we enhance MLLMs with human-like reasoning,

enabling thoughtful processing of trigger objects and precise recommendations. By leveraging zero-shot Chain-of-Thought (CoT) prompting in models like GPT-4V and Qwen2.5VL-Max, we incorporate structured reasoning into the trigger-instruction dataset, improving MLLMs' ability to match trigger content with instructions.

To guide the model, We designed a three-step reasoning trajectory to guide the model in processing trigger objects. First, in entity recognition and summarization, MLLMs extract key entities (e.g., phone numbers, addresses, dates) from text and images, organizing them into structured themes. Next, in the contextual relevance analysis, the model links these summaries to user intent, connecting entities like dates or locations to actions such as saving or navigating. Finally, in the instruction generation step, the model synthesizes the reasoning into context-aware, user-focused recommendations. Formally, for a single sample S_i in the dataset, which consists of the trigger object q_i and the ground truth instruction a_i, we provide a_i directly to the MLLM, ensuring both consistency and precision. Given a rich prompt template with in-context examples p_i^e, MLLM constructs the reasoning steps r_i based on the provided correct answer. The input and output format for the MLLM is as follows:

$$r_i = MLLM(p_i^e, q_i, a_i). \tag{1}$$

Equation 1 represents the generation of high-quality reasoning traces under teacher forcing with gold answers, used to bootstrap the initial training dataset. After constructing the reasoning dataset as shown in Figure 3, we perform supervised fine-tuning (SFT) on MLLMs. During training, the model is provided only with the prompt p_i (without in-context examples) and the trigger object q_i, generating predicted reasoning steps $\hat{r}_i$ and predicted answers $\hat{a}_i$:

$$\hat{r}_i \ , \hat{a}_i = MLLM(p_i, q_i). \tag{2}$$

Equation 2 shows how the trained MLLM learns to independently produce reasoning and instructions given only trigger context, improving autonomy. This approach equips the MLLM with reasoning capabilities for complex tasks while eliminating the need for large-scale models and intricate prompt engineering. Specifically, we introduce two special tokens, <$REASONING$> and </$REASONING$>, marking the start and end of the reasoning process, thereby enabling autonomous reasoning.

3.2 Template-Augmented Structured Reasoning

After fine-tuning on a reasoning dataset, MLLMs are capable of structuring reasoning to analyze complex content and relationships of trigger objects, enabling accurate instruction recommendations. However, the accuracy of this reasoning is challenged by inherent randomness and hallucination tendencies, with no explicit supervision to ensure the correctness of the reasoning steps (Zhang et al., 2025).

To address this, we propose the Reasoning Template Library. This library uses high-level, solution-oriented templates for structured reasoning, reducing inaccuracies and inconsistencies. Built using closed-source MLLMs' summarization capabilities, it distills common problem-solving patterns from the dataset. By identifying recurring strategies, we developed robust templates that ensure efficient and precise instruction recommendations for diverse trigger objects.

As shown in the lower center of Figure 2, each template includes four key components in a structured metadata format: **Template Name** (e.g., "Hotel Reservation Information Extraction"), **Tag Description** with keywords for easy search (e.g., "Travel," "Reservation," "Hotel"), a brief summary of **Application Scenarios**, and **Reasoning Steps** outlining reasoning steps (e.g., "Extract hotel name," "Identify check-in date," "Recommend calendar reminder"). This metadata enables efficient retrieval, ensuring quick, accurate searches based on keywords or problem characteristics for relevant templates.

As shown in Figure 2, after building the reasoning template library, the next step is integrating these templates with the MLLM to enhance its reasoning. The process begins when the trigger object (e.g., a hotel reservation confirmation) is provided to the MLLM, which generates initial reasoning outlining task steps. However, in complex scenarios, this reasoning may be incomplete. To address this, we use vector-based retrieval to find the most relevant template by calculating the similarity between the initial reasoning vector and each template's vector, formalized as:

$$\begin{aligned} &j = \text{argmax}_i(\text{Sim}(f(\hat{r}), \{f(D_{T_i})\}_{i=1}^{N})), \\ &\text{where} \quad \text{Sim}(f(\hat{r}), \{f(D_{T_i})\}_{i=0}^{n}) >= \delta. \end{aligned} \tag{3}$$

where $f(\hat{r})$ represents the embedding of the initial reasoning, and $\{f(D_{T_i})\}_{i=1}^{N}$ represents the embeddings of the templates in the library. $Sim(\cdot,\cdot)$ is the similarity function, which measures how closely the reasoning steps of each template align with the task at hand. We set a threshold δ (recommended range: 0.5–0.7) to ensure the selected template is suitable for the given trigger object. The most relevant template T_j is selected, and its reasoning steps are used to update the initial reasoning.

To ensure adaptability in dynamic smartphone usage scenarios, our template library supports continual evolution. During inference, when a trigger object results in low similarity to all existing templates (i.e., no suitable template passes the similarity threshold δ), we log the reasoning trace generated by the MLLM as a candidate for future template distillation. These reasoning traces are periodically clustered based on semantic similarity, and representative examples are selected and summarized by Qwen2.5VL-Max into new candidate templates. Before adding any newly distilled template $D_{T_{\text{new}}}$ to the library, we compute its embedding $f(D_{T_{\text{new}}})$ and compare it against the existing templates $\{f(D_{T_i})\}_{i=1}^{n}$. A new template is added only if the maximum similarity is below a threshold δ, ensuring informativeness and non-redundancy:

$$\max\left(\text{Sim}(f(D_{T_{\text{new}}}), \{f(D_{T_i})\}_{i=1}^{n})\right) < \delta. \quad (4)$$

Here, $\text{Sim}(\cdot,\cdot)$ denotes the cosine similarity between two embeddings, and δ is typically set to 0.5 to balance coverage and redundancy. This condition helps prevent duplicate entries, ensuring that only novel and informative templates are added. As a result, the template library can continuously evolve over time, capturing new reasoning strategies and accommodating rare edge-case scenarios encountered during real-world deployment.

The final step is to instantiate the reasoning by inputting the retrieved template and trigger object into the MLLM to generate the updated reasoning steps. This can be represented as:

$$\hat{r}_{updated} \leftarrow MLLM(T_j, q_i). \quad (5)$$

where $\hat{r}_{updated}$ represents the updated reasoning steps. Equation 5 represents the final reasoning refinement, injecting template guidance into the inference trajectory.

This process refines reasoning to better align with task requirements. For example, with a hotel reservation trigger object, the initial MLLM reasoning might only extract the hotel name and check-in date. By retrieving a relevant template, the reasoning is enriched with details like check-out date, room type, number of guests, and actions such as setting a reminder or providing navigation. This template-driven approach improves accuracy, reduces computational demands, and enables easier deployment without additional training.

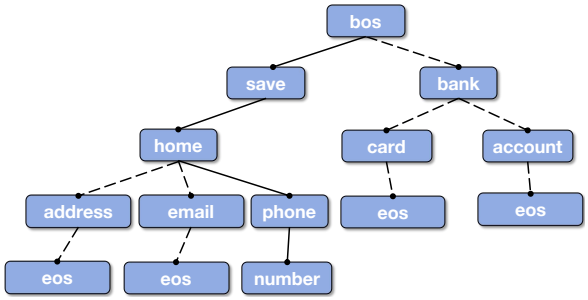

Figure 4: The Illustration of Prefix Tree Searching.

3.3 Prefix-Tree-Based Constrained Decoding

To prevent the model from generating irrelevant instructions during inference, we implement constrained decoding with a prefix tree built from the MLLM's tokenizer and candidate instructions. After the end token (</$REASONING$>) of the reasoning process, the model switches to the prefix tree, masking logits for invalid tokens and ensuring only valid sequences are generated, as shown in Figure 4. To build the prefix tree, we tokenize all valid instruction sequences using the MLLM's tokenizer and recursively construct trie nodes, marking valid transitions. During inference, the decoder filters logits using the current tree node's valid token set, ensuring efficient decoding. The tree is rebuilt dynamically when the instruction library updates and supports O(L) time decoding per token, where L is the sequence length. For example, selecting "save" leads to options like "home," "address," "email," and "phone." It then selects "phone," followed by "number," forming the instruction "save phone number." This approach eliminates post-processing and reduces MLLMs' hallucination, ensuring precise outputs.

4 Experiments

4.1 Datasets and Template Library Construction

To train and validate MIRA, we built a dataset from 1,000 smartphone users, representing diverse de-

mographics and usage patterns. Each sample was annotated by at least three users, ensuring robust inter-annotator agreement ($\kappa = 0.85$). The dataset includes 4,952 training pairs and 956 testing pairs, providing a reliable basis for evaluating MIRA's performance in real-world scenarios. As detailed

Model	Method	Recall	Precision	F1-score	HR@1	HR@3
InternVL2.5-2B	Zero-shot	0.2904	0.3042	0.2971	0.3829	0.4012
	Vanilla-SFT	0.4115	0.4201	0.4158	0.4942	0.5052
	MIRA	0.7164	0.7382	0.7271	0.8051	0.8351
Qwen2.5VL-2B	Zero-shot	0.3043	0.3207	0.3122	0.3941	0.4223
	Vanilla-SFT	0.4964	0.4882	0.4923	0.5051	0.5321
	MIRA	0.7489	0.7397	0.7443	0.8151	0.8451
InternVL2.5-8B	Zero-shot	0.3145	0.3319	0.3230	0.4512	0.4783
	Vanilla-SFT	0.5254	0.5827	0.5526	0.5963	0.6128
	MIRA	0.9283	0.9154	**0.9218**	0.9354	0.9516
Qwen2.5VL-7B	Zero-shot	0.3294	0.3424	0.3358	0.4589	0.4924
	Vanilla-SFT	0.5678	0.5731	0.5704	0.6012	0.6841
	MIRA	**0.9286**	**0.9239**	0.9121	**0.9542**	**0.9629**

Table 1: Quantitative Comparisons Between MIRA and Baseline Methods: The best results are in **bold**, and the second-best results are underlined. All metrics indicate better performance with higher values.

in Section 3.2, we use Qwen2.5VL-Max to extract high-level insights from the training data, which are then used to construct a structured thought template library containing approximately 80 templates. We utilize **jina-embeddings-v3**[*] for template retrieval. While we leverage a closed-source model for high-level insight extraction during template construction, the reasoning patterns distilled from these summaries are model-agnostic and serve as generalizable abstractions for diverse scenarios. In future work, we plan to incorporate open-source models and crowdsourced annotations to enhance cross-model generality and robustness.

4.2 Baselines and Metrics

In our experiments, we did not compare with MLLM4Rec or LLM4Rec methods, such as MLLM-MSR (Ye et al., 2024), Rec-GPT4V (Liu et al., 2024c), LLMRank (Hou et al., 2024), and NoteLLM-2 (Zhang et al., 2024), as they focus on sequence recommendation tasks requiring user behavior data. These methods target different tasks than our instruction recommendation framework. Instead, we compared MIRA with two baseline methods: zero-shot prompting with in-context learning (Dong et al., 2022) and supervised fine-tuning on the original dataset. These methods are more aligned with our task and serve as a relevant benchmark for evaluating MIRA's performance.

[*]https://huggingface.co/jinaai/jina-embeddings-v3.

Experiments were conducted on four MLLMs: InternVL2.5 (Chen et al., 2024) (2B and 8B) and Qwen2.5VL (Bai et al., 2023) (2B and 7B). We evaluated MIRA using four standard recommendation system metrics: recall, precision, F1-score, and hit rate. All experiments were performed on two GPUs with 32GB of memory.

4.3 Experimental Results

4.3.1 Comparison with baselines.

Table 1 presents the model performance, where MIRA consistently outperforms baseline methods across models of varying sizes: InternVL2.5 (2B and 8B) and Qwen2.5VL (2B and 7B). Notably, MIRA achieves substantial improvements across all metrics. For instance, on Qwen2.5VL-7B, MIRA reaches a macro F1-score of 0.9121 and HR@3 of 0.9629, significantly surpassing Vanilla-SFT. These improvements stem from MIRA's modular architecture, enhancing reasoning and ensuring accurate recommendations. Furthermore, MIRA's superior performance on smaller models like InternVL2.5-2B and Qwen2.5VL-2B underscores its efficiency, making it well-suited for real-world deployment with constrained resources.

Model	initial reasoning	with Template
InternVL2.5-2B	0.6041	0.7271 (↑ **20.4%**)
Qwen2.5VL-2B	0.6428	0.7443 (↑ **15.8%**)
InternVL2.5-8B	0.7451	0.9218 (↑ **23.7%**)
Qwen2.5VL-7B	0.7348	0.9121 (↑ **24.1%**)

Table 2: Ablation study on the impact of template-augmented reasoning on instruction recommendation performance.

4.3.2 Depth Analysis.

An ablation study was conducted to evaluate the impact of the template-augmented structured reasoning method. The study compares instruction recommendation performance using initial reasoning versus template-enhanced reasoning, measured by the F1 score, as shown in Table 2. The results demonstrate a significant improvement with template-enhanced reasoning. InternVL2.5-2B saw a 20.4% increase, Qwen2.5VL-2B improved by 15.8%, reaching 0.7443, while larger models showed even greater gains: InternVL2.5-8B improved by 23.7%, and Qwen2.5VL-7B by 24.1%, reaching 0.9121. Template retrieval mitigates hallucination issues common in unsupervised reasoning, significantly boosting recommendation accuracy.

We further evaluated MIRA (Qwen2.5VL 7B) against two state-of-the-art multimodal large language models—Qwen2.5VL-Max and GPT-4V—both commonly deployed via API in industrial applications. All models were tested using the same trigger objects and full templates under a zero-shot Chain-of-Thought (CoT) prompting setup ("Let's think step by step") (Kojima et al., 2022). The evaluation considered four key metrics: F1-score, average token length, inference time, and model size. As shown in Table 3, MIRA achieved the highest F1-score of 0.9121, outperforming both GPT-4V (0.879) and Qwen2.5VL-Max (0.861). It also demonstrated superior token efficiency, requiring only 116 tokens on average—far fewer than GPT-4V (817) and Qwen2.5VL-Max (807). Despite having just 7 billion parameters, MIRA completed inference in 11.2 seconds, faster than GPT-4V (11.3s) and comparable to Qwen2.5VL-Max (10.7s). These results highlight MIRA's strong balance between accuracy and efficiency. Its compact architecture enables faster and lighter inference without compromising performance, making it highly suitable for deployment in resource-constrained environments such as smartphones and edge devices—where both responsiveness and computational cost are critical.

Model	F1-score	Token Length	Inference Time	Model Parameters
GPT-4V	0.879	817	11.3s	>500B
Qwen2.5VL-Max	0.861	807	**10.7s**	>500B
MIRA	**0.9121**	**116**	11.2s	**7B**

Table 3: Analysis of MIRA compared to Qwen2.5VL-Max and GPT-4V on key industrial metrics: The best results are in **bold**.

To further investigate the robustness of the template matching process, we conducted a sensitivity analysis on the similarity threshold δ used in Equation 3. We evaluated instruction recommendation performance using the F1-score as the primary metric, varying δ across multiple settings. As shown in Table 4, $\delta = 0.6$ consistently yields the highest F1-score across different MLLMs. Lower thresholds (e.g., $\delta = 0.4$) tend to retrieve overly generic templates, leading to irrelevant or misaligned reasoning steps. In contrast, higher thresholds (e.g., $\delta = 0.8$) significantly reduce the number of matched templates, resulting in degraded performance due to limited reasoning support. These results highlight the importance of properly tuning δ to balance retrieval coverage and reasoning precision.

Model	$\delta = 0.4$	$\delta = 0.5$	$\delta = 0.6$	$\delta = 0.8$
InternVL2.5-2B	0.6892	0.7145	**0.7271**	0.7008
Qwen2.5VL-2B	0.7014	0.7312	**0.7443**	0.7221
InternVL2.5-8B	0.8893	0.9122	**0.9218**	0.9051
Qwen2.5VL-7B	0.8945	0.9012	**0.9121**	0.8958

Table 4: Sensitivity analysis of the similarity threshold δ for template retrieval. The best results are in **bold**.

4.3.3 Failure Case Analysis.

We examined 100 incorrect predictions from MIRA to understand common failure patterns. Three major types emerged: (1) Entity Omission: MLLMs occasionally ignore subtle entities like timestamps in footnotes; (2) Template Misalignment: Vector retrieval retrieves a loosely relevant template, leading to incorrect reasoning paths; (3) Ambiguity in Triggers: When triggers contain overlapping intent signals (e.g., calendar + contacts), MIRA may prioritize one over the other. Future improvements will incorporate multi-template aggregation and confidence-based filtering.

4.3.4 User study.

We invited 100 participants to evaluate 500 trigger objects, each with 1 to 3 instruction recommendations generated by two MIRA versions based on Qwen2.5VL-7B and InternVL2.5-7B. Participants selected recommendations that aligned with their expectations. The evaluation metric was the validity ratio, defined as the proportion of selected recommendations meeting participants' expectations out of the total provided. Our method achieved validity ratios of 93% and 95% for the two versions, respectively, demonstrating its real-world effectiveness.

5 Conclusion

We proposed MIRA, a framework leveraging MLLMs for instruction recommendations on smartphones. By enabling users to obtain task suggestions through a simple long-press on images or text, MIRA streamlines AI task execution, reducing cognitive load and enhancing user interaction efficiency. Key innovations include structured reasoning, template-augmented reasoning, and prefix-tree-based constrained decoding, which enhance recommendation accuracy and consistency. Experiments and user studies show that MIRA outperforms existing methods, offering efficient resource use and positioning it as an ideal solution for AI service integration on mobile devices.

Limitations

While MIRA offers substantial improvements in multimodal instruction recommendation, several limitations remain that point to promising directions for future research.

First, **the current trigger modality coverage is limited**. MIRA primarily supports text and image inputs, which restricts its applicability in more diverse smartphone contexts involving audio, video, or sensor data. To expand its generality, we plan to explore multimodal extensions that incorporate audio transcriptions (e.g., voicemail), video scene understanding (e.g., meeting highlights), and sensor signals (e.g., location or step count), enabling richer and more adaptive instruction recommendations.

Second, **the reliance on a predefined template library may constrain adaptability**. While the template-augmented structured reasoning mechanism significantly enhances accuracy, its performance may degrade on previously unseen or long-tail tasks. Although we adopt a dynamic update mechanism to evolve the template library (see Section 3.2), the approach still depends on effective template coverage and accurate retrieval. Additional improvements such as multi-template aggregation or fallback strategies may be needed to enhance generalization.

Third, **real-world deployment raises issues of robustness, scalability, and privacy**. Despite reducing hallucination through constrained decoding and template guidance, MIRA may still encounter reasoning errors in highly complex or ambiguous triggers. Moreover, its effectiveness hinges on high-quality and diverse training data, especially for capturing rare user intents or edge cases. Lastly, since MIRA operates on potentially sensitive content like images, documents, or messages, future deployments must ensure privacy through techniques such as on-device inference, secure model serving, and data anonymization. We also aim to explore differential privacy to further mitigate risk.

Overall, these limitations provide a roadmap for extending MIRA into a more flexible, reliable, and privacy-conscious framework in future work.

Abstract

System-level programming is essential for modern enterprise infrastructure, enabling the automation and management of complex systems through declarative code. Developers write this code based on schemas, which themselves are a form of code that defines constraints like data types and required fields. These schemas help ensure operational correctness and smooth integration across systems. However, as enterprise schemas become complex, manually writing code adhering to these constraints becomes challenging for developers. Large Language Models (LLMs) have demonstrated potential in code generation and natural language understanding, particularly in zero-shot and few-shot settings. However, applying LLMs to handle constraints represented in code, essential for system-level programming rather than natural language, has not been explored. Hence, we introduce `ConCodeEval`, a study across two key dimensions: format and constraint efficacy, with a first-of-its-kind benchmark involving two novel experiments for code constraints across five representations (JSON, YAML, XML, Python, and natural language). Our findings suggest that conscious choice of representations can lead to optimal use of LLMs in enterprise use cases involving constraints. Nonetheless, LLMs continue to struggle significantly with code constraints, motivating the need for innovation in this direction.

1 Introduction

System-level programming is the backbone of modern enterprise infrastructure, enabling developers to define, manage, and automate complex systems seamlessly. Numerous enterprises use concepts like Infrastructure as Code[1] (IaC) to let developers write declarative code. Such code must adhere to constraints called schemas, which define rules, including data types, required fields, and valid value ranges, ensuring operational correctness and smooth integration. For instance, the schema in Listing 1 mandates an array of even numbers within specific bounds, containing 1 to 7 elements.

Listing 1: The JSON sample generated (highlighted in yellow) by the Granite 20B model does not adhere to the *minContains* and subsequent numerical constraints specified in the schema.

````
Write a JSON sample with field values as per the
     JSON format schema given below.

{
    "type": "array",
    "contains": {
        "type": "number",
        "multipleOf": 2,
        "exclusiveMinimum": 0,
        "exclusiveMaximum": 65535
    },
    "minContains": 1,
    "maxContains": 7
}

JSON sample:
```
[2, 3, 4, 6, 8, 10, 12, 14]
```
````

Schemas are crucial in real-world enterprise settings. For instance, deploying a database service in an OpenShift cluster involves writing compliant code with the correct attributes, such as the number of instances, port number to expose, compute to allocate, etc. Developers write system-level code in structured Domain Specific Languages (DSLs) such as JSON, YAML, XML, or Python, adhering to strict schema constraints. However, enterprise schemas are often complex and difficult to learn, slowing development and increasing errors. As a result, the need for automated and accurate systems for system-level programming is increasing leading to products such as Ansible Lightspeed (Lig).

LLMs have shown great promise in generating coherent text and code in zero-shot and few-shot settings, making them highly appealing for system-level coding (Brown et al., 2020; Roziere et al.,

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1466–1479
July 28-30, 2025

2023; Mishra et al., 2024). Using LLMs to handle constraints represented in natural language (NL) has been extensively explored for tasks like poem generation and summarization (Sun et al., 2023). However, Unlike these natural language tasks, constraints are often represented as code for system-level programming; hence, evaluating LLMs requires a different approach. In addition to assessing how well models adhere to constraints expressed in natural language, we must examine their ability to process, interpret, and generate structured formats while ensuring schema compliance. To ensure this, we evaluate LLMs under two key dimensions: **Format Efficacy** and **Constraint Efficacy**.

Format efficacy involves studying the performance of LLMs on varying constraint representations that form the input and output representations downstream enterprise use cases can consume. Specifically, we aim to answer the following research questions (RQ) for format efficacy: 1) Which format is optimally suited for constraint and output representation? 2) What is the trade-off between performance and context length cost?. While constraint efficacy involves studying LLMs' performance on various schema constraints within a format. Precisely, we aim to answer the following research questions related to constraint efficacy: 1) How does performance vary across different types of constraints? 2) What are the ideal positions for constraints in the schema for better adherence?

We prepare first-of-its-kind benchmark test set[2] and conduct two experiments involving 5 schema formats (JSON, YAML, XML, Python, and NL) and 3 output formats (JSON, YAML, and XML) resulting 15 combinations of use cases to investigate the aforementioned research questions. 1) Data as Code Generation (Section 2.1. 2) Data Validation (Section 2.2). This study provides insights into leveraging LLMs effectively for system-level programming tasks involving code constraints in enterprises.

Our contributions are:

1. First-of-its-kind study of language models for crucial industry use case of system-level programming involving code format constraints across four key dimensions: Format and Constraint efficacy.

2. A benchmark test set consisting of 602 schema samples, each containing multiple instructions. Each schema sample in our test set is represented in 5 different language formats (JSON, YAML, XML, Python, and NL).

3. Comparative and qualitative analysis of state-of-the-art language models involving code generation from fine-grained schema instructions and code validation against schemas. To the best of our knowledge, we are the first to evaluate LLMs code constraint competency.

2 Experiments

2.1 Data as Code Generation in DSL

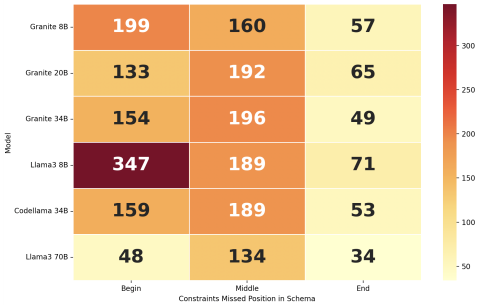

Figure 1: Uniform trend of steep decline in performance across models for constraints positioned in the middle and beginning of the JSON schema context and output for data as code generation experiment. We divide the schema into 3 portions, Begin, Middle, and End, and put the violated constraints based on their locality into either of these three buckets.

Description. Given the schema, the experiment (see Listing 1) aims to produce a compliant data sample in DSL code format. We draw inspiration from several use cases (see Appendix A.3), including synthesizing schema-compliant data from LLMs' parametric memory to train and evaluate smaller-sized models (Song et al., 2020) and generating diverse sets of samples to be used in product test pipelines. For reliable DSL code generation, LLMs need to be schema-aware.

Dataset. We synthetically prepare 602 schemas for each of the 5 representations having combinations of various constraints (Appendix A.4). First, we prepare JSON schemas using our combinatorial tool to generate a good mix of constraints. A combinatorial data generation tool factors in constraints of interest, constraint-specific information, and combinatorial preferences to generate the schemas. We then convert each JSON schema

Table 1: Zero shot results for both the experiments. Models scoring the highest accuracy the majority of times across all output representations for a particular schema are labeled with 🏆. Gen Acc represents the accuracy of valid samples for DSL generation experiment. Val Acc represents the accuracy of the binary classification validation experiment.

to XML and YAML schemas using openly available automatic lossless language-to-language translation tools. Further, we include resource-rich general-purpose language - Python using the Pydantic library generated using the Gemini-1.0-pro (Team et al., 2023) model as a code translation task. We extend our evaluation to NL representation generated using rule-based templates. We[3] ensure equivalence of the generated schemas across languages. We plan to open-source all the scripts used for data preparation. Table 3 gives details regarding schema token length.

Evaluation metric. Each schema-compliant code output LLM generates is awarded one point where schema compliance is checked using a schema validator tool. We then utilize the accuracy metric (Gen Acc) over all samples to benchmark performance across the models. Additionally, we also report the percentage of samples generated with the invalid root data type (RTV%) and invalid samples (IS%) in Table 5. The root data type is the data type of the whole DSL sample. For example, the root data type of sample represented in Listing 1 is *array*. For IS and RTV metrics, the lesser the number, the better the performance.

Experimental setup. We report greedy decoding results since it performed slightly better than beam search with a beam width of 3. We perform inference for all the models in $bfloat16$ precision and a max new token limit of 1024 tokens.

Prompts. We experiment with zero- and 3-shot prompting for each model. For 3-shot prompting, we identify errors from the zero-shot setting, then select shots similar to the most frequent errors. We observe that most errors made by all the models are regarding short schema and the schema having root type of array as shown in sample 1. An example of a 3-shot prompt for a DSL generation experiment is shown below. Examples of prompts are in Appendix 1.

[3]The schemas are manually validated by the paper's authors.

Table 2: Few shot results for generation (3 shots) and validation (2 shots) experiments. Models scoring the highest accuracy the majority number of times across all output representations for a particular schema are labeled with 🏆. Gen Acc represents the accuracy of valid samples for DSL generation experiment. Val Acc represents the accuracy of the binary classification validation experiment.

2.2 DSL Validation

Description. There is a growing body of work (Hada et al., 2024) on showing promising usage of LLMs as evaluators in many tasks. On similar lines, given the DSL sample and schema to validate, this experiment (see Listing 2) aims to determine the validity of the provided sample against the constraints through boolean question answering (QA). Also, the experiment is highly motivated from various use cases (see Appendix A.3) and throws light on LM's understanding of the relation between requirements and output in various representations.

Dataset. We synthetically prepare 602 schemas across 5 representations having combinations of hard and soft constraints. First, we prepare JSON schemas using our combinatorial tool to generate a good mix of constraints. We then convert each JSON schema to XML and YAML schemas using automated tools to ensure equivalence across representations. Further, we include Python representation using the Pydantic library as a resource-rich general-purpose language in our evaluation generated using the Gemini-1.0-pro (Team et al., 2023) model as a code translation task. We extend our evaluation to natural language representation generated using rule-based templates over the JSON schema. We[4] ensure equivalence of the generated schemas across languages by manually eyeballing the samples.

Listing 2: In the JSON sample, values for fields *stingo* and *anisic* do not adhere to schema constraints. But the Granite 34B model gives the incorrect answer (highlighted in yellow) as *yes*.

```
Question:
Does the JSON sample { "tamil": false, "baser": null
     , "anisic": 1906.34, "stingo": "officiis tellus
     . illum modi odit quas mattis nunc", "
     pigheadedness": 52.0 } adhere to all the
     constraints defined in JSON format schema
{
  "type": "object",
  "properties": {
    "tamil": { "type": "boolean" },
    "baser": { "type": "null" },
    "anisic": { "type": "number", "multipleOf": 17.0
         2 },
    "stingo": { "type": "string", "maxLength": 20 },
    "pigheadedness": {"type": "number", "
         exclusiveMinimum": 27.65410407394338, "
         maximum": 93.85523810367313 } },
  "additionalProperties": false
}
Respond to yes or no.
Answer:
```
yes
```
```

Evaluation metric. Since it is a boolean QA experiment, we use Macro average F1 (see Table 6)

[4]The generated Python samples are manually validated by the paper's authors.

and Accuracy (Val Acc) as evaluation metrics (see Table 1).

Experimental setup. The decoding strategy used here is similar to the data generation experiment as mentioned in Section 2.1. We perform inference in $bfloat16$ precision and a max new token limit of 1024 tokens. For beam search decoding, we use the beam width of 3.

Prompts. The goal of this experiment is to answer *yes* or *no*. We experiment with zero- and few-shot prompting. With few shot prompting, we provide one example each of *yes* and *no* answers. Results for few-shot prompting and examples of prompts are given in Appendix (Table 2).

Language	Max schema tokens	Avg schema tokens
XML	3316	364.82
JSON	1954	208.23
YAML	1295	135.09

Table 3: Schema length comparison using Llama3 tokenizer

3 Format Efficacy

3.1 Objective

To identify the most effective schema representation and output format for system-level programming while employing language models. Since schemas can be represented in various structured formats, including JSON, YAML, XML, Python, and even NL, determining which format best enables constraint adherence for language models while balancing context-length costs is critical.

3.2 RQ1: Which format is optimally suited for constraint and output representation?

Finding 1. In the data as code generation experiment (section 2.1), models best understand (Table 1) NL across all outputs. At the same time, JSON and YAML schemas perform well (Table 2) for constraints in code despite their limited presence in pre-training data. Surprisingly, models struggle with constraints in Python, likely due to a bias toward generating general-purpose Python code rather than schema-specific patterns. In contrast, JSON and YAML schemas benefit from their rigid structures and alignment with schema-centric applications, making them easier for models to interpret.

Finding 2. Using the same schema and output representation does not always enhance performance. For instance, in Table 2, YAML as schema and JSON as output representation performed better than YAML for both representations.

Finding 3. Although NL representation excels in generation experiments, it degrades the validation performance of larger models like 70B. Like generation experiment, models perform sub-optimally when schema and output representations are the same. In line with the first experiment, XML stands as a challenging language for models. The Llama3 70B model performs best in validation as in the first experiment, with other models hovering around 50% Val Acc, likely reflecting the random choice given the binary nature of the experiment. Smaller models, particularly the Llama3-8B with natural language representation, show notable improvement, as its pre-training combines NL and code.

Key takeaway. NL is a favorable language for schema representation, however, since its possible that enterprises lean more toward structured languages for better interoperability in which case JSON and YAML are ideal candidates for schema representation with JSON being favourable candidate for output representation. Nonetheless, the inconsistency in performance across experiments and model sizes underscores need for better schema comprehension and improved training strategies for NLP tasks involving validation.

3.3 RQ2: What is the trade-off between performance and context length cost?

Findings. From section 3.2 key takeaway, JSON and YAML are ideal candidates for schema representation which form the context to the LLM. From Table 3, representing schema in YAML on an average takes $\sim$35% less tokens than JSON. However, while choosing YAML would mean taking a drop of $\sim$14% in Gen Acc and $\sim$4% in Val Acc performance compared to JSON.

Key takeaway. Enterprises should be cognizant of such tradeoff and choose ideal representation that fits their use case. Further, better tokenizer training techniques might lead to lower token expenditure for the desired representation.

Constraint	Llama3 8B	Llama3 70B
type	302	49
exclusiveMinimum	18	44
multipleOf	170	42
minLength	47	21
contains	22	12
exclusiveMaximum	22	12
maximum	11	2
maxLength	7	19
additionalProperties	4	0
minimum	4	15

Table 4: Both the models, least and best performing, irrespective of their performance, show a similar distribution of mistakes for each constraint.

4 Constraint Efficacy

4.1 Objective

To examine how language models handle various types of constraints embedded within schemas. Enterprise schemas enforce structural (e.g., required fields, data types) and semantic (e.g., dependencies, value constraints) rules.

4.2 RQ1: How does performance vary across different types of constraints?

Findings. The analysis of the results shows that LLaMA3 8B and 70B exhibit similar patterns of missing constraints when generating JSON samples from a given schema (Table 4). In particular, constraints such as type, multiple, and exclusiveMinimum are often missing, while constraints such as maximum, additionalProperties, and minimum are more frequently followed. The high error rate in fundamental constraints *type* can be because training data contains many JSON-like samples where *type* is implicit rather than explicitly stated. The reason behind missing constraints like *exclusiveMinimum* and *multipleOf* may be because they involve high numerical precision. LLMs treat numbers as tokens, leading to potential rounding errors or incorrect enforcement.

Key takeaway. LLMs struggle with numerical constraints underscoring need for better techniques throughout the stack from tokenizer to model training. For enterprises, a rudimentary solution is to integrate constrained decoding or use post-processing validation to correct missing constraints after generation.

4.3 RQ2: What are the ideal positions for constraints in the schema for better adherence?

Findings. We categorize the constraints of the schema into three sections based on tokens: beginning (first 30%), middle (next 40%), and end (last 30%). Later, we perform a needle-in-the-haystack experiment for the data-as-code generation. The heatmap in Figure 1 shows the statistics of constraints missed at every position for JSON to JSON generation. It reveals a consistent trend where models struggle the most with constraints positioned at the beginning of the schema, followed by the middle. In contrast, constraints at the end are least frequently missed. This suggests that models may prioritize constraints appearing later in the schema, likely due to the left-to-right decoding nature of autoregressive models, causing early constraints to be overwritten or ignored. We also observe that constraints in the middle position of the schema are frequently missed. This aligns with previous findings that the middle part of the long context is often missed (Liu et al., 2024). For the data validation task, we analyze attention maps, which reveal a similar trend where the model pays less attention to the middle part of the schema (Figure 2).

Key takeaway. This suggests that important constraints should be placed at the end of the schema or the beginning for longer schemas, depending on the use case.

5 Related Work

Generation: There is extensive work (Muennighoff et al., 2024; Cassano et al., 2023) on

evaluating capabilities of LLMs for various code tasks such as code completion, translation, etc, for resource-rich languages like Python. Despite there being work (Cassano et al., 2023) on multi-lingual code, there is scant attention to low-resource languages such as DSLs, though having crucial importance. One notable work (He et al., 2024), studies the bearing of prompt format in DSLs with LLM performance, however, does not include impact of output formats and controllability aspect in terms of code constraints crucial for enterprises. Further, using LLMs as evaluators for low-resource languages is gaining interest, however limited, mainly focusing on languages like XML and INI (Lian et al., 2023).

Controllability of LLMs: While LLMs can handle coarse-grained constraints like sentiment, they struggle with fine-grained constraints, such as ending a text with a specific word (Sun et al., 2023). Code schemas often require such fine-grained control, and to our knowledge, we are the first to explore LLM controllability for constraints in code.

6 Conclusion

We evaluate LLMs for system-level programming across two key dimensions: Format Efficacy and Constraint Efficacy. Format efficacy examines how LLMs handle different constraint formats, while constraint efficacy assesses their performance on various schema constraints within a format. We conduct two novel experiments to study these aspects: Data as Code generation and DSL validation. We evaluate LLMs across 5 schema(YAML, JSON, Python, XML, NL) and 3 output formats(YAML, JSON, XML). Our findings reveal that model performance does not directly correlate with a language's presence in pre-training data. JSON and YAML are best suited for system-level programming, and enterprises should convert Python and XML formats to one of these for better LLM performance. We also observe that schema constraint locality affects performance, with constraints in the start and middle being most frequently violated. Placing critical constraints at the end improves reliability. We hope our work drives innovation in improving LLM capabilities for crucial industry use case of system-level programming involving code constraints.

7 Limitations

While we explore the DSL validation task by generating *yes* or *no*, exploring the model's reasoning can give a more comprehensive analysis of LLM's understanding. Further, one can include more complex constraints in the future for general-purpose programming languages, like coding style constraints to write code along with natural language prompts and schema.

Ethics Statement

Custom-created datasets have been created synthetically using open-source tools. The language models, tools, and frameworks used for evaluation are open source and can be used without copyright issues.

A Appendix

A.1 Prompts

This section defines the prompts which are used for models. We report different prompts for every model tried here and report the best-performing prompt results. Generally, the model consists of a System Prompt followed by a prompt template specific to the model.

A.1.1 Common prompt

For zero shot inference, we use a common prompt as it is for all the models irrespective of the model's prompt format and we observe best results for Task-1 with this prompt. The prompt is as follows.

Listing 3: common prompt

```
Write an {input_representation} sample with field
    values as per the {output_representation}
    format schema given below.

{schema}
```

```
{output_representation} sample:
```

A.1.2 Granite model family

The granite model generally follows the question-answering format. Task-1 prompts for granite family models are as follows.

System prompt:
System:
You are an intelligent AI programming assistant, utilizing a Granite code language model developed by IBM. Your primary function is to assist users in code explanation, code generation and other software engineering tasks. You MUST follow these guidelines: - Your responses must be factual. Do not assume the answer is *yes* when you do not know, and DO NOT SHARE FALSE INFORMATION. - You should give concise answers. You should follow the instruction and provide the answer in the specified format and DO NOT SHARE FALSE INFORMATION.
Prompt 2:

Listing 4: QA-prompt-1

```
{System prompt}

Question:
Write an {input_representation} sample with field
     values as per the {input_representation} format
      schema given below.

{schema}

Answer:
```

Prompt 3:

Listing 5: QA-prompt-2

```
{System prompt}

Question:
Write an {input_representation} sample with field
     values as per the {output_representation}
     format schema given below. Please wrap your
     code
answer using ```

{schema}

Answer:
```

{output_representation} and {input_representation} are the variables where {input_representation} take the values JSON, YAML, XML, Python, and natural language. {output_representation} takes the values JSON, YAML, and XML.

A.1.3 Llama family

For codellama $34B$ model we wrap the common prompt in [INST] and [/INST] tags. For the llama3-8B model, we use the System prompt along with user tags [5].
System prompt: You are a helpful, respectful, and honest assistant. Always answer as helpfully as possible, while being safe. Your answers should not include any harmful, unethical, racist, sexist, toxic, dangerous, or illegal content. Please ensure that your responses are socially unbiased and positive. If a question does not make any sense or is not factually coherent, explain why instead of answering something not correct. If you don't know the answer to a question, please don't share false information.
Other than this, similar to the granite family, we try Question answering format and instruction to wrap the output in quotes (“‘).
Few shot prompt

Listing 6: Few shot prompt

```
{System prompt}

Your task is to write a JSON sample with field
     values as per JSON format schema.
You are given a few examples demonstrating the same.

JSON format schema:
{
    "type": "array",
    "contains": {
        "type": "boolean"
    },
    "minContains": 0
}
JSON sample:
```
[true, true, false]
```
JSON format schema:
{
    "type": "string",
    "format": "idn-email"
}
JSON sample:
```
"hchavezexample.org"“‘JSON format schema:"type":
     "array","items": "type": "number","multipleOf":
     5.82,"exclusiveMinimum": 3.069158195370172JSON sample:“‘
```

## A.2 Limitations of Constrained Decoding

This section outlines some common problems with constrained decoding and emphasizes why it cannot be a complete and viable solution for factoring in schemas to generate compliant text using language models.

[5] https://huggingface.co/meta-llama/Meta-Llama-3-8B-Instruct
```

Example 1 (Lllama3 8B):

```
{
   "type": "array",
   "contains": {
      "type": "object",
      "properties": {
         "cockboats": {
            "type": "number",
            "minimum": 6.838020040763691,
            "exclusiveMaximum":
9.08848414476941,
            "multipleOf": 8.93
         },
         "remeditate": {},
         "endocrinology": {
            "type": "null"
         },
         "subvillain": {
            "type": "boolean"
         },
         "tubularian": {
            "type": "null"
         },
         "jingoed": {
            "type": "null"
         },
         "neoplasties": {
            "type": "null"
         }
      },
      "additionalProperties": true
   },
   "minContains": 0
}
```

Example 1 (Lllama3 70B):

```
{
   "type": "array",
   "contains": {
      "type": "object",
      "properties": {
         "cockboats": {
            "type": "number",
            "minimum": 6.838020040763691,
            "exclusiveMaximum":
9.08848414476941,
            "multipleOf": 8.93
         },
         "remeditate": {},
         "endocrinology": {
            "type": "null"
         },
         "subvillain": {
            "type": "boolean"
         },
         "tubularian": {
            "type": "null"
         },
         "jingoed": {
            "type": "null"
         },
         "neoplasties": {
            "type": "null"
         }
      },
      "additionalProperties": true
   },
   "minContains": 0
}
```

Figure 2: Attention maps for Llama3 8B and 70B model for Data validation experiment. The more the intensity of color, the more attention is given to that part of input by the model.

A.2.1 Inference Performance Bottleneck

Constrained decoding often negatively affects inference throughput, widely mentioned as one of the major drawbacks in many works (Wang et al., 2024; Pimparkhede et al., 2024; Geng et al., 2023) due to involvement of token-level operations keeping track of the schema constraints and tokens generated so far. This latency can be a factor of the complexity of the schema, tokens generated so far, and the nature of the constrained decoding implementation. Further, advances such as batched inference [6] are not yet there for constrained decoding limiting their scalability and practical use.

A.2.2 Complex Engineering Effort

Implementing a constrained decoding system can involve instrumenting at the decoding phase of the language model while keeping track of the tokens generated so far and structured schema adherence which can involve implementation specific to a schema representation and may not be possible to generalize to any schema representation. For instance, most of the openly available constrained decoding systems [7] have limited support and not generalized to various schemas such as XML and output formats such as YAML and others. It is worthwhile to note that some approaches tend to convert scehmas to context free grammars, however, this approach is possible with common schema representations such as Python pydantic. Additionally, implementing such a system requires deep domain expertise.

A.2.3 Model Performance Bottleneck

LLMs have multiple failure modes that can likely be triggered through constrained decoding. Many works show that LLMs are sensitive to the text being fed into them and often deteriorate the model's performance. Some examples being the reverse curse from (Berglund et al., 2024), where LLM understanding "A is B" may not guarantee to learn "B is A". Another work (Chen et al., 2024) shows that the order of the premises can have a substantial impact on the performance often affecting negatively. Such failures can be triggered when the natural flow of text generation is interrupted through constrained decoding over autoregressive generation. The problem can worsen when it involves mixed generation of structured output and unstructured NL text.

[6] https://github.com/microsoft/batch-inference

[7] https://github.com/outlines-dev/outlines

A.2.4 Limited Scope

Since constrained decoding needs access to the decoding phase of the language model, its often not possible to apply such decoding to hosted or gated LLM deployments.

Applying constrained decoding to some common use cases is not obvious. Given n structured schemas from s_1 to s_n, unstructured NL text output as k and structured output as u. Common use cases in natural language processing (NLP) such as summarization involve the following input-output relationship. For some arbitrary schema i, $s_i \rightarrow u$. Further typical use cases involve factoring in n multiple schemas and generate m multiple structured outputs $(s_1...s_n) \rightarrow (k_1...k_m)$.

Employing constrained decoding in such use cases is not viable since in the first use case, tasks that output u cannot leverage constrained decoding and schema has to go into LLMs as input. When multiple schemas and structured outputs are involved, its not obvious to choose the right schema for decoding a particular structured output. Such common use cases substantially limit the scope of using constrained decoding.

A.3 Task Motivation

A.3.1 Data as Code Generation Task

This section describes use cases from enterprise and research points of view motivating data as code generation seed tasks in our study.

Enterprise Use Cases: (i) Test case structured data generation to test application interfaces such as REST API endpoints. Often, enterprises have a large number of services exposing API endpoints that have to be tested, and LLMs can be a drop-in solution to generate test case data at scale. (ii) Structured configuration data generation for a particular use case and domain. Enterprise applications such as Kubernetes use DSLs for configuration and usage, preparing them require deep domain expertise and there is increasing motivation (Pujar et al., 2023) to employ LLMs in enterprises to generate DSL code. (iii) Some more downstream tasks involving structured data, such as forms and tables often represented in a programmable format such as JSON, can leverage LLMs to generate structured data to fill forms or tables leveraging the schema.

Research Use Cases: (i) Since DSLs are typically low resource languages, LLMs are often em-

		Output Representation					
		JSON		YAML		XML	
Model	Schema	IS (%)	RTV (%)	IS (%)	RTV (%)	IS (%)	RTV (%)
Llama3 8B	JSON	**1.9**	50.1	1.8	49.8	**1.6**	73.9

Granite 34B		2.3	**1.9**	**2.4**	**8.9**	9.86	**63.42**
Codellama 34B		2.8	60.4	2.9	34.5	**7.88**	65.51

Table 5: Task 1 zero shot results having IS and RTV metric values. IS denotes the percentage of invalid samples and RTV denotes the percentage of sample root data type errors. For IS and RTV, the lesser the value better the performance.

ployed (Song et al., 2020) to synthesize data from LLMs to train and evaluate smaller-sized models. (ii) This task acts a as a seed for similar NLP use cases such as code translation.

A.3.2 DSL Validation Task

This section describes use cases from an enterprise and research perspective that motivate our study's DSL validation seed task.

Enterprise Use Cases: (i) Given the schema, employing LLMs to generate domain-aware suggestions over the provided structured data is not viable with traditional schema validators, which only pinpoint syntactic errors and cannot provide semantic suggestions. Such as providing optimizations over the existing resource YAML in Kubernetes while complying with resource schema. (ii) In an assistive chat system, the constraints are often in NL representation from the user, which is not machine-readable, and LLMs should be able to understand such constraints. (iii) Quick interoperability across different schema and data representation versions. Often in enterprises, schemas can be in a particular version that is incompatible with the structured data version. For instance, the schema could be in an older JSON schema version such as Draft 0 and data in Draft 7, in such cases LLMs can come handy to perform validation at scale.

Research Use Case: Understanding LLMs' capability in validating the given structured data against the schema across representations can provide seed evidence for more complex tasks such as automatically fixing data in compliance with the given schema.

A.4 Schema Examples

This section provides schemas across 5 representations from Listings 7 to 11. All the schemas are equivalent in terms of constraints.

Listing 7: Sample schema using JSON Schema

```
{
    "type": "object",
    "properties": {
        "footbaths": {
            "type": "boolean"
        },

Abstract

Consumers often face inconsistent product quality, particularly when identical products vary between markets, a situation known as the dual quality problem. To identify and address this issue, automated techniques are needed. This paper explores how natural language processing (NLP) can aid in detecting such discrepancies and presents the full process of developing a solution. First, we describe in detail the creation of a new Polish-language dataset with 1,957 reviews, 540 highlighting dual quality issues. We then discuss experiments with various approaches like SetFit with sentence-transformers, transformer-based encoders, and LLMs, including error analysis and robustness verification. Additionally, we evaluate multilingual transfer using a subset of opinions in English, French, and German. The paper concludes with insights on deployment and practical applications.

1 Introduction

Dual quality of products refers to practices where companies sell items under the same brand and similar packaging in different markets, yet present them with significantly altered composition or quality parameters (The European Consumer Organisation (BEUC), 2018). This phenomenon has sparked growing controversy among consumers, especially within the European Union (EU), where it is perceived as a potential violation of fair competition rules (The European Consumer Organisation (BEUC), 2018). From a sociological and economic perspective, dual quality practices raise multifaceted concerns about market trust, purchasing behaviours and the perception of fairness among consumers (Veselovská, 2022; Bartkova and Sirotiaková, 2021). Multiple reports published by consumer organizations and EU research services suggest that offering products with distinct ingredients or characteristics under identical branding constitutes a widespread international issue (The European Consumer Organisation (BEUC), 2018; European Parliament, 2019; European Commission, 2023). The above reasons and EU regulations—such as the amended Directive on Unfair Commercial Practices—recognize dual quality as misleading conduct, which may require enforcement at the national level (Chambers; EU Monitor) (also, see more details in Appendix A). Our recent research project focused on creating a solution to support a national agency from one of the EU countries to address the above problem, namely the Office of Competition and Consumer Protection (UOKiK) in Poland (https://uokik.gov.pl/en).

The main goal of the project was to automate the detection of unfair commercial practices using natural language processing (NLP) methods. The project, currently in the proof-of-concept stage, is enabling the automated collection and analysis of product-related data from e-commerce sites and social media. It comprises a data retrieval module (intelligent web crawling, scraping, cleaning, and preprocessing) and a text analysis module that includes language identification, sentiment analysis, aspect base sentiment analysis, and the detection of consumer reviews[1] that may indicate potential dual quality issues in products.

In this paper, we focus on the last and most novel of these components for detecting dual quality reviews, describing the entire process from data preparation, through extensive evaluation of different approaches, to deployment. To our knowledge, no available dataset or model is aimed at recognizing dual quality-related reviews. While several articles (discussed further in Section 2) approach

[1] In this article, we use the terms 'reviews' and 'opinions' interchangeably to refer to consumer expressions regarding a product. While 'review' may often imply a structured evaluation, we also include informal opinions that may indicate perceptions of dual quality.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1480–1497

dual quality from sociological, economic, and legal perspectives, our study takes a different approach presented in Figure 1.

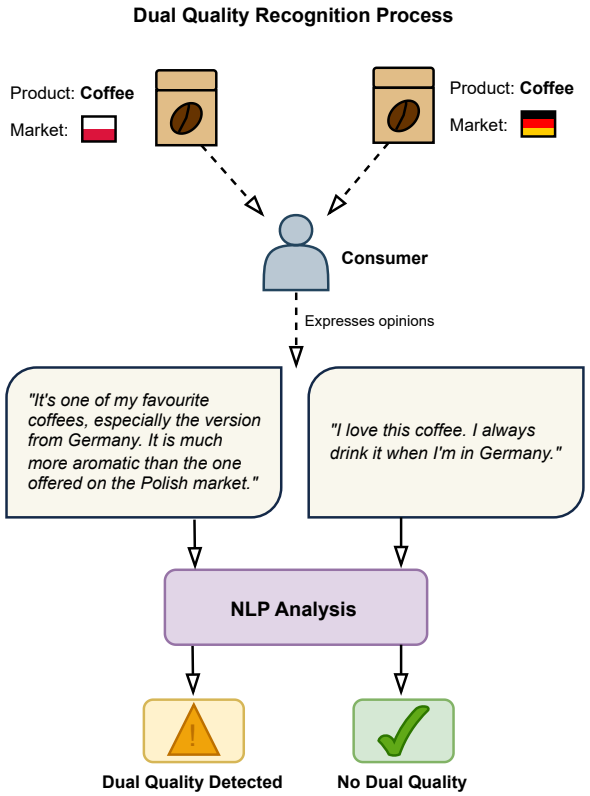

Figure 1: Illustration of the NLP-based workflow for recognizing dual quality consumer reviews. The dual quality detection system flags reviews for potential issues when a consumer explicitly notes a difference between product versions from different markets. This illustration exemplifies the process with a Polish consumer assessing products from Polish and German markets; the reviews shown are English translations of the original Polish texts for clarity and wider accessibility.

The main contributions of this work can be summarized as follows:

– Proposition of new NLP task: detecting the dual quality issues in product reviews.

– A coherent methodology for dataset construction and preparation of a corpus of 1,957 human-verified product reviews, 540 of which potentially exhibit dual quality.

– A comprehensive evaluation of Polish and multilingual models, including a presentation of various metrics, error analysis, and robustness verification conducted primarily for Polish.

– Expansion of the dataset to include product reviews in other key languages such as English, German, and French, demonstrating the system's multilingual capabilities.

2 Related Work

Economic and social research on dual quality products highlights the erosion of consumer trust when identical branding masks disparities in product quality across EU Member States. Studies indicate that these discrepancies, particularly in food products, impact consumer perceptions of fairness and lead to behavioral changes in purchasing decisions (Bartková et al., 2018; Bartková, 2019; Bartkova et al., 2021; Bartkova and Sirotiaková, 2021). Research has further demonstrated that wealthier consumers are more aware of the issue and seek alternatives in other markets, whereas lower-income consumers are more likely to adapt their behavior to avoid lower-quality products (Bartkova and Sirotiaková, 2021). The perception of dual quality as an economic problem is also evident, as lower-quality ingredients often correspond to price disparities that disadvantage consumers in specific regions (Závadský and Hiadlovský, 2020).

Additionally, empirical studies confirm that public perception of dual quality is shaped by exposure to media reports and political discourse, leading to heightened scrutiny of multinational corporations and their regional product differentiation strategies (Veselovská, 2022). While some scholars argue that manufacturers may justify product variations based on local market preferences, research suggests that these practices often lack transparency and leave consumers feeling deceived (Bartkova and Veselovska, 2023). Moreover, comparative consumer tests confirm that dual quality is not confined to food products but also extends to household and personal care items, reinforcing the need for regulatory intervention (Bartková and Veselovská, 2024). Given the strong consumer opposition across Europe, particularly in Central and Eastern European countries, economic research increasingly supports regulatory measures to curb these practices and ensure consistent product quality across EU markets.

From an computer science perspective, the topic of applying NLP techniques to e-commerce platforms and customer behavior analysis is widely studied. Among these works, we can point out customer reviews analysis (Botunac et al., 2024; Satjathanakul and Siriborvornratanakul, 2024; Mamani-Coaquira and Villanueva, 2024), product question answering (Shen et al., 2023; Wang et al., 2023), product categorization (Gong et al., 2023),

moderation of e-commerce reviews (Nayak and Garera, 2022), product feature extraction from the web (Fuchs et al., 2022), customer service support (Obadinma et al., 2022), data augmentation in e-commerce (Avigdor et al., 2023), fake news detection (Hu et al., 2023), predictive quality in manufacturing (Tercan and Meisen, 2022), or intent classification (Parikh et al., 2023). However, none of these works address the dual quality problem directly or consider how to harness consumer opinions—such as reviews from the Internet, e-commerce platforms, or social media—to help resolve this issue. Thus, a clear research gap exists in applying NLP-based methods to detect or analyze dual quality products.

3 DQ Dataset

3.1 Dataset Creation Methodology

In the first stage of our work, we collected a large dataset of reviews in Polish, sourced from the e-commerce platform CENEO[2] and the discussion forum on beauty, makeup, and cosmetics, WIZAZ[3]. Our preliminary tests have shown that the problem of dual quality does not occur often in reviews, and thus randomly selecting a set of opinions and giving them to annotators is an inefficient approach to building a dataset. Therefore, we prepared a methodology to optimize this process, which consists of the following steps:

① Find dual quality reviews on the Internet by searching for publicly available articles that describe the problem of dual quality. Such articles often included examples of products along with the differences observed depending on the sales market, which we extracted. In addition, some articles had comment sections where people shared their experiences with the dual quality issue, which we also collected. In this way, we obtained **117** dual quality reviews.

② Randomly select **300** reviews from the CENEO / WIZAZ dataset as standard opinions that do not indicate a dual quality problem. These reviews have been verified to ensure that they are standard. Along with the examples obtained in step ①, these formed the base dataset.

③ Train a model using a few-shot learning method to detect dual quality reviews based on the prepared base or an extended dataset (subsequent iterations). We adopted this approach due to the limited amount of training data. The model was implemented using the SetFit (Sentence Transformer Fine-tuning) framework (Tunstall et al., 2022) and a sentence transformer for the Polish language st-polish-paraphrase-from-distilroberta[4].

④ Apply the model trained in step ③ to all reviews of the CENEO / WIZAZ dataset. The results of the classification were sorted according to the probability returned by the model.

⑤ Select up to **200**[5] reviews with the highest probability of indicating a dual quality problem, which did not appear previously in the dataset. Then perform manual verification of the selected reviews. If a review did not indicate a dual quality issue, it was labeled as a standard review. During this step, we noticed that some reviews mentioned other problems, including, for example, the product being possibly counterfeit, deterioration in product quality over time, or the received product does not match the order. Annotators labeled such opinions as other problems and added additional information regarding the type of problem mentioned in the review. For training the model in step ③, the reviews labeled as other problems and standard were combined. The outcome of this step and the base dataset constituted the extended dataset.

⑥ Return to step ③ to increase the size of the dataset.

Steps ③, ④, and ⑤ were repeated **7** times, allowing us to expand the base dataset with **1,303** examples (in last iteration only **103** new reviews were selected). We then applied the model, trained on the entire dataset prepared so far, to classify the reviews imported into the demo version of our system. Reviews were sourced from Polish and international e-commerce sites. Of these reviews, **237** were labeled as dual quality, which we manually verified and changed if necessary. As a result of the entire process described above, we obtained a DQ (**D**ual **Q**uality) dataset consisting of **1,957** unique examples. o ensure annotation accuracy, we conducted cross-validation and identified examples where the models were most often wrong. After verifying these errors, in **67 (3.4%)** cases the label was incorrect and was changed. The whole above process is shown in Figure 4.

[2] https://www.ceneo.pl/

[3] https://wizaz.pl/forum/

[4] At the time of the dataset creation (beginning of 2023) it was the top Polish sentence transformer, as confirmed by Dadas et al. (2024b).

[5] Initially, many reviews were classified as dual quality, making a probability threshold unsuitable. Selecting 200 enabled swift human verification, speeding up subsequent iterations.

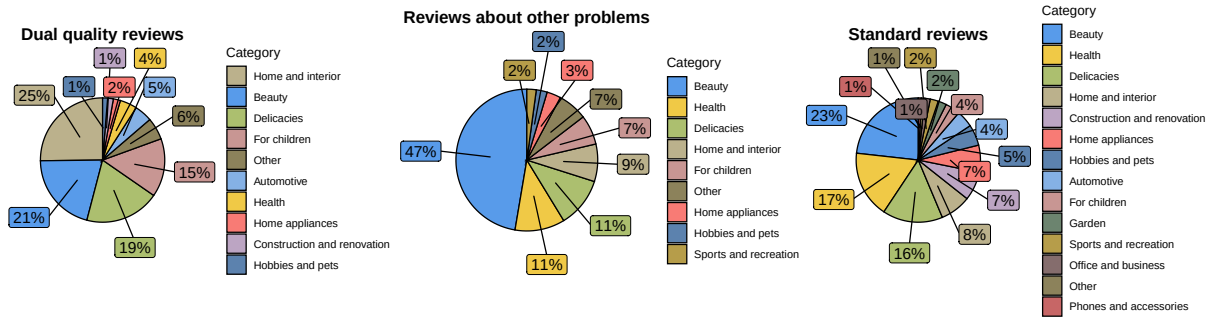

Figure 2: Charts illustrating the distribution of product categories across various types of reviews.

3.2 Dataset Statistics

The statistics of the DQ dataset are presented in Table 1. The dataset consists of **1,957** records, of which **540** are labeled as dual quality, **281** as other problems, and the rest are standard opinions. Of the dual quality reviews, **107**[6] were from the Internet, **265** from the CENEO / WIZAZ collection, and **168** from our demo system. The dataset is unbalanced, with over half of the reviews belong to the standard class. This characteristic was intentionally maintained because, in the real world, reviews on dual quality and other problems occur less frequently than others. For experimental purposes, the dataset was divided into three subsets: train, test and valid, containing **1,200** (∼**61%**), **500** (∼**26%**), and **257** (∼**13%**) reviews, respectively. The review texts in the dataset consist of **261** characters and **41** words on average.

	# reviews			
label	**all**	**train**	**test**	**valid**
dual quality	540	331	138	71
other problems	281	172	72	37
standard	1136	697	290	149
total	1957	1200	500	257

Table 1: DQ dataset statistics.

In addition, in Figure 2 we present pie charts depicting the distribution of product categories across various types of reviews[7]. A few interesting patterns in these distributions are worth describing. For instance, although *Beauty*, *Delicacies*, *Health*, and *Home & Interior* are large categories overall, *Home & Interior* has an exceptionally high share among dual quality reviews (25%, compared to 13% overall), suggesting that this type of issue might be more commonly perceived in products related to household items. Similarly, *For children* makes up only 7% of all reviews but appears more prominently (15%) in dual quality reviews. Meanwhile, *Beauty* reviews account for nearly half (47%) of the 'other problems' category, indicating that consumers in that segment may encounter a broader range of product issues beyond dual quality concerns.

4 Experiments

4.1 Experimental Setup

The problem was defined as a three-class classification (see Table 1). Evaluation of various methods was performed on a test set. The training set and the validation set were used for approaches that required training/fine-tuning. Each experiment was repeated five times[8], setting a different seed value (if applicable), and the results presented in the tables are average values.

4.2 Methods

Baseline is a naive method of assigning a dual quality class to a review if there are references to another country in the text.

SetFit + sentence transformers is an approach in which a sentence transformer model is first fine-tuned using contrastive learning and then used as text embedding for a logistic regression model. In the experiments, we used sentence transformers previously tested on the PL-MTEB benchmark by Poświata et al. (2024). We selected seven multilingual models namely: LaBSE (Feng et al., 2022), paraphrase-multilingual-mpnet-base-v2, paraphrase-multilingual-MiniLM-L12-v2

[6] In the results of the final dataset verification, of the 117 dual quality reviews initially found, 10 were classified as standard.

[7] All product reviews categorized by product type reader may see in Figure 6.

[8] This rule was not applied to Baseline, which is deterministic, and successive runs always produce the same result.

Method	Dual Quality class			All classes			
	Precision	Recall	F1	Accuracy	mPrecision	mRecall	mF1
Baseline	$42.4_{\pm 0.0}$	$84.8_{\pm 0.0}$	$56.5_{\pm 0.0}$	$55.2_{\pm 0.0}$	$37.8_{\pm 0.0}$	$46.5_{\pm 0.0}$	$39.5_{\pm 0.0}$

Table 2: Average scores with standard deviation for all evaluated methods. The Precision, Recall, and F1 metrics were calculated considering only the dual quality class; the other metrics were for all classes, with 'm' as the macro average. Bold values indicate the highest scores for the type of method, and blue highlights the highest scores for each metric.

(Reimers and Gurevych, 2019), three e5 models (Wang et al., 2024) and mGTE (Zhang et al., 2024). Additionally, we choose four sentence-transformer models dedicated to the Polish language: st-polish-paraphrase-from-mpnet, st-polish-paraphrase-from-distilroberta (Dadas et al., 2024b) and two mmlw models (Dadas et al., 2024a).

Transformer-based encoders involves training pre-trained language model with classification head on top (a linear layer on top of the pooled output). We included evaluations of multilingual BERT (mBERT) (Devlin et al., 2019), multilingual XLM-RoBERTa (Conneau et al., 2020), and models specifically trained for Polish, such as HerBERT (Mroczkowski et al., 2021) and Polish RoBERTa (Dadas et al., 2020).

LLMs Advanced frontier models such as DeepSeek (DeepSeek-AI et al., 2025, 2024) and GPT-4o (OpenAI et al., 2024) were selected to evaluate how effectively cutting-edge LLMs handle dual quality review detection tasks under different prompting scenarios, including zero-shot and few-shot configurations, both with and without additional instruction (see more details about used prompts in Table 9).

4.3 Main Results

The experimental results from Table 2 clearly indicate notable differences among the three groups of tested models. Sentence-transformer models using SetFit generally achieved moderate precision scores (around 70-77%), suggesting that compressing sentence semantics into a single vector might result in information loss or inadequate semantic representation. Transformer-based encoders, particularly the larger, language-specific models such as polish-roberta-large-v2 (84.6%) and herbert-large-cased (81.5%), exhibited significantly stronger performance, comparable even with state-of-the-art conversational large language models (LLMs). Among LLMs, instructive prompting strategies (providing clear definitions of classes without explicit examples) improved performance, with the best precision results of 86% and 85.7% achieved by GPT-4o models with and without examples, respectively. It should be noted that the GPT-4o model with zero-shot instr. prompt achieved very good results for other measures as well. Interestingly, explicit few-shot examples sometimes distort the models and reduce detection efficiency overall. This may suggest that the chosen examples may not be representative and therefore helpful.

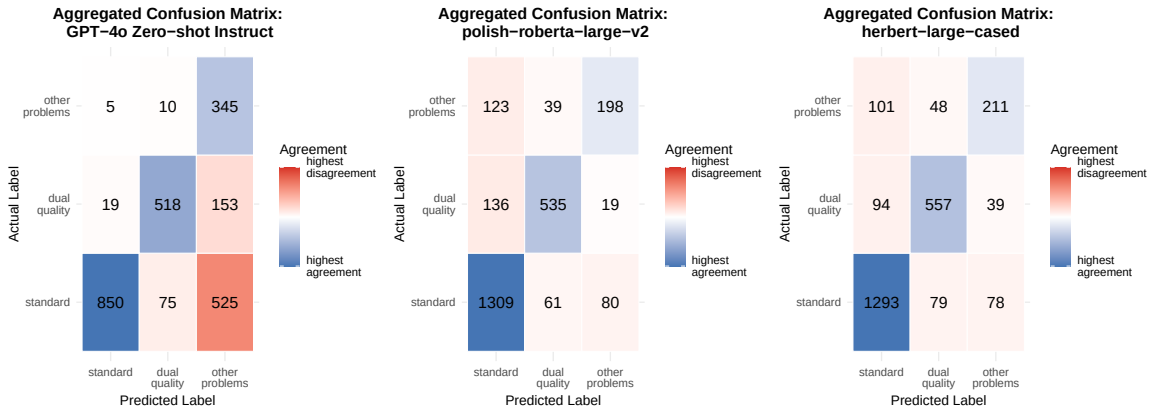

Figure 3: Confusion matrices aggregated from five experiments for selected models.

4.4 Errors Analysis

We conducted a detailed error analysis for selected models using classification confusion matrices visualized through heat maps. Specifically, we selected three representative models: GPT-4o (zero-shot+inst.), polish-roberta-large-v2 and herbert-large-cased. Figure 3 shows that the GPT-4o model exhibits substantial confusion between standard and 'other problems' reviews, while errors between standard and dual quality are less frequent. The polish-roberta-large-v2 model frequently identifies the standard reviews, achieving high accuracy for this category, but often misclassifies dual quality opinions as standard. Model herbert-large-cased often recognizes the dual quality reviews, achieving a high detection rate but also producing the most false positives for this class. Additional comparative analyses are presented in Figure 7 and Figure 8.

4.5 Robustness

As an additional experiment, we verified robustness of selected models, i.e., whether a slight change in the text, which does not significantly affect its meaning, can change the model's decision. We generated five additional test sets, which resulted from modifications to the original test set. The modifications are described in Table 3. We tested three selected models, the results are shown in Table 4. The percentage of differences in predictions was between 2.6 and 5.0. More often, larger text modifications like pl_chars influenced the change in decision.

4.6 Multilingual Transfer

To verify generalizability across markets and languages, we also explored multilingual transfer capabilities of our solution. For this purpose, we created a multilingual subset of reviews in English, German, and French (200,000 reviews for each language) selected from the AMAZON (Keung et al., 2020) dataset and our demo system. Next, we trained SetFit with paraphrase-multilingual-mpnet-base-v2[9] on the DQ dataset, and applied it to these reviews. Then we selected 500 AMAZON reviews and 200 reviews from demo system with the high-

Name	Description
period	Remove (if present) or add (if absent) a period at the end of the review.
first_letter	Change the capitalization of the first letter of the first word in the review. If the first word is written in uppercase, change it to lowercase.
lower	Change text of the review to lowercase.
pl_chars	Replace the Polish characters *ą, ę, ć, ł, ń, ó, ż, ź* with their corresponding Latin alphabet characters, i.e., *a, e, c, l, n, o, z*.
pl_chars_once	The operation is the same as pl_chars, except that each letter can be changed once.

Table 3: Descriptions of modifications applied to the test set for robustness verification.

Modification	gpt-4o	polish-roberta	herbert
period	$4.0_{\pm 0.0}$	$4.2_{\pm 1.0}$	$5.0_{\pm 0.9}$
first_letter	$4.0_{\pm 0.0}$	$2.8_{\pm 0.7}$	$2.6_{\pm 0.8}$
lower	$5.0_{\pm 0.0}$	$4.6_{\pm 0.5}$	$4.2_{\pm 0.7}$
pl_chars	$5.0_{\pm 0.0}$	$4.6_{\pm 1.2}$	$4.6_{\pm 0.8}$
pl_chars_once	$4.0_{\pm 0.0}$	$4.0_{\pm 1.4}$	$3.6_{\pm 0.8}$

Table 4: Robustness verification results for GPT-4o (zero-shot+inst.), polish-roberta-large-v2 and herbert-large-cased. The values are the average and standard deviation of the model's decision disagreement for the original and modified reviews. To ensure consistent behavior in the GPT-4o model, we set the temperature to 0.0, resulting in a standard deviation of 0.0 across runs.

[9]One of the top multilingual sentence transformer at that time (2023).

Method	Dual Quality class			All classes			
	Precision	Recall	F1	Accuracy	mPrecision	mRecall	mF1
Transformer-based encoders							
xlm-roberta-base	$69.5_{\pm 2.3}$	$\mathbf{66.9_{\pm 6.8}}$	$67.9_{\pm 2.9}$	$\mathbf{73.0_{\pm 1.0}}$	$55.5_{\pm 1.1}$	$55.1_{\pm 2.1}$	$55.0_{\pm 1.7}$
xlm-roberta-large	$\mathbf{84.8_{\pm 3.8}}$	$63.1_{\pm 4.8}$	$\mathbf{72.3_{\pm 4.0}}$	$72.6_{\pm 2.7}$	$\mathbf{60.1_{\pm 2.7}}$	$\mathbf{56.7_{\pm 3.9}}$	$\mathbf{57.5_{\pm 3.3}}$
LLMs							
deepseek-v3 zero-shot+inst.	$85.9_{\pm 1.8}$	$52.3_{\pm 0.8}$	$65.0_{\pm 0.3}$	$49.5_{\pm 0.7}$	$63.4_{\pm 1.3}$	$\mathbf{58.7_{\pm 1.0}}$	$49.1_{\pm 0.7}$

Table 5: Evaluation results for selected models on a multilingual dataset.

est dual quality scores. Manual verification showed that most were actually standard, so we randomly limited standard reviews to 130, yielding **206** final examples (**58** dual quality, **18** other problems, **130** standard). The dataset thus prepared was used as a multilingual test set. We conducted an experiment in which we tested methods based on multilingual models trained as in Section 4.1 on the Polish training subset or, in the case of LLMs, using the same prompts. The results for the selected models are presented in Table 5. Considering the precision of the classifier, the highest score was achieved by the DeepSeek-V3 (91.9%) model, interestingly in this case, adding examples to the instructions in the prompt gave a higher score. Of the group of transformer-based encoders, the highest score was achieved by xlm-roberta-large (84.8%). Although the difference in performance on the basis of precision is significant, it is important to note the low values of the recall measure for LLMs, compared to encoders. All results for this experiment are available in Table 11.

5 Deployment and Practical Considerations

During the evaluation, a key objective was to achieve high precision, thereby minimizing the number of false positive recommendations. Since each flagged instance undergoes final verification by a human analyst, the primary goal is to reduce the analyst's workload by minimizing the number of irrelevant alerts. This approach accepts the possibility of missing some true dual quality cases (i.e., allowing for a certain level of false negatives) in favor of ensuring that the identified cases are highly likely to be accurate. A product with several dual quality reviews will be selected for further analysis to verify whether this issue genuinely exists in its case.

The proposed solution is implemented as a standalone service within a local infrastructure and is exclusively dedicated to UOKiK employees (Poland's Office of Competition and Consumer Protection). The system is currently not accessible to the public or external users. Although the system can analyze multilingual content, the current deployment prioritizes support for the Polish language to align with the context of Polish consumers and UOKiK's mandate within the Polish market.

Given the results of the evaluation and the above assumptions, we would recommend using the polish-robert-large-v2 model for a production deployment. Selecting the locally deployable model presents a pragmatic and efficient choice, particularly when minimizing external dependencies and ensuring consistent, low-latency inference. It should be noted that this language-specific component is modular; for deployment within other European consumer protection agencies analogous to UOKiK, the model could be readily substituted with an equivalent model fine-tuned for the respective national language (e.g., a German BERT for a German institution) or multilingual model like XLM-RoBERTa.

6 Conclusion

In this work, we presented the entire process of preparing a solution for detecting the problem of dual quality based on product reviews. Our three key findings are: First, mentions of dual quality in product reviews are rare, in our case appearing only a few hundred times. Second, smaller language-specific transformer-based encoders finetuned for the task perform comparably to larger LLMs. Finally, including examples in prompts for LLMs can degrade performance compared to using only task-specific instructions.

A Dual Qulity Regulations

The regulatory response to dual quality has evolved significantly within the European Union. The European Commission's 2017 guidelines clarified that while product differentiation is not inherently illegal, misleading consumers violates EU consumer protection laws (European Parliament, 2017, 2019). The Commission's Joint Research Centre (JRC) introduced a harmonized testing methodology to assess product composition variations (Commission, 2018; European Commission, 2023) systematically. Additionally, the Omnibus Directive amended Directive 2005/29/EC, classifying dual quality marketing as misleading when substantial differences exist without a legitimate justification (Chambers). These measures aim to enhance market transparency and prevent unfair commercial practices. However, challenges remain in enforcement and uniform interpretation across Member States (EU Monitor). Recent research shows that while the prevalence of dual quality food products declined from 31% in 2018 to 24% in 2021, concerns persist regarding non-food items, as similar discrepancies have been identified in household and personal care products (European Commission, 2023).

Furthermore, consumer advocacy organizations such as BEUC argue that enforcement mechanisms must be strengthened to ensure compliance across all product categories (The European Consumer Organisation (BEUC), 2018). The SAFE initiative also supports enhanced consumer education and reporting mechanisms to empower individuals to identify and challenge dual quality practices (Safe Food Advocacy Europe (SAFE)). These ongoing legal and regulatory efforts underscore the EU's commitment to fair competition and consumer protection, yet continued vigilance and adaptation of enforcement strategies remain necessary.

B DQ Dataset Details

B.1 Annotation Process Details

We established a structured data labelling policy to annotate the data, i.e., assign each opinion or review to its appropriate category. This policy provides clear classification criteria for opinions categorized as *dual quality*, *other problems*, or *standard* (see Table 6 for detailed definitions). The annotation process followed predefined guidelines to ensure consistency and reliability, and where

necessary, ambiguous cases were resolved through annotators' review.

Examples of labeled reviews from the DQ database, annotated according to the established data annotation protocol and accompanied by annotator comments, are presented in Table 7.

Label	Description
dual quality	The review contains information about the fact that the customer bought the same product in two countries and noticed a difference in quality, performance, composition, etc. It is not necessary to give the exact names of the countries, phrases such as "abroad" or "in our country" are sufficient. The customer is comparing two same products or groups of products. Indicating a difference in price, availability or using a general statement such as "there are differences between products purchased in France and Poland" are **NOT** classified as dual quality, but as standard review.
other problems	The review does not identify the problem of dual quality, but provides information about other problems, among which we can distinguish: – differences in products due to a different place of purchase (same market), place of packaging or batch received, – problems with the product itself that require deeper analysis e.g., deterioration over time, – practices that are illegal and/or violate customer rights e.g., the product is probably counterfeit, suspected fraud, misleading the customer, no instructions in the required language, no expiration date, etc..
standard	A standard product review in which the comments described are about the product itself and do not indicate problems addressed by the labels "dual quality" or "other problems".

Table 6: Annotation Guidelines.

B.2 Other Problems Identified in Products or Services

When labeling the data, annotators identified opinions explicitly reflecting dual quality issues and comments pointing to specific problems related to services or products. These additional insights enabled deeper exploration and facilitated the creation of a comprehensive taxonomy of consumer issues. Figure 5 demonstrates that more than half of the reported problems concern probable counterfeit products, differences dependent on the place of purchase within the same market, quality deterioration over time, mismatches between received products and orders, misleading information, suspicions of fraud, and variations related to packaging, batch, or package size. Recognizing and categorizing these issues may be crucial for targeted interventions and regulatory measures to strengthen consumer trust and improve market standards beyond dual quality considerations alone.

C Experiments Details

Baseline For the baseline model, the text was first lemmatized. Then the following phrases were searched: `anglia, angielski, szkocja, szkocki, irlandia, irlandzki, walia, walijski, dania, duński, finlandia, fiński, norwegia, norweski, szwecja, szwedzki, szwajcaria, szwajcarski, estonia, estoński, łotwa, łotewski, litwa, litewski, austria, austryjacki, belgia, belgijski, francja, francuski, niemcy, niemiecki, włochy, włoski, holandia, niderlandzki, holenderski, usa, kanada, kanadyjski, meksyk, meksykański, ukraina, ukraiński, rosja, rosyjski, białoruś, białoruski, polska, polski, czechy, czeski, słowacja, słowacki, węgry, węgierski, rumunia, rumuński, bułgaria, bułgarski, grecja, grecki, hiszpania, hiszpański, brazylia, brazylijski, portugalia, portugalski, australia, australijski, nowa zelandia, maoryjski, gruzja, gruziński, izrael, hebrajski, egipt, arabski, turcja, turecki, chiny, chiński, korea, koreański, japonia, japoński, indie, hinduski.`
If one or more of the above phrases were found, the review was classified as dual quality.

SetFit + sentence transformer During training, we used the following hyperparameters: learning rate=2e-5 (same for sentence transformer fine-tuning and logistic regression classifier), batch size=8, epochs=1, number of iterations for contrastive=1. We adopted AdamW optimizer.

Transformer-based encoders During training, we used the following hyperparameters: learning rate=2e-6, batch size=8, epochs=10. We adopted AdamW optimizer.

LLMs The models were evaluated using APIs. For the main experiments the temperature was set to 0.1, for robustness verification to guarantee determinism it was reduced to 0.0. The prompts used are shown in Table 9.

Type	Prompt
zero-shot	Assign the following review to one of three classes: “dual quality”, “other problems” or “standard”. In your answer, provide only the name of the class, without additional comment. Review text: <*review*>
few-shot	Assign the following review to one of three classes: “dual quality”, “other problems” or “standard”. **Examples:** The capsules are better than those on the Polish market from the same company. – dual quality Good coffee taste. Country of origin: Germany. It is not as acidic as the one bought in the country. – dual quality My favorite scent. However, I think it’s much less long-lasting than the one I bought at Sephora last time. – other problems The powder may be from Germany, but it’s made in the Czech Republic - misleading the customer. – other problems Decent product. It slightly alleviates eye pain and fatigue. I use it occasionally. – standard It’s okay, I didn’t notice much difference between the "Polish" and "German" version. – standard In your answer, provide only the name of the class, without additional comment. Review text: <*review*>
zero-shot+inst.	Assign the following review to one of three classes: “dual quality”, “other problems” or “standard”. **Guidelines for each category:** **"dual quality"** – The review includes information that the customer purchased the same product in two different countries and noticed a difference in quality, performance, composition, etc. It is not necessary to specify the exact names of the countries; phrases like "abroad" or "in our country" are sufficient. The customer compares two identical products or groups of products. Indicating a difference in price, availability, or a general statement such as "there are differences between products purchased in France and Poland" is not classified as dual quality. **"other problems"** – The review does not indicate an issue of dual quality but provides information on other problems, which can include: differences in products resulting from a different place of purchase (same market), place of packaging, or the received batch; problems with the product itself requiring deeper analysis, such as deterioration in quality over time; practices that are illegal and/or violate customer rights, such as the product potentially being counterfeit, suspicion of fraud, misleading the customer, lack of instructions in the required language, lack of an expiration date, etc. **"standard"** – A standard product review where the comments pertain only to the product itself and do not indicate the problems discussed in the "dual quality" or "other problems" categories. In your answer, provide only the name of the class, without additional comment. Review text: <*review*>

Enhancing Marker Scoring Accuracy through Ordinal Confidence Modelling in Educational Assessments

Abstract

A key ethical challenge in Automated Essay Scoring (AES) is ensuring that scores are only released when they meet high reliability standards. Confidence modelling addresses this by assigning a reliability estimate measure, in the form of a confidence score, to each automated score. In this study, we frame confidence estimation as a classification task: predicting whether an AES-generated score correctly places a candidate in the appropriate CEFR level. While this is a binary decision, we leverage the inherent granularity of the scoring domain in two ways. First, we reformulate the task as an n-ary classification problem using score binning. Second, we introduce a set of novel *Kernel Weighted Ordinal Categorical Cross Entropy (KWOCCE)* loss functions that incorporate the ordinal structure of CEFR labels. Our best-performing model achieves an F1 score of 0.97, and enables the system to release 47% of scores with 100% CEFR agreement and 99% with at least 95% CEFR agreement—compared to $\approx 92\%$ CEFR agreement from the standalone AES model where we release all AM predicted scores.

1 Introduction

Automated Essay Scoring (AES) systems aim to evaluate the quality of candidate writing using computational methods. These systems are increasingly adopted in large-scale assessments due to their speed, consistency, and scalability (Xu et al., 2020; Lottridge et al., 2023; Shermis and Wilson, 2024; Xu et al., 2024). A common goal is to assign a proficiency level based on frameworks such as the Common European Framework of Reference (CEFR) (CoE, 2001), which defines levels from A1 (beginner) to C2 (advanced). Unlike traditional classification tasks, these levels are ordinal—with the levels ranked in terms of increasing levels of proficiency.

To enhance accuracy in high-stakes settings, many AES systems adopt a hybrid marking system, where a separate confidence model evaluates the automarker score for a response and only releases a score when it meets a minimum confidence threshold (Xu et al., 2021; Singla et al., 2022; Del Vecchio et al., 2018). However, confidence modelling in AES remains underexplored. Most current methods rely on standard regression or classification approaches (Johan Berggren et al., 2019), and while some work has considered the ordinal nature of AES (Johan Berggren et al., 2019; Mathias and Bhattacharyya, 2020), very few have applied ordinal techniques to confidence estimation (Malinin et al., 2017; Del Vecchio et al., 2018; Loukina and Yoon, 2019; Funayama et al., 2020; Gao et al., 2024; Orwat et al., 2024).

In this paper, we show how redefining the classification approach and adopting innovative *ordinal loss functions* can optimise confidence model performance. We begin by framing the task as a binary classification problem: predicting whether the AES system score places candidates in the correct CEFR grade. We introduce an increase in granularity, which allows us to explore how fine-grained information impacts confidence estimation and score release decisions, through two extensions: (1) an N-ary CEFR classification that estimates the full probability distribution over CEFR levels, and (2) a score-binning approach with N-ary classification at the score level, which groups continuous scores into interpretable bins aligned with human marking tolerances. Finally, we introduce a novel loss function—KERNEL WEIGHTED ORDINAL CATEGORICAL CROSS-ENTROPY (KWOCCE)—which penalises misclassifications based on the distance between predicted and examiner CEFR levels, building on foundational work by Frank and Hall (2001), and more recent studies that incorporate class distances into loss functions to yield better-calibrated and more robust models (de la Torre et al., 2018;

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1498–1507
July 28-30, 2025

Castagnos et al., 2022; Polat et al., 2025).

KWOCCE generalises prior approaches such as Class Distance Weighted Cross-Entropy (Polat et al., 2025) and log-based ordinal losses (Castagnos et al., 2022), enabling exploration of linear, logarithmic, exponential, and Gaussian penalty schemes. The goal is to penalise large misclassifications more heavily while tolerating minor disagreements, aligning with real-world marking practice.

We evaluate our approach in a human-in-the-loop Hybrid Marking System (HMS), where an LLM-based AES engine generates scores and a downstream confidence model determines whether scores are released or escalated for review. To assess real-world utility, we report the percentage of AES scores that can be released at different thresholds of minimum CEFR agreement. Our results show that the proposed KWOCCE loss significantly improves control over score release decisions: up to $\approx 47\%$ of AES scores can be released with 100% CEFR agreement, and up to $\approx 99\%$ with at least 95% CEFR agreement, compared to $\approx 92\%$ CEFR agreement from the unaided AES system, where all predicted scores are released.

Contributions:

- We demonstrate the importance of granularity in confidence modelling.
- We frame AES confidence estimation as an ordinal classification problem, leveraging the structure of CEFR labels.
- We propose the KWOCCE loss, incorporating kernel-based distance penalties into the cross-entropy objective.
- We show that KWOCCE improves confidence calibration and score release reliability over standard approaches, supporting safer and more robust AES deployment.

This work connects AES to broader advances in ordinal classification and NLP, responding to calls for better alignment between machine predictions and human assessment standards (Amigo et al., 2020; Castagnos et al., 2022), integrating methods from uncertainty estimation, ordinal classification, and kernel-based loss design to improve scoring reliability and trustworthiness.

2 Background

Despite growing interest in AES, few studies explicitly address both scoring and confidence estimation. AES is often framed as a standard regression or classification task (Johan Berggren et al., 2019; Mathias and Bhattacharyya, 2020), where confidence is assumed to be reflected by outputs like softmax probabilities or prediction intervals. However, these are not always well-calibrated and may fail to capture real-world reliability—particularly in high-stakes educational contexts.

One reason for this gap may be the focus on accuracy as the key metric in AI benchmarks, often at the expense of prediction confidence and calibration (Banachewicz and Massaron, 2022). In response to fairness and out-of-domain concerns, some commercial systems prioritise aberrancy detection over intrinsic confidence modelling (Loukina and Yoon, 2019; Gao et al., 2024). Earlier solutions combined automated and human marking (Burstein et al., 2013), but this adds cost and sidesteps the core issue of model uncertainty.

Recent work has explored confidence estimation in deep neural networks, especially when no natural confidence score is available. Malinin et al. (2017) and Del Vecchio et al. (2018) used ensembles and synthetic data to model uncertainty and detect out-of-distribution inputs. Singla et al. (2022) showed that confidence modelling can help decide when to escalate AES responses, highlighting that some low-confidence errors are more critical due to their impact on final candidate results.

This issue becomes particularly salient in scenarios where scores are not only assigned but also *banded* into levels depending on which band of scores the AES score lies in, such as the CEFR framework used in second language assessments (CoE, 2001). In such settings, errors near band boundaries (e.g., predicting B1 instead of B2) may have a disproportionate effect on outcomes, and thus merit different treatment from errors within a band. Confidence modelling, in this context, must therefore consider not only the likelihood of error but also the potential impact of that error (Orwat et al., 2024).

Beyond the assessment community, the NLP field has begun exploring ordinal classification and distance-aware loss functions as tools for improving confidence calibration. Castagnos et al. (2022) introduced a log-based loss that penalises distant misclassifications more heavily, enhancing both accuracy and interpretability. Polat et al. (2025) proposed a class-distance-weighted cross-entropy for medical severity classification, while de la Torre et al. (2018) adapted the weighted Kappa metric

into a loss for ordinal deep learning. These works show the benefits of aligning model objectives with ordinal label structure—especially when near-miss predictions carry partial credit. However, such approaches remain rare in AES.

In this work, we extend the literature by developing a hybrid marking system (HMS) that incorporates kernel-weighted ordinal classification for confidence modelling in AES. Our approach builds on insights from assessment, uncertainty estimation, and NLP tasks of an ordinal nature to propose a principled, loss-driven strategy for score release: only high-confidence predictions—determined by both prediction certainty and ordinal agreement—can be released without human review (unless also separately flagged by ancillary aberrant detection systems). This strikes a balance between automation and rigour.

3 Data

This study uses a proprietary dataset from a high-stakes second-language English exam. Candidates write two extended responses, each analytically scored by a certified examiner on a 0–20 scale. The scores for both parts are summed to produce a component-level score out of 40 and then mapped using proprietary cut scores to one of three possible CEFR levels for the target proficiency band of the exam (CoE, 2001).

Examiner scores and CEFR levels represent a qualitative assessment of learner's second language proficiency relative to the CEFR, providing an overall judgement of writing quality.

Training and evaluation sets were selected using stratified random sampling to reflect the empirical score distribution and candidate demographics (AERA et al., 2014; Lottridge et al., 2020; McCaffrey et al., 2022; Xu et al., 2024). As a result of the empirical distribution, both raw scores and CEFR levels follow an approximately normal distribution

The confidence modelling approaches explored in this paper are model agnostic, in that they can be trained and applied to any automarker model. To provide a baseline for assessing the performance of the reported confidence models, we additionally trained a bespoke automarker. This is a transformer-based encoder model with a regression head, trained on 100,000 test-specific responses, with a validation set of 25,000 responses. The confidence model used a disjoint, larger training set of 231,603 responses, with a validation set of 57,901 responses, capturing variance in the automarker while avoiding task overlap. The final evaluation set consists of 644 responses from 322 candidates, in line with prior commercial AES sample sizes (Bennett and Zhang, 2015; Shermis, 2022; Firoozi et al., 2023). A gold-standard reference score was created via a multi-marking exercise: 15 certified examiners rated all responses, and a fair average (FA) score was derived using Multi-Faceted Rasch Measurement to account for rater effects (Wolfe, 2004; Xu et al., 2024).

For evaluation purposes, we report two directly interpretable, domain specific agreement metrics, both computed at the component level (sum of the two part level scores), where candidate outcomes are determined. The first metric, RMSE, is reported on a 0–40 scale and reflects raw score agreement based on the sum of scores across both of the candidates' two test responses. The second metric, % CEFR Agreement, is an accuracy-based measure of categorical agreement, capturing the percentage of cases where the automarker assigns the same CEFR level as the FA reference score. This metric focuses on agreement in the final outcome for the examinee, which is critical for high-stakes decision-making. We use CEFR agreement over any other metrics such as QWK, because it has better interpretabilitiy for operational use (Di Eugenio and Glass, 2004; Jr and and, 2011; Yannakoudakis and Cummins, 2015; Xu et al., 2021).

3.1 Baseline Automarker Performance

Table 1 shows baseline automarker (AM) performance, assuming 100% of predicted scores are released (i.e., no confidence model is applied to filter outputs). The AM predicts scores for part-level responses. At the component level (summing up the scores from the two parts), it performs well, achieving an RMSE of 1.09 and CEFR agreement of 91.61% with the fair-average reference scores. That is, the AM's predicted scores already closely align with the ground-truth CEFR levels. However, despite the high agreement, there remains room for improvement—particularly in controlling which scores are released, which is critical for high-stakes applications.

Comparison Type	RMSE	CEFR Agreement
Raw[1] Automarker	1.095	91.61

Table 1: Raw performance of Auto-marker

4 Experiments

As described in Section 1, we frame the problem as a binary classification task: determining whether an automarked score is confident or not in predicting the expected CEFR level for a candidate. Our approach progressively refines the confidence modelling by leveraging the granularity of scoring data.

Hybrid Marking System (HMS) Framework

The proposed HMS features an AM and a downstream confidence model. The AM outputs the score for a candidate response and also generates LLM embeddings. The confidence model subsequently uses these embeddings, AM scores, and the CEFR cut scores to predict confidence on a 0–1 scale, with 1 indicating full confidence that the predicted score for a particular response agrees with the expected CEFR level.

By integrating the AM with a confidence model, the HMS enables nuanced human scoring where confidence is low, helping underpin assessment accuracy and reliability. The confidence model determines whether the generated automarker score is released or the response instead flagged for human review based on a predefined confidence threshold. Designed for diverse assessment contexts, including high-stakes testing and formative evaluation, HMS ensures both precision and adaptability.

4.1 Experiment 1: Core Architecture

The confidence model was developed through iterative refinements aimed at improving confidence score assignment for AM predictions. Initial models used simple correctness-based measures, while later versions incorporated statistical insights into model behaviour and score distributions.

The following subsections describe each stage of this progression.

4.1.1 Binary Classification

The first approach framed confidence estimation as a binary classification task, labelling each prediction as correct (1) or incorrect (0) based on alignment between the AM score and the true CEFR level. Using Cross-Entropy (CE) loss, the final probability output was interpreted as the confidence score. While simple and interpretable, this baseline lacked granularity in uncertainty estimation.

[1] *Raw* refers to scores assigned without additional QA filtering.

4.1.2 CEFR-Level N-ary Classification

Further analysis showed that AM performance varied across the score range, with greater reliability in data-rich regions. We therefore moved to an N-ary classification model, where N is the number of CEFR levels. Using Categorical Cross-Entropy (CCE) loss, the model produced a probability distribution over CEFR levels. Confidence was taken as the probability assigned to the CEFR predicted by the AM. This formulation offered more nuanced uncertainty estimates, particularly in cases with competing CEFR probabilities.

4.1.3 Score-Level Binned N-ary Classification

To further increase granularity, we extended the N-ary classification by treating individual score points as separate classes. We then applied binning based on CEFR cut scores, summing probabilities of score points within each CEFR band to compute cumulative confidence. The confidence score was derived similarly to the CEFR-level model but benefited from finer resolution, better capturing subtle variations in AM reliability across the score spectrum.

4.1.4 Core Architecture Results

Classifier Type	Accuracy	Precision	Recall	F1
Binary	0.578	0.579	0.997	0.733
CEFR N-ary	0.642	0.693	0.869	0.772
Score Binned N-ary	0.913	0.913	1.000	0.954

Table 2: Comparison of classifier performance across architectures

We performed a threshold analysis on the confidence scores generated by each architecture, using a thousand increments. Here, a true-positive would be when a confidence score is above threshold and the predicted score corresponds to the expected CEFR level. A true-negative would be when both the confidence is below threshold and there is a mismatch with respect to the fair average CEFR level. Metrics reported in Table 2 correspond to the threshold yielding the best F1 score. Results show consistent improvement with increasing classification granularity, likely due to richer input information and greater tolerance for near-miss predictions. Consequently, the cumulative CEFR probability approach offers a more robust basis for downstream confidence estimation. We adopt the Score Binned N-ary classifier as the standard for subsequent experiments.

4.2 Experiment 2: Ordinal Category Classification (OCC)

Given the ordinal nature of the problem, we incorporated ordinal relationships into our classification framework. Our OCC benchmark was established using Keras' OCC loss (Hart, 2017). Additionally, we developed the Kernel Weighted Ordinal CCE (KWOCCE) loss function to enforce ordinal constraints, better capturing the inherent ordering information.

4.2.1 Keras OCC Loss

This loss function extends the standard Categorical Cross-Entropy by introducing a weighting mechanism that penalises predictions based on their distance from the true class. The mathematical formulation of the OCC loss is as follows:

$$\text{loss}(\mathbf{y}, \hat{\mathbf{y}}) = (w(\mathbf{y}, \hat{\mathbf{y}}) + 1) \cdot \text{CE}(\mathbf{y}, \hat{\mathbf{y}}) \quad (1)$$

$$w(\mathbf{y}, \hat{\mathbf{y}}) = \frac{|\arg\max_i \mathbf{y} - \arg\max_i \hat{\mathbf{y}}|}{K - 1} \quad (2)$$

Here, K represents the total number of classes, $\mathbf{y}$ is the one-hot encoded true class vector, $\hat{\mathbf{y}}$ denotes the predicted probability vector and $\text{CE}(\mathbf{y}, \hat{\mathbf{y}})$ is the standard cross-entropy loss. The weighting factor w scales the loss proportionally to the absolute difference between the predicted and true class indices, normalised by $K - 1$. This approach ensures that misclassifications closer to the true class incur a lower penalty than those further away, effectively capturing the ordinal nature of the categories.

4.2.2 KWOCCE

Keras' OCC loss penalises misclassifications based on distance from the true class using linear scaling, assuming that all ordinal gaps carry equal severity. However, in practice, not all errors are equally consequential; e.g., misclassifying CEFR level 1 as level 2 is less severe than as level 5. To better reflect such distinctions, we propose KERNEL WEIGHTED ORDINAL CATEGORICAL CROSS-ENTROPY (KWOCCE): a family of loss functions that apply nonlinear, distance-aware penalties via kernel functions. These refinements improve ordinal classification, enhance robustness, and yield more interpretable confidence estimates.

4.2.2.1 Kernel Functions

Each kernel function determines how severely a misclassification is penalised based on its distance from the true class. Unlike fixed linear weights, kernel-based schemes allow more nuanced penalisation that aligns with the ordinal structure of CEFR scores. We define $x = \hat{y} - y$, where $\hat{y}$ is the predicted class and y is the true class, and N is the number of classes, and α and β, where applicable, are tuned hyperparameters.

Linear

$$K_{\text{linear}}(x, N) = \max\left(0, 1 - \frac{|x|}{N}\right) \quad (3)$$

The linear kernel provides a straightforward extension of the Keras OCC loss by scaling penalties proportionally to the absolute classification error. It maintains consistency with ordinal relationships, it does not distinguish between large and small misclassifications beyond the direct ordinal gap.

Logarithmic

$$K_{\log}(x, N; \alpha) = \max\left(0, 1 - f_{\log}(x, N; \alpha)\right) \quad (4)$$

$$f_{\log}(x, N; \alpha) = \frac{\alpha \log(1 + |x|)}{\log(N)} \quad (5)$$

The logarithmic kernel introduces a progressively decreasing penalisation for larger errors. This function better reflects real-world grading practices, where extreme misclassifications are rare but possible, and minor deviations should not be overly penalised. This approach is particularly useful in settings where small deviations (e.g., 1 to 2) are common and tolerable, whereas larger deviations (e.g., 1 to 5) should still be significantly penalised.

Exponential

$$K_{\exp}(x; \alpha, \beta) = \max\left(0, f_{\exp}(x; \beta)\right) \quad (6)$$

$$f_{\exp}(x; \beta) = \alpha\left(1 - \frac{1}{1 + \exp(\beta - |x|)}\right) \quad (7)$$

The exponential kernel provides a sharper distinction between minor and severe errors. This function assigns minimal penalties to near-correct predictions, while exponentially increasing penalties for larger misclassifications. This is particularly useful in high-stakes assessment settings, where confidence in high-accuracy predictions is crucial.

Gaussian

$$K_{\text{gaussian}}(x;\alpha) = \max\left(0, f_{\exp}(x;\alpha)\right) \quad (8)$$

$$f_{\exp}(x;\alpha) = \exp\left(-\left(\frac{x}{\alpha}\right)^2\right) \quad (9)$$

The Gaussian kernel applies a bell-shaped penalty, ensuring that small classification errors are barely penalised, while large errors receive exponentially higher penalties. This model best aligns with human grading behaviour, where minor misjudgements are tolerated, but gross errors significantly impact the assigned CEFR.

4.2.2.2 Kernel-Weighted Cross-Entropy Loss

To integrate the kernel weighting into our classification framework, we modify the standard cross-entropy loss function to account for ordinal misclassification penalties. This ensures that correct or near-correct predictions incur lower penalties, while distant misclassifications are progressively penalised according to the chosen kernel.

$$\mathcal{L}(\mathbf{y}, \hat{\mathbf{y}}) = -\sum_{i=1}^{N} w_i \log \hat{y}_{ic_i} \quad (10)$$

Here, $\mathbf{y}$ is the true one-hot label, $\hat{\mathbf{y}}$ is the predicted probability vector, c_i is the true class index, and w_i is the kernel-derived penalty based on the distance between predicted and true classes.

4.2.2.3 Reduction Method

The final loss value is calculated using a mean reduction approach. This computes the average loss across all samples, ensuring that the gradients remain stable and are not dominated by a small subset of extreme misclassifications.

$$\mathcal{L}_{\text{mean}} = \frac{1}{N}\sum_{i=1}^{N} \mathcal{L}_i \quad (11)$$

4.2.3 OCC Results

Loss function	100% CEFR Agree		95% CEFR Agree	
	RMSE	% Release	RMSE	% Release
Benchmark	0.912	29.80	1.143	91.83
Keras OCC	0.854	36.31	1.049	91.97
KWOCCE Linear	1.006	47.35	1.068	98.16
KWOCCE $\text{Log}_{\alpha=3}$	0.854	19.86	1.057	98.89
KWOCCE $\text{Exp}_{(\alpha=1,\beta=3)}$	0.964	41.01	1.062	99.12
KWOCCE $\text{Gaussian}_{\alpha=0.5}$	0.940	35.73	1.057	98.75

Table 3: Comparison of OCC Loss Performance at 100% and 95% CEFR Agreement Thresholds

All OCC models were evaluated using standard NLP metrics as well as domain-specific validation metrics to better assess real-world impact. Our primary validation metric is the percentage of AM scores that can be released under each model for a particular threshold of CEFR agreement. We operationalise this as the percentage of exact CEFR agreement achieved with our gold-standard fair average (FA) reference. More specifically, at each confidence threshold, we identify the particular set of automarker scores that are "high confidence" (i.e. those that are at or above the confidence threshold). These high confidence automarker scores are then swapped in over the corresponding FA scores and used to determine a revised set of CEFR levels. Finally, the resulting level of agreement is calculated by comparing the overlap between this revised set of CEFR levels and the CEFR level achieved if no automarker scores had been released and candidates received only Fair Average scores.

Table 3 compares the performance of different confidence models at two thresholds: a maximum of 100% agreement and a minimum of 95%. Both represent meaningful improvements over the AM's unaided agreement level of $\approx 92\%$.

At 100% CEFR agreement, the best RMSE values are achieved by Keras OCC (0.8544) for 36.31% released and KWOCCE Log ($\alpha = 3$) (0.8537) for 19.86% released, indicating that these methods produce the most reliable confidence scores. RMSE remains relatively stable across models, and always lower than the unaided AM RMSE (1.095), suggesting that the confidence mechanism helps reduce grading variance when the system is more certain.

KWOCCE Linear achieves the highest percentage of AM scores released (47.35%), indicating its ability to more confidently identify and correctly classify high-certainty responses. This suggests stronger alignment between the model's confidence scores and the ground-truth CEFR labels.

At 95% CEFR agreement, all KWOCCE variants outperform both Keras and Benchmark baselines in every metric except RMSE. However, in this setting, RMSE is considered a secondary metric—our primary concern is accurate CEFR assignment. Small RMSE variations are tolerable as long as they remain substantively low and better than the unaided AM RMSE. Performance for intermediate thresholds between 99% and 96% CEFR agreement is reported in Appendix A.

Table 4 presents results for the final downstream

Model	Precision	Recall	F1-Score	F0.5-Score	Accuracy	AUC-ROC
Benchmark	0.913	1.000	0.954	0.929	0.913	0.848
Keras OCC	0.935	1.000	0.966	0.947	0.935	0.793
KWOCCE Linear	0.935	1.000	0.966	0.947	0.935	0.557
KWOCCE $\text{Log}_{\alpha=3}$	0.936	1.000	0.967	0.948	0.936	0.755
KWOCCE $\text{Exp}_{(\alpha=1,\beta=3)}$	0.938	0.998	0.967	0.949	0.936	0.738
KWOCCE $\text{Gaussian}_{\alpha=0.5}$	0.936	1.000	0.967	0.948	0.936	0.806

Table 4: Model Binary Classification Metrics

binary classification task: determining whether the model is confident in the CEFR agreement of AM scores. While the benchmark model using standard CCE loss achieves high AUC-ROC and perfect recall, these metrics alone are insufficient. Precision, F1, F0.5, and Accuracy suggest that explicitly modelling ordinal structure leads to better convergence and more reliable decision-making. Performance on the original CEFR-level classification task can be found in Appendix B.

5 Conclusion

Our experiments show that the most granular architecture—the Score-level Binned N-ary Classifier—consistently performs best. A clear trend emerges: increasing granularity improves confidence modelling. These gains are evident across standard NLP metrics (Precision, Recall, F1, F0.5, AUC-ROC, and Accuracy) and domain-specific validation metrics, such as the % AM released at different CEFR agreement thresholds.

Our findings show that a candidate's likelihood of receiving the appropriate outcome is best determined by models that respect the domain's ordinal structure—leveraging raw score information, the inherent order of CEFR labels, and KWOCCE loss functions that penalise large misclassifications more heavily. Our best-performing model (*KWOCCE Linear*) enabled the release of up to $\approx 47\%$ of scores with 100% CEFR agreement, and up to $\approx 99\%$ with at least 95% CEFR agreement—compared to $\approx 92\%$ CEFR agreement from the unaided AM system, which released 100% of scores with no confidence control. Thus, we achieve our goal of greater control over score release, leading to higher operational reliability, while still enabling greater volumes of automarker scores to be released in principle—resulting in a more favourable trade-off between coverage and reliability. The refined control enabled by fine-grained confidence modelling offers a promising step towards more ethical and effective automated test scoring.

Limitations

The model used in this preliminary study was trained and evaluated on data from a single exam with a particular proficiency distribution. Although the evaluation dataset is multi-marked, representative, and comparable in size to other commercial AES datasets, it remains relatively small compared to test sets in other domains. Future work will assess the efficacy of the novel functions on models trained using a wider range of simulated and operational data, as well as evaluated using larger datasets as well as including data from other exams.

A CEFR Agreement threshold metrics

Loss function	RMSE	% Released
Benchmark	1.022	61.65
Keras OCC	1.025	69.46
KWOCCE Linear	1.046	68.24
KWOCCE $\text{Log}_{\alpha=3}$	1.031	65.10
KWOCCE $\text{Exp}_{(\alpha=1,\beta=3)}$	1.025	69.36
KWOCCE $\text{Gaussian}_{\alpha=0.5}$	1.034	64.35

Table 5: Loss Performance at 99% CEFR Agreement

Loss function	RMSE	% Released
Benchmark	1.031	66.04
Keras OCC	1.028	79.28
KWOCCE Linear	1.020	74.27
KWOCCE $\text{Log}_{\alpha=3}$	1.022	74.55
KWOCCE $\text{Exp}_{(\alpha=1,\beta=3)}$	1.035	75.03
KWOCCE $\text{Gaussian}_{\alpha=0.5}$	1.021	74.61

Table 6: Loss Performance at 98% CEFR Agreement

Loss function	RMSE	% Released
Benchmark	1.099	74.23
Keras OCC	1.016	83.58
KWOCCE Linear	1.021	79.91
KWOCCE $\text{Log}_{\alpha=3}$	1.011	81.31
KWOCCE $\text{Exp}_{(\alpha=1,\beta=3)}$	1.021	77.67
KWOCCE $\text{Gaussian}_{\alpha=0.5}$	1.031	77.96

Table 7: Loss Performance at 97% CEFR Agreement

Loss function	RMSE	% Released
Benchmark	1.105	83.40
Keras OCC	1.039	90.59
KWOCCE Linear	1.051	96.51
KWOCCE $\text{Log}_{\alpha=3}$	1.034	83.95
KWOCCE $\text{Exp}_{(\alpha=1,\beta=3)}$	1.030	87.02
KWOCCE $\text{Gaussian}_{\alpha=0.5}$	1.022	87.20

Table 8: Loss Performance at 96% CEFR Agreement

In Tables 5, 6, and 7, we see that Keras OCC performs reliably well, between 99% and 97% CEFR agreements, followed by models trained using KWOCCE losses. In Table 8, we see that KWOCCE linear outperforms all models by a gap of almost 6% in the % AM-released metric. We also see that the OCC functions maintain a stabler lower RMSE than the benchmark, which goes towards the argument of better reliability.

B NLP Metrics

In Table 9, the F1 scores (0.9071 for all OCC models) indicate strong correctness when averaged over all classifications. The OCC model scores are consistently higher than the standard benchmark model with CCE loss.

Loss function	Precision	Recall	F-1	F-0.5
Benchmark	0.9057	0.9057	0.9057	0.9057
Keras OCC	0.9071	0.9071	0.9071	0.9071
KWOCCE Linear	0.9071	0.9071	0.9071	0.9071
KWOCCE $\text{Log}_{\alpha=3}$	0.9071	0.9071	0.9071	0.9071
KWOCCE $\text{Exp}_{(\alpha=1,\beta=3)}$	0.9071	0.9071	0.9071	0.9071

Abstract

The advancement of Large Language Models (LLMs) has led to significant improvements in various service domains, including search, recommendation, and chatbot applications. However, applying state-of-the-art (SOTA) research to industrial settings presents challenges, as it requires maintaining flexible conversational abilities while also strictly complying with service-specific constraints. This can be seen as two conflicting requirements due to the probabilistic nature of LLMs. In this paper, we propose our approach to addressing this challenge and detail the strategies we employed to overcome their inherent limitations in real-world applications. We conduct a practical case study of a conversational agent designed for the e-commerce domain, detailing our implementation workflow and optimizations. Our findings provide insights into bridging the gap between academic research and real-world application, introducing a framework for developing scalable, controllable, and reliable AI-driven agents.

1 Introduction

Large Language Models (OpenAI, 2022, 2023; Antrophic, 2024; Touvron et al., 2023) have exhibited exceptional performance improvement across various language tasks, making them highly valuable in numerous industries. Beyond their language task performance, several works (Schick et al., 2023; Yao et al., 2023b; Qin et al., 2024) demonstrate the model's ability to effectively utilize external tools to tackle complex tasks in various domains, including coding (Zhang et al., 2024a), travel planning (Xie et al., 2024), recommendation (Wang et al., 2024), and scientific research (Gottweis et al., 2025). This ability rapidly led to the advancements of Conversational Agents, which aim to assist users with real-world tasks, such as booking restaurants or purchasing gifts, by interacting with external systems.

Despite their excellent performance, many challenges still exist in building real-world agents (Sadek et al., 2023). First, because of the nature of the probabilistic next-token generation of LLMs, the agents randomly fail to comply with business requirements for specific domains. For example, considering a conversational e-commerce agent, the agent should retrieve the exact metadata of products to prohibit recommending cigarettes or alcohol to an underage user. However, occasionally, the agent uses its pre-trained knowledge instead of retrieving the external metadata, resulting in a wrong hallucinated response (Zhang et al., 2024b). This drawback becomes particularly apparent in cases where strict compliance with business requirements exists. Second, there is a general demand for response formatting capabilities for the agent. In the case of mobile-targeted agents, due to their small screen size, the model should respond with a specific format, such as a length limit and emoji bullets. Furthermore, for certain products, the e-commerce agent must strictly comply with specific constraints, such as avoiding hype or exaggerated advertisements or ensuring proper attribution and source citation. Last, prompt engineering involves writing detailed descriptions into the system prompt to ensure that LLMs follow these requirements. The more detailed requirements are, the longer the system prompts will be; thus, the comprehensive system prompt degrades the latency and accuracy of response (Levy et al., 2024).

In this paper, we present our work on building a conversational e-commerce agent that runs on a mobile messenger. Figure 1 shows an example conversation between a user and the agent about purchasing a birthday gift for a friend. The agent helps the user explore products through search and recommendation, obtain detailed information about

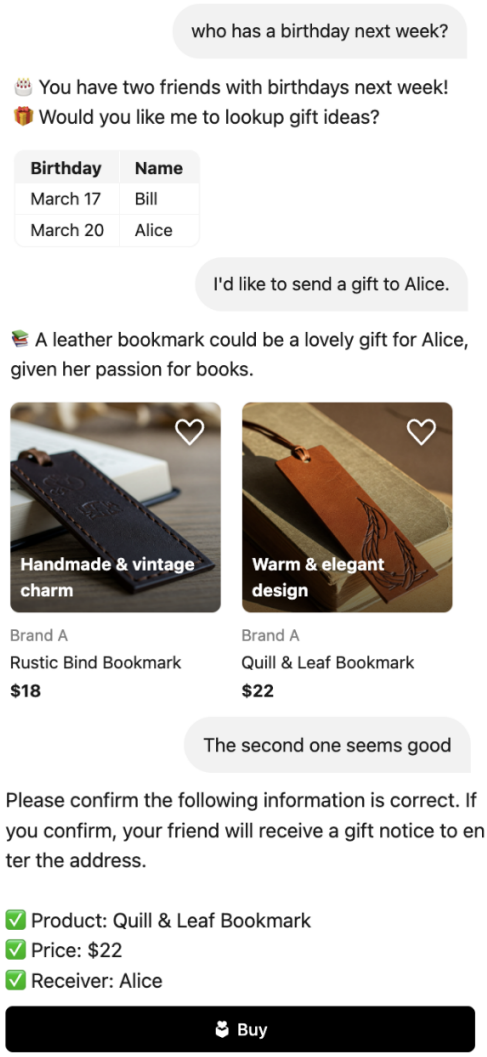

Figure 1: A mobile messenger conversation between a user and our e-commerce agent. The first two turns require external tool calls to respond without hallucination. There are also output format constraints to make the responses readable in a mobile environment, such as emoji bullets.

a product, and purchase the product. Furthermore, using social relationships in the messenger platform, the user can check the birthdays of his/her friends and send gifts. We adopt a hybrid approach that leverages a directed acyclic graph (DAG) workflow to guide the agent's behavior, instead of relying on end-to-end generation from LLMs. This design enables flexible interactions while ensuring strict compliance with scenario-specific requirements. While the DAG framework efficiently handles the complex business requirements, fine-tuning becomes nontrivial since each message of the chat history comes from different states. To tackle this problem, we present a dataset construction and training approach that enables effective fine-tuning despite state-dependent chat histories. We begin with converting our requirements into a workflow graph. Then, we implement the workflow as a prototype agent with LLMs and several system prompts. After gathering annotated conversations between human annotators and the prototype agent, we used the conversations to train our agent models carefully. We repeat this process iteratively to achieve the required response quality. Thanks to the hybrid approach and training, the agent shows a 52% improvement in task accuracy and a 50% improvement in format adherence compared to the baseline, outperforming GPT-4o performance. Our main contributions are as follows:

- **Multi-State DAG Framework:** Real-world agents must comply with many scenario-dependent constraints. We present a graph-based framework, each state with distinct prompts, tools and execution rules adhering to the specific constraints of the state. Traversing the graph seamlessly represents the wide range of expected scenarios, while efficiently distributing constraint handling across appropriate states.
- **Training Strategy on DAG Framework:** We introduce a dataset construction and training strategy specifically designed to overcome the challenges posed by state-dependent message histories in our DAG framework. This further enhances the precision of the agent to meet even the stringent demands of sensitive domains such as e-commerce.
- **Real-World Example:** We show a real-world working example using the two methods above. Our empirical results clearly demonstrate that even state-of-the-art LLMs fall short in achieving satisfactory performance in the e-commerce domain, underscoring the necessity of our proposed hybrid approach for practical deployment.

2 Background

2.1 Conversational Agents

Traditional dialog-based frameworks such as Rasa (Rasa Technologies, 2019) and Talkamatic (Larsson and Berman, 2016) manage conversations using rule-based state tracking, offering reliability and interpretability. However, they often lack the flexibility and reasoning capabilities of modern LLM-based agents.

Recent advances in LLMs such as GPT-4 (OpenAI, 2023), Claude (Antrophic, 2024), Mixtral (Jiang et al., 2024), Qwen (Yang et al., 2024), and Deepseek (DeepSeek-AI, 2024) have driven rapid progress and shifted expectations regarding the fluency and capabilities of conversational agents. LLMs can invoke external tools when provided with natural-language descriptions and instructions. Toolformer (Schick et al., 2023) demonstrates how LLMs formulate calls of external tools with appropriate parameters based on a few examples and textual instructions. ToolLLM (Qin et al., 2024) shows that LLMs can use multiple external tools to answer user questions. Agents with reasoning capabilities like ReAct (Yao et al., 2023b), Chain-of-Thoughts (Wei et al., 2022), and Tree-of-Thoughts (Yao et al., 2023a) show significant performance improvements.

As LLM-based agents become more capable and widely adopted, much effort has also been devoted to evaluating their performance across various domains, such as general agents (Liu et al., 2024; Ma et al., 2024), travel planning (Xie et al., 2024), games (Costarelli et al., 2024), coding (Zhang et al., 2024a), and scientific research (Gottweis et al., 2025). These evaluation methods vary slightly in detail, but they all essentially measure how successfully a requested task has been accomplished.

2.2 Challenges in Production-grade Conversational Agents

Even with recent advances in LLM-based agents, significant challenges still remain in building production-grade conversational agents (Kocaballi et al., 2022; Sadek et al., 2023; Han et al., 2024). One major limitation of existing approaches is their narrow focus on the task accuracy of agents' execution results. This overlooks several crucial aspects, including specific requirement following and output formatting, which can be equally important in assessing an agent's performance regarding production-grade agents (Hua et al., 2024). For example, consider an e-commerce agent that recommends products to a user. If a recommendation includes a compliance-violating description, it should be regarded as a failure, even if the user ends up selecting the product. Addressing such issues often requires more detailed and restrictive system prompts, which in turn increase inference costs due to longer context lengths.

Several industry-specific agent frameworks highlight the importance of such aspects. For instance, Amazon Bedrock[1] offers post-processing steps to control the agent response. Google Vertex AI Agents[2] adopts LangChain[3], an open-source framework for building agents with predefined workflows, to enhance adherence to requirements. MARCO (Shrimal et al., 2024) is a notable approach that considers not only the accuracy but also the validity of output formatting. However, MARCO relies on a separate guardrail component to verify and retry faulty outputs using reflection prompts, which can significantly degrade both response latency and overall accuracy.

2.3 Graph-based Agent Frameworks

Due to their high expressivity and controllability, graphs are widely adopted to model complex workflows in various agent frameworks, such as Dify[4] and LangGraph[5]. In these frameworks, an agent $\mathcal{A}$ is modeled as a workflow graph $\mathcal{G}$, defined by a tuple $(\mathcal{V}, \mathcal{E})$ where $\mathcal{V}$ is a set of nodes and $\mathcal{E} \subset \mathcal{V} \times \mathcal{V}$ is a set of directed edges. Each node $v \in \mathcal{V}$ has a computational routine f_v that executes external tools for the agent, or LLMs. The routine returns a tuple (o_v, v_n) where o_v is a tool or LLMs response, and v_n is a successor node, one of the nodes connected to v in graph $\mathcal{G}$. From this graph structure, running the agent is considered as a graph traversal. The agent starts with the initial node v_{init}, which is the entry node of the graph. It iteratively moves to the successor nodes until it reaches the final node v_{final} and returns its output $o_{v_{final}}$.

While existing frameworks simplify the construction and deployment of graph-based LLM agents, our research focuses on methodologies for achieving production-grade responses, including a practical approach to fine-tuning tightly coupled graph–LLM agents.

3 Methodology

In this section, we introduce our framework to build conversational agents with an example of an e-commerce agent. We convert our agent workflow into a workflow graph, build a prototype agent with a general LLM to collect a high-quality dataset, and train LLMs to enhance the agent's behavioral control in complex tasks.

[1] https://aws.amazon.com/bedrock/agents/
[2] https://cloud.google.com/products/agent-builder

[4] https://dify.ai/
[5] https://langchain-ai.github.io/langgraph/

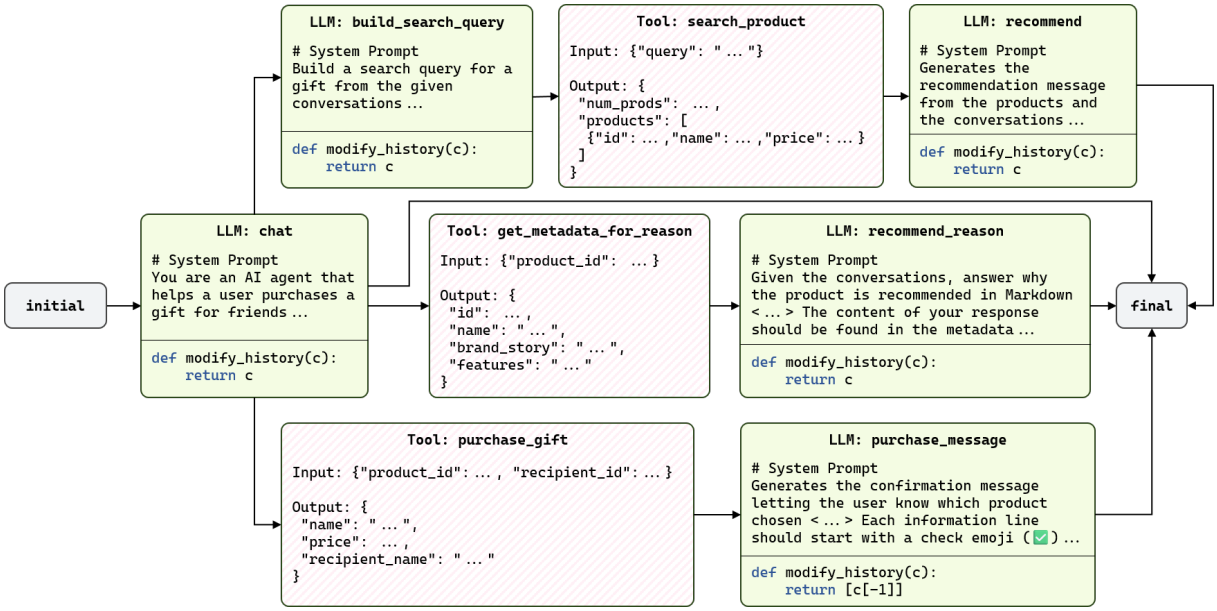

Figure 2: An example workflow graph. Each LLM calling node (green colored) has its system prompt and a custom routine (`modify_history`) to manipulate conversation histories. The tool nodes (pink striped) are used to call pre-defined external tools and have the schemas for input and output. For clarity, we only show nodes related to gift recommendations and omit some content of the system prompts, including few-shot examples of the responses.

3.1 Workflow Graph Design

While following compliance is crucial to building production-grade conversational agents, we observe that LLMs often struggle to adhere to complex conditional rules. We add a specific structure to nodes calling LLM in the workflow graph to enhance compliance-following stability. Each LLM calling node v has its system prompt s_v describing constraints applied in that context with few-shot examples and a custom computational routine that manipulates the given conversational history to prevent the LLM from hallucinating. Each node that calls an external tool has two schemas: one for input and another for output. Constrained decoding (Willard and Louf, 2023; Dong et al., 2024) is applied if the output from the LLM node needs to be passed as input to the tool node.

Figure 2 illustrates an example workflow graph for our agent. Nodes that invoke LLMs are shown in green, while those that call external tools are depicted with pink diagonal stripes. Each LLM-invoking node is associated with a system prompt that encodes rules such as Markdown formatting and emoji usage (e.g., `recommend_reason`, `purchase_message`). By default, these nodes use the full conversation history as input. However, some nodes, like `purchase_message`, remove all the previous conversation history except the purchase information (the last turn of history) by their `modify_history` subroutine. This manipulation helps mitigate hallucination by limiting access to irrelevant prior information.

In the example, you can see that the workflow graph is designed with a general-purpose chat node (`chat`) as its initial entry point. From the node, the LLM may suggest tool calls to effectively route to appropriate task-specific nodes, or handle out-of-scenario user queries via general chat. In the latter case, it may respond using its internal knowledge or gently guide the user toward a more relevant task. After reaching `final` you can restart from `initial` for multi-turn conversations.

3.2 Data Collection with Prototype Agent

We constructed a dataset comprising conversations between human annotators and our agent, structured as a list of (x_i, o_i) pairs, where x_i denotes the i-th input message from an annotator and o_i is the corresponding agent response. The data collection process consists of three steps: (1) building a prototype agent, (2) recording interactions, and (3) correcting erroneous examples.

Building a Prototype Agent A key challenge in collecting data for agents handling complex tasks is generating appropriate agent responses. Annotators can easily answer simple questions, such as "Who are you?", but struggle with queries that involve multi-step reasoning, such as "Recommend a

wine that goes well with sirloin steak." This difficulty arises because they must consider and imagine multiple steps, including tool calls and workflow graph traversals, to generate a single answer. To address this, we built a prototype agent using GPT-4o and our workflow graph to generate initial draft responses that annotators could then refine.

Recording Interactions In this step, annotators interact with the prototype agent as end users. The agent automatically records all interactions, including the full graph traversal history and the results of any external tool calls.

Correcting Erroneous Examples The final step involves reviewing and correcting erroneous agent responses. Annotators examine all interactions and outputs for each conversation and revise any errors they identify. To assist with this process and reduce human error, we provide automated checkers that help detect issues and verify corrections. One particularly useful tool is a static type checker for tool call arguments, which are typically structured as JSON objects. Annotators often produce ill-formatted JSON, especially when dealing with complex schemas.

3.3 Fine-Tuning with Response Masking

We employ a fine-tuning approach with the dataset to enhance the agent's stability. For each node v calling LLMs, we formulate the agent interactions into a chatbot-style sequence $(s_v, x_1, o_1, x_2, o_2, ..., x_n, o_n)$ where s_v is a system prompt for the node v, x_i denotes i-th observations (user messages or tool results), and o_i is i-th response of the agent.

Standard multi-turn training strategies often optimize the model on all assistant outputs in the conversation history. However, in the graph-based agent setting, this can degrade the model's ability to follow system prompts consistently, as responses in the same conversation may originate from different nodes with distinct instructions.

For example, consider a workflow graph with two LLM nodes v_1 and v_2, a conversation history for v_1 can be formulated as $(s_{v_1}, x_1, o_1, x_2, o_2, x_3, o_3)$ where o_2 is generated by v_2, while the other responses o_1 and o_3 are generated by v_1. In such a case, training on o_2 under the prompt s_{v_1} would introduce conflicting supervision, as o_2 reflects the constraints of v_2.

To address this, we apply loss masking during training, excluding responses generated by other nodes from the loss calculation. This prevents the model from learning under mismatched prompt constraints and helps maintain system prompt fidelity for each node.

4 Experiment

In this section, we detail our experiments to evaluate agents in our service scenarios.

4.1 Experimental Setting

Dataset We used a subset of our dataset collected as described in Section 3.2. The test set contains 161 conversations between the human annotators and the agent, containing 2100 turns.

Evaluation Protocol We conducted turn-level assessments following previous studies (Chen et al., 2024; Qiao et al., 2025). Each turn is paired with a reference response annotated by the annotators, and evaluated across three dimensions: First, we measure accuracy, which indicates whether the agent selects the correct tool and provides appropriate arguments. Due to the flexibility of certain arguments (e.g., search queries for gift recommendations), we employ an LLM-as-a-Judge approach (Zheng et al., 2023) to verify argument validity. Second, we assess format adherence, which checks whether the agent's response conforms to the predefined message format using a strictly coded validator. Finally, we evaluate response quality using the LLM-as-a-Judge method, comparing the agent's response to the reference in terms of clarity, helpfulness, and relevance. The first two metrics are binary (0 or 1), while response quality is scored on a 3-point scale (1 to 3).

Model We evaluated both open-source and proprietary LLMs to show that our approach is general for various models and is not limited to our internal model. We use Qwen 2.5 32B (Yang et al., 2024) and Gemma 3 27B (Gemma Team, 2025) for open-source baselines as their model sizes are comparable to our internal model and align well with our performance and latency goals. Our internal model also falls within the 27B-32B parameter range. It is built upon an open-source base model and further trained on internal datasets to better support Korean, the target service language, more details are provided in Appendix B. For proprietary LLMs, we use GPT-4o[6], one of the strongest SOTA models currently available and presumably larger

[6]The specific model version is gpt-4o-2024-11-20.

	Qwen 2.5 (32B)			Gemma 3 (27B)			Internal Model			GPT-4o	
Metric	**B**	**WG**	**WG-FT**	**B**	**WG**	**WG-FT**	**B**	**WG**	**WG-FT**	**B**	**WG**
Accuracy	0.578	0.616	0.884	0.622	0.711	0.887	0.744	0.790	**0.890**	0.864	<u>0.888</u>
Format Adherence	0.734	0.813	<u>0.969</u>	0.692	0.882	0.966	0.655	0.951	**0.987**	0.778	0.964
Response Validity	2.816	2.831	2.880	2.821	2.849	<u>2.911</u>	2.893	2.874	**2.953**	2.856	2.882

Table 1: Qualitative results on our test dataset. The accuracy and format adherence are the ratio of valid responses over the total, while the response quality is rated between 1 and 3. For each model, we evaluate multiple agent architectures including Basic (B), Workflow Graph (WG), and Workflow Graph with Fine-Tuning (WG-FT). The top performance of each metric is marked as bold, and the second one is underlined.

in scale. We use it as a high-end baseline to provide a performance reference point for our experiments. We use o3-mini[7] as a judge for the LLM-as-a-Judge evaluation, leveraging its reasoning ability to judge with complex rules.

Agent Architecture We tested four agent architectures. Basic (B) is a baseline architecture that uses a single system prompt and a tool-calling mechanism proposed by the original model providers. In this setting, we concatenate all node-specific instructions—such as compliance constraints and output formatting rules—into a single prompt without structural separation. Workflow Graph (WG) is our workflow graph-based architecture, as we describe in Section 3.1. Workflow Graph with Fine-Tuning (WG-FT) is an agent with a fine-tuned model by the method described in Section 3.3.

4.2 Results

Table 1 summarizes the experimental results of our agents compared to the baselines. Due to its strong general performance, GPT-4o achieves the highest score for all metrics among the models for the basic agent architecture. However, GPT-4o still fails to consistently follow the required output formatting. Other open-source models, such as Gemma 3 27B and Qwen 2.5 32B, also suffer from incorrect tool selection and low accuracy.

Applying our workflow graph structure to the agents enhances format adherence and accuracy for all models. The accuracy is improved by up to 14% over the basic architecture. Formatting errors are dramatically reduced thanks to the shorter and more focused system prompts in our workflow graph. For our internal model, the format adherence improved from 0.655 to 0.951, representing a 45% relative improvement. The format adherence of other models also increased by up to 27%. Response quality also improved for most models under the graph-based architecture, with only a negligible drop observed for the internal model.

The fine-tuning with response masking further improves the agent in all metrics, making our internal model-based agent outperform the GPT-4o-based one. Other open-source models also achieve comparable performance with GPT-4o across all evaluation metrics.

Evaluation	**Internal >= GPT-4o (%)**
Regular chat	42.42
Safety	60.53
Product recommendation	82.42
Messenger-related features	60.61
Overall	63.29

Table 2: Human assessment results on our e-commerce agent in a real-world environment. The testers are provided with two responses from our model and GPT-4o, and they are requested to choose better models.

4.3 Human Assessment

We deployed *AI Shopping Mate*[8] on both KakaoTalk[9] application and the web. (see Appendix D for details). The agent covers over one million products across various categories. In this real-world setting, we conducted comparative "battle" tests similar to Chatbot Arena (Chiang et al., 2024), evaluating our internal model against GPT-4o. All external systems and integrations connected to the agent were kept identical across both models. Each tester submitted a message and received two anonymized responses—one from each model. They were then asked to select the better response or mark them as

[7] https://openai.com/index/openai-o3-mini/

[8] https://mate.kakao.com/shopping

[9] https://www.kakaocorp.com/page/service/service/KakaoTalk?lang=en

a tie. Table 2 summarizes the results of the human assessment. We categorize the requests into four types: (1) Regular chat, (2) Safety—requests intended to provoke unsafe or inappropriate outputs, (3) Product recommendation, and (4) Messenger-related features such as birthday reminders.

Our agent using the internal model outperformed the GPT-4o-based agent in all categories except regular chat. From follow-up interviews, we found that language fluency significantly influenced human preference—an aspect that was difficult to capture via LLM-as-a-Judge evaluation. We leave further investigation of this aspect for future work.

5 Conclusion

In this study, we presented our framework for building conversational agents that address key challenges in utilizing LLMs and graphs for complex and necessary compliances. We demonstrated that our agent with the internal model outperforms the GPT-4o-based agent for our e-commerce agent scenarios. Our framework's generic design allows it to be adapted for agents across various domains wherever complex tasks need to be executed correctly.

6 Limitations

Our framework has several limitations in terms of data collection and evaluation. First, the data collection process is highly human-dependent, requiring significant time and effort from annotators. Moreover, the collected conversations may exhibit demographic bias, as the annotator pool was limited in terms of gender and age. As a potential remedy, LLM-based simulation where an LLM acts as a user interacting with the agent could be explored in future work.

Second, evaluating response quality remains a challenge. Although we define rules for high-quality responses and employ LLM-as-a-Judge with reference answers, this approach may not fully reflect human preferences. To further support the validity of our evaluation framework, future work could examine the correlation between human judgments and LLM-based assessments more systematically.

Ethical Considerations

In this work, we incorporate multiple safeguard mechanisms to ensure the safe and ethical use of our conversational agent. Real-time filtering is applied to both user inputs and model outputs to mitigate hate speech, stereotyping, and sensitive social content. A multi-layered policy distinguishes between generalized group criticism and statements based on personal experience, guiding the model to maintain neutrality even in borderline cases.

To protect personal information and rights, our system detects sensitive data such as social security and bank account numbers in real time. It also issues warnings for content potentially related to intellectual property violations and enforces uniform responses when risks are detected. In addition, we apply annotation guidelines designed to minimize personal bias by differentiating between unjust generalizations and fact-based individual descriptions.

Acknowledgments

We would like to thank the following team members and contributors for their valuable support throughout the development of the AI Shopping Mate service. We thank the AI Model Platform Development Team—including Oseok Han, Jeonghyeon Lee, Bomi Hong, Hyukjin Kwon, Junyoung Jeong, and Minho Gil—for their work on building the agent platform. We also thank the Adaptive AI Team—including Hyungsuk Noh, Songmin Han, Yongwook Jeong, Suin Lee, Taehyun Jung, Kyushik Min, and Gyuju Han—for constructing the service metadata. We are grateful to Geonhee Lee, Jongmyung Gong, and Hyunwoo Yoo for developing the search functionality. We also thank Yuri Lee and Jihye Park for their support in service collaboration, and Sooyeon Lee and Dain Kim for their contributions to service enhancement. Finally, we thank the annotators from Linkage Lab for their assistance in data collection.

Appendix

A Implementation Details

Training We implement our fine-tuning strategy using the Axolotl framework,[10] which supports flexible dataset construction and various parameter-efficient fine-tuning methods such as LoRA (Hu et al., 2022). We adopt LoRA-based fine-tuning and optimize hyperparameters based on validation loss. To apply our proposed loss masking method, we leverage Axolotl's support for segment-level input masking, allowing us to exclude responses generated by irrelevant nodes from the loss calculation. After fine-tuning, we merge the adapters into the base models to reduce latency during the serving phase.

Serving To serve our models, we use vLLM (Kwon et al., 2023) and SGLang (Zheng et al., 2024) to deploy open-weight and internal models. We also build our custom agent platform traversing our workflow graph. The platform is responsible for communicating with our models, executing external tools, and delivering responses to end users.

B Internal Model

We use an internal LLM in our experiments. While the model is not publicly disclosed, we provide details to support reproducibility. It is built upon an open-source model in the 27B-32B parameter range. To adapt it for Korean-language services, we conducted additional continuous pretraining and instruction tuning using internal Korean datasets. After the tuning stage, we applied model merging techniques (Goddard et al., 2024) to refine performance across both general-purpose and domain-specific tasks. Our internal model serves as a key testbed in our experiments and is comparable in scale to Qwen 2.5 32B and Gemma 3 27B.

C Evaluation Prompts

Figures 3 and 4 are prompts for evaluating the accuracy of tool execution and response quality using the LLM-as-a-Judge approach. For each turn to be evaluated, we pack conversation history, tools, agent response, and a reference response in the same format as the prompt. The judge LLM returns a score, which we extract from the output. If parsing fails, we retry until a valid score is obtained.

D Service Deployment

We deployed *AI Shopping Mate* into the Korean market in two forms: (1) as a chatbot in the KakaoTalk messenger and (2) as an independent web service. Regardless of its form, our service provides the same features. When users specify the gift context—recipient, occasion, and budget—the service delivers a personalized gift recommendation. The service has been publicly available since December 2024 and is fully powered by the architecture described in this paper. We are planning to integrate *AI Shopping Mate* into KakaoTalk Gift [11], a top-tier sending gift service with 20M users.

Figure 5 presents example interfaces from the web-based version of our service. Figure 5a illustrates an instance where a user searches for friends whose birthdays fall in June. In this scenario, the agent adheres to the specified response requirements, ensuring that each friend card displays the gifts previously exchanged with that friend. Figures 5b and 5c depict scenarios involving gift recommendations, either for a user's friend or based on the context from a user, respectively. Figure 5d demonstrates the provision of a detailed explanation for a recommended product. It is noteworthy that, in accordance with our service's operational requirements, the agent first presents the brand story associated with the product before detailing the rationale for its recommendation. Our workflow graph structure is adapted to meet these requirements.

```
You are requested to evaluate the decided tool
    call by a language model. You are given the
    following information as follows:
  - <tools>: The list of tools that are
      available to the model.
    - <name>: The name of the tool.
    - <description>: The description of the tool.
    - <arguments>: The arguments that the tool
        receives.
  - <history>: The chat history between the user,
      the model and the tool response.
    - <message>: the message that was sent by the
        user, the model or the tool. The sender
        of the message is given as `role`
        attribute.
  - <reference_tool_call>: The reference answer
      that the model has decided to make.
    - <name>: The name of the tool.
    - <arguments>: The arguments that the tool
        will be called with.
  - <tool_call>: The tool call that the model
      has decided to make.
    - <name>: The name of the tool.
    - <arguments>: The arguments that the tool
        will be called with.

The tool call should be evaluated based on the
    following criteria:
  - The required arguments of the tool must be
      extracted.
  - The arguments should be extracted from the
      chat history.
  - If the tool requires some price or quantity
      ranges, they should be extracted from the
      chat history.
    - The start of the range should not be same
        as the end of the range.
  - The arguments extracted could be different
      from the reference tool call, but should
      be semantically similar.

Evaluate the arguments of tool call comparing it
    with the reference tool call, and determine
    whether the tool call is appropriate or not
    in terms of the criteria above.
Your response should be in the following format:
- Reason: <reason for the score in at most 3
    sentences in one line>
- Score: <1 if the tool call is appropriate else
    0>
```

Figure 3: Evaluation Prompt for Task Accuracy.

```
You are requested to evaluate the linguistic
    quality of the generated response. You are
    given the following information as follows:
  - <history>: The chat history between the
      user, the model and the tool response.
    - <message>: the message that was sent by
        the user, the model or the tool. The
        sender of the message is given as `
        role` attribute.
  - <response>: The response generated by the
      model.
  - <reference>: The reference response that
      the model has respond.

Evaluate the response based on the following
    criteria:
  - The content of response should match with
      that of the reference response.
  - The response should be written in Korean,
      unless there is a specific instruction
      to use another language.
  - The response should be fluent and natural.
  - The response should be grammatically
      correct.
  - The response MUST not contain unnecessary
      characters (such as Chinese characters,
      special characters, etc.) or non-
      understable characters. This is critical
       for the response to be considered valid.

  - The response should be completed, and
      contain no repeated or cut-off words.
  - The response will be presented in a small-
      size smartphone screen; thus, the
      following conditions should be also met.
    - All the tool results except `
        purchase_gift` tool results are
        displayed in the screen as cards. The
        duplicated response with the tool
        results should be considered as
        invalid.
    - Emoji-containing response is considered
        as good.

Evaluate the response and score it on a scale
    of 1 to 3 in terms of the criteria above.
- 1: not valid
- 2: somewhat valid
- 3: highly valid

Your response should be formatted as follows:
- Reason: <reason for the score in at most 3
    sentences in one line>
- Score: <score>

Note that only the two lines in your response
    are allowed.
```

Abstract

Document question answering plays a crucial role in enhancing employee productivity by providing quick and accurate access to information. Two primary approaches have been developed: retrieval-augmented generation (RAG), which reduces input tokens and inference costs, and long-context question answering (LC), which processes entire documents for higher accuracy. We introduce EXPLAIN (**EX**tracting, **P**re-summarizing, **L**inking and enh**A**c**IN**g RAG), a novel retrieval-augmented generation method that automatically extracts useful entities and generates summaries from documents. EXPLAIN improves accuracy by retrieving more informative entity summaries, achieving precision comparable to LC while maintaining low token consumption. Experimental results on internal dataset (ROUGE-L from 30.14% to 30.31%) and three public datasets (HotpotQA, 2WikiMQA, and Quality, average score from 62% to 64%) demonstrate the efficacy of EXPLAIN. Human evaluation in ant group production deployment indicates EXPLAIN surpasses baseline RAG in comprehensiveness.

1 Introduction

Document question answering requires processing large volumes of text to provide precise answers to user queries. Two primary approaches address this challenge: retrieval-augmented generation (RAG) and long-context (LC) question answering.

RAG methods improve computational efficiency by retrieving relevant document segments before generating answers, thus reducing input tokens and inference costs. However, this can lead to less precise answers due to the limited context (Xu et al., 2024b; Yu et al., 2024). In contrast, LC methods achieve higher accuracy by processing entire documents, but at the cost of increased computational resources (Li et al., 2024). The main challenge is finding a balance between accuracy and computational efficiency.

Many current QA systems utilize RAG approaches with various enhancements for retrieval accuracy, but improving document understanding while maintaining low inference costs remains a significant challenge.

To address these problems, we introduce EXPLAIN (**EX**tracting, **P**re-summarizing, **L**inking and enh**A**c**IN**g RAG), which enhances the retrieval-augmented generation approach by integrating advanced extraction and summarization techniques. EXPLAIN automatically extracts potentially useful entities from documents and generates concise summaries that retain essential information, achieving precision comparable to LC methods while maintaining lower token consumption.

The EXPLAIN method first extracts entities likely relevant to the query, then pre-summarizes these entities to create a condensed version of the document. Finally, it enhances the RAG process using these summaries to generate more accurate and comprehensive answers.

We evaluate EXPLAIN using an internal dataset focused on financial and human resources services and three public datasets: HotpotQA(Yang et al., 2018), 2WikiMQA(Ho et al., 2020), and Quality(Pang et al., 2022). Experimental results demonstrate significant improvements, with EXPLAIN achieving a ROUGE-L score increase from 30.19% to 30.31% on our internal dataset and an average score increase from 62% to 64% on the public datasets.

Following deployment in a production environment in September 2024, human evaluation indicates that EXPLAIN outperforms baseline RAG approaches in terms of detail and comprehensiveness, validating its practical applicability in real-world scenarios.

Our contributions can be summarized as follows:

[†]Corresponding authors.
This work was conducted during the internships of Yaozhen Liang, Xiao Liu, and Jiajun Yu at Ant Group.

Proceedings of the 63rd Annual Meeting of the Association for Computational Linguistics (Volume 6: Industry Track), pages 1520–1529

- We propose EXPLAIN, a retrieval-augmented method enhanced by entity summarization, improving RAG accuracy while controlling token consumption.

- We conduct experiments on three public datasets and one proprietary financial dataset, with results showing consistent performance improvements across all benchmarks.

- We demonstrate the method's effectiveness in production environments through successful deployment and positive human evaluation.

2 Related Works

2.1 Retrieval-Augmented Generation

In recent years, large language models (LLMs) have excelled in various natural language processing tasks (Achiam et al., 2023)(Dubey et al., 2024)(Yang et al., 2024), yet they often struggle with knowledge-intensive tasks that require specific domain knowledge. Retrieval-Augmented Generation (RAG) has emerged as a promising approach to address these challenges by retrieving external documents to supplement the model's knowledge (Lewis et al., 2020)(Gao et al., 2024). Recent advancements in RAG have explored the integration of summary-enhanced generation and retrieval-augmented generation in long contexts.

2.1.1 Summary Augmented Generation

Summary-enhanced generation leverages LLMs' ability to produce diverse summaries, improving comprehension and response accuracy for long documents. Methods like RECOMP (Xu et al., 2023) and Raptor (Sarthi et al., 2024) use extractive and abstractive techniques to condense documents, while GraphRAG (Edge et al., 2024) constructs entity graphs to capture semantic relationships. Inspired by these methods, our approach simplifies the process by extracting key entities and generating concise noun-based summaries and enhances the model's understanding by focusing on core content.

2.1.2 Retrieval-Augmented Generation in Long Context

With the expansion of LLMs' context lengths, models can now process entire documents in a single pass, offering a more comprehensive understanding (Achiam et al., 2023)(Dubey et al., 2024)(Yang et al., 2024). However, this also introduces challenges in efficiently integrating retrieval and generation. Approaches like OP-RAG (Yu et al., 2024) use retrieval to filter irrelevant text, maintaining accuracy while reducing inference overhead. Inspired by this, our method employs entity noun summaries to replace irrelevant text blocks, further reducing context length and improving response accuracy. By focusing on key entities, we enhance the model's ability to understand queries and contexts, offering a novel perspective on retrieval-augmented generation.

2.2 Information Extraction

Information Extraction is an important domain in Natural Language Processing (NLP) that extract structured information from plain text automatically (Xu et al., 2024a). Traditional Information Extraction method (Wang et al., 2022) (Yamada et al., 2020) (Han et al., 2020) (Lu et al., 2022) training different model using human annotate data in different format for different downstream tasks. These approaches achieve powerful performance but face difficulty in collecting large-scale and high-quality data. The lack of high quality annotated data limits the extensibility of these approaches. Recently, LLMs (Dubey et al., 2024; Achiam et al., 2023; Yu et al., 2025) achieve impressive performance in all NLP tasks. People become interested in extracting information using LLMs. OneKE (Gui et al., 2024) introduce a high-quality dataset contained 0.32B tokens to fine-tuned LLMs to adapt to the IE task. PIVOINE (Lu et al., 2023), YAYI-UIE (Xiao et al., 2024) and INSTRUCTIE (Gui et al., 2023) employ intruction-tuning of open-source LLMs which achieve notable successes on IE. (Edge et al., 2024) Use a human-written few-shot instructions to iteratively extract entities and relations from plain text. In this work, we employ LLMs to perform entity summary after entity extraction, which further aggregate information needed for question answering. Since we don't have the prior knowledge about what exactly kind of entities down stream question needed, we can just extract all possible entities that might be useful. In this case, entity extraction become entity noun extraction. In our method, we use noun extraction pipeline to extract entity.

3 Methodology

We introduce EXPLAIN, a novel RAG paradigm designed to achieve higher accuracy with lower

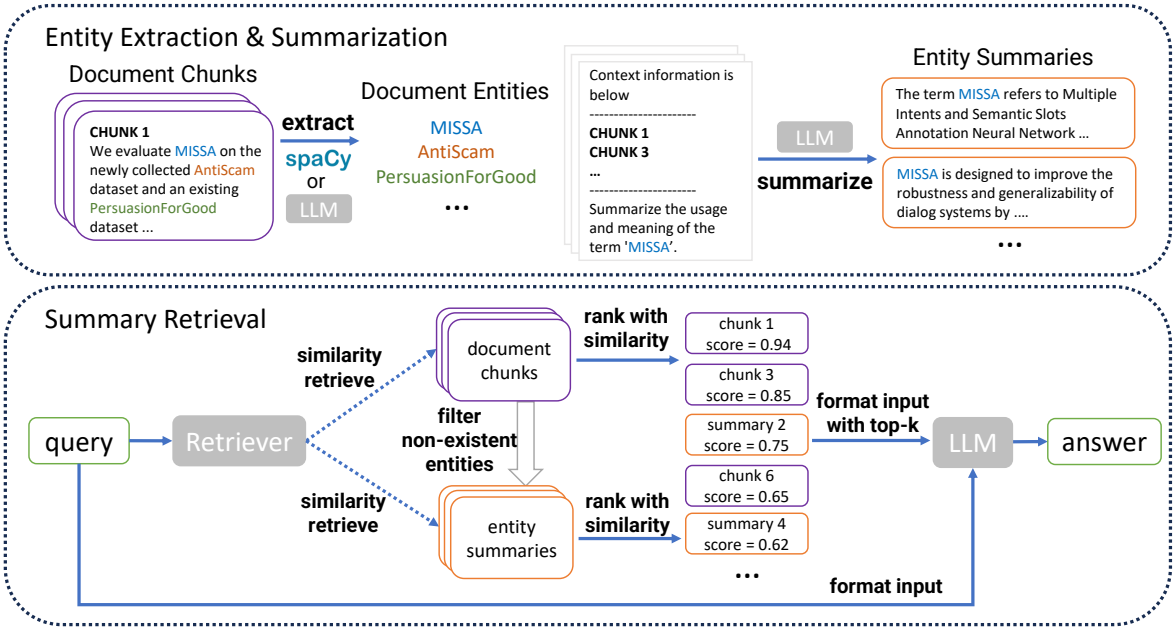

Figure 1: Main Framework of EXPLAIN.

inference consumption. As shown in Figure 1, EXPLAIN extracts entities from source documents, performs entity linking to resolve ambiguities, and generates concise summaries for these entities. When answering questions, it retrieves relevant documents and entity summaries, replacing low similarity documents with relevant entity summaries to enhance contextual information while decreasing inference consumption.

3.1 Entity Extraction

To enhance extraction rates and reduce costs, we employ a noun extraction method as a substitute for traditional entity extraction. We utilize the *en_core_web_sm*[*] pipeline in the spaCy library[†] for sentence segmentation and syntactic analysis, extracting complete nouns from sentences as entities. Given a document D divided into chunks $c_1, c_2, ..., c_n$, we extract entity nouns from each chunk to form entity sets $E_i = \{e_{i1}, e_{i2}, ..., e_{ik}\}$. We define two dictionaries: Context2Entity$(c_i) = E_i$ tracks entities in each chunk, and Entity2Context$(e_j) = \{c_k \mid e_j \in \text{Context2Entity}(c_k)\}$ records chunks containing each entity. While fast, spaCy extraction may introduce noise, so we also develop an LLM-based extraction method that produces less noise but requires more processing time.

[*] https://github.com/explosion/spacy-models/releases/tag/en_core_web_sm-3.8.0

[†] https://spacy.io/

3.2 Entity Linking

Algorithm 1 Jaccard Similarity-Based Entity Linking

Require: List of entity names `entname`; similarity threshold thr

Ensure: List of linked groups of entities `linkedgroups`

Initialize $n \leftarrow$ length of `entname`
Initialize `linkedgroups` $\leftarrow$ list containing n singleton sets: $\{\{e_1\}, \{e_2\}, \ldots, \{e_n\}\}$
Initialize a Union-Find data structure UF with elements $e_1, e_2, \ldots, e_n$
for $i = 1$ to $n - 1$ **do**
  for $j = i + 1$ to n **do**
    Calculate the Jaccard similarity $J(e_i, e_j)$ between `entname[i]` and `entname[j]`
    if $J(e_i, e_j) > T$ **then**
      UF.Union(e_i, e_j)
    end if
  end for
end for
`linkedgroups` $\leftarrow$ groups formed by UF **return** `linkedgroups`

To address the issue of entities appearing in different forms across a document, we develop an entity linking algorithm using n-gram Jaccard Sim-

ilarity:

$$J(s_1, s_2) = \frac{|N(e_1, n) \cap N(e_2, n)|}{|N(e_1, n) \cup N(e_2, n)|} \quad (1)$$

where $N(e, n)$ represents the set of n-grams extracted from entity e. As shown in In Algorithm 1, we initially assign each entity to its own distinct entity set. We then iteratively merge entity sets when their average Jaccard similarity exceeds a threshold T. For each merged set, we select the shortest entity name as the representative. After the iteration process completes, all entities with sufficient Jaccard similarity will be linked together within the same entity set.

3.3 Entity Summarization

For each entity e_i, we collect the fragments containing it using $C = \text{Entity2Context}(e_i)$ and randomly select a subset C' that fits within LLM context limits. To enhance summary completeness, we prompt the LLM to provide multiple discrete aspects of the entity's meaning and usage, citing relevant sentences before summarizing. These separate items serve as retrieval objects, improving performance over simpler summarization approaches. The prompt used for this process can be found in Appendix A.

3.4 Entity Summary Enhanced RAG

Given a question q, EXPLAIN retrieves document chunks $C = \{c_1, c_2, \ldots, c_n\}$ and extracts entity summaries E. A re-ranker orders both based on similarity to q. We replace lower-scoring chunks with higher-scoring entity summaries, using thresholds maxEntSumm and maxChunkRepl to balance entity summaries with contextual information. The final context consists of the most relevant entity summaries and document chunks, enhancing question answering quality.

4 Experiment

4.1 Datasets and Baselines

4.1.1 Datasets

We evaluate our method on three public and one private: (1) **HotpotQA** (Yang et al., 2018) is a question answering dataset featuring natural, multi-hop questions, with strong supervision for supporting facts to enable more explainable question answering systems. We use test split from LongBench (Bai et al., 2023) and report F1 score; (2) **2WikiMultihopQA** (2WikiMQA) consists of up to 5-hop questions that are synthesized using manually designed templates to ensure that they cannot be solved through shortcuts. We use test split from LongBench and report F1 score; (3) **QuALITY** (Pang et al., 2022) is a question answering dataset over stories and articles collected from Project Gutenberg and the Open American National Corpus. This is a multiple-choices dataset. The Model is required to select the correct one among four given options. Following (Xu et al., 2024b), we use official validation set as test set and report Exact Match score for QuALITY. We report Exact Match (EM) metrics, EM-V (common questions) and EM-H (hard questions), where EM-V and EM-H denote the EM scores on the common and hard question subsets of the validation set; (4) Internal QA Dataset: A Chinese QA dataset from real-world corporate scenarios containing 11,109 instances (10,000 for testing, 1,109 for validation). Performance is measured using ROUGE-L. We treat all documents as a single document for entity processing. Due to permission issues, the documents we collect in this dataset are only chunks related to the questions from the complete documents. Therefore, we are unable to test Self-Route and Long Context on this benchmark which requires full text.

4.1.2 Baselines

We implement five baselines to evaluate the effectiveness of our method: (1) **No Context**: a method that only gives LLMs input question without any documents. (2) **Standard RAG** (Lewis et al., 2020): formats input with input question and top-k retrieved document chunks. (3) **RAG+Reranker**: addtionally rerank top-k document chunks with reranker compared to Standard RAG. (4) **Long Context** (Li et al., 2024): formats input with question and full documents. (5) **Self-Route** (Li et al., 2024): let LLMs to route whether to use RAG+Reranker or Long Context according to if the retrieved document chunks can answer the question. More details of the implementation are shown in B

4.2 Main Results

The results of our offline experiments are presented in Table 1. our method, EXPLAIN, demonstrates impressive performance across all benchmarks. For the multi-hop question answering benchmarks, HotpotQA and 2WikiMQA, EXPLAIN outperforms other methods. Compared to Standard RAG and

Table 1: Main results on HotpotQA, 2WikiMQA, QuALITY and Internal QA Dataset. All results are in %. *Avg Token* denotes the average token consumption. The best result is in **bold** and the second best is underlined. ↑ denotes that a larger value is better, while ↓ denotes that a smaller value is better.

Dataset	HotpotQA		2WikiMQA		Quality			Internal QA Dataset		
Metric	F1 ↑	Avg Token ↓	F1 ↑	Avg Token ↓	EM-V ↑	EM-H ↑	Avg Token ↓	ROUGE-L ↑	F1 ↑	Avg Token ↓
No Context	9.67	**100**	20.28	**98**	34.87	26.48	**195**	7.21	1.23	**175**
Standard RAG	56.70	4380	56.38	4181	80.22	60.28	4256	30.14	20.41	1778
RAG+Reranker	56.39	4380	59.23	4181	79.53	60.66	4256	30.19	20.66	1778
Self-Route	51.30	5146	56.58	5146	80.41	59.71	4306	-	-	-
Long Context	47.75	12873	55.96	7187	**81.49**	**65.92**	5870	-	-	-
Explain (Ours)	**60.33**	4013	**62.78**	3893	80.41	60.00	3882	**30.31**	**21.05**	1738

RAG+Reranker, EXPLAIN achieves an F1 score improvement of 3.63% on HotpotQA and 3.55% on 2WikiMQA, while reducing average token usage by 135. This indicates that EXPLAIN effectively filters and utilizes relevant information, enhancing accuracy. In the Quality benchmark, where the context provided is a complete document relevant to the question, the Long Context method achieves the highest accuracy due to its comprehensive use of context. However, it also incurs the highest token consumption. EXPLAIN strikes a balance between efficiency and effectiveness, achieving near-top accuracy while using 200 fewer tokens than Standard RAG. In the Internal QA Dataset, EXPLAIN achieves a 0.39 increase in F1 score and a 0.12 increase in ROUGE-L score, with token consumption comparable to Standard RAG. This further demonstrates EXPLAIN's ability to enhance answer accuracy while maintaining low token usage.

Across all benchmarks, the 'No Context' method achieves very low scores, indicating that the questions are challenging and that the model cannot generate correct answers without external documents. In HotpotQA and 2WikiMQA, the contexts provided include both relevant documents necessary for reasoning and additional irrelevant documents. When input documents are not ranked by similarity, the model can be misled by irrelevant information, leading to decreased performance. As a result, the Long Context method underperforms on these benchmarks. Similarly, the irrelevant information confuses the selection process, resulting in lower performance of Self-route.

Overall, the experimental results indicate that EXPLAIN's entity summarization approach effectively guides the model in understanding questions, reducing interference from irrelevant information. This leads to improved accuracy and reduced token consumption, showcasing EXPLAIN's potential in complex question answering tasks.

4.3 Trade-off between inference token usage and accuracy

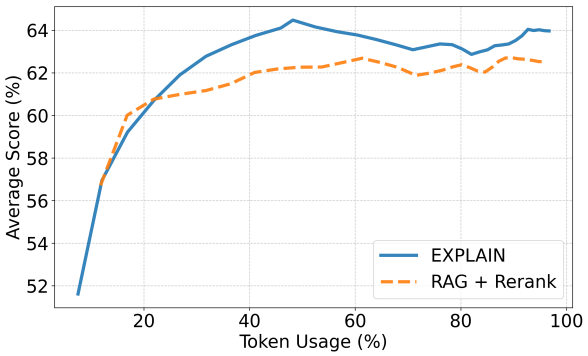

Figure 2: Token Usage(%) v.s Average Score(%) in HotpotQA, 2WikiMQA and Quality. We fix number of entity summaries to 10 and increase number of document chunks to increase token usage in each run.

In this section, we discuss the trade-off between accuracy and inference token consumption of EXPLAIN. As shown in Figure 2, we computed the average scores on three datasets: HotpotQA, 2WikiMQA, and Quality. We control token consumption by adjusting top-k for RAG+Reranker and maxChunkRepl for EXPLAIN. The token consumption percentage is computed as: (1) per-instance: the ratio between tokens consumed by inserted text chunks and tokens in the full relevant context, and (2) macro-level: the average across all instances. We plot the relationship between the average scores and this token consumption percentage. It can be observed that, in most cases, when the token usage percentage matches the baseline method RAG+Reranker, our method achieves approximately 1% to 2% higher score than the baseline. This demonstrates that our model consistently and steadily outperforms the baseline across these three benchmarks by effectively utilizing contex-

Table 2: Ablation results on HotpotQA, 2WikiMQA, and QuALITY. All results are in %. *Avg Token* denotes the average token consumption. The best result is in **bold** and the second best is underlined. ↑ denotes that a larger value is better, while ↓ denotes that a smaller value is better.

Dataset	HotpotQA		2WikiMQA		Quality

tual information.

4.4 Ablation of EXPLAIN Components

We investigate the impact of various EXPLAIN components on model performance across HotpotQA, 2WikiMQA, and Quality datasets. Results are summarized in Table 2. We conducted ablations by modifying several key components of our system. First, we compared SpaCy versus LLM-based entity extraction methods. We also evaluated performance with and without the entity linking step. Additionally, we tested individual versus aggregated entity summary retrieval to assess granularity effects. Finally, we contrasted context-based versus full-document retrieval scopes. Our findings reveal several important insights about the system design. For entity extraction, SpaCy extracts 11.16% more entities than the LLM-based method, producing 20.26% more summaries. While this introduces some noise, the performance impact remains limited. Given SpaCy's computational efficiency, we adopt it in our final model despite the slight performance decrease. Regarding entity linking, omitting this step causes only marginal performance degradation. At a similarity threshold of 0.7, entity linking reduces entity count by 5.86%, primarily decreasing computational overhead in downstream steps without significantly affecting accuracy. The summary granularity experiments showed that aggregating all summaries of an entity into a single retrieval item significantly reduces performance while increasing token consumption. This suggests that consolidated summaries introduce irrelevant information that distracts the model from the query's focus. The impact of retrieval scope varies by dataset characteristics. For Quality, where the retriever's context already covers 72.5% of the full text, expanding to full-document retrieval has minimal effect. However, for HotpotQA and 2WikiMQA, full-document retrieval decreases performance by introducing less relevant entity summaries that confuse the model. These ablations demonstrate the robustness of EXPLAIN's design choices and highlight the importance of granular, context-relevant entity summaries in improving model performance.

4.5 Impact of maxEntSumm and maxChunkRepl on Performance

In this section, we examine the impact of the parameters $maxEntSumm$ and $maxChunkRepl$ on performance. The parameter $maxEntSumm$ determines the maximum number of entity summaries retrieved, while $maxChunkRepl$ determines the maximum number of context chunks that can be replaced by these summaries. In practice, we found that the average length of context chunks is 110 tokens, whereas entity summaries average 35 tokens. Replacing context chunks with shorter entity summaries can reduce token consumption. However, increasing $maxChunkRepl$ too much can lead to a loss of important context, as many questions are context-dependent. This often results in a decrease in accuracy that outweighs the benefits of adding more entity summaries. As shown in 3, settings with $maxChunkRepl$ of 20 and 10 generally perform worse than a setting of 5, due to excessive loss of context. On the other hand, increasing $maxEntSumm$ introduces more new information but also increases token usage. Through parameter searching, we find that setting $maxEntSumm$ to 10 provides a good balance, achieving optimal results across the datasets. This analysis highlights the importance of carefully balancing these parameters to optimize both token efficiency and model accuracy.

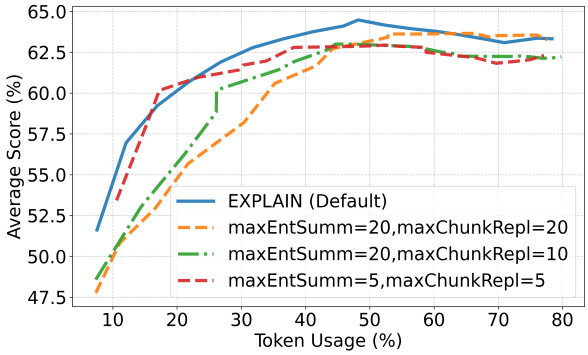

Figure 3: Token usage vs. F1 score in in HotpotQA, 2WikiMQA and Quality validation set. We increase number of contexts to increase token usage in each run.

Table 3: Vote results of online experiment.

Vote result	Accuracy	Comprehensiveness
EXPLAIN win	13.79	30.04
Tie	57.29	53.70
Baseline win	28.92	16.26

4.6 Online Experiments

We conducted a month-long online experiment involving 892 HR and financial queries handled by Ant Group's internal Q&A chatbot. Three company volunteers evaluated responses, comparing EXPLAIN against **RAG+Reranker** baseline, which has been consistently used to handle HR and financial inquiries in the ant group, on three metrics:

- **Accuracy:** The proportion of characters correctly addressing the user's question.
- **Comprehensiveness:** The extent to which the response covered all necessary information
- **Hallucination:** Instances where responses contradicted relevant documents

For each query, the evaluators were presented with the question, relevant internal documents, and two anonymized model responses. They selected which response performed better on accuracy and comprehensiveness, and mark if a response has any Hallucination. As shown in Table 3, for accuracy, EXPLAIN achieved 13.79% wins, 28.92% losses, and 57.29% ties against the baseline. Regarding comprehensiveness, EXPLAIN demonstrated a significant advantage with 30.04% wins, 16.26% losses, and 53.70% ties. For hallucinations, 2.5% of EXPLAIN's answers and 1.8% of the baseline's answers were marked, suggesting the entity summarization step does not significantly contribute to hallucination occurrence. Due to company data security policies, specific examples cannot be shared. Our analysis suggests that the lower accuracy win rate of EXPLAIN may be related to the nature of HR and financial queries, which typically require more detailed and contextualized answers than those found in public benchmarks. In these scenarios, EXPLAIN often introduces entity summaries or term definitions before providing the main answer. While this approach enhances comprehensiveness and better addresses the information needs of enterprise users, it can sometimes affect accuracy assessments. The additional contextual information may make the core answer less direct or introduce minor inaccuracies in supplementary details, which can impact strict accuracy evaluations even when the main point is correctly addressed.

5 Conclusion

In this work, we introduce EXPLAIN, a novel paradigm for document question answering based on the Retrieval-Augmented Generation framework. EXPLAIN addresses two key challenges: (1) the precision limitations of RAG-based methods due to restricted retrieved context, and (2) the high token cost of long-context-based approaches. By extracting potentially relevant entities from source documents and generating concise summaries for each, EXPLAIN enriches the information available during answer generation. These entity summaries are incorporated alongside retrieved passages, enabling the model to provide more accurate and comprehensive responses. Experimental results on public benchmarks demonstrate that EXPLAIN achieves superior inference accuracy and generation quality compared to the original RAG framework, without incurring additional real-time inference token costs. Furthermore, our month-long online experiment in a real-world corporate Q&A setting confirms that EXPLAIN significantly improves the comprehensiveness of responses to complex HR and financial queries, while maintaining a low hallucination rate. These findings highlight EXPLAIN's practical value for enterprise applications, where thorough and context-rich answers are essential.

A Prompts used in EXPLAIN

A.1 summary prompt

summary prompt

our primary task is to summarize the usage and significance of the given term within the provided context. For each item in your summary, start by quoting the most relevant part of the original context using quotation marks and then provide a concise summary explaining the term's usage or significance in that context. Ensure each summary item is self-contained, capturing a complete idea or fact that can stand alone. Using '\n' to separate different items. Context information is below. **<CONTEXT>** Based on the context information, summarize the usage and significance of the term '**<ENTITY NAME>**'. For each item in your summary, start by quoting the most relevant sentence from the context using quotation marks, and then provide a concise summary explaining the term's usage or significance. Ensure that each summary item is both comprehensive and concise, and contains enough information to be understood independently, avoiding pronouns or references that rely on other sentences for context. Using '\n' to separate different items.

A.2 extract prompt

extract prompt

lease extract all the nouns and noun phrases in the context. Do not include any pronouns in your extraction. Provide the extracted nouns and noun phrases, separate them by commas, and do not provide any other text. Context: **<CONTEXT>** Please extract all the nouns and noun phrases in the Context. Do not include any pronouns in your extraction. Provide the extracted nouns and noun phrases separate them by commas and do not provide any other text.

B Experimental Settings

In our experiments, we employ the LLaMA3.1-8B-Instruct (Dubey et al., 2024) model as the foundational language model for the English dataset and the Qwen2.5-8B-Instruct (Yang et al., 2024) model for the Chinese dataset. For document preprocessing, we implement sentence-level chunking. We utilize spaCy's $en\_core\_web\_sm$ and $zh\_core\_web\_sm$ for English and Chinese sentence segmentation and respectively preprocess documents into chunks not exceeding 128 tokens. We encode and retrieve documents using the $dense\_vecs$ encoding method from BGE-m3 (Chen et al., 2024) and rerank the retrieved documents according to score from BGE-reranker-v2 (Chen et al., 2024). For entity extraction, we again utilize spaCy's $en\_core\_web\_sm$ and $zh\_core\_web\_sm$ for English and Chinese respectively and develop custom rules to extract nouns from sentences. For entity linking, we set the Jaccard similarity threshold T to 0.7. The LLaMA3.1-8B-Instruct and Qwen2.5-8B-Instruct models are employed for summarizing entities in English and Chinese. We retrieve top 40 chunks most similar to query for all baselines and EXPLAIN. We set maximum number of retrieved entity summaries $maxEntSumm$ to 10 and maximum number of document chunks that can be replaced $maxChunkRepl$ to 5 for EXPLAIN in HotpotQA and 2WikiMQA, $maxEntSumm$ to 10 and $maxChunkRepl$ to 7 in Quality and $maxEntSumm$ to 2 and $maxChunkRepl$ to 2 in Internal QA Dataset.

EcoDoc: A Cost-Efficient Multimodal Document Processing System for Enterprises Using LLMs

Abstract

Enterprises are increasingly adopting Generative AI applications to extract insights from large volumes of multimodal documents in domains such as finance, law, healthcare, and industry. These documents contain structured and unstructured data (images, charts, handwritten texts, etc.) requiring robust AI systems for effective retrieval and comprehension. Recent advancements in Retrieval-Augmented Generation (RAG) frameworks and Vision-Language Models (VLMs) have improved retrieval performance on multimodal documents by processing pages as images. However, large-scale deployment remains challenging due to the high cost of LLM API usage and the slower inference speed of image-based processing of pages compared to text-based processing. To address these challenges, we propose EcoDoc, a cost-effective multimodal document processing system that dynamically selects the processing modalities for each page as an image or text based on page characteristics and query intent. Our experimental evaluation on TAT-DQA and DocVQA benchmarks shows that EcoDoc reduces average query processing latency by up to 2.29× and cost by up to 10×, without compromising accuracy.

1 Introduction

Enterprises are increasingly leveraging Generative AI applications to process and extract insights from vast collections of documents across domains such as finance, legal, healthcare, and industry. These documents contain a mixture of structured (tables, forms) and unstructured (free text, scanned, typewritten, handwritten notes) data, requiring robust AI systems for retrieval, comprehension, and response generation. Recent advancements in Retrieval-Augmented Generation (RAG) (Lewis et al., 2020) frameworks have enabled enterprises to integrate domain-specific retrieval with large-scale generative models, improving contextual relevance in AI-driven document understanding. However, efficiently handling multimodal enterprise documents, those with both textual and visual elements, remains a significant challenge in large-scale deployments due to computational and cost constraints.

Metrics	Text-based (Traditional)	Page Image (VLM)	Text + Page Image (Both)	EcoDoc (ours)
Ingestion time	Slow	Fast	Slowest	Fast
Query processing time	Fast	Slower	Slowest	Fast
Cost (LLM API usage)	Low	Higher	Highest	Low
Accuracy	Low	High	Highest	Highest

Table 1: Comparison of document processing methods on various metrics in the pipeline.

Traditional document processing pipelines primarily relied on text-based retrieval, where documents were parsed through Optical Character Recognition (OCR), and the images were passed through captioning models generating image descriptions as text and stored in retrievable text chunks for downstream processing. While effective for text-heavy documents, this approach struggles with visually complex documents, where critical information is embedded in tables, charts, and layout-specific structures. More recently, Vision-Language Model (VLM)-based indexing and retrievers such as ColPali (Faysse et al., 2025) and VisRAG (Yu et al., 2025) has emerged as a promising alternative, allowing for direct processing of page images without explicit text extraction. This prevents information loss that occurs during OCR-based parsing and enables a richer, more holistic document representation. With VLM-based page embedding techniques, enterprises can now index multimodal documents more efficiently, ensuring both faster retrieval and higher fidelity in captured information (Faysse et al., 2025).

Despite advancements in indexing techniques, the inference phase continues to be a major bot-

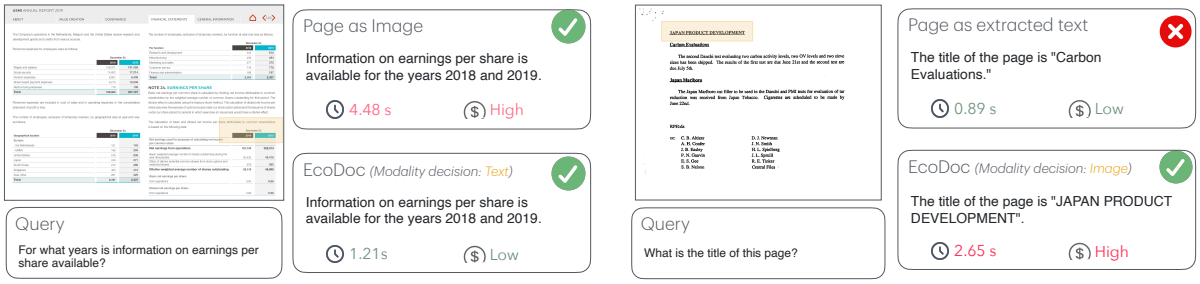

Figure 1: Illustration of EcoDoc's effectiveness in choosing the right representation for inference. Relevant context for the query is highlighted . (a) A query from TAT-DQA (Zhu et al., 2022) containing both tabular and textual data, where EcoDoc opted for cost-efficient text representation over image. (b) A query from DocVQA (Mathew et al., 2021) on a typewritten document, where despite OCR successfully extracting text, the query required position-aware processing, leading EcoDoc to process the page as an image for improved accuracy.

tleneck in large-scale deployments. For example, in a product catalog query scenario, we observed that performing inference using a Vision-Language Model (VLM) incurs approximately 40% higher computational costs and results in twice the latency compared to text-based inference. However, accuracy remains a critical factor for many enterprise applications. To address this, some enterprises (Anthropic, 2024) adopt a dual representation strategy, where each document page is processed as both text and image during inference. While this approach enhances accuracy, it substantially increases computational costs and latency. Table 1 presents a comparative analysis of cost, latency, and accuracy trade-offs across different multimodal document processing approaches.

To optimize the inference phase, this paper introduces EcoDoc, a system that dynamically selects the most efficient representation of a document page for processing through Large Language Models (LLMs). Based on the context of pages relevant to a given query, EcoDoc adaptively chooses between image or text. This adaptive strategy maintains the accuracy benefits while significantly enhancing inference speed and reducing computational costs. As a result, it enables scalable, cost-effective, and accurate document processing for large-scale enterprise applications.

Figure 1 illustrates EcoDoc's effectiveness in selecting the optimal representation during inference. In Figure 1(a), EcoDoc determines that text-based processing is sufficient, enabling lower-cost inference while maintaining accuracy comparable to the image-based approach. On the other hand, in Figure 1(b), EcoDoc selectively opts for image-based processing despite its higher computational cost, ensuring a more accurate response when necessary. This adaptive selection strategy optimizes both efficiency and accuracy based on the specific requirements of the query.

In summary, our contributions in this paper are as follows:

- We propose EcoDoc, a multimodal document processing system designed to optimize cost and latency for large-scale enterprise deployments.
- EcoDoc introduces a dynamic modality selector that intelligently chooses between processing each page as an image or text based on the query and the content of the retrieved pages.
- We evaluate EcoDoc on two benchmarks - DocVQA (Mathew et al., 2021) and TAT-DQA (Zhu et al., 2022), highlighting significant cost savings (up to 10×) and query processing time improvement (up to 2.29×) while maintaining comparable accuracy.

2 EcoDoc System

In this section, we introduce EcoDoc, as shown in Figure 2. EcoDoc extends the Retrieval-Augmented Generation (RAG) framework (Lewis et al., 2020) to handle multimodal enterprise documents. It operates in two phases: the indexing phase and the question-answering phase.

2.1 Indexing (Data Ingestion)

In the indexing phase, documents undergo an offline preprocessing step to optimize retrieval efficiency during inference. Rather than applying a

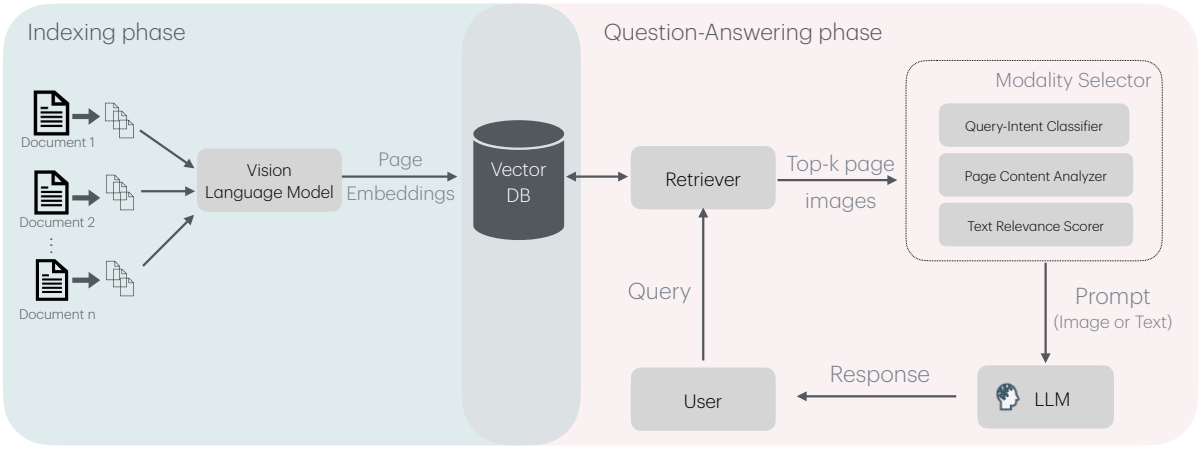

Figure 2: EcoDoc system workflow. The left side shows the document ingestion pipeline, while the right side illustrates the query-answering pipeline. The modality selector dynamically selects the appropriate page representation (i.e., image or text) to be processed by the LLM for generating the answer.

multi-stage pipeline involving Optical Character Recognition (OCR), layout analysis, image captioning, and text chunking for every page, EcoDoc adopts a simplified yet effective approach by converting each page into an image, as proposed in ColPali (Faysse et al., 2025). This image representation is then processed through a vision-language model (VLM), which generates dense embeddings that capture both textual and visual semantics in a unified representation. These embeddings are stored in a vector database. By leveraging page-level embeddings, EcoDoc avoids the computational overhead of extracting and processing individual text and visual elements.

2.2 Question Answering

The question-answering process begins with the retrieval stage, where a retriever selects the most relevant pages from a vector database in response to a given textual query. EcoDoc performs a similarity search over the precomputed page embeddings to identify the top-k pages that are most relevant to the query. These top-k pages then serve as input to the next phase, where answers are generated using large language models (LLMs).

2.2.1 Challenges

Traditionally, page images are passed into the LLM for answer generation. However, processing images directly is considerably more time-consuming and expensive than using their textual counterparts. Our observations indicate that leveraging page images instead of their text versions results in a 2$\times$ increase in average query processing latency and a 40% rise in average cost. This disparity arises because visual data demands greater computational resources and processing power, making image-based queries less efficient.

Notably, not every query necessitates processing the page image. Some queries can be adequately answered using only the text extracted from the page image, while others require the richer context provided by the visual representation. For instance, questions related to visual structure, layout, or non-textual elements of a page may benefit from image-based processing. Conversely, queries centered on textual content can often be resolved more efficiently using the text version alone.

By dynamically selecting the appropriate representation - either the page image or its textual version for each query, we can significantly reduce both the processing time and cost associated with answer generation. The challenge, however, lies in determining when to rely on the image and when to use the text. To address this, EcoDoc employs a sophisticated hybrid approach. It analyzes the content of the retrieved pages, interprets the intent behind the user query, and strategically decides whether to process the image or the text. This strategic selection optimizes resource usage while ensuring accurate and efficient answers.

Now, we describe how EcoDoc addresses these problems by analyzing the contents of the retrieved pages, the intent of the user query, and finally taking a hybrid approach in the following section.

2.2.2 Selecting Right Modality

Given a query, EcoDoc first determines the most suitable representation - image or text, for generating the answer. Although it could rely on LLMs to make this decision directly, invoking the LLM for every query would significantly increase both cost and processing time. To address this challenge, EcoDoc employs a more efficient, precomputed approach by generating two distinct lists of potential questions: one comprising questions best answered using images and the other containing questions that are more effectively addressed through textual representations.

EcoDoc utilizes a *Query-Intent Classifier* that leverages the following prompt to pre-generate a set of representative queries using an LLM.

Prompt for generating list of queries

You are an expert in document understanding. Your task is to generate representative user queries that would be issued to a document question-answering system. For each query, classify the preferred modality required to answer it accurately:

• `"text"`: The query can be answered reliably using only OCR-extracted plain text from the document.

• `"pageimage"`: The query requires visual cues such as layout, spatial relationships, formatting, tables, handwritten elements, or other non-textual features.

Generate a list of 10 diverse queries for each modality. For each query, provide a short explanation of why the specified modality is required.

Expected JSON Output Format:

```
{
  "text_samples": [
    { "query": "...", "reason": "..." },
    ...
  ],
  "pageimage_samples": [
    { "query": "...", "reason": "..." },
    ...
  ]
}
```

Table 2 shows a set of sample queries generated by the LLM. Questions that involve understanding the visual layout, spatial relationships, or visual characteristics of the page often require processing the image representation. In contrast, queries that focus on retrieving specific facts or textual information can typically be answered more efficiently using the text version. For example, questions like "Is there a signature at the bottom?" or "What color is the chart?" rely on visual cues from the image, whereas queries such as "List all items in the table" or "What is the invoice number?" can be addressed directly from the text data.

Sample Queries	
Text-based Inference	**Image-based Inference**
1. What is the invoice number?	1. Is there a signature at the bottom of the page?
2. What is the date of the document?	2. What color is the chart in the top-right corner?
3. Who is the sender of the letter?	3. How many tables are present in the document?
4. List all line items in the invoice.	4. Is there a company logo on the first page?
5. What is the total amount due?	5. What is the title at the top of the document?
6. What is the shipping address?	6. Which section is in bold and underlined?
7. What is the name of the customer?	7. Is there a table with three columns on the page?
8. What are the terms and conditions?	8. Does the document include any handwritten notes?
9. What is the product description listed?	9. What is the label directly above the chart?
10. Who signed the contract?	10. Is the footer visible on the page?

Table 2: Sample query set generated by the LLM for the Query-Intent Classifier.

To classify a new query, EcoDoc computes query text embedding and compares it against the embeddings of the pre-generated questions in both lists. The similarity between the query embedding and each question embedding is computed. For each modality class, the similarity scores across all associated questions are averaged. The corresponding class - image or text, with the highest averaged similarity is then assigned to the query, guiding the decision on whether to process the each of the retrieved pages as an image or text.

If the decision is to use the image representation, the page is directly fed as an image to the LLM to generate an answer. On the other hand, if text-based processing is selected, additional steps are taken to ensure that the extracted text is relevant to the query. To facilitate this, EcoDoc employs a *Page Content Analyzer* that utilizes a layout detector to determine the presence of textual content on the page. If text is detected, the page is processed using an OCR engine to extract the text. The extracted content is then evaluated for relevance to the original query using semantic similarity, computed by the *Text Relevance Scorer*. If the similarity score exceeds a predefined threshold (empirically set to 0.45), the OCR-extracted text is used to generate the answer. Otherwise, the page is processed as an image to ensure that any important visual context is not overlooked.

This hybrid decision-making process enables EcoDoc to balance computational efficiency, cost, and answer accuracy. Visually rich or non-textual pages are processed as images to retain critical context, while pages with relevant, structured text are handled via faster, more cost-effective text-based inference. This adaptive strategy reduces the reliance on expensive image processing while improving the relevance and quality of the answers generated.

3 Performance Evaluation

To assess the performance of EcoDoc, we report the system's efficiency - measured by latency and cost and the accuracy of the generated responses. Response accuracy is evaluated through manual inspection of the generated results.

3.1 Datasets

To evaluate the effectiveness of EcoDoc, we benchmark against two widely used datasets: DocVQA (Mathew et al., 2021) and TAT-DQA (Zhu et al., 2022). These datasets are ideal for evaluating document-and-query-dependent modality selection, as they represent a diverse mixture of textual and visual elements, including images, charts, tables and handwritten texts. TAT-DQA, with its emphasis on financial documents, contains structured text-heavy and tabular data, while the DocVQA, focused on industrial documents, includes more visually rich scanned, typewritten and handwritten texts, offering a balanced evaluation set across different document types.

3.2 Experiment Setup

In the experimental setup, we utilize the ColPali (Faysse et al., 2025) framework provided by Byaldi[1] for indexing. The dataset consists of pages stored as images, which are used to create the embeddings. Since the indexed data only stores compact page embeddings rather than full document images, the system maps the retrieved embeddings back to their corresponding original documents and pages based on the mapping established during data ingestion. EcoDoc's retriever module ensures that the exact source pages are fetched for further processing. Only the top k retrieved pages are passed to the response generation phase and in our experiments, we evaluate top-1 and top-4 retrieval results. For generating responses, we specifically use GPT-4o (OpenAI, 2024), leveraging its capabilities to process the retrieved context and produce accurate answers. We use processing document pages as images as the baseline for comparison.

3.3 Results

In this work, our primary focus is on optimizing inference cost rather than enhancing retrieval accuracy. To ensure a fair evaluation of our proposed techniques, we report accuracy and inference cost metrics only for queries where the top-k retrieved pages contain the necessary context required to generate a correct response using LLMs. By narrowing our evaluation to these cases, we can better isolate the impact of inference cost optimization without conflating it with potential retrieval errors.

Method	DocVQA		TAT-DQA	
	k=1	k=4	k=1	k=4
Baseline	0.52	0.73	0.66	0.70
EcoDoc	0.52	0.73	0.65	0.69

Table 3: Query response accuracy

3.3.1 Query Response Accuracy

To evaluate response accuracy, we compare EcoDoc's adaptive inference strategy against a baseline on the DocVQA and TAT-DQA benchmarks across varying retrieval depths ($k = 1$ and $k = 4$). As shown in Table 3, EcoDoc achieves accuracy on par with the baseline while significantly reducing reliance on image-based processing. On DocVQA, EcoDoc matches the baseline performance with accuracy scores of 0.52 and 0.73 for $k = 1$ and $k = 4$, respectively. On TAT-DQA, EcoDoc attains scores of 0.65 and 0.69, closely approximating the baseline's 0.66 and 0.70. These results indicate that EcoDoc incurs only a marginal 1% reduction in accuracy on TAT-DQA, demonstrating its effectiveness in maintaining high answer quality while optimizing processing efficiency.

3.3.2 Inference cost

To evaluate the inference efficiency, we measure and report the latency and LLM API usage costs for both the baseline and EcoDoc. Figure 3 presents the average response time, showing that while the baseline approach (processing pages as images) achieves high accuracy, it also incurs the highest latency due to the computational need for image-based processing. Similarly, Figure 4 shows the normalized compute cost per query, where EcoDoc demonstrates significantly lower processing costs by efficiently prioritizing text-based inference.

In TAT-DQA, EcoDoc reduced latency by 1.35× and lowered costs by 10× compared to the baseline. In DocVQA, EcoDoc achieved a 2.29× reduction in latency, while cost savings reached 4.17×. The high cost savings in TAT-DQA can be attributed to the higher proportion of text-based processing, which is cheaper. However, the higher latency is due to the complexity of the queries, which re-

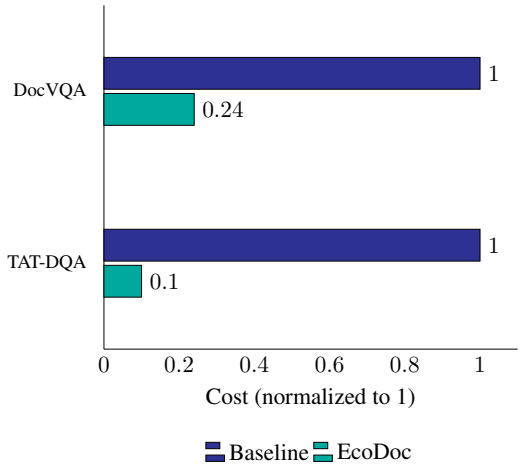

Figure 4: Relative cost comparison on TAT-DAQ and DocVQA datasets.

quire more reasoning and produce longer outputs, thereby increasing inference time. Conversely, in DocVQA, the relatively lower cost savings stem from increased reliance on image-based processing. Nevertheless, the queries in DocVQA require more concise information retrieval, contributing to faster inference. These improvements are driven by EcoDoc's dynamic modality selection, which prioritizes text processing when sufficient and selectively applies image-based inference only when necessary, optimizing both cost and latency.

3.4 EcoDoc Deployment

We describe a deployment use case where EcoDoc is utilized to analyze an extensive product catalog encompassing shipping and packing supplies, as well as other industrial supplies and bulk business goods. The catalog contains thousands of products, each accompanied by a brief description, weight, dimensions, product images, and pricing information. As shown in Figure 5, a user poses the query "What can I use to ship my guitar?". EcoDoc processes the query and retrieves two relevant products from the catalog, suitable for shipping both small and large guitars. Additionally, EcoDoc presents brief information about each recommended product, including its description and specifications. To enhance user confidence and ensure transparency, EcoDoc also displays corresponding product images, allowing the user to visually verify the items and confirm their suitability for shipping needs. Overall, using EcoDoc reduced deployment costs by 70% and processed queries twice as fast compared to the baseline, where each page was always processed as an image.

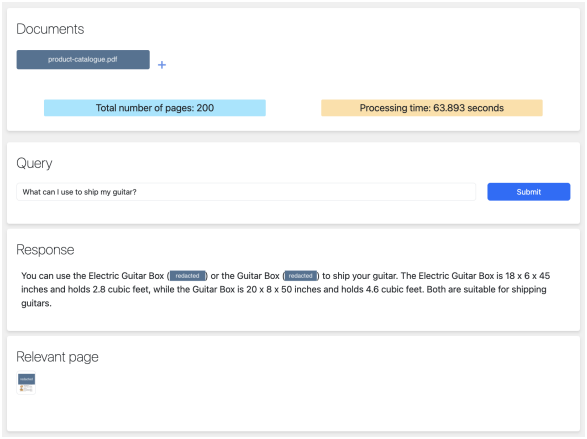

Figure 5: Deployment use case of EcoDoc analyzing a product catalog to identify suitable shipping supplies for a guitar, presenting relevant products with descriptions, specifications, and images to assist the user in making informed decisions.

4 Related Work

Multimodal document processing has garnered significant attention due to its potential in handling diverse tasks across text and image modalities. Multimodal retrieval encompasses tasks such as identifying texts that respond to queries related to specific images (Hu et al., 2023a; Luo et al., 2023), retrieving text-image pairs for question answering (Chang et al., 2022), and finding images that match textual descriptions (Han et al., 2017). To address the diverse nature of these tasks, UniIR Wei et al. (2023) proposed a universal multimodal retrieval model capable of handling a wide range of retrieval scenarios across modalities.

The integration of retrieved multimodal information has proven beneficial for applications like

in-context learning (Tan et al., 2024; Liu et al., 2023) and knowledge incorporation (Hu et al., 2023b; Luo et al., 2021), with use cases spanning from answer generation to image synthesis (Sharifymoghaddam et al., 2024). However, much of the existing research relies on curated academic datasets, where modalities are neatly separated, preprocessed, and aligned (e.g., images with corresponding captions). This structured setup does not fully align with real-world retrieval-augmented generation (RAG) scenarios, where documents often present unstructured and interleaved modalities.

Recent advancements aim to mitigate these challenges by developing models that encode entire document images directly for retrieval tasks. For instance, DSE (Ma et al., 2024), ColPali (Faysse et al., 2025) and VisRAG (Yu et al., 2025) simplify the RAG pipeline by treating documents as images, reducing preprocessing complexity and streamlining retrieval. Nevertheless, these methods introduce new challenges, such as increased query processing times and higher costs associated with large language model (LLM) API usage.

In light of these limitations, EcoDoc proposes a dynamic strategy that intelligently determines when to input image data or text data into the LLM. By evaluating query-specific factors such as content complexity and multimodal context, EcoDoc optimizes the decision-making process to reduce LLM API usage cost and processing overhead. This strategy not only enhances system efficiency but also strikes a balance between leveraging visual and textual information, ensuring improved performance and cost-effectiveness in multimodal document processing.

5 Conclusion

In this work, we introduced EcoDoc, a cost-efficient system for multimodal document processing that optimizes inference by leveraging document structure and query intent. By incorporating text-to-visual density analysis, query-to-page-text semantic similarity, and query intent classification, EcoDoc significantly reduces latency and cost while preserving high accuracy during inference. EcoDoc effectively balances cost and performance, surpassing systems that process multimodal documents solely as images. Through evaluations on datasets from diverse domains, we showed that EcoDoc achieves substantial efficiency improvements without sacrificing response quality.
