> SUMMARY. A remarkable regularity of distribution of Arabic verbal roots in the vocabulary is shown to exist. Presented results suggest that similar regular distributions of semantic units in other languages may be found with the help of word formation rules and vocabulary statistics. Possible applications in approaching the problem of "true" multiple meaning in MT are being discussed.

The notion of "semantic unit" may be formulated in several ways $/ 1 /$ so that the application of this term makes its explicit definition indispensable. It seems that difficulties in defining it arise from the fact that like most general terms it should be related to some definite theory. At present we do not possess any sufficiently strong and general theory of the semantics of natural lancuages, though important preliminary steps in this direction have already been made / / For this reason most semantic investigations of natural languages still preserve the "artisanlike" character stressed by 1. Coyoud and all definitions of the semantic notions remain ratber tentative - as well as all the more general conclusions drawn from such investigptions. This, too, holds true for the present contribution, in which an empirical fact is described and some remarks on its possible applications to the problem of the "true" multiple meaning have been made.

For tilis paper it seems advisable to hold apart two notions: that of the "concept" and that of the "semantic unit". Given a generative descriptional device $G$ /Eranmar/ and a projective systen of the type proposed by Katz and Fodor $S$ /senantics/we can describe a semantic concept in aluncuage $I$ as a set of n-tuples of symbols from $G$ and $S$, ordered or partially ordered by the relations which define the formal rules of these systers, and havine a comon derivation in 3 . Thie broad frane allows us to recard as a concept every dictionary entry except for the "cramatical words" which do not jossess any derivations in 3 - and leaves us a wide marcin of freedeon in constructing arbitraty "conoet -systems: aiti a wiori established features.

In a similar way we may describe a semantic unit as a set of n-tuples of G-symbols, G-rules of wora foration and 0 -symbols, ordered or jantially ordered by means oi relations which define the formal rules of these systems, and huvine a oominon derivation in $G$ from some $G-s y m b o l$ uniquely related to some $\dot{\text { sumbol. This allows us to relate with tio notion of }}$ a sementic unit the linguistic notions of morphene for more strictly: senanteme/ and of "word family", defined in terns of Srammatical derivations.

The thesauric aproach to the problem of meaning. in iT /s.e.g.j/ pays tribut to the idea of ordering the symbols within the concepts, but at the same time it brincs to licht the problem of multiple meanine. This problem has been much discussed already /s.e.e.4/, but it is still far from beine solved in all its aspects. Generally speakine tho main difficul-
ty arises from the fact that the "concept-systems" of lancuares are not isomorphio and even ir we mana@e to bring taen closer together there remains some amount of "looseness" within tie concepts themselves, $\mathcal{E}$ iving rise to the problem of "true" multinle meaning. The "contextual" multiple meanins may be resolved - in princiqle, at least - by extendine the notion of concepts both in the source and in the taraet lameuages to niole sentenoes or even lareer utterances; this is allowed by our "broad" treatment oif this notion, not suecifying the maximal size of the n-tuples of symbols. By this extension the inner structure of concepts makes the relations defining the isomorphism of the "conoept -systems" more apparent; thus even such cases as the adequate translation of the fussian ugnemenulas the English "changinc /the order of integration/"and "varying /argument/" are theoretically resolvable. Yet there exist instances where the extension of concept would have to $c \circ$ beyond limits and to Linvolva the whole lunguge: these are cases of "stylistic' difeerence in wich there are not apmarent reasons for choosin. one of the possible synongins instead of the otion but where tiae ufepence ic distinctly felt by competent bilincual speakers. The provem is imortant for the translation of literary pieces, especially poetry; by the mesent stand ou it is still an "acscienic" exoblen, of course, but it exists after all. it iay be best illustrated by the question whether taere are "better: and "worse" translations of monsensical expressions, suck as the famops "furiously sleeping iceas". iedative answer would mean that every translation is equally sood, which in turn would mean that only "meanineful" sentences are translatable; in tiat case
the im problems would be "enriched" with the whole load of philosophical questions - an embarassing development, certainly.

Vaguely felt differences between the intrinsic "sementic values" of different elenents of laneuage have given rise to the notions of "size" oy "content" of sementic elenents $/ 5 /$ and several attempts - both to define these notions and to furnish models of the underlyine mechanism have been wacie /5,6/. The main assumption - based on observations of lillis - aas that there existed a "natural hierarchy" of concepts in netural languages, forming a tree or at least a lattice aitin sone definite statistical properties.

The present paper gives some resulte of an investigation undertaken in order to test this hy wotieses. Because of the marvelous clarity of the gramatjoal structure srabic has been chosen as a "laboratory exanple". about go: of srabic semantemes ane verbal roots, with very fem exce, tions consistine of three consonants $C_{1}-C_{c}-C_{3}$; the usual dictionary
 kasara "to break" litt. "he has broken"/. "here are inore than ten differont verba? stem-pattems i.e. word formation rules, modyfying the basic meaning oz the root in a sfecific way; thus the stem-pattern II: $C_{1} a C_{2} C_{2} a C_{3} a$ adds to the basic meaninc tire shade of intensity, e.g. hasara "to breazs hassaru "to smasi"; the stem-pattern III is conetive, the IV - cuusative, ato.
sll the triliteral vorbel roots in the arabic vocabulary iuve been divided iuto semurato olusses cooonding to thair ability to form $s=1, a, \ldots, n$ arferent stons. . . om $h_{d}$
the number of stem-patterns was considered and further amlicable mord formation rules /substantivisations, adjeotivisations etc./ were disregarded this classification is a very mough aprovimation to the hypothetical underlying hierarohy. It has been ascuned that the number of stem-patterns defining a givon class may be approximately viewed as an arionent of the "oontent: or "semantic value" oi the semantic units belonging to this class and thet - if the hypothetical hierarchy was really based on this principle - the number of roots with greater s sioula be sinaller than that with smaller $s$. Baranov's mrabic-Russian Dictionary /7/ has been used for counting the roots and it has been found that the relation between $s$ /the number of stem--patterns odaracterizing the Eiven class; and $r$ fine nunber of roots belongine to this class/ was not only inversly proportional but also nearly functional and tiat the distribution of roots in the Arabic vocabulary may be described as a simple function $r / s /=M / A s^{2}+B s+C /$, where is is the sun-total of roots and $A, B$ and $C$ are specific constants. The goodness oi fit has been tested by the chi-square distribution and it has been found that the differences between the empirical data and the theoretical distribution - except for one value - do not exceed 0.3 sicnificance.level.

In order to estimate the possible differences between farticular dictionarins - wich could arise from differences between the materials used for their compilation two samples of ca. 700 items each have been taken from two different dictionaries $/ 7,3 /$ and the distribution of roots in them compared with each other and with the over-all distribution.

All the distributions show a striking similarity, rendering nearly identical obi-square values. $x /$

This result is a strong argument for the general validity of the discussed distribution in Arabic - and this fact in its turn speaks in favour of the existence of "natural hierarchies" of the semantic units in general.

| $x /$ The figures are as follows: |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 1 | 2 | 3 | 4 | 5 | 6 | 7 | 8 | 9 | N |
| $\begin{aligned} & \text { Baranov's } \\ & \text { Dictionary } \end{aligned}$ | 988 | 714 | 586 | 411 | 254 | 154 | 74 | 18 | 10 | 3209 |
| theoretical <br> distribution | 974 | 754 | 561 | 398 | 262 | 155 | 76 | 26 | 4 |  |
| sample <br> /Baranov/ | 213 | 163 | 131 | 99 | 55 | 25 | 18 | 3 | 1 | 708 |
| sample <br> /Wehr/ | 229 | 163 | 117 | 95 | 50 | 26 | 13 | 3 | 1 | 697 |

The constants for Baranov's Dictionary are:
$A=0.004419, B=0.082, C=0.3812$
It seems very probable that similar regular distributions might be found in other languages, too - perhaps the ensemble of the "semantic parameters" would have to be much wider and the "trial and error" investigations would require more time but the whole work can be easily mechanised. The idea of interconnections between the syntactic and semantic structures of language is not new in structural linguistics /s.9 and 10/ and investigations along these lines have already been led in the domain of computational linguistics under direction of P.Garvin /11/. My suggestions go towards discovering such regular
distributions which would facilitate the task of finding more strict correlations between the synonyms within particular concepts on computational basis. The underlyina assumption is that the "universes of discours" in various languages are of about the same "sizel /whatever it would mean - but such an assumption is tacitely made in every translation/, and that the semantic units underlying the components of concepts are ordered according to their "content", so that the problem of "true" multiple neaning in certain cases may be solved by means of matching the components of concepts of the source and tareet lancuages on the basis of their "semantic value".

As an illustration let us consider a fe:: equivalent
 the Koranic Sura 84 , beine translutions of srabic verba derived from roots all beloneing to the same class / 5 stan -patterms/, i.e. accoraing to our assumption having about the same "senantic value". The "value" or cormesponding tnelisin vents has bean tentatively estimated by the number of diterent sum-entios in Chambers's ath Century Dictionury fumbers in brackets/:
arabic
infatara

Garra
sawiya
sala

## Enclish

$$

/ 4 \cdot / \text { to sulit } & / 16 / \\
/ \mathbb{N} \cdot / \text { to severe } & / 3 / \\
\text { to deceive } & / 5 / \\
\text { to beguile } & / 4 / \\
\text { to shape } & / 13 / \\
\text { to fashion } & / 11 / \\
\text { to roast } & / 9 / \\
\text { to burn } & / 30 /
\end{array}
$$

The applied "method" being unsystematic and ad hoc the example allows no generalisations but it may illustrate cur areument that the problem of "true" multiple meaning arises in cases of "expressive language" from the fact that even when the ocncepts of source and target languages agree there is no correlation between their respective components except for differences between their "value", based on differences on tie paradigmatic level. Thus e. $\mathbb{S}$. for the concept "applyiné heat on something ${ }^{1}$ two different semantic units could have been arbitrarily chosen by the two interpreters, as they recarded tin subsets of synonyms witian the concepts as unordered. .iy sugeestion is that these subsets might be at least partially ordered by means of the intrinsic value of the semantic units underlying them and that correlations between them micht be established in more objective terms of numeric measures of their content.
